Abstract: Patellofemoral pain (PFP) is one of the most common joint disorders, inflicting about one-quarter of Americans. The incidence of PFP is several times higher in females than in males. The vastus medialis oblique (VMO) and vastus lateralis (VL) are important medial and lateral patella stabilizers, while the VMO, vastus medialis longus (VML) and VL are synergists for leg extension. There are neuromuscular control imbalances among the VL, VML, and VMO in individuals with PFP. However, differences in neuromuscular control of the patella between the sexes have not been clearly elucidated. In addition, muscle fatigability can differ across muscles and sex. This, also, has not been investigated for control of the patella. The goal of this study is to investigate the impact of sex and neuromuscular fatigue on VL, VML and VMO activity during a sustained fatiguing 20% maximal voluntary isometric contraction (MVIC). All fatigue tasks were quarterly staged into 1^{st}, 2^{nd}, 3^{rd}, and 4^{th} fatigue phases. Surface EMG of the VL, VML, and VMO was recorded. Peaks of VMO-VL and VMO-VML EMG cross-correlation and peak EMG RMS amplitudes of each muscle (normalized to MVIC amplitudes) during the four phases were calculated. With sexes pooled, a repeated-measures ANOVA revealed that both VMO-VL and VMO-VML cross-correlation peaks increased with fatigue ($p<0.05$). Thus, fatigue causes an increase in common drives to all three muscles. When grouped by sex, the VMO-VML cross-correlation peaks increased to a greater degree with fatigue in males than in females (at 3^{rd} and 4^{th} fatigue phases, $p<0.05$). EMG RMS amplitudes of all three muscles also increased with fatigue ($p<0.05$). However, across all 4 fatigue phases, normalized VMO EMG RMS amplitudes were lower in females than in males (at 4^{th} phases, $p<0.05$), and VL EMG RMS amplitudes were higher in females than in males (at 1- 4^{th} phases, $p<0.05$). This demonstrates that healthy females may generate greater relative lateral pull on the patella than healthy males, which could cause patellar mal-tracking. Additionally, females displayed a lower correlation in VMO-VML medial synergistic activity during fatigue which could also lead to destabilization of the patella and PFP. This study was the first to reveal that sex-differences in neuromuscular control of the patella are exacerbated by neuromuscular fatigue.

Title: Spatio-temporal organization of mutual information between high-gamma neural envelope and muscle activity

Authors: *W. LIANG, V. PAPADOURAKIS, N. HATSOPOULOS;
Univ. of Chicago, Chicago, IL

Abstract: High gamma band amplitude of local field potential (LFP) in the primary motor cortex (M1) is known to modulate during movement [1], but it is unclear whether there is any spatio-temporal structuring in this modulation. This is an important issue because the relationship between physical layout on the cortical sheet and temporal organization of information could inform us about cortical information processing as well as provide mechanistic insights regarding energy saving with predominant local connections. To explore this question, we collected neural signals from 128 electrodes in M1 as well as electromyography (EMG) from 13 muscles of the shoulder, elbow, and hand, while a rhesus macaque performed 8-direction reaches constrained by a 2D exoskeletal robot. We computed the Hilbert envelope of the LFP between 100Hz and 200Hz; bandpass filtered EMG between 20 to 1000Hz followed by rectification and smoothing. Then we discretized the signals into (roughly) equal-occurrence bins for single variables, and computed mutual information between each EMG at a particular time point with each neural envelope independently at various leads and lags, spanning from -600 ms to 400ms relative to muscle activity. Finally we obtained a 3-way tensor (i.e. 3D array, electrodes*time lead/lag*muscles) of mutual information. To understand its potential low-dimensional structure, we performed CANDECOMP/PARAFAC (canonical decomposition/ parallel factors, CP) decomposition using alternating least squares [2], which approximates the tensor as a sum of outer products (i.e. factors) of 3 vectors (one for each dimension). We found that 3 factors could capture 77.8% of total variance. Information peaked with a short lead of 20ms for two major factors; and major hand muscles or wrist muscles each share spatio-temporal dynamics among themselves. We further rearranged the electrode vector into 2D cortical space and observed significant spatial gradients pointing towards the central sulcus. The lateral caudal M1 seems particularly informative, which is especially so for the extensor digitorum muscle we recorded from; coincidentally microstimulations at these locations caused hand movement in our previous somatotopic mapping. We will also explore short temporal trajectories and small groups of electrodes to expand the current single time/location analyses.

Title: Improving the repeatability of MUNIX using multi-channel surface electromyography

Authors: *Y. CAO[1], C. ZHANG[2], F. GAO[1], Y. ZHANG[2];
[1]Hangzhou Dianzi Univ., Hangzhou, China; [2]Univ. of Houston, Houston, TX

Abstract: Motor Unit Number Index (MUNIX) is a neurological technique that provides a susceptive biomarker for monitoring innervation conditions in patients with neurodegenerative diseases. A satisfactory repeatability is essential for the clinical interpretation of MUNIX results. This study represents the first effort to evaluate the effect of channel number on the repeatability of MUNIX.
Five healthy subjects (27±2 years, one female) participated in this study. 128 channels of high-density surface electromyography (EMG) signals were recorded from the biceps brachii muscles of the dominate arms. Participants were instructed to perform isometric voluntary contractions at 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80% and 100% of maximal voluntary contraction. Multi-channel MUNIX is calculated by the weighted sum of single-channel MUNIX of all selected channels, with weight determined by the channel-specific CMAP amplitude. Trial-to-trial repeatability was estimated by the coefficient of variation (CV) of MUNIX from three experiment trials. A channel number of 1, 2, 4, 8, 16, 32, 64 and 128 were selected to assess its effect on the repeatability of MUNIX.
A significant lower trial-to-trial CV was observed when two or more EMG channels were included, compared to the CV of single-channel MUNIX. Concretely, CV of 2.9%, 2.6%, 2.3%, 2.3%, 2.3%, 2.1%, 2.0% and 1.8% was found for 1, 2, 4, 8, 16, 32, 64 and 128 channel MUNIX results, respectively.
Our results have demonstrated that increasing the number of channels can be an effective method to improve the repeatability of MUNIX. Additive myoelectric information is expected to provide a more comprehensive sampling of the motor unit information and further benefit MUNIX repeatability. However, the proposed multi-channel MUNIX method will complicate the experiment procedure and analysis when more channels are included, and it remains a trade-off between results consistency and evaluation complexity.

Title: Facilitation from the anterior and middle parts of the deltoid to biceps brachii motoneurons in humans

Authors: *T. YOSHIMOTO, M. NITO, M. JIMENJI, W. HASHIZUME, A. NAITO;
Dept. of Anat. and Structural Sci., Yamagata Univ., Yamagata city, Japan

Abstract: Effects of low-threshold afferents from the anterior (DA), middle (DM) and posterior parts of the deltoid muscle (DP) to biceps brachii muscle (BB) motoneurons were studied in 7 healthy human subjects using a post-stimulus time-histogram (PSTH) and electromyogram-averaging (EMG-A) methods. As conditioning stimulation, electrical rectangular pulses (1.0 ms duration) were delivered to the axillary nerve branch innervating DA (DA nerve), DM (DM nerve) and DP (DP nerve) with the intensity below the motor threshold. In the PSTH study, motor unit firings of BB were recorded with a pair of needle electrodes. The stimulation to the DA and DM nerves induced a peak (facilitation) in 25/39 and 28/47 BB motor units, respectively. The remaining respective 14 and 19 received no effects by the stimulation. The central synaptic delay of the facilitation from the DA and DM nerves was 0.2±0.3 (mean ± S.D. ,n=8) and 0.1±0.1 (n=8) ms longer than that of the homonymous BB facilitation, respectively. In the EMG-A study, the stimulation to the DA and DM nerves induced a peak (facilitation) in rectified and averaged EMGs of BB recorded with bipolar surface electrodes. The facilitation from the DA and DM nerves diminished by tonic vibration stimuli (TVS) to the DA and DM muscle bellies, respectively, and recovered 30 to 40 minutes after removal of TVS. In both the PSTH and EMG-A studies, such facilitation was never provoked by cutaneous electrical stimulation. The conditioning stimulation to the DP nerve induced no effect. These findings suggest that facilitation from DA and DM to BB motoneurons exists in humans. The facilitation should be mediated by group Ia afferents though a monosynaptic path in the spinal cord.

Abstract: We have found that discriminable myoelectric activity can be detected and decoded from the forearm of a person with chronic tetraplegia (C5 motor/C6 sensory American Spinal Injury Association Impairment Scale B spinal cord injury). Residual myoelectric activity after neurological injury may provide a robust control signal for neuroprosthetics and assistive devices. Electromyographic (EMG) activity was measured using a wearable sleeve containing 150 electrodes in a high-density EMG array covering the surface area of the forearm as the participant attempted voluntary movements, including flexion/extension of the fingers, hand open/close, flexion/extension and pronation/supination of the wrist, and flexion/extension of the elbow. The participant had normal strength of the elbow flexors and was able to extend his wrist fully with gravity removed but not against gravity with resistance. He had no visible movement of the elbow extensors, wrist and finger flexors, or finger abductors, despite producing low myoelectric activity. Individual finger flexion/extension movements were classified using multinomial logistic regression. The accuracy of each decoded movement was calculated as the proportion of samples classified correctly out of all samples. Thumb finger trials were classified with the highest accuracy (88%), followed by middle (76%), index (67%), pinky (65%), and, lastly, ring (33%). A one-sided T-test with alpha 0.05 was performed and showed that classification accuracies were significantly better than chance ($p=0.0037$). While accurate decoding of movement intent is essential for neuroprosthetic control, an analysis of signals generated by spared motor units can also provide a representation of the single unit spiking output of motor neurons in the spinal cord. Therefore, filtered EMG signals were decomposed into constituent trains of motor unit action potentials and waveforms were extracted for each channel. The activity of more than 30 motor neurons were identified, active specifically during pronation/supination of the wrist (4 units), flexion/extension of the elbow joint (7 units), and attempted movements of individual fingers (1-5 units). Additionally, a neural connectivity analysis was performed based on the power of the common oscillations of the identified motor neurons in the delta, alpha, and beta bands, showing clear common synaptic inputs. This neural interface technology has the potential to not only provide a non-invasive control strategy for neuroprosthetics but also may serve as a tool for studying the reorganization and recovery of spinal networks after neurological injury, such as stroke and spinal cord injury.

Title: Wavelet-based analysis of plantar flexor muscle recruitment strategies while hopping at different frequencies

Authors: *H. KIM, K. KIPP;
Physical Therapy, Marquette Univ., Milwaukee, WI

Abstract: Vertical hopping provides a simple model to study the function of plantar flexor muscles during dynamic activities, such as those encountered in sports. Given that chronic musculoskeletal injuries (e.g. Achilles tendinosis) are prevalent in sports that require repeated high-effort dynamic activities (e.g. basketball), knowledge about muscle activation strategies may provide insight into the neuromuscular demands and may inform injury prevention strategies. Using wavelet-based intensity analysis may help quantify muscle activation strategies and motor recruitment patterns. Therefore, the purpose of this study was to identify changes in recruitment strategies of plantar flexor muscles during double limb vertical hopping at different frequencies. We hypothesized that the intensity of soleus (SL) and medial gastrocnemius (MG) activation across all wavelets would increase as hopping frequency decreased (i.e., hopping height increased). Ten collegiate athletes (5 males, 5 females; Height: 177.5±8.4 m; Mass: 74.1±10.3 kg) performed double limb vertical hopping at three frequencies (slow: 2 Hz; medium: 2.2 Hz; fast: 2.4 Hz) in random order. Force plate and electromyography (EMG) were used to collect ground reaction force (GRF) and muscle activation data. The EMG data were analyzed during the ground contact phase. Wavelet intensity analysis was used to analyze intensity of muscle activation in the time-frequency domain. Thirteen non-linearly scaled wavelets with center frequencies (Fc) between 4-361 Hz were used. The total intensity of each wavelet was calculated by summing time-series intensity from each wavelet. The intensity of the wavelet with Fc of 4 Hz was excluded because of noise. The intensity of each wavelet at the different hopping frequencies were compared with Kruskal-Wallis and Dunn's post-hoc tests (alpha = 0.05). The Kruskal-Wallis test revealed that for the SL, wavelet intensities with low Fc (12, 23, 59 Hz) differed significantly across hopping frequencies, while none of the wavelet intensities from the MG differed. The post-hoc tests for the SL showed that the intensities of wavelets with Fc of 12, 23, 59 Hz increased by approximately 142% ($p<0.001$), 187% ($p<0.01$), and 163% ($p<0.05$), respectively. Inconsistent with our hypothesis, the results indicated that the intensity of SL activation did not increase across all wavelets. Moreover, the increase in SL recruitment occurred at lower wavelet frequencies, which may indicate that as the hopping speed decreased

(hopping height was increased) the activation of slow motor units increased, while GM recruitment did not differ between hopping frequencies.

Title: Decoding of motor unit firing behavior across postures during isolated finger extension

Authors: *N. RUBIN[1], H. HUANG[1], X. HU[2], C. DAI[3], Y. ZHENG[2];
[1]NC State Univ., Raleigh, NC; [2]UNC Chapel Hill, Chapel Hill, NC; [3]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: In recent decades decomposing surface EMG signals into individual motor unit firings has developed as a promising method to characterize firing patterns in a noninvasive manner. However, decompositions are often applied to signals acquired only in one postural configuration. The motor units recorded within a surface electrode's pickup range may be different due to the mechanical changes both electrodes and musculature would undergo across postures in a realistic setting. To investigate the robustness of decomposition's ability to identify the same motor units across postures, we recruited eight able-bodied subjects who performed isometric extensions of individual finger digits in three postural configurations of the wrist (pronated, neutral, supinated). Subjects followed a force trajectory varying between 0-50% of their maximum voluntary contraction while high-density EMG simultaneously recorded muscular activity of the extensor digitorum communis. Results indicate decompositions from EMG recorded in a neutral posture only identify a subset (mean < 40%) of units decomposed in recorded signals from other postures, indicating the method may not be robust to shifts in an electrode's pickup range. Of motor units identified in a given posture, we consistently observe a preference in firing rate between postures at the same force level. This coincides with prior work suggesting a coupling of a motor unit's firing to the mechanical effectiveness of innervated muscle fibers in order to maximize efficiency of an individual's overall neural drive.

Title: Implantable multichannel wireless recording with support for custom electrode configurations

Authors: *J. C. LANDES, B. CROFTS, S. HIATT, D. MCDONNALL, A. M. WILDER; Ripple Neuro, Salt Lake City, UT

Abstract: Most electrophysiology experiments utilize neural recording devices that transmit data via percutaneous electronics. Percutaneous connections prevent the skin from healing fully and present a constant danger of infections that can track down the electrodes and be difficult to treat. Early failure of these experiments substantially limits the viability of long-term animal studies; thus, there is a need for an implantable recording device that eliminates percutaneous connections at an affordable cost. We have developed a low-cost inductively powered implantable device for recording multiple independent channels of EMG or LFP data. The recorded data is transmitted wirelessly to an external transceiver in real-time. The present design records up to 32 single referenced signals with 12-bit resolution at 2000 samples per second. Exposed solder pads allow for the attachment of custom electrodes through a resealable interface for multi-month animal electrophysiology experiments. The implant consists of a recording ASIC (application-specific integrated circuit) to amplify, filter, and digitize biopotential signals inside an electronics package that is inductively powered and transmits high-bandwidth data via infrared (IR) telemetry. The implant is potted in medical grade epoxy and can easily be attached to bipolar epimysial electrodes, ECoG grids, microwires, or custom electrodes. The implanted device has a footprint of 23 mm x 32 mm x 5 mm, which is comparable to other long-term recording devices implanted in non-human primates. Sensors are included for detecting system failures associated with water ingress or overheating. An external transceiver provides power and data transfer at distances up to 14 mm implant depth and alignment offsets of up to 10 mm and ±30°. The implant communicates with existing Ripple Grapevine Neural Interface systems through the external transceiver for data acquisition, and an additional magnetic coupling component allows for fast and robust alignment of the transceiver and implant in freely behaving animals. Three prototype implants with EMG electrodes consisting of stainless steel, helically-coiled leads in silicone tubes, have surpassed the 1-year mark in accelerated lifetime soak testing in an elevated temperature saline bath. Implants have been and continue to be tested on wireless communication and neural recording capability. Additional support for high frequency sampling (30,000 samples per second) will be implemented in future iterations of the implant making it

suitable for recording single-unit activity from microelectrodes in addition to EMG and field potentials.

Title: Decoding hand motion intent using novel ultrasound imaging of the forearm muscles

Authors: B. MUKHERJEE[1], A. DHAWAN[1], S. PATWARDHAN[1], W. M. JOINER[2], ***S. SIKDAR**[1];
[1]Bioengineering, George Mason Univ., Fairfax, VA; [2]Dept. of Neurobiology, Physiol. and Behavior, Univ. of California, Davis, Davis, CA

Abstract: The vast majority of all trauma-related amputations in the United States involve the upper limbs. The development of multiarticulated myoelectric prosthetic hands in recent years have the potential to improve the quality of life and function of individuals with limb loss, but the ability to control these devices continues to be limited. A significant number of individuals who receive an upper extremity myoelectric prosthesis eventually abandon use of the system, primarily because of their limited functionality. Therefore, there continues to be an unmet need for an intuitive control approach that enable many different movements/abilities.We propose a paradigm shift in the field of prosthetic control using ultrasound imaging for sensing muscle deformation associated with volitional motor intent. This method is called sonomyography. We hypothesized that this method would enable more intuitive movement decoding, as ultrasound can resolve signals from deep within the tissue, and provides a rich signal source for decoding

intent. We investigated the use of sonomyography to decode volitional motor intent in 7 subjects (6 men and one woman) with upper limb loss (age range: 30-68 years, years since amputation: 1-50 years). Five subjects had unilateral traumatic amputation at a transradial level, one subject had a congenital transradial limb loss, while another subject had wrist disarticulation and transhumeral amputation. All subjects were tested in a virtual environment where they were asked to volitionally perform different imagined movements while their forearm muscles were imaged in cross section using a commercial ultrasound transducer. The image sequences were analyzed using a supervised learning algorithm to identify patterns of muscle deformation corresponding to the different performed movements. Our results show that subjects with traumatic limb loss achieved classification accuracies of 96.8-100% for for between 4 to 11 distinct movements within an hour of training. The subject with congenital limb loss had classification accuracy of 85% for 5 distinct movements. This is a significant improvement over myoelectric control methods, including state-of-the-art pattern recognition, which typically takes 10 weeks of intensive training to achieve similar motion discriminability. We attribute these improvements to the fact that sensing mechanical muscle deformation enables the control signal to be congruent to the user's innate residual proprioception and phantom limb schema, making our paradigm intuitive and adaptable.

Title: Using novel imaging techniques to examine selective control of the residual musculature of upper-extremity amputees

Authors: *S. PATWARDHAN[1], A. DHAWAN[2], B. MUKHERJEE[1], W. M. JOINER[4], S. SIKDAR[3];
[1]Bioengineering Dept., [2]Computer Sci. Dept., [3]Bioengineering, George Mason Univ., Fairfax, VA; [4]Dept. of Neurobiology, Physiol. and Behavior, Univ. of California, Davis, Davis, CA

Abstract: Amputees often cite difficulty of use as a key factor for abandoning their prosthesis, creating a pressing need for an improved control methodology. A major challenge of using traditional surface electromyography electrodes has been the difficulty in achieving intuitive and robust proportional control of multiple degrees of freedom. To address this problem, we used a control method (sonomyography) that overcomes several limitations of myoelectric control. In sonomyography, muscle mechanical deformations are sensed using ultrasound, as compared to electrical activation, and therefore the resulting control signals can directly control the position of the end effector, making it more congruent with the remaining proprioception within the residual limb. Ultrasound imaging can non-invasively resolve individual muscles and detect dynamic activity within different functional compartments. We tested sonomyography with 5 upper-extremity amputees (4 traumatic and 1 congenital) and 5 able-bodied subjects. In the task, dynamic ultrasound images measured contracting muscle deformations during actual motions of the limb, or approximated motions in the residuum. This signal was used to move a screen cursor to a series of targets, and hold the cursor at that location within a quantization bound. Performance metrics consisted of position error (the mean error between the cursor and the target position), stability error (the standard deviation of the cursor position from the target position), task completion rate and movement time. Both traumatic and congenital amputee subjects with no prior experience of using a sonomyography-based interface were able to demonstrate fine graded control of an end-effector controlled by muscle activation patterns in the remaining forearm with position and stability errors being below 3.5% and 12.1%, respectively. Consistent with Fitts's law, movement time was significantly correlated and increased with task difficulty for all participants ($R > 0.85$). Finally, the average task completion rate was higher than 94%. Our results demonstrate the potential of using sonomyographic signals for intuitive dexterous control of multiarticulated prostheses with potential clinical applications in fundamental investigations of motor control and biomechanics.

Title: Probing the relationship between motor cortex and upper limb muscles during spontaneous natural movements

Authors: *X. MA[1], K. L. BODKIN[1], A. FARSHCHIAN[1], E. ALTAN[1], M. E. FRACOL[2], L. E. JANES[2], F. A. MUSSA-IVALDI[1,3,4], L. E. MILLER[1,3,4];
[1]Dept. of Physiol., [2]Dept. of Surgery, [3]Dept. of Biomed. Engin., [4]Dept. of Physical Med. and Rehabil., Northwestern Univ., Chicago, IL

Abstract: Primary motor cortex (M1) needs to generate control signals to synergistically activate many combinations of muscles in order to perform the diverse movements of daily living. Most existing sensorimotor studies have investigated the mapping from M1 activity to muscles by training monkeys to perform a few instructed movements in highly restricted conditions. Motivated by the demand of extending those in-lab studies to a wider realm, here we propose to explore the interaction between M1 and muscles during more natural movements of unrestrained monkeys. We implanted an electrode array in hand M1 and intramuscular electromyographic (EMG) leads in the arm and hand of one monkey. We simultaneously recorded these signals wirelessly while the monkey was in a plastic telemetry cage in which it could perform various free-form hand movements. We performed temporal clustering of the EMG signals to categorize the monkey's various movements. We divided the entire dataset into short time bins and projected the EMG from selected muscles within each time bin to a low dimensional space using nonlinear methods. We found that low-dimensional projections of time bins with similar EMG patterns were adjacent. This allowed us to use conventional clustering algorithms to sort hours of continuous recordings into identified categories of movements that had similar muscle activity patterns. We then investigated the consistency of the relationship between M1 and muscle activity across these movement categories. We built a variety of linear and nonlinear decoders to predict EMG from M1 recordings. We found that recurrent neural network (RNN) based decoders could achieve EMG predictions as good as those for in-lab tasks when training and testing with data from the same category of movements. RNNs consistently outperformed linear Wiener filter-based decoders. However, such single-category decoders, whether linear or nonlinear, could not make accurate EMG predictions across categories. We also trained the decoders with samples from a combination of categories, which allowed RNN decoders to yield accurate EMG predictions for all categories included in the training set, but still not on held-out categories. Linear decoders remained inaccurate even with robust training data. From these results we posit that there could be a number of nonlinear components involved in the interaction between M1 and muscles for natural movements, for which the motor system needs to produce a diversity of muscle activity patterns. Categorizing these unstructured movements has enabled us to compare different M1 and EMG activity patterns in an organized way, and therefore probe those components quantitatively.

Title: Development of a comprehensive brain-computer interface decoder of natural movements

Authors: *A. FARSHCHIAN, X. MA, E. ALTAN, K. BODKIN, M. E. FRACOL, L. E. JANES, E. PERREAULT, S. SOLLA, F. MUSSA-IVALDI, L. MILLER;

Abstract: Brain-computer interfaces (BCIs) have emerged as a clinically viable solution to help survivors of spinal cord injury operate assistive devices or to restore movement after paralysis. A central component of a BCI is a decoder that predicts movement to provide kinematic control of a computer cursor or a robotic arm, or to produce artificially generated muscle activity to restore movement of a paralyzed arm through functional electrical stimulation. Most existing BCI decoders are built for simple, stereotyped tasks performed in laboratory settings, and fail to operate across the wide range of activities of daily living. To build a more general decoder, we have developed a wireless BCI that simultaneously records motor cortical neural activity and the activity of multiple arm muscles throughout a range of natural, unconstrained behaviors (foraging, feeding, and grooming) while the monkey is in its cage. We show that current decoding techniques fall short of generalizing across these tasks and of providing reliable muscle activity predictions, probably due to 1) the performance of multiple tasks with higher variability in each execution, 2) periods of time when substantial cortical activity is present with no muscle activity, and 3) inherently noisier wireless recordings in a cage. To compensate for these shortfalls, we are beginning to pursue recent techniques in the field of Natural Language Processing and Machine Translation to build a comprehensive decoder that works by mapping short sequences of neural activity onto similar sequences of muscle activity. In brief, we project each neural activity sequence onto multiple low-dimensional subspaces. In each subspace, we create shorter sequences (subsequences) through linear combinations of the projected sequences. Finally, we concatenate the subsequences to get a transformed sequence of neural activity that has the same length as the original sequence. We use this transformed sequence of neural activity as the input to an autoregressive network that predicts a sequence of muscle activity. This work is part of an ongoing effort to adapt Machine Learning (ML) techniques to characterize and decode neural activity. We have recently demonstrated that ML techniques for domain adaptation can be extended to successfully unveil the stable statistics of neural activity during stereotyped laboratory tasks. Here we propose an ML-based decoder designed to account for

short term features of neural dynamics. Accurate muscle predictions across the rich variety of observed cage behaviors would lead to a general BCI capable of sustained performance across a wide range of activities of daily living.

Title: Reaction times in response to multi-electrode intracortical microstimulation are faster than to limb perturbations

Authors: ***J. SOMBECK**[1], L. E. MILLER[2,1,3,4];
[1]Dept. of Biomed. Engin., [2]Dept. of Physiol., [3]Dept. of Physical Med. & Rehabil., Northwestern Univ., Chicago, IL; [4]Shirley Ryan AbilityLab, Chicago, IL

Abstract: Tetraplegic patients using brain-machine interfaces (BMIs) can now make visually-guided reaches with robotic arms. However, in addition to vision, restoring proprioceptive feedback to these patients will be critical, as evidenced by the movement deficiencies in patients with proprioceptive loss. Proprioception is critical in large part because it provides much faster feedback than vision. Intracortical microstimulation (ICMS), which can be used to elicit conscious percepts in monkeys and humans, is a promising approach. The reaction time (RT) in response to single-electrode stimulation, though, is typically slower than that to tactile and often even visual cues, implying that ICMS cannot provide fast enough feedback, making it unsuitable for restoring proprioception. Fortunately, for most sensory modalities, the RT decreases with increased stimulus intensity. Thus, it may be that stimulation intensities beyond what has previously been used will result in faster RTs. To test this, we compared the RT to ICMS applied through multi-electrode arrays in area 2 of somatosensory cortex to that of limb perturbations and visual cues in a simple RT paradigm. We found that the RT to single-electrode ICMS decreased with increased amplitude, frequency, and train length. For the highest single-electrode stimulation we tested routinely, 100μA at 330Hz, 78% of electrodes resulted in slower RTs than limb perturbations, with latencies similar to that of a visual cue. While increasing the stimulation amplitude beyond 100μA resulted in faster RTs, sustained stimulation at this level may cause damage to tissue surrounding the electrodes. Alternatively, by stimulating through multiple

electrodes (mICMS), a large amount of current can be injected while keeping that through each electrode at a safe level. We found that stimulation with greater than 480μA equally distributed over 16 electrodes produced RTs about 20ms faster than limb perturbations, roughly the conduction delay to cortex from the periphery. At constant total current, increasing the number of electrodes resulted in slower RTs, possibly because the current on some electrodes fell below an activation threshold. To determine if the distance between electrodes influences the mICMS RT, we stimulated through small groups of adjacent and non-adjacent electrodes. Adjacent electrodes resulted in slightly, but not significantly, slower RTs than non-adjacent electrodes. Together, these results suggest that it may be possible to use mICMS to provide fast feedback. Spatial-temporally patterned mICMS may be needed in future neuroprosthetics to convey useful somatosensory information.

Title: Dimensionality of neural subspaces for the control of natural and stereotyped movements

Authors: *E. ALTAN[1], K. L. BODKIN[1], J. A. GALLEGO[2], A. FARSHCHIANSADEGH[1], X. MA[1], F. A. MUSSA-IVALDI[1], S. A. SOLLA[1], E. J. PERREAULT[1], L. E. MILLER[1]; [1]Northwestern Univ., Chicago, IL; [2]Ctr. De Automatica Y Robotica, Arganda Del Rey, Spain

Abstract: Activity of primary motor (M1) cortical neurons likely reflects the coordination observed in muscles across motor tasks, from simple movements to highly dexterous ones. Like synergistic muscle activity, population activity in M1 appears to be constrained to a low-dimensional subspace within the space of all possible patterns. This neural coordination can be quantified through the intrinsic dimensionality (ID) and covariance patterns of neural population activity. Here, we focused on the ID. Previous laboratory studies have shown that the ID was not only much smaller than the number of recorded neurons, but even smaller than the number of involved muscles. However, the relation between M1 activity during natural tasks that might be more relevant to the activities of daily living and that of the more common repetitive laboratory tasks remains unknown. Is the low ID of M1 a byproduct of constrained laboratory behaviors? If so, is the ID of M1 activity during unconstrained behaviors such as grooming, foraging, or feeding, higher than that of laboratory tasks? A reasonable expectation is that some natural behaviors, such as grabbing a bar with a power grasp, are simple and low-dimensional, whereas

others, like playing with toys, may be complex and high-dimensional. Here, we used a two-step approach to estimate the ID of recordings from the hand area of M1 as monkeys performed different motor tasks in the laboratory and while engaged in natural behaviors in their home cage. We first denoised the neural signals using a deep learning method that identifies common signals in two random, non-overlapping samples of the electrode channels recorded in each session. We then estimated the ID of the denoised neural signals using Fisher Separability Analysis. Surprisingly, we found that the IDs of neural recordings during natural behaviors ranged between 2 and 5 for randomly selected, one-minute lengths of data, comparable to those of laboratory tasks. The IDs associated with natural behaviors were smaller than those of some laboratory tasks (visually guided wrist flexion/extension movements) but larger than those of others (power grasp). An interpretation of this finding is that ID alone may not suffice to describe differences in neural population activity across behaviors, and that additional measures, such as covariance, may be necessary. Importantly, the low ID we observed across natural and laboratory tasks suggests that neural decoders for individual behaviors can operate on a low-dimensional subspace of the neural signals. It remains to be seen if it is possible to construct a general decoder that can operate across a range of subspaces, each associated with a specific behavior.

Abstract: Coordinating the activity of groups of muscles is critical for motor function, and underlies diverse movements such as respiration, walking, reaching, and grasping. However, a major barrier to understanding how the brain coordinates muscle activation is that electromyographic (EMG) activity is noisy, making it difficult to interpret on a moment-to-moment basis. Furthermore, the standard approach to processing EMG (i.e., rectification and smoothing) treats temporal complexity in EMG signals as noise. Here, we developed a new method to "de-noise" EMG signals that are recorded simultaneously from multiple muscles. Our working model is that the coordinated activity of muscles during movement is the output of a dynamical system. Thus, by accurately modeling these underlying dynamics we might substantially de-noise EMG. To test this we used Latent Factor Analysis via Dynamical Systems (LFADS), a deep learning technique we previously developed to model the dynamics of neuronal population activity. LFADS uses artificial recurrent neural networks to uncover nonlinear dynamics from high-dimensional data in an unsupervised manner. Notably, the statistics of EMG are substantially different from neuronal population spiking activity, necessitating key modifications to the LFADS modeling architecture. We tested our model on intramuscular EMG recorded from 12-14 muscles from two paradigms: (1) rat hindlimb during locomotion and (2) monkey forearm during an isometric center-out wrist force task. When applied to the rat locomotion data, the model produced single-trial representations of muscle activity that improved joint angle and joint velocity decoding for eight different joints. Similarly, when applied to the monkey data, the single-trial representations from LFADS produced more accurate predictions of the force applied by the monkey to the manipulandum. Interestingly, the EMG was also substantially more predictable from simultaneously-recorded M1 population activity. Ultimately, our results suggest that modeling the dynamics of EMG recorded from multiple muscles uncovers more informative representations of muscle activation than traditional approaches, and may open new avenues to studying temporal coordination of individual muscles and their precise control through inputs from motor cortex.

Title: Modeled muscle spindle primary afferents predict firing rates of cuneate nucleus neurons in the awake monkey

Authors: *C. VERSTEEG[1], K. P. BLUM[2], J. WALLNER[2], S. SNYDER[2], R. H. CHOWDHURY[3], J. ROSENOW[5], L. E. MILLER[4];

Abstract: The cuneate nucleus (CN) is the first potential site for somatosensory transformations in the CNS. For simplicity, we previously modeled the activity of these neurons during reaching movements using the position and velocity of the hand, as is typically done for somatosensory cortical neurons. However, given their location only one or two synapses from the sensory afferents, models based on afferent receptor signals might be more appropriate. Muscle spindle responses to length change have a complex nonlinear relation to motion, including history dependence, which may significantly affect modeled CN activity. In this study, we predict the firing of CN neurons during reaching using simulated muscle spindle activity. We implanted three monkeys with Utah microelectrode arrays (MEA) in CN. We captured the kinematics of the arm using a custom motion tracking system while the monkeys performed a center-out reaching task with the ipsilateral limb. We did sensory mappings of the receptive fields (RFs) of CN neurons, tentatively identifying those that received muscle spindle inputs by a combination of passive arm movements, muscle palpation, vibration, and light brushing to reveal cutaneous fields. We used a previously published musculoskeletal model to compute the lengths of 39 muscles of the arm. We ran these muscle kinematics through existing models of the muscle spindle primary and secondary afferents to compute simulated firing rates of one representative muscle spindle per muscle. We fit Poisson generalized linear models (GLMs) relating the simulated spindle firing rates to the firing rate of individual CN neurons. These models performed better than extrinsic kinematic encoding models (including only the position, velocity, and acceleration of the hand). Furthermore by changing simulated gamma drive, we tested various hypotheses about its control, including fusimotor set and alpha-gamma coactivation hypotheses. Because movements included both actively generated and passively imposed conditions, we could test how these gamma-drive hypotheses generalized across conditions. This approach will not however, allow us to disentangle the effects of altered gamma drive from those due to descending input from sensorimotor cortex. In order to understand how proprioceptive information changes as it moves centrally, it is important to understand the behavior of the sensors in the periphery. By modeling muscle spindle afferents, we show that the firing at the level of CN is related more closely to the peripheral receptor signals than to muscle length change or hand movement.

Title: Lateral connectivity may underlie cortical organization of proprioception

Authors: ***K. P. BLUM**[1,2], Y. WU[4], R. H. CHOWDHURY[2], A. A. FAISAL[5], L. E. MILLER[1,2,3,6];

Abstract: As in the visual system, proprioceptive signals must be projected from a high-dimensional peripheral representation - from skeletal muscles, tendons, joints, and skin receptors -- to a two-dimensional cortical sheet. However, despite the critical role of proprioception in movement, we know relatively little about this process compared to its analog in the visual system. To understand the neural principles by which peripheral proprioceptive afferent signals undergo this transformation from high- to low-dimensional spaces, we used a neural-network model of the proprioceptive afferent system based on variational auto encoders. The final latent layer of this network was designated as the simulated “cortical” layer, with Poisson neurons organized in a two-dimensional grid. The overall goal of the network was to reconstruct the simulated proprioceptive inputs to the network from the latent cortical layer which was subjected to lateral inhibition and Poisson-sampled spiking. We trained this network using simulated proprioceptive afferent signals generate from data collected from a monkey performing a planar reaching task. The network weights were found through several training epochs to find the optimal representation of the peripheral inputs. We found several emergent properties within this self-organizing map that reflect classical properties of S1 neurons. First, the modeled neurons exhibited cosine tuning to movement direction. The preferred directions (PDs) of the neurons were distributed across all directions, despite a more nonuniform distribution of PDs for the peripheral inputs themselves. As for actual S1 neurons, these PDs were biased toward and away from the body. At a less localized level, we found small “neighborhoods” of simulated neurons with similar PDs. This finding also reflects our earlier observation that neurons recorded from a given electrode are more likely to have similar PDs that those recorded on different electrodes. In all, these results demonstrate principles by which the proprioceptive system may represent

peripheral inputs in cortex. Local clustering of similarly tuned proprioceptive neurons could be advantageous for coordination of multi-joint feedback and postural control. In the brain, these local clusters may carry additional functional relevance, such as task-level feedback for different movement contexts. Beyond these questions of basic science, these findings may be important for efforts to restore somatosensory function through intracortical microstimulation, as the topography of proprioceptive cortex could greatly affect the ability to elicit naturalistic sensations.

Abstract: Spike-timing-dependent plasticity promotion has been shown previously in *in vivo* experiments in animal studies. For example, spike-triggered stimulation of one brain site triggered from spikes recorded in another site can modify synaptic connections between the sites in monkeys. Here we present evidence of changes in neural activity that could reflect spike-timing-dependent plasticity promotion in human recordings. We stimulated primary somatosensory cortex (S1) at a fixed lag (20 ms) from spikes recorded from supramarginal gyrus (SMG) of a 35-year-old tetraplegic patient with Neuroport microelectrode arrays (Blackrock Microsystems). In a stimulation condition, with the patient at rest, stimulation was delivered over 15 minutes to eight channels in S1, selected to include the electrode with highest spike-spike correlation with SMG, and spacing the remaining seven to limit charge per phase per area. Pre-

and post-stimulation recordings (200 s) were compared to quantify changes in functional connectivity assessed by correlation measures. In a control condition, the same set of stimulation channels was used, but stimulation pulses were delivered randomly, at an average rate equal to that of the stimulation condition.
On average, 71.5 of 96 channels in S1 showed a significant decrease in firing rate correlation (Kruskal-Wallis test, $p<0.05$, corrected for false discovery rate) with the selected recording channel after stimulation (n=2), versus 3.3 channels for the control condition (n=3), showing significant difference between the two conditions (t-test, $p<0.05$). The number of channels with significant increase in spike correlation was not significantly different between two conditions (1.5 versus 8.7 channels). Furthermore, there was no significant difference in firing rate between control and stimulation conditions (t-test, $p<0.05$), including the selected recording channel. These results demonstrate the possibility of using spike-triggered stimulation for inducing cortical plasticity in humans. Future data collection will allow us to explore this effect in more detail with different parameters, such as the lag between spike and stimulation, and the channel pairs for stimulation and recording. For instance, we will examine if there are lags that produce increased activity rather than decrease in activity. In addition, different methods for quantifying connectivity will be examined.

Bioelectronic Med., Feinstein Inst. for Med. Res., Manhasset, NY; [6]Electrical and Computer Engin., [7]Biomed. Engin., Univ. of Utah, Salt Lake City, UT

Abstract: Stable, sensitive electrodes are fundamental to the robust operation of brain-machine interfaces (BMI), devices which read out brain activity to control assistive devices and write feedback information back into the brain. The purpose of this work is to quantify failure modes of long-term implantation in the human cortex by using SEM to observe defects in the electrode metallization and insulation. We examined two microelectrode arrays, implanted in the cortex of a human tetraplegic research participant for five years, in a scanning electron microscope (SEM). These "Utah" microelectrode arrays (NeuroPort, Blackrock Microsystems, Salt Lake City, UT) were implanted in anterior intraparietal area (AIP) and Brodmann's area 5 (BA5). While implanted, both arrays showed similar recording trends, with initially high impedances, but then gradually decaying over the implant lifetime. Action potentials recorded from the two arrays could be variable across sessions and between arrays but the number of units was consistent on average over time. Five years after implant, the arrays were explanted intact and examined under SEM. We scored each electrode on a scale from 0 (poor quality) to 5 (high quality) for the condition of the platinum metallization at the electrode tip and the insulation along the electrode shaft. The AIP array scored 2.3 ± 1.0 (a.u., metallization) and 4.6 ± 0.7 (a.u., insulation) whereas the BA5 array scored 1.5 ± 1.3 (metallization) and 2.8 ± 1.3 (insulation), indicating that the BA5 array electrodes were in generally worse condition both in terms of the metallization and insulation. Perhaps due to this difference in conditions, metallization quality was a good predictor of electrode impedance (measured *in vivo* two months prior to explant) for the AIP array (linear regression; $p<0.05$) but not for the BA5 array. Insulation quality was not strongly predictive of impedance in either array. These findings begin to quantify the relationship between the physical condition of microelectrodes implanted in cortex and their capacity to record electrical activity. The data presented here are especially important as multi-year clinical trials of BMIs in human are becoming more common and could lead to improved manufacturing practices or novel electrode designs to improve long-term performance of BMIs.

Engin., Univ. of Utah, Salt Lake Cty, UT; [6]Avanos Med., Alpharetta, GA; [7]Blackrock Microsystems, Salt Lake City, UT

Abstract: Translation of penetrating multielectrode array (MEA) technologies into clinical use has been hampered by the difficulty in achieving long-term stable recording and stimulation performance. Performance degradation has been attributed to abiotic and biotic processes. This study quantitatively assesses degradation of Utah Slanted Electrode Arrays (USEAs) implanted in the peripheral nerves of human subjects for up to 17 months. The purpose of this work is to determine the abiotic failure mechanisms for these MEAs and the associated impact on impedance and performance, so that this knowledge can be leveraged to mitigate the degradation mechanisms. One such mitigation is electrode material innovation, and we show that recent advancements in this direction are promising based on accelerated stimulation stability test results.

A total of 7 USEAs were implanted in 3 subjects: HS1, HS2, and HS3; for 3, 14, and 17 months, respectively. After explantation, electrode condition was analyzed by SEM and scored based on evident damage: 1 (little), 2 (modest), 3 (significant), and 4 (severe). Mean and median damage values ranged 2.04 to 2.77, and 2 to 3 respectively, and statistically significant differences were observed between the electrode arrays for different subjects, and thus the associated differing indwelling times ($p=0.004$ between HS1 and HS2 arrays). HS3 arrays received much less stimulation that HS1 and HS2 arrays, but the degradation values (2.77, 2.63. 2.52) indicated worse degradation was observed. Prior results have also indicated there is not a correlation between stimulation doses up to 19 mC and the tip degradation. Statistical analysis of this data is in process, and is expected to further support that in-dwelling time best correlates with electrode degradation for the 7 USEAs studied here, as opposed to stimulation dose, electrode impedance, or location on array. Additional spatial statistical comparisons will be executed to identify patterns or associations between these electrode characteristics.

In addition, we used the stimulation-stability method developed within the lab to compare the stability of the current practice Blackrock metallization, which has already benefited from technology transfer from the HAPTIX program, to the current optimized Utah tip metallization. Preliminary results have suggested that the Utah metallization can more reliably tolerate a dose of 1 million biphasic pulses using 2.1 mA of stimulation current, representing 840 mC of injected charge.

Abstract: Several neuroprosthetic learning studies have shown that after an initial phase of exploration, spatiotemporal activity patterns that lead to desired outcomes are selected and consolidated. It is known that 'indirect' neurons, that do not directly control a neuroprosthetic effector, show a suppression of modulation depth across learning but can also demonstrate task related tuning. It is possible that these cells become incorporated into functional neuronal assemblies that help coordinate neurons that directly drive an effector- but it is not clear why this particular subset of neurons becomes involved, and how they may act to stabilize and reinforce output. Using chronic single and multi-photon calcium imaging, we created a Brain-Machine Interface (BMI) paradigm in which mice learned to perform a neuroprosthetic task using the coordinated activity of a small ensemble of neurons in sensorimotor cortex (L2/3), guided by auditory feedback (Clancy, 2014). This approach provides long-term access to hundreds of neurons, referenced to an easily quantified output layer of a few neuron's activity. We find that a subset of the local cortical population gradually converges to form highly reproducible, spatiotemporally organized sequences that precede and follow the activity of output neurons. Similar time-locked, repeatable sequences of neural activity are known to underlie many forms of memory and sensory guided behavior, from the tracking of behaviorally relevant variables to the planning and coordination of movements. Neuroprosthetic tasks may provide key insights as to how these patterns self-organize and refine in a case where the link between behavior and individual neuron activity is well defined. In this poster we examine the formation, structure and stability of these emergent, spatially organized network patterns.

Title: Isolating cell-type specific subpopulations of motor cortex neurons during neuroprosthetic learning

Authors: *N. VENDRELL LLOPIS[1,2], C. FANG[2], A. J. QU[2], M. KITANO[1], R. M. COSTA[3], J. M. CARMENA[1,2];
[1]Dept. of Electrical Engin. & Computer Sci., [2]Helen Wills Neurosci. Inst., Univ. of California-Berkeley, Berkeley, CA; [3]Zuckerman Mind Brain Behavior Inst., Columbia Univ., New York, NY

Abstract: Projections from cortex to the striatum are governed by two different types of neurons, pyramidal tract (PT) and intratelencephalic (IT). These subpopulations of neurons differ in electrical properties, belong to different functional circuits and may be diversely involved in cognitive processes. However, it is still unclear how PTs and ITs may contribute to learning due to the immense complexity of cortical interconnections and the innate variability of natural behavior. In order to investigate the functional roles of these projecting neurons during learning, we labeled the different cortical subpopulations using retrograde labeling via viral infection and took advantage of a neuroprosthetic task that links directly the activity of neurons with the behavior of the animal. Mice learned to modulate the activity of either PT or IT labeled neurons to control a one-dimensional auditory cursor linked to a sucrose water reward. Here, we investigate PT and IT functional role during learning while monitoring large-scale neural dynamics surrounding the two distinct cortical cell types across multiple cortical layers.

Title: The sheep (Ovis aries) as a clinical translational model for intracortical microelectrodes

Authors: *I. N. MCNAMARA[1], M. STRAKA[2], M. HANNA[2], K. SAHASRABUDDHE[2], K. BOERGENS[2], R. J. EDGINGTON[2], Y. KONG[2], H. S. SOHAL[2], M. R. ANGLE[2];
[2]Neurosci., [1]Paradromics Inc., Austin, TX

Abstract: Successful clinical translation of a medical device depends on the appropriate selection of the animal model used for preclinical testing. For intracortical electrodes used inapplications including brain machine interfaces, the choice has historically been non human primates (NHPs). These safety studies are often performed with concurrent testing of basic science experimental hypotheses and thus require extensive animal training on specific sensory or motor tasks before device implantation. For a device-oriented translational model that does not require training-based task performance, other preclinical models with similar structure and function to the human brain should be considered. Here we show the benefits of using sheep as an animal model for clinical translation.

The sheep brain is similar in anatomy to the human brain, especially in terms of sulci and gyri formation. Interestingly, the sheep brain is the neurosurgery model of choice for practicing procedures before deploying surgical techniques on human patients. Sheep have been used as a preclinical model for deep brain stimulation (Lentz L), a therapy for treating various neurological disorders. To date, sheep have been used for chronic cortical recordings for stentrode technology (Opie et al. 2018), as well as Electrocorticographram (ECoG) recordings for mapping areas of the sensory areas of the cortex (Gkogkidis et al. 2017). However, sheep have not been used for intracortical electrode studies in part because detailed studies are lacking for comprehensive structure and function of sensory areas.

Here we characterize structural and functional cortical sensory areas in the sheep cortex. We show histological analysis to delineate the cortical layers in various sensory areas, such as visual, auditory and motor cortices. Immunofluorescent imaging was performed to confirm the gross morphology (Nissl), presence of neurons (NeuN), and meningeal structure (IgG). In addition, we performed electrophysiological characterization through both functional ECoG mapping and intracortical recording of various sensory areas. We are able to obtain high fidelity spikes and ECoG recordings to enable the formation of sensory maps.

The sheep brain is a good translational model for intracortical microelectrodes. Their brains are similar to humans and from a device standpoint, any technological innovations (e.g. novel device insertion strategies) in this model will translate well to the human cortex. Further, neural activity can be used to form sensory maps in a similar way as primates, with a faster turnaround time than common NHP experiments and therefore streamlining the device testing pathway.

Abstract: Microwire electrode arrays provide a scalable means of recording from large ensembles of neurons *in vivo*, particularly when these arrays are bonded to high density complementary metal-oxide semiconductor (CMOS) readout circuits [1,2]. Here we describe a custom neural recording system that can be bonded to microwire electrode arrays for large scale extracellular recording in a head-fixed *in vivo* preparation. The system supports up to 65,536 channels, read out simultaneously at up to 39,000 samples per second and 12 bits of resolution. The total system bandwidth is 30 gbps, which can be streamed directly to disk or viewed in real-time through a digital oscilloscope running on a web browser. This system represents a significant improvement over existing CMOS microelectrode arrays in terms of data throughput and overall usability. We report our first demonstration of the system in rat cortex, recording in a head-fixed in-vivo preparation from arrays of <2,000 wires. We will also report on early work adapting the system for use in a large animal preparation [3] for arrays >10,000 wires. This system paves the way for future, implantable devices based on large scale microwire-CMOS arrays.

Title: Histological confirmation of contents of neurotrophic electrode after recording for a decade

Authors: *P. R. KENNEDY[1], **M. GEARING**[2];
[1]Neural Signals Inc, Duluth, GA; [2]Emory Univ., Atlanta, GA

Abstract: The Neurotrophic Electrode (NE) is designed to record longitudinally the same identifiable neural signals over years. Prior recordings endured 1.4 years in rats and 1.3 years in monkeys and up to four years in humans. In the one human (MR) in whom histology was available, it was not satisfactory due to technical problems with the autopsy. The present histological result was obtained from subject ER, 13 years after implantation with final recordings at year ten. He was too ill to function and perform conditioning studies at that time, but at year nine conditioning studies were satisfactorily performed (3) indicating that the recorded signals were not noise. Instead, they were functional single units. Autopsy was performed at the time of death, and histological findings are presented here.
Histological analysis: The neural tissue inside the NE was processed in the Neuropathology/Histochemistry Core laboratory at Emory University. H&E stain demonstrated basic neuropil with no neurons. Immunohistochemistry for neurofilaments revealed ingrown neurites. Myelination of the axons has been demonstrated with LFB-PAS stain. In addition, GFAP immunostain demonstrated no significant gliosis.
These results suggest that the neural activity is associated with neurofilament-containing neuronal processes.

Title: Grasp force task reveals onset-offset response in ECoG high-frequency band

Authors: *M. P. BRANCO, S. GEUKES, E. J. AARNOUTSE, M. J. VANSTEENSEL, Z. V. FREUDENBURG, N. F. RAMSEY;
Neurol. and Neurosurg., Univ. Med. Ctr. Utrecht, Utrecht, Netherlands

Abstract: One emerging goal of research using Brain-Computer Interfaces (BCIs) is movement restoration. Using electrocorticogram (ECoG) signals, multiple hand movement features have been successfully decoded from the surface of the somatosensory cortex (SMC), both in a discrete (e.g. hand gestures) and a continuous (e.g. fingertip trajectories) manner. In order to design a BCI system that can accurately manipulate objects, continuous decoding of grasp force is necessary. This has been done in previous studies, where the high-frequency band (HFB; >70Hz) power changes provided discriminative information for an accurate decoding of grasping force. However, as the models used in previous studies contained information from multiple features over multiple areas in the brain, it remains unclear what parameters are encoded by the HFB signals and how these are represented temporally. To investigate this, and to gain insight in the temporal dynamics of the HFB during grasping movements, we continuously modeled the ECoG HFB response recorded from 9 subjects with intractable epilepsy while performing three different grasp force tasks: namely, fast impulse-like responses, continuous dynamic force and isometric force contractions. Using these three tasks, we investigated how the HFB follows the force profile. We compared two models, one based on the exerted force magnitude and another based on the derivative of the exerted force (i.e., movement onset-offset), with the mean HFB signal over electrodes in four different cortical regions-of-interest: all electrodes, electrodes covering the primary motor cortex, the central sulcus and the primary somatosensory cortex. We show that a model based on the force onset and offset consistently shows a better fit to the HFB when compared with a model based on the force profile, especially for the subjects implanted with high-resolution ECoG grids, and that the best fit was irrespective of the electrode location. This suggests that HFB power, although useful for continuous decoding, is not continuously related to force but rather to the changes in movement. This information can be taken into consideration in understanding and decoding neural signals, in particular for BCI.

Title: Demonstration of an optimized, large-scale optogenetic interface for non-human primates

Authors: *D. J. GRIGGS[1], W. K. S. OJEMANN[2], K. KHATEEB[2], M. CHU[1], A. YAZDAN-SHAHMORAD[3];

Abstract: High spatial and temporal precision and cell type specificity make optogenetics a powerful tool for studying fundamental neural mechanisms and developing neurorehabilitation techniques. To these ends, we recently introduced an optimized large-scale optogenetic interface for non-human primates (NHPs) [1].
Briefly, this interface consists of a flexible recording and stimulating micro-electrocorticography (μECoG) array which we have integrated into a transparent silicone artificial dura to make a "μECoG-dura". Surgical implantation of the μECoG-dura provides both optical access to about 5 cm^2 of the brain and μECoG recording capability which collectively enable large-scale cortical optogenetic experimentation. This interface improves upon the stability and scale of our previous interface iterations [2]. Previously, optical access to the brain was limited to 2-3 weeks due to opaque tissue growth across the optical window, μECoG recording hardware was prone to corrosion, and the setup was limited to 2-3 simultaneous optical stimulation channels. Here, we will validate that our optimized design allows for months of optical access, is corrosion resistant, and supports up to 16 LEDs for simultaneous optical stimulation, thus improving the stability and scale of the interface.
We will genetically modify cortical neurons of the NHP with convection enhanced delivery (CED), a pressure based injection approach, to efficiently obtain uniform, widespread viral vector delivery [2]. After transduction and interface implantation, various optical and electrical stimulation protocols will be employed to modulate neural activity and the results will be recorded by the μECoG-dura.
If successful, our experiments will validate the stability and scale of the interface design by (1) increasing the length of time of optical access to neural tissue from a few weeks to several months, (2) demonstrating no significant corrosion to electrical recording hardware, and (3)

demonstrating neural modulation via various optogenetic and electrical stimulation protocols as measured by μECoG recordings.
This work will set the stage for the development of stable, large-scale, multi-modal neural modulation protocols. Such protocols may be designed to help answer fundamental questions of cortical organization and plasticity and develop neurorehabilitation techniques.

Title: Laminar decoding of the rat forelimb during a knob supination task

Authors: *J. O. USORO[1], C. KUNG[1], W. E. VOIT[2], S. A. HAYS[1], J. J. PANCRAZIO[1];
[1]Bioengineering, [2]Materials Sci., The Univ. of Texas at Dallas, Richardson, TX

Abstract: Introduction: Brain-machine interfaces enable the decoding, i.e. the translation, of neuronal activity into movement kinematics that can be used to control neuroprostheses[1]. To date, most motor decoding applications use the standard Utah electrode array, which is limited to recording neuronal activity in a single depth within the cortex. Evidence suggests however, that there may be laminar differences in sensory- and movement-encoding neurons[2], particularly for complex behaviors. In this study, we investigate the feasibility of using laminar arrays to decode a novel, wrist-supination task, and characterize layer-specific contributions of neuronal activity involved in this movement in a rodent model.
Methods: All procedures were approved by the Institutional Animal Care and Use Committee at the University of Texas at Dallas. Female Sprague Dawley rats were trained to perform a knob supination task[3]. Afterwards, rats were surgically implanted with either shape memory polymer (SMP, IC-5-16E, Qualia Labs, Inc., USA) or NeuroNexus (A1x16-3mm-100-177-CM16LP,

NeuroNexus Technologies Inc., USA) probes in the forelimb representation of the left motor cortex. Neuronal activity was recorded while the rats performed the task, and both the neural and supination data were fed into a decoding algorithm. The algorithm was first trained on test data before making predictions on new data sets. Accuracy of the algorithm was assessed by its ability to predict successful supination trials.
Results: Neural activity was recorded during all sessions, with one session recording from 20 single units across 16 channels. Visual inspection of the raster plot from this trial revealed fairly consistent activity from electrodes that were deeper in the cortex, whereas the activity at shallower electrode sites were temporally modulated by the task, indicating that these movement-evoked potentials may be a result of directionally- or kinematically-tuned neurons. From this activity, preliminary analysis indicated that the algorithm was approximately 70% accurate in predicting successful supination trials in the test data.
Conclusions: Based on preliminary results, we were able to successfully decode wrist supination using laminar probes. Data collection and analysis is ongoing however, and will allow us to refine the algorithm for more accurate predictions, further characterize laminar contributions to the supination task, and investigate the efficacy of using SMP probes for chronic motor decoding.

Title: The effects of frontal cortex lesions on sensorimotor BCI control features

Authors: ***Z. V. FREUDENBURG**[1], M. J. VANSTEENSEL[2], E. J. AARNOUTSE[3], K. J. MILLER[4], N. F. RAMSEY[2];
[1]Dept. of Neurol. and Neurosurg., [3]Neurol. and Neurosurg., [4]Neurosurg., [2]Univ. Med. Ctr. Utrecht, Utrecht, Netherlands

Abstract: The sensorimotor cortex is a frequently targeted brain area for the development of Brain-Computer Interfaces (BCIs) for communication in people with severe paralysis and

communication problems. It is widely acknowledged that this area displays an increase in high-frequency band (HFB) power and Event Related Desynchronization (ERD) in the lower frequency band (LFB) during movement, as well as low-frequency Event Related Synchronization (ERS) upon cessation of movement. The ability to modulate the neural signal in the sensorimotor cortex by imagining or attempting to move is crucial for the implementation of sensorimotor BCI in people who are unable to execute movements. However, most common causes of loss of motor function, such as stroke, are themselves associated with significant damage to the brain, potentially affecting the functional modulation of HFB, LFB ERD, and LFB ERS control features. While BCIs aim to target non-compromised brain regions, LFB functional features are often driven by remote brain regions and thus may be affected even when HFB control features are present. Here we analyzed HFB and LFB features of 24 subjects implanted with ECoG electrode grids for epilepsy monitoring who were evaluated to be MRI negative (no indications of cortical or sub-cortical lesions; 9 subjects) or who had MRI abnormalities (15 subjects). We used HFB power as a selection criterion for electrodes over the primary motor cortex (M1), central sulcus (CS) or primary somatosensory cortex (S1) that responded to hand movements, and compared the LFB features of these electrodes between lesion and non-lesion subjects. We show that the mere presence of MRI abnormalities is not always associated with deviant LFB features. Yet, when lesions are located in the frontal cortex (6 subjects), both ERD and ERS LFB features in M1 and CS are significantly different from those of MRI negative subjects. Interestingly this was not the case for S1. These results indicate that damage to the frontal cortex can affect the sensorimotor rhythms even in the absence of direct damage to the motor cortex. Since altered sensorimotor features may affect BCI control, and may require dedicated decoding algorithms, our findings call for a careful evaluation of individuals intending to use a sensorimotor BCI.

Title: Performance of wireless Utah slanted electrode arrays in cat: The SARA-USEA

Authors: *D. R. HILGART[1], D. J. WARREN[1], S. J. BARRUS[2], G. A. CLARK[1];
[1]Biomed. Engin., Univ. of Utah, Salt Lake City, UT; [2]Ripple LLC, Salt Lake City, UT

Abstract: Here we describe the first successful use of a chronically implanted, wireless, 64-channel stimulation system (Stimulating and Recording Array, SARA; Ripple, LLC) attached to a Utah Slanted Electrode Array (USEA; Blackrock Microsystems). USEAs have been shown to interface effectively with peripheral nerves in both animal models and humans (Brinton et al., George et al., and Hansen et al., SfN 2019). Localized peripheral nerve stimulation is potentially advantageous for restoration of function for both spinal cord injury and limb loss. To date, access to chronically implanted USEAs has been through percutaneous wire connections that are prone to infection and wire breakage. The SARA is designed to be fully implanted under the skin, and interfaces with an external wireless transceiver through infrared telemetry, radio frequency telemetry, and inductive power. We implanted one SARA-USEA device in the sciatic nerve of 5 felines. Devices were tested under anesthesia at 1, 4, 13, and 26 weeks post-implantation, with tissue samples acquired at the last test date. At the time of implant and at all subsequent tested time points, the SARA-USEA device successfully demonstrated the ability to be powered by and communicate with external hardware wirelessly through the skin. Devices were tested by stimulating groups of 1 to 4 electrodes and measuring the resulting muscle compound action potential (mCAP) in 4 lower leg muscles, as well as measuring the impedance of each electrode. At the time of abstract submission, 2 animals have reached the 26-week time point, 2 have reached the 13-week time point, and 1 animal provided only impedance data for the 13-week time point for reasons unrelated to the device. At the latest time point available for each animal, between 54 and 64 electrodes remained functionally connected (impedance < 300 kΩ), and 46-64 electrode groups per animal evoked suprathreshold muscle responses (mCAP > 0.5 mV). Responses were often highly selective among muscles, demonstrating precise control over nerve fiber activation. Such precision is important in clinical settings for providing selective activation of paralyzed muscles after spinal cord injury or stroke, or precise sensory feedback in an individual with amputation. This work has been performed in compliance with current Good Laboratory Practice regulations to demonstrate safety and efficacy. Its results will support and Investigational Device Exemption submission to the FDA prior to clinical study.

Title: Sub-cortical human brain modulation during response conflicts in a modified Stroop task

Authors: *K.-H. CHEN[1], R. MARTIN DEL CAMPO-VERA[1], R. SEBASTIAN[1], D. R. KRAMER[1,2], S. KELLIS[1,2,3,4], B. LEE[1,2];

Abstract: Human brain modulation during response conflict (e.g. the modified Stroop task) has been studied primarily using functional magnetic resonance imaging (fMRI) due to its non-invasive nature. Few studies have examined modulation with intracranial electroencephalography (iEEG); however, one recent study found theta oscillations (3-8 Hz) in hippocampus relevant to successful task response. Neural activity during these tasks in other regions of the limbic system and in other frequency bands such as in beta band (13-30 Hz) of iEEG have been less well documented. In this study, five epilepsy patients (20-50 years; three females) were implanted with intracranial depth electrodes (AD-TECH, Oak Creek, WI). Participants gave informed consent to participate in an IRB-approved study in which they performed the modified Stroop Task with four variations: (A) naming a color block; (B) reading color words in white font; and naming the font color when the word is congruent (C) or incongruent (D) with that color. Neural signals were recorded (NeuroPort, Blackrock Microsystems, Salt Lake City, UT) and spectral power during the response phase was normalized to the rest phase. Consistent with previous work, we observed significant change in beta band in hippocampus head and tail (n=3 patients; Kruskal-Wallis ANOVA, Multiple Comparison Test, $p < 0.05$) between variants A and D. We also found significant change in beta band in amygdala (n=3; $p < 0.05$) and orbital frontal cortex (n=3; $p < 0.01$) between these two variants. When comparing task variations B and D, amygdala again showed significant change in the beta band (n=3; $p < 0.05$). Based on these results, we observe that, in addition to hippocampus as shown in prior studies, the amygdala and orbitofrontal cortex are also recruited during response conflict tasks. This finding suggests roles for these two brain areas beyond emotional processing.

Title: Neuromodulatory assessment of depth-EEG oscillations in reaching arm movements

Authors: *R. MARTIN DEL CAMPO VERA[1], K.-H. CHEN[1], R. SEBASTIAN[1], D. R. KRAMER[1,2], S. KELLIS[1,2,3,4], B. LEE[1,2];

Abstract: With many human intracranial studies of motor neurophysiology focusing on cortical areas, the role of subcortical brain areas in movement has not been as well investigated. An increase in the use of stereotactic electroencephalography (sEEG) for clinical treatment of epilepsy has led to more opportunities to record from deeper brain structures. This study examines spectral power across multiple subcortical structures during reaching movements. Five people (four female) aged between 20 and 50 years old, had AD-TECH depth electrodes implanted as part of their epilepsy monitoring, targeting orbitofrontal, frontal, insula, amygdala, hippocampus, temporal, precentral, parietal, and occipital brain areas. They gave informed consent to participate in an IRB-approved study of reaching movements while in the epilepsy monitoring unit. The participants performed a reaching task during which, after a brief period with no visual stimulus, they pointed to a dot displayed in the center of the screen (fixation), then reached to one of eight targets, equidistantly spaced around the unit circle, illuminated on the screen (response). Broadband neural activity was recorded at 2,000 samples per second (NeuroPort, Blackrock Microsystems, Salt Lake City, UT), and spectral power was computed in alpha (8-13 Hz), beta (13-30 Hz), low gamma (30-80 Hz), and high gamma (80-150 Hz) frequency bands. In each of these bands, we tested whether power increased or decreased during movement. We found that the hippocampus was the most common area among participants (four out of five) to exhibit a significant change between fixation and response (two-sample bootstrap hypothesis test for difference of means; $p<0.05$), followed by the amygdala in three participants. Significant changes in spectral power in other brain structures were also observed but only in two or fewer participants. In keeping with prior literature, spectral power significantly decreased in the beta band in 71% of targeted brain structures and increased in the high gamma band in 75%. In contrast, we observed mixed changes in alpha and low gamma. These results suggest that neural circuits in hippocampus and amygdala modulate during motor control. If robust across persons, such modulation could be incorporated into a brain-machine interface system to allow those with limited physical movement to operate a neuroprosthesis through their neural activity.

Title: Calcium signals from layer 2/3 of motor cortex encode lever movement

Authors: *J. HAN[1], S. ZHANG[2], R. WANG[2], Y. REN[2];
[1]The Second Affiliated Hosp., Zhejiang Univ. Sch. of Med., Hangzhou, China; [2]Qiushi Acad. for Advanced Studies of Zhejiang Univ., Hangzhou, China

Abstract: Previous motor brain-machine interfaces (BMIs) studies mainly harnessed spike activity from pyramidal neurons in layer 5 with electrophysiological recordings. But the activity of neuron population in layer 2/3 was seldom studied because of the difficulty in electrophysiological recording technique. Here we used a miniature fluorescent microscope (Miniscope) systems to collect calcium signals of neurons in layer 2/3 in primary motor cortex (M1) of C57BL/6J mice (male, aged 8-12 weeks) during a lever-pressing task. We tried to exam whether the movement of lever could be decoded with calcium signals obtained from layer 2/3 in M1. We firstly trained mice to press a lever to get water as rewards. Virus was then injected into the M1 cortex to express GCaMP6f. The calcium signals from the layer2/3 of M1 were collected when mice were performing lever-pressing task. Meanwhile, a pressure sensor was used to record the pressure values on the lever. We found that less than half (about 40%) of the calcium signals from layer 2/3 showed a significant increase when the mouse was pressing the bar. However, in this group of press-related calcium signals, only a few (less than 5%) of them are pressure value-related, that is, with the increase of pressure, the calcium transients of neurons also increases correspondingly, and vice versa. The neuronal activity in layer 2/3 also showed a positive correlation with the pressure value, that is, the higher the pressure value, the stronger calcium signal of the neuronal population. And furthermore, this correlation was held continuously during the task period. These results indicates that a subset of calcium signals in layer 2/3 are highly correlated with the lever-pressing task in mice, and the pressure values maybe encoded only by several neurons in a pattern similar to "sparse coding". Or we can interpret it as information about pressure values stored primarily in several individual neurons. Moreover, the pressure value could be continuously decoded by the calcium signals of neuronal activity in layer 2/3. It undoubtedly provides a new idea for motion decoding. In the future, scientists may decode the motion information of rodents or even higher primates through the interneurons in the superficial layer.

Title: Recording neural activity with a battery-free wireless neurosensor

Authors: *C. MONCION[1], J. BORGES[2], D. BORREGO[3], L. BALACHANDAR[1], S. BOJJA-VENKATAKRISHNAN[4], J. L. VOLAKIS[4], J. RIERA DIAZ[1];

Abstract: Surgical outcome in patients with drug-resistant epilepsy relies on accurate localization of epileptogenic foci, a step achievable using ECoG recording while patients are implanted for several days. The use of FDA approved wired amplifiers for ECoG data acquisition poses risks for these patients due to wires left protruding from the scalp, including infection and severe discomfort. Current wireless solutions (Neuropace RNS System) require the use of a power source, which can generate tissue-damaging heat. We have proposed a battery-free wireless neurosensing system (WiNS), consisting of an implant, an external interrogator antenna and a demodulation circuit (Fig. 1A). The implant is designed to be placed directly on top of the cortex through a craniotomy (Fig. 1A). Wireless communication is achieved using a RF carrier signal (2.4 GHz) supplied with the interrogator, that mixes, via an anti-parallel diode pair (APDP) in the implant, with the neuronal electric potential difference across a pair of electrodes, and then transmitted back to the interrogator (Lee, Kiourti, and Volakis 2017). In Moncion et al. (2019), we demonstrated that this ground-breaking technology can record electrophysiological signals of a variety of amplitudes, ranging from a few mV (ECG) down to μV (somatosensory evoked potentials). As we aim to apply this technology to epilepsy clinical practice, it is critical to evaluate signal distortion and detectability of interictal epileptiform discharges (IEDs), a hallmark of epilepsy. To this end, we implanted the WiNS in 5 rats with pilocarpine model-induced chronic temporal lobe epilepsy (TLE). To quantify signal distortion, IEDs were simultaneously recorded using a commercially-available wired system (AD Instrument Animal BioAmp) while the rats were under sedation and fixed to a stereotaxic. Results indicate that negligible distortion of the smaller type of IED, specifically spikes (Fig. 1B). Furthermore, we compared spike detection between WiNS and the wired system also indicating an inconsequential difference (Fig. 1C).

Title: Evidence of a memory trace in motor cortex after short term learning

Abstract: Many different neural activity patterns can lead to the same behavior. Does learning a new task change what neural activity patterns the brain uses to perform a previously learned task? We hypothesized that learning a new task might leave a memory trace, such that after learning a new task, the neural activity patterns used to perform the original task have changed. In particular, the original task might be performed using neural activity patterns that exhibit a "trace" of the newly-learned task. That is, the neural activity patterns after learning might remain somewhat appropriate for the newly-learned task while the subject is performing the original task. A difficulty in addressing this hypothesis is that in most tasks, the causal relationship between neural activity and behavior is unknown. To overcome this, we leveraged a brain-computer interface (BCI). In a BCI, the mapping between neural activity and behavior is specified by the experimenters. Multielectrode arrays were implanted in the primary motor cortex of rhesus monkeys, so that monkeys could control the movement of a computer cursor by volitionally modulating the activity of ~90 neural units. Monkeys proficiently used an intuitive “original” mapping in a baseline period, and then the mapping was switched to a perturbed “new” mapping that had to be learned through trial and error. After several hundred trials, we returned to the original mapping in a washout period. A major benefit of this experimental paradigm is that it allows us to quantify how appropriate neural activity is for a given mapping, even when that mapping is not currently being used. To evaluate whether learning a new mapping leaves a memory trace in motor cortex, we quantified the extent to which neural activity patterns produced by the animal during the washout period would be useful for driving the cursor using the perturbed mapping, and compared this to neural activity patterns produced during the baseline period. We found evidence of a memory trace, in that neural activity during the late portion of the washout period was more appropriate for the perturbed mapping than neural activity during the baseline period. This result held when we controlled for behavioral differences between the baseline and washout periods. Overall, our findings suggest that learning a new task brings neural activity to a novel solution for the original task that also provides benefit for the new task. This phenomenon may be a mechanism by which the brain could more rapidly learn when re-exposed to the same perturbation, a phenomenon known as “savings”.

Title: Transcutaneous spinal cord stimulation of the cervical cord modulates lumbar locomotor networks

Authors: T. S. BARSS, B. PARHIZI, *V. K. MUSHAHWAR;
SMART Network, Univ. of Alberta, Edmonton, AB, Canada

Abstract: The overall goal of this project is to investigate the contribution of the cervical networks of the spinal cord to the improvement of walking capacity after spinal cord injury (SCI). We recently demonstrated that active engagement of the arms coordinately with the legs in an arm and leg (A&L) cycling paradigm significantly improves walking speed in people with incomplete SCI compared to their baseline levels (Zhou et al, 2018a). Importantly, these increases were significantly larger than those obtained by legs-only cycling. Moreover, while legs-only cycling resulted in increases in walking speed that were similar to those reported using gait-specific interventions such as bodyweight-supported treadmill training, A&L cycling training resulted in twice larger increases in walking speed (Zhou et al, 2018a). These larger increases were partly the result of improvements in corticospinal drive and modulation of cervico-lumbar connectivity (Zhou et al, 2017, 2018b).
In this study, we examined the effect of transcutaneous spinal cord stimulation (tSCS) on the modulation of cervico-lumbar connectivity, in an effort to determine its use in combination with A&L cycling to further enhance the gains in walking capacity. Thirteen neurologically-intact adults participated in the study. The excitability of the H-reflex elicited in the soleus muscle was examined under 6 different conditions: 1) arms held in a static position (‘arms static’) without tSCS; 2) arms static with tSCS applied to the lumbar region of the spinal cord; 3) arms static with tSCS applied to the cervical cord; 4) arms cycling without tSCS; 5) arms cycling with tSCS applied to the lumbar cord; and 6) arms cycling with tSCS applied to the cervical cord.
The amplitude of the soleus H-reflex was significantly suppressed by ~25% when the arms were cycling (without tSCS) relative to arms static (without tSCS). Very interestingly, tSCS applied to the cervical cord with arms static also significantly suppressed the soleus H-reflex by ~25%.

However, arms static with tSCS applied to the lumbar cord did not suppress the soleus H-reflex. The combination of arms cycling with cervical tSCS or lumbar tSCS did not result in additional suppression of the soleus H-reflex beyond that obtained with arms cycling alone.
The results suggest that both rhythmic activation of the cervical spinal cord through voluntary arm cycling or tonic activation of the cervical spinal cord through tSCS significantly modulate the activity of the lumbar locomotor networks. This further demonstrates the importance of engaging the cervical networks actively along with the legs in rehabilitation interventions for improving walking capacity after SCI.

Title: Duration dependence of the medium-latency M2 stretch reflex in the ankle plantarflexors

Authors: *R. C. VAN 'T VELD[1], E. H. F. VAN ASSELDONK[1], A. C. SCHOUTEN[1,2]; [1]Biomechanical Engin., Univ. of Twente, Enschede, Netherlands; [2]Biomechanical Engin., Delft Univ. of Technol., Delft, Netherlands

Abstract: Motorized assessments of the short-latency M1 and medium-latency M2 stretch reflex are performed to understand the physiological origins of these responses and for spasticity assessment. For ramp-and-hold assessments, M1 magnitude increases with stretch velocity in both upper and lower limb, while the dependence of M2 on stretch duration has only been shown in the upper limb. This M2 dependence includes a minimum stretch duration required to elicit M2 and a maximum duration at which M2 plateaus. The M2 duration dependence has not been shown in the lower limb and, if it exists, minimum and maximum threshold durations may differ. The goal of this study is to systematically explore M2 duration dependence in the ankle plantarflexors.
Eight healthy volunteers (4 men, 19-29y) participated in this study. 30 different dorsiflexing perturbations were applied to the right ankle joint with varying durations (36-137 ms) and velocities (1.3-3.4 rad/s). All perturbations used ramp-and-hold profiles with a fixed parabolic acceleration curve (max. 140 rad/s^2). Participants were seated and instructed to generate a 3 Nm plantarflexing background torque. The experiment consisted of 12 blocks with 2 min. of rest in between, and with all 30 perturbations used once, in randomized order, in every block. Soleus

(SOL) electromyography (EMG) was 5Hz high-pass filtered, rectified and sorted per condition, removing all stretches outside the background torque criterion (3±0.2 Nm). M2 magnitudes were taken as average of the logarithm of the area under the curve of a 30 ms window, which started 25 ms after M1 onset. Linear mixed models (LMM) with subjects as random factor were used to test velocity and duration as predictor (N=240).
For perturbations with a 36-60 ms duration, SOL M2 depended on duration, not velocity (duration p=0.009, velocity p=0.183). The LMM with duration predictor explained 89% of the total variance and M2 magnitude increased with duration. For perturbations with a 60-137 ms duration, M2 depended on velocity, not duration (duration p=0.777, velocity p<0.001). The LMM with velocity predictor explained 91% of the total variance. For these longer durations, M2 magnitude reached a plateau value and this plateau value increased with velocity.
Similar to the upper limb, M2 in the SOL muscle was found to depend on stretch duration. For short durations (<60 ms) M2 increased with duration, while M2 plateaus for long durations (>60 ms). This M2 plateau magnitude depended on stretch velocity, which has not been reported in the upper limb. Our results highlight the importance of reporting and accounting for stretch duration and velocity for motorized M2 assessments in the lower limb.

Title: Development of dual vestibulospinal pathways responsible for trunk postural control in Xenopus

Authors: ***D. LE RAY**, A. OLECHOWSKI-BESSAGUET, F. M. LAMBERT, R. GRANDEMANGE, L. CARDOIT, G. BARRIOS, E. COURTY;
Univ. Bordeaux CNRS Umr5287 - INCIA, Bordeaux, France

Abstract: Vestibular information is critical for the control of locomotion and posture. In quadruped vertebrates, the control of posture was demonstrated to rely mainly on vestibulospinal pathways acting directly on both body axial and limb extensor muscle systems. However, several studies in the last decade also suggested a substantial modulation of spinal axial networks by central commands arising from lumbar segments during active locomotion. Especially, we have

previously shown that an ascending lumbar drive overwhelms the descending control of thoracic postural circuitry to adjust body posture during limb-based swimming in the aquatic frog Xenopus laevis. We therefore undertook the investigation of the central pathways and effectors responsible for the control of posture in Xenopus and their developmental adaptation to metamorphosis-induced changes in biomechanical apparatus. We show that most axial motoneurons (MNs) in tadpole rostral spinal segments 6-8 undergo dramatic morphological modifications during metamorphosis, which results in juvenile thoracic postural MNs exhibiting particular dendritic arborization allowing them to gather information from both sides of the cord. Such juvenile MNs respond to vestibular natural stimulation with early position- and delayed velocity-related discharges, the latter occurring simultaneously with ipsilateral hindlimb extensor bursts. Furthermore, thoracic MNs monosynaptically respond to electrical stimulation of the two brainstem vestibulospinal nuclei and to stimulation of ascending interneurons located in the rostral lumbar cord. Finally, we show that vestibulospinal fibers activate rostral lumbar interneurons projecting into thoracic segments. Altogether, our results complete the scheme of the vestibulospinal control of posture by clearly demonstrating the existence of a novel pathway, which implicates a lumbar relay, conveys specific vestibular velocity-related inputs to thoracic MNs, and participates in trunk postural stabilization in the absence of active locomotion.

Title: Alteration of sensory-motor reflex gain in different environmental contexts

Authors: E. WITTS, M. MATHEWS, S. THOMPSON, *A. J. MURRAY;
Sainsbury Wellcome Ctr., Univ. Col. London, London, United Kingdom

Abstract: The generation of coordinated movement relies on sensory input being correctly interpreted in order to produce appropriate motor output. Even relatively simple sensory-motor reflexes, such as the motor corrective response generated after a postural perturbation must be tuned to salient features of the environment. One example of this sensory-motor gain control is the increase in motor response to vestibular stimulation during threatening conditions. In this context the same sensory stimulus produces an altered motor response dependent on the

environmental context, however, the neural circuit mechanisms for this modulation of sensory-motor gain are not well understood.
Here, we have developed a novel behavioural paradigm where mice in an enclosure must generate a postural correction in response to a lateral balance perturbation. We altered the environmental context by varying the height of the walls of the enclosure, and recorded hindlimb EMG responses under two environmental conditions one with a high-walled (less-threatening) enclosure and one with a low-walled (more threatening) enclosure. This task therefore allowed us to measure vestibulo-motor responses to a stereotyped stimulus while varying the spatial context.
We found that identical magnitudes of postural perturbation produced different motor responses in different environmental contexts. In particular, a more threatening context produced larger peak EMG responses than a less threatening environment. To investigate the neural circuits responsible for this alteration of sensory-motor gain we probed the function of the lateral vestibular nucleus (LVN), an area of the brainstem that gives rise to the lateral vestibulospinal tract and is known to be required for generating postural corrective responses. Transient inhibition of the LVN via the expression of archaerhodopsin and implantation of an optical fibre resulted in a greatly reduced EMG response in both threatening and non-threatening conditions, suggesting the LVN is required for the generation of this postural correction. To probe the neural circuits that influence LVN activity we performed monosynaptic rabies tracing selectively from lateral vestibulospinal tract (LVST)-neurons. We found that LVST neurons receive a diverse array of inputs, particularly from multiple cortical and cerebellar regions as well as areas involved in providing sensory feedback. Our current investigations are focussed on functionally probing the inputs to the LVN in order to understand the circuits that alter sensory-motor reflex gain.

Title: Comparison of femoral nerve and quadriceps muscle stimulation onto soleus motor output: Potential role for Golgi tendon organ feedback

Authors: *M. A. LYLE, E. JOHNSON, F. KIRKLAND, D. LUO, C. VARAN;
Emory Univ., Atlanta, GA

Abstract: Force feedback from Golgi tendon organs (GTOs) has widespread intermuscular projections implying a role in motor coordination, but the functional implications have been

difficult to determine. This is because methods to study GTO circuits use nerve stimulation or muscle stretch, which also activate muscle spindle afferents. Muscle contraction naturally activates GTOs and reduces spindle firing due to fascicle shortening. Thus, muscle stimulation-evoked twitches provide an opportunity to bias GTO activity and thus study their intermuscular actions more selectively than nerve stimulation; we have recently demonstrated strong support for this premise in the cat. Here, we tested the hypothesis that stimulation-evoked twitches can be used to bias GTO feedback in humans. The hypothesis was evaluated by comparing the effects of femoral nerve and quadriceps (Q) muscle stimulation onto soleus motor output. Femoral nerve stimulation evokes short latency excitatory spindle feedback and long duration inhibition onto soleus currently attributed to recurrent inhibition. Thus, we hypothesize femoral n stimulation, but not Q stimulation, will elicit excitatory feedback onto the soleus; Stimulation-evoked twitch force magnitude will relate to the magnitude of inhibition; Acute muscle fatigue will reduce GTO input (i.e. twitch force) and thus the magnitude and duration of soleus inhibition. Participants are seated on a HUMAC dynamometer. EMG was recorded from the soleus and stimulation electrodes applied to vastus medialis and lateralis motor points, and the femoral n in the femoral triangle. Stimulation/twitch force relations were identified for the femoral n and Q by stimulating at 1-3x motor threshold while recording knee torque. Stimulation-evoked interactions were evaluated by stimulating the femoral n or Q while subjects held 20% soleus MVIC with visual feedback. Two to three stimulation intensities for femoral n and Q, matched for twitch-evoked forces were completed. A Q stimulation fatigue protocol was used until twitch torques reduced by ~50%, followed by a conditioning trial with the same prefatigue current. To date, short latency excitation has been observed with femoral n but not with Q stim. In all individuals, increased soleus inhibition with increased stimulation intensity was found. Preliminary results suggest acute Q fatigue may be a way to distinguish recurrent inhibition from GTO feedback. Our data suggest muscle twitches naturally bias GTO feedback (i.e. lack excitatory feedback onto the soleus; relation of twitch force and soleus inhibition). Evaluating GTO feedback with muscle stimulation is anticipated to help advance the role of GTOs.

Title: Evidence for non-linear summation of inhibitory inputs from the length and force-dependent feedback sources onto feline ankle extensor muscle

Authors: *E. KAJTAZ[1], S. F. MCMURTRY[1], A. M. DE BOEF[1], L. R. MONTGOMERY[2], D. R. HOWLAND[3,4], T. NICHOLS[1];
[1]Sch. of Biol. Sci., Georgia Inst. of Technol., Atlanta, GA; [2]Dept. of Neurolog. Surgery, [3]Kentucky Spinal Cord Injury Res. Center, Dept. of Neurolog. Surgery, Univ. of Louisville, Louisville, KY; [4]Robley Rex VA Med. Ctr., Louisville, KY

Abstract: Specific and unique roles can be assigned to two main muscle mechanoreceptors: muscle spindles have been, almost universally, described as sensors of muscle length and change in its length, whereas the activity of Golgi tendon organs (GTO's) is a function of muscle active force. The respective connectivity of these two pathways, length and force-dependent feedback, forms a neural network of widely distributed sensory inputs in the spinal cord: each motoneuronal pool receives an excitatory length feedback from its homonymous muscle, inhibitory length feedback from its antagonistic muscles, and inhibitory force-dependent feedback from its close synergists and/or distant heteronomous muscles. The question emerges how the two sources of inhibition converge onto recipient motoneuronal pools. The experiments described in this abstract tested the hypothesis that two sources of inhibition, Ia reciprocal inhibition originating from antagonistic muscle spindles and Ib inhibition originating from heteronomous and synergistic GTO's, converge linearly onto recipient extensor motoneurons. If they do, that would mean that interneuronal pools mediating length-dependent reciprocal inhibition and force-dependent inhibition are separate and independent. If, however, the magnitude of inhibition from both sources concurrently is smaller than the summation of magnitudes from individual sources, that may suggest that, at least partially, Ia and Ib inhibitory interneuronal pools are shared resources across these two inhibitory pathways. We utilized the decerebrate cat and measured the magnitude of inhibitory feedback between extensor and flexor muscles spanning the ankle joint of the feline hind limb. Following the recovery from lateral T9-T10 thoracic hemisection, decerebration and removal of anesthesia, three paired muscles, denoted as recipient and two donors of inhibition, were stretched in different combinations, and intermuscular interaction assessed as a change in the stretch reflex magnitude of the recipient muscle due to the stretch of each donor and both of them together. Detailed analysis is underway. Preliminarily, we observed that the magnitude of inhibition from combined sources is smaller than the sum of inhibition magnitudes from each source individually. These observations suggest that stiffness of each muscle, and therefore a joint, is determined globally by non-linear convergence of feedback from many external sources throughout the limb and body. Title: Effects of age' vestibular and visual systems on the soleus H reflex

Authors: ***A. CELIK**, F. J. ROJAS, M. CEPERO GONZALEZ, D. M. KOCEJA, K. KITANO; Indiana Univ., Bloomington, IN

Abstract: The vestibular system, visual and proprioceptive pathways provide information about control of posture, movement and balance. Loss of postural control directly leads to a greater incidence of falling in the elderly population causing serious health problems. One important neuromuscular mechanism instrumental in the control of posture and balance is the reflex system. However, the age-related changes of vestibular and visual systems and their relationship with the reflex system are not clear. The purpose of this study was to investigate the effects of age, the vestibular and the visual systems on the modulation pattern of the soleus H reflex. Seventeen neurologically healthy volunteers were categorized by age in two groups: young (n = 8, mean age = 22.1±5.0 yr) and elderly (n = 9, mean age = 59.3±12.8 yr). Maximal soleus H-reflex (H-max) and motor response (M-max) amplitudes were determined prior to testing at each condition while subjects were lying supine on a tilt table for standardization. Stimulation intensity was set to evoke a 5-10% M-wave on each trial. Participants received 5 test H-reflex stimuli in two conditions, static 60º and dynamic 60º on a tilt table. Both tilt conditions were performed with vision and no vision. A 3-way repeated-measures analysis of variance (ANOVA) 2 (groups: young/old) x 2 (condition: static/dynamic) x 2(vision: vision/no vision) was used to assess changes in H-reflexes. All data were expressed relative to the H-reflex amplitude at 0º static on the tilt table. The results showed a significant 3-way interaction (p= 0.038). The old group showed greater H-reflex amplitude in the no vision condition at static 60º (vision: 0.97; no vision: 1.23) whereas in the young group less modulation was demonstrated in the same condition (vision: 1.15; no vision: 1.12). These results suggest in young subjects the vestibular system produced a suppression of the H-reflex with or without visual input; however in the old group vision was necessary for this suppression. The interaction between the visual and vestibular systems as we age needs to be further explored.

Title: Treadmill perturbations to evoke stretch reflexes during gait in children with cerebral palsy

Authors: *E. FLUX[1], L. SLOOT[1,2], J. HARLAAR[3,1], A. I. BUIZER[1], M. M. VAN DER KROGT[1];
[1]Dept. of Rehabil. Medicine, Location VUmc, Amsterdam UMC, Amsterdam, Netherlands; [2]Institude for Computer Engin., Heidelberg Univ., Heidelberg, Germany; [3]Dept. of Biomechanical Engin., Delft Univ. of Technol., Delft, Netherlands

Abstract: Introduction Spasticity, i.e. exaggerated velocity-dependent stretch reflexes, is one of the key impairments in neurological diseases, but its effect on gait is unclear. Treadmill accelerations can be used to quantify calf muscle reflexes during gait in healthy adults [1]. This study examined the applicability of this method for children, both typically developing (TD) and with cerebral palsy (CP). **Methods** 15 TD and 20 CP children walked 6 minutes on a split-belt instrumented treadmill at comfortable speed. Backward treadmill accelerations were unexpectedly applied at three intensities to the most affected (CP) or right leg (TD) just after initial contact. 3D kinematics were collected and EMG was recorded for soleus and gastrocnemius and normalized to peak in unperturbed walking. Muscle-tendon lengths and velocities were calculated using OpenSim. Effect of perturbations was evaluated on knee and ankle angles, muscle-tendon velocity and RMS EMG [2]. Spasticity was classified as low (N=12) or high (N=8) using physical examination. **Results** Perturbations with increasing intensity resulted in increased ankle dorsiflexion, up to 5.7±1.5° (TD) and 3.8±2.1° (CP), without changes in knee angle. This caused increased stretch velocity of calf muscles, resulting in increasing bursts of muscle activity up to 3 (TD) and 3.5 (CP) times the unperturbed value. Reactions in CP were much more variable than in TD. Children with high spasticity showed 0.6 and 0.8 times less muscle lengthening, but 1.3 and 1.4 times higher increases in RMS EMG than TD children and CP children with low spasticity respectively. **Discussion** The results indicate that stretch reflexes can be evoked using treadmill perturbations in both TD and CP children. The lower and more variable changes in joint angles and muscle-tendon lengthening in CP are likely due to altered posture in early stance, but does not interfere with the reflex evoking ability. The

enhanced muscle response in children with high spasticity indicates that treadmill perturbations are a promising method to assess spasticity during gait. [1] Sloot, PLoS One 2015

Title: Modulation of human soleus H-reflex induced by visual perturbation

Authors: *K. KITANO, A. M. PHIPPS, D. M. KOCEJA;
Indiana Univ., Bloomington, IN

Abstract: An H-reflex and related techniques have been widely used to evaluate postural control mechanisms at the spinal level in humans. Previous studies have demonstrated that human posture is controlled by tactile sensory, proprioceptive, vestibular, and visual systems. Additionally, it has been known that soleus H-reflex is modulated through changes in ankle angle (proprioception), body orientation (vestibular system), and aging. The purpose of the study was to evaluate whether visual perturbation has an effect on human soleus H-reflex modulation. Four young adult subjects participated. Each subject had no history of neuromuscular disease and were of a normal fitness level. An EMG signal was collected from the right soleus at 2 kHz

sampling rate and stimulating electrodes were placed at the right popliteal fossa. Control H-reflex amplitudes were set at 20% of M-max. Subjects stood on a force plate that was enclosed within a motorized, moveable wall. The size of wall enclosure was approximately 70 cm (W) x 70 cm (D) X 230 cm (H) and the color was white. Subject's vision was limited in front and both side aspects in the enclosure box. In order to administer visual perturbation, the walls were moved for 2.2 sec at 9.3 cm/sec. Direction of the wall movement was set away from a subject and initial distance between the wall and subjects was approximately 40 cm. Test stimulation was delivered at 0 msec, 100 msec, 200 msec, 400 msec, 800 msec, and 1600 msec after wall movement. Alpha-level was set at 0.05. The results showed a significant difference between the amplitudes at 400 msec and at 1600 msec (88.8% vs. 105% of a control value, respectively). Results suggest that spinal mechanisms are modulated by visual information.

Title: 4d-EEG: Signal propagation through the brain based on EEG and diffusion MRI

Authors: *F. C. T. VAN DER HELM[1], O. G. FILATOVA[2], Y. YANG[2], P. MACEIRA-ELVIRA[2], R. TIAN[2], G. KWAKKEL[3], Y. TAKEDA[4], O. YAMASHITA[4], J. P. DEWALD[5]; [1]Biomechanical Engin., [2]BIomechanical Engin., Delft Univ. of Technol., Delft, Netherlands; [3]Rehabil. Med., Vrije Univ. Med. Ctr., Amsterdam, Netherlands; [4]Neural Information Analysis Laboratories,, ATR, Kyoto, Japan; [5]Physical Therapy and Human Movement Sci., Northwestern Univ., Chicago, IL

Abstract: Neuroimaging techniques, such as fMRI and dMRI, have a high spatial resolution. However, low temporal resolution of fMRI provides less insight of dynamic changes of brain activity. In contrast, electro-neurophysiological techniques, such as electroencephalography (EEG), have an excellent temporal resolution to measure such transient events, however are hindered by its low spatial resolution. The goal of this study is to enhance the spatial (3D)

resolution of EEG with dMRI, and combine this with the fast dynamic changes in EEG over time (1D) resulting in signal propagation through the brain (4D-EEG).
This proof-of-principle study used a novel multimodal brain imaging technique namely Variational Bayesian Multimodal Encephalography (VBMEG), which aims to improve the spatial resolution of EEG for tracking the information flow inside the brain, using constraints derived from anatomical MRI and diffusion MRI. EEG data were acquired from two individuals suffering from a stroke as well as two able-bodied participants. Electrical stimuli were delivered sequentially at their index finger in the left and right hand, respectively. A source localization method (sLORETA) was used to estimate EEG sources at each time instant, resulting in high Variance Accounted For (VAF above 80%). EEG sources were combined with the tracts obtained with dMRI. A Multivariate Auto-Regressive (MAR) model was used to estimate the causal relationship between the EEG sources in time, which is effectively the signal propagation through the brain.The MAR model between sources resulted in a high VAF (above 90%) in the cross-validation test.
The estimated dynamic information flow was compared between chronic hemiparetic stroke and able-bodied individuals. The results demonstrate that stroke patients had considerable activity in the contralesional hemisphere, through the corpus callosum. This methodology may lead to the development of a quantitative tool for monitoring functional changes of the cortical neural networks after a unilateral brain injury. This will facilitate the research into neuroplasticity and the diagnosis and treatment of stroke rehabilitation.

Title: Contributions of extrinsic tail muscles to the rat tail nociceptive withdrawal response through reconstruction: Role of non-linearity

Authors: *A. M. BRAZELL, J. Q. NGUYEN, C. L. CLELAND;
James Madison Univ., Harrisonburg, VA

Abstract: Neural control of movement is complex. Synergies have the potential to lessen computational complexity, especially in the rat tail, which is controlled by over 300 muscles or muscle fascicles. Currently, we are using EMG to identify muscle activation and synergies. In addition, we have developed a “reconstruction” approach to characterize the patterns of muscle

activity associated with the nociceptive withdrawal response (NWR). In this approach, we first recorded the tail movement in response to a noxious heat stimulus using high-speed video. Second, we recorded the tail movements ("movement primitives") produced by manual stretch of the tendons originating from individual extrinsic muscles in anesthetized rats. Third, we mathematically reconstructed the observed movement by *linearly* adding the movement primitives to determine the pattern of muscles activation that could have created the movement. However, one potential limitation of this approach is that movement primitives are unlikely to add linearly. The specific aim of our current experiment seeks to test linearity by determining to what extent the movement primitives sum linearly, and if they don't, how we can more accurately model their nonlinear summation. In anesthetized, adult Sprague-Dawley rats, we pulled on one tendon, a second tendon, and then both tendons simultaneously to create movement which we quantified via video tracking. We then compared linear summation of the individual movements to the combined movement. Our results demonstrate that for small movements the movement primitives sum linearly, however the summation is up to 30% sublinear for large movements. We will use these results to devise a mathematical model for adding muscle primitives that accounts for the size of the movement primitive, so that our calculated sum in the previous experiments more accurately matches the observed NWR movement.

Title: Patterns of activity of intrinsic tail muscles during the heat evoked nociceptive withdrawal response in the rat

Authors: *A. B. PEROE, S. M. EVANS, H. IZADPANAH, C. L. CLELAND;
James Madison Univ., Harrisonburg, VA

Abstract: Motor control is complicated by muscular redundancy. Synergies provide one potential solution to simplify computational complexity. The rat tail, which is controlled by over 300 extrinsic and intrinsic muscles or muscle fascicles, is an ideal model system to use electromyography (EMG) to explore the role of muscular synergies in a hyper-redundant limb or appendage. Previous studies in our laboratory recorded muscle activity from intrinsic tail muscles; however their approach did not allow for selective recording from intrinsic tail muscles. Our goal was to develop a method for selectively recording muscle activity from the six intrinsic tail muscles and to use the method to explore synergies within these muscles. Rats (Sprague-

Dawley) were briefly anesthetized to insert into the tail bipolar fine wire electrodes, each of which consisted of 36g, multi-stranded stainless-steel wires, de-insulated by a distal diagonal cut. The de-insulated portions were positioned as close as possible to reduce cross-talk. Electrodes were placed into dorsolateral, lateral and ventral muscles that span coccygeal vertebrae. Either six electrodes were placed in each of the six muscles at the same level to evaluate cross-talk, or within one muscle type at seven locations to evaluate the pattern of muscle activity. Under isometric conditions, heat stimuli (980nm laser) were delivered to the lateral surface at multiple locations along the tail and single unit EMG was discriminated. Our results demonstrated the intrinsic muscles of the tail be recorded with minimal cross talk between adjacent muscles at the same level. The left and right dorsolateral muscles, which are in close contact with each other, showed only <20% crosstalk for motor unit potentials >50mV. No cross-talk was observed between the other pairs of muscles.

Title: Dependence of the nociceptive withdrawal response on stimulus location in the intact, unanesthetized rat

Authors: *B. SIMPSON, M. FERLAZZO, M. RUGGERI, C. EVANS, C. L. CLELAND; James Madison Univ., Harrisonburg, VA

Abstract: The nociceptive withdrawal response (NWR) is characterized by withdrawal of the limb to avoid noxious stimuli. Although the NWR has been studied in humans and spinalized animals, it is unclear whether there is a dependence on stimulus location in intact, unanesthetized, non-human animals. The aim of our research was to use high speed video of the intact, unanesthetized rat's limb to determine if there is an effect of stimulus location on the NWR evoked by heat and electrical stimuli. Rats (n=7) were stimulated at five locations on the plantar surface of the hind foot and two opposing locations (anterior, posterior) on the lower leg using either heat (980nm laser) or electrical current (3xT, 5 pulses). The resulting movement associated with the NWR was quantified in the sagittal plane with high speed video (500 fps) to determine the time course of joint angle (ankle, knee, hip) and conventional video underneath to determine the initial and final location of the foot in the frontal plane. Preliminary results demonstrate that the heat-evoked NWR consisted of three sequential phases: 1) slow rostral/dorsal "lean" that included slight extension at the ankle, 2) rapid flexion around the ankle,

knee and hip, and 3) rapid replacement of the foot on the surface in the rostral or caudal direction. Unexpectedly, the rapid flexion around the ankle, knee, and hip did not depend on plantar stimulus location ($p>0.05$, Linear Mixed Effects). Similarly, stimuli delivered to the anterior and posterior aspects of the lower leg resulted in similar movements. In contrast, the early, slow ankle extension was significantly greater for caudal stimuli delivered to the foot ($P<0.00001$, LME). Electrical stimuli resulted in a vastly different movement. The upward movement was greater, the foot was always replaced in the caudal direction, and the contralateral hind leg was often lifted. For both stimuli, the magnitude of response greatly exceeded similar responses in humans. In summary, the NWR appears more complex than previously appreciated, including at least three different components which vary in their dependence on stimulus location. The disparate results of electrical stimulation were especially intriguing, since electrical stimulus is commonly used in human studies of the NWR.

Title: Neural excitability during single-limb balance following a lateral ankle sprain

Authors: *K.-M. KIM[1], J. KIM[1], O. DAHMAN[1], Y. AN[2], K. KIM[3];
[1]Kinesiology and Sport Sci., Univ. of Miami, Coral Gables, FL; [2]Dept. of Kinesiology and Dance, New Mexico State Univ., Las Cruces, NM; [3]Human Physiology, Performance, Protection & Operations Lab., KBRwyle, Houston, TX

Abstract: There is clear evidence that single-limb balance (SLB) impairs following lateral ankle sprain (LAS) and poorer SLB is associated with a higher risk of LAS. However, the underlying neurophysiological mechanism remains unclear. Previous research suggested that proprioceptive deficits that arise from damaged mechanoreceptors within the injured ligaments following LAS. However, there is emerging evidence, suggesting that efferent motor control of SLB such as neural excitability of lower leg muscles may change following LAS. Thus, the purpose of the study was to investigate the neural excitability of soleus muscle during SLB following LAS. The present study utilized a case-control study design with two groups: LAS and healthy control. A total of 16 subjects participated in the study: 8 subjects with LAS within two weeks of the injury onset (5 females; age=20±2.2yrs, height=172.2±7.6cm, mass=70.6±10.1kg) and eight healthy

controls without any history of ankle sprain (4 females; age=21±3.0yrs, height=174.7±10.4cm, mass=67.3±14.4kg). All participants have completed two separate tests of neural excitability in random order while balancing with injured limbs in the LAS group or side-matched limbs in the healthy control group. The tests were for eliciting (1) Hoffmann reflex (H-reflex) to estimate spinal excitability and (2) motor evoked potential (MEP) to quantify corticospinal excitability. For H-reflex peripheral electrical stimulations to the tibial nerve were utilized to elicit not only H-reflex but also motor responses. We recorded five trials of maximum H-reflexes (H-max) and motor responses (M-max). For MEP transcranial magnetic stimulation (TMS) was used to excite a cortical area innervating the soleus muscle. We collected ten trials of MEP at a TMS intensity of 120% of active motor threshold. Both averages of H-max and MEP responses were normalized to the M-max average to allow for between-group comparisons. We performed two independent t-tests with the alpha level was set at <0.05. There were no significant group differences for Hmax/Mmax ratio (LAS: 0.57±0.23 and healthy control: 0.61±0.10, p=0.62) and for MEP/Mmax ratio (LAS: 0.11±0.07 and healthy control: 0.14±0.09, p=0.39). These preliminary results indicate that spinal and corticospinal excitability may not change following LAS, and suggest that other neurophysiological mechanisms may contribute to single-limb balance deficits following LAS.

Title: Exposure to genistein in male and female Long-Evans rats affects reproductive physiology and behavior

Authors: *F. A. GUARRACI, M. ALI, M. BROYLES, L. K. DAVIS, C. M. GONZALEZ, D. LUCERO, L. STARY;
Southwestern Univ., Georgetown, TX

Abstract: The present study was designed to examine the effects of neonatal genistein exposure on measures of reproductive physiology and behavior. Approximately 24 hours after birth, male and female Long-Evans rat pups were injected daily with genistein (0.15 mg/kg, s.c.; n=23) or olive oil (n = 22) for 5 days, beginning on postnatal day (PD) 1. After weaning at PD 23, preputial separation in males and vaginal opening in females were examined daily until all subjects reached puberty. For all female subjects, we examined vaginal cytology daily for 28 days starting ~ PD 55. Two months after monitoring estrous cyclicity, the female subjects were given the opportunity to interact with a gonadally intact male or a sexually receptive female rat

on the day of behavioral estrus to assess sexual motivation (i.e., partner-preference test with and without physical contact). For all male subjects, we assessed the development of male copulatory behavior once weekly for 3 weeks beginning ~ PD 55. On week 4, sexual motivation was assessed using the partner-preference test (without physical contact). We found that neonatal exposure to genistein had no effect on puberty onset in male or female rats. However, female subjects exposed to genistein displayed more irregular estrous cycles than controls. Neonatal genistein exposure also altered the development of male copulatory behavior, as indicated by increased mount frequency and increased intromission frequency. In contrast, neither female nor male sexual motivation was affected by genistein. The results of the present study have important implications for the development of reproductive physiology and behavior in human neonates exposed to genistein in soy-based baby-formula.

Title: Perinatal SSRI exposure and rat sexual behavior

Authors: *E. M. S. SNOEREN[1], J. HEGSTAD[2], D. J. HOUWING[3], J. D. OLIVIER[4], R. HEIJKOOP[2];
[1]Dept. of Psychology, UiT the Arctic Univ. of Norway, Tromsø, Norway; [2]Dept. of Psychology, The Arctic Univ. of Norway, Tromsø, Norway; [3]Groningen Inst. for Evolutionary Life Sci., Univ. of Groningen, Groningen, Netherlands; [4]Neurobiology; Unit Behavioral Neurosci., Univ. of Groningen/ GELIFES, Groningen, Netherlands

Abstract: Perinatal exposure to SSRIs might have long-lasting effects on the developing child. Regarding sexual behavior, the time of SSRI exposure appears to be crucial: previous studies showed that prenatal exposure did not affect male copulatory behavior, while postnatal exposure decreased the number of mounts, intromissions and ejaculations. In females, on the other hand, it was shown that postnatal SSRI exposure increased proceptive and receptive behavior. To date, little is known about sexual behavior of rats under more naturalistic circumstances, where sexual competition and partner choice might play a role. Our study aims to investigate perinatal fluoxetine exposure in rats and the effects on male and female sexual behavior during the complete behavioral estrous cycle in a seminatural environment.

Dams received a daily dose of 10 mg/kg fluoxetine (FLX) per day or vehicle (CTR) from gestational day 0 until weaning on postnatal day 21. In 5 cohorts of 8 rats (4 males, 4 females), the offspring (n=10) were tested in a seminatural environment during 8 consecutive days. To induce sexual receptivity (without which copulation will not take place), females were hormonally primed on day 7. All male and female copulatory behaviors were scored and categorized in "copulatory bouts", defined as the time between the initial mount or intromission (males) or lordosis (females) and the beginning of a period of sexual inactivity lasting for more than 60 min. We studied the timing and content of the bouts, as well as which conspecifics were engaged in the behavior. Furthermore, we studied the display of other social and conflict behaviors over the course of the copulatory bouts.

Sci., Univ. of Tokyo, Bunkyo-ku, Tokyo, Japan; [4]Dept. of Med. Sports, Teikyo Heisei Univ., Ichihara, Chiba, Japan; [5]Dept. of Developmental Anat. and Regenerative Biol., Natl. Def. Med. Col., Tokorozawa, Saitama, Japan

Abstract: Fibroblast Growth factor 5 (FGF5) broadly expresses in the central nervous system. However, our knowledge of the function is limited except for the blood brain barrier, and little has been known especially on the behavioral regulation. In this study, we first demonstrated behavioral characteristic of FGF5 null mutant male mice, compared to that of wild-type (WT) males. When exposing to odors of sexually mature males and receptive females simultaneously, WT males explored female odor significantly longer than male odor, while FGF5 null males displayed significantly shorter investigation for either odors than WT males, frequently resulting in no preference. In sexual behavior tests, FGF5 null males showed significantly lower sexual activities and longer latency in ejaculation than WT males. Furthermore, FGF5 null males showed higher anxiety-like behavior in the elevated plus maze, spent longer time in the closed

arms that WT males did. In the tube dominance test, FGF5 null males frequently lost to WT males.
Since we found severe dysfunction in sociosexual behavior of FGF5 null mice, we reexamined FGF5 mRNA expression in the mouse forebrain, indicating that FGF5 gene expresses broadly such as in the olfactory bulb (OB), the amygdala, the hippocampus, and the hypothalamus. Immunohistochemistry (IHC) and in situ hybridization (ISH) studies detected the signals in common in the hippocampus, the cerebral cortices, and the thalamic reticular nucleus. However, the signals were generally weak and able to confirm the PCR results only partly. Furthermore, the inconsistency was found between IHC and ISH. Intense signals in the granular layer of CA2, CA3 and dentate gyrus, but weak in CA1, of the hippocampus were observed by ISH, while immunoreactive patchy particle (not cellular form) were found in the hippocampus including CA1 by IHC. ISH detected weak signals in the OB, but IHC failed. The current study demonstrates that secretory FGF5 in the central nervous system is involved in neural regulation of sociosexual behavior, suggesting to concern some psychiatric disease in human, similar to FGF2, through binding FGF receptor 1 (FGFR1).

Abstract: The Major Pelvic Ganglion (GPM) of male rat is an autonomic structure responsible for modulating pelvic organs, including the prostate gland. This, is regulated by hormones such as prolactin (PRL) and testosterone (T) and is also controlled by the GPM, which receives preganglionic fibers from the Pelvic (PvN) and Hypogastric (HgN) nerves. MPG controls the function of prostate gland by the release of noradrenaline and acetylcholine. It is know, that

performance of sexual behavior induces an increase in the serum levels of prolactin (PRL) and testosterone (T), as well as its receptors in the prostate and increase in the neuronal activity of the GPM, but it has not been reported if this sexual behavior also increases the expression of receptors for acetylcholine (M3), noradrenaline (α1a), androgens (AR) and prolactin (PRLR) in MPG. On the other hand, there is evidence that PvN and HgN axotomy promotes alterations in prostatic cytoarchitecture. Therefore, another objective of the present study was to evaluate the effect of suspension of the nervous control by bilateral section of pelvic and hypogastric nerves, on the expression of the mentioned receptors, in order to correlate them with the observed histological changes. Methods: Wistar male rats of 3 months of age were used to form the following groups: intact (INT), sexually expert (S.E), false surgery (SHAM), and denervated of PvN, HgN and PvN+HgN. GPM was extracted 15 days post-surgery and levels of expression of receptors were analyzed: adrenergic (α1a), muscarinic (M3), androgens (AR) and prolactin (RPRL). Results: Sexual behavior did not alter the expression of any of the receptors analyzed. Axotomy of both nerves induced a significant increase in the expression of the AR and M3 receptor, however it did not alter the expression of PRL nor adrenergic (α1a) receptors. Conclussion: The sexual behavior does not alter expression of analyzed receptors, but damage in preganglionar neurotransmission induced by the denervation produced an increase of the RA and M3 receptor. This suggests that histological alterations observed in prostate of denervated animals may be a consequence of alteration in expression of at least these two receptors.

Title: Sexual behavior induces morphometric changes in major pelvic ganglion and prostate

Authors: *V. SÁNCHEZ-ZAVALETA[1], A. MATEOS-MORENO[1], G. E. ARANDA-ABREU[2], D. HERRERA-COVARRUBIAS[2], J. MANZO[2], R. TOLEDO-CÁRDENAS[2], J. SUÁREZ-MEDELLIN[2], M. E. HERNÁNDEZ-AGUILAR[2];

Abstract: Background: The prostate is an important sexual gland for reproductive success, since it contributes 30 percent of whole content of semen, so it plays a fundamental role for male fertility. This gland is regulated by hormones such as androgens, estrogens and prolactin, but it also receives innervation from postganglionic fibers that emerge from the major pelvic ganglion (MPG), which in turn contains preganglionic fibers from the pelvic and hypogastric nerves. On the other hand, the prostate responds to sexual behavior, since it induces an increase in prostatic fluid synthesis. However, to date there are no studies that indicate how this physiological stimulus impacts on this gland. Therefore, the aim of this study was to evaluate the effect of the execution of sexual behavior on the histological characteristics not only of the prostate but also of the GPM. **Methodology:** Twelve male Wistar rats three months old were used for the experiment, distributed in two groups: without sexual experience (Naive) and sexually experienced (SE) subjects. **Results**: Sexual behavior promoted a significant increase in whole MPG area ($p < 0.05$), number of SIF cells ($p < 0.05$), as well as in neural soma ($p < 0.001$); while in the ventral and dorsolateral prostates increased the alveolar area ($p < 0.001$), epithelial height ($p < 0.001$) and nucleus area of epithelial cells ($p < 0.001$). **Conclusions:** Sexual experience induces beneficial histological changes in both, MPG and prostate, which suggests that this behavior is an important factor that favors maturation processes in both structures. It should be noted that this work is the first to show the effect of sexual behavior on the histology of an autonomic ganglion such as MPG.

Title: Sex-specific regulation of central vasopressin in mouse sociosexual behavior

Authors: *K. SHIMIZU[1,2], K. NAKAMURA[3], Y. KONDO[2];
[1]Kansei, Behavioral, and Brain Sci., Univ. of Tsukuba, Ibaraki, Japan; [2]Dept. of Animal Sci., Teikyo Univ. of Sci., Yamanashi, Japan; [3]Natl. Res. Inst. Child Hlth. & Develop., Setagaya, Japan

Abstract: Arginine Vasopressin (AVP) has been known as not only a hormone regulating blood pressure and water metabolism in the kidney but also a central peptide regulating various behaviors including social behavior. Two types of AVP receptors, v1a and v1b, are expressed in the brain, and many studies has been investigating the function of each of them. However, it

remains unclear how central AVP regulates sexual behavior in male and female mice. In this study, we examined the effect of double-KO (dKO) of v1a and v1b on sociosexual behaviors in male and female mice, comparing to those of wild-type (WT) mice. Male subjects were intact and female subjects were ovariectomized and primed with estrogen and progesterone. In the weekly sexual preference tests exposing to airborne odors of mature males and receptive females, both WT and dKO mice showed clear preference for the opposite-sex odor to the same-sex odor. Sexual behaviors were tested in enriched large cage equipped with several objects which prompted social interactions (In the female tests, the area accessible to stimulus males was restricted a half of the cage by tethering to measure female pacing behavior). The dKO males showed significantly increased numbers of pursuing and approaching behaviors than WT males did, resulting in significantly larger number of mounts in dKO males. In contrast, dKO females had decreased number of approaching behaviors to stimulus males than WT females did, resulting significantly smaller number of mounts received. In WT and dKO females, we additionally tested for the preference of soiled beddings collected from home cages of intact males and receptive females. WT females showed significantly longer time spent for nose-contact investigation to the male soiled beddings than female one, while no difference was found in investigation time of dKO females for male and female soiled beddings. Our current data demonstrate that central AVP regulates male and female mouse sexual behavior in completely opposite way, inhibitory in males and facilitatory in females. Furthermore, this study also showed that central AVP is not involved in regulation of the preference for volatile, airborne odors, but modulates the preference for involatile chemicals detected by the vomeronasal organs.

Title: The effects of a long-acting gonadotropin-releasing hormone receptor antagonist on sexual reward in male rats

Authors: *L. E. KAPP, H. A. DUFALA, C. M. DINGLE, W. R. HAWLEY;
Psychology, Edinboro Univ. of Pennsylvania, Edinboro, PA

Abstract: The rewarding aspects of sexual behaviors serve to reinforce the subsequent expression of the behaviors themselves. In male rats, gonadectomy reduces the preference for

environments previously associated with sexual behaviors, which is indicative of sexual reward. In this study, sexual reward and consummatory sexual behaviors in male rats were examined following treatment with degarelix, a long-acting gonadotropin-releasing hormone (GnRH) receptor antagonist that has been used to attenuate androgen receptor signaling as part of the treatment for prostate cancer. The rewarding aspects of sexual behavior were assessed in a three-chambered conditioned place preference (CPP) maze that featured distinct visual cues on the external walls of the end chambers. Male rats received a set of sexual training trials and a single probe trial once a week for four consecutive weeks in order to establish and examine their preference for the sex-associated side. Twenty-four hours after the final pre-drug probe trial, half of the rats were administered degarelix (1.5 mg/kg) and the other half were administered a vehicle control (5% mannitol). One week later, all rats were tested on a post-drug probe trial to reassess their preference for the sex-associated side of the maze. Degarelix significantly reduced the preference for the sex-associated environment relative to the opposite end-chamber that was not associated with sexual experience. Consummatory sexual behaviors were examined once a week over the course of the following three weeks. Results revealed that degarelix treated rats exhibited deficits in nearly all aspects of sexual behavior, including the latency to achieve first mount, intromission, and ejaculation, as well as the total number of intromissions and ejaculations.
Degarelix also significantly reduced the weights of the androgen-sensitive bulbourethral glands and seminal vesicles, which confirmed the drug's bioactivity. The results from this study are the first to uncover the effects of a long-acting GnRH receptor antagonist on sexual reward and provide an important step for future studies that seek to understand the biochemical factors that modulate sexual reward in animal models of androgen deprivation therapy. Given that the reduction in the rewarding aspects of sexual behavior that results from androgen deprivation therapies may produce adverse consequences to psychological health and relationship satisfaction, the ultimate goal of future studies would be to identify alternative pharmacotherapies or behavioral interventions that maintain the rewarding aspects of sexual behavior independent of androgen signaling.

Title: Administration of a gonadotropin-releasing hormone receptor antagonist reduces sexual incentive motivation in male rats: The role of sociosexual stimulation

Authors: P. A. GREEN, L. E. KAPP, H. A. DUFALA, J. L. BARNES, J. L. BARWELL, C. M. DINGLE, *W. R. HAWLEY;
Psychology, Edinboro Univ., Edinboro, PA

Abstract: For those suffering with prostate cancer, treatment with the long-acting gonadotropin-releasing hormone (GnRH) receptor antagonist degarelix has been shown to decrease androgen receptor signaling and correspondingly reduce prostate-specific antigens. Unfortunately, androgen deprivation therapies such as these are associated with deficits in sexual motivation. Consequently, it was expected that administration of degarelix would also decrease sexual motivation in male rats, an effect similar to that which occurs following gonadectomy. In addition to gonadal hormones, sexual motivation is modulated by a variety of other social and environmental factors. For instance, when older male rats were allowed to mount a sexually receptive female immediately prior to testing sexual incentive motivation (SIM) they subsequently exhibited a preference for a female relative to a male sexual incentive. Therefore, because mounting behaviors in male rats can be maintained for several weeks after gonadectomy, it was expected that a brief exposure to a female sexual incentive would attenuate the effects of degarelix on SIM in male rats. Sexually experienced male rats were treated once with either a vehicle solution (5% mannitol) or a dose of degarelix (1.5 mg/kg) that rapidly and drastically reduces androgen signaling for over one month. SIM testing was conducted in a three-chambered maze that featured a male and a sexually receptive female incentive individually confined behind separate smaller stimulus chambers. A single stimulus chamber was placed into each of the larger end chambers of the maze. The first SIM test was conducted one week after treatment and subsequent tests were conducted once every 7 days thereafter. However, 15 minutes prior to each SIM test, half of the rats in each treatment condition were exposed for 10 minutes to a sexually receptive female with whom they could sexually interact with. Rats treated with degarelix spent significantly less time in the vicinity of the female relative to the male. Although a brief exposure to a sexually receptive female tended to increase levels of activity on the SIM test in degarelix treated rats, as indicated by the total number of end chamber entries, it was not sufficient to enhance the preference for a female incentive. However, this may have been due to the fact that the drug nearly abolished all mounting behavior only one week after treatment. These results stand in contrast to the effects of gonadectomy that have been reported previously as they suggest that chemical suppression of testosterone with degarelix is highly effective at rapidly reducing SIM and mounting behaviors in male rats.

Title: Insulin improves sexual motivation in diabetic female rats evaluated in two paradigms

Authors: *A. K. HERNÁNDEZ-MUNIVE[1], D. REBOLLEDO-SOLLEIRO[2], A. FERNÁNDEZ-GUASTI[1];
[1]Ctr. De Investigación Y Estudios Avanzados, México, Mexico; [2]Univ. Nacional Autónoma de México, México, Mexico

Abstract: The relationship between diabetes mellitus (DM) and sexual dysfunction in women has shown controversial results. The animal model mostly used to study the alterations in DM is the administration of streptozotocin (STZ), a drug that destroys B-pancreatic cells. When STZ is administered in the adult stage, the animal shows some symptoms of DM1: polyphagia, polydipsia, polyuria, hyperglycemia and weight loss. In preclinical studies, it has been reported that females treated with STZ showed an altered estrous cycle, a reduction in sexual receptivity and an increased aggressiveness, changes that were restored when insulin was exogenously administered. However, the motivational component of copulation in hyperglycemic rats has not been studied. The aim of this study was to evaluate female sexual motivation (FSM) in a model of DM1 in two paradigms: the partner preference (PP) and the incentive sexual motivation (ISM). DM1 was modeled in OVX Wistar rats by injecting STZ diluted in citrate buffer [50 mg/kg, i.p., for 2 consecutive days]. Ten days later, female rats were treated with estradiol benzoate (10 μg, -24 h) and progesterone (3 mg, -4 h). Also, a group of STZ-treated animals were administered with a long-acting insulin analogue (glargine) every 12 hours for 10 days (2-4U). Body weight was recorded at the beginning and at the end of the study and glucose levels were also reported (only animals with blood glucose values ≥ 350 mg/dl were considered for the study). For PP we registered the time in each compartment, the time of interaction with each stimulus and the preference of these animals. In the ISM test, we calculated the time that the female stays in each incentive zone and the time the female invests sniffing the wall that isolates the stimuli. In both tests, a castrated male (CM) and a sexually experienced male (SEM) were used as stimuli. STZ-treated OVX rats lost body weight and had increased blood glucose levels. In the PP test, control females spent more time with an SEM, while the hyperglycemic females stayed the same amount of time with the CM and the SEM and 4 out of 11 STZ-treated females preferred to remain in the box of the CM. Similarly, in the ISM arena, the control females spent

more time in sexual incentive zone, while the treated with STZ remained the same amount of time in the vicinity of the both stimuli, however, there was no difference between STZ and control females in the time spent sniffing the wall that isolated the stimuli. All these changes (in PP and ISM) were reversed with insulin to values comparable of those of the control group. Our data suggest that severe hyperglycemia decreases FSM and that insulin fully recovers such diminution.

Title: Modulating sexual behavior in female rats with tibial nerve electrical stimulation

Authors: *L. L. ZIMMERMAN[1,2], G. MENTZELOPOULOS[1,3,2], H. J. PARRISH[3,2], B. D. LUMA[4], J. B. BECKER[4,5], T. M. BRUNS[1,2];

Abstract: Female sexual dysfunction affects millions of women worldwide yet there are limited treatment options. In previous work, we have established that electrical stimulation of the tibial nerve can drive increases in vaginal blood flow in anesthetized female rats, indicating the potential to be used as a treatment for genital arousal deficiencies. Here, we are studying whether tibial nerve stimulation driven genital arousal can affect sexual motivation, which would indicate potential for treating genital arousal disorders as well as decreased sexual interest in women. Female rats were ovariectomized to eliminate hormonal control over sexual motivation and trained to use an operant apparatus. The apparatus has two chambers, with the female required to nose-poke to open a door between chambers to access a sexually active male. Nose pokes on a fixed interval (FI) 15 second schedule was used to quantify extent of sexual motivation. Once a week each rat was randomly assigned to one of five conditions: no stimulation & no hormone treatment, no stimulation & partial hormones, stimulation & no hormones, stimulation & partial hormones, no stimulation & full hormones. Tibial nerve stimulation was applied with a percutaneous wire at 20 Hz for 30 minutes at an amplitude twice the motor threshold prior to placement in apparatus. For hormone conditions, 10 μg 17 β-estradiol benzoate was administered 48 hours prior to testing, and 100 μg (partial dosing) or 500 μg (full dosing) progesterone was

administered 4-5 hours in advance. Each rat was tested twice per condition, for a total of 10 weeks of testing. To date, animals receiving stimulation without hormones, on average, nose poked more times per interval and spent more time in the male zone than animals receiving neither hormones nor stimulation, but less than animals receiving hormones without stimulation. Future studies will evaluate whether repeated tibial nerve stimulation over time has a cumulative effect on the sexual behavior of females.

Title: Lateral hypothalamic control of male and female sexual motivation

Authors: *K. J. JENNINGS, W. J. GIARDINO, L. DE LECEA;
Psychiatry and Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: Stimulation of the lateral hypothalamus (LHA) has long been known to facilitate sexual motivation. Among the multiple cell types that populate the LHA, neurons that produce the neuropeptide hypocretin (Hcrt, also known as orexin) are strong candidates to promote sexual motivation. Hcrt neurons drive arousal and reward-seeking behavior and are hypothesized to support expression of motivated behavior. To determine the role of LHA-Hcrt neurons in male and female sexual motivation, we first used fiber photometry to record calcium activity of LHA-Hcrt neurons while mice interacted with an opposite-sex conspecific. LHA-Hcrt calcium activity is increased during appetitive sexual behavior and decreased during consummatory sexual behaviors in both sexes. LHA-Hcrt activity is higher during appetitive behavior that progresses to consummatory behavior than during appetitive behavior that does not lead to consummatory behavior, consistent with a role in sexual motivation. We next used targeted optogenetic manipulation of LHA-Hcrt neurons during specific social behaviors to probe the causal role of LHA-Hcrt neurons in male and female sexual behavior. These data confirm the functional role of LHA-Hcrt neurons in male and female sexual motivation and broaden our understanding of LHA-Hcrt regulation of motivational and emotional states.

Title: Sexual motivation throughout adolescence in the female rat and its c-Fos expression correlate

Authors: *D. AGRATI, M. ARMAS, G. MARIN, G. BEDO;
Facultad De Ciencias, Univ. De La Republica, Montevideo, Uruguay

Abstract: Sexual behavior in the female rat is highly motivated. However, although this behavior begins to be expressed during adolescence, sexual motivation has been poorly studied during this period. The present study aimed to explore the expression of the sexual motivation of female rats along adolescence. In order to achieve this, the incentive value of a sexually active male for middle (39-43 days-old) and late (49-53 days-old) adolescent and adult (90-110 days-old) female rats in late-proestrus was assessed in two models: a) male vs. non-receptive female preference test in a Y-maze without physical access to the stimuli, and b) emission of 50 kHz ultrasonic vocalization (USV) in response to a brief interaction without physical contact with a male or a non-receptive female. The brains of the females that underwent the USV emission test were processed 65 min after the initiation of the test for quantifying c-Fos protein expression as an index of neural activation. Results show that, although all sexually active females, regardless of their age, preferred the male over the female in the Y-maze, late-adolescent and adult rats performed more effort to obtain the male when compared to middle-adolescent rats. Accordingly, late-adolescent and adult females emitted more 50 kHz USV after interacting with a male than with a female, but the emission of USV in response to both social stimuli did not differ in the middle-adolescent group. Preliminary analysis of c-Fos expression suggests a differential activation of neural areas involved in the expression of sexual motivation among ages. These results strongly suggest that the sexual motivation of the female rat increases throughout adolescence and provide elements for understanding maturation processes of the neural circuits that regulate the sexual behavior of female rats.

Title: The facilitating effects of acute oxytocin treatment on pacing and proceptive sexual behaviours are dose-dependent

Authors: *C. E. MAC CIONNAITH[1], E. GOMEZ-PERALES[1], J. G. PFAUS[2], W. BRAKE[1]; [1]Concordia Univ., Montreal, QC, Canada; [2]Univ. Veracruzana, Veracruz, Mexico

Abstract: Several studies have reported that oxytocin (OT) administration increases lordosis quotients in female rats. However, the lordosis reflex is only one of many behaviours that are important during mating in the female rat. Proceptive behaviours (i.e. solicitations and hops and darts) and pacing are important for successful impregnation. Therefore, the current study tests the effects of different doses of oxytocin on a variety of sexual behavioural measures. Thirty female Long-Evans (LE) rats were randomised to be intraperitoneally injected with 20µg OT, 50µg OT, or saline one minute prior to copulation (n = 10 per group). Females copulated with an LE male in unilevel Plexiglass pacing chambers for 30 minutes. Trials were recorded and scored for: female entries to the male compartment, the latency to return to the male after leaving the male's compartment, solicitations, hops and darts, intromissions and ejaculations received, and the amount of time spent with a male. All behaviours were analysed with one-way ANOVAs, followed by Holm-adjusted group comparisons. Females treated with 50µg OT took longer to return to the male chamber and made fewer entries to the male's compartment compared to the 20µg OT group. They also received fewer intromissions and ejaculations. Additionally, females treated with 50µg OT made fewer hops and darts and fewer solicitations than females given 20µg OT. Conversely, 20µg OT females made more proceptive behaviours and entries to the male compartment compared to 50µg OT females. There was also a trend for females given 20µg OT to make more solicitations and hops and darts than saline treated females. Thus, OT may acutely facilitate female sexual behaviour, but these effects are dose dependent; 20µg OT facilitates sexual behaviours whereas 50µg OT is inhibitory.

Title: Potential progesterone regulated dopaminergic projections to β-endorphin neurons in the arcuate nucleus

Authors: *D. LE, C. E. CARLSON, S. BERMANI, M. LA FOREST, T. CHUON, M. ESKANDER, K. SINCHAK;
Biol. Sci., California State University, Long Beach, Long Beach, CA

Abstract: In ovariectomized (OVX) rats, a priming dose of 2μg of estradiol benzoate (EB) induces the release of β-endorphin (β-END) from neurons of the arcuate nucleus of the hypothalamus (ARH) that project to the medial preoptic nucleus (MPN). This activates and internalizes μ-opioid receptors (MOR), which initially inhibits sexual receptivity (lordosis). Progesterone infused into the ARH rapidly facilitates lordosis and reduces the activation of MPN MOR by upregulating membrane associated classical progesterone receptors (PGR). Our lab has shown previously that ARH PGR complex with and signals through Src family kinase (Src) on the plasma membrane in the ARH that also interacts with dopamine D1 receptor to facilitate lordosis. This PGR-Src-D1 interdependent signaling has been localized to a subpopulation of the ARH β-END neurons, suggesting that a progesterone responsive dopaminergic input to ARH β-END neurons should exist. In this experiment, we tested the hypothesis that progesterone signals through a dopaminergic neuron which projects to β-END neuron in the ARH to regulate sexual receptivity. OVX Long Evans rats were treated with 2μg EB or oil, and rats were perfused 48 hours later. Brain sections through the ARH were processed for doubled labeled immunohistochemistry for PGR-tyrosine hydroxylase (TH; marker for potential dopamine neurons), Src-TH, and β-END-TH. A subpopulation of potential dopamine neurons were immunopositive for TH and PGR, and EB treatment increased the number of TH-PGR positive ARH neurons, indicating that progesterone responsiveness was increased in potential ARH dopaminergic neurons. A subpopulation of neurons were also immunopositive for both Src and TH indicating that a similar PGR-Src mechanism could rapidly regulate the activity of these neurons. Lastly, we observed very little co-localization of β-END-TH immunoreactivity. However, TH immunopositive fibers were in close proximity to immunopositive β-END cell bodies and processes. These results support our hypothesis that progesterone may signal through PGR-Src signaling complexes to activate a subpopulation of potential dopaminergic neurons that project to β-END neurons to reduce their neurotransmission and facilitate lordosis.

Title: From pheromone sensation to reproductive behavior: Identifying the pathway of prostaglandin sensation into the GnRH system in the zebrafish

Authors: *G. N. MCHUGH[1], A. MARCHAND[1], S. RAMAKRISHNAN[2];
[1]Biol., [2]Neurosci. Program, Univ. of Puget Sound, Tacoma, WA

Abstract: Mating, social communication, and social behaviors are modulated through pheromones. In many species this is essential for triggering behaviors associated with reproduction, and hence reproductive success. In most vertebrates studied to date, Gonadotropin Releasing Hormone neurons in the brain have been shown to control reproduction. Of the three populations of GnRH neurons, the extrahypothalamic ones in the terminal nerve associated with the olfactory bulb (TN-GnRH) have been linked to integrating chemosensory and visual stimuli from conspecifics thereby modulating reproductive behaviors. It is therefore likely that pheromonal signals from conspecifics are conveyed to the GnRH system. Prostaglandin (PG) is a pheromone released by female zebrafish to synchronize the timing of spawning behaviors with ovulation. This study investigated the potential link between prostaglandin as a pheromonal signal and TN-GnRH neurons in the brain of male zebrafish. A stable transgenic line of zebrafish with GnRH3 neurons tagged with green fluorescent protein (GFP) was used in this study. We observed behavioral responses of male zebrafish after exposure to 0.1 μM pheromonal PG or 0.1 μM vehicle control (DMSO). Male fish were individually placed in a testing tank and prostaglandin injected into one corner, following which behavior was recorded for 9 min with Ethovision 10 software. Behavioral testing showed that fish interacted with the zone of PG injection more than DMSO tests ($p=0.0432$). Fish exposed to prostaglandin also swam significantly faster ($p=0.0410$) and further ($p=0.0400$) than control treated fish during testing. Immediately after behavioral testing, we used c-*fos* immunohistochemical staining to identify cells in the olfactory bulb and telencephalon expressing immediate early genes. Zebrafish brains (n=8; 4 PG, 4 DMSO) were dissected and imaged using an inverted epifluorescent microscope at 488nm excitation / 512nm emission and 560 excitation / 645 emission. Imaging showed c-*fos* activation of cells in the terminal nerve near GnRH3-GFP neurons, but no co-localization. In order to identify potential intermediary cells, we used calretinin immunohistochemical staining

of chemosensory cells under the same imaging protocol (n=6). We found anatomical proximity between chemosensory neurons and GnRH3-GFP neurons in the terminal nerve. Prostaglandin pheromonal signals can thus be passed on to TN-GnRH3 neurons via chemosensory cells. Double labeling of chemosensory cells with calretinin, along with prostaglandin activated c-fos under a GnRH3-GFP background could confirm this connection.

Title: Too much of a good thing: The effect of aversive distributed clitoral stimulation on odour conditioned partner partner and 50-kHz ultrasonic vocalizations

Authors: *C. A. GERSON[1], C. E. MAC CIONNAITH[1], M. RIVEST-BEAUREGARD[1], E. GOMEZ-PERALES[1], P. S. B. CLARKE[2], J. G. PFAUS[3], U. SHALEV[1];

Abstract: Clitoral stimulation (CLS) offers a unique approach to investigating sexual conditioning and 50-kHz ultrasonic vocalizations (USVs). Adult female rats find distributed CLS rewarding as it mimics stimulation received during paced copulation. Distributed CLS induces conditioned partner preference (CPaP) and elicits 50-kHz USVs, both of which indicate reward. The reinforcing potential of CLS however shifts as properties of its application changes. For instance, female rats fail to develop CPaP for a scented male when distributed CLS is previously paired with an inaccessible male and odour. One property of CLS application our lab has yet to assess is tactile intensity, *i.e.* bristle hardness of the paintbrush used to deliver CLS. As distributed CLS is typically delivered using a soft bristle paintbrush, it is unknown whether changes in tactile intensity influences USV emission and CPaP development, and/or whether hard bristle distributed CLS is potentially aversive. To date, aversive sexual conditioning in rodents has only utilized pain as an aversive stimulus. The present study tested the hypothesis that hard bristle distributed CLS paired with an odor can induce condition partner aversion. Changes in USV emission in response to the tactile intensity of CLS administration were also assessed during odor conditioning. Forty-eight ovariectomized females were hormonally primed with estradiol benzoate and progesterone and randomly assigned to one of six conditioning groups (n = 12/group): (1) scented hard bristle CLS vs. unscented sham CLS; (2) unscented hard

bristle CLS vs. scented sham CLS;(3) scented soft bristle CLS vs. unscented sham CLS; (4) unscented soft bristle CLS vs. scented sham CLS; (5) scented hard bristle CLS vs. unscented soft bristle CLS; (6) scented soft bristle CLS vs. unscented hard bristle CLS. Distributed CLS consisted of lightly brushing the clitoris using either a soft or rough No. 4 paintbrush while sham CLS was performed by lifting the base of the tail. CLS was applied every 5 sec for 1 min after a 2 min inter-CLS interval no-CLS and repeated for 5 cycles for total session duration of 15 minutes. Vocalization recordings were conducted during the 12 alternating conditioning trials, which were followed by a final open-field partner-preference test. Preliminary behavioral results suggest a slight conditioned aversion to rough brush CLS that unexpectedly generalized to soft brush CLS. USV calls are currently being analyzed. *Keywords: Distributed Clitoral Stimulation, Ultrasonic Vocalization, Sexual Conditioning, Sexual Aversion*

Title: Neuroendocrinological mechanisms that mediate the coordinated regulation of reproduction and sexual behavior

Authors: *S. TOMIHARA[1], D. KAYO[1], S. KANDA[2], Y. OKA[1];
[1]Dept. of Biol. Sci., Grad. Sch. of Sci., Univ. Tokyo, Tokyo, Japan; [2]AORI, Univ. Tokyo, Chiba, Japan

Abstract: Successful reproduction requires the coordinated regulation of gametogenesis and sexual behavior. In fact, sexual behavior is observed only when the animal is in the reproductive state. However, little is known about the neuroendocrinological mechanisms for such regulation. In the present study, we examined possible involvement of gonad-derived factors, which are secreted from mature gonads, in the regulation of sexual behavior in a teleost, medaka. Here, we developed and used a semi-automatic system to efficiently and accurately analyze sexual behavior. First, we analyzed the female sexual behavior after ovariectomy and found that the ovariectomized female stayed away from male to avoid male courtship. Administration of one of

the sex steroid hormones, estrogen, to ovariectomized females, reinstated the clasping-like behavior (clasping continued for a shorter period than the intact female) in some pairs. However, the estrogen administration did not reinstate the avoidance behavior. From these results, we considered that estrogen may play some important roles and administered Fadrozole-hydrochloride (an inhibiter of estrogen synthesis) to female. After this treatment, the females did not attain clasping with male, although they normally accepted male courtship. Second, we examined the contribution of estrogen receptors for the behavioral activation by gene-knockout analysis and found that estrogen receptor 2b (Esr2b)-deficient females did not attain clasping with male despite the normal acceptance of male courtship. Interestingly, they had normal ovary, exhibited normal secondary sex characteristics and ovulated normally; they are in the reproductive state. The present results indicate that estrogen signaling via Esr2b plays an important role in the sexual behavior sequence of female medaka as a specific activator of clasping behavior after the acceptance of male courtship. Furthermore, some kind(s) of ovary-derived non-estrogenic factors may play a role in the male acceptance. Because Esr2b is known to be expressed in some brain regions (Zempo *et al.*, 2013), the present results suggest the existence of a neuroendocrinological mechanism in which Esr2b-expressing neurons receive estrogen secreted from mature ovary and then activate clasping behavior.

Title: Sexually dimorphic neuropeptide B neurons in the ventral telencephalon, a leading candidate for the regulator of female reproductive behavior, show estrogen dependence and diurnal changes in their neuronal activities

Authors: *M. NAKAJO[1], T. HIRAKI-KAJIYAMA[3], K. OKUBO[2];
[1]Dept. of Biol. Sciences, Grad. Sch. of Sci., [2]Dept. of Aquatic Bioscience, Grad. Sch. of Agr. and Life Sci., The Univ. of Tokyo, Tokyo, Japan; [3]Lab. for Systems Mol. Ethology, RIKEN Ctr. for Brain Sci., Saitama, Japan

Abstract: Sexual reproduction requires not only gonadal maturation to attain fertility, but also reproductive-state dependent behavior so-called sexual behavior. For coordination of both under the control of the central nervous system, sex steroid signals such as estrogen (E) play pivotal roles, which is considered to be an essential regulatory system in vertebrates. Previous

physiological and histological studies in both teleosts (Koyama et al., 1984, Satou et al., 1984, Zempo et al., 2013) and mammals (Munchrath & Hofmann, 2010, Lee et al., 2014) have suggested that estrogen receptor (ER)-expressing neurons localized in several brain regions such as the preoptic area (POA), ventral telencephalon (Vs/Vp), and hypothalamus are involved in the regulation of reproductive behaviors. However, the detailed neural circuit including these neurons largely remains unclear.Our previous study discovered in medaka (*Oryzias latipes*) that neuropeptide B (Npb)-expressing neurons localized in Vs/Vp represent female-biased and E-dependent *npb* expression, which is explained by the co-expressed ERs (Hiraki et al., 2014). Therefore, in the present study, to examine possible E-dependent regulation of these neuronal functions in females, we performed neurophysiological analysis. Using female transgenic medaka whose Npb neurons are specifically labeled by GFP (*npba*:*gfp*), we analyzed spontaneous neuronal activities of Vs/Vp Npb neurons by on-cell patch clamp recording in various conditions. First, we discovered their time-of-day dependent changes. Their firing frequency in the early light period (10 AM - 2 PM) when medaka usually start to mate (Mean±SEM; 1.3±0.24 Hz) is significantly higher than that in the middle light period (2 - 6 PM) (0.59±0.11 Hz, $p<0.01$, Steel-Dwass test). Next, we used ovariectomy (OVX) in combination with E supplement (OVX+E) technique. Compared to Sham-operated individuals (1.1±0.30 Hz), OVX ones showed significantly lower frequencies (0.24±0.091 Hz, $p<0.05$, Steel-Dwass test) in their neuronal activities in the early period of the light cycles, which were restored in OVX+E ones (0.78±0.20 Hz). Furthermore, as for the firing patterns, Vs/Vp Npb neurons of Sham-operated fish occasionally showed bursting whereas OVX ones mostly showed silent type, indicating that the firing activity of Npb neurons and Npb release are dependent of E signals. Intriguingly, our previous behavioral analysis indicated that *npb* knockout female medaka have abnormality in mating (Hiraki-Kajiyama et al., in review). Taken together, the present study strongly suggests that Vs/Vp Npb neurons regulate female-specific sexual behaviors specifically in the presence of E.

Title: Steroid-independent spatial working memory is associated with steroid-independent sexual behavior in b6d2f1 male mice

Authors: *C. D. DAVID[1], B. N. WYROSDIC[2], H. WAN[1], S. YITBAREK[1], J. PARK[3];
[1]Univ. of Massachusetts Boston, Boston, MA; [2]Univ. of Massachusetts-Boston, Hull, MA;
[3]Psychology, Univ. of Massachusetts, Boston, Boston, MA

Abstract: In rodents, gonadal steroids play a critical role in the modulation of a wide array of behaviors, including social interaction and cognitive performance. Animals generally experience a reduction or complete inhibition of male sexual behavior following castration. Similarly, castration is associated with decreased performance of spatial, working, and reference learning and memory in males of many species; administration of replacement steroids, including testosterone or estradiol, increases performance on a variety of cognitive tests to levels observed prior to castration. However, between individuals and across species, the role of steroids on these behaviors is highly variable. In a prior study in our lab, two proteins involved in cognitive behavior, amyloid precursor protein and tau, were shown to play a significant role in steroid-independent male sex behavior in B6D2F1 hybrid male mice. Thus, we used this mouse model, in which a large proportion of the males retains the complete repertoire of male reproductive behavior long after castration, to probe a potential relationship between steroid-independent male sexual behavior and steroid-independent cognition. After identifying males as either "maters" (retaining steroid-independent male sex behavior) or "non-maters," animals were tested in an 8-arm radial arm maze. Maters outperformed non-maters in the number of errors committed during the maze ($p < 0.01$). We also observed a trend that maters completed the maze more quickly than non-maters ($p < 0.10$). Our data demonstrate that retention of male sexual behavior and cognitive performance in the absence of gonadal steroids may be linked and warrant further investigation into potential mechanisms underlying these behaviors. Specifically, we plan to further investigate the role of *amyloid precursor protein* and *microtubule associated protein tau* in the hippocampus. Furthermore, we found that the animals' weight had a group-specific effect when predicting number of errors and was included as a covariate in corresponding analyses. These results indicate that the predictive value of weight may reflect different responses to food deprivation or greater motivation to seek food rewards in the maze, identifying additional future routes of inquiry and compelling us to compare expression of genes involved in metabolism, such as leptin receptor b (*Ob-Rb)*, and genes related to motivation, such as dopamine receptor 2 (*D2R*).

Title: Influence of maternal conditions in sexual preference of male progeny

Authors: *A. HERNANDEZ-GONZALEZ, A. FERNANDEZ-GUASTI;
Farnacobiologia, Ctr. De Investigacion y Estudios Avanzados Del I, Mexico, Mexico

Abstract: Sexual preference is typically presented in the same way among all species: males usually prefer an estrous female for sexual interaction while receptive females generally prefer a sexually active male. However, also in all species, there is a subpopulation of males with same-sex preference. The most studied reason underlying this preference is a decrease in androgens aromatization in certain brain areas during development that leads to an altered sexual differentiation process. However, the experimental inhibition of aromatase in rats only produces a same sex preference in around half of the subjects. Multiparity and gestational stress have also been proposed as causal factors for same-sex preference. Here we evaluated the possible involvement of multiparity, gestational stress and aromatase inhibition on sexual preference and sexual behavior of the male progeny. We evaluated the role of these factors individually and their putative interaction. We used males whose mothers were primiparous or multiparous (4 or more deliveries); stressed (restriction stress for the last 10 gestation days) or non-stressed; and treatment with the aromatase inhibitor, letrozole (0.56µg/kg/from G10 to delivery). Sexual preference was established in a three-compartment cage, where animals could choose between a sexually experienced male and a receptive female.
We found that letrozole induced a 40% of males with preference for another male, 30% of prenatally stressed males presented same sex preference, and there was a lack of interaction between letrozole and gestational stress because only 50% of males submitted to both treatments had same-sex preference. A 34% of the male progeny of multiparous dams preferred the sexually active male.
High levels of feminine sexual behavior were displayed by males with same sex preference regardless of the cause (gestational stress, multiparity or aromatase inhibition), indicating that all treatments interfered with the defeminization process.
Present data suggest that stress and the inhibition of aromatase do not interact to produce same-sex preference and that multiparity may play an important role in this phenomenon.

Title: Rapid changes in sociosexual behaviors around transition to and from behavioral estrus, in female rats housed in a seminatural environment

Authors: *O. LE MOENE[1], **E. HERNANDEZ-ARTEAGA**[2], X. CHU[3], A. AGMO[4];
[1]Dept. of Psychology, Univ. of Tromso, Tromsø, Norway; [2]Inst. De Neurociencias, Univ. de Guadalajara, Guadalajara, Mexico; [3]Dept. of Psychology, Norwegian Univ. of Sci. and Technol., Trondheim, Norway; [4]Dept. of Psychology, Univ. of Tromsø, Tromsø, Norway

Abstract: Intact female rats display sexual behaviors only during a portion of the estrus cycle. This portion, behavioral estrus, coincides with the proestrus/estrus phase as determined by vaginal cytology, and with peak serum concentrations of estradiol and progesterone. In standard experimental setups, intact females gradually changes from complete non-receptivity to full receptivity in the beginning of behavioral estrus and vice versa at the end of estrus. However, in naturalistic settings, the change in receptivity is almost instantaneous. In order to eliminate possible rapid fluctuations in ovarian steroids as causes of the sudden on- and offset of sexual activity, we assessed the changes in sociosexual behaviors around the beginning and end of behavioral estrus in ovariectomized females sequentially treated with estradiol benzoate (18 μg/kg) and progesterone (1 mg/rat). Females were housed in a seminatural environment, in groups of three males and four females. We scored female and male behavior during the 8 minutes preceding and following both the first and last lordosis of behavioral estrus. Immediately before the first lordosis, there was a sharp increase in female paracopulatory behaviors and male pursuit of the females. According to a co-occurrence analysis, the beginning of behavioral estrus was characterized by both pro- and anti-social behaviors. Male sexual behavior was absent before the beginning of estrus. The end of estrus was marked by a sudden decrease in female paracopulatory behavior, as well as male pursuit of the females and male sexual activity. The behavioral changes associated with both the beginning and end of behavioral estrus suggest that the females became attractive to the males only when fully receptive and that they lost this attractivity while still being fully receptive. In fact, it is known that receptivity requires less hormone exposure than attractivity. Both during transition into and out of behavioral estrus, most behavioral changes occurred within three minutes. Since these rapid changes cannot correlate with ovarian hormone fluctuations in these ovariectomized females, the almost instantaneous transition may be caused by mechanisms similar to a phase shift in the function of critical structures within the brain.

Title: Proestrus evokes transcriptional changes in genes encoding ion channel and calcium homeostasis-regulating proteins in GnRH neurons of mice

Authors: *Z. LIPOSITS[1,2], N. SOLYMOSI[3], I. FARKAS[4], C. VASTAGH[5];
[1]Endocrine Neurobio., Inst. of Exptl. Medicine, HAS, Budapest, Hungary; [2]Fac. of Information Technol. and Bionics, Pázmány Péter Catholic Univ., Budapest, Hungary; [3]Ctr. for Bioinformatics, Univ. of Vet. Med., Budapest, Hungary; [4]Endocrine Neurobio., Inst. of Exptl. Medicine, HAS, Budapest, Hungary; [5]Endocrine Neurobiolgy, Inst. of Exptl. Med., Budapest, Hungary

Abstract: In late proestrus, GnRH neurons exhibit increased firing (*Farkas et al., PLoS One, 2013*) and frequency of mPSCs (*Farkas et al., eNeuro, 2018*). These events are indicative of a proestrus-driven plasticity of GnRH neurons with involvement of ion channels. This study examined the effects of proestrus on expression of genes encoding ion channel and calcium homeostasis-regulating proteins in GnRH neurons of regularly cycling, GnRH-GFP transgenic mice (*Suter et al., Endocrinology, 2010*). Met- and proestrous mice were sacrificed between 16:00 and 18:00 h. LCM was used for collecting GnRH neurons that were studied by Mouse Genome 430 PM Arrays and q-RT-PCR. Voltage-gated sodium channels responded with upregulation of the alpha subunits (*Scn2a1, Scn3a* and *Scn9a*). Within the voltage-gated potassium channel class, *Kcna1, Kcnd3, Kcnh3 and Kcnq2* were upregulated, while others (*Kcna4, Kcnc3, Kcnd2* and *Kcng1*) underwent downregulation. It also had impact on inwardly rectifying potassium channel subunits manifested in enhanced expression of *Kcnj9* and *Kcnj10* genes, whereas *Kcnj1, Kcnj11* and *Kcnj12* subunit genes were downregulated. The two-pore domain potassium channel subfamily also showed differential expression with upregulation of *Kcnk1* and reduced expression of 3 subunit genes (*Kcnk7, Kcnk12* and *Kcnk16*). Changes in expression of chloride channels involved both the voltage-gated (*Clcn3* and *Clcn6*) and the intracellular (*Clic1*) subtypes. Regarding the pore-forming alpha 1 subunits of voltage-gated calcium channels, two (*Cacna1b and Cacna1h*) were upregulated, while *Cacna1g* showed downregulation. The ancillary subunits were also differentially regulated (*Cacna2d1, Cacna2d2, Cacnb1, Cacnb3, Cacnb4, Cacng5, Cacng6* and *Cacng8*). Genes encoding proteins regulating the intracellular calcium homeostasis were also influenced (*Calb1, Hpca, Hpcal1, Hpcal4, Cabp7, Cab 39l, Cib2*). The findings indicate that the altering gonadal hormone milieu in proestrus contributes to remodeling of ion channels which is a prerequisite of preovulatory GnRH surge.

Title: Coexpression of glutamate and multiple neuropeptides in the midbrain GnRH neurons suggests various neuromodulatory functions

Authors: *C. UMATANI[1], S. KANDA[2], T. KARIGO[3], Y. OKA[1];
[1]The Univ. of Tokyo, Tokyo, Japan; [2]AORI, Univ. Tokyo, Chiba, Japan; [3]Biol. and Biol. engineering, Caltech, Pasadena, CA

Abstract: Vertebrates generally have three paralogous genes for gonadotropin releasing hormone (GnRH). One of *gnrh* paralogues, *gnrh2,* is expressed in the midbrain tegmentum neurons, and this expression is the most conserved among vertebrates and may play important roles (Okubo et al., 2008, Muske et al, 1993). Midbrain GnRH2 neurons project broadly to the whole brain except the pituitary, show pacemaker-like action potential firing, and are suggested to show neuromodulation via GnRH2 peptide release (Kanda et al., 2010, Karigo and Oka, 2013). In addition, intracerebroventricular injection of GnRH2 suggested that GnRH2 decrease food intake in goldfish and zebrafish. However, a recent study reported that gnrh2/3 double KO zebrafish can grow almost normally (Marvel et al., 2018), and the function of GnRH2 is still controversial. For a functional characterization of the GnRH2 neuronal system, we examined the possible transmitter co-expression by single cell RNA-seq followed by confirmation with dual *in situ* hybridization using Japanese medaka (*Oryzias latipes*). Here, we found that all midbrain GnRH2 neurons express corticotropin releasing hormone (*crh*) and cocaine- and amphetamine-regulated transcript (*cart*) in addition to *gnrh2*. About 45 % of CRH neurons in the midbrain tegmentum express *gnrh2*. One of the *cart* paralogues, *cartch4* (*cart* in chromosome 4), is expressed only in the midbrain GnRH2 neurons. There was no sexual difference in either *crh* or *cartch4* expression in the midbrain GnRH2 neurons. Unlike the terminal nerve GnRH3 neurons, which also have neuromodulatory functions and show regular pacemaker activities (Umatani et al., 2015, Umatani and Oka, 2018), the midbrain GnRH2 neurons were suggested to express neither GnRH receptors nor NPFF receptors, whose receptors are important for regulation of pacemaker firing of terminal nerve GnRH3 neurons (Abe and Oka, 2000, Saito et al., 2010). Thus, firing patterns of midbrain GnRH2 neurons may be regulated by different mechanisms

from the terminal nerve GnRH3 neurons. On the other hand, the midbrain GnRH2 neurons expressed vesicular glutamate transporter as in the terminal nerve GnRH3 neurons. Thus, midbrain GnRH2 neurons were suggested to release glutamate in addition to three neuropeptides: GnRH2, CRH, and CARTch4. Because CRH plays an important role in stress responses and the expression of *cartch4* was not affected by fasting (Murashita and Kurokawa, 2011), the midbrain GnRH2 neurons may have various neuromodulatory functions as well as a regulation of food intake.

Abstract: Metabolic hormones influence reproduction in accordance with the actual energy balance. This control may occur at multiple levels of the HPG axis, although the majority of these interactions takes place centrally in the hypothalamus. It has been shown earlier (Kimura et al., 1987), that secretin, a member of the gut-brain hormone family, modulates the luteinizing hormone (LH) level, albeit the underlying mechanisms have not been examined till date. In order to elucidate the involved cellular mechanisms, *in vitro* electrophysiological experiments were carried out in GnRH-GFP neurons of male mice. Whole-cell patch-clamp measurements demonstrated increased frequency of the postsynaptic currents (sPSCs) (118±2.64 %) and that of the GABAergic miniature postsynaptic currents (mPSCs) (147.6±19.19 %) after 100 nM secretin administration. Resting membrane potential also became depolarized by 12.74±4.539 mV. Frequency of evoked action potentials also increased to 144.3±10.8 %. The secretin-triggered

elevation of the frequency of mPSCs was prevented by using either a secretin receptor antagonist (3μM) or intracellularly applied G-protein-coupled receptor blocker (GDP-β-S; 2mM) supporting the involvement of secretin receptor in the mechanism. Concerning the known downstream pathway to secretin receptor, intracellular blockade of protein kinase A (PKA) activity with KT-5720 (2μM) or intracellular inhibition of the neuronal nitric oxide synthase (nNOS) by NPLA (1μM) attenuated the stimulatory effect of secretin on mPSCs. These data suggest that the direct activation of GnRH neurons via secretin receptor occurs through the cAMP/PKA/nNOS signaling pathway, resulting in nitric oxide release. In turn, NO can bind to its receptor, the soluble guanylyl cyclase (sGC), expressed in GABAergic axon terminals innervating GnRH neurons (Farkas et al., 2016). The NO-sGC interaction in the presynaptic axon terminals leads to increased vesicular GABA release which, in turn, excites GnRH neurons via GABA-A receptors.

Title: Modulation of leteinizing hormone pulse frequency by optogenetic stimulation of arcuate nucleus kisspeptin neurones along the oestrus cycle

Authors: *M. VOLIOTIS[1], X. LI[3], R. DE BURGH[3], G. LASS[3], K. T. O'BYRNE[3], **K. TSANEVA-ATANASOVA**[2];
[2]Mathematics, [1]Univ. of Exeter, Exeter, United Kingdom; [3]King's Col. London, London, United Kingdom

Abstract: Gonadotrophin-releasing hormone (GnRH) is secreted in a pulsatile manner under the control of the neural oscillator known as the hypothalamic GnRH pulse generator. Evidence suggests that this neural construct comprises kisspeptin neurones in the arcuate nucleus (ARC) of the hypothalamus that co-express neurokinin B (NKB) and Dynorphin (Dyn), also known as KNDy. What initiates and maintains the rhythmic activation of the KNDy neural network to drive pulsatile secretion of GnRH is unknown. We have developed a mathematical model of the KNDy neural network, which revealed that the level of network excitability controls the network oscillatory dynamics. Furthermore, mathematical analysis predicts that alterations of network excitability can have distinct effect on pulse generator frequency depending on the levels of sex-

steroids modulating the balance between NKB and Dyn signalling. To test this model prediction we used optogenetics by injecting a viral vector carrying channelrhodopsin into the ARC of female Kiss-Cre mice. The implanted fibre-optic canulae in the ARC allows for optic stimulation of KNDy neurones. LH dynamics was monitored by collecting serial blood samples (5µl, tail-tip) at 5min intervals for 2.5h. In line with our model predictions, continuous optic stimulation at 5Hz (473nm, 5ms) for 90min increased LH pulse frequency in estrous animals, but decreased frequency in diestrous animals. Taken together these data demonstrate that a continuous low frequency stimulation of KNDy neurones modulates the mode of LH secretion depending on the sex steroid background.

Title: Excitatory GABAergic inputs to GnRH neurons are required for female reproduction

Authors: *M. WATANABE, A. FUKUDA;
Dept Neurophysiol, Hamamatsu Univ. Sch. Med., Hamamatsu, Japan

Abstract: Gonadotropin-releasing hormone (GnRH) neurons form the final common pathway for the central regulation of reproduction. γ-aminobutyric acid (GABA) has long been thought to be one of the major players in the regulation of GnRH secretions. While GABA is generally considered to be an inhibitory neurotransmitter in the adult brain, GABA has been reported to excite GnRH neurons *in vitro* experiments. However, the functional significance of the excitatory action of GABA on GnRH neurons *in vivo* remains entirely elusive. Intracellular Cl^- concentration ($[Cl^-]_i$) determines the polarity of $GABA_A$ mediated synaptic input. GABA acts excitatory when $[Cl^-]_i$ is high, due to the high expression of the Na^+-K^+-$2Cl^-$ cotransporter (NKCC1), which includes Cl^- into the cell, and the low expression of the K^+-Cl^- cotransporter (KCC2), which excludes Cl^- out of the cell. To examine the precise physiological functional role of the excitatory action of GABA *in vivo*, we generated a transgenic mouse (GnRH-tTA::KCC2-tetO) in which KCC2 can be induced selectively to GnRH neurons using tetracycline controlled gene expression system. In this mouse, GABA action could be reversibly switched from excitatory to inhibitory *in vivo* selectively in GnRH neurons in specific time point. Application of muscimol, $GABA_A$ receptor agonist, inhibited the spontaneous firing of GnRH neurons in

acute slice of GnRH-tTA::KCC2 tetO mice. Female GnRH-tTA::KCC2-tetO mice failed to exhibit the estrous cyclicity, ovulation and pregnancy. Ovarian histology revealed an abundance of immature follicles. Furthermore, female GnRH-tTA::KCC2-tetO mice showed advanced vaginal opening. On the other hand, male GnRH-tTA::KCC2-tetO mice showed the normal fertility. These results suggest that the excitatory action of GABA on GnRH neurons play a crucial role in the female reproduction.

Title: Feed restriction reduces neurokinin B expression in young male sheep

Authors: A. N. RENWICK, J. R. SOMMER, C. M. MERKLEY, ***C. C. NESTOR**;
Animal Sci., North Carolina State Univ., Raleigh, NC

Abstract: The central integration of internal and external cues ultimately control reproduction via regulation of hypothalamic gonadotropin-releasing hormone (GnRH) neurons, which are the final common pathway from the brain controlling luteinizing hormone (LH) secretion from the anterior pituitary. While undernutrition is known to suppress GnRH/LH secretion, the central mechanisms that govern this regulation remain to be determined. Based on growing evidence that KNDy (Kisspeptin/Neurokinin B/Dynorphin) neurons represent the GnRH pulse generator, and the important role for NKB signaling in GnRH/LH pulse generation, we hypothesized that undernutrition would reduce the number of NKB neurons in the arcuate nucleus (ARC) of the hypothalamus of male sheep. Six wethers (approximately 5 months of age) were evenly divided into a fed to maintain body weight (Fed) group or a feed restricted to lose 15-20% of pre-study body weight (FR) group. Weekly blood samples (every 12 minutes for 4.5 hours) were taken via jugular venipuncture and plasma was stored at -20°C until the time of radioimmunoassay. Weekly body weights were recorded and feed amounts were adjusted to achieve desired body weights. At Week 13, animals were euthanized following blood collection, and brain tissue containing the hypothalamus was collected. Hypothalamic tissue was sectioned and immunohistochemistry for NKB in the ARC was performed. At Week 13, the average percent change in body weight was clearly evident (Fed, 10.23 $\pm$ 7.2% vs FR, -17.03 ± 2.8%), and although not significantly different between Fed and FR groups, mean LH was dramatically reduced in two of three FR wethers compared to controls. The number of NKB-immunopositive

neurons was significantly less in FR animals (26.4 ± 9 cells/hemi-section), compared to Fed animals (89.2 ± 23 cells/hemi-section). Therefore, the reduction in NKB cell numbers observed here may be an important upstream contributor to the decrease in GnRH/LH pulses that occur during chronic negative energy balance. Further, together with our previous work showing a decrease in kisspeptin neurons with feed restriction, this work provides the first evidence that NKB plays a role in the central mechanism governing GnRH/LH secretion during times of undernutrition in male sheep.

Title: Synaptic input to kisspeptin/neurokinin B/dynorphin (KNDy) neurons is reduced in a mouse model of polycystic ovarian syndrome

Authors: *A. M. MOORE, L. M. COOLEN, M. N. LEHMAN;
Brain Hlth. Res. Inst., Kent State Univ., Kent, OH

Abstract: Polycystic ovarian syndrome (PCOS) is the leading cause of infertility in reproductive age women. PCOS women display increased luteinizing hormone (LH) pulse frequency, indicative of increased pulsatile gonadotropin-releasing hormone (GnRH) release due to impaired central steroid hormone feedback. Neurons in the arcuate nucleus that co-express kisspeptin, neurokinin B and dynorphin (KNDy cells) are postulated to mediate steroid hormone feedback and are implicated as the GnRH/LH pulse generator. We hypothesized altered synaptic input by upstream populations regulating KNDy neuron activity may result in LH hypersecretion in PCOS. To investigate this, we used a prenatal androgen (PNA)-induced mouse model of PCOS to study excitatory glutamatergic synaptic input to KNDy cells. Pregnant Kiss1-Cre/yellow fluorescent protein (YFP) mice were injected with dihydrotestosterone (250µg) or sesame oil vehicle on days 16, 17 and 18 of pregnancy. PNA (n=4) female and prenatal vehicle-treated (PNV) male (n=3) and female (n=4) offspring were studied as adults. Triple-label immunofluorescence was performed on coronal brain sections for YFP (marker for kisspeptin), synaptophysin (SYN; synaptic terminal marker) and vesicular glutamate transporter 2 (vGluT2). KNDy soma in rostral, middle and caudal arcuate regions were imaged (10 cells/region/animal)

using confocal microscopy and the density of closely-apposed triple-labeled (SYN+vGluT2+YFP), double-labeled (SYN+vGluT2) and single-labeled SYN puncta analyzed. The density of SYN+vGluT2+YFP ($p<0.01$) and SYN+vGluT2 ($p<0.05$) inputs to KNDy soma was lower in PNA females compared to PNV males and females, indicating PNA treatment causes loss of glutamatergic input to KNDy cells from both kisspeptin and non-kisspeptin glutamatergic cells. In addition, the density of SYN inputs was lower in PNA females compared to PNV males and females ($p<0.05$), signifying loss of synaptic input from a non-glutamatergic source. These data indicate PNA treatment reduces synaptic input to KNDy neurons from multiple neuronal phenotypes. The mechanism by which reduced glutamatergic input increases LH in PNA mice is unclear, although loss of glutamatergic kisspeptin input may represent reduced KNDy-KNDy connections that impair steroid hormone feedback.

Title: Physiological characterization of GnRH neurons derived from human embryonic stem cells

Authors: B. I. FORDYCE[1], C. R. JOHNSTON[1], K. L. KEEN[1], *E. TERASAWA[2]; [1]Primate Ctr., Univ. of Wisconsin, Madison, WI; [2]Pediatrics and Primate Ctr., Univ. of Wisconsin Madison, Madison, WI

Abstract: The pulsatile release of the gonadotropin-releasing hormone (GnRH) is critical for mammalian reproductive function. Consequently, hypogonadotropic hypogonadism (IHH) patients who do not have GnRH neurons or their upstream regulatory neurons in the hypothalamus are not able to conceive and need gonadal steroid hormone treatments for their entire lives. As part of a long-term goal to use GnRH neurons derived from IHH patient's induced pluripotent stem cells (iPSC) as a treatment tool, this lab was recently successful in generating GnRH neurons from human embryonic stem cells (hESC) and human-iPSC. With the ultimate goal in mind, the present study evaluated characteristics of GnRH neurons derived from hESC. Differentiated GnRH neurons were perifused with artificial cerebrospinal fluid over a period of six hours, and perifusates were continuously collected in fractions at 10 min intervals. Various known exocytotic stimuli for GnRH neurons were applied for 20 min periods at 90 min intervals, and GnRH levels in the perifusates were measured via radioimmunoassay. After the

experiments, cells were fixed and subjected to immunohistochemical analysis to confirm the presence of GnRH neurons. Results are summarized: First, we found that hESC-derived GnRH neurons released the GnRH peptide in a pulsatile manner with an inter-pulse interval of 59.5±3.3 min, which is very similar to the interval in primary GnRH neurons derived from monkey fetuses (46.6 ± 4.0 min) as well as *in vivo* release (43.5 ± 1.8 min) in the adult monkey hypothalamus. Second, we found that hESC-derived GnRH neurons respond to kisspeptin, neurokinin B, estradiol, and high potassium by significantly increasing GnRH release (all at $p<0.01$). The question of whether iPSC-derived GnRH neurons behave similar to hESC-derived GnRH neurons is currently under examination. Collectively, the results indicate that hESC-derived GnRH neurons exhibit physiological characteristics similar to those in primary GnRH neurons *in vitro* as well as in the rhesus-monkey hypothalamus *in vivo*.

Title: Projections of suprachiasmatic nucleus vasopressin neurons regulate preoptic kisspeptin neuron electrical activity

Authors: *B. B. JAMIESON, R. E. CAMPBELL, R. PIET;
Dept. of Physiol., Univ. of Otago, Dunedin, New Zealand

Abstract: In female rodents, appropriate timing of the surge of gonadotropin secretion that triggers ovulation is critical to their reproductive success. The central circadian clock in the suprachiasmatic nucleus (SCN) is thought to time the preovulatory surge by activating circuitry that ultimately controls gonadotropin secretion. We have used an anatomical and functional approach to investigate the innervation of preoptic area (POA) kisspeptin neurons, which are thought to drive the preovulatory surge, by a group of SCN neurons that produce vasopressin (AVP).Diestrous female *AVP-ires2-cre* mice, which express cre recombinase (cre) in AVP neurons, were injected in the SCN with an adeno-associated viral (AAV) vector carrying a cre-dependent sequence for the fluorescent reporter mCherry. This revealed innervation of the POA by SCN AVP neurons, closely apposing 44.6 ± 6.6% (N = 6 mice) of POA kisspeptin neurons, and suggesting putative synaptic inputs. Diestrous and proestrous *AVP-ires2-cre* mice expressing the green fluorescent protein (GFP) in kisspeptin neurons were injected in the SCN with an AAV

carrying a cre-dependent sequence for channelrhodopsin (ChR2), and brain slices were taken for patch-clamp electrophysiological recordings. In whole-cell voltage clamp recordings, the vast majority (92%) of POA GFP-expressing kisspeptin neurons (n = 26, 9 mice) did not display fast postsynaptic currents in response to brief blue-light stimulation of ChR2-expressing axons in diestrous or in proestrous mice. High-frequency blue-light stimulation (20 Hz, 60 s) did, however, increase action potential firing in 59% of kisspeptin neurons recorded in the cell-attached patch clamp configuration (n = 17, 9 mice; $p < 0.05$ vs control). Further, this response appears to occur in proestrus (n = 8, 4 mice; $p < 0.05$ vs control) rather than diestrus (n = 9, 5 mice; $p = 0.4$ vs control; two-way ANOVA). Using the vasopressin 1 receptor (V1R) antagonist, Manning compound, blue light-evoked increases in action potential firing were prevented (n = 8, 4 mice; $p > 0.99$ vs control), indicating that this response was mediated by V1R activation.This work suggests that although SCN AVP neurons project to the POA, they may not communicate with POA kisspeptin neurons via fast amino acid neurotransmission, but rather through the release of AVP acting at V1 receptors. This reveals a mechanism through which the biological clock may control the POA kisspeptin neurons and stimulate the onset of the preovulatory surge release of gonadotropins.

Title: Asymmetries on the estradiol receptors, kisspeptin and GnRH content between the left and right hypothalamus during the estrous cycle of the rat

Authors: *C. C. SILVA-MENDEZ[1], E. OLVERA[2], A. FLORES[3], R. LIBRADO[3], I. ARRIETA[3], R. GUTIÉRREZ[3], R. DOMÍNGUEZ[3], M.-E. CRUZ[3];

Abstract: Ovarian functions are regulated by the hypothalamic-pituitary-ovarian axis. At the hypothalamus, neurons located at the preoptic and anterior hypothalamic area synthetize the gonadotropin releasing hormone (GnRH). GnRH stimulates the secretion of the luteinizing hormone and the follicle stimulating hormone, which in turn will modulate processes as ovulation and hormone secretion. The estradiol secreted by the ovaries exerts positive and

negative feedback on the hypothalamus by binding to its receptors at the kisspeptin-cells located at the anteroventral periventricular area and the arcuate nucleus, respectively. We and others have shown anatomic and functional asymmetries between the left and right hypothalamic centers related to ovarian regulation. Since those asymmetries depends on the estrogenic environment, we hypothesized that the content of key proteins involved on the hypothalamic integration of ovarian signals i.e. estradiol receptors, kisspeptin and GnRH, is asymmetric depending on the stage of the estrous cycle and the time of the day. Groups of 24 intact rats were euthanized at 08:00, 11:00, 14:00 and 17:00 hours of each stage of the estrous cycle. Brains were extracted and the left and right hypothalamus were dissected from the preoptic area to the mediobasal hypothalamus and processed for western-blot analysis of protein content. We found that, in estrous, estradiol receptor-α (ERα) content was similar in both sides of the brain while those of estradiol receptor-β (ERβ) and kisspeptin were asymmetric on most of the time points analyzed. At metestrous, no differences on the content of the three proteins were found. In diestrous, ERα on the left side was similar during all time points, on the other side, the content on the right side displayed a sinusoidal pattern with a peak during the morning. ERβ was consistently higher while kisspeptin showed no differences. At proestrous, ERα and ERβ on the left, but not on the right side showed a sinusoidal pattern with a peak concomitant with the preovulatory rise on gonadotropin serum levels. Kisspeptin and GnRH content on the right side decreased during the afternoon and no changes on the left side were detected. We concluded that the central regulatory mechanisms of ovarian functions that involves the estradiol receptors, kisspeptin and GnRH on the left and right sides of the hypothalamus are asymmetric. These asymmetries depends on the stage of the estrous cycle and the time of the day.

Title: Unraveling the subsets of MCH neurons associated with reproductive control

Authors: *B. G. BEEKLY, C. F. ELIAS;
Mol. and Integrative Physiol., Univ. of Michigan, Ann Arbor, MI

Abstract: Pulsatile release of luteinizing hormone (LH) is necessary for reproductive development and function. Due to the complexity of the hypothalamic-pituitary-gonadal (HPG) axis, the factors governing LH release remain incompletely understood. Melanin-concentrating hormone (MCH) neurons have well-characterized roles in many fundamental processes, but while they project to reproductive control sites such as the medial preoptic nucleus and the median eminence, the nature of their effect on the HPG axis is unclear. This is due in part to the heterogeneity of MCH neurons and their widespread distribution. In rats, two populations of MCH neurons have been neurochemically defined: a medial group expressing cocaine- and amphetamine-related transcript (CART) and targeting cortex, rostral brainstem, and hypothalamic nuclei associated with reproductive control; and a lateral, CART-negative group targeting the caudal brainstem. Based on their projections, we hypothesize that MCH/CART neurons can induce pituitary LH release. We used immunohistochemistry and viral tracing methods in MCH neurons to elucidate their neurochemical profile and projection patterns. We observe that in mice, as in rats, medial MCH neurons colocalize with CART and project to reproductive control sites including the medial and ventrolateral preoptic areas. Interestingly, our initial studies also suggest that the MCH/CART system is sexually dimorphic. In the regions examined, males have more CART neurons, fewer MCH neurons, and a lower percentage of total CART neurons expressing MCH. We also used chemogenetic technology to probe the functional differences in these populations. By activating anatomically distinct subsets of MCH neurons and analyzing serum LH levels, we found that stimulating medial groups of MCH neurons increased blood LH while more lateral MCH neurons did not achieve this effect. Collectively, these data indicate that medial MCH/CART neurons modulate the HPG axis. Further studies will be performed to evaluate the physiological relevance of these findings.

Title: Relation of firing to release in gonadotropin-releasing hormone (GnRH) neurons

Authors: *X. CHEN[1], R. A. DEFAZIO[1], S. M. MOENTER[2];
[1]Mol. and Integrative Physiol., [2]Mol. and Integrative Physiology, Intrnl. Medicine, and Obstetrics and Gyne, Univ. of Michigan, Ann Arbor, MI

Abstract: In vertebrates, the secretion of the gonadotropins, luteinizing hormone (LH) and follicle-stimulating hormone (FSH) by the pituitary is triggered by the pulsatile release of GnRH from neurons located in the preoptic area of the hypothalamus. In brain slices, GnRH neurons often exhibit an episodic action potential firing activity that is regulated by steroid feedback and resembles the pattern of LH release. There is no direct evidence, however, showing how GnRH neuron firing rate relates to GnRH release. To begin to study this, long-term (1 to 1.5 h) simultaneous measures of spontaneous firing rate using extracellular recording and GnRH release using fast-scan cyclic voltammetry (FSCV) were made in sagittal brain slices from gonad-intact male GnRH-GFP mice. Slices were scanned for pairs of GnRH neurons with overlapping processes; GnRH release was monitored from where the GFP-identified cells/processes overlapped, and firing was recorded from one (n=5) or both (n=1) of the GnRH neurons. When GnRH neurons were active (61-742 spikes/10min), the number of GnRH release events and release duration were higher than when neurons were quiescent (0-20 spikes/10min) (events/10min: 6.5±0.5 vs. 1.7±0.5, $p<0.0001$; duration/10min: 215.3±17.2 vs. 35.6±10.4s, $p<0.0001$; n=22 active and 17 quiescent 10-min bins from 6 mice). In contrast, within periods of neuronal activity the coordination between firing rate and GnRH release was less distinct. Kisspeptin triggered both GnRH neuron firing and GnRH release. Interestingly, preliminary data reveal GnRH release occurs as much as 175s before firing during kisspeptin treatment, consistent with reports that release in the preoptic area can be action potential independent. Combined current-clamp and FSCV recordings were used to examine the effects of membrane depolarization without spikes. Depolarization of the membrane potential to ~-40mV for 500ms initiated GnRH release in the absence of action potentials (n=2 cells). These early results suggest a clear but loose correlation between GnRH neuron firing and GnRH release. On the one hand, high GnRH neuron activity appears required to trigger robust GnRH release; on the other hand, firing frequency and GnRH concentration change in active GnRH neurons are not tightly coordinated. Depolarization alone without spikes can also initiate release. Future work will use current-clamp to regulate the number of spikes and examine how steroid feedback alters firing rate to release coupling.

Title: Corticotropin-releasing hormone (CRH) has no effect on arcuate kisspeptin neuron firing activity in female mice

Authors: *C. PHUMSATITPONG[1], S. M. MOENTER[2];
[1]Mol. and Integrative Physiol., [2]Mol. and Integrative Physiology, Intrnl. Medicine, and Obstetrics and Gyne, Univ. of Michigan, Ann Arbor, MI

Abstract: Stress has been shown to alter the reproductive system via several possible target sites. Corticotropin-releasing hormone (CRH) increases gonadotropin-releasing hormone (GnRH) activity via CRHR1 and reduces this activity via CRHR2; both of these actions require estradiol. Elevated GABA transmission mediates, at least in part, the excitatory actions of CRH, but the mechanisms for inhibitory effects are unknown. Kisspeptin neurons in the hypothalamic arcuate nucleus provide estradiol-sensitive activation of GnRH neurons and various stressors (restraint, metabolic stress and immunological stress) or CRH peptide can decrease *Kiss1* mRNA expression in these cells. Arcuate kisspeptin neurons appear to express CRH receptors by immunofluorescence. We hypothesized that CRH inhibits arcuate kisspeptin neuron firing activity and that this response is modulated by estradiol. To test this, mice expressing GFP under the Tac2 promoter (coexpressed with *Kiss1*) were ovariectomized and either implanted with a capsule producing a physiological circulating level of estradiol (OVX+E) or not treated further (OVX). Targeted extracellular recordings of firing rate were made of arcuate kisspeptin neurons in the afternoon during estradiol positive feedback. Basal, bath-application of CRH, and wash out periods were examined. Basal firing rate was higher in OVX than OVX+E mice ($p<0.01$), indicating estradiol regulation of arcuate kisspeptin neurons is different from anteroventral periventricular kisspeptin neurons. CRH (100nM) did not alter firing rate of arcuate kisspeptin neurons in the OVX+E group (n=6, con 0.09±0.05 Hz, CRH 0.09±0.04, wash 0.25±0.14 Hz, $p>0.9$). In the OVX group, firing rate in some (2 of 7) kisspeptin neurons increased by ≥30% after CRH treatment, but continued to show further increases in activity during the wash period (n=7, con 0.64±0.27 Hz, CRH 0.75±0.29 Hz, wash 1.03±0.24 Hz, $p=0.045$ con vs CRH). To distinguish a technical from a biological phenomenon, we performed a vehicle-treatment experiment. A similar pattern of a mild increase during the vehicle treatment followed by continued increase during the wash was observed (OVX+E n=4, con 0.18±0.11 Hz, vehicle 0.26±0.18 Hz, wash 0.77±0.55 Hz, $p>0.2$; OVX n=5, con 0.87±0.34 Hz, vehicle 0.91±0.38 Hz, wash 1.89±0.65 Hz, $p>0.5$). These data suggest the increase in firing rate that is observed during CRH treatment in OVX group is a technical phenomenon. While it remains possible that a biological response is masked by this technical change, the results suggest that under these conditions CRH does not acutely alter arcuate kisspeptin neuronal activity regardless of estradiol status in female mice.

Title: Three types of voltage-gated potassium currents in AVPV kisspeptin neurons

Authors: *J. R. STARRETT[1], S. M. MOENTER[2];
[1]Mol. and Integrative Physiol., [2]Mol. and Integrative Physiology, Intrnl. Medicine, and Obstetrics and Gyne, Univ. of Michigan, Ann Arbor, MI

Abstract: Ovulation is stimulated by a switch in gonadotropin-releasing hormone (GnRH) and luteinizing hormone (LH) release from repeated brief episodes (pulses) to a continuous surge lasting several hours. Pulses are regulated by estradiol negative feedback and the surge is initiated by estradiol positive feedback. Interestingly, GnRH neurons do not express detectable levels of estrogen receptor α, which is needed for both negative and positive feedback. Feedback thus likely involves ERα-expressing afferents. The neuropeptide kisspeptin (Kiss1) excites GnRH neurons. Most *Kiss1*-expressing neurons in the anteroventral periventricular (AVPV) nucleus express ERαand estradiol increases the firing rate of these cells, suggesting they may convey positive feedback to GnRH neurons. The mechanisms by which estradiol increases firing of AVPV-Kiss1 cells are not completely understood. Voltage-gated potassium currents strongly influence neuronal firing activity and can be regulated by steroids. We tested the hypothesis that voltage-gated potassium currents are modulated by estrous cycle stage. Voltage-clamp recordings were made of AVPV-Kiss1 neurons in brain slices from Kiss1-GFP mice on the afternoon of diestrus (negative feedback) and proestrus (positive feedback). The macroscopic K^+current was found to consist of three components: a fast-inactivating, a slow-inactivating and a non-inactivating component, likely mediated by distinct populations of channels. We compared the pharmacology of the two transient components. The fast-inactivating component was relatively resistant to tetraethylammonium (TEA, 20 mM) but was blocked by 4-aminopyridine (4-AP, 5mM), suggesting it is mediated by Kv4 channels. The slow-inactivating component was blocked by TEA and was comparatively more resistant to 4-AP. Fast and slow components displayed different voltage-dependence of activation. The fast component began to activate at membrane potentials close to the action potential threshold (~40-50 mV), suggesting it may affect spike initiation, whereas the slow component began to activate at more depolarized potentials (~ -10 mV), suggesting it may modulate spike width and neurosecretion. Preliminary data from pharmacological studies suggest the amplitude of the fast component may be increased

on proestrus. Computational models are being developed to test if estrous cycle modulation of these currents contributes to the increases in AVPV-Kiss1 neuron firing frequency and bursting observed during estradiol positive feedback.

Title: Sex-specific consequences of post-weaning social isolation on social behavior, affective behavior, and kisspeptin neural circuitry in Long Evans rats

Authors: *B. L. KINLEY[1], D. M. WALKER[2], R. F. KYNE[1], N. VENTURA[1], E. J. NESTLER[2], M. J. PAUL[1];

Abstract: Childhood and adolescence are critical periods for social and affective development. However, they are also times of increased vulnerability to stress. For example, post-weaning social isolation (PSI) can lead to long-term behavioral and neural changes that persist into adulthood. The neuropeptide, kisspeptin, plays a critical role in reproduction, including the onset of puberty, and recent studies suggest that extra-hypothalamic kisspeptin cell groups may also influence affective behaviors. Kisspeptin cells and fibers increase markedly during early adolescence. To our knowledge, however, no one has tested whether PSI impacts the development of kisspeptin circuitry. In this study, we tested whether PSI has a lasting impact on social behavior, affective behavior, and kisspeptin cells and fibers in medial amygdala (MeA) and lateral septum (LS) of male and female Long Evans rats. Rats were weaned at 21 days of age and housed either alone (Isolated) or in groups of 2-3 rats/cage (Group-housed). After 3 weeks of isolation, Isolated rats were group-housed for the remainder of the experiment. At 10 weeks of age, all rats were tested in Social Preference, Marble Burying, and Light/Dark Box tests, with 1 day between behavioral tests. Rats were euthanized 1-2 days after the Light/Dark Box test, and brains were removed and processed for kisspeptin immunohistochemistry. Isolated males showed a lower social preference score, buried more marbles, and spent more time in the light zone of the light/dark box than their group-housed counterparts. Isolated and Group-housed females did not differ in these measures, although time in the light zone of the Light/Dark Box test approached significance (Isolated females > Group-housed females, P=0.06, Fisher's PLSD).

Kisspeptin staining in Group-housed rats was sexually dimorphic, with greater numbers of cells in the MeA of males, but greater fiber staining in the LS of females. Preliminary analyses indicate that PSI had no effect on the number of kisspeptin cells in the MeA, but selectively increased kisspeptin fiber staining in the LS of males. These findings demonstrate sex-specific consequences of PSI on social behavior, affective behavior, and kisspeptin neural circuitry.

Title: Kisspeptin and the neuroendocrine regulation of growth hormone release

Authors: *C. D. FORADORI[1], B. K. WHITLOCK[2], J. A. DANIEL[3], A. D. ZIMMERMAN[1], L. O. MACKAY[1], C. C. READ[1], B. P. STEELE[1], J. L. SARTIN[1];

Abstract: Kisspeptin (Kp) is a neuropeptide which is widely accepted as a critical regulator of the neuroendocrine control of reproduction in all mammals. Kp is the most potent stimulator of hypothalamic gonadotrophin releasing hormone (GnRH) release ever studied. Kp, by way of its stimulation of GnRH release, causes luteinizing hormone and follicle stimulating hormone release, leading to subsequent stimulation of gonadal steroid synthesis, gamete maturation, and ovulation. Although Kp is a stimulator of GnRH secretion and therefore the hypothalamic-pituitary-gonadal axis, new findings suggest Kp can also regulate additional neuroendocrine processes including the release of growth hormone (GH). We have shown that central delivery of Kp causes a robust rise in plasma GH in fasted but not fed sheep. We postulate that Kp works with the established neurocircuity implicated in the control of GH release. GH release from somatotropes of the pituitary is under direct control of GH releasing hormone (GHRH) and somatostatin (SS). GHRH and SS are secreted by cells in the arcuate and periventricular nuclei, respectively, and transported to the pituitary via the hypophyseal portal vascular. Somatotropes are stimulated by GHRH and inhibited by SS. Another cell group expressing neuropeptide Y (NPY) is upstream of GHRH and SS cells. Activation of NPY neurons in the arcuate nucleus of

the hypothalamus has been shown to increase GH release working through GHRH and SS cells. Our proposed model linking Kp to the NPY-GHRH/SS control of GH release is supported by findings from our lab that 1) Central Kp treatment induces GH release, 2) Kp fibers contact NPY cells, 3) NPY cells express the Kp receptor which increases in the fasted state, 4) pretreatment with a NPY receptor antagonist blocks the effects of Kp-induced GH release, and 5) Kp infusion stimulates NPY and GHRH cells and inhibits SS cells. However, as stated above, Kp can only induce GH in short-term fasted animals. In examining GH release associated with short-term fasting, the prominent role of the gut derived peptide ghrelin was considered to be a potential intermediary. Indeed, when systemic ghrelin release is blocked in fasted animals or if fasted animals are pretreated with a ghrelin receptor antagonist, Kp-induced GH was eliminated or reduced, suggesting the presence of ghrelin is required for Kp-induced GH release in fasted animals. Our findings support the hypothesis that during short-term fasting, systemic ghrelin concentrations increase, leading to alterations in the NPY-GHRH-SS system permitting Kp activation of NPY cells. In turn, NPY stimulates GHRH cells and inhibits SS cells, resulting in GH release from somatotropes.

Title: Colocalization of NK3R and KOR mRNA in KNDy and non-KNDy neurons in the ovine arcuate nucleus

Authors: *W. HE[1], L. M. COOLEN[1], R. L. GOODMAN[2], M. N. LEHMAN[1];
[1]Brain Hlth. Res. Inst., Kent State Univ., Kent, OH; [2]West Virginia Univ., Morgantown, WV

Abstract: Compelling evidence in sheep and other species suggest that KNDy (kisspeptin/neurokinin B/dynorphin) neurons of the arcuate nucleus (ARC) are responsible for the pulsatile secretion of gonadotropin-releasing hormone (GnRH). Neurokinin B (NKB) is hypothesized to mediate the initiation of GnRH pulses by acting on neurokinin 3 (NK3R/*TAC3R*) receptors within the KNDy network. In contrast, dynorphin (DYN) by acting on kappa opioid receptor (KOR) in KNDy and GnRH cells, has been linked to termination of GnRH pulses. However, it is unknown if there are other NKB or DYN-responsive neuronal populations

in the ARC that may contribute to the regulation of KNDy neurons and pulse generation. Therefore, we used RNAscope, a sensitive *in situ* hybridization technique that allows detection of multiple mRNA transcripts in the same cell, to examine kisspeptin, *TAC3R* and *KOR* co-expression in the ARC of luteal phase ewes. Adult ewes (n=4) were perfused, hypothalami sectioned coronally (12 µm), and RNAscope using ovine-specific probes were used to analyze the expression of *TAC3R*, *KOR*, and *kisspeptin* (as marker for KNDy cells). Results showed that *KOR* and *TAC3R* mRNAs are co-expressed in 94% of KNDy cells. However, the KNDy cells only constitute 33% of total *KOR* cells and 52% of total *NK3R* cells in the ovine ARC, suggesting the presence of a non-KNDy neuronal population that also respond to DYN and/or NKB. Among this non-KNDy population, *KOR*/*TAC3R* and *KOR*-only expressing cells constitute the majority with 40% and 56%, respectively. Hence, only a very small portion of ARC cells express *TAC3R* only: 98% of total *TAC3R* cells co-express either KNDy and/or *KOR* and 91% of non-KNDy *TAC3R* cells co-express *KOR*. Together, these findings indicate three populations of ARC neurons that are potentially involved with GnRH pulse secretion: KNDy cells expressing both *TAC3R* and *KOR*, non-KNDy cells either co-expressing *KOR* and*TAC3R* or *KOR* alone. It is also notable that all *TAC3R* cells are either KNDy and/or *KOR* positive and together could be defining different components of the NKB responsive pulse generator.

Title: Morphological characterization of the intrinsic neurons in the ovary of young and senescent rats

Authors: *J. M. BRAVO[1], A. ESPINOSA[2], Y. CRUZ[3], C. MORAN[2];
[1]Univ. Autonoma De Tlaxcala, Tlaxcala, Mexico; [2]Benemérita Univ. Autonoma de Puebla, Puebla, Mexico; [3]Univ. Autonoma Tlaxcala, Tlaxcala, Mexico

Abstract: The extrinsic innervation of the ovary participates regulating their activity; like as follicular development, steroidogenesis, ovulation and reproductive cycles. The intrinsic innervation of the ovaries has been shown in various mammals, including the Wistar rat. The aim of the present study was to recognize the intrinsic neurons of the ovaries and their biochemical characteristics in young and senescence rats. We used adult female rat CII ZV strain of 3, 12 and 15 months old. The identification of the neurons was performed using the

immunohistofluorescence techniques to Neu-N and tyrosine hidroxylase (TH) antibodies, using ovarian slices made with cryostat. The results show immunoreactivity to Neu-N and TH in the interstitial gland, around the follicles and corpus luteum. The measurement of the neurons was performed in neurons immunopositive to Neu-N. Neuron diameter was longer in old rats (15 months: 12.2±3.0 μm, 12 months: 10.8±2.5 μm, 3 months: 8.7±1.4μm. $p < 0.01$ ANOVA followed by Tukey); the area of the perikarya was also higher in old animals (15 months: 87.5±0.5 μm^2, 12 months: 60.3±0.5 μm^2 and 3 months: 62.9±1.1 μm^2, $p < 0.01$ ANOVA Followed by tukey). Moreover the number of neurons decreases in older the animals; thus we can infer that there is an aging-related compensatory effect that involves anatomical and functional plasticity of the neuronal system of the ovary, extrinsic and intrinsic. Our results suggest the participation of the innervation in the maintenance of ovarian functions through the reproductive life span of females.

Abstract: The hypothalamus-pituitary axis is responsible for regulating the hormone levels of prolactin (PRL) and testosterone. PRL is a polypeptide hormone synthesized and secreted mainly by specialized cells of the adenohypophysis. Testosterone is a steroid hormone synthesized, in greater proportion, by Leydig cells. Both PRL and T are necessary for the proper functioning of the prostate. In pathological processes, such as prostate cancer, there has been an important relationship between PRL and testosterone, and there are studies that relate both hormones to the

regulation of the activity and gene expression of matrix metalloproteases (MMPs); being MMP2 and MMP9 the most studied. MMPs are highly linked to the ability of cancer cells to migrate and their level of malignancy, so the increase in these is related to the progression and development of cancer. Therefore, the activity of MMP2 and MMP9 was evaluated in culture media of LNCaP cells stimulated with PRL (50 nM) and testosterone (0.1 nM), or with both hormones, it was observed that MMP9 increases its activity in the treatments with PRL, Testosterone and both hormones. The results show that in the treatment with 0.1nM of testosterone it decreases the expression of STAT3, while the expression of STAT5 is increased in the treatment with both hormones. The cells treated with PRL, testosterone or both had different structural changes. The cells treated with 50 nM of PRL were characterized for presenting blebs, the cells treated with 0.1 nM of testosterone formed extensions of actin filaments (lamellipodia and filopodia). In conclusion, PRL and testosterone induce migration in LNCaP cells with formation of blebs, lamelipodia and filopodia, regulating the activation of MMP9 that is correlated with the STAT5 and STAT3 pathways.

Abstract: Prolactin (PRL) is a polypeptide hormone synthesized and secreted mainly by specialized cells of the pituitary gland. Estradiol (E_2) is a sexual steroid hormone of the estrogen group and it is the most potent natural estrogen in humans. The release of both hormones is controlled by neural stimuli and their levels are regulated by the hypothalamic-pituitary axis. PRL participates in the development of the mammary gland and in the production of milk proteins in pregnancy and lactation. It exerts diverse biological effects through its interaction with specific membrane receptors that are widely distributed in the organism. E_2 has effects on the growth, development and differentiation of tissues, although its main action is observed in reproductive organs. In addition to both their physiological functions, it has been shown that they also participate in the development of pathologies such as breast cancer, however, it is not clear whether these hormones have any involvement in cell migration, a crucial step in the development of metastasis, and in the regulation of the activity of matrix metalloprotease 2 (MMP-2), that is related to the cell migration process. We found that PRL (2 nM) increased cell migration in MCF-7 cells and E_2 seems to have no effect and we evaluated the effect of stimulation with PRL and E_2 in MMP-2 activity in the conditioned medium from MCF-7 cells.

Title: Estradiol rapidly modulates excitatory synapse properties in a sex and region specific manner in the nucleus accumbens core and caudate putamen

Authors: *A. A. KRENTZEL, L. BARRETT, J. MEITZEN;
North Carolina State Univ., Raleigh, NC

Abstract: Estradiol acutely facilitates sex differences in striatal-dependent behaviors and neurotransmitter release where females are more sensitive to the rapid actions than males; however, little is understood of the mechanism. In striatal regions in adult rodents, estrogen receptors feature exclusively membrane expression both on terminals and dendrites. This suggests that estradiol can directly modulate striatal neurons or the terminal projections onto

those neurons. We tested whether estradiol rapidly modulates excitatory synapse properties onto medium spiny neurons (MSNs) of two striatal regions, the nucleus accumbens core and caudate-putamen in adult (P60-P90) female and male rats. Using whole-cell patch clamp, we recorded MSN intrinsic properties to determine if these properties were predictive of estrogen sensitivity. We then recorded mini-excitatory post-synaptic currents (mEPSC) and bath applied 100nM 17β-estradiol to record the changes to mEPSC frequency, amplitude, and decay. Estradiol exhibited bidirectional and sex-specific acute effects in the nucleus accumbens core: mEPSC frequency robustly decreased in response to estradiol in female MSNs, and mEPSC amplitude moderately increased in response to estradiol in both males and female MSNs. This increase in mEPSC amplitude is associated with more excitable MSNs. No MSN intrinsic electrical property associated with changes in mEPSC frequency or decay. Estradiol did not acutely modulate mEPSC properties in the caudate-putamen of either sex. This is the first demonstration of acute estradiol action on MSN excitatory synapse function. Importantly, female-specific sensitivity in the nucleus accumbens may explain female-biased sex differences observed in striatal behaviors. A robust decrease in mEPSC frequency for females suggests pre-synaptic changes to excitatory terminals projections into the core, providing a potential mechanism to explore in future studies.

Title: Estrogen controls the electrical properties of mouse tuberoinfundibular dopamine (TIDA) neurons: A novel substrate for sex hormone control of prolactin secretion

Authors: J. FERRARIS[1,2], R. AMMARI[1], *C. BROBERGER[1,2];
[1]Dept. of Neurosci., Karolinska Institutet, Stockholm, Sweden; [2]Dept of Biochem. and Biophysics, Stockholm Univ., Stockholm, Sweden

Abstract: Neuroendocrine tuberoinfundibular dopamine (TIDA) neurons tonically inhibit pituitary prolactin secretion. After parturition elevated prolactin activates a number of maternal

functions, including lactation, but the hormone also exhibits a peak during proestrus in rodents. This peak depends on a decrease in dopaminergic tone triggered by estradiol (E2), partly by inhibition of dopamine synthesis. However, the membrane properties and firing pattern of TIDA neurons provide an additional level of control in the lactotropic axis. Furthermore, E2 is now known to modulate neuronal electrophysiology by both acute and chronic actions. These observations raise the possibility that sex hormones control of TIDA neurons may involve regulation of the excitability and discharge configuration of these neurons.
To address this issue, we used whole-cell patch clamp recordings in acute hypothalamic slices from postpubertal female mice expressing tdTomato under control of the dopamine transporter promoter. Recordings were performed during a) natural variations of sex hormones (estrous cycle), b) chronic changes in hormone levels (ovariectomy) and c) acute application of E2 in vitro.
Similar to males, TIDA neurons in female mice exhibited a spectrum of firing patterns from silent, to tonic to phasic. In males, the absolute majority of TIDA neurons can are regular oscillators. However, 50% of the cells exhibited tonic firing during estrus whereas, during diestrus, 70% of cells showed an oscillatory pattern. Ovariectomy altered the distribution of firing patterns among TIDA neurons, in which the firing frequency was increased, and action potential amplitude decreased. In response to bath application of E2, TIDA neurons depolarized, an effect also observed in the presence of tetrodotoxin, suggesting a role for postsynaptic modulation. The depolarization was dose-dependent and at higher concentrations resulted in depolarization block, with successive stunting and the abolishment of action potentials.
These findings indicate that the membrane properties of TIDA neurons may be subject to both acute and long-term regulation by gonadal steroids. This modulation may be involved in shaping the serum profile of prolactin during both the estrous cycle and in the nursing mother.

Title: Characterization of phoenixin and thimet oligopeptidase (EP24.15) in neural circuits associated with the regulation of neuroendocrine processes

Authors: J. Z. GLUCKSMAN[1], M. R. DEJOSEPH[2], K. D. PHILIBERT[3], *J. H. URBAN[2]; [1]Ctr. for Neurobio. of Stress Resilience and Psychiatric Disorders, Rosalind Franklin Univ. of Med. and Scien, North Chicago, IL; [2]Ctr. for Neurobio. of Stress Resilience and Psychiatric

Disorders, [3]3Biochemistry and Mol. Biol. and Ctr. for Proteomics and Mol. Therapeut. and Midwest, Chicago Med. Sch/Rosalind Franklin Univ. Med. & Sci., North Chicago, IL

Abstract: The recently identified neuropeptide phoenixin (Phx) is distributed throughout the hypothalamus, central amygdala (CeA) and bed nucleus of the stria terminalis (BST). It has received attention for its role in the regulation of a number of homeostatic neuroendocrine systems including anxiety, vasopressin release and reproductive hormone secretion where Phx increases GnRH peptide release and receptor expression, increases Kisspeptin (Kiss) mRNA, and modulates ovarian cyclicity. The responses to neuropeptides are not only mediated by the local release of the neuropeptide, but also by modification of the peptide through enzymatic processing in the synaptic space. This enzymatic processing can shift the affinity of the peptide for various receptor subtypes, or in many cases, degrades the peptide thereby inactivating it and its downstream actions. EP24.15 (EC 3.4.24.15, thimet oligopeptidase) is a neuropeptide processing metalloenzyme that is expressed throughout the hypothalamus and other brain regions. EP24.15 plays a major role in the regulation of GnRH by processing the hormone and thus, inactivating binding to the GnRH receptor. As we have shown recently, EP24.15 not only modifies GnRH but other neuropeptides such as Kiss and dynorphin that are part of the reproductive neuroendocrine circuit. These current studies were designed to demonstrate the physiological and biochemical regulation of Phx in male and female animals in the context of reproduction by examining the association of Phx with EP24.15 within the hypothalamus. Using an immunohistochemical approach, we demonstrated Phx immunoreactivity in areas of the brain related to stress (CeA; BST) and reproduction (hypothalamic arcuate nucleus); EP24.15 was also highly expressed in these regions. To determine whether Phx was a substrate for EP24.15 we employed a combination of *in silico* structural models, mass spectrometry, enzyme kinetics, and high resolution, respectively. Enzyme kinetics indicated a single cleavage site in Phx and that the Km and Vmax for this reaction were comparable to published values for GnRH and Kiss. The data demonstrates that EP24.15 can potentially cleave Phx *in vivo* as an additional layer of control to the elaborate mechanism of reproduction. A better understanding of novel, regulated peptides that integrate stress and reproductive processes will provide insight into brain circuitry for moderating reproductive function.

Title: Gabaergic cells expressing estrogen receptors in limbic and hypothalamic regions are sensitive to testosterone levels

Authors: *L. ZAVALA[1], V. S. HERNANDEZ[1], O. R. HERNANDEZ[1], L. E. EIDEN[2], L. ZHANG[1];
[1]Natl. Autonomus Univ. of Mexico, Mexico City, Mexico; [2]Sec Molec Neurosci, NIH, NIMH-IRP, Bethesda, MD

Abstract: We have previously reported the existence of a novel cell population in the medio-central nucleus of the lateral habenula complex of the rat, which consists in GABAergic and estrogen receptive neurons (GERNs). These cells co-express SLC32A1, the RNA encoding for the vesicular GABA transporter, and ERα, the RNA encoding for the oestrogen receptor α. The GERNs in habenula are shown to integrate glutamatergic input from hypothalamic neurons containing vasopressin and orexin, as well as from serotonin and TH positive neurons in the raphe nuclei and SN/VTA. All those afferent neurons are androgen receptive (express androgen receptor) and the oestrogen synthase aromatase are found at their axon terminals. In this work we further investigate the presence of GERNs in other limbic regions of the brain and how the testosterone levels modulate their density. Using the RNAscope technique, we compared the effect of testosterone up-regulation (testosterone supplementation) or downregulation (castration) on the density of GERN in male rats. Preliminary results show that castration produced a significant decrease in GERN's density in BNST (56.9%), LS (86.12%), DG (33.4%) to control rats (100%). Testosterone supplementation caused a significant increase in GERN density at DG (4 folds). These results suggest that testosterone can induce a subpopulation of neurons expressing ERα to express a GABAergic phenothype thus influencing the information processing in the limbic system.

Title: Effects of social closeness on the menstrual synchronization in young college females

Authors: K. CAO[1], X. ZHANG[1], ***R. ZHANG**[2,1];
[1]NorthWest Univ., Xi An, China; [2]Childrens Hospital, Harvard Med. Sch., Boston, MA

Abstract: Most organisms exhibit biological rhythms by synchronizing their behavioral and physiological activities with cyclic changes in the environment. Circadian time-keeping mechanisms preserve homeostasis by synchronizing internal physiology with predictable variations in the environment. The women's menstrual cycle are subjected to the lunar circadian regulation with a period around 29.5 days. In current study, we confirmed, as previously reported, women's menstrual circle were synchronized, at variable extent, in the same dormitory. Then, we asked how and why women's menstrual circle were regulated and affected reciprocally by investigating their saliva endocrinology profile and social behaviors pattern. Total 163, aged 18 -19 years old college female students who live in total 36 dormitories (4-6 people/room) were recruited. By questionnaire and survey, we collected information include 1) monthly menstrual circle dated in both solar and lunar calendar; 2) food preference (carbohydrates, protein, fat, snacks); 3) monthly social events; We measured the students' 1) bodyweight and body composition; 2) body temperature at start and end day of menstrual circle, and non-menstrual circle day. The inner social status and the closeness among individuals in the same dormitory were investigated through a designed conflict scene behavior observation that was performed in a blinded manner to both the participants and observers. The saliva cortisol, testosterone and melatonin concentration were measured by ELISA. We found that the bodyweight, basal metabolic rate, and their social status (dominant, subordinate, irrelated relationship) are related to the menstrual synchronization. We conclude that menstrual-related biological rhythms are individually regulated by their own endogenous profile. The exogenous social closeness reciprocally impacted on the menstrual circle among young female students.

Title: Association of the vaginal microbiota with menstruation, mood, and diet in healthy, young women

Authors: *S. D. SONG[1], K. ACHARYA[1], C. DEVENEY[2], M. R. WALTHER-ANTONIO[3], M. J. TETEL[1], N. CHIA[4];

[1]Neurosci. Dept., [2]Psychology Dept., Wellesley Col., Wellesley, MA; [3]Dept. of Obstetrics & Gynecology, [4]Dept. of Surgery, Mayo Clin., Rochester, MN

Abstract: The human microbiome, the microorganisms and their metabolites that reside in and on the human body, profoundly influences health and disease. However, studies of the vaginal microbiota, the microbes residing in the vaginal tract, are few and limited in scope. The vaginal microbiota is critical for maintaining women's health, and vaginal microbial dysbiosis is implicated in endometrial and ovarian cancers. However, very little is known about the endogenous factors that influence vaginal microbial composition and stability. The present study tests the hypotheses that vaginal microbial composition is associated with menstruation, contraceptive use, mood, and diet. Volunteer participants from a college provided daily vaginal swab samples for 2 months, while recording menstruation, contraceptive use, mood, and daily diet using a mobile application. Diet data were linked to nutritional information provided by the college's dining food provider. Vaginal microbial diversity, as measured using the Shannon Index, was significantly greater during menses (Wilcoxon signed rank, $p < 0.001$). This increase in diversity was even more dramatic among participants not using contraceptives (paired t-test, $p = 0.005$, 95% CI [0.27, 0.97]) than those using contraceptives (paired t-test, $p = 0.021$, 95% CI [0.05, 0.43]). Preliminary analyses revealed trends between vaginal microbial diversity and mood, with higher diversity on average corresponding to higher happiness ratings ($R^2 = 0.37$, $p = 0.28$) and greater mood variability ($R^2 = 0.36$, $p = 0.28$). However, these trends did not reach significance, likely due to the low number of participants with usable mood data ($n = 5$). Diet analyses reveal that those following a vegetarian or vegan diet tend to have increased average vaginal microbial diversity compared to non-vegetarians (Wilcoxon rank sum, $p = 0.18$). This trend also did not reach significance due to few participants following a vegetarian or vegan diet ($n = 5$). We are currently analyzing temporal effects of mood and diet on the vaginal microbiota. Our goal is to establish baseline knowledge on how healthy vaginal microbiota fluctuates over time, and the role of ovarian hormones, mood, and diet in this dynamic. Ultimately, our goal is to track these participants for 10-20 years in the hope of identifying early biomarkers of reproductive tract cancers in women.

Title: Genomic profiling of spontaneous X chromosome nondisjunction mice reveals Turner syndrome relevant pathways

Authors: *U. DATTA, M. SAUL, V. PHILIP, E. CHESLER;
The Jackson Lab., Bar Harbor, ME

Abstract: Turner's syndrome is a developmental disorder due to sex chromosome nondisjunction and an XO genotype. Patients have short stature, hormonal and cognitive characteristics, marked with non-verbal learning disability, dyscalculia, and social cognitive impairments. This has been assumed to be attributed to pseudoautosomal gene function. Diversity Outbred mice have an elevated frequency of these events (about 1%). Like their human counterparts, XO female mice lack a second X chromosome and thus may serve as a naturally occurring murine model of Turner's syndrome. Derived from the same eight founders as those of the Collaborative Cross inbred strains through randomized breeding, the Diversity Outbred population harbors a high level of allelic diversity and heterozygosity, thereby representing the heterogeneity of the affected population. In the present study, Diversity Outbred mice were classified as males or females based on genotype information. XO females were identified by lack of heterozygosity on X chromosome. Males with partial duplication of the X chromosome were also identified by heterozygous calls on the distal portion of the X chromosome. Examination of the genotypes on the sex chromosomes revealed six XO females (out of 432 total females) and twelve males (out of 429 total males) with partial X chromosome duplication. Preliminary analysis of global gene expression in striatum was carried out using RNA-seq on 3 XO females. A total of 783 differentially expressed genes were identified, of which 146 genes were up-regulated and 637 genes were down-regulated in XO females compared to euploid females. Among the downregulated genes was Xist, a non-coding RNA involved in X inactivation. GeneWeaver identified a significant overlap with CREB- and zif268-regulated neuronal plasticity related genes. Interesting downregulated candidates include the X-encoded magnesium transporter gene Magt1 and the NMDA receptor subunit gene Grin2a. Further interrogation of these genes and mechanisms may help explain the neurobiological basis of deficits in Turner's syndrome.

Abstract: The episodic nature of chronic pain has been described in animal models as latent pain sensitization. For example after remission from inflammatory or postsurgical pain, assessed by normalization of mechanical pain threshold, injection of opioid receptor inverse agonists reinstates pain hypersensitivity (Campillo et al., Eur J Pharmacol 2011; Corder et al., Science 2013; Walwyn et al., J Neurosci 2016). To investigate whether latent sensitization is also occurring in neuropathic pain and neuroimmune mechanisms are involved, male and female mice were treated with 3 daily injections of cisplatin (2 mg/kg) to induce a transient neuropathic pain. Mice developed mechanical pain hypersensitivity that resolved after 3 weeks. Interleukin (IL)-10 was significantly upregulated in the spinal cord during and after remission from cisplatin-induced neuropathic pain. One week after remission, injection of a neutralizing antibody anti-IL-10 reinstated mechanical pain hypersensitivity in both male and female mice treated with cisplatin whereas the same treatment had no effect on naïve mice. To determine the downstream mechanism of the reinstatement of pain hypersensitivity by inhibition of IL-10 signaling, we performed RNA-sequencing analysis of dorsal root ganglion (DRG) tissue. Remission and reinstatement of pain hypersensitivity were associated with a change in gene expression of more than 250 genes. Bioinformatics analysis identified *Oprd1* as the main regulator of the balance between remission and reinstatement of pain. *Oprd1* encodes the delta opioid receptor (DOR) which has already been implicated in latent sensitization after inflammatory pain (Walwyn et al., J Neurosci 2016). Q-PCR data confirmed that *Oprd1* is upregulated in the DRG during remission and that this upregulation is mediated by IL-10 signaling. IL-10 signaling is also necessary for DOR agonist-induced analgesia. Furthermore naltrindole, a DOR antagonist, reinstated pain hypersensitivity after remission from neuropathic pain in both sexes. In conclusion, upregulation of *Oprd1* in the DRG by spinal IL-10 is necessary to maintain remission from neuropathic pain. Recurrence of chronic pain may result from the dysregulation of IL-10 - DOR interaction.

Title: Toll-like receptor 4 expressed on LysozymeM^{+} immune cells mediates neuropathic mechanical hypersensitivity development in male, but not female mice

Authors: *T. A. SZABO-PARDI, L. R. BARRON, N. M. AGALAVE, M. D. BURTON; Brain and Behavioral Sci., Univ. of Texas at Dallas, Richardson, TX

Abstract: Chronic pain is a disease affecting more than 1 billion people worldwide. Understanding how the immune system promotes inflammation and pro-nociception following traumatic injury is paramount to the development of effective therapeutics to combat neuropathic pain. It is well accepted that neuropathic pain is maintained in part by microglia, however mechanisms of neuropathic pain development present a point of treatment to prevent maturation of chronic neuropathic pain. Recent literature has delved deeper into the interface of neuro-immune interactions which have brought to light sexual dimorphisms in pain development that warrant further investigation. Studies provide a direct link between TLR4 activation and neuropathic pain in male mice, however, the specific cells expressing TLR4 that are responsible for these effects remains a point of contention. Toll-like receptor 4 (TLR4) is a pattern recognition receptor (PRR) expressed on various cell types, including cells of the innate immune system with activation leading to pro-inflammatory cytokine production and tissue sensitization. This study focuses on investigating peripheral actions of LysozymeM^{+} (LysM) immune cell activation and infiltration via TLR4 in the dorsal root ganglia (DRG), along with its effects on behavioral pain phenotypes. We hypothesize neuropathic pain in males is dependent on TLR4 expressed on peripheral LysM^{+} cells while females utilize an alternative signaling pathway. We have employed two unique *Cre*/LoxP transgenic models that allow for specific deletion or reactivation of a floxed TLR4 allele utilizing LysM as a promoter of *Cre* expression. We used a spared-nerve injury (SNI) model of neuropathic pain after which mice are subject to von Frey and cold allodynia measures. In addition, we assayed recruitment and polarization of macrophages and T-cells in the DRG following SNI using flow cytometry. Results indicate that TLR4 acting on LysM^{+} peripheral immune cells is both necessary and sufficient to produce neuropathic mechanical hypersensitivity during early timepoints following SNI in male, but not female mice. No differences are observed in cold allodynia. Lastly, flow cytometry reveals male mice have enhanced anti-inflammatory (M2) macrophage polarization 3D post-SNI as compared

to females. We have observed a robust, sexually dimorphic effect when TLR4 is removed from $LysM^+$ peripheral immune cells. Our data suggest that TLR4 acting on immune cells mediates neuropathic pain development in male, but not female mice.

Title: Gut microbiota derived dietary polyphenol metabolites promote cognitive resilience to anxiety and depression through immunological mechanisms of the gut-brain-axis

Authors: *S. WESTFALL, F. CARACCI, T. FROLINGER, U. IQBAL, G. M. PASINETTI; Neurol., Icahn Sch. of Med. At Mount Sinai, New York, NY

Abstract: Neuroinflammation promotes stress-induced neuropsychiatric disorders including depression and anxiety. Recently, we showed that gut microbiota-derived metabolites mitigate chronic inflammation and microglia activation promoting cognitive resilience to depression and anxiety; however, the metabolites' anti-inflammatory mechanisms remain to be elucidated. The gut-brain-axis describes a battery of humoral and neuronal modes of bidirectional communication between the gut and the brain that heavily influence the immune system's development and resistance to external stress. The purpose of this study is to dissect how modulating immune-mediated GBA signaling with an optimized synbiotic can protect against neuroinflammation and its associated disorders. The synbiotic, combining dietary polyphenol-rich prebiotics and probiotics, was designed and tested using a novel *in vitro* model of the human gastrointestinal tract called the A-BIOME (A bioreactor imitation of the microbiota ecosystem) and optimized for metabolite production. The polyphenolic precursor is a Bioactive Dietary Polyphenol Preparation (BDPP) containing grapeseed extract, concord grape powder and resveratrol and once combined with probiotics, production of plasma- and brain-bioavailable metabolites was significantly enhanced. Following 28 days of chronic unpredictable stress (CUS) in mice, the synbiotic promoted resilience to depressive-like behavior to a greater extent than BDPP alone, but to the same extent as BDPP in metrics of anxiety-like behavior. Circulating and central levels of proinflammatory cytokines, including IL-1β, TNFα and IL-6 elevated by the CUS protocol, were also reduced by the synbiotic to a greater extent than BDPP. Biochemical analyses confirmed the altered immune profile indicating that the synbiotic could be acting on

mechanisms of sterile inflammation including NLRP3 inflammasome activation in peripheral monocytes, intestinal enteroendocrine cells or brain-derived microglia, altered recruitment of lymphocyte subsets to the brain, or modulation of microglia activation in the prefrontal cortex. Nanostring immunophenotyping technology revealed that the synbiotic promotes differentiation of regulatory T cells over cytotoxic T cells, reducing the neuroinflammatory phenotype and associated neuropsychiatric phenotypes. Overall, synbiotics can normalize the production of bioactive polyphenolic metabolites with neuroactive properties and used as novel therapeutic strategies for neuroinflammatory conditions including depression, anxiety, Alzheimer's disease and multiple sclerosis.

Title: Investigating GM-CSF as a mediator of gut-brain signaling in addiction-like behaviors

Authors: *K. E. LUCERNE[1], E. S. CALIPARI[2], A. GODINO[3], D. D. KIRALY[4];
[1]Nash Family Dept. of Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Pharmacol., Vanderbilt Univ. Sch. of Med., Nashville, TN; [3]Nash Family Dept. of Neurosci., [4]Psychiatry / Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Recent work suggests that the resident bacteria of the gastrointestinal tract, collectively dubbed the gut microbiome, can have profound effects on brain and behavior including in multiple neuropsychiatric diseases. While the majority of work in this field has focused on affective, neurodevelopmental, and neurodegenerative disorders, our group has demonstrated that depletion of the gut microbiome markedly alters the rewarding properties of cocaine. While the precise mechanisms underlying gut-brain communication are not fully understood, one potential mechanism is via the extensive effects of the gut microbiome on immune system function. To investigate potential gut-immune-brain signaling in models of

addiction, we performed quantitative multiplex serum cytokine analysis on animals with a normal microbiome or antibiotic-induced microbiome depletion that were administered either cocaine or saline. While many cytokines were altered either by microbiome depletion or cocaine treatment, there were few that demonstrated a strong interaction between the conditions. Of particular note was granulocyte-macrophage colony-stimulating factor (GM-CSF) which was robustly increased by cocaine only in animals with a normal gut microbiome. Enzyme linked immunosorbent assay (ELISA) confirmed the cocaine-induced increase of GM-CSF in animals with normal gut microbiome that were self-administering cocaine. Interestingly, GM-CSF expression showed a positive correlation with levels of drug intake over the self-administration sessions. To assess the role of GM-CSF as a mediator of gut brain signaling in behavioral response to cocaine we utilized a cocaine conditioned place preference (CPP) assay. For these studies animals either drank control water or had their microbiome depleted with antibiotics, and also received daily injections of GM-CSF (10μg/kg) or vehicle throughout cocaine CPP in a 2x2 design. Microbiome-depleted animals that received vehicle injections developed a robust place preference for low doses of cocaine in agreement with our previously published findings. However, microbiome-depleted animals that received injections of GM-CSF displayed place preference similar to control levels. Taken together, these data suggest that cocaine-induced GM-CSF signaling is dependent on a normal gut microbiome and plays a key role in the rewarding effects of cocaine. This introduces a new line of gut-immune-brain communication with clinical translational potential.

Title: Neuroinflammatory modulation of nicotine dependence

Authors: *E. L. ANDERSON[1], A. O. ADELUYI[1], J. R. TURNER[2];
[1]Col. of Pharm., Univ. of South Carolina, Columbia, SC; [2]Col. of Pharm., Univ. of Kentucky, Lexington, KY

Abstract: Introduction: Neuroinflammation and associated gliosis has been demonstrated to be a primary mediator of many neurological disorders, including in CNS trauma, ischemia, stroke, and neurodegenerative diseases. However, while their role has been extensively examined in neurology, this is much less true in psychiatry, especially in substance use disorders. It is thought that discrete microenvironments in the select brain regions may polarize the immune effector cells, namely microglia, to a reactive state. We examined these changes in the nucleus accumbens (ventral striatum), which is a region reliably shown to underpin many behavioral characteristics of substance use disorders as well as the withdrawal symptomology.
Methods and Results: Our preliminary IHC and qPCR data indicates that significant neuroinflammation can be detected in the ventral, but not the dorsal striatum, following withdrawal from chronic nicotine in mice. Furthermore, previous studies have suggested that microglial activation can contribute to neuronal damage through release of reactive oxygen and nitrogen species and inflammatory cytokines. In line with these findings, we detect significantly increased levels of both reactive oxygen species as well as pro-inflammatory cytokines in the ventral, but not dorsal, striatum.
Significance and Conclusions: Our current experiments investigate whether pharmacological compounds possessing both structurally and mechanistically distinct mechanisms for inhibiting microglial activation, such as ibudilast and minocycline, will reduce the molecular hallmarks of neuroinflammation during nicotine withdrawal. Further, because these processes are known to be able to regulate nicotine-induced upregulation and assembly of nicotinic acetylcholine receptors, a phenomenon that can be correlated to anxiety-like nicotine withdrawal behaviors, future studies will examine the effects of these inhibitors on modulating nicotinic receptor expression.

Title: microRNAs in inflammatory neurodegeneration and multiple sclerosis

Authors: *I. WINKLER[1], J. ENGLER[1], G. SALINAS[2], L. BAL[1], B. SCHATTLING[1], O. PLESS[3], M. FRIESE[1];
[1]Ctr. for Mol. Neurobio. Hamburg (ZMNH), Hamburg, Germany; [2]Transcriptome and Genome Analysis Lab. (TAL), Univ. of Göttingen, Göttingen, Germany; [3]Screening Port, Fraunhofer Inst. for Mol. Biol. and Applied Ecology IME, Hamburg, Germany

Abstract: Multiple sclerosis (MS) is a chronic-inflammatory disease of the central nervous system (CNS) characterised by CNS immune cell infiltration, axonal demyelination and neurodegeneration. Chronic CNS inflammation results in neuronal stress response networks with alteration of synaptic signalling and signal transduction, thereby perpetuating neurodegeneration and consecutive neurological deficits. Coordination of translation by microRNAs (miRNAs) is a fundamental mechanism to respond to changes in the cellular environment. However, whether and how inflammation impacts on neuronal gene expression by regulating miRNAs and whether this determines neurodegeneration is unknown. By comparing healthy and inflamed neuronal transcriptomes and miRNome we demonstrate that mRNA transcripts involved in synaptic signaling and plasticity are significantly under-represented in inflamed neurons, while at the same time newly identified inflammation induced miRNAs are predicted to target these transcripts. Of these miRNA candidates, miR-92a was identified most prominently induced. Mechanistically, we identified exogenous glutamate to regulate miR-92a expression in primary neurons, while concomitantly the predicted target mRNA cytoplasmic polyadenylation element-binding protein 3 (CPEB3) was downregulated. Luciferase reporter assays proved a direct inhibition of CPEB3 translation mediated by miR-92a. Further, to investigate miR-92a function during neuroinflammation, we performed EAE in respective knock-out mice. Specific deletion of miR-92a led to an accelerated EAE disease course and clinical symptoms, implying a neuroprotective role of miR-92a upregulation. Currently, we decipher the interaction network of miR-92a and CPEB3 and its implications for neuronal survival during inflammation. Together, we present a new approach offering an understanding of miRNAs governing synaptic function and contributing to neuronal integrity during CNS inflammation. This will provide insights into the role of miRNAs in the pathogenesis of MS and opportunities for intervening in MS-associated neurodegeneration.

Title: Characterization of a unique microglia subtype in secondary thalamic injury after ischemic stroke

Authors: *Z. CAO[1,2], S. HARVEY[1,2], T. C. CHIANG[1,2], M. Y. CHENG[1,2], G. K. STEINBERG[1,2];
[1]Neurosurg., Stanford Univ., Stanford, CA; [2]Stanford Stroke Ctr., Stanford, CA

Abstract: Introduction: Stroke affects brain connectivity and causes network-wide deficits. In particular, the ipsilesional thalamus undergoes degeneration after cortical stroke and impedes functional recovery. Previously we demonstrated that neuroinflammatory responses are critically involved in the development of secondary thalamic injury. In this study, we focus on characterizing microglia changes in the secondary thalamic injury after stroke. **Methods**: Left middle cerebral artery was permanently occluded to generate cortical ischemic stroke in male C57BL6J mice (12-15 weeks). Brain sections were collected from post-stroke days (PD) 1, 3, 7, 14, 28, 56 and 84. Immunostaining was used to detect microglia/macrophage activation (Iba-1, Tmem119 and CD11c) in the ipsilesional thalamus (iTH). Flow cytometry was used to analyze iTH samples collected at PD28. Furthermore, qPCR was used to quantify the expression of microglia-associated genes in iTH among Naïve, PD7 and PD28 groups. **Results**: In iTH, Iba-1$^+$ cells exhibited ramified morphology at PD1, became hyper-ramified between PD3-7, and appeared as rod-shaped at PD14. Bushy/amoeboid microglia/macrophages were shown at PD28. At PD 56-84, most microglia/macrophages returned back to resting/ramified status. These morphological changes suggested a gradual and progressive activation of microglia/macrophages in iTH. Iba-1$^+$Tmem119+ cells were observed at early phases (PD1-7), but the expression of Tmem119 significantly decreased between PD14-56. Interestingly, a population of CD11c$^+$ cells appeared in the thalamic injured area between PD14-28 and most were Iba-1$^+$, suggesting they were CD11c$^+$ microglia/macrophages. Flow cytometry analysis further confirmed that resident microglia (CD45^{int} CD11b$^+$) are the major population and CD11c$^+$ microglia is a subtype of microglia in iTH at PD28. Several microglial activation related genes (CD11c, Trem2, CX3CR1, CSF1R and TLR2) were significantly increased at PD28 iTH compared to naïve and PD7. **Conclusion**: Our results show that dynamic microglia changes occurs during the development of secondary thalamic injury, with progressive changes in morphology and gene expressions. In addition, we have identified a unique subtype of microglia (CD11c$^+$) in the secondary thalamic injury. Future studies will explore the roles of CD11c$^+$ microglia in the secondary thalamic injury and long-term stroke outcome.

Title: Long-term high fat diet precipitates peripheral sensitization independent of obesity in female mice

Authors: *J. A. TIERNEY[1], M. D. BURTON[2];
[2]Behavioral and Brain Sci., [1]Univ. of Texas at Dallas, Richardson, TX

Abstract: Worldwide there were 422 million adults over the age of 18 diagnosed with type II diabetes, as of 2014. Up to 50% of people diagnosed with diabetes will develop painful diabetic neuropathy (PDN) at some point. It is known that free fatty acids (FFAs), which are a large component of western diet (WD), lead to obesity, “metainflammation”, and type II diabetes. Free fatty acids have been proposed to interact with various receptors in the digestive and immune system to mediate inflammation and metabolic disorder. Our hypothesis is that circulating free fatty acids contribute to the pain associated with PDN. To test this hypothesis we utilized a diet regimen where animals had ad libitum access to high-fat diet (HFD) containing 60% of calories from fat for over 40 weeks. Male and female C57/B6 mice were placed on HFD or kept on chow diet at 6 weeks of age and weighed once every week. At 13 weeks on diet we began assessing mechanical hypersensitivity using the von Frey up-down method, thermal sensitivity at 4°C and 50°C, and fasting glucose levels once per week until week 29. At week 29 a Glucose Tolerance Test was performed to assess glucose insensitivity. Male mice on HFD gained significant weight and reached obesity levels by week 12 on diet, whereas the female mice on HFD gained weight, but never reached significant levels of obesity. For over 40 weeks long-term HFD caused peripheral mechanical hypersensitivity in male and female mice starting 17 weeks after diet initiation. Female mice developed mechanical hypersentivity in the absence of obesity and glucose insensitivity, whereas male mice did develop glucose insensitivity when assessed with a GTT at week 29 on diet. There were no significant differences observed in standard hot plate, or cold plate tests. However, at week 39 on diet dynamic hot and cold sensitivity was tested and both male and female mice on HFD were more sensitive to changes in temperature. These results show that diets high in saturated fats play a role in the development of pain in both males and females in the presence or absence of obesity.

Title: Gut-brain interactions in a mouse model of Phelan-McDermid syndrome

Authors: *A. OSMAN, N. MERVOSH, D. D. KIRALY;
Dept. of Psychiatry, Ichan Sch. of Med. At Mount Sinai, New York, NY

Abstract: Phelan-McDermid syndrome (PMS) is a neurodevelopmental disorder caused by haploinsufficiency of the Shank3 gene. PMS has been identified as one of the most frequent monogenic causes of Autism Spectrum Disorder (ASD). Despite its high prevalence, there are currently few FDA-approved pharmacotherapies for treatment of ASD including PMS. In recent years, a mounting body of evidence has demonstrated that the gut microbiome, can influence brain development and behavior. A significant subset of patients with ASD also present with gastrointestinal disturbances, and sequencing of the gut microbiota has shown alterations in the bacterial makeup of stool from patients with ASD. To identify a possible role for gut microbiome in the development of ASD, we used a mouse model of PMS in which exons 4-22 of the Shank3 gene have been deleted resulting in total knockdown of Shank3 expression ($Shank3^{KO}$). We then investigated the effect of Shank3 deletion on the microbiome and metabolome as well as the effects of a depleted gut microbiome on autism-like behaviors in the $Shank3^{KO}$ model. 16s sequencing of cecal contents demonstrated that $Shank3^{KO}$ results in marked shifts in microbiome composition at the phylum and class levels. $Shank3^{KO}$ mice also displayed altered levels of numerous amino acids and short chain fatty acid metabolites – effects that were exacerbated by Abx treatment. For behavioral experiments wildtype, heterozygous and homozygous $Shank3^{KO}$ littermates were divided into control and antibiotic-depletion (Abx) groups at weaning (postnatal day 21). The Abx group received a cocktail of broad spectrum non-absorbable antibiotics daily via drinking water. On postnatal day 60 animals were subjected to behavioral testing using three-chambered social interaction, marble burying and open field. Behaviorally, $Shank3^{KO}$ KO mice demonstrated decreased social interaction, a deficit which was exacerbated by microbiome depletion. Medial prefrontal cortex (mPFC) was dissected from animals following behavioral testing to assess pathways linked to this gene x microbiome interaction. Preliminary pathway analysis shows that multiple synaptic plasticity-related pathways are differentially affected by microbiome depletion in $Shank3^{KO}$ mice. Taken together our results demonstrate that shank3 KO results in significant changes to the gut flora and metabolome which may be linked to the social deficits observed in these animals. Additionally, the autistic-like behaviors in $Shank3^{KO}$ mice are exacerbated by depletion of the gut microbiome. These findings suggest the possibility of gene x microbiome interactions in this translationally relevant model of autism spectrum disorder.

Title: Optogenetic stimulation of glutamatergic and cholinergic potentials in the vagus nerve mediating peripheral neuroimmune signaling

Authors: *E. H. CHANG[1], T. TSAAVA[3], A. M. KRESSEL[4], S. S. CHAVAN[2], K. J. TRACEY[2];
[1]Bioelectronic Med. and Biomed. Sci., [2]Lab. of Biomed. Sci., Feinstein Inst. For Med. Res., Manhasset, NY; [3]Lab. of Biomed. Sci., Feinstein Inst. at Northwell Hlth., Manhasset, NY; [4]Lab. of Biomed. Sci., Feinstein Inst. of Med. Res., Manhasset, NY

Abstract: The inflammatory reflex is a neural circuit that relays information between the periphery and the brain via the vagus nerve to regulate levels of peripheral inflammatory cytokines. The reflex is comprised of sensory afferents and motor efferent fibers within the vagus nerve, each mediated by a different neurotransmitter system. Sensory afferent information from the periphery to the brainstem is glutamatergic in nature and represents about 80% of all fibers within the vagus nerve. Motor efferents originate in the brainstem to innervate target organs, such as the heart and spleen, and use cholinergic signaling. To examine the neural signaling that is associated with sensory afferent and motor efferent activation, we used nerve cuff electrodes combined with optogenetics to record light-evoked compound action potentials (CAPs). We used three strains of transgenic mice expressing light sensitive channelrhodopsin (ChR2) in distinct genetically defined neuronal populations. Light-evoked CAPs were recorded from TRPV1-ChR2-YFP, Vglut2-ChR2-YFP, and ChAT-ChR2-YFP mice. Two-channel cuff electrodes placed onto the cervical vagus nerve recorded CAPs in response to light pulses (473 nm light at 1, 10, or 20 Hz, 60 s between trains) delivered by a fiber optic. For sensory afferent activation, TRPV1-ChR2 evoked CAPs were characterized by rapid rise times with peak-to-peak amplitudes of 3.55 ± 0.02 mV (mean ± SEM). Vglut2-ChR2 evoked CAPs were multimodal and characterized by substantially larger mean amplitudes 10.21 ± 0.07 mV. In comparison, motor efferent activation of ChAT-ChR2 evoked CAPs had a mean peak amplitude of 1.8 ± 0.02 mV, significantly than TRPV1 (Mann-Whitney, $P<0.005$) and VGlut2 CAPs ($P<0.0001$). These large differences in sensory afferent and motor efferent light-evoked activation may be attributed to the number of fibers represented by each group. Immunohistochemical analysis of vagus nerves cross-sections from TRPV1-ChR2-YFP mice (n = 4) showed that TRPV1 fibers occupy the majority of the cross-sectional area and do not overlap with labeled myelinated fibers. Additional immunohistochemical analysis will show whether ChAT-positive fibers account for <20% of the vagus nerve. These fiber-specific CAPs can help us to understand the nature of signals within the sensory and motor arcs of the mouse vagus nerve. Once coupled to peripheral cytokine measures, they can provide insights into the type of neural activation necessary to activate the inflammatory reflex. These findings are also relevant to emerging neuromodulation and bioelectronic approaches aiming to activate specific nerve fibers or neurotransmitter populations for therapeutic benefit.

Title: The role of microglia in the sculpting of developing stress circuits by early-life adversity

Authors: *J. L. BOLTON[1], M. SHAO[1], S. OTHY[2], J. BECK[1], X. BAI[1], C. KOOIKER[1], I. PARKER[3], M. D. CAHALAN[2], T. Z. BARAM[1];
[1]Anat. & Neurobio., Univ. of California-Irvine, Irvine, CA; [2]Physiol. & Biophysics, [3]Neurobio. and Behavior, Univ. of California- Irvine, Irvine, CA

Abstract: BACKGROUND: Early-life adversity can have a profound and lifelong impact on an individual's risk for emotional disorders such as depression by modulating the maturation of brain circuits. We find that early-life exposure to an impoverished environment and unpredictable maternal care (in a limited bedding and nesting [LBN] paradigm) provokes major alterations in cognitive and emotional function, including anhedonia, accompanied by aberrant connectivity between the hippocampal-limbic system and reward/pleasure-related regions. Within the hypothalamus, this early-life adversity causes an increase in the number of excitatory synapses onto corticotropin-releasing hormone (CRH)-expressing neurons in the paraventricular nucleus (PVN). Such synaptic changes suffice to induce large-scale and enduring epigenomic changes in the expression of neuronal genes, including *Crh*. However, the mechanisms by which early-life adversity modulates synapse development or persistence in developing brain circuits remain unknown. Here, we test the hypothesis that microglia contribute to normal synapse reduction on CRH neurons in the developing PVN, and that adverse early-life experiences interfere with this function.
METHODS: To interrogate microglial function, we employed dual-reporter transgenic mice with visible CRH+ neurons and microglia and two-photon time-lapse imaging in acute slices of the PVN. We obtained these hypothalamic slices from P8 mice that were reared in LBN or control cages from P2 to P8. We visualized live microglial process dynamics and their interactions with CRH+ neurons. In fixed tissue, we utilized 3D-reconstruction confocal

microscopy and immuno-detection of synaptic markers to quantify in high-resolution the developmental trajectory of synapse density and engulfment by microglia.
RESULTS: Early-life adversity augmented the number of vGlut2+/PSD95+ excitatory synapses onto CRH+ neurons by the end of the LBN experience (P10), without altering the number of CRH+ neurons or microglia. Inhibition of microglia increased the density of excitatory synapses onto CRH+ neurons, phenocopying adversity. Live-imaging revealed that microglial process dynamics were diminished in the PVN of LBN mice, along with decreased microglial engulfment of excitatory synapses.
CONCLUSIONS: Microglia are potential contributors to early-life experience-dependent sculpting of stress-sensitive circuits. Ongoing studies include manipulation of microglial function during development to assess if this prevents stress-related emotional disorders in adulthood, thereby providing novel targets for therapeutics or preventative interventions.

Title: Hypothalamic and pulmonary vasopressin production during tuberculosis: A link to pathogenesis

Authors: *M. A. ZETTER[1], J. BARRIOS[1], B. MARQUINA-CASTILLO[1], D. MATA[1], A. QUINTANAR-STEPHANO[2], R. HERNANDEZ-PANDO[1];

Abstract: Tuberculosis (TB) is a highly prevalent chronic infectious disease characterized by granulomatous inflammation and immunopathology that affect primarily the lungs but also interferes with host metabolism and neuroendocrine function. Vasopressin (VP), a well-recognized stress hormone is apparently overproduced and responsible for altered water metabolism during TB. Due to the immunomodulatory effects of VP, here we tried to elucidate whether it influences the pathophysiology of pulmonary TB using a Balb/c mouse model of progressive infection. Our findings indicate that as active pulmonary TB progressed, hypothalamic VP mRNA increase, reaching an acme on the first month of infection,

characterized by a protective immune phenotype in our mice model, to then decrease. Additionally, VP mRNA was detected at the infected lung and contained inside macrophages within the granuloma, the histopathological hallmark of TB since early infection. During pneumonic process, VP was found in foamy macrophages, which are deleterious to the control of infection. Functional studies using pharmacologic compounds showed that agonism of VP receptor provoked marked fibrosis, higher bacilli burdens and increased synthesis of the cytokine TGFβ at lungs. Conversely, non-selective blockade of VpR improved protective immunity reflected in increased inflammatory areas and reduced pulmonary bacterial loads. These effects were a consequence of vasopressinergic inhibition of bacterial clearance by alveolar macrophages, as cell culture assays showed. We conclude that hypothalamic VP synthesis is induced during the onset of pulmonary infection, and produced at the infected lung during late stages, worsening immunopathology and hampering bacilli elimination. These observations highlight the pathophysiological effects of Vp during chronic peripheral inflammation and suggest the possible manipulation of the vasopressinergic system by tubercle bacilli. Furthermore, our results suggest that mycobacteria could drive vasopressin-mediated behavioral changes in infected individuals. Additional research is needed to understand these points.

Title: Inflammatory signals from the periphery to the brain can mediate fatigue-like behavior in a mouse model of radiation therapy

Authors: *B. S. WOLFF, S. A. ALSHAWI, L. N. SALIGAN;
Natl. Inst. of Nursing Res., NIH, Bethesda, MD

Abstract: Fatigue is a common and distressing symptom following radiation therapy for cancer, and it can be frequently undertreated in clinical practice. The neurobiology underlying fatigue is poorly understood, though it is believed inflammatory signals may play a role, as pro-inflammatory cytokines can induce fatigue symptoms in humans and fatigue-like behavior in animals. To help understand how inflammation may lead to fatigue, we use our previously established mouse model of radiation-induced fatigue, in which male mice receive radiation targeted to their pelvic region to mimic treatments for prostate cancer. Mice exposed to this

peripherally-targeted irradiation show a substantial reduction in voluntary running wheel activity (VWRA), which we interpret as fatigue. In current experiments, we first establish that inflammation is contributing to the fatigue by using minocycline, an antibiotic and anti-inflammatory drug, and by using mice lacking MyD88, an important immune signaling adaptor protein. We found that both minocycline-treated mice and MyD88 knockout mice showed a smaller decline in VWRA than control mice after irradiation. In addition, we tested an array of cytokines and other biomarkers in both blood and brain to investigate possible molecular mechanisms both for the fatigue induced by radiation and for its reversal by the two anti-inflammatory manipulations. We found substantial changes in immune signaling in the blood as well as in the brain, which may help us understand how peripheral inflammation signals the brain to produce fatigue-like changes in behavior.

Title: Inflammatory biomarkers in depression and schizophrenia -comparison in patients and healthy control participants

Authors: *F. KLAUS[1], F. CATHOMAS[1], K. GÜTTER[1], M. HARTMANN-RIEMER[1], R. SCHLEGEL[1], E. SEIFRITZ[1], S. KAISER[2];
[1]Dept. of Psychiatry, Psychotherapy and Psychosomatics, Psychiatric Hospital, Univ. of Zurich, Zurich, Switzerland; [2]Dept. of Mental Hlth. and Psychiatry, Geneva Univ. Hosp., Geneva, Switzerland

Abstract: Depression (major depressive disorder, MDD) and schizophrenia (SZ) are heterogeneous mental disorders with a high burden on the individual and societal level as well as limited treatment options. According to the current state of research, the etiology of both is multi-factorial and recent evidence suggests that a subgroup of patients display a pro-inflammatory state. However, studies that directly compare blood biomarkers across different diagnostic entities remain sparse. In order to generate further knowledge about underlying

pathomechanisms, we assessed peripheral inflammation-related biomarkers. We examined patients meeting the DSM-IV criteria for schizophrenia (male/female (M/F): 31/14), MDD (M/F: 18/26) and healthy controls (HC) (M/F: 9/10). Inclusion age was 18-65 years. Exclusion criteria were: any neuropsychiatric diagnosis (HC), any other than the above mentioned DSM-IV Axis I disorders (patients), any autoimmune or chronic inflammatory disorder, anti-inflammatory drugs or any acute infections. C-reactive Protein (CRP), cytokines and chemokines were assessed in plasma / serum using the Olink Inflammation panel, analyzing 92 inflammation-related proteins. We used one-way analysis of variance (ANOVA) to investigate the differences of the inflammation variables between the three groups. To correct for multiple comparisons, overall significant values of the ANOVA were corrected using the false discovery rate (FDR). Post-hoc comparisons using Bonferroni were applied only to biomarker parameters that remained significant after FDR-correction. Analysis of covariance (ANCOVA) was conducted to control for BMI, age and sex as covariates. Several inflammatory biomarkers were elevated in SZ (including CRP, CXCL11, FGF21, IL6, MCP3, TRAIL) and MDD (including FGF21, TRAIL), with some cytokines being decreased in SZ (including CCL28, CXCL11) and in MDD (including DNER, IL18, MCP2) compared to healthy participants. Analysis of covariance revealed that BMI and age influenced CRP, CCL28, IL6 (no significant differences after introduction of covariates) and DNER, TRAIL (no significant differences after introduction of covariates in HC vs MDD). The preliminary results of this exploratory study support the hypothesis of an underlying inflammatory process in SZ and MDD. Further investigation of associations with biomarker alterations and clinical symptoms could potentially identify transdiagnostic subgroups and foster hypothesis-generation on underlying pathomechanisms in order to inspire new therapeutic targets for severe mental illnesses.

Title: Irritability and its associations with immuno-vascular risk factors in the aging brain

Authors: *D. COTTER, M. YOU, S. WEINER-LIGHT, N. DJUKIC, M. ALTENDAHL, S. M. WALTERS, C. A. LINDBERGH, A. M. STAFFARONI, W. RIVERA-CONTRERAS, A. KARYDAS, Y. COBIGO, A. WOLF, J. KRAMER, F. ELAHI, K. CASALETTO;
Memory and Aging Center, Dept. of Neurol., Univ. of California, San Francisco, San Francisco, CA

Abstract: Introduction
Neuropsychiatric symptoms have been associated with immuno-vascular disorders as early as the 19th century. Age-associated neurovascular changes are pervasive and contribute to functional decline. Anecdotally, clinicians report increased irritability in patients with CVD. Despite this, there is very little evidential support for irritability as a marker of compromised cerebrovascular health. To address this gap, we examined the link between irritability and quantitative measures of immuno-vascular risk such as white matter integrity, systemic inflammation, and clinical vascular risk factors.
Methods
370 older adults with diagnoses ranging from typical aging to mild cognitive impairment (MCI) (age M=71, 55.2% female, education M=17.5, 91% CDR=0) underwent a comprehensive neurobehavioral examination and fasting blood draw, to quantify plasma-based inflammatory markers. Irritability was assessed using the Neuropsychiatric Inventory Questionnaire (NPI-Q), which evaluates both presence (Yes/No) and severity (mild, moderate, severe) of symptoms. A subset (N=290) underwent a 3T brain MRI within 6 months of the neurobehavioral examination, blood draw, and NPI-Q. Measures of white matter integrity included fractional anisotropy (FA) and mean diffusivity (MD). Systolic blood pressure (BP) was used as a clinical vascular risk factor. Results were analyzed using multivariable regression models controlling for age, gender, and education.
Results
Greater severity of irritability was significantly related to lower FA and higher MD (FA $\beta = -0.11$, $p < 0.04$; MD $\beta = 0.12$, $p < 0.02$), increased TNF-α ($\beta = 0.11$, $p < 0.03$), and systolic BP ($\beta = 3.05$, $p < 0.03$). There were no significant associations between irritability and white matter hyperintensity volumes, nor with other markers of systemic inflammation (IL-6, CRP).
Conclusions
Neuropsychiatric symptoms are common comorbidities of neurodegeneration, and could be considered prodromal. Our data indicate that irritability is linked with both systemic molecular measures of inflammation and CNS structural consequences of its dysregulation. In addition, irritability is associated with systolic BP, an important vascular risk factor. Given that inflammation and white matter changes are known risk factors for neurodegeneration, irritability may be a symptomatic harbinger of age-associated immuno-vascular dysregulation. Future research should aim to define the mechanisms related to the nuanced interplay between neuroinflammation and psychiatric symptomatology.

Title: Toll-like receptor 4 contributes to sex-specific cocaine-induced behaviors

Authors: *J. S. ARCENEAUX[1,2,3], D. T. KASHIMA[2,4], C. A. GRUETER[2,5], B. A. GRUETER[1,2,3,5];
[1]Biochemistry, Cancer Biology, Neuroscience, and Pharmacol., Meharry Med. Col., Nashville, TN; [2]Vanderbilt Brain Inst., [3]Vanderbilt Ctr. for Addiction Res., [4]Med. Scientist Training Program, [5]Anesthesiol., Vanderbilt Univ., Nashville, TN

Abstract: Substance use disorders (SUDs) affect more than 7% (19.7 million people) of the US population. While men are twice as likely to develop SUDs, women are more sensitive to the negative consequences of drugs of abuse and have increased propensity of relapse to drug-seeking behavior. Toll-like receptor 4 (TLR4), a component of the innate immune system, is implicated in drug-related behavior. However, the contribution of TLR4 to the temporal components of cocaine experience is largely unknown. To determine the contribution of TLR4 to cocaine-induced behavior, the behavioral properties of wildtype (WT) and TLR4 knockout mice (TLR4.KO) were compared following cocaine exposure. Locomotor sensitization and place conditioning assays were used to elucidate how TLR4 modulates cocaine-induced behavior. We find that TLR4 deficiency results in differential expression of cocaine-induced locomotor sensitization between males and females. While both male and female TLR4.KO mice had reduced locomotor responding during the development of cocaine sensitization, female TLR4.KO mice exhibited robust enhancement of sensitization expression following a challenge dose of cocaine. In addition, female TLR4.KO mice had prolonged retention of associative memory following cocaine exposure and displayed reinstatement following a subthreshold dose of cocaine. Taken together, these results suggest TLR4 contributes to behavioral adaptations in response to cocaine experience.

Title: Hippocampal neuroimmune signaling mediates heroin-conditioned suppression of peripheral nitric oxide

Authors: *J. E. PANICCIA, C. L. LEBONVILLE, S. V. PAREKH, M. E. JONES, *D. T. L. LYSLE;
Dept. of Psychology and Neurosci., The Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Heroin and heroin-paired cues impair the peripheral immune response to pathogens. Specifically, exposure to heroin-conditioned stimuli (CS) is sufficient to elicit pronounced suppression of peripheral measures of nitric oxide (NO) production in response to a lipopolysaccharide (LPS) challenge. Our laboratory has established that the cytokine interleukin-1β (IL-1β) within the dorsal hippocampus (DH) is critical during CS exposure for the heroin-conditioned response to occur. The current set of experiments built on these findings and examined the role of DH IL-1 receptor type 1 (IL-1R1) during presentation of these heroin-paired cues. In experiment 1, male rats underwent five conditioning sessions in which heroin (1 mg/kg, s.c.) was paired with a distinct context for 1 h every other day. This context served as the CS. Six days following the last conditioning session, animals received bilateral intra-DH infusions of either IL-1 receptor antagonist (IL-1RA; 1.25 μg/0.6 μL per hemisphere) or vehicle 30 min prior to CS exposure or home cage stay. Immediately following 60 min in the heroin-paired context, or equivalent time in home cage, all rats were administered LPS (1 mg/kg, s.c.) to induce an immune response and tissue was collected 6 h later. Direct antagonism of IL-1R1 within the DH significantly blocked heroin-conditioned suppression of peripheral NO production. Thus, experiment 2 examined the consequence of CS exposure on both IL-1β and IL-1R1 protein within the dentate gyrus, CA3, and CA1 subregions of the DH. Rats underwent the conditioning procedure outlined above, and on test day, tissue was collected at 4 time points: 0, 30, 60, or 120 min post CS onset. Interestingly, we observed a time-dependent, sub-region specific increase in IL-1R1 immunoreactivity within the dentate gyrus 120 min following CS onset. Additionally, there were no significant differences detected in DH IL-1β expression. Collectively, these studies establish that stimulation of DH IL-1R1 is required for the context-heroin association driving conditioned immunomodulation, and that changes in receptor

expression, rather than IL-1β itself, mediate this heroin-conditioned response.

Title: Cytokine alterations differentially influence context-dependent amphetamine locomotor sensitization in female Long Evans rats

Authors: *B. PLOTKIN[1], C. A. CALHOUN[2], B. M. MASON[3], J. GALINDO[4], C. VALENCIA[4], S. DONALDSON[5];
[1]Umass Boston, Boston, MA; [2]Psychology, [3]Univ. of Massachusetts Boston, Boston, MA; [4]UMass Boston, Boston, MA; [5]Psychology, Univ. of Massachusetts, Boston, MA

Abstract: The development of sensitization to psychostimulants such as amphetamine suggests that repeated exposure causes neuroplasticity changes that are persistent. Indeed neural changes have been reported in critical learning and reward-related brain systems following chronic amphetamine and recently, alterations in central chemokines and cytokines have also been noted. The current investigation was designed to evaluate the sex differences in the context-dependent effects of repeated, intermittent amphetamine (AMPH; 4.0 mg/kg, 4 days, every 48 h). Adult Long Evans male and female rats (n=7-10 per group) were divided into context-dependent (locomotor activity cages) groups CD+SAL and CD+AMPH, and context-independent (CI; home cage injections) groups CI+SAL and CI+AMPH. All animals were administered a low dose (1.0 mg/kg AMPH) CHALLENGE in the LMA cages following a 3-day withdrawal. Animals were sacrificed on the final day of testing and brains were flash frozen and stored at -80 C for immunohistochemistry. Results indicate that AMPH-treated males and females displayed increased LMA including distance traveled, vertical counts, and stereotypies on the CHALLENGE day. Interestingly, CD+AMPH groups displayed the greatest CHALENGE day responses, highlighting the importance of contextual drug associations. Immunohistochemical data support these behavioral differences with the largest increases in protein levels for the chemokine CXCL12 and its canonical receptor, CXCR4, in the medial prefrontal cortex (mPFC), striatum (STR), and ventral tegmental area (VTA) of CD+AMPH animals. In sum, our results provide evidence for sex-dependent differences in response to an intermittent AMPH regimen and reveal that AMPH exposure after withdrawal in a *familiar* environment increases sensitization. These behavioral differences parallel increases in CXCL12 and CXCR4 proteins,

implicating a potential interaction of neuroimmune activation and contextual cues in AMPH sensitization.

Title: Neutrophil-mediated effects at the meningeal barrier following chronic stress

Authors: *S. L. KIGAR[1], C. T. HIGHAM[1], N. E. WRIGLEY[1], V. H. SUN[2], M. L. LEHMANN[1], A. ELKAHLOUN[3], M. HERKENHAM[1];
[1]Natl. Inst. of Mental Hlth., Bethesda, MD; [2]MIT, Cambridge, MA; [3]Natl. Human Genome Res. Inst., Bethesda, MD

Abstract: Chronic stress is a potent risk factor in the etiology of depression, and both stress and depression are associated with holistic changes to organismal immunity. Bidirectional communication pathways between the brain and peripheral immune systems have been described (Herkenham & Kigar, 2016), though less is known about how chronic stress changes the dialogue. Our lab has recently shown that neurovascular events (NVEs) associated with damage to the blood brain barrier (BBB) are evident in the brain parenchyma of chronically stressed animals exhibiting depressive-like behavior (Menard et al., 2017; Lehmann et al., 2018). Damage to the BBB allows for direct interaction of the peripheral immune system and brain, precipitating a sterile injury response and subsequent wound resolution by immune cells. Interestingly, patients who have recently experienced a stroke or traumatic brain injury—conditions associated with overt damage to the BBB and massive infiltration of peripheral immune cells into the brain—are at heightened risk for development of major depression (Pedroso et al., 2016; Jorge et al., 2004), suggesting depression may be causally linked with BBB damage. Understanding the mechanisms preceding appearance of these NVEs is thus of high priority for developing novel, effective treatments for depression. To address this, using multiparametric flow cytometry, we first examined the spatiotemporal dynamics of the peripheral immune response to chronic social defeat (CSD) in mice via accumulating exposure to stress. CSD stress is a well-characterized, ethologically validated model to induce depressive- and anxious-like behavior in rodents. Our results strongly imply activation and trafficking of neutrophils into the leptomeninges from circulating blood over time. Further, meningeal single

cell RNA sequencing reveals pericyte decline in CSD-stressed animals. Pericytes are a critical cellular component of the neurovascular unit that support BBB-integrity, and are sensitive to reactive oxygen species (ROS)-induced apoptosis (Amano, 2005). Work exploring the putative role for neutrophil-induced pericyte apoptosis via ROS-release as a causative pathway for BBB-breakdown is ongoing.

Title: Developmental consequences of prenatal electronic cigarette aerosol exposure on offspring behavior and neuroinflammation

Authors: *F. CHACE-DONAHUE[1], A. KAZAKOVA[1], J. S. CHURCH[1], J. L. BLUM[2], J. R. RATNER[2], J. T. ZELIKOFF[2], J. J. SCHWARTZER[1];

Abstract: In an effort to decrease the rates of smoking tobacco, electronic cigarettes (e-cigs) have been proposed as an effective smoking cessation tool. Despite the growing popularity of e-cigs, little is known about their toxicological impacts. This is particularly concerning given that e-cig use is marketed as a “safer alternative” to conventional tobacco cigarettes during pregnancy for both the mother and fetus. To examine the behavioral and developmental consequences of maternal e-cig use, pregnant female CD-1 mice were randomly assigned to one of three treatment groups (n=9 per group) and exposed daily to either filtered air (control), propylene glycol and vegetable glycerol (50:50 PGVG, vehicle), or to PGVG with 16mg/ml nicotine. Whole-body exposures were carried out for 3 hours per day throughout gestation. Adult male and female offspring from each treatment group were assessed for learning & memory deficits using the Novel Object Recognition task, social-emotional processing using the Social Approach task, anxiety-like behavior using the Elevated Plus Maze, resignation or depressive-like behavior using the Forced Swim Task, and repetitive motor stereotypies using the Marble Burying task. Nicotine-exposed male offspring exhibited hyperactivity in several tasks and reduced resignation

in the forced swim task. In addition, adult female offspring of dams exposed throughout gestation to PGVG plus nicotine displayed a small but significant increase in body weight. At the time of sacrifice following behavior measurements, male and female brains were examined for region-specific differences in cytokine expression using multiplex immunoassays to identify the neuroimmunological consequences of maternal e-cig use on offspring brain development. These findings provide substantial evidence of adverse developmental consequences of maternal e-cig use during pregnancy and persistent behavioral changes in adult offspring.

Title: Breast cancer hijacks the brain to impair memory in mice

Authors: *S. KENT[1], S. N. DE LUCA[1], A. ARMSTRONG[1], A. K. WALKER[2];
[1]La Trobe Univ., Bundoora, Australia; [2]Neurosci. Res. Australia, Randwick, Australia

Abstract: Cognitive impairment and mood-related symptoms are highly prevalent in cancer patients with non-central nervous system tumors; common symptoms include learning, memory and concentration difficulties. Until recently these symptoms have been attributed to chemotherapy (referred to as ‘chemobrain’). However, recent clinical studies show that so-called ‘chemobrain’ can present prior to cancer treatment. These findings suggest that the stress of a cancer diagnosis or the tumour itself may be responsible for cognitive impairment in some cancer patients. We recently demonstrated using mouse models of syngenic, orthotopic breast cancer that a solid peripheral tumour alone is sufficient to induce hippocampal-dependent memory impairment via (neuro)inflammation. Whether triple negative breast cancer is capable of inducing hippocampal independent memory impairment or mood-related symptoms remained unknown, and the neurocellular culprits responsible for these symptoms in triple negative breast have not been explored. Here, we investigated hippocampal-dependent and hippocampal independent fear conditioning and depression-like behaviour using sucrose preference in response to two orthotopic, syngenic mouse models of mammary adenocarcinoma. 4T1.2 tumor cells syngenic to BALB/C mice or E0771 tumor cells syngenic to C57BL/6J mice vs vehicle were injected into the left 4^{th} mammary fat pad. Tumors induced depression-like behaviour indicated by reduced sucrose preference ($p < 0.05$), and in contrast to previous findings showing poorer novel object recognition, tumours enhanced hippocampal-dependent fear conditioned memory ($p < 0.05$). No difference is hippocampal-independent memory was observed. It is

possible that increased freezing in the fear conditioning task is due to increased sensitivity to shock in tumour bearing mice caused by inflammation. Tumour bearing mice exhibited splenomegaly indicating elevated peripheral inflammation and increased microglial activation in the hippocampus ($p < 0.05$). Examination of cytokine gene expression in the hippocampus confirmed increases in pro-inflammatory cytokines *Il1b* and *Tnfa* and reductions in anti-inflammatory *Il10*. Taken together, these findings suggest that a solid peripheral tumour is sufficient to induce depression-like behaviour and modulate hippocampal-dependent memory which coincides with markers of peripheral and central inflammation. Future research should investigate whether tumour-induced neuropathy may explain differential findings between hippocampal-dependent memory tasks.

Title: A20: A predisposing factor for neurolupus?

Authors: *C. DAEMS[1], Z. CALLAERTS-VEGH[2], G. VAN LOO[3], R. D'HOOGE[2], P. CALLAERTS[1];
[1]Lab. of Behavioral and Developmental Genet., [2]Lab. of Biol. Psychology, Univ. of Leuven, Leuven, Belgium; [3]VIB-UGent Ctr. for Inflammation Res., Univ. of Gent, Gent, Belgium

Abstract: Neuropsychiatric lupus (NPSLE) refers to the neurological and psychiatric symptoms seen in patients with systemic lupus erythematosus (SLE). An important question regarding the pathogenesis of NPSLE is whether the symptoms are caused primarily by intrinsic mechanisms in the CNS or develop as a consequence of systemic autoimmunity. Even though, significant insights have already been gained from studies using SLE mouse models, none of these models are based on genes that are associated with SLE.
In this research, the influence of *TNFAIP3* heterozygosity on behavior and CNS associated defects were evaluated in a C57BL6 mouse model. *TNFAIP3* is a well-known susceptibility locus for SLE and encodes the ubiquitin-editing enzyme, A20. This protein is a strong negative regulator of the nuclear factor-κB (NF-κB) pathway. Its important anti-inflammatory function has been shown in an A20 loss-of-function mouse model, where animals died prematurely due to severe organ inflammation.
Females and males at the age of 10±2 weeks were subjected to an extensive behavioral analysis,

evaluating motor function, emotional and social behavior, cognitive function and disease-related behavior. A20 heterozygous mice ($A20^{+/-}$) showed subtle cognitive defects in comparison to wildtype littermates. Evaluation of the neuroinflammatory profile uncovered the presence of pro-inflammatory and anti-inflammatory mediators in the hippocampus of male $A20^{+/-}$ mice. The presence of a subtle cognitive deficit and the increased neuroinflammatory profile in hippocampi of A20 heterozygous mice suggests that A20 heterozygosity predisposes to deficits in brain homeostasis maintenance.
Besides a genetic predisposition, environmental factors are known to have an important contribution to the development of neuropsychiatric symptoms. In order to mimic the disease pathogenesis more closely, an immune challenge (LPS) was delivered in the cerebroventricular system. This challenge further exacerbates behavioral impairments, related to anxiety, cognitive function and sensorimotor gating. The deficits were predominantly present in females, which suggests an important contribution of hormonal factors in inflammation and behavioral changes in NPSLE.
We propose that A20 heterozygosity is predisposing for NPSLE, and that further mechanistic insight and possible therapeutic interventions can be studied in this mouse model that recapitulates key hallmarks of the disease.

Title: Differential effects of TLR4 deficiency on hippocampal neurogenesis in male and female adult and aged mice

Authors: *M. G. CONNOLLY[1], O. L. YOST[1], M. E. GIEDRAITIS[2], O. V. POTTER[3], L. S. MATHENY[1], C. E. RINDOKS[1], R. A. KOHMAN[1];

Abstract: Toll-like receptor 4 (TLR4) is primarily responsible for initiating an innate immune response following pathogen recognition. However, TLR4 is also expressed on neural progenitor cells and has been reported to regulate hippocampal neurogenesis. For instance, young male TLR4 knockout mice show increases in new cell proliferation and the proportion of doublecortin

(DCX) positive cells (Rolls et al., 2007). Currently, it is unknown if these changes are present in both sexes and persist with aging. Therefore, the present study evaluated whether TLR4 deficiency alters hippocampal neurogenesis in young (3-4 months) and aged (18-20 months) male and female TLR4 deficient (TLR4−/−; B6.B10ScN-Tlr4lps-del/JthJ) and wild type (WT) mice. New cell survival was evaluated by quantifying bromodeoxyuridine (BrdU)-positive cells in the granular cell layer of the hippocampus 32 days after BrdU exposure. Results showed that young TLR4-/- females had a greater number of BrdU positive cells than TLR4-/- males and WT females, indicating enhanced new cell survival in young TLR4-/- females. Aged WT mice showed the expected decrease in new cell survival compared to young WT mice and this deficit was maintained in the aged TLR4-/- mice. Additional measures currently in progress will determine whether TLR4-/- mice show altered new cell differentiation by comparing proportions of BrdU-positive cells that co-label with a neuron or astrocyte marker. Further, differences in proliferation rates are being evaluated by quantifying Ki-67-positive cells. Preliminary results show that the absence of TLR4 regulates new cell survival in a sex- and age-dependent manner.

Abstract: The endotoxic effect from gram negative bacteria is primarily due to the lipopolysaccharides (LPS). LPS activates the innate immune response through a Toll-like receptor 4 (TLR4) known as the CD14/TLR4/MD2 receptor complex in mammals. The Toll receptors are conserved from primates to insects. However, in insects the peptidoglycan recognition proteins (PGRPs) are the receptors which respond to LPS from gram negative bacteria. These PGRPs activate the Immune Deficient (IMD) signaling cascade. There is a

family of these receptors known in Drosophila melanogaster but their expression profiles in different tissues has yet to be fully elucidated. We examined a variety of model preparations to better understand the acute actions of exposure to LPS of Serratia marcescens to better understand the varied mechanisms of action. There is a differential, dose dependent effect of LPS in increasing and decreasing HR heart rate (HR) in the larval medicinal blow fly (Phaenicia sericata) and a fruit fly (Drosophila melanogaster). LPS depressed evoked and miniature (quantal) EJPs while hyperpolarizing the skeletal muscle in larval Drosophila, but increased EJPs with no effect on muscle membrane potential at the crayfish NMJ. Both NMJs are glutamatergic. LPS had no effect on sensory transduction of proprioceptive sensory neurons in crayfish and blue crab. LPS at the cholinergic frog NMJ depressed synaptic transmission with no effect on muscle membrane potential. LPS depressed sensory-CNS-motor nerve circuits in both crayfish and larval Drosophila. Synaptically-evoked population spikes in field CA1 of the mouse hippocampus were also significantly reduced by acute LPS applications. The varied effects of LPS in different model systems paves the way to examining differential cellular mechanisms induced by acute exposure to LPS.

Title: Optogenetic activation of dopaminergic neurons in ventral tegmental area induces peripheral immune responses

Authors: *T. KAYAMA, Y. IKEGAYA, T. SASAKI;
Grad. Sch. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: Dopaminergic neurons in the ventral tegmental area (VTA) is a main part of the brain reward system. Recent reports using a Designer Receptors Exclusively Activated by Designer Drugs technology have demonstrated that pharmacogenetical activation of VTA dopaminergic neurons induces activation of peripheral immunity system, which resulted in increases in the resistance for bacterial infection and the reduction of cancer volume (Shaanan et al., 2016;

2018). However, the pharmacogenetic method has a limited temporal resolution and it is thus impossible to precisely estimate how long and when the activation of VTA neurons was required to induce immune responses. In this study, we addressed to create an experimental system that more accurately replicates physiological conditions by utilizing an optogenetic approach. Here, we crossed DAT-Cre with RCL-ChR2(H134R)/EYFP mice, yielding a bigenic mouse line in which the expression of ChR2 is driven by dopamine transporter (DAT)-promoter, which has been proven to be dopaminergic neuron specific. In these transgenic male mice, photostimulation was applied to the VTA for 12 hours and their serum samples were collected from the caudal vein 3, 9, 24 hours after the photostimulation. The Bio-plex multiple cytokine assay system revealed that the serum concentrations of several types of immune-related cytokines were increased, compared with sham control groups, demonstrating that increased activity of dopaminergic VTA neurons leads to the activation of the peripheral immune system. Similar tests were applied to two additional mouse groups; one in which a male mouse was kept housed with a single female mouse for 10 days, and the other in which a male mouse was kept housed in an enriched environment with several toys and a running wheel for 10 days. Especially in the former animal group, but not the latter animal group, the concentrations of a subset of cytokines were increased, similar to the VTA photostimulation group. These results suggest that housing with female mice are effective to mobilize immune responses through the activation of the VTA reward system. We are now testing detailed physiological mechanisms by using a multi-channel electrode array system.

Title: The endogenous neurosteroid (3α,5α)3-hydroxypregnan-20-one (3α,5α-THP) inhibits pro-inflammatory toll-like receptor (TLR)-MyD88-dependent signaling in immune cells and brain

Authors: *I. BALAN[1], T. O'BUCKLEY[1], R. SCHLEICHER[1], G. BOERO[1], L. AURELIAN[2], L. A. MORROW[1];
[1]Univ. of North Carolina, Chapel Hill, NC; [2]Stanford Univ. Sch. of Med., Stanford, CA

Abstract: 3α,5α-THP has protective activity in addictions, depression, traumatic injury and epilepsy. These conditions are regulated by multiple TLRs, suggesting that 3α,5α-THP may

inhibit TLR signaling. We have recently shown that 3α,5α-THP inhibits TLR4 activation in RAW264.7 macrophages and the brain of alcohol-preferring (P) rats. However, its effect on other TLR signals and the potential difference between males and females, are currently unknown. We examined the effect of 3α,5α-THP on agonist-induced activation of the TLR2 and TLR7 signals, which are MyD88-dependent and the TLR3 signal, which is TRIF-dependent in RAW264.7 cells. We found that Pam3Cys (10 μg/ml; 24h) activates TLR2 signaling, evidenced by increased levels of TRAF6, pERK1/2, pCREB and pATF-2. Increased expression was completely inhibited by 3α,5α-THP (1 μM, $p<0.05$). Imiquimod (1 μg/ml; 24h) activated TLR7 signaling, resulting in pIRF7 increase (30%) that was completely inhibited by 3α,5α-THP (1 μM, $p<0.05$). By contrast 3α,5α-THP did not inhibit the Poly-IC- (TLR3 agonist; 25 μg/ml; 24h) induced increase in CXCL10, suggesting that 3α,5α-THP selectively inhibits the activation of signals that function through MyD88. Consistent with the findings for RAW264.7 cells, 3α,5α-THP inhibited MCP-1 and pIRF7, but had no effect on pIRF3 levels in P rat nucleus accumbens (NAc). We found a sex difference in baseline MCP-1 (55% higher in male vs. female) and pIRF7 (45% higher in female vs. male). In both sexes, 3α,5α-THP (15 mg/kg; IP) administration significantly reduced the levels of MCP-1 (40% in females; 25% in males) and pIRF7 (55% in males and females). 3α,5α-THP inhibition of MCP-1 levels was also found in the P rat ventral tegmental area, amygdala, hypothalamus and hippocampus, indicating that 3α,5α-THP inhibits pro-inflammatory TLR signal activation throughout brain. However, TLR activation can also increase anti-inflammatory signals and we have previously shown that P rats have significantly lower levels of the TLR4-associated anti-inflammatory chemokine CX3CL1 in the NAc than their non-alcohol preferring NP counterparts. Significantly, 3α,5α-THP administration increased the NAc levels of CX3CL1 in both female (45%, $p<0.05$) and male (30%, $p<0.05$) P rats, suggesting that it corrects a neuroimmune imbalance in P rats. Collectively, the data indicate that the 3α,5α-THP therapeutic potential involves modulation of MyD88-dependent TLR signaling pathways resulting in diminished pro-inflammatory signal activation, both in immune cells and throughout the brain.

Abstract: Background: Prior studies suggest that the neuropeptide, PACAP, is dysregulated in post-traumatic stress disorder (PTSD). Studies *in vitro* and animal models have confirmed that PACAP signaling plays an essential role in stress homeostasis. However, there is a lack of studies in humans examining longitudinal changes in PACAP in relation to experimentally-controlled trauma recall or other stressful paradigms. The anatomical distribution of PACAP suggests it may be regulated by the vagus nerve, which could explain some neuroimmune functions ascribed to PACAP. Noninvasive cervical vagus nerve stimulation (nVNS) is used experimentally in treating neuropsychiatric disorders. In the current study we examined longitudinal changes in PACAP in an experimental paradigm that also examined the influence of nVNS.

Methods: A total of 36 subjects with previous traumatic experienced were recruited (12 with PTSD diagnosis) for a multi-day double-blinded study of nVNS. After a baseline psychological and health assessment, patients were randomly assigned to nVNS stimulation or sham stimulation, and underwent a protocol that includes both trauma recall and non-personalized mental stressors. Blood was collected at baseline (day 1 before any experimental stressor or VNS) and after the stressors on days 1, 2 and 3. Linear mixed-effects models were used to assess changes in PACAP over time (in response to stressors) and its relation to the nVNS stimulation. The ratio of PACAP to baseline levels was compared over the three days of the protocol. Linear regression was used to examine the correlation between the concentrations of PACAP and other immune molecules (log-transformed).

Results: Adjusted for age, sex, BMI, race, and education level, PACAP blood levels continuously increased during the procedure (1st day: 9%, 95%CI: [1.00, 1.18]; 2nd day: 14%, 95%CI: [1.04, 1.25]; 3rd day: 15%, 95%CI: [1.03, 1.28]). This increase was consistently lower in the VNS compared to the sham stimulated group. The log PACAP concentration was significantly, positively associated with (log) IFN-γ (β=0.14, p=0.022) and ghrelin (β=0.15, p=0.05), and significantly negatively correlated with IL6 (β=-0.13, p=0.048), IL13 (β=-0.25, p=0.006), and IL5 (β=-0.27, p=0.013).

Conclusions: This is the first report of PACAP in humans undergoing a trauma recall paradigm.

Trauma or stressful tasks were associated with increased PACAP blood levels. However, the association in VNS treatment to PACAP blood levels still needs to be established in a Phase 2 study. Combined with correlated inflammatory cytokines, PACAP may be a biomarker to show or predict the treatment effect of VNS in PTSD.

Title: Inflammatory challenges inflict dramatic transcriptional responses in pituitary gland at single-cell level

Authors: *T. YAN, R. WANG, R. LIN, M. LUO;
Natl. Inst. of Biol. Sci., Beijing, China

Abstract: Immune challenges such as viral or bacterial infections cause tissue inflammations and have profound effects on the hypothalamic-pituitary-adrenal (HPA) axis. Pituitary gland is the endocrine center of the brain and is actively involved in the regulation of inflammatory events. However, very little is known about the transcriptional response of pituitary cells during immune challenge. In this study, we established inflammatory mouse models using immune stimuli such as lipopolysaccharides (LPS) and polyinosinic:polycytidylic acid (poly I:C) with a series of doses and durations, and performed single-cell RNA sequencing (Smart-seq2) on over 4000 individual cells from mouse pituitary gland. Concordantly, we identified 6 major cell clusters (Somatotropes, Corticotropes, Melanotropes, Lactotropes, Thyrotropes, Gonadotropes) in the pituitary gland with corresponding markers, which is consistent with previous knowledge. Within these cells, short-term, high-dose LPS administration invoked dramatic increase of

mRNA levels in genes related to immune response. The transcriptional state of these cells returned to normal after 3-5 weeks of recovery, but some genes appeared to be upregulated compared to control group. Pseudo-time analysis of single-cell transcriptome trajectory also confirmed that the procedure of inflammatory response was followed by recovery to normal state. The results from this study extends our knowledge of the transcriptional response of pituitary single cell during inflammatory challenge, and provide valuable information regarding the hormonal regulation with HPA-axis during inflammatory responses.

Abstract: Sleep is a physiological state defined by periods of inactivity, low sensory response and homeostasis regulation. Despite mayor advantages in our knowledge of neural circuits, genes and biological processes that underlie sleep in *Drosophila melanogaster*, the specific molecular pathways that orchestrate this response remains unknown. Previous studies have shown that peptoglycan fragments from bacterial cell walls processed by macrophages such as muramyl peptides (MPs) can induce sleep behavior. This finding combined with other recent studies suggest that macrophages play a role on sleep regulation even in the absence of infection. We have previously shown that *pumilio* (*pum*), a translational repressor, produces an abnormal sleep pattern when is knocked down. In a screen to identify the specific tissues responsible for pumilio actions on sleep, we found that *pum* knockdown in hemocytes decreases sleep, while its

overexpression increases sleep. To dissect the mechanisms by which *pum* manipulations in hemocytes change sleep, we are currently investigating the expression of hemocytes products such as antimicrobial peptides and inflammation markers using Real-time PCR. Moreover, we are examining the impact of *pum* manipulations on hemocyte levels using GFP-labeled hemocytes and fluorescence microscopy. Our studies not only support the idea of a nobel role of hemocytes on sleep regulation but also provide further insights into the mechanisms by which *pum* regulate sleep behavior.

Title: Adeno-associated virus (AAV) persistently alters cortical expression of immune genes that can regulate circuit structure and function

Authors: *C. M. SURIANO[1,2], J. VERPEUT[1,2], L. M. BOULANGER[1,2];
[1]Princeton Neurosci. Inst., [2]Dept. of Mol. Biol., Princeton Univ., Princeton, NJ

Abstract: Recombinant viruses have revolutionized neuroscience research and hold promise for human gene therapy. Viruses allow researchers to alter endogenous gene expression or insert exogenous genetic material to visualize and manipulate neural circuits. Recombinant adeno-associated virus (AAV) is among the most commonly used viruses in neuroscience, in part because it has strong neuronal tropism, is non-replicative, persists in postmitotic cells, and is nonpathogenic. Immune responses to AAV administration in the periphery can reduce viral safety and efficacy, but AAV administration in the nervous system is not typically associated with significant inflammation, possibly due to the brain's immune privileged status. However, growing evidence suggests that several immune proteins also play critical roles in neural homeostasis. Therefore, we assessed changes in the expression of immune genes and protein levels 4 days and 21 days post-AAV injection, respectively, and compared AAV-injected samples to sham-injected and unoperated controls. Here we show that unilateral injection of a virus encoding only a fluorescent marker (AAV8-*mCherry*) into adult mouse motor and somatosensory cortex significantly alters levels of immune proteins that regulate synaptic

transmission and plasticity, including the classical MHCIs H2-K and H2-D, complement component C3, and the tyrosine kinase Fyn. AAV8-*mCherry* rapidly increases *H2-K, H2-D, C3* and *Fyn* mRNA levels in somatosensory but not motor cortex. Three weeks post-injection, H2-K, H2-D, C3, and Fyn protein levels are significantly elevated in somatosensory cortex, while only H2-K and C3 levels are elevated in motor cortex. In hippocampus, which was not directly injected and showed lower viral *mCherry* expression, AAV8-*mCherry* causes rapid increases in mRNA levels for most of the genes examined but no lasting increases in protein levels. In contrast, hippocampal immune protein levels are decreased three weeks after cortical sham injections. Our results demonstrate that a form of AAV commonly used as a negative control ("empty virus") in neuroscience research significantly and persistently disrupts the expression of immune genes that can regulate neuronal structure and function. These results suggest that sham-injected and/or unoperated controls may be necessary to isolate the effects of virally-delivered tools from the circuit impacts of the neuroimmune response to the virus itself.

Title: A circadian gated spinal reflex circuit regulates LPS sensing and subsequent inflammation

Authors: *E. SOTO-TINOCO[1], E. SANTACRUZ[2], R. M. BUIJS[2];
[1]Univ. Nacional Autónoma De México, Ciudad de México, Mexico; [2]Univ. Nacional Autónoma de México, Ciudad de México, Mexico

Abstract: The autonomic nervous system (ANS) regulates the intensity of the inflammatory process in response to endotoxin, but how is the brain informed about the immune challenge has remained elusive. We hypothesized that the sensory afferent part of the ANS is responsible for sensing lipopolysaccharide (LPS) and allow the efferent ANS to modify its output towards immune organs. We show that sensory neurons located in the spinal cord become activated shortly after an LPS challenge by LPS-induced prostaglandin production. Denervation studies show that the inflammatory signal is transmitted by liver spinal and not vagal afferents. The

circadian system, which strongly influences the ANS output, imposes rhythmicity on the entrance of hepatic sensory input, establishing a differential sensitivity to LPS. This allows a high inflammatory response to happen during the active period of the animal, while attenuating its intensity during the resting phase of the animal. This study unravels the circuit used to transmit the peripheral LPS signal to the brain. Hereby, the hepatic spinal sensory nerves, strongly influenced by the circadian system, allow the immune organs to mount an efficient inflammatory response at the moment when it is most likely needed.

Title: Severe neonatal anemia in mice causes poor growth and neuroinflammation that are modulated by erythropoietin treatment

Authors: *G. SINGH, M. K. GEORGIEFF, T. GISSLEN;
Neonatology, Univ. of Minnesota, Minneapolis, MN

Abstract: Background: Premature infants are at risk for severe anemia particularly due to illness requiring frequent blood collection. Optimal treatment for phlebotomy-induced anemia (PIA) is unresolved, however recent evidence suggests that more severe anemia results in poorer neurodevelopmental outcomes. In our mouse model of PIA, we found significant neurodevelopmental deficits at adult ages and RNA-seq analysis of the hippocampal transcriptome showed an upregulation of pro-inflammatory pathways at postnatal (P) day 14. Erythropoietin (EPO) is an emerging treatment for PIA and has shown improved neurodevelopmental outcomes in neonates. EPO receptors are involved in downstream signaling of pro and anti-inflammatory pathways and therefore may play a role in modulating inflammation.
Objective: To determine the severity of neuroinflammation following severe PIA and whether erythropoietin treatment alters inflammatory phenotype.
Design/Methods: Neonatal mice were phlebotomized from P3 to P13 via facial venipuncture. Blood was drawn twice daily at 5.25 uL/g until goal hematocrit (hct) of 18% was reached and once thereafter (3.5 µL/g) to maintain Hct levels. A subset of these pups were treated with 5000 U/kg i.p. huEPO twice a day. Gene expression in the hippocampus was measured by qPCR and one hemisphere of each brain was used to obtain brain protein levels. Tissue from non-

phlebotomized pups was used as a control.
Results: PIA to hct of 18% caused significantly less growth in comparison to non-anemic controls, but growth normalized to control levels following EPO treatment. PIA increased signs of neuroinflammation resulting in a 33% increase in IL-6 concentration in the brain. Moreover, there was a 25% increase in hippocampal gene expression of the P65 NFκB subunit. After treatment with EPO, the increased IL-6 level in the brain persisted; gene expression of P50 and P65 NFκB subunits increased over non-EPO treated anemic levels. In contrast, EPO treatment caused increased concentration of the anti-inflammatory cytokines TGF-β and IL-10.
Conclusion(s): Severe anemia results in poor growth and neuroinflammation. EPO treatment of anemia improved growth and increased anti-inflammatory cytokine concentration. Activation of anti-inflammatory pathways may be one mechanism by which EPO is neuroprotective in the setting of neonatal anemia.

Title: Effects of sensory denervation on the proliferation of testicular cells

Authors: *G. LEON[1], J. C. FLORES-ALONSO[2], U. QUIRÓZ-LÓPEZ[1], R. REYES-LUNA[1], J. R. LEON[1];
[1]Facultad de Ciencias Biológicas, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico; [2]Ctr. de Investigación Biomédica de Oriente, Inst. Mexicano del Seguro Social, Atlixco,Puebla, Mexico

Abstract: Uncontrolled cell proliferation can be generated in most organs of the body, causing the formation of tumors. The testicle can also present this type of anomalies among the cells that compose it, however it is not well understood what are the mechanisms that could be regulating this change in the cells. It has been reported that sensory innervation is involved in processes of metastasis and cell proliferation in some types of cancer, such as pancreatic ductal adenocarcinoma, basal cell cancer and breast cancer. However, it is unknown if this sensory innervation, also present in the testes, participates in cell proliferation and in the development of tumors of testicular origin. Therefore, the objective in this work was to evaluate the role of sensory innervation in the proliferation of testicular cells. Twenty-four mice of the CD1 strain of 35 days of age were used, which were divided into 4 groups; Two groups were induced to proliferate testicular cells by daily administration for 4 days of aqueous extract of *Echeveria gibbiflora* at a dose of 100mg / Kg of weight intraescrotally, later one of these groups (Ext +

Caps) was denervated with Capsaicin by the administration of 125mg / kg subcutaneously, while the other group induced only received Capsaicin vehicle (Ext + Vh); a third group only received vehicle extract (Vh); and finally the fourth group was not administered any substance and it was assigned as absolute control (TA). The animals were maintained for 35 days after the administration of Capsaicin and subsequently were sacrificed. The testicles and epididymis were dissected for further analysis. The weight of the testes, motility, vitality and sperm concentration, DNA fragmentation (comet test), cell proliferation by immunohistochemistry for Ki67 and immunoexpression of CGRP (sensory fiber neurotransmitter) were analyzed and compared. Our results showed that the weight of the testes did not change significantly in any of the experimental groups. The percentage of motility and vitality as well as the concentration of sperm decreased in the Ext + Vh group compared to the other experimental groups. The fragmentation of sperm DNA was not affected in any of the groups. In the Ext + Vh group, cellular conglomerates were observed in the testis with an intense Ki67 label, in the same way the Leydig cells were positive to the proliferation label with ki67. In addition, the expression of CGRP was found to be associated with cell conglomerates as well as with Leydig cells. We conclude that the sensory innervation inhibits sperm production and inhibits its motility, which could probably also inhibit the cellular proliferation mechanisms characteristic of testicular cancer.

Title: New insight into the neuro-immune dialogue: A role for the α7 nicotinic acetylcholine receptor in mediating monocyte-derived macrophage migration

Authors: V. YAKUBENKO[1], K. CUI[1], M. M. ADDORISIO[2], D. L. WILLIAMS[1], ***V. A. PAVLOV**[2];
[1]Quillen Col. of Medicine, Ctr. of Excellence in Inflammation, Infectious Dis. and Immunity, East Tennessee State Univ., Johnson City, TN; [2]The Feinstein Inst. For Med. Res., Manhasset, NY

Abstract: The α7 nicotinic acetylcholine receptor (α7nAChR) on macrophages has a key mediating role in the neuronal control of inflammation through the vagus nerve-based *cholinergic anti-inflammatory pathway*. Genetic α7nAChR deficiency has been associated with exacerbated pro-inflammatory responses in murine endotoxemia and other inflammatory

conditions. Activation of cholinergic signaling significantly decreases TNF and other pro-inflammatory cytokine production via α7nAChR-mediated mechanisms in endotoxin-stimulated macrophages. However, the role of α7nAChR in the regulation of other macrophage functions remains poorly understood. Here we tested the hypothesis that cholinergic signaling via α7nAChR alters macrophage migration and accumulation in organs during murine endotoxemia. We studied the migration of adoptively transferred α7nAChR knockout (KO) monocytes to the liver, lung and spleen of mice after LPS-administration. Briefly, monocyte progenitors were isolated from bone marrow of WT and α7nAChR-deficient (KO) mice using negative selection with antibodies conjugated to magnetic beads. Isolated monocytes were labeled with red PKH26 (WT) or green PKH67 (α7nAChR $^{-/-}$) fluorescent dyes, mixed in equal amounts and injected in tail vein of WT mice 20 min before the injection of LPS (12 μg/ml). The development of endotoxemia was manifested by the drop of body temperature (24-30 ^{0}C) in the experimental mice. After 48 hours, lungs, livers and spleens were isolated, digested and analyzed using multicolor flow cytometry (Fortessa-X20) and imaging flow cytometry (ImageStream X Mark II). Recruited fluorescently-labeled macrophages were detected as a red positive signal in Quadrant 4 (WT macrophages) and a green positive signal in Quadrant 1 (α7nAChR $^{-/-}$). α7nAChR deficiency resulted in significantly decreased accumulation of macrophages in liver (~10 folds), lung (~4 folds) and spleen (~3 folds) ($P<0.01$). The morphology of migrated macrophage was verified by imaging flow cytometry (ImageStream X Mark II). These results indicate a role for α7nAChR in the recruitment of monocytes to the site of acute inflammation that may be associated with α7nAChR regulation of adhesive receptors on macrophages. These findings present a new mechanism of cholinergic regulation during the neuro-immune dialogue in inflammation. Further studies are required to determine the adhesive receptors, which contribute to this process, and clarify the molecular mechanism of α7nAChR-dependent monocyte/macrophage migration.

Title: Optogenetic stimulation of cholinergic neurons in the brainstem induces splenic nerve activity and attenuates systemic inflammation

Authors: A. M. KRESSEL, T. TSAAVA, E. H. CHANG, Q. CHANG, V. A. PAVLOV, K. J. TRACEY, ***S. S. CHAVAN**;

Abstract: The inflammatory reflex is a well-defined neural circuit composed of afferent and efferent fibers that travel via the vagus nerve to regulate peripheral tumor necrosis factor (TNF) production. Electrical stimulation of the efferent fibers reduces splenic TNF output in an animal model of endotoxemia. However, the exact origin of these vagus nerve fibers in the brainstem and the means by which they innervate the spleen to modulate TNF levels is not yet understood. Using optogenetics, we selectively stimulated cholinergic neurons in the dorsal motor nucleus of the vagus nerve (DMN), the autonomic brainstem nucleus from which the efferent vagus nerve fibers originate. A fiber-optic cannula was inserted using stereotactic guidance into the DMN of transgenic mice expressing channelrhodopsin under the choline acetyltransferase promoter (ChAT-ChR2-EYFP mice). Mice were subjected to either optogenetic or sham stimulation (n=20 per group) for five minutes (473nm laser, 20Hz, 25% duty cycle). After 24 hours, animals were subjected to endotoxemia by intraperitoneal administration of lipopolysaccharide (0.25mg/kg), blood was collected after 90 minutes, and serum TNF were quantitated. Optogenetic stimulation of the cholinergic neurons in the DMN of ChAT-ChR2-EYFP mice significantly decreased endotoxin-induced serum TNF levels compared to sham controls (p=0.0004). Splenic nerve activity, recorded during DMN stimulation using a cuffed two-channel electrode, was significantly increased over baseline. Administration of bupivacaine in the cervical vagus nerve eliminated this effect, implicating a functional synapse between the vagus and splenic nerves. These studies provide the first direct evidence for the central origin of the efferent vagus nerve fibers regulating TNF production during endotoxemia, and suggest novel anti-inflammatory approaches based on targeting DMV cholinergic signaling. This study was funded by NIH/NIGMS/NIAID.

Title: Trpv1 sensory nerves modulate antigen specific immune responses

Authors: *A. TYNAN[1], M. GUNASEKARAN[1], T. TSAAVA[1], E. KARA[1], S. S. CHAVAN[1,2,3], K. J. TRACEY[1,2,3];
[1]Inst. for Bioelectronic Med., Feinstein Inst. for Med. Res., Manhasset, NY; [2]Elmezzi Grad. Sch.

of Mol. Med., Manhasset, NY; [3]Donald and Barbara Zucker Sch. of Med. at Hofstra/Northwell, Hempstead, NY

Abstract: We have previously demonstrated that local sensory neurons play a role in regulating antigen trafficking through the lymphatic system *in vivo*. However, the specific subsets of sensory neurons involved are unknown. To investigate this, we characterized antigen-specific immune responses in mice selectively lacking a specific neuronal population. Here we show that TRPV1 expressing neurons are required to develop an antigen specific immune response. To understand the role of TRPV1 expressing neurons, we generated TRPV1-Cre/Lox-diphtheria toxin A (DTA) mice to specifically ablate TRPV1 expressing neurons. Specific genetic ablation of TRPV1-lineage neurons results in a failure to generate a robust antigen-specific antibody response following immunization (Anti-KLH IgG levels Day 28, Wild type 8243.64 U/ml versus TRPV1 ablated 1068.60 U/ml). However, *in vitro* stimulated B-cells from TRPV1-ablated mice produce similar levels of IgG as wild type littermate controls suggesting that there is not a B-cell intrinsic defect in TRPV1-ablated mice. Co-culture of splenocytes with sensory neurons results in an increased level of antibody production. Direct activation of TRPV1+ signals by selective optogenetic stimulation (5 minutes, 473nm laser, 10Hz, 50% duty cycle) results in a significant decrease of antigen trafficking to the popliteal lymph node as compared to sham controls (sham 11012691 AFU versus photostimulated 5330646 AFU, $p<0.05$). These findings, together with our previous studies, reveal that TRPV1-expressing sensory neurons modulate antigen-specific immune responses. This implicates a neuro-immune crosstalk in both physiological and pathological conditions, and raises the exciting possibility that the nervous system collaborates with the immune system to regulate antigen-mediated responses.

Title: Investigating subcortical regulation of systemic immunity with mass cytometry

Authors: *J. C. BORNIGER[1], E. GANIO[1], B. GAUDILLIERE[1], L. DE LECEA[2]; [1]Stanford Univ., Stanford, CA; [2]Psychiatry, Stanford Univ. Dept. of Psychiatry and Behavioral Sci., Stanford, CA

Abstract: How does the brain influence the immune system? Can we harness this connection to treat disease? A swath of studies have demonstrated that stress or fatigue can exacerbate sickness or promote disease development. Reciprocally, the placebo effect and the health benefits of meditation are real. These phenomena illustrate bi-directional control of the immune system by the brain. However, exactly how discrete parts of the brain modulate immunity remains largely unknown. Here, we use cell-type chemogenetics to activate (Gq) or inhibit (Gi) hypocretin neurons in the lateral hypothalamus and then collect blood for immunoprofiling using mass cytometry (CyTOF). Unlike flow cytometry, mass cytometry uses isotope-conjugated antibodies instead of fluorophores. This allows many more (>50) epitopes to be labeled with single cell resolution, and there is virtually no overlap between signals. We present an experimental protocol that can be used to test the role of discrete circuits in systemic immunity in an unbiased fashion. Using this protocol, we demonstrate dynamic changes in the immune system that occur in response to central neuromodulation. Future work will focus on additional subcortical circuits and investigate how deep brain stimulation in human subjects influences immune parameters.

At Mount Sinai, New York, NY; [5]Lab. of Neuroendocrinology, Rockefeller Univ., New York, NY; [6]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Although several human studies have shown correlational relationships between peripheral cytokines and aggressive traits, causal links between cytokine action in the brain and aggressive behavior have not been established. Previously, we have shown that IL-1β in the dorsal raphe nucleus has suppressive effects on aggressive behavior. Male CD-1 mice with low levels of aggression (termed non-aggressors) showed higher level of IL-1β in the dorsal raphe nucleus compared to animals with higher aggressive behavior (termed aggressors). Also, both pharmacological antagonism and genetic deletion of IL-1 receptors in the dorsal raphe nucleus caused an increase of aggressive behavior in male mice. In this study, we aimed to understand temporal changes in the levels of IL-1β during aggressive behavior. We found that there was a phasic increase in IL-1β in the blood during aggressive encounter, but this change was observed similarly in both aggressors and non-aggressors. To examine temporal change of IL-1β level in the brain, we used in vivo microdialysis to collect dialysate from the dorsal raphe nucleus and then measured IL-1β via ELISA assay. We found a differential response pattern of IL-1β level during aggressive encounter in aggressors and non-aggressors. These data also supports an involvement of endogenous IL-1β in aggressive behaviors, however, the source of IL-1β in the dorsal raphe nucleus is still not clear and requires further investigation.

Title: The vagus nerve is critical for the rapid and widespread fos response in the brain following oral administration of a physiologically active bacteria

Authors: *A. BHARWANI[1], C. WEST[1], K. CHAMPAGNE-JORGENSEN[1], K.-A. MCVEY NEUFELD[1], J. RUBERTO[1], W. KUNZE[1], J. BIENENSTOCK[1], P. FORSYTHE[2];
[2]Med., [1]McMaster Univ., Hamilton, ON, Canada

Abstract: While the literature is replete with evidence of gut-brain signalling, it is unknown which brain regions are recruited in response to bacterial signals, and how the neuronal response evolves following acute versus chronic exposure to such signals. Additionally, while several

pathways have been proposed to mediate such interactions, including neural, immune, and humoural signals, it is unclear whether bacteria recruit multiple pathways, and whether these transmit information to distinct regions of the brain.
Male Balb/c mice were orally administered a single dose of saline or a live or heat-killed preparation of a physiologically active bacterial strain, *Lactobacillus rhamnosus* (JB-1). 165 minutes later, depression-like behaviour was measured during the tail suspension test, mesenteric vagal afferent fibre firing was recorded, and c-Fos immunoreactivity in the brain was mapped. Mice also underwent sub-diaphragmatic vagotomy to investigate whether severing the vagus prevented JB-1-induced c-Fos expression. Finally, we examined the ΔFosB response and tail suspension test behaviour following acute versus chronic bacterial treatment.
Live, but not heat-killed bacteria significantly induced c-Fos expression in the basolateral and central amygdala, ventral hippocampus, periaqueductal grey, dorsal raphe nucleus, and locus coeruleus. Both live and heat-killed bacteria increased c-Fos expression in the paraventricular nucleus of the thalamus and facilitated firing of vagal fibres, absent behavioural changes. Severing the vagus prevented JB-1-induced c-Fos immunoreactivity in all regions except the ventral hippocampus and dorsal raphe nucleus. Only chronic, not acute treatment induced widespread ΔFosB in distributed brain regions, some of which previously exhibited no c-Fos response to a single dose.
These data identify regions that respond to bacteria-derived signals and highlight the differential response to acute versus chronic treatment. Moreover, the data suggest that the vagus nerve is critical for the widespread c-Fos response but also indicate the recruitment of additional signalling pathways. Future research will need to identify the gene targets of Fos proteins and their role in the observed behavioural changes.

Title: Sex differences in fibroblast growth factor 9 expression and function in dopamine neurons

Authors: *K. G. WALLIN-MILLER[1], M. L. KIELHOLD[1], D. R. KLIAMOVICH[2], B. MOGHADDAM[3];
[1]Oregon Hlth. and Sci. Univ., Portland, OR; [3]Behavioral Neurosci., [2]OHSU, Portland, OR

Abstract: Biological sex is a critical factor in the development and symptomology of most brain illnesses. Having a Y-chromosome is the single strongest risk factor for developing ADHD, autism, schizophrenia, Parkinson's disease, and substance use disorder. Notably, dopamine neurotransmission and function figure significantly in these disorders either as a primary measure of pathophysiology (e.g. Parkinson's disease) or target of effective treatments (e.g. ADHD). Recent studies have shown that organizational principals of dopamine neurons are not sexually dimorphic. The functional differences may, therefore, rely on secondary factors that are sex specific. Within the Y-chromosome, we hypothesized that a key culprit may be the SRY gene. SRY is expressed in dopamine (DA) cells and is involved in regulation of the DA system only in males. SRY is upstream of fibroblast growth factor 9 (FGF9), stimulating production of this protein, which has been implicated in male sex development. We find that FGF9 is expressed in dopamine neurons in the VTA and substantia nigra of both male and female adolescent and adults. The expression was significantly higher in males than females suggesting that this factor has important roles beyond sexual differentiation, influencing adolescent and adult brain function. Using a Cre-dependent viral knockdown of FGF9 in tyrosine hydroxylase-positive cells, we selectively inhibited expression of this protein in midbrain dopamine cells of both sexes. FGF9 infusion in adult VTA was not associated with measurable behavioral effects. FGF9 knockdown in dopamine cells of adolescents, however, causes behavioral changes in young adulthood that included increased anxiety-related behavior in both sexes and increased responsiveness to amphetamine selectively in females. FGF9 knockdown did not affect the size or number of dopamine cells present in the midbrain but led to activation of microglia supporting the notion that FGF9 has protective pro-inflammatory effects on dopamine neurons. We conclude that FGF9 contributes to dopamine-related sex differences and may be a critical factor for increased vulnerability to develop psychiatric disorders.

Title: CCL2/CCR2 chemokine system in embryonic hypothalamus: Involvement in sexually dimorphic stimulatory effects of prenatal ethanol exposure on peptide-expressing neurons in embryo

Authors: G. Q. CHANG, O. KARATAYEV, D. S. S. K. BOORGU, ***S. F. LEIBOWITZ**; The Rockefeller Univ., New York, NY

Abstract: Maternal consumption of ethanol during pregnancy is known to increase the offspring's risk for developing alcohol use disorders and associated behavioral disturbances. Studies in adolescent and adult animals suggest the involvement of both neuroimmune and neurochemical systems in the brain that control these behaviors. To investigate how these systems interact to mediate these behavioral disturbances, we recently investigated in rats (Chang et al., 2015, 2018) a specific population of neurons in the lateral hypothalamus (LH), which express the inflammatory chemokine C-C motif ligand 2 (CCL2) and its main receptor CCR2 that are positively related to ethanol intake and also co-express the orexigenic neuropeptide, melanin-concentrating hormone (MCH), which similarly promotes ethanol drinking and related behaviors. In adolescent offspring, we demonstrated that maternal intraoral administration of ethanol at low-to-moderate doses (1-3 g/kg/day) from embryonic day 10 (E10) to E15 increases the expression and levels of CCL2 and CCR2 in the LH, their colocalization with MCH, and the consumption of ethanol. We also found that these neuronal and behavioral effects of ethanol are mimicked by maternal administration of CCL2 and blocked by a CCR2 antagonist administered during pregnancy, and that they are sexually dimorphic, consistently stronger in female adolescent offspring. To understand the developmental origin of these effects, we examined in this study the effects of maternal ethanol administration (2 g/kg/day, E10-E15) on the CCL2/CCR2 and MCH systems in the LH of the embryo. At E19, we obtained very similar results to those observed in adolescent rats, with prenatal ethanol exposure increasing the expression and density of CCL2 and CCR2 cells identified as neurons and also MCH neurons and their colocalization with CCL2. We also showed these effects in the embryo to be reversed by maternal administration of a CCL2 antibody (1 and 5 µg/day, i.p., E10-E15) that neutralizes endogenous CCL2 and the receptor antagonist INCB3344 (1 mg/day, i.p., E10-E15) that blocks CCR2. Notably, we discovered that these effects in the embryo are already sexually dimorphic, consistently stronger in female than male embryos, with endogenous CCL2 in males totally unresponsive to ethanol. These results, which link the CCL2/CCR2 system both anatomically and functionally to MCH neurons in the embryonic LH, suggest an important role for this neuroimmune system in mediating ethanol's sexually dimorphic, stimulatory effect on MCH neurons that may contribute to the higher levels of adolescent risk factors for alcohol use disorders described in females.

Title: Fractalkine signaling mediates postoperative neuroinflammation and cognitive dysfunction in tibial fracture-induced model

Authors: *B.-N. KOO[1], I. CHO[2], E. KAM[2];
[1]Dept. of Anesthesiol. and Pain Medicine,Yonsei Univ. Col. of Med., Seoul, Korea, Republic of;
[2]Anesthesia and Pain Res. Institute,Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Post-operative pain is common complication after surgery and closely associated with development postoperative delirium (POD) and postoperative cognitive dysfunction (POCD). Orthopedic surgery can lead to persistent pain and remain a main cause of morbidity. The previous studies suggested regulation of neuro-immune interactions is important during neuropathic pain and fractalkine receptor, CX3C chemokine receptor 1 (CX3CR1) plays a key role in pain and inflammation. Therefore, we performed orthopedic surgery and confirmed CX3CR1 and inflammatory mediator levels in the spine and brain regions. In this study, we used a model of tibial fracture with intramedullary pinning in mice. After surgery, we assessed pain behavioral test, and cognitive/anxiety tests Also, we confirmed the levels of pro-inflammatory cytokines such as interleukin (IL)-1β, IL-6 and Tumor necrosis factor alpha (TNF-α) in the lumbar spine, and brain regions. The level of CX3CR1 was also measured in same regions. Also, treatment of gabapentin and blocking fractalkine by neutralizing fractalkine after surgery, we evaluated cognitive ability and pain symptom**.** After tibial fracture surgery, mice showed mechanical allodynia. In addition, learning and memory impairment were induced after tibial fracture compared to the control. Also, the anxiety-related behavior was increased after tibial fracture in open field test and in elevated plus maze test. The level of inflammatory cytokines, such as IL-1β, IL-6 and TNF-α, were upregulated after tibial fracture and *Cx3cr1* transcrips were upregulated at 2 days after tibial fracture. Also, treatment of gabapentin and blocking fractalkine signaling after surgery, we observed that mice showed improved cognitive ability and pain symptom. Collectively, we proved that tibial fracture surgery triggered proinflammatory cytokines and CX3CR1expressoin in the lumbar spine and brain regions. Also, this surgery induced abnormal pain hypersensitivity and cognitive dysfunction. It is likely that inflammation and CX3CR1 is mainly involved in pathology of pain-mediated cognitive dysfunction after orthopedic surgery. Consolidating results, we suggest that blocking fractalkine signaling pathway may have potential as an effective therapeutic target or prevent the induction of POCD.

Title: Regulation of plasma cell formation by splenic nerve-dependent neural activities

Authors: *X. ZHANG, B. LEI;
Tsinghua Univ., Beijing City, China

Abstract: It is increasingly clear that the immune system, traditionally thought as an autonomous system, is under regulation by the nervous system. However, it is not clear whether adaptive immune responses can be regulated by direct neural pathway instead of through the neuroendocrine route. We developed surgical splenic denervation for mouse and investigated its effect on B-cell immune responses. We verified the efficiency of our denervation by tyrosine hydroxylase staining on splenic tissue sections by immunohistochemistry. Following immunization with antigen, denervated mice produced fewer antibody-producing plasma cells than did sham-operated mice, whereas germinal center formation was not affected. These data suggest splenic nerve activities may regulate the developmental process of plasma cell formation. In probing the neurotransmitter involved, we found that acetylcholine could promote B cells to differentiate into plasma cells in vitro and in vivo, and that choline acetyltransferase-competent T cells may help relay sympathetic signals from the splenic nerve to acetylcholine-responsive B cells. We further found that expression of acetylcholine receptor, particularly the nicotinic subunit alpha9, is important for B cells to generate plasma cells of normal frequencies. Together, these results suggest neural activities propagated via the splenic nerve can regulate plasma cell formation during a T-dependent adaptive immune response. Work is ongoing to investigate brain regions that control this peripheral pathway and bodily behaviors that may invoke this neuro-immune connection to modulate immunity.

Title: Prenatal allergic inflammation affects striatal microglia, monoamine turnover, synaptic patterning, and behavioral inhibition

Authors: *K. M. LENZ, C. N. DYE, C. DODSON, R. GILFARB, A. JOSHI, A. I. SAULSBERY;
Psychology, The Ohio State Univ., Columbus, OH

Abstract: *In utero* exposure to maternal allergic or atopic conditions increase risk for neurodevelopmental disorders that are more common in males (e.g., autism, ADHD), yet little is known about how prenatal inflammation alters sex-specific brain development. We previously showed that prenatal allergen exposure programs hyperactivity and a loss of attentional flexibility in males and females, and decreased social behavior in males only. Here, we tested whether early life allergic inflammation impacts brain development via altering microglia function. Adult female rats were sensitized to ovalbumin (OVA), bred and challenged on gestational day (GD) 15. Fetal or neonatal brains were assessed for microglia number and phagocytic activity or cytokine and phagocytosis gene expression in developing medial prefrontal cortex (mPFC) or dorsal striatum. Other animals were grown to adulthood and dendritic spine density and gene expression for dopamine and histamine receptors were assessed. We found increased gene expression for interleukin 6 and the phagocytic marker CD68 in both males and females acutely post-OVA. OVA increased microglia number in the forebrain post-challenge. In the striatum, but not mPFC, on postnatal day (PD) 0, phagocytic microglia counts were increased in males, but not females. Adult striatum, but not mPFC, showed decreased dendritic spine density in both males and females after OVA exposure prenatally, but males only showed decreased striatal levels of histamine receptor 3 and dopamine receptor 2. These studies show that prenatal allergic inflammation alters microglia function and striatal development, particularly in males, and microglia may thus regulate sex-specific risk for neurodevelopmental disorders.

Title: Stretching does not improve behavioral and immune responses during sickness behavior, after stress challenge, and in healthy rats

Authors: *M. C. GALVÃO, A. C. S. SAMPAIO, P. S. RODRIGUES, C. R. SALMON, N. MOREIRA, M. M. BERNARDI, T. B. KIRSTEN;

Abstract: Yoga combines physical and respiratory techniques and meditation that stimulate well-being. It has been pointed out as a strategy against sedentarism because it not demands physical conditioning or complex infrastructure. Few studies correlate yoga practice in animal models. Stretching of the back of rats has revealed promising results after injury. However, there are no studies on behavior and well-being, which are the main focuses of yoga. The present study evaluated the use of stretching in different contexts, including in healthy rats, during sickness behavior, and after stress challenge. Adult male Wistar rats were submitted to stretching twice a day, for three consecutive days. Sickness behavior was induced by a single moderate dose of lipopolysaccharide (LPS). Psychological stress was induced by a single restraint session. Behavior of rats was evaluated in an open-field. Serum interleukin (IL-)1 beta (proinflammatory cytokine) was also evaluated. LPS decreased locomotion and rearing frequencies, increased immobility time, and increased IL-1 beta levels; i.e., LPS induced sickness behavior. Stress decreased rearing and immobility, and increased self-grooming, as well as decreased the time spent in central zone and increased the time spent in peripheral zone. LPS and stress factors presented interaction only by the decrease of the immobility of the rats. LPS and stretching factors presented interaction only by the increase of the self-grooming of the rats. There was no interaction between the other factors. In conclusion, LPS induced sickness behavior and stress induced stereotyped behavior and anxiety in rats. However, stretching seems not to have been able to ease the symptoms sickness behavior and of stress.

Title: Sex differences in the association between temperament and immune response to antigen challenge in rats

Authors: *K. C. MICHAEL[1], K. KING[2];
[2]Psychology, Biol., [1]Univ. of Minnesota Morris, Morris, MN

Abstract: Animals differ in their exploratory behavior in novel environments; some set out immediately while others are slow to leave a familiar base and return frequently to it. Previous work has shown shorter lifespan in low-exploratory male rats, but also in high-locomotive female rats. These disparities in lifespan and behavior may be driven by immune function.
We conducted two experiments, one using lipopolysaccharide (LPS) to stimulate an innate response, and another using keyhole limpet hemocyanin (KLH) to stimulate antibody production. In both studies, we observed rat exploratory behavior in two open-field arenas: one with a novel social partner and one with novel objects. Both used a tube from the cage as a home base. Rats were thus classified as high- (HE) or low-exploratory (LE). LPS Study: 12 young adult Sprague-Dawley rats, 6 female and 6 male. Rats were administered 20ug/kg of LPS or saline IP. Blood was collected from tail vein at 0, 2, 4, 6, 10, and 24 hours post-injection. track blood levels of C-reactive protein (CRP), corticosterone (CORT), and TNF-α in order to analyze individual differences in dynamics of their immune responses.
LE rats had significantly higher CORT and TNF-α levels when compared to HE rats. (t_{Cort}= 2.997, $p<0.05$; t_{TNF}=3.559, $p<0.05$). TNF-α levels were higher for both LE and HE male rats compared to female rats. Within HE rats, however, males had significantly higher TNF-α levels than females (t_{TNF}=-3.055, $p<0.05$). Male rats had higher CORT, CRP, and TNF-α responses than female rats across exploratory groups and treatment groups (t_{Cort}= 3.866, $p<0.05$; t_{TNF}=5.454, $p<0.05$; t_{CRP}=4.493, $p<0.05$).
KLH Study: 12 young adult Sprague-Dawley rats, 8 female and 4 male. Rats were injected IP with KLH at age 4 months, then re-injected 30 days later. Blood was collected from tail vein at 0, 1, 2, 5, and 14 days post-second exposure to analyze IgM antibody production.
Dynamics varied greatly - males peaked at a moderate IgM level, while females had much greater variability in both peak IgM and decline over time. In males but not in females, IgM dynamics in response to KLH were predicted by exploratory behavior: LE males produced more total IgM over 14 days.

Rats in both studies are currently living out their natural lifespans. As of this writing, LE males are trending toward shorter lifespans than HE males. Within males, there was a correlation between total IgM production and lifespan. No relationships are yet apparent for females. While small, the results of these studies suggest a sex difference in the relationship between exploratory behavior, immune function, and lifespan. This could provide new angles from which to study individual differences in health outcomes.

Title: Pathogenic infection in male mice changes sperm small RNA profiles and transgenerationally alters offspring behaviour

Authors: *S. TYEBJI[1,2,4], A. J. HANNAN[4,3], C. J. TONKIN[1,2];
[1]The Walter and Eliza Hall Inst. of Med. Res., Melbourne, Australia; [2]Dept. of Med. Biol., [3]Dept. of Anat. and Neurosci., The Univ. of Melbourne, Melbourne, Australia; [4]Florey Inst. of Neurosci. and Mental Hlth., Melbourne, Australia

Abstract: Background: Perturbations in an animal's homeostasis can induce changes in the epigenetic blueprint that regulates normal neurodevelopment. Host organisms respond to pathogenic intrusions by initiating inflammatory and immune responses, while pathogens are known to actively manipulate the host in order to survive. Recent studies indicate that such host-pathogen interactions result in long-term changes in host epigenomes. When such epigenetic reprogramming occurs in the germline, its effects may become transgenerational. Here, we used mice infected with *Toxoplasma gondii* (*T. gondii*) parasites as a model to elucidate, for the first time, whether paternal infections can induce heritable behavioural changes and impairments in offspring learning and memory. Results: *T. gondii* cysts were detectable in infected mouse testis as early as 4 weeks post-infection (wpi), along with significantly reduced sperm count and altered sperm morphology. Offspring (F1) born to infected sires showed a pronounced anxiety and depression-like phenotype, along with impaired cognition in the male offspring, while the female offspring only displayed working memory impairments, when compared to littermates

conceived from an uninfected sire. Remarkably, the anxiety phenotype persisted in the male grand-offspring (F2, via the paternal line) of infected sires. In addition, both the male and female grand-offspring displayed changes in spatial and social recognition memory. To identify the biological mechanism of these transgenerational changes, we sequenced the small RNA obtained from the sperm of infected and uninfected mice. 26% of total small RNAs observed were dysregulated in sperm from infected mice compared to that from uninfected mice. In addition, we identified significant fold changes in a large proportion (23.7%) of detected microRNAs. Pathway analysis revealed that the validated targets of the differentially expressed genes were significantly enriched in several biochemical and cellular pathways, indicating an altered developmental trajectory of embryos conceived from infected fathers. Conclusions: Our results demonstrate for the first time a transgenerationally inherited link between paternal pathogenic infections and changes in offspring behaviour. One potential epigenetic mechanism may involve modification of sperm small RNA load in response to infection.

Title: Revealing repair roles for inflammatory leukocytes in neurovascular dysfunction caused by chronic social defeat

Authors: *M. L. LEHMANN, C. POFFENBERGER, S. KIGAR, M. HERKENHAM;
NIH, Bethesda, MD

Abstract: Psychosocial stressors, which contribute to the development of affective disorders in humans, induce central and peripheral immune pathway signaling that is increasingly thought to be relevant to the pathophysiology of depression. Previously, we showed that 14 days of chronic social defeat (CSD), a model of psychosocial stress, triggered a change in blood-brain barrier (BBB) permeability coupled with the leakage of intravascular substances into brain parenchyma, i.e., microhemorrhages. Peripheral monocyte subtypes that express chemokine receptor CCR2 have been implicated in the pathogenesis of several different disease processes. This pathology includes vascular permeability associated with inflammation and microhemorrhage. We wanted to understand how $CCR2^{+}$ cells contribute to the BBB pathologies that occur in response to CSD. We found that CSD induced significant declines in behavioral tests of sociability paired with scattered microhemorrhages in brain, but it had no effect on either the anatomical distribution or

density of $CCR2^+$ cells adhered to vasculature. However, a substantial elevation in numbers of adhered $CCR2^+$ cells was detected if mice were given seven days to recover from CSD stress in a homecage environment. We hypothesized that $CCR2^+$ cells have restorative functions and are involved with mediating vascular repair in previously stressed mice. We show that $CCR2^+$ cell trafficking to the BBB is dependent on the cessation of stress but not the duration of stress. We further determined that Corticosterone (CORT) secreted during stress inhibits cell trafficking to the BBB and found that chemical adrenalectomy increased the number of $CCR2^+$ cells adhered to the BBB after CSD. The effects were further interrogated using combinations of CCR2 functional knockouts and CORT administration to determine a causal role for $CCR2^+$ cells in the repair of vascular dysfunction after CSD stress.

Title: Effects of estrogen on host gut microbial population and their metabolites in rats with chronic restraint stress

Authors: *M. XU[1], K. KROLICK[2], J. ZHU[4], H. SHI[3];
[1]Dept. of Biol., [2]Biol., [3]Miami Univ., Oxford, OH; [4]Dept. of Human Sci., Ohio State Univ., Columbus, OH

Abstract: The brain-gut axis bidirectionally communicates between the brain and the gut with diverse population of microorganisms, whose metabolites change constantly and feedback to the brain. Stress affects brain function and gut microbiome. Both female rodents and women display sex-specific stress responses dependent on estrogen status. It is unclear how the sex hormone estrogen affects gut microbial population and their metabolites when undergoing chronic stress. In this study, gut microbiota-metabolite relationship was characterized using integrated genomic analysis and MS-based metabolic profiling in rats with and without stress and estrogen. Female Sprague Dawley rats received either sham operation thus having intact ovaries and normal estrogen levels (Sham), or were ovariectomized (OVX) and received either oil (OVX+Oil) or estradiol (OVX+E2) replacement. Rats underwent either daily one-hour restraint stress or no-stress for 13 days. Gut and trunk blood were collected on the last day. Plasma corticosterone (CORT) levels from tail-bleed blood during stress were measured using ELISA. Cecum DNA was extracted for Illumina-based 16S rRNA gene sequencing to determine microbial population and LC-MS/MS-based metabolic profiling to determine microbial metabolites. Metabolic profile

was plotted using PLS-DA to show separation by using MetaboAnalyst 4.0. Stress significantly increased CORT levels of OVX+Oil rats during the entire stress period. In contrast, stress increased CORT levels of Sham and OVX+E2 rats at the beginning of the stress period comparing to their respective no-stress groups, but such increase disappeared at the end of the stress period. Microbial metabolic analysis indicated separation in major metabolic pathways between stress and no-stress rats of Sham group. Interestingly, some pathways were also separated between stress and no-stress OVX+E2 rats, but not OVX+Oil rats. Therefore, when estrogen level was reduced as seen in OVX-Oil rats, the hypothalamus-pituitary-adrenal (HPA) axis stress response persisted, as indicated by increased CORT levels throughout the stress period. However, a diminished stress response involving gut microbiota was observed, as indicated by overlapping patterns of microbial metabolites between no-stress and stress OVX-Oil rats. Normal levels of estrogen seen in Sham and OVX+E2 groups; however, relieved stress response involving the HPA axis but persisted the response involving gut microbiota. We conclude that estrogen may benefit brain-gut homeostasis, at least partially, via relieving prolonged stimulation of the HPA axis but maintaining microbial sensitivity to stress.

Sci., Univ. Autonoma de Nuevo Leon, Monterrey, Mexico; [4]Sch. of Hlth. Sci., Univ. de Monterrey, San Pedro Garza, Mexico

Abstract: Maternal overnutrition during pregnancy leads to metabolic disturbance including obesity, hyperphagia and inflammation in the offspring. It is still unknown the molecular effects of nutritional programing over inflammation and ghrelin sensitivity in the offspring. Here we aim to elucidate the role of hypercaloric diet-induced maternal programming on hypothalamic microglia activation and ghrelin-sensitive hyperphagia in the offspring. We used a nutritional programing model exposing female Wistar rats to Chow or Cafeteria diet from pre-pregnancy to weaning. We quantified daily basal and fasting-refeeding food intake, and food intake after central or subcutaneous ghrelin administration. Hypothalamic ghrelin sensitivity and microglia activation were evaluated by immunofluorescence against Iba-1 and c-Fos markers, and TBK1 pathway by western blot. Also, proinflammatory effects of palmitic acid (PAL), palmitoleic acid, stearic acid, linoleic acid or C6 ceramide incubation in microglia primary cell culture were determined by TNF-α, IL-6 and IL-1β production using ELISA assays. Finally, plasma glucose homeostasis and food intake sensitive to intracerebroventricular (i.c.v.) ghrelin (1μg/μl) administration were analyzed following PAL (40μg/μl), lipopolysaccharide (2μg/μl) or artificial cerebrospinal fluid (control) administration for 5 days. Here, we demonstrated that maternal nutritional programing by cafeteria diet exposure promotes hyperphagia in the offspring following 14h fasting and subcutaneous ghrelin injection, compared with matched controls. These effects corelate with an increased expression of microglia marker Iba-1 and neuronal activation marker c-Fos in the hypothalamus. Furthermore, we identified that 24h PAL stimulation promotes TNF-α, IL-6 and IL-1β secretion, and TBK1 activation in microglia primary cell culture. Of note, LPS and PAL i.c.v. injection for 5 days reproduces the hyperphagic effects of maternal cafeteria exposure following central ghrelin administration, which also correlates with microglia activation and neural c-Fos expression. Together, maternal nutritional programing primes hypothalamic ghrelin-sensitive hyperphagia and microglia activation in the offspring, which is replicated by palmitic central administration.

[1]APC Microbiome Ireland, [2]Dept. of Anat. and Neurosci., Univ. Col. Cork, Cork, Ireland

Abstract: Aging is defined as a slow deterioration process of various homeostatic functions throughout the lifespan. With the advance of aging, a low-grade inflammation commonly known as "inflamm-aging" occurs. This can impair various mechanisms crucial for maintaining homeostasis, particularly in the brain. A growing body of literature suggests an involvement of the gut microbiota in mediating inflamm-aging, but the effect on the aging brain remains understudied. Thus we sought to investigate the relationship between the aging brain and the microbiome. We hypothesized that transferring the microbiome of young (by fecal microbiota transplantation (FMT)) to aged mice may have a beneficial impact on inflamm-aging, and age-associated neuroimmune, neurobiological and behavioral changes. Male adult (3 months) and aged (22-23 months) C57BL/6 mice received bi-weekly FMT (young to aged, aged to aged, young to young) for 3 weeks (100 ul via oral gavage, 100 mg/ml) followed by behavioral investigations focusing on cognitive (novel object recognition, spontaneous alternation behavior, social recognition and memory, Morris Water Maze) and anxiety-like behaviour (open field and elevated-plus maze) while continuing bi-weekly FMT for additional 5 weeks. Systemic and gut-associated immunity was analyzed by flow cytometry. Neuroimmunity by immunohistochemistry to specifically investigate brain-region specific responses revealed by behavioral changes. Our data confirmed increased inflammation in aged mice in gut-associated immunity (mesenteric lymph nodes (mLNs)), the blood and the brain (hippocampus). This was distinctly alleviated by FMT from young to aged mice in mLNs targeting CD103+ dendritic cells and CD69+ T-killer cells. Ongoing analysis will investigate if FMT from young mice has also a beneficial impact on systemic and neuroimmunity in aged mice. Aged mice exhibited behavioral impairments that were ameliorated when aged mice received FMT from young mice. Further analysis will reveal if microbiota transplantation from young to aged mice is capable of modifying brain chemistry that will have implications for therapeutic interventions ameliorating age-associated functional decline. Collectively, our data contributes to a better understanding of the microbiota-gut-immune-brain axis in aging and the influence of specific microbiome manipulations in this interplay.

Title: The impact of the microbiota on acute stress induced monocyte trafficking

Authors: *G. M. MOLONEY[1], M. VAN DE WOUW[2], J. M. LYTE[3], M. BOEHME[4], T. DINAN[5], J. CRYAN[3], G. CLARKE[3];

Abstract: It is well-known that acute stress induces activation of the immune system, resulting in a mobilization of immune cells. These changes are largely due to stress-induced increases in glucocorticoids. In particular, monocytes are affected as their prevalence decreases in the peripheral circulation, indicating stress-induced trafficking into other tissues. This is important as repeated acute stressors result in an enhanced monocyte trafficking into the brain, which is often associated with neuroinflammation. As such, understanding how we can modulate stress-induced monocyte trafficking might provide novel insights into how we can attenuate chronic stress-associated neuroinflammation. The microbiota has been implicated as a promising therapeutic target for modulating immune responses, and even brain physiology and behaviour. As such, we wondered whether the microbiota could play a role in modulating acute stress-induced monocyte trafficking.Here we investigated stress-responses of male mice devoid of any bacteria (i.e., germ-free, GF), as well as GF mice colonized with a conventional microbiota (i.e., germ-free colonized, GFC). Mice were either sacrificed at baseline or underwent 15 minutes of restraint stress, after which they were sacrificed after 0, 45 or 240 minutes. Plasma corticosterone, adrenaline and noradrenaline was quantified using ELISAs. Blood and splenic monocyte subpopulations were quantified using flow cytometry. At baseline, GF mice showed elevated adrenaline, noradrenaline, and corticosterone levels, as well as decreased LY6Chigh and LY6Cmid monocytes, but not LY6Clow monocytes. Interestingly, all these changes were attenuated in GFC mice. Acute stress induced an increase in conventional, GF, as well as GFC mice. In response to acute stress, conventional mice showed an increase in circulating noradrenaline levels, which were absent in GF mice. Furthermore, stress-induced a decrease in circulating LY6Chigh and LY6Cmid monocytes, but not LY6Clow monocytes, which returned to baseline after 240 minutes in normal mice, but not GF and GFR mice. The same was observed

for splenic LY6Chigh monocytes, which are known to be continuously stored and subsequently utilized in response to an immune stimulation. These results reveal novel kinetics of monocyte subtype-specific trafficking induced by acute stress, which shows a decreased recovery when the microbiota is absent and even after subsequent recolonization. Overall, these data show a promising role for the microbiota in modulating acute stress-induced monocyte trafficking, which could have important implications in chronic stress-associated neuroinflammation.

Title: The impact of strain, sex, and early life stress on microbiota diversity, composition, and behaviour

Authors: C. FRANCELLA, J. LAI, K. RILETT, ***J. A. FOSTER**;
Dept of Behavioural Neurosci. and Psychiatry, McMaster Univ., Hamilton, ON, Canada

Abstract: Microbiota-brain communication influences behaviour and brain function. Studies have shown that microbiota composition and diversity are influenced by host genetics, diet, and other environmental factors. Inbred (C57BL/6, Balb/C, FVB) and outbred (CD1) mice were bred in house or pregnant dams were ordered from outside supplier. Mice were exposed to immune challenge with lipopolysaccharide (LPS) at postnatal day (P) 3 and maternal separation at P9 (16 h overnight). Behavioural assessment of growth and development as well as behaviour (righting reflex, ultrasonic vocalizations in response to brief maternal separation, open field, sociability and grooming) was conducted. At P24, fecal samples were collected. Microbiota composition was determined by amplifying the 16S rRNA gene variable 3 (v3) region and then sequenced using the Illumina MiSeq platform data analyzed using DADA2, a Bioconductor pipeline. Alpha and Beta diversity analyses were conducted using the phyloseq package in the R software. Strain-, sex-, and early life stress-related differences in behaviour were observed. Strain was found to be significantly associated with microbial alpha diversity among the samples (PERMANOVA $p<0.001$ for all metrics). For beta diversity, strain, sex and treatment were significant with strain contributing the greatest amount of variation ($R^2=0.19$), followed by treatment ($R^2=0.004$) and sex ($R^2=0.003$). Alpha diversity was significantly associated with

ultrasonic vocalization, sociability, and self-grooming behaviour. Additional analysis of microbiota-behaviour associations related to strain, sex, and stress are ongoing. In parallel, the role of source (in house vs supplier), operator, and co-caging/litter effects will be presented. These findings are important to determining the influence of genetic and environmental factors on gut microbiota and will advance our understanding microbiome-brain signaling pathways on neurodevelopment and behaviour.

Abstract: There is increasing evidence for a role for the gut microbiota in regulating brain, behavior and immunity across the lifespan. Aging is associated with distinct deteriorations in cognition and increases in central and peripheral inflammation. Moreover, altered microbiota diversity and composition is also a hallmark of the ageing processes. Previous studies have shown that by targeting the microbiome it is possible to affect neuroimmune signaling in midlife and in ageing. However it is unclear if the age associated changes in microbiota composition is sufficient to alter neuroimmunity.
Thus, in this study we used microbiota deficient germ-free mice as a background to assess whether age-associated microbiota can differentially impact host neuroimmunity, physiology, and behavior by transferring microbiota from aged or young mice into young germ-free mice. After four weeks of bi-weekly fecal microbiota transplant mice underwent a cognition-related behavioral test (novel object recognition), then were immediately culled. RNA from the hippocampus was isolated, purified, and sequenced to determine how an aged vs. young

microbiota alters hippocampal gene expression. Flow cytometry was performed on blood and mesenteric lymph nodes to quantify differences in systemic and gut-associated immunity which may contribute to the inflammatory phenotype commonly observed in aging.
Germ-free mice who received microbiota from an aged donor displayed an increase in trafficking receptor expression on inflammatory monocytes accompanied with a trend towards elevated systemic proinflammatory markers suggesting that the microbiota of an aged individual may mimic some of the signs of systemic inflamm-aging. Our ongoing analysis will reveal whether the transplant of microbiota from aged donor mice to young germ-free recipient mice also alters brain chemistry and other aspects of neuroimmunity differently than microbiota transplanted from young donor mice. Interestingly no change in cognitive behavior between groups was identified using the novel object recognition behavioral test.
Taken together this research will illuminate the causal significance of changes in microbiota composition in exacerbating specific aspects of aging. Moreover, it opens up the opportunity of further targeting the microbiome for generating health brain ageing strategies.

Title: The influence of the gut microbiome on fundamental synaptic neurophysiology

Authors: *K. J. O'RIORDAN, H. DARCH, B. BUTLER, R. O'CONNOR, T. G. DINAN, J. CRYAN;
Univ. Col. Cork, Cork, Ireland

Abstract: The microbiota (the trillions of microorganisms within and on our bodies) are key regulators of communication and function along the bidirectional gut-brain axis. This communication is facilitated via various routes including the immune system, the vagus nerve, and the enteric nervous system and involves direct or indirect effects of microbial metabolites such as short-chain fatty acids (SCFAs), branched chain amino acids and peptidoglycans. It is becoming increasingly evident that the microbiota are crucial in maintaining homeostasis, and that through targeting, novel therapeutic strategies could emerge.

The extent to which the microbiome can exact long-lasting neuroplastic changes in the host's brain is understudied, and currently unresolved. As a result, we examined the involvement of the microbiome in neuroplasticity from two different approaches. To start, we modelled the situation of microbial dysbiosis with altered brain concentrations of microbial metabolites. We focused on area CA1 of the murine dorsal hippocampus in a multichannel *ex-vivo* recording paradigm. Our initial findings suggest that a physiologically relevant, but high concentration of sodium acetate applied directly to slices, acutely affected LTP induction when present during the induction stimulation. Results from other microbially derived SCFAs are pending.
A powerful way to study the impact of microbiota on brain function has been via analyising the extreme situation of growing up germ-free (GF). Previous studies have shown that GF mice have alterations in arborisation, neurogenesis as well as changes in plasticity-related proteins such as brain derived neurotrophic factor in the hippocampus. In tandem with testing GF mice, GF littermates were transferred to conventional housing to re-introduce a microbiome during adulthood. Comparisons of hippocampal neuroplasticity between these groups and conventional internally-bred C57BL/6 mice highlight the impact of gross microbiome alterations during, and outside of, critical neurodevelopmental windows. Initial results indicate altered synaptic efficacy as measured by an input-output protocol, altered short-term plasticity as tested using a paired-pulse protocol, and impaired long-term potentiation (LTP) at 1 hour post theta-burst tetanus. We conclude that alterations seen in hippocampal neurophysiology must be as a result of the lack of a microbiome during critical neurodevelopmental periods, perhaps through altered synaptogenesis or axonal myelination.

Title: Sex- and timing-specific effects of antibiotic-induced microbiota depletion during murine early life: Are there critical windows in microbiota-gut-brain axis development?

Authors: *C. S. COWAN, A. VENTURA-SILVA, M. VAN DE WOUW, M. SCHVERER, E. TEICHMAN, M. G. CODAGNONE, T. DINAN, J. CRYAN;
Univ. Col. Cork, Cork, Ireland

Abstract: Childhood psychiatric and neurodevelopmental disorders are alarmingly common, yet current gold-standard treatments fall short in creating lasting, meaningful improvements for many individuals. To improve outcomes, it is imperative to enhance our understanding of pathways to disordered neurodevelopment. The current study is based on two hypotheses regarding possible pathways. The first is that problems arise due to disruption of sensitive periods of neuroplasticity. The second is that psychiatric health is closely intertwined with gastrointestinal health and immunity, and more specifically, that the microorganisms resident in the gastrointestinal tract (the gut microbiota) can influence neural, immune and behavioral outcomes.
To identify critical windows of microbial influence on neurodevelopmental outcomes, an antibiotic cocktail (ABX) was administered during one of three developmental time windows (postnatal: postnatal days [P]2-9; pre-weaning: P12-18; post-weaning: P21-27). The ABX consisted of ampicillin, gentamicin, vancomycin and imipenem to provide broad-spectrum depletion of the microbiota. Following treatment in early life, behavioral outcomes were assessed in adulthood. In terms of learning and memory, the novel object recognition test showed that pre- or post-weaning ABX, but not postnatal ABX, enhanced recognition memory in males only. In the 3 chamber social interaction test, preference for a novel social partner was decreased by postnatal ABX only in males, but by pre- or post-weaning ABX in females.
Overall, these results provide evidence that disturbance of the microbiota during specific early-life windows has long-lasting effects on behavioral outcomes, in a sex-dependent manner. Ongoing research is focusing on the neurobiological and neuroimmune basis of such effects. This supports the hypothesis that there are sensitive periods in the microbiota-gut-brain axis and sets the stage for further research to explore the neural and psychological implications of these effects.

Title: Polyphenols reverse anxious and depressive-like behaviours in the maternal separation model: A role for the gut microbiome?

Authors: *F. DONOSO[1,2], S. EGERTON[1,3], P. FITZGERALD[2], S. GITE[3], C. STANTON[3,2], T. G. DINAN[1,2], J. F. CRYAN[1,2];
[1]Univ. Col. Cork, Cork, Ireland; [2]APC Microbiome Ireland, Cork, Ireland; [3]Teagasc Food Res. Ctr., Cork, Ireland

Abstract: Stress related mental disorders, including depression and anxiety, are currently a major public health concern. In addition, accumulated evidence suggests that early life stress can exert long-lasting changes on the brain, and this early adversity is associated with increased risk for developing depression in adulthood. The maternal separation model in rats is a robust paradigm to study the effects of early life stress, which presents a consistent depressive and anxious phenotype in adult animals including microbiota imbalance. On the other hand, natural phytochemicals known as polyphenols have demonstrated therapeutic potential in treating stress related disorders and affecting microbiome composition. However, the underlying mechanisms are unclear. Therefore, we decided to investigate the potential antidepressant and anxiolytic effects of polyphenols in maternally separated male rats. Sprague Dawley rats were separated from their mothers (MS) 3 hours per day during postnatal day 2 through 12, and compared to a group of pups that were not separated (NS). At 8 weeks of age, MS and NS male rats underwent a dietary intervention with the naturally-derived polyphenols xanthohumol and quercetin, as well as with a phlorotannin extract (polyphenol-enriched fraction) and fluoxetine, for 8 weeks (n = 10 per group). MS rats showed increased immobility time and reduced swimming time in the forced swim test compared to NS rats, which is associated with depressive-like behaviour. In addition, MS rats showed increased anxiety in the open field test by spending less time in the centre of the arena compared to NS rats. Intriguingly, treatment with quercetin, xanthohumol and the phlorotannin extract prevented these MS-induced depressive and anxious-like behaviours. Maternal separation is also associated with alterations in the hypothalamic-pituitary-adrenal (HPA) axis and elevated concentrations of glucocorticoids. Therefore, we examined the effects of polyphenols on HPA axis regulation. As expected, MS rats showed increased release of corticosterone in plasma compared to NS following acute stress, which was inhibited with xanthohumol treatment. Thus, these results suggest that polyphenols have potential

antidepressant and anxiolytic effects in MS rats that could be partially mediated by modulation of the HPA axis. Current studies are investigating the effects of polyphenols in modulating neuroimmune pathways, the neurochemical balance of monoamines, and the potential implication of the gut-microbiota-brain axis in polyphenol mediated improvements in depressive and anxious behaviours in MS rats.

Title: Inducible co-stimulatory molecule (ICOS) alleviates astrogliosis and attenuates chemotherapy induced-peripheral neuropathy in mice

Authors: *I. SANKARANARAYANAN[1], D. FERREIRA-TAVARES[2], G. L. MEJIA, JR[2], C. PAIGE[3], M. D. BURTON[4], T. J. PRICE[5];
[1]Sch. of Natural Sci. and Mathematics, [2]Sch. of Behavioral and Brain Sci., [3]Cognition and Neurosci., [4]Behavioral and Brain Sci., Univ. of Texas At Dallas, Richardson, TX; [5]Sch. of Behavioral and Brain Sci., UTD, Richardson, TX

Abstract: Paclitaxel is a chemotherapy drug used to treat breast and ovarian cancer. The primary dose-limiting side effect of paclitaxel is a peripheral neuropathy that is caused by damage to peripheral nerves and the dorsal root ganglia (DRG). This neuropathy often results in neuropathic pain for which there are no effective treatments. Neuronal-immune interactions occur in chemotherapy-induced peripheral neuropathy (CIPN) and have been implicated both in the development and progression of disease as well as in disease resolution. Based on previous studies suggesting that T cells play an active role in CIPN resolution, we investigated the potential role of ICOS (Inducible co-stimulatory molecule), an immune checkpoint molecule that is expressed on the surface of activated T cells, as a costimulatory mechanism for the resolution of CIPN. First, we observed an increase in the number of T cells in paclitaxel treated mice in lumbar DRG when compared to control animals. We found that intrathecal administration of ICOS agonist antibody alleviates mechanical hypersensitivity caused by paclitaxel and advances the resolution of pain in female mice. Paclitaxel treatment caused a robust astrocytes gliosis in the spinal dorsal horn and a satellite glial cell gliosis in lumbar DRG. We did not observe signs of microgliosis in the spinal cord with paclitaxel treatment. Administration of ICOS agonist

antibody reduced astrocyte and satellite cell gliosis in mice that were treated with paclitaxel. Our findings support a model wherein ICOS agonist antibody, upon engagement with T cells, induces an expansion of anti-inflammatory cytokines such as IL10, IL4 that facilitate the resolution of paclitaxel-induced peripheral neuropathy.

Title: Impact of zinc supplementation associated with cafeteria diet on recognition memory in rats

Authors: *S. D. OLIVEIRA[1], J. P. NETO[1], G. S. FEIJÓ[1], J. JANTSCH[1], R. M. ARENA[1], B. F. DENIZ[1], M. GIOVENARDI[1], M. PORAWSKI[2], R. P. GUEDES[2];

Abstract: Introduction: Obesity triggers a systemic pro-inflammatory profile, which affects the central nervous system, predisposing the development of neurological diseases. Zinc is a mineral with potential anti-inflammatory action, thus it may play a role as a neuroprotective agent in obesity.
Objective: To evaluate the effects of zinc supplementation on metabolic parameters and memory of Wistar rats that received cafeteria diet.
Materials and Methods: This study was approved by the IACUC 570/18. Twenty-eight Wistar rats were divided into 4 groups: standard diet (SD); SD+ zinc; cafeteria diet (CAF); CAF+zinc; The diet was administered for 20 weeks and zinc treatment started from the 16th week until the end of the diet protocol. The memory was evaluated by the novel object recognition test and the recognition index was calculated. Weight gain and visceral fat were quantified. Insulin, glucose and triglycerides levels were evaluated in the plasma, as well as TNF-alpha levels in plasma and liver. Data were evaluated by two-way ANOVA followed by Bonferroni test considering $p<0.05$ as significant.
Results and Conclusion: Animals that received CAF showed higher weight gain and visceral fat than SD. CAF also caused an increase in insulin, glucose and triglycerides in the plasma. TNF-

alpha was also increased in the plasma and in the liver of obese rats. Zinc supplementation did not provide any beneficial effect on these parameters. However, in the object recognition test, obese animals presented a worse performance, and zinc treatment was able to reverse this deficit. Thus, our results demonstrate that zinc supplementation is not sufficient to avoid metabolic dysfunction caused by cafeteria diet, but it may be important to decrease memory deficits caused by obesity.

Title: Effects of BCAA or Zinc supplementation on neuroinflammatory parameters of obese rats

Authors: *R. P. GUEDES, G. S. FEIJÓ, S. DE OLIVEIRA, J. JANTSCH, L. F. DE CASTRO, B. FERRARY DENIZ, A. C. DE MOURA, M. GIOVENARDI, M. PORAWSKI;
Federal Univ. of Hlth. Sci. of Porto Alegre, Porto Alegre, Brazil

Abstract: Obesity is characterized by a production of pro-inflammatory mediators that leads to neuroinflammation. Among a range of commercial supplements which have known immune properties, we can highlight Zinc (Zn) and the branched chain amino acids (BCAA). Here, we aim to evaluate if 4 weeks of Zn or BCAA supplementation can affect memory and neuroinflammation in obese rats. Wistar rats were divided in the following groups: standard diet (SD); SD+Zn; SD+BCAA; high-fat diet (HFD); HFD+Zn; HFD+BCAA (n=6/group). The diet was administered for 20 weeks and the supplementation with BCAA (750mg/kg/day) or Zn (1,2 mg/kg) was performed by gavage from the 16th week. The study was approved by the local ethical committee (protocol #536/17). Object recognition memory (recognition index, IR); Immunohistochemistry for GFAP and gene expression (IL-6 and TNF-α) were evaluated. The results were analyzed by two-way ANOVA followed by Bonferroni ($p<0.05$). There was an interaction between diet and supplementation in the IR ($p=0.0069$), Zn supplementation reverted the memory impairment caused by HFD. No differences were found in IL-6 gene expression in cerebral cortex and hippocampus. TNF-α gene expression in hippocampus was increased

following HFD (p=0.0069). The number of astrocytes in cerebral cortex was reduced following HFD (p=0.0001) without an effect of Zn or BCAA supplementation. In hippocampus, dentate gyrus (DG) and CA1 areas showed a decrease in GFAP-positive cells in HFD-fed rats after Zn or BCAA supplementation (DG: p=0.0021; CA1: p=0.015). Sholl analysis showed that HFD decreased the number of primary ramifications (p<0.0001), total length of the longest ramifications (p<0.0001) and the total number of intersections of astrocytic processes (p<0.0001) in the cerebral cortex. Also, in the DG there was an interaction in the number of intersections (p=0.037), Zn prevented the increase in the number of intersections after HFD. In CA1, there was an interaction in the total length of the ramifications (p<0.0001), BCAA prevented the decrease in the length of ramifications after HFD. Zn supplementation is able revert the memory impairment caused by obesity. However, neither Zn nor BCAA supplementation were capable to dampen HFD-elicited neuroinflammation.

Abstract: Introduction: Inflammatory mediators released by adipose tissue in obesity can trigger a neuroinflammatory profile that culminates in behavioral changes and neurological diseases. Evidence suggests that omega-3 (n3) plays an anti-inflammatory role by binding on its receptors GPR40 and GPR120. Activation of these receptors in the central nervous system may play a role in neuroprotection. **Objective:** To evaluate the effects of n3 supplementation associated with cafeteria diet in behavior and metabolic profile in Wistar rats.**Methodology:** 48 Wistar rats (IACUC/UFCSPA 117/13) were divided into 4 groups: CT (control diet); CT+n3; CAF (Cafeteria Diet); CAF+n3. The diet was administered for 20 weeks, with supplementation

starting at the 16th week. Weight gain and visceral fat were quantified; plasma levels of glucose, triglycerides and insulin were measured. Elevated plus maze and social recognition memory were conducted. Data were evaluated by two-way ANOVA followed by Bonferroni ($p<0.05$ considered significant), with exception of social recognition memory test that was analyzed by t-test. **Results:** CAF and CAF+n3 groups presented a significant increase in the weight gain and in the visceral fat depot ($p=0.0001$) compared to the control groups. CAF groups presented higher levels of glucose ($p=0.0001$) and triglycerides ($p=0.0001$) compared to the control groups. In behavioral tests, CAF group showed a lower permanency in the open arms in the elevated plus maze compared to the other groups, suggesting that untreated obese rats presented anxiety-like behavior. The percentage of the interaction between the 4th exposure of the juvenile rat 1 and the only exposure of the juvenile 2 in the social memory test did not present a statistically significant difference between CT groups (CT: $p=0.818$; CT+n3: $p=0.264$). The CAF and CAF+n3 groups interacted more with the juvenile 2 compared with the 4^{th} exposure of the juvenile rat 1 ($p=0.033$, $p=0.040$, respectively).**Conclusion**: Omega-3 supplementation does not provide a protection in metabolic parameters following cafeteria diet, but it exerts an interesting effect on the CNS by reverting the anxiety-like behavior in obese rats. In addition, cafeteria diet may increase social memory but n3 does not interfere in this type of behavioral response.

Title: Social enrichment attenuates chemotherapy induced neuroinflammation and affective behavior via oxytocin signaling

Authors: *W. H. WALKER, II[1], A. C. DEVRIES[2];
[1]Neurosci., [2]Med., West Virginia Univ., Morgantown, WV

Abstract: Patients receiving chemotherapy frequently display increases in anxiety and depression. However, the precise mechanism for chemotherapy-induced neuropsychological effects remains unknown. We hypothesized that chemotherapy increases neuroinflammation; thus, altering anxiety-like and depressive-like behavior. Adult (>8 weeks) female Balb/C mice received two injections, separated by two weeks, of vehicle (0.9% saline) or chemotherapeutic

cocktail (9 mg/kg doxorubicin (A) and 90 mg/kg cyclophosphamide (C)). Following the second injection tissue was collected at one of four timepoints (day 1, 3 ,5 or 7). Mice displayed increased peripheral inflammation one day following, and neuroinflammation seven days following, the completion of one cycle of dose-dense AC therapy. Because of the demonstrated beneficial effects of social enrichment on a multitude of diseases, we examined whether social enrichment could attenuate the increase in peripheral and central inflammation following chemotherapy administration. Singly housed mice receiving AC therapy display increased depressive-like (forced swim test) and anxiety-like (open field test) behavior with a concurrent increase in neuroinflammation and reduced neurogenesis. Pair housing mice throughout chemotherapy treatment lead to an attenuation in neuroinflammation, depressive-like behavior, and loss of neurogenesis. The beneficial effects of social enrichment have previously been associated with increased oxytocin signaling within the brain. Therefore, we sought to determine if ICV administration of oxytocin to singly housed animals could recapitulate the protective effects of pair housing. Indeed, administration of oxytocin to singly housed mice receiving chemotherapy mirrored the effects of pair housing. Additionally, administration of oxytocin antagonist to pair house mice receiving chemotherapy increased depressive-like behavior; thus, mirroring the effects of single housing and demonstrating a potential role for oxytocin. Together, these data add to the growing literature detailing the negative side effects of chemotherapy and provide further evidence that social enrichment may be beneficial in offsetting some of the adverse side effects.

Title: Prenatal immune activation via TLR7 induces sex-dependent behavioral and neurophysiological alterations

Authors: *G. MISSIG[1], J. O. ROBBINS[1], E. L. MOKLER[1], N. MEHTA[1], C. J. MCDOUGLE[2], W. A. CARLEZON, Jr[1];
[1]McLean Hosp., Belmont, MA; [2]Psychiatry, Harvard Med. Sch., Lexington, MA

Abstract: Epidemiological evidence indicates that immune activation during pregnancy via infection or autoimmune disease is a risk factor for neuropsychiatric illness. Work from our lab and others has demonstrated that prenatal immune can cause long-lasting behavioral and neurophysiological alterations in offspring. Previous prenatal immune activation protocols have primarily involved administration of agents to mimic infection that target subtypes of the toll-like receptor (TLR) family, a class of receptor proteins that regulate innate immune responses. As examples, TLR3 recognizes Poly I:C and TLR4 recognizes lipopolysaccharide (LPS). In this study we examined the role of TLR7 in prenatal immune activation, considering evidence that this receptor subtype is implicated in the etiology of autoimmune diseases. We administered subcutaneous injections of the selective TLR7 agonist imiquimod (IMQ, 5.0 mg/kg) or vehicle to timed-pregnant dams (C57BL/6J mice) on embryonic days (E) 12, 14, and 16. Mice exposed to prenatal IMQ exhibit a behavioral phenotype characterized by decreases in anxiety-like behavior, a fragmentation of social behavior, and alterations in ultrasonic vocalizations. This phenotype is readily distinguishable from those seen following prenatal activation of TLR3 and/or TLR4. Mice exposed to prenatal IMQ have normal baseline locomotor activity but are hyperactive in response to various types of stimuli including the presence of a social partner, circadian cues, or gonadal hormone fluctuations. Overall, underlying this phenotype is a propensity for "conditional hyperactivity", reflected by an exaggerated response to some types of internal and external stimuli. Additionally, prenatal IMQ exposure causes a decrease in microglia density and an increase in the number of microglia ramifications in numerous brain areas, with particularly strong effects in striatum. RNA-sequencing of the dorsal striatum revealed that prenatal IMQ exposure induces differential expression of hundreds of genes with virtually no overlap in differentially expressed genes between males and females. Considered with the existing literature, our findings suggest that early immune system activation can promote various—and sometimes even opposite—developmental trajectories, depending on the type and/or pattern of TLRs activated.

Title: The limited bedding and nesting paradigm as a naturalistic model of postpartum depression

Authors: *R. DELLA VALLE, J. M. SCHWARZ;
Univ. of Delaware, Newark, DE

Abstract: The Limited Bedding and Nesting (LBN) paradigm has been widely used to study the effect of adverse early experiences on brain development and behavior in the affected offspring, but very few studies have examined how limited resources in the peripartum period affect dams outside of documenting their disrupted maternal care. Postpartum depression affects around 15% of mothers, and suicide associated with postpartum depression is one of the leading causes of maternal death in first world countries. Key risk factors for postpartum depression include low social support, low socioeconomic status, unemployment, and negative life events during pregnancy. All of these risk factors have a common theme: psychological, social, or physical resource scarcity, suggesting that the LBN paradigm could provide a novel and naturalistic model for examining its effects on the risk of postpartum depression using rodents. Pre-clinical research on post-partum depression (PPD) has until now focused largely on the contributions of sex hormones and psychosocial stress, with very little focus on the impact of inflammation despite the growing body of evidence that inflammation may contribute to depression. Previous research in our lab has repeatedly demonstrated anhedonic behavior in unstressed dams at P1. This anhedonia is associated with elevation of the pro-inflammatory cytokine IL-6, and is rescued by pre-treatment with an IL-6 receptor antibody. We have also demonstrated postpartum changes in CNS inflammation and microglia density as well as changes in peripheral immune function. The current project aims to explore whether using chronic LBN as a stress paradigm during and following pregnancy provides more robust, chronic changes in anhedonic behavior, and whether these are associated with changes in inflammatory state caused by either the peripartum period itself, or LBN stress.

Singapore, Singapore; [3]Dept. of Microbiology and Immunol., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Congenital Zika virus (ZIKV) exposure is associated with fetal brain microcephaly and other serious birth defects. However, adult ZIKV infection and its consequences on brain function and behavioural change are largely unknown. Here, using the established type-I interferon receptor knockout (A129) mouse as well as wild-type B6 mice, we evaluated long-term neuropathological and behavioral consequences of adult ZIKV infection in mice. ZIKV infection in wild-type B6 mice did not trigger any behavioral deficits due to lack of viral replication in the brain. In contrast, ZIKV infection in A129 mice resulted in normal motor function and behaviors, except for increased stereotypy and repetitive behaviors. And this specific behavioral change observed in ZIKV-infected A129 mice could be rescued by small molecules that block viral replication. Taken together, adult ZIKV infection can result in specific behavioral changes in mice if ZIKV replication can be persisted, but did not result in neurological change Guillain-Barré Syndrome (GBS)-like manifestations.

Abstract: The activation of maternal immune system by a prenatal infection during pregnancy is a risk factor to develop psychiatric disorders in the offspring. One of the pathogens associated with considerable number of mental disorders, is the parasite *Toxoplasma gondii.* Epidemiological studies have shown the presence of high levels of IgG anti-*T. gondii* in neonates and young adults who later developed schizophrenia. The absence of the parasite and the high

levels of IgG's found in those patients suggest the transplacental transfer of anti-*T. gondii* IgG antibodies, which could bind fetal brain structures possibly due to molecular mimicry inducing alterations in neurodevelopment. The objective of this study was to determinate if the behavioral impairment observed in progeny of rats immunized with *Toxoplasma gondii* are related with the formation of pathogenic antibodies which can alter neuronal processes during the gestation. The female rats were immunized three times (one per week) with the *Toxoplasma gondii* lysate or PBS three weeks before gestation. At day 18 of gestation, fetus brains were obtained and fixed in 4% paraformaldehyde, dehydrated and embedded in paraffin to search for IgG joined to brain structures by means of immunofluorescence assay, using an anti-rat IgG-Cy5 antibody. Additionally, serum of the control female rats and immunized rats was obtained, in order to look for antibodies able to recognize brain proteins also by using immunofluorescence assay. Fetus brains from immunized mothers showed presence of antibodies joined to brain structures that were recognized by the anti-rat IgG-Cy5, while control group did not show any change. Serum of female immunized rats also reacted with normal fetus brains, but it was not found reactivity with the serum from control group. These results suggest the formation of pathogenic antibodies induced by *T. gondii* immunization, with ability to pass toward brain of fetus during gestation and this impacts behavioral profile of the progeny.

Univ., Taipei, Taiwan; [6]Psychiatric Res. Center,Taipei Med. Univ. Hosp., Taipei, Taiwan

Abstract: FK506-binding protein 51 (FKBP51) encoded by the *Fkbp5* gene is a negative feedback co-chaperone of glucocorticoid receptor (GR) and has been linked to many stress-related mental disorders involving dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis. Peripheral inflammation has been suggested as a pathogenic inducer for anxiety disorder, but the role of FKBP51 in the inflammation-associated anxiety remained unknown. Here we used *Fkbp5*-deficient (*Fkbp5*-KO) mice treated with a single intraperitoneal injection of lipopolysaccharide (LPS) to study the behavioral and neurochemical changes after transient peripheral inflammation. We found that *Fkbp5* deletion did not affect LPS-induced transient sickness, whereas significantly increased anxiogenic response, not locomotor hypoactivity, in both open-field test and elevated plus maze test performed 7 days after the LPS injection. LPS injection induced a transient inflammation as well as glucocorticoid-mediated stress responses in both liver and hippocampus by increasing their *Tnfa* and *Fkbp5* gene expressions, respectively; and *Fkbp5* deletion attenuated the inflammatory response only in the hippocampus but not in the liver. The *Fkbp5*-dependent hippocampal inflammation is followed by a delayed upregulation of GR in the hippocampus, and this response was diminished in *Fkbp5*-KO. Neurochemical changes further revealed that LPS injection induced a *Fkbp5*-dependent elevation of hippocampal glutamic acid decarboxylase 65 (GAD65), the inhibitory GABA synthesizing enzyme, whereas $GABA_A$ receptor, serotoninergic $5HT_{1A}$ receptor or excitatory NMDA receptor subunits were not affected. In sum, these results suggest that FKBP51 may regulate immune-mediated hippocampal GR and GABAergic neurotransmission, thereby dampen the anxiety and stress susceptibility secondary to acute peripheral inflammation.

Theme and SAHMRI Microbiome Res. Lab., South Australian Hlth. and Med. Res. Inst., Adelaide SA, Australia

Abstract: Neuroinflammatory pathways have been implicated in major depressive disorder (MDD) development and antidepressant response. Decreasing pro-inflammatory signaling may be beneficial to MDD, and dysregulation in three major inflammatory systems has been described in this condition: i) low-grade chronic pro-inflammatory status with caspase 1 (CASP1) overproduction, ii) interferon gamma (INFG) over production driven by type 1 T helper (Th1) cells, and iii) increased oxidative stress with nitric oxide (NO) overproduction by NOS2 (NO synthase 2). We investigated the effect of simultaneous deficit in these 3 pro-inflammatory pathways in depressive-like behavior and the gut microbiome using a triple knockout mouse model lacking CASP1, INFG receptor, and NOS2 (Casp1, Ifngr, Nos2)-/-. At baseline, these animals showed decreased depressive- and anxiety-like behavior, and increased hedonic-like behavior and locomotor activity. They were resistance to developing anhedonic-like behavior and had a heightened emotional state following stress compared to wild-type (wt) mice. Plasma ACTH and CORT levels did not differ between the triple knockout and wt mice following chronic stress. Fecal microbiota differed in this mouse model in comparison to wt mice at baseline and showed reduced changes in response to chronic stress. Concomitant deficit in multiple pro-inflammatory pathways has antidepressant-like effects at baseline and confers resilience to stress-induced anhedonic-like behavior. Gut microbiome composition changes suggest that CASP1, IFNGR and NOS2 play a role in sustaining microbiome homeostasis.

Title: The role of gut microbiota in chemotherapy-induced anxiety-like behavior

Authors: A. LAHOUD[1], K. JORDAN[1], B. HAYNES[1], S. VICKERY[1], J. KAUR[1], K. A. SULLIVAN[2], ***L. M. PYTER**[1];
[1]Ohio State Univ., Columbus, OH; [2]Neurosci., The Ohio State Univ., Columbus, OH

Abstract: The gut microbiome influences neurobiology and anxiety-like behavior in rodents. Anxiety is a common behavioral symptom of cancer patients, often attributed to peripheral

inflammation after chemotherapy. Chemotherapy also has adverse effects on the intestines (e.g., diarrhea, shifts community structure of the gut microbiota). However, little is known about the potential role of the gut microbiome in chemotherapy-induced anxiety. This work assessed the causality of chemotherapy-induced shifts in the gut microbiota on anxiety-like behavior. Gut microbiotal alteration was induced by feeding C57Bl/6 mice broad-spectrum antibiotic-containing chow (or control) for one week prior to and during paclitaxel chemotherapy treatments (30 mg/kg; i.p.; every other day for 6 injections) or vehicle (n=10/group). Anxiety-like behavior was tested using the open field test immediately or one week after treatment; body mass and food intake were recorded throughout. Antibiotics modulated sickness behavior (not anxiety-like behavior) such that fatigue and hippocampal (CXCL10, CCL2) and peripheral (IL-1, CXCL1, IL-6) inflammation were exacerbated in chemotherapy+antibiotic-treated mice relative to chemotherapy controls, whereas antibiotics did not affect behavior/inflammation in vehicle-treated controls. These results suggest that the gut microbiota modulates inflammation and behavioral changes after chemotherapy.

Title: Chronic inhaled corticosteroids during development minimize allergic asthma symptoms but exacerbate comorbid anxiety symptoms

Authors: *S. A. CAVIGELLI, J. CAULFIELD, H. KAMENS;
Pennsylvania State Univ., University Park, PA

Abstract: Allergic asthma is the most common chronic condition for developing youth. The condition occurs during significant brain maturation, and is often comorbid with internalizing disorders, particularly anxiety. In a mouse model, we have found that experimentally-induced allergic asthma symptoms during development lead to adult anxiety-related behavior and serotonergic (5-HT) and corticotropin-releasing hormone (CRF)-related gene expression in emotion regulation brain areas. In the current study, we tested whether chronic inhaled corticosteroids (ICS), frequently used to control allergic asthma symptoms in youth, exacerbate or diminish developmental allergen-induced adult anxiety-related behavior and gene expression. We bred Balb/cJ mice and assigned same-sex littermates to one of 8 conditions in a 2x4 study

design (2: allergen vs. vehicle exposure 3 times/week during postnatal days 7-56; 4: vehicle vs. low- vs. mid- vs. high-dose ICS exposure 3 times/week during postnatal days 21-56). Results indicate that chronic low- and mid-dose ICS treatment during development attenuated allergen-induced lung inflammation ($p<.05$), and significantly increased anxiety-related behavior on the elevated plus maze ($p<.05$). We are analyzing 5-HT- and CRF-related gene expression in the prefrontal cortex and ventral hippocampus. ICS doses also led to decreased body weight, which is a well-documented side effect of ICS treatments in children, suggesting that the intranasal steroid treatment in a mouse model may mimic ICS treatment in children. Overall, results indicate that one of the most common maintenance regimens for allergic asthma in youth may exacerbate asthma-associated anxiety symptoms.

Title: The impact of developmental chronic variable social stress and asthma on anxiety-like brain gene expression, anxiety-like behavior, and stress response

Authors: *J. I. CAULFIELD, H. M. KAMENS, S. A. CAVIGELLI;
The Pennsylvania State Univ., University Park, PA

Abstract: Allergic asthma is the most common chronic condition diagnosed in children (9.5 percent of youth under 18yrs). Individuals with asthma have a significantly increased risk for developing an anxiety disorder compared to people without asthma, and this comorbidity can occur as early as adolescence. Asthma is highly prevalent in urban areas, and many aspects of urbanization impact the risk for developing/worsening of asthma. Social interactions are an important aspect of healthy living, and chronic social stressors (isolation and reorganization) that are part of urban environments negatively impact health. Minimal research has focused on how the social stress component of urban environments affects asthma and comorbid anxiety development. Here, we examine BALB/cJ mice as adults after developmental exposure to house dust mite (HDM; 3 exposures per week from postnatal day [P] 7-56) and chronic variable social stress (CVSS; 5 weeks of repeated cycling between isolation and social reorganization from P25-59). We examined general anxiety-like behavior using the elevated plus maze (EPM) and social anxiety-like behavior using the Social Approach-Avoidance Test (SAAT) on P66 and P71. Females exposed to HDM tended to spend more time on the open arms of the EPM compared to

vehicle females, whereas males exposed to HDM tended to spend less time on the open arms than vehicle males (p=0.07). In the SAAT, with the social target present, mice that experienced CVSS made fewer entries into the interaction zone compared to controls (p=0.035), but time spent interacting was not different between groups. At P76, we collected lung, prefrontal cortex, and hippocampus to examine immune and stress-related RNA gene expression and protein changes following these chronic developmental challenges. Corticosterone (CORT) was also measured from serum in response to a restraint stress challenge. Since preliminary results suggest that HDM exposure results in a lower baseline CORT level compared to vehicle, here we expect the CORT response to restraint stress to also be blunted vs. vehicle. The results from this study will provide important insight into a potential mechanism for how asthma is linked to anxiety in an at-risk population, which could inform future treatments for patients.

Title: Investigation of early exposure to clomipramine on central inflammatory markers in maternal and non-maternal Sprague-Dawley rats

Authors: *C. M. RAGAN, B. N. REGULA, L. M. GIELDA;
Purdue Univ. Northwest, Westville, IN

Abstract: Hormonal fluctuations that occur during the peripartum period can lead to alterations in brain chemistry that result in postpartum mood and anxiety disorders. Furthermore, these brain and behavioral differences observed during the postpartum period may be a result of early-life perturbations in development. Recent research has highlighted the role of the immune response in the pathogenesis of these mood and anxiety disorders in non-maternal populations. In non-maternal populations, inflammation in brain regions such as the orbitofrontal cortex (OFC) is 30% higher in people with obsessive-compulsive disorder (OCD) compared to healthy controls. Less is known about inflammation in the brain of postpartum females. Using a pharmacologically-induced model of OCD in Sprague Dawley rats, twice daily we exposed pups to the tricyclic antidepressant, clomipramine, during postnatal days 9-16 or a saline control. We observed that during the postpartum period, rat mothers previously-exposed to clomipramine during early development engaged in more passive nursing postures and more OCD-like behavior compared to control dams. The rat mothers that experienced early exposure to

clomipramine also expressed more pro-inflammatory IL-1 beta in the OFC compared to saline control dams. Our findings suggested that increased inflammation in the OFC may be a mechanism associated with OCD behavior in maternal and non-maternal populations.

Abstract: Breast cancer survivors exhibit pervasive cognitive disruption for years post-treatment. In addition to memory and attention deficits, dysregulated sleep-wake activity cycles are frequently reported in this population, and flattened cortisol circadian (24-h) rhythms correlate with dysregulated cognition. Given that memory, activity, and cortisol all exhibit circadian rhythms in healthy humans, we hypothesized that both tumor biology and cancer treatments negatively impact physiological and behavioral circadian rhythms. Here, we use mouse models of non-metastatic breast cancer (tumor-bearing mice), breast cancer survivors (tumor-resected mice), and paclitaxel chemotherapy (30 mg/kg, 6 i.p. injections) to examine the extent to which tumors and cancer treatments independently attenuate cognition and circadian rhythmicity in behavior and physiology in female mice. Behavioral rhythms of wheel running were altered in tumor-bearing and tumor-resected mice compared to sham surgery control mice and running wheel activity was decreased in mice receiving chemotherapy. Blood was also collected at multiple points throughout a 24-hour period to analyze rhythms in corticosterone impacted by tumors and chemotherapy. Corticosterone rhythms were attenuated by the presence of a tumor, which was rescued by tumor resection. Chemotherapy decreased cognitive performance as assessed by memory recall for a contextual fear conditioning task, but paclitaxel

did not affect corticosterone rhythms. Overall, the implications of this work may lead to circadian-focused targets of resynchronizing physiology to ameliorate cancer- and chemotherapy-induced cognitive disruption.

Title: Lipopolysaccharide induces motivational deficits like behavior mediated by alteration of brain metabolites in mice

Authors: *K. ADACHI, M. MARUI, T. HAYASHI, M. NAGASAWA;
Meijo Univ., Nagoya-Shi, Japan

Abstract: Motivational deficits are one of initial symptoms of mental disorder induced by chronic stress (e.g. depression and anxiety). However, the underlying mechanism of motivational deficits is poorly understood, unraveling of that provides the preventive strategy of mental disorder. Recently, cytokine hypothesis in mental disorder has been proposed, since there are a lot of evidences about the relationships between chronic stress and brain inflammation. Thus, lipopolysaccharide (LPS) model has been paid attention to study the mechanisms for chronic stress. LPS injection induces the inflammatory response as well as chronic stress in animal body including the brain, resulting in the release of inflammatory cytokines. Therefore, we examined to evaluate motivated behavior in mice injected LPS, to verify the alteration of brain metabolites in the state of motivational deficits induced by chronic stress. Male eight-week old ICR mice were freely explored in the experimental arena (width: 60 cm × length: 60 cm × height: 40 cm) for 5 minutes, followed by the intraperitoneal injection of phosphate buffered saline (10 ml/kg) or LPS solution (400 μg/ 10 ml/kg). After 24 hours from an injection, every mice were re-explored the same experimental arena in which two novel objects were placed for 5 minutes. In this experiment, the total duration for exploring the objects was observed as an index for motivated behavior in mice. Immediately after each behavioral observation, the mouse was sacrificed under anesthesia, and the hippocampus was dissected from the whole brain. Biological metabolites extracted from the hippocampus were subjected to GC-MS. The total duration for exploring the objects was significantly decreased in LPS group, indicating the motivational decline. The metabolome analysis proposed the alterations of metabolic pathway in the hippocampus under the state of motivational deficits. To elucidate the mechanisms for the

motivational deficits, we focused on LPS model. The motivational deficits-like behavior was induced by LPS treatment. In accordance with that, various metabolic dysfunctions were observed in the hippocampus. Consequently, these results suggest that LPS model is an effective model to evaluate motivation, and the metabolic alterations in the brain play a key role in the onset of motivational deficits.

Title: The role of choroid plexus in health and disease

Authors: *V. OLIVEIRA MOREIRA[1], A. PLANQUES[2], K. ARNAUD[1], A. PROCHIANTZ[1], A. DI NARDO[1];
[1]Col. De France, Paris, France; [2]Inst. Jacques Monod, Paris, France

Abstract: The choroid plexus is a richly vascularized structure located in brain ventricles and is responsible for the production of CSF containing a large panel of molecules essential for various brain functions. We have shown that two proteins expressed by the choroid plexus are modulators of adult neurogenesis: the OTX2 homeoprotein transcription factorand the amyloid precursor protein (APP). OTX2 is highly expressed in the choroid plexus and is secreted into the CSF resulting in its transfer into astrocytes of the ventricular-subventricular zone (V-SVZ) and rostral migratory stream (RMS). When OTX2 is sequestered in the CSF of adult mice, we observed altered expression of astrocyte-specific extracellular matrix proteins, resulting in slowed neuroblast migration in RMS and decreased newborn neurons in the olfactory bulb. APP is also highly expressed in the choroid plexus and its soluble domain is released into the CSF. When APP levels were reduced in the adult mouse choroid plexus, we observed decreased proliferation in both neurogenic niches: V-SVZ and hippocampus dendate gyrus (DG). Increasing APP levels resulted in increased proliferation in both niches. To gage the impact on brain function of extracellular APP coming from choroid plexus, we expressed, specifically in choroid plexus of adult wild type mice, the human APP bearing SwInd mutations of familial Alzheimer disease. After 6 months, proliferation in V-SVZ and DG were significantly reduced. After 12 months, mice showed reversal learning deficits in open field behavior experiments and showed impaired plasticity in LTP measured by high frequency stimulation of hippocampus

slices. Our studies allowed us to highlight novel molecules from choroid plexus secretome involved in neurogenesis and brain functions.

Title: VEGF-C induced meningeal lymphangiogenesis in C57BL/6J mice enhances small molecular weight solute drainage from brain into lymphatics associated with the nasal conchae: A quantitative *in vivo* MRI study

Authors: Y. XUE[1], L. S. B. BOISSERAND[2], X. LIU[1], H. LEE[1], J.-L. THOMAS[2], *H. BENVENISTE[1];
[1]Anesthesiol., [2]Neurol., Yale Sch. of Med., New Haven, CT

Abstract: Rationale: Cerebrospinal fluid (CSF) continuously exchanges with interstitial fluid (ISF) via the brain-wide glymphatic system (GS) to remove waste including Aβ and tau. Ultimate exit routes for waste solutes from the GS involves lymphatic vessels (LV) associated with meninges covering the brain and cranial nerves. Previous studies have shown that cranial meningeal LV are defective in neurodegenerative states and efforts to increase lymphangiogenesis with VEGF-C have therefore been proposed as a therapeutic strategy for maintaining efficient waste drainage across the lifespan to prevent neurodegeneration and cognitive decline. Currently, there is a gap in knowledge as to how efficient VEGF-C-induced meningeal lymphangiogenesis would be as a GS accelerator of waste drainage. Here we introduce a new, quantitative and time efficient magnetic resonance imaging (MRI) approach to quantify the effect of VEGF-C induced meningeal lymphangiogenesis on GS solute drainage. **Methods:** To induce meningeal lymphangiogenesis, adeno-associated virus (AAVs) encoding mouse VEGF-C (AAV-mVEGF-C) was administrated into CSF via the cisterna magna (CM) in 4-week old C57BL/6J (WT) mice, as previously reported (N = 6). Control WT mice were injected with AAVs encoding soluble mVEGFR3$_{4\text{-}7}$-Ig (VEGFR3 ectodomains that do not bind VEGF-C) (AAV-control) (N = 6). Four weeks later the mice underwent MRI for characterization of GS transport. The mice were anesthetized with ketamine/xylazine and received intra-CM

injection of Gd-DOTAREM (1:20; 1μl/min, 7 min). All MRI was done on a 9.4T MRI instrument. Fifty min after administration of Gd-DOTAREM, T1 maps were acquired at a spatial resolution of 100x100x100 μm. The volume of T1 voxels = 400-1600ms (representative of DOTAREM-solute tissue levels and GS transport) was extracted from whole brain and nasal conchae masks from each mouse and compared across groups.
Results and conclusions: GS transport in whole brain as represented by voxels with T1 values of 400-1600ms, was similar between control and AAV-mVEGF-C treated mice (AAV-control treated mice (N = 6): 262 ± 52 mm^3 vs AAV-mVEGF-C-treated mice (N = 5): 268 ± 42 mm^3, p = 0.78). In contrast, T1 values of Gd-DOTAREM associated with nasal conchae was found to be ≈20% higher in AAV-mVEGF-C treated mice (N = 5) when compared to AVV-control mice (N = 6): 11 ± 1 mm^3 vs 9 ± 2 mm^3, p = 0.035). AAV-mVEGF-C treated mice showed increased LV growth in cranial meninges and nasal conchae, compared to AAV-control treated mice. Therefore, increased CSF/ISF Gd-DOTAREM efflux correlates with LV growth in meninges and nasal conchae.

Title: Endothelial LRP1 controls cerebrovascular integrity and neuronal survival via the CycA-MMP9-NFkB pathway

Authors: *A. M. NIKOLAKOPOULOU[1], Y. WANG[1], Q. MA[2], A. SAGARE[1], A. MONTAGNE[1], M. HUUSKONEN[1], Z. ZHAO[1], B. ZLOKOVIC[1];

Abstract: The blood-brain barrier (BBB) is a major clearance site for Alzheimer's amyloid beta (Aβ) protein. This process is mediated by the receptor-mediated transport across the BBB into the peripheral circulation via the low-density lipoprotein receptor-related protein 1 (LRP1), which is a major receptor for both Aβ and apolipoprotein E. Whether LRP1 has other functions at the BBB remains, however, less clear. Here, we established a mouse model with endothelial specific deletion of LRP1, and found that endothelial LRP1 is required for the maintenance of BBB integrity, as identified by increased deposition of extravascular blood-derived IgG and

fibrin accumulates, and neuronal accumulation of systemically injected exogenous cadaverine molecule. Moreover, BBB breakdown that develops at 2 months of age in these mice, leads at 4 months of age to neuronal loss and behavioral deficits. Mechanistically, LRP1 loss from endothelium led to upregulation of cyclophilin A, a pro-inflammatory cytokine, which transcriptionally activated metalloproteinase-9 (MMP9) causing degradation of the capillary basement membrane and tight junction BBB proteins. These data point to a new role of endothelial LRP1 in vascular and neuronal protection.

Title: NMDA receptor signaling regulates function and integrity of the blood brain barrier

Authors: C. LEE, ***D.-G. KIM**;
Korea Brain Res. Inst., Daegu, Korea, Republic of

Abstract: The brain is the center of the cognitive function and it receives tremendous oxygen and glucose from peripheral system in a very selective manner through its vascular system called the blood brain barrier (BBB). Several *in vitro* and *in vivo* studies have shown that signaling systems can control the permeability of the BBB and suggests that it may be the key to control the sophisticated molecular delivery system to the brain from periphery. In this study, we have focused on the glutamate, which is one of the most abundant neurotransmitter in the brain, may be able to control the permeability of the BBB as an important signaling pathway to control the permeability of the BBB to enhance the molecular delivery to the brain. And we have hypothesized that this may occur through the N-Methyl-D-aspartate (NMDA) receptor signaling which is one of most well characterized neurotransmitter receptors mediating long term potentiation. To test this, we have used *in vitro* BBB model and tested the effect of the NMDA receptor signaling. We have observed rapid and reversible significant changes in the permeability of the *in vitro* BBB by NMDA receptor activation mediated by its calcium influx. Further, *in vivo* study showed that the NMDA receptor activation can transiently induce changes in the BBB permeability suggesting its potent and reversible permeabilization of the BBB. Lastly, we generated vascular specific NMDA receptor knock out mouse and we have found that the permeability of the BBB is also affected from these mice indicating that the NMDA receptor

signaling pathway is one of the core component controlling the permeability of the BBB. Overall, NMDA receptor signaling in the brain endothelial cell affects the permeability of the BBB and possibly neuronal or astrocytic glutamate may be the major signal to control the molecular delivery to the brain in a need base manner.

Title: Magnetic resonance-guided focused ultrasound-mediated gene therapy delivery to brain tissue post-surgical resection

Authors: *M. A. STAVARACHE, G. M. WINSTON, M. YUAN, A. ZANELLO, E. M. JURGENS, M. G. KAPLITT;
Neurosurg., Weill Cornell Med. Col., New York, NY

Abstract: The standard treatment of malignant gliomas (GBM), the most common subtype of primary brain tumors, consists of surgery, followed by radiotherapy and chemotherapy. In recent years, advancements in molecular virology led to development of oncolytic viral therapy using genetically engineered oncolytic viruses designed to selectively replicate and kill cancer cells without harming normal tissue. The GBM's highly invasive, infiltrative nature, relative resistance to radiation and chemotherapy, and physiological isolation due to the blood-brain-barrier (BBB) contribute to a poor prognosis. T[MS1] he promising results of viral therapy suggests the need [MS2] for an update in the standard of care [MS3] for GBM therapy. We have previously reported our results using magnetic resonance-guided focused ultrasound (MRgFUS), a novel technique that temporarily and safely disrupts the BBB, to deliver Oncolytic Herpes Simplex Virus-1 (oHSV-1) to specific areas in the brain. Here, we focused on its efficiency in delivering oncolytic viral therapy to the residual tissue following the resection of a portion of brain parenchyma. Sprague-Dawley rats (200-250g) underwent unilateral brain parenchyma resection at the cortical level. Forty [MS4] days later, the rats underwent simultaneous sonication in resection area under MRI control with intravenous administration of dsRed tagged-oHSV-1 at a titer 5*10^8 pfu and albumin-coated gas-filled microbubbles[MS5] . Intravenously administered Gd-DTPA contrast agent confirmed the BBB disruption in T1-weighed images collected post-sonication. A separate group underwent a second sonication session, one week later, following the same protocol. The animals were sacrificed at 2-, 8-days and one-month later, with the brain, liver, heart, and lungs processed for histological analysis. Immunostaining of dsRed, our gene reporter, showed a strong expression in the parenchyma delimiting the

resection area. Immunostaining for neuronal marker NeuN showed no neuronal death in the sonicated area, while GFAP (astrocytic marker) and Iba-1 (microglial marker) staining revealed a transitory local inflammatory response detected only in the animals perfused 2- and 8-days post-FUS. No off-target dsRed staining was detected. Gross observation revealed no behavioral abnormalities in the days post-sonication. These results suggest that MRgFUS can be utilized for non-invasive delivery of larger sized viruses such as oHSV-1 to targeted areas post-surgical resection, which can increase the effectiveness of oncolytic virus therapy in GBM patients.

Title: Hyperinsulinemia induced brain microvessel insulin resistance correlates with reduced insulin transport

Authors: *L. S. WATSON[1], C. J. SMITH[2], A. S. WILLIAMS[1], C. SIMS-ROBINSON[1]; [1]Neurol., [2]Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: During Alzheimer's disease and stroke, two of the most common age related neurodegenerative disorders, patients present with systemic hyperinsulinemia. Systemic hyperinsulinemia is associated with reduced CNS insulin levels, however the mechanisms underlying this are not well understood. Insulin is fundamental in the brain for neuroplasticity, and has anti-apoptotic, -inflammatory, -thrombotic, and -vasodilatory properties. Insulin must be transported across the blood brain barrier (BBB). Some have suggested this occurs via insulin receptor-mediated transcytosis. Thus, the purpose of the following studies are to determine the impact of hyperinsulinemia on insulin transport across the BBB. In the current study, at four weeks of age, B6 mice were placed on either a standard diet (STD) or a high-fat diet (HFD) for 6 and 24 weeks. Hippocampal microvessels were extracted and the levels of serine-phosphorylated insulin receptor substrate, a docking protein that can inhibit insulin receptor function, were measured. Furthermore, these microvessels were stimulated with insulin to determine the ability to activate downstream insulin signaling. We observed evidence of insulin resistance in HFD microvessels and impaired insulin signaling. To explore whether these alterations impacts insulin

transport, we utilized primary brain endothelial cells, a key component of the BBB, and exposed the cells to hyperinsulinemic conditions to evaluate insulin resistance, signaling, and transport. Our data demonstrates that insulin resistance and impaired insulin signaling correlates with reduced transport. Future studies will seek to validate these findings in more complex BBB systems.

Title: Pericyte loss leads to circulatory failure and pleiotrophin depletion causing neuron loss

Authors: *B. V. ZLOKOVIC, A. M. NIKOLAKOPOULOU, A. MONTAGNE, K. KISLER, Z. DAI, Y. WANG, M. HUUSKONEN, A. P. SAGARE, D. LAZIC, M. D. SWEENEY, Z. ZHAO; Keck Sch. of Med. of the Univ. of Southern California, Los Angeles, CA

Abstract: Brain pericytes are the vascular mural cells located within the basement membrane of blood microvessels between brain endothelial cells, astrocytes and neurons. Pericytes maintain blood-brain barrier integrity, regulate cerebral blood flow (CBF) and participate in the clearance of brain toxic byproducts and degenerate in multiple neurological disorders. Understanding the role of pericytes in the brain has been challenging due to the lack of pericyte-specific models; studies so far have used mouse models. where pericyte deficiency is caused by aberrant signaling between endothelial-derived platelet-derived-growth factor B (PDGF-B) and PDGF-receptor β (PDGFRβ) in pericytes Here, we report the development of an inducible pericyte-specific Cre line utilizing a double-promoter approach with the platelet-derived growth factor receptor-β (Pdgfrβ) and chondroitin sulfate proteoglycan-4 (Cspg4) promoters, and show Cre-dependent expression of a dtTomato reporter only in brain pericytes, but not in oligodendrocytes, oligodendrocyte progenitor cells, vascular smooth muscle cells, brain endothelial cells, astrocytes or microglia. To specifically ablate pericytes, we crossed pericyte-specific Cre mice with the iDTR mice carrying a Cre-dependent human diphtheria toxin receptor (DTR). After acute pericyte ablation with diphtheria toxin, mice developed a severe loss of cerebral blood flow, blood-brain barrier breakdown, rapid loss of neurons and behavioral deficits. Pericyte loss led to depletion of pleiotrophin (PTN), a neurotrophic growth factor, which is highly enriched in

pericytes compared to other brain cell types. Replacing depleted PTN in pericyte-ablated mice prevented neurodegeneration and improved performance in behavioral tests regardless of the continuous blood-brain barrier dysfunction triggered by pericyte loss. These data suggest a rapid neurodegeneration cascade connecting pericyte loss to acute circulatory failure and loss of neurotrophic PTN, both required to cause neurodegeneration. Thus, replenishment of pericytes or pericyte-related neurotrophic factors may play a crucial role in developing therapies for brain diseases associated with pericyte loss.

Title: Regulation of blood-brain/spinal cord barrier integrity by Hedgehog-responsive astrocytes in the adult mouse CNS

Authors: H. WANG, Z. XU, Z. XIA, M. RALLO, ***M. P. MATISE**;
Neurosci. & Cell Biol., Rutgers-RWJMS, Piscataway, NJ

Abstract: The blood-brain/spinal cord barrier (BBB) plays a central role in maintaining CNS homeostasis. Disruption of the BBB commonly occurs following CNS injury, and is recognized as critical in the etiology of many diseases affecting the CNS, including MS, ALS and AD. Restoration of the BBB is also crucial for functional recovery following injury or disease. BBB permeability is regulated by several distinct cell types that together form the Neurovascular Unit (NVU), including blood vessel endothelial cells, pericytes, and astrocytes. Prior studies have shown that astrocytes are critically involved in maintaining the BBB, although their specific role in controlling permeability is not fully defined. One signaling pathway implicated in BBB homeostasis involves the Sonic Hedgehog (Shh) protein. However, recent evidence indicates that the pathway plays an unexpected and distinct role in regulating the BBB than has been previously suggested.
Our current work, and data from other labs, has revealed that the canonical Hedgehog (Hh) pathway is selectively active in a sub-population of resident astrocytes located in the gray matter (GM) of the adult mammalian CNS, as shown by the expression of *Gli1*, a Shh target gene and

pathway effector. These cells are distributed widely in the GM of the brain and spinal cord, but not the white matter, and extend endfoot processes to blood vessels. Transcriptome analysis of FACS isolated Gli1+ spinal cord cells shows specific enrichment of canonical Hh pathway transduction components including *Gli1*, *Gli2*, *Gli3*, and *Ptch1*, the receptor for Hh proteins. These observations indicate that Gli1+ cells possess a distinct molecular genetic identity that distinguishes them from other glial cell populations in this tissue, and also suggest that they have a unique function. Consistent with this, targeted genetic inactivation or pharmacologic inhibition of the Hh pathway in Gli1+ astrocytes in adult mice results in rapid but transient breakdown of the BBB, as indicated by extravasation of intravenously-injected tracers and other vascular proteins. Notably, this disruption appears to specifically affect transcytosis but not paracellular diffusion barriers. Together, these findings reveal a critical role for Hh signaling in a unique subset of protoplasmic, perivascular reactive astrocytes in the normal maintenance of the BBB. Furthermore, our studies clarify the role of the Hh pathway in regulating the BBB by demonstrating that signaling in astrocytes, but not other cells of the NVU, is primarily involved.

Title: Transport of macromolecules from CSF-to-brain: Biodistribution of endogenous IgG and intrathecal antibodies or oligonucleotides reveals the importance of perivascular pathways

Authors: B. WILKEN-RESMAN[1], *M. E. PIZZO[2], R. THORNE[2];
[1]Div. of Pharmaceut. Sci., [2]Univ. of Wisconsin-Madison, Madison, WI

Abstract: The specific mechanisms governing CSF-to-brain transport of large endogenous or exogenous macromolecules (e.g., 150 kDa antibodies and ~7-8 kDa antisense oligonucleotides (ASOs)) are currently not well understood, despite their importance for interpretation of ongoing clinical trials, understanding of approved therapeutics, and insight into physiological processes such as immune surveillance. Studies suggest that diffusion primarily governs transport in the

ISF-filled 40-60 nm wide brain extracellular spaces, but convective flow may occur in CSF compartments and perivascular spaces surrounding blood vessels. However, the anatomical boundaries of the PVS and its role in CSF/ISF exchange are only just beginning to emerge (Pizzo et al. J Physiol. 2018; Abbot et al. Acta Neuropath. 2018). Additional factors yet to be investigated may significantly alter the CSF-to-brain distribution of macromolecules, e.g., physicochemical characteristics, CSF protein binding, and binding to leptomeningeal fibroblast-like cells. Here, we intracisternally infused labeled macromolecules into the CSF of rats at a physiological flow rate and investigated the CNS distribution. *Ex vivo* fluorescence imaging of brain sections revealed: (i) striking perivascular transport throughout the brain indicating bulk flow and (ii) a gradient at the brain surface consistent with Fickian diffusion. ASOs with different chemical modification and sequences revealed unique differences in perivascular and diffusive signal for i) a fully phosphorothioated oligonucleotide, ii) a partially phosphorothioated ASO containing a 2'MOE modification, and iii) an ASO with neutral phosphorodiamidate morpholino (PMO) modifications. Thorough understanding of the mechanisms underlying antibody and ASO distribution in the brain and impact of molecular weight, sequence, binding, and electrostatic interactions are needed. Intrathecal antibodies and endogenous IgG were predominantly localized within the meninges and perivascular spaces around vessels of all calibre, with somewhat limited penetration into the brain parenchyma. Endogenous IgG distribution within the CNS closely resembled the distribution resulting from intrathecal application of labeled IgG, suggesting tracer biodistribution from the CSF to brain has additional relevance for understanding CSF:ISF exchange of endogenous proteins within the central compartment. Our results provide critical guidance for understanding and improving drug delivery of macromolecules as well as interpreting the results of clinical trials utilizing CSF injection and/or infusion paradigms.

Title: Chronic exposure to electronic cigarettes or cigarette smoke causes BBB compromise and neuroinflammation in mice

Authors: *N. A. HELDT[1,2], S. GAJGHATE[1], A. SELIGA[1], M. WINFIELD[1], N. REICHENBACH[1], S. ROM[1,2], Y. PERSIDSKY[1,2];
[1]Dept. of Pathology and Lab. Med., [2]Ctr. for Substance Abuse Res., Lewis Katz Sch. of Med. At Temple Univ., Philadelphia, PA

Abstract: Electronic cigarette (EC) use has grown substantially since entry into the US market, particularly among adolescents and combustible tobacco users. Despite growing popularity and claims of harm reduction, the health effects of these products outside the lung is poorly understood. Several constituents of cigarette smoke (CS) with known neurovascular and inflammatory effects are present in EC liquids or formed during the generation of vapor. The present study characterizes the impact of EC exposure on neuroinflammation and blood-brain barrier (BBB) function, and provides comparison of outcomes with reference cigarette exposure normalized to comparable levels of nicotine delivery. Additionally, the contribution of nicotine to observed effects is elucidated through comparison with EC liquids which are verified to be nicotine-free. C57BL/6 mice are exposed to 2 hrs of daily EC vapor or CS, beginning at 8 wks of age. Changes in BBB gene expression are first characterized by whole exome sequencing of isolated brain microvessels following chronic (2 month) EC exposure. Several pro-inflammatory genes are upregulated following exposure including chemokines (Cxcl10, Ccl2), adhesion molecules (Icam1, Pecam1, E-Sel, P-Sel) and transcription factors (Nfatc3, Irf1). EC exposure increases BBB permeability to sodium fluorescein (by 30%) and alters localization of tight junction proteins occludin and claudin 5. Leukocyte - brain endothelia interactions are also impacted. Following intracerebroventricular administration of TNFalpha (mimicking encephalitis), leukocyte recruitment and adhesion to cerebral vasculature is 1.5-fold greater in mice exposed to EC compared with room air control. Lastly, we assess the impact on cognition and anxiety through several measures (novel object recognition, open field, plus-maze, Y-maze). No deficits in cognition or change in affective state are evident following EC exposure based on the outcomes measured, though novel object recognition is impaired following comparable CS exposure. The effects of EC are noted to be partly independent of nicotine content, suggesting that additional compounds within e-liquid or generated during vapor production are contributing to the observed BBB effect of EC. Based on our findings, long-term EC exposure compromises BBB function and induces neuroinflammation, although there is reduced neuroimmune impact when compared with a comparable dose of CS.

Title: What are the mechanisms of blood-brain barrier dysfunction in disease?

Authors: *C. P. PROFACI, K. BAJC, J. P. MILLER, T. Z. ZHANG, R. DANEMAN;
Univ. of California San Diego, La Jolla, CA

Abstract: The blood-brain barrier (BBB) is a set of properties unique to central nervous system (CNS) endothelial cells (ECs) that comprise the inner walls of blood vessels. In contrast to peripheral vessels, which allow extensive exchange of molecules and ions between the blood and tissue, CNS ECs exert tight control over what can enter the parenchyma. BBB dysfunction is a key component of many neurological conditions, including multiple sclerosis (MS), stroke, epilepsy, and traumatic brain injury (TBI). Despite the vastly different triggers of these diseases, in each case vascular permeability causes an influx of blood-borne molecules, disruption of ionic homeostasis, and an increase in immune cell extravasation. These events contribute to the dysfunction, damage, and even degeneration of neurons, ultimately worsening clinical outcomes. Identifying common molecular changes in ECs during disease could point towards a therapeutic target for reducing BBB dysfunction in wide range of neurological diseases.
To investigate the molecular changes occurring in CNS ECs during disease, we isolated ECs from four disease models during BBB dysfunction and performed RNA sequencing. A set of 198 genes was upregulated across multiple conditions, suggesting a common pathway for BBB dysfunction regardless of the trigger of disease. To further probe this BBB dysfunction pathway, I focused on Pdlim1, a cytoplasmic protein previously unexplored in the context of the BBB. Pdlim1 is not expressed in healthy CNS ECs, but its expression is upregulated in ECs across all four disease models, exclusively in regions of BBB permeability. To manipulate Pdlim1 expression *in vivo*, I created a mouse line that overexpresses Pdlim1 in ECs. I found that overexpressing endothelial Pdlim1 is protective in a model of multiple sclerosis. To further probe the mechanistic role of Pdlim1, I isolated endothelial cells from control and transgenic mice and performed RNA sequencing to determine how overexpression of Pdlim1 affects the transcriptional profile of CNS ECs.

Title: Blood brain barrier contributing to brain changes in patients with obstructive sleep apnea

Authors: *L. EHLERT[1], B. ROY[1], E. DANIEL[1], M. LAI[1], D. KANG[2], R. AYSOLA[2], E. WEN[2], M. WOO[3], R. M. HARPER[4], R. KUMAR[1];
[1]Anesthesiol., [2]Med., [3]Sch. of Nursing, [4]Neurobio., Univ. of California at Los Angeles, Los Angeles, CA

Abstract: Obstructive sleep apnea (OSA) patients show brain damage in sites that control autonomic, cognitive, and mood functions, as well as compromised blood brain barrier (BBB) function in global gray and white matter areas. However, it is unclear whether altered BBB function in OSA subjects contributes to brain changes in the condition. Our aim was to examine relationships between regional brain changes and BBB integrity in OSA subjects. We acquired diffusion tensor imaging (DTI) and diffusion-weighted pseudo-continuous arterial spin labeling (DW-pCASL) data from 14 treatment-naïve OSA subjects (age 43.75±9.11 years; AHI 36.2±20.6 events/hour; 8 males) using a 3.0-Tesla MRI scanner. Using DTI data, whole-brain mean diffusivity (MD, indicative of brain changes) maps were calculated, normalized to a common space, and smoothed. Using DW-pCASL data, whole-brain BBB indices were calculated. The smoothed MD maps were used to examine relationships between regional brain changes and BBB integrity in OSA subjects with partial correlation procedures (SPM12; covariates, age and sex; uncorrected $p<0.005$). Significant positive correlations emerged between brain changes and BBB indices in the cerebellum, medulla, pons, vermis, temporal gyrus, frontal gyrus, prefrontal gyrus, lingual gyrus, insula, para-hippocampus, and anterior, mid, and posterior cingulate, and negative correlations in selective cerebellar, temporal, and frontal areas. Newly-diagnosed, treatment-naïve OSA subjects show significant correlations between regional brain changes and BBB integrity in various sites involved in autonomic, mood, and cognition functions. The findings indicate that alterations in the BBB function may play a crucial role in the development of brain injury in the condition.

Title: Research of brain extracellular space in China

Authors: *H. HAN[1,2];
[1]Peking Univ. Third Hosp., Beijing, China; [2]Beijing Key Lab. of Magnetic Resonance Imaging (MRI) Equipment and Technique, Beijing, China

Abstract: Brain extracellular space (ECS) provides the immediate living environment for neural cells and accounts for approximately 15%-20% of the total volume of living brain. 25 years ago, as an interventional radiologist, the author was engaged in studying the early diagnosis and treatment of cerebral ischemic stroke, the parameter of brain ECS was firstly derived from the raw data of calculating the BBB permeability in the cerebral ischemic region in 2004. Since then, the author and his team have been working on developing novel measuring method of ECS: tracer-based MRI, which can measure brain ECS parameters in the whole brain scale and make the dynamic drainage process of the brain interstitial fluid (ISF) drainage visualized. By using the new method, the team discovered a new division system in the brain, named regionalized ISF drainage system. The ISF in the caudate nucleus can drain to ipsilateral cortex and finally into the subarachnoid space, which maintained the pathway of ISF- cerebrospinal fluid (CSF) exchange. However, the ISF in the thalamus was eliminated locally in its anatomical division. After verifying the nature of the barrier structure between different drainage divisions, the author proposed the hypothesis of "regionalized brain homeostasis". Thus, we demonstrate that the brain is protected not only by the BBB, which avoids potential exogenous damage through the vascular system, but is also protected by an internal ISF drainage barrier to avoid potentially harmful interference from other ECS divisions in the deep brain. Together with findings on the drainage route of ISF-cerebrospinal fluid (CSF) and the CSF-lymph system by the other research groups, a more detailed picture of ISF drainage pathways in the whole brain can be built. With the new findings and the proposed hypothesis, an innovative therapeutic method for the treatment of encephalopathy with local drug delivery via the brain ECS pathway has been established. In present, the above new method and the findings have been applied in the field of neuroscience, new drug development, development, aging, aerospace medicine and new artificial neural network modeling.

Title: Identification of vigilance states in freely behaving animals using thalamocortical activity and Deep Belief networks

Authors: *J. HARROD[1], P. L. PURDON[2], E. N. BROWN[4], F. J. FLORES[3];
[1]Harvard-MIT Hlth. Sci. and Technol., Cambridge, MA; [2]Anesthesia, Critical Care, and Pain Mgmt., Massachusetts Gen. Hosp., Charlestown, MA; [3]Anesthesia, Critical Care and Pain Med., Massachusetts Gen. Hosp., Cambridge, MA; [4]MIT, Cambridge, MA

Abstract: Identifying the relationships between behavioral and neural activity lies at the core of neuroscience research. In controlled experiments, the behavior can be constrained without ambiguity by the experimental setup. However, there are situations where this relationship must be inferred in freely behaving animals. This is particularly true in studies that require the identification of vigilance states, such as active wakefulness or non-REM sleep. This task is often carried out by experimenters, based on protocols and guidelines developed to reduce bias and variability. However, the variability between the states identified by different experimenters for the same dataset can be as high as 80 %. Therefore, it is highly desirable to have a method that can aid the researchers to discover patterns on the electrophysiological activity and assign them to vigilance states. While many procedures have been proposed in this direction, the recent developments in artificial neural networks offer a new and powerful methodology to address this problem. Here we aim to develop a robust deep learning classifier/labeling system for raw thalamocortical data. We implanted male Sprague-Dawley rats, weighing between 500-700 g, with depth electrodes aiming at prefrontal cortex and anterior thalamus, and recorded neural activity while allowing the animals to freely behave in a home cage. The raw traces were segmented into two-second windows, and each window was labeled visually by three researchers to build the training set. In order to perform sleep classification, we trained a supervised DBN (Deep Belief Network) based on binary Restricted Boltzmann Machines (RBMs) with a top-layer linear classifier. The RBMs were trained for 20 epochs with a 100x100 hidden layer structure and a learning rate of 1. The top-layer linear classifier was then trained for 150 epochs with a learning rate of $1x10^{-3}$and 20% dropout. Training and test data was divided using an 80/20 split, for a total of 170 epochs with a batch size of 16. This model achieved a 5-fold cross-validation

accuracy greater than 90% on the dataset. Training the model took less than 300 seconds on average across the 5-fold cross-validation. Based on this performance, we have demonstrated that it is possible to implement and train a deep learning model to high accuracies on rodent thalamocortical data for the identification of vigilance states. Also, the training time required to achieve this high performance suggests that this model might be easily trained to similar performance levels on other rodent datasets.

Title: Interhemispheric connectivity during sleep arousals measured by scalp EEG

Authors: *J. V. LIU, H. K. YAGGI;
Yale Sch. of Med., New Haven, CT

Abstract: Introduction: During sleep, arousals occur spontaneously and are identified by the transient increases of high-frequency (8-45 Hz) signals in the scalp EEG. It is clinically important to identify and score arousals in sleep studies (polysomnographies), because frequent arousals are associated with sleep fragmentation and poor sleep quality. Here we investigated the transient changes of interhemispheric connectivity during sleep arousals to provide new insights into the neural mechanisms of sleep arousals.
Methods: We analyzed polysomnography data from the MrOS study on 1000 community-dwelling elderly men (http://sleepdata.org). This dataset was chosen because EEG signals from both hemispheres (C3-A1 and C4-A2) were measured. The EEG signals were decomposed into five frequency bands (delta: 1-4; theta: 4-8; alpha: 8-13; beta: 13-25; gamma: 25-45 Hz), and the EEG power (amplitude) as well as the interhemispheric EEG coherence were computed for each frequency band, at a high temporal resolution by using a 10-second sliding time window.
Results: During arousals, EEG powers in high-frequency bands (8-45 Hz) showed transient increases, maximizing to 1.5-2.0 times the baselines at around 10 seconds after arousal onset. In contrast, the interhemispheric EEG coherence in alpha and beta bands did not significantly change during arousals. The interhemispheric EEG coherence in delta, theta and gamma bands all had significant transient decreases during arousals, and the decreases were larger during rapid eye movement (REM) sleep than during non-REM sleep. Remarkably, the transient increases in EEG powers in the gamma band (highest frequency) were strongly correlated with the transient decreases in the interhemispheric EEG coherence in the delta band (lowest frequency) across subjects. **Conclusions:** During sleep arousals, there are transient decreases in the interhemispheric connectivity that are most significant in the delta band (slow wave frequency) of EEG, and are strongly associated with the transient increases in high-frequency EEG powers. We hypothesize that both the interhemispheric connectivity decrease and the high-frequency EEG power increase are driven by disruptions to the thalamocortical oscillations during sleep arousals.

Title: Competing roles of slow waves and delta waves on memory consolidation

Authors: *K. GANGULY[1], T. GULATI[2], J. K. KIM[3];
[1]UCSF, San Francisco, CA; [2]Ctr. for Neural Sci. & Med., Cedars Sinai Med. Ctr., West Hollywood, CA; [3]Neurol., Univ. of California San Francisco, San Francisco, CA

Abstract: Sleep has been implicated in both selective memory consolidation as well as forgetting of memories after prolonged awake periods. However, it is unclear what physiological process governs the fundamental balance between memory strengthening and weakening. Here we specifically tested how activity-dependent processing during sleep might differentially regulate these two likely competing processes. We specifically examined how neural reactivations during NREM sleep are causally linked to strengthening versus forgetting of the "motor memory" of novel skills gained through practice. We specifically recorded populations of neurons in the primary motor cortex of rats while they were trained on a brain machine interface (BMI) task and subsequent sleep. Strikingly, we found that high amplitude slow-waves (SW; <4 Hz) and delta-waves (δ; 1-4 Hz) have dissociable and competing roles in memory consolidation during sleep. By modulating cortical spiking linked exclusively to SW or δ using closed-loop optogenetic methods, we could respectively weaken or strengthen memory reactivations and thereby bidirectionally modulate sleep-dependent performance gains. We further found that changes in the precise temporal coupling of spindles (10-14 Hz) to SW could account for such effects. Thus, our results indicate that neural activity driven by SW and δ may have competing roles during sleep-dependent memory processing.

Title: Sleep attenuates late neuronal auditory responses in rat perirhinal cortex

Authors: *Y. SELA[1], A. J. KROM[2,3], L. BERGMAN[2], N. REGEV[2], Y. NIR[1,2];
[1]Sagol Sch. of Neurosciences, [2]Physiol. and Pharmacology, Sackler Sch. of Med., Tel Aviv Univ., Tel Aviv, Israel; [3]Dept. of Anesthesia, Hadassah Hebrew Univ. Hosp., Jerusalem, Israel

Abstract: How behavioral states affect sensory processing remains unclear. Sleep entails reduced behavioral responsiveness to external stimuli, but its effects on sensory pathways remain elusive. Previous work established that, contrary to the classical "thalamic gating" notion, responses in primary auditory cortex (PAC) are comparable across wakefulness and sleep. We hypothesized that robust differences emerge downstream in higher-order regions, and tested this by comparing auditory responses across wakefulness and sleep in PAC (n=7) and rhinal cortex (RC, n=9). To monitor PAC and RC activity, 16/32-channel microwire arrays were implanted into the temporal lobe of ten adult rats. Epidural EEG, EMG, and video were used for sleep scoring. After recovery, sleep stabilization, and habituation to stimulation, acoustic stimuli (pure tones, band-limited noise, click-trains, and ultrasonic vocalizations) were presented in a soundproofed environment to freely-moving rats. Sleep scoring (4s epochs) and spike sorting were performed offline. We isolated 485 neuronal clusters (203 in PAC, 282 in RC, 79% were auditory responsive), and divided them according to response latency to 'early responders' (<20ms, prominent in PAC) vs. 'late responders' (with typical latencies around 40-80ms, prominent in RC). Early-responding units responded similarly across wakefulness, NREM sleep, and REM sleep (5-12% attenuation), replicating previous reports. In contrast, late-responding units exhibited robust attenuation during NREM sleep (median: 44% reduction) and a significant - albeit more modest - attenuation during REM sleep (median: 33% reduction). Late auditory responses beyond PAC are significantly attenuated during sleep, possibly reflecting a disruption in inter-cortical signaling and/or 'fading out' of response fidelity with accumulating propagation. Differential RC responses during sleep pave the way to dissecting the underlying mechanisms.

Title: Chronic sleep deprivation and circadian disruptions differently affect the brain's resting state functional connectivity, impulsivity and attentional performance

Authors: *R. ZHANG[1], D. TOMASI[1], E. SHOKRI-KOJORI[1], C. E. WIERS[1], G.-J. WANG[1], N. D. VOLKOW[1,2];
[1]Natl. Inst. on Alcohol Abuse and Alcoholism, Lab. of Neuroimaging, Natl. Inst. of Hlth., Bethesda, MD; [2]Natl. Inst. on Drug Abuse, Natl. Inst. of Hlth., Bethesda, MD

Abstract: Chronic sleep deprivation and disruption of circadian rhythms can impair brain function and cognitive performance. But limited studies have investigated the effect of chronic sleep deprivation and mild circadian disruptions associated with daily work life. In this study, we examined the effect of work-related chronic sleep restrictions and circadian alterations on attention and impulsivity and how it relates to changes in resting-state functional connectivity (RSFC).
Fifty-six (43.9 ± 13.6 years, 26 male) healthy subjects participated in this study. The work-related sleep deprivation and the circadian rhythm were assessed by the differences between weekdays and weekend days in terms of sleep duration and sleep midpoint using one-week actigraphy data. All subjects underwent 3Tesla BOLD-fMRI in resting-state conditions (eyes open; 15 min). We examined the correlation between weekday-weekend variation in RSFC, as well as impulsiveness and attentional performances assessed by Barratt Impulsiveness Scale (BIS), and the accuracy and reaction time during a visual attention task (VAT).
We found that weekday-weekend variation in sleep duration and sleep midpoint were independent of each other and differently affected RSFC and behavior. Regarding sleep duration, larger differences between weekdays and weekend were associated with lower cognitive complexity, a BIS subscale. Subjects with larger variation had lower RSFC within the default mode network (DMN), higher RSFC between the salience network (SN) and the DMN, and lower RSFC between the frontoparietal network (FPN) and the inferior frontal gyrus (IFG). In contrast, referring to sleep midpoint higher weekday-weekend variation was associated with worse attentional performance in VAT and lower RSFC between SN and occipital cortex, and with overall lower thalamocortical RSFC especially between thalamus and frontal cortex. Our findings suggest that sleep deprivation and circadian disruptions differently affect functional networks (DMN, SN FPN) modulated by dopamine. As sleep deprivation and changes of circadian rhythms are often confounded with each other, it's essential for future studies to identify their specific contributions to RSFC and its relation to performance.

Abstract: Sleep is essential for both cognition and physiological maintenance of healthy brain function. During sleep, slow waves in neural activity contribute to memory consolidation, and cerebrospinal fluid (CSF) clearance of metabolic waste products from the brain is increased. Whether these two processes are related is not known. We exploited recently developed techniques for accelerated multimodal neuroimaging to simultaneously measure CSF flow, blood-oxygenation-level-dependent (BOLD) signals, and neural dynamics in the human brain. We studied thirteen subjects at 3 Tesla using fast fMRI (TR<400 ms) and EEG as they fell asleep in the scanner. We discovered a large oscillation in CSF flow that appears during non-rapid eye movement (NREM) sleep. This CSF oscillation was tightly locked to a coherent pattern of oscillating electrophysiological and hemodynamic signals: neural slow waves were followed by oscillations in the vasculature, respiration, and CSF flow. We next hypothesized a potential mechanism: as broadly coherent low-frequency neural signals increase in NREM sleep, they induce cerebral blood volume changes locked to neural activity, throughout the cortical gray matter. This large-scale contraction and expansion of total brain tissue volume in turn draws CSF into and out of the head, due to constant intracranial volume. Using a biophysical model, we found that the coupled timing of these oscillations was consistent with a model in which increased slow waves of coherent neural activity drive blood volume decreases, which then induces pulsatile CSF inflow on a macroscopic scale. These findings suggest that the low-frequency neural activity that defines NREM may also enhance clearance of metabolic waste products from the brain, due to increased mixing and clearance of solutes generated by these CSF waves. Our results therefore suggest that the cognitive and physiological effects of sleep are linked through coupled oscillatory neural, vascular, and mechanical processes.

Title: Ancestral neural signatures of sleep

Authors: *L. C. LEUNG[1], G. X. WANG[1], R. MADELAINE[1], G. SKARIAH[1], K. KAWAKAMI[4], K. DEISSEROTH[2], A. E. URBAN[3], P. MOURRAIN[1];
[1]Psychiatry and Behavioral Sci., [2]Bioengineering & Psychiatry & HHMI, Stanford Univ., Stanford, CA; [3]Psychiatry and Genet., Stanford Univ., Palo Alto, CA; [4]Natl. Inst. of Genet., Mishima/Shizuoka, Japan

Abstract: While slow wave sleep (SWS) and paradoxical/rapid eye movement sleep (PS/REM) have been found in mammals, birds and lizards, it is unclear whether these neuronal signatures are found in the non-amniotic animals that comprise about half of all vertebrate species. Although a bona-fide sleep state has been well established in adult and larval zebrafish through behavioral criteria, it is unknown whether the lack of an expanded neocortex precludes the expression of these signatures and whether a common functional significance of such sleep patterns exists across vertebrates. To delve into such questions, we developed a non-invasive fluorescence-based polysomnography (fPSG) for the teleost vertebrate zebrafish, leveraging its optical clarity, compact size, linear rostrocaudal brain organization as well as the conservation of sleep neurochemistry. Through unbiased, brain-wide Ca^{2+} imaging coupled with assessment of eye movement, muscle dynamics and heart rate, we report two major sleep signatures: Slow Bursting Sleep (SBS) and Propagating Wave Sleep (PWS) which share commonalities with SWS and PS/REM states, respectively. In contrast to desynchronous activity during wake, SBS is characterized by oscillating synchronous dorsal pallium activity coupled with reduced muscle, eye and heart activity, while PWS features brain-wide travelling waves leading to muscle atonia, loss of eye movement and heart arrhythmia. Our live imaging data also identifies for the first time a potential role for ependymal cell activation as an initial event in the transition to sleep dynamics. We also found that fish ependymal cells are activated by melanin-concentrating hormone (MCH), a neuropeptide implicated in mammalian PS/REM, but whose sleep role in fishes has been debated since its 1983 discovery in salmon when its eponymous pigmentation

role was revealed. We show that MCH signalling bears both pigmentation and sleep regulatory roles consistent with our previous finding that zebrafish MCH2 is the true orthologue of the mammalian MCH gene. As such, MCH signal disruption in the fish leads to a dramatic reduction in behavioural sleep quantity and perturbs the generation of PWS signatures. Together, the observations of SWS- and PS-like neural and muscular activities in a teleost suggest that common neural signatures of sleep may have emerged in the vertebrate brain over 450 million years ago.

Title: Dynamic alterations in spontaneous neural activity at the sleep onset period: A simultaneous EEG-fMRI study

Authors: *T. ISHII[1], T. KOIKE[2], E. NAKAGAWA[2], M. SUMIYA[2], T. ASO[1], N. SADATO[2]; [1]Human Brain Res. Center, Kyoto Univ. Grad. Sch. of Med., Kyoto, Japan; [2]Natl. Inst. for Physiological Sci., Okazaki, Japan

Abstract: The sleep onset period, involving so-called stage N1 sleep largely, is characterized by a reduction in the amount of alpha activity and the appearance of slower theta waves compared to wakefulness. Various kinds of physiological and psychological changes are also apparent, such as slow eye movements, changes in muscle tonus and the hypnagogic dream-like mentation. Because of these diverse changes, the definition of the sleep onset period itself has still been the object of much discussion. These phenomena are thought to be the reflection of dynamic alterations in the brain during the transition period, however, details of these changes have still been uncovered. Here, we aimed to investigate a dynamic shift in the brain activity at sleep onset using the method of EEG-fMRI simultaneous recording. Seventeen healthy subjects (9 females, 21.8±2.5 years) participated in the study. Simultaneous EEG/fMRI recording was performed during an hour's nap in a 3T-MRI scanner. An MR-compatible EEG system placed according to the international 10/20 electrode system was used for polysomnographic recordings. Real-time online monitoring of EEG was performed by experimenters outside a scanner room. To record the transition period between awake and sleep multiple times during a session, an experimenter inside a scanner room touched a subject's foot for inducing arousal when a shift to NREM sleep stage 1 was observed. After corrections for gradient-induced and cardioballistic artifacts, EEG data were scored according to the AASM criteria in 30s epochs. Based on sleep stages defined

by polysomnographic findings, we examined changes in brain activation patterns between stages and performed functional connectivity analyses of fMRI data. The activation of the thalamus and basal ganglia significantly reduced during NREM sleep stage 1 compared with stage W ($\alpha <$ 0.05, corrected). Functional connectivity analyses revealed that connectivity between the thalamus and cortical regions reduced sharply in the descent to sleep stage. Meanwhile, cortico-cortical connectivity including the default mode network maintained at the sleep onset period. Our data support the hypothesis that reduced thalamocortical connectivity which leads to limit the capacity of the brain to integrate information is associated with the transition of consciousness at sleep onset. The present findings also suggest that intrinsic BOLD fluctuations do not necessarily reflect conscious mentation.

Title: Firing dynamics of identified parietal cortical pyramidal cells and interneurons in nonREM sleep

Authors: *S. BORDÉ, R. G. AVERKIN, J. HORVÁTH, V. DASHKOVSKYI, B. BOZSÓ, V. SZEMENYEI, G. TAMAS;
Univ. of Szeged, Szeged, Hungary

Abstract: The nonREM sleep is characterized by interchanging periods of up (active) and down (silent) states which appear in packets separated by short microarousals or by REM sleep episodes. Temporal progression of nonREM packets is characterized by an increase in the power of spindle band oscillations in the cortex together with a surge in the activity of low-firing putative pyramidal neurons, while high-firing putative pyramidal cells and fast-firing putative interneurons decrease their activity (Watson et al., 2016). However, the high-firing and fast-firing neurons might include several cell classes with unknown contribution to sleep packets. To reveal the firing dynamics of anatomically identified pyramidal cells (PCs), fast spiking interneurons (FSIs) and regular spiking interneurons (RSIs) during nonREM sleep, we applied juxtacellular recording and labelling of parietal cortical neurons during natural sleep in Wistar rats (Averkin et al., 2016). Deep layer PCs and layer 3 PCs were more active compared to layer 2

PCs with sporadic firing encompassing nonREM packets. The firing of deep and superficial layer FSIs had the highest frequency which gradually increased as nonREM packets progressed and this was in correlation with an increasing power of spindle frequency band network oscillations. Cell to cell variability was found in the firing of RSIs with increasing, decreasing or stable firing rates during nonREM packets. Contribution to successive spindles during the timecourse of nonREM packets was cell class dependent, with only a subpopulation of FSIs with spindle trough related firing showing a change by increasing firing. Firing around the end of the delta waves (down-to-up state transitions) started with a peak of FSI activity followed by different classes of PCs and RSIs and the order of peak firing latencies for cell classes remained stable during of nonREM packets. In conclusion, cell class specific shifts in relative firing contribution might characterize nonREM sleep packets and ongoing spindle oscillations.

Title: Functionally related brain areas exhibit a higher proportion of simultaneous sleep spindles

Authors: *F. KATSUKI, J. T. MCKENNA, Y. BOLORTUYA, J. M. MCNALLY, R. E. BROWN;
Dept. of Psychiatry, VA Boston Healthcare System/Harvard Med. Sch., West Roxbury, MA

Abstract: Abnormalities in sleep spindles, 10-15 Hz waxing-and-waning cortical electrical oscillations observed in non-rapid-eye-movement (NREM) sleep, have been reported in patients with various neuropathological conditions, most notably schizophrenia, and may contribute to deficits in memory consolidation. However, much remains to be learned about the functional role of spindles in memory formation. Sleep spindles are known to be distributed heterogeneously among cortical and subcortical regions both in humans and rodents. Here, we hypothesized that

anatomically and functionally related brain areas would exhibit more common spindle events, providing a possible substrate for associative synaptic plasticity. To test this hypothesis, we recorded local field potentials (LFP) simultaneously from different regions and assessed what proportion of the spindles detected in different areas were common events.
LFP recordings were performed in wild-type mice (C57BL6J). Two LFP electrodes were implanted in each mouse with a different combinations of brain regions: 1) Secondary motor cortex (M2) bilaterally (N=4), 2) Prelimbic cortex (PrL) and Dorsomedial striatum (DMS) ipsilaterally (N=4), a corticostriatal circuit involved in goal-directed behavior and cognitive flexibility; and two cortical areas with less robust connectivity, 3) M2 and PrL ipsilaterally (N=4), and 4) M2 and Infralimbic cortex (IL) ipsilaterally (N=4). Eight hours of data during the light phase was analyzed. A MATLAB-based offline automated sleep spindle detection algorithm was used to detect NREM sleep spindles in each electrode (Uygun et al., 2018). Detected spindles in each electrode were then compared between electrodes within each animal to identify spindle events that occurred simultaneously in both areas ("common" spindles with >90% duration overlap).
Average percentages of common spindle events between areas were: 58±13% between bilateral M2, 42±5% between PrL and DMS, 21±1% between M2 and PrL, and 23±4% between M2 and IL. Thus, consistent with our hypothesis, anatomically and functionally-related brain areas showed a higher proportion of common spindles (bilateral M2 recordings and PrL-DMS) than those areas with less strong connectivity (M2-PrL and M2-IL). However, even functionally and anatomically separated pairs exhibited ~20% common spindles, possibly representing "global" spindles.
Further investigation of the proportion of common/uncommon spindles in functionally-related brain areas following training on behavioral tasks may provide mechanistic insights into how and whether sleep spindles facilitate synaptic plasticity and memory consolidation.

Title: Cortical sleep rhythms drive coordinated corticostriatal activity during motor skill learning

Authors: *S. M. LEMKE[1], D. RAMANATHAN[2], K. GANGULY[1];
[1]UCSF, San Francisco, CA; [2]UCSD, La Jolla, CA

Abstract: Specific rhythms of neural activity in motor cortex during sleep are known to play a role in motor skill learning. These rhythms, including sleep spindles and slow oscillations, are believed to drive plasticity critical for the increased speed, consistency, and efficiency of movements that characterize skill learning. While we also know that inter-area plasticity is required to learn motor skills, whether such plasticity is driven by sleep rhythms remains unknown.
Plasticity in the projections from primary motor cortex (M1) to the dorsolateral striatum (DLS) is central to motor skill learning. Here, we recorded neural activity across M1 and DLS in rats to investigate whether activity patterns during sleep play a role in motor skill learning. We hypothesized that during sleep after training, sleep spindles and slow oscillations in M1 drive coordinated activity across M1 and DLS and that this activity plays a role in shaping the corticostriatal projections critical for skill learning.
To test this, we classified sleep spindles and slow oscillations in M1 during slow wave sleep after training and show that, in fact, M1 sleep rhythms drive coordinated activity across M1 and DLS. We show that M1 and DLS modulation during spindles is increased when spindles are nested in slow oscillations and that these nested spindle events are uniquely related to offline improvements in performance. This work aims to establish a role of sleep in driving interarea plasticity during motor skill learning.

Title: Decoding electrophysiological arousal state from fast fMRI data

Authors: *S. D. WILLIAMS[1], U. AGRAWAL[3], J. CHEN[4], B. SETZER[2], N. FULTZ[4,2], L. D. LEWIS[2];

Abstract: During changes in arousal, the brain undergoes shifts in dynamics that can be either global or confined to local cortical regions. For example, slow wave oscillations can appear in one cortical area but not in another, termed local sleep. Tracking these local changes in arousal with high spatial and temporal resolution could clarify how arousal-related changes in dynamics affect neural computation and cognitive function. Here we estimate arousal levels from fMRI signals alone, suggesting that fMRI dynamics in local brain regions contain information about arousal. We leveraged technological advances in fMRI that have enabled subsecond whole brain imaging with concurrent EEG. The fast image acquisition allowed us to directly measure and localize low-frequency oscillations (0.1-1 Hz) in the fMRI signals. We imaged 12 subjects as they transitioned between wakefulness and sleep inside the scanner. We collected simultaneous EEG-fMRI (TR=367 milliseconds) data from the subjects in two sessions, a sleep-restricted (4 hours of sleep) session and a well-rested (at least 6 hours of sleep) session. We estimated arousal state from the spectral dynamics of the EEG signals, and then built a Random Forest (RF) model that predicts EEG arousal from the fMRI data alone. We extracted several features from the fMRI data, including percent signal change, 0.1-1 Hz power, and temporally-lagged versions of the features. We used our RF model to (1) characterize the minimal features necessary to extract from fMRI data in order to accurately predict arousal state, and (2) estimate the individual contribution of each feature using the importance scores generated by the RF model. We find that (1) an RF model trained on dynamics extracted from a local cortical region (volume: 5% of cortical grey matter) generates above-chance predictions of EEG arousal in novel subjects, and (2) both the amplitude and frequency content of fMRI signals contribute to this prediction, rather than only a single feature type. Our findings are consistent with previous work showing that arousal can be decoded from information contained in fMRI, and further show unique contributions of time-varying fMRI dynamics. In addition, our results demonstrate the feasibility of predicting arousal state using a model trained only on data from a single cortical region. This work suggests that temporally-varying fMRI dynamics in local brain regions can be used to track fluctuations in arousal state.

Title: Temporal organization of brain electrical activity in obstructive sleep apnea: Sex differences

Authors: *Z. MUNOZ-TORRES[1,2], U. JIMÉNEZ-CORREA[3];
[1]Phychobiology and Neuroscience, Fac. of Psychology, [2]Ctr. de Ciencias de la Complejidad (C3), [3]Clin. of Sleep Disorders, Fac. of Med., Univ. Nacional Autonoma de Mexico, Mx., Mexico

Abstract: Obstructive sleep apnea (OSA) is a syndrome characterized by repetitive cessation (apnea) or reductions (hypopnea) of breathing during sleep. OSA is associated with snoring, sleep fragmentation, nocturnal hypoxemia, excessive daytime sleepiness, cognitive difficulties and depressive and anxiety symptoms. Epidemiologic studies have consistently shown a male predominance of OSA. Hormonal differences, breathing control, upper airway anatomy and fat distribution have been described as causes of the sexual differences in OSA. Additionally, clinic manifestations are more accentuated in men than in women, but white matter structural integrity is more affected in women than men. To our knowledge, there has been no previous studies exploring gender differences in electrical brain activity features of OSA. To determine differences in temporal organization of brain activity between genders across sleep and wakefulness in two different severity levels of OSA, polysomnography was performed in 45 patients with untreated OSA (22 women and 23 men) and power spectral density (1-50 Hz) was compared between groups. OSA men during sleep showed lower power spectral density of fast frequencies than women. Men with severe OSA in comparison to moderate, showed lower Sigma power during Non-REM, and higher Delta frequencies during REM sleep. In contrast, women groups (severe/moderate) did not show significant differences in power. The group of severe apnea was characterized by lower power during wakefulness of Beta and higher power of Delta during REM sleep. These findings contribute to providing alternative explanations for some of the gender differences in OSA. While the diagnosis is the same for men and women, the evolution of the syndrome induces substantial differences in the oscillatory brain activity. This study emphasizes the importance of understanding the differential effects on men and women of sleep disorders, and thereby achieve better knowledge of the underlying neural mechanisms in order to improve therapeutic outcomes.

Title: Strong cortical activation of task related neural activity during REM and SWS sleep precedes rapid learning of a motor skill

Authors: M. J. ECKERT[1], B. L. MCNAUGHTON[1,2], ***M. TATSUNO**[1];
[1]Dept. of Neurosci., The Univ. of Lethbridge, Lethbridge, AB, Canada; [2]Dept. of Neurobio. and Behavior, The Univ. of California, Irvine, Irvine, CA

Abstract: Neural activity during rest is hypothesized to participate in the consolidation of memory traces. Many studies have demonstrated that neural activity recorded during performance on a behavioral task is replayed during subsequent rest and sleep. Approximately 1 hour (or less) of rest following training is typically recorded in such studies, and these data often show reactivation during SWS that is initially strong but decays within 1/2 to 1 hour. Pre-play of neural activity prior to a task or experience has also been demonstrated, although support for pre-play is not consistent. To date there is little evidence for replay or pre-play during REM sleep, with the exception of one study, which showed pre-play (Louie and Wilson, 2001). This is surprising given that behavioral studies support a role for REM sleep in the consolidation of motor skill learning in particular. We provide evidence that activation of task related neural activity patterns occurs during pre-task REM sleep as well as post-task SWS in rats learning a novel motor skill. We implanted 5 rats with tetrode arrays in the forelimb region of primary motor cortex and recorded single-unit activity on a single pellet reaching task. Daily recordings included a 3 hr pre-task sleep period, 30 min training on the reaching task, and 3 hr post-task sleep. Rats were naive to the task at the start of recording (except a brief test of paw preference) and daily recordings continued until they reached asymptotic levels of performance. Two of the rats showed rapid learning on the task, becoming very skilled within 5-6 days. The other three rats exhibited a slower and more variable gain in proficiency across 2 weeks, although they ultimately achieved success rates similar to the rapid learners. The first principal component of reach related activity (Peyrache et al., 2009) exhibited activation during both SWS and REM sleep. SWS activation was strongest immediately following the training session and was associated with spindle oscillations. REM activation was strongest in pre-task sleep and was accompanied by an increase in the amount of pre-task REM sleep. In the rapid learning rats, the strongest REM and SWS activation co-occurred on days just prior to large performance gains, whereas strong REM and SWS activation was more distributed across training days in gradual learning rats. Pre-task REM activation and post-task SWS activation were both significantly associated with neck EMG activity. Our data suggest that coordinated REM and SWS activation facilitates rapid skill learning, and further suggest a possible evolution of sleep activation of task activity that is initially stronger in SWS and later becomes stronger in REM sleep.

Title: Modulation of the cortical population dynamics by phasic activation of the locus coeruleus

Authors: *E. DURÁN, M. YANG, R. NEVES, N. K. LOGOTHETIS, O. ESCHENKO;
Max Planck Inst. For Biol. Cybernetics, Tuebingen, Germany

Abstract: Synchronized population activity in cortex is a hallmark of slow-wave sleep, quiet wakefulness, or anesthesia. Rhythmic fluctuations of neuronal membrane excitability are reflected in extracellular field potentials as delta (1-4 Hz) or large-amplitude slow (~ 1Hz) oscillations (SO); the latter are indicative for Up-to-Down-states transitions. The Up-states comprise periods of neuronal membrane depolarization accompanied by sustained spiking activity; the Down-states are associated with membrane hyperpolarization and neuronal silence. The level of cortical synchronization depends on the input from a number of subcortical neuromodulatory centers, including the brainstem nucleus Locus Coeruleus (LC). The LC regulates cortical excitability via its direct or indirect ascending projections and norepinephrine (NE) release in the target regions. We have previously demonstrated that phasic LC activation causes transient cortical desynchronization. Here, we sought to characterize the effect of transient NE release on the cortical population dynamics at a fine temporal scale. To this end, we quantified the effects of the direct electrical stimulation of LC (LC-DES) on the Up/Down-state transition in the medial prefrontal cortex (mPFC) in urethane-anesthetized rats. Biphasic electric pulses (0.4 ms, 0.02-0.05 mA) were applied to the LC unilaterally at 50 Hz for 200 ms while mPFC activity was monitored ipsilateral to the simulation site. The effect of LC-DES on cortical population activity depended on the phase SO. The LC-DES presented within an Up-state prolonged the ongoing Up-state for 94.3 ± 21.3 ms and caused ~20% increase of the firing rate in the mPFC. In addition, Down-states coincided with LC-DES were followed by a rapid transition to Up-state in ~20% of trials. Our results suggest that the effect of NE release on cortical population dynamics strongly depends on the cortical state preceding LC activation.

Title: Sleep spindle quality reflects spatio-temporal dynamics of oscillatory activity within cortical networks in mice

Authors: *C. BLANCO DUQUE[1], L. KRONE[1], M. C. KAHN[1], P. ACHERMANN[3], D. M. BANNERMAN[2], E. OLBRICH[4], V. V. VYAZOVSKIY[1];
[1]Physiology, Anat. and Genet., [2]Exptl. Psychology, Univ. of Oxford, Oxford, United Kingdom; [3]Inst. of Pharmacol. and Toxicology, Univ. of Zurich, Zurich, Switzerland; [4]Max Planck Inst. for Mathematics in the Sci., Leipzig, Germany

Abstract: Sleep spindles (SS) are field potentials that occur at 10-15 Hz during NREM sleep. SS are thought to play a role in sensory processing and memory consolidation; however, their origin and biological function remains uncertain. In part, this results from a limitation of traditional SS detection methods, which treat SS as all-or-none phenomena, and often do not take into account their complex spatio-temporal dynamics. To address this limitation, we used a novel methodological framework, which treats brain signals as a superposition of stochastic harmonic oscillators whose frequency and damping vary in time. To detect SS, we fit autoregressive models to EEG and LFP signals -recorded in adult male C57BL6 mice- from the primary somatosensory cortex using 16-ch microwire arrays (n=6) and 16-ch laminar probes (n=7). SS events are detected based on the damping of the signal within a 10-15Hz frequency band. SS events display significant diversity in their spatial extent (e.g. in how many LFP channels they manifest simultaneously) and their strength of damping, which we refer to as “spindle quality index” (SQI 1-5 = strong-to-weak damping). Low quality SS (i.e. weak oscillations) occur at a higher rate (SQI1: 3.6/min ± 0.2) than high quality SS (SQI5: 0.1/min ± 0.01). Furthermore, we find that SQI is strongly associated with the duration and spatial synchronisation of SS. Specifically, SS with low SQI are predominantly local (37% ± 0.2 of all LFP channels) and transient (1.2s ± 0.06), whereas SS with high SQI last longer (2.3s ± 0.3) and encompass larger cortical regions (77%, ± 0.07 of all LFP channels; low vs high SQI: $p<0.001$). In addition, there is a strong positive correlation between SQI, or spatial synchrony of local LFP SS events, and the power density in the SS frequency range in the frontal EEG ($r=0.99$, $p=0.0001$). Finally, we investigated the relationship between SQI and the occurrence of recently reported infra-slow oscillation in SS activity. Our preliminary results confirm that SS occur in bursts, lasting on

average 14.4s ± 0.2 and comprised of 1 spindle every ~2.38s ± 0.005. These SS bursts exhibit a 0.02Hz oscillation (i.e. with a ~50s period) and 0.36/min ± 0.01 incidence during NREM. During the last quartile of NREM sleep episodes there was a 15% ± 0.07 increase in SQI within a given burst, which was not apparent in first three quartiles. In summary, we demonstrate that SS are not all-or-none phenomena, but show a continuum in their properties, which until now remained underappreciated. We conclude that considering the quality dimension of SS is necessary for providing a complete understanding of their underlying network dynamics and biological function in health and disease.

Title: Optogenetic activation of medial prefrontal cortex fibers in the dorsal raphe (DR) increases dark phase sleep-like behavior and requires hypocretin/orexin (OX) neuropeptides

Authors: *N. E. MOLINA[1], E. A. BERRY[2], K. THOMPSON[3], M. ISHIBASHI[4], C. S. LEONARD[5];
[2]Cell Biol., [1]New York Med. Col., Valhalla, NY; [3]NYMC, Valhalla, NY; [4]Dept. of Neurophysiol., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [5]Dept Physiol, New York Med. Coll, Valhalla, NY

Abstract: The neural circuit changes resulting from the loss of OX signaling, which underlie the sleep disorder narcolepsy, are not well understood. Evidence indicates that OX signaling at serotonin (5-HT) DR neurons and their connections to the amygdala are important in suppressing cataplexy, a key symptom of narcolepsy that is characterized by abrupt behavioral arrests during waking that are enhanced by positive emotions. Since suppressing activity in mPFC reduces cataplexy, and mPFC projects to both amygdala and DR, we used excitatory optogenetics to investigate the ability of mPFC->DR projections to modulate cataplexy in narcoleptic (OX-null) mice. Bilateral mPFC microinjections of AAV1-CAG-Chronos-GFP delivered > 4w prior to beginning experiments resulted in robust Chronos-GFP expression in mPFC and DR terminals. Optical stimulation of PFC terminals in brain slices produced monosynaptic EPSCs and disynaptic IPSCs in 5HT and putative GABA DR neurons in slices from WT and OX-null mice, and these PSCs faithfully followed light pulses up to 40Hz. For behavioral experiments, we

implanted a fiber optic near the midline in the DR of both WT and OX-null mice. We found that 20Hz optical stimulation (5ms pulses, for 10s every 20s) did not alter open field locomotion in either genotype but was aversive for both genotypes in a real-time place preference test. Cataplexy- and sleep-like events (CLEs and SLEs) were scored blindly during the 1st 4h of the active period in the home cage under four experimental conditions: baseline, optical stimulation, emotional arousal (given chocolate m&ms), arousal + stimulation). CLEs were significantly increased in arousal conditions in OX-null mice, but were not altered under stimulation conditions, suggesting that mPFC afferents may not target neurons regulating cataplexy. In contrast, SLEs were decreased in arousal conditions in both WT and OX-null mice. Unexpectedly, SLE number & total duration increased considerably (> 3x) in stimulation conditions for WT, but not OX-null mice. During SLEs, mice typically assumed a head-down, resting posture in the nest, but these events were not tightly linked to each stimulation epoch. This suggests that mPFC afferents do not gate SLEs but increase sleep drive. The absence of this effect in OX-null mice suggests mPFC afferents may induce SLEs by suppressing wake-promoting OX neuron output, perhaps via direct 5-HT mediated inhibition. Collectively, our findings suggest a novel pathway for top-down control of sleep-wake circuits which may relate to reduced NREM slow-wave activity and cognitive decline observed in age-related PFC atrophy.

Title: Effects of learning and sleep on ribosome phosphorylation and ribosome-associated mRNAs in different hippocampal neuronal populations

Authors: *J. DELORME[1], V. K. KODOTH[2], S. J. ATON[2];
[1]Neurosci. Grad. Program, [2]Molecular, Cellular, and Developmental Biol., Univ. of Michigan, Ann Arbor, MI

Abstract: Sleep plays a critical role in hippocampus-dependent memory consolidation. Research has found substantial sleep-associated alterations to hippocampal circuit connectivity and

network activity patterns. It remains unclear whether and how sleep-associated activity alterations affect intracellular pathways critical for synaptic plasticity in the hippocampus. Recent data have suggested that sleep may regulate protein synthesis. To characterize the influence of sleep and prior learning on protein synthesis, we have characterized activity-associated phosphorylation of ribosomal subunit S6 (pS6) in the hippocampus using immunohistochemistry. Surprisingly we have found that both sleep and prior learning alter ribosome phosphorylation across both excitatory (CaMKIIa-expressing) and inhibitory (somatostatin- and parvalbumin-expressing) neurons of the rodent hippocampus (DG, CA1, & CA3). To further characterize which mRNAs might be translated into protein during post-learning sleep, we employed the translating ribosome affinity purification (TRAP) technique to isolate mRNA associated with ribosomes from excitatory neurons (CaMKIIa-CRE×Rpl22-HA) and those associated with phosphorylated ribosomes (pS6) from the hippocampus, under different experimental conditions. Our data show that not only does sleep differentially affect ribosome-associated mRNA species in different hippocampal neuron populations, but a learning task (contextual fear memory - CFM) also leads to subsequent changes in ribosome-associated mRNA profiles, in a sleep-dependent manner.

Title: Sleep spindles and gamma brain connectivity during NREM sleep: An insight from intracranial electrodes

Authors: V. ZAPATA[1], D. HENAO[1], L. MAYOR[1], M. NAVARRETE[2], M. LE VAN QUYEN[3], ***M. VALDERRAMA**[1];

Abstract: Sleep is highly necessary for several functional and cognitive processes. Specifically, it is thought that during non-REM (NREM) sleep an active memory consolidation process takes place, where recently acquired information is distributed between different brain areas for its long-term storage. This communication is mediated by the action of slow oscillations that modulate the coordinated occurrence of thalamocortical spindles and cortical and hippocampal gamma and ripples events. In particular, it is believed that the precise occurrence of spindles and gamma/ripples oscillations facilitates the transfer of information between hippocampal and cortical regions during sleep. In order to study the dynamic interaction among these areas,

different studies have reported the evolution of brain connectivity over different sleep stages leading to the identification of functional most connected areas. However, most of these analyzes have been based on fMRI or scalp EEG techniques that do not allow the mapping of brain activity at specific intracerebral locations with high temporal resolution. Here, we studied the brain connectivity during NREM sleep through complex networks constructed from intracranial electrodes. We aim at identifying most connected areas for spindles (8-18Hz) and gamma (30-100Hz) activities due to their relevance in cognitive processes. For this, brain graphs where constructed from intracranial recordings of 13 epileptic patients that were implanted for the treatment of their epilepsy. In particular, we investigated how the connectivity strength changed across the night for each of the recorded regions. In total, we analyzed 159 sleep hours during seizure-free nights and 1052 intracranial electrodes located over 32 brain regions, mainly in temporal and frontal cortices and parahippocampal areas. Results were focused on NREM sleep stages N2 and N3, and Wake periods. We report a statistically significant (p-value < 0.05) increase of global brain connectivity in spindles and gamma for most of the patients (>60%) during NREM than wake. Most connected regions during NREM and wake periods were consistent between the two ranges of gamma activity (30 to 49Hz, and 51 to 99Hz), but not between slow (8 to 12Hz) and fast (12 to 18Hz) spindles. Most connected electrodes were found in the precental gyrus and the insula during NREM sleep for slow spindles and gamma activity. During fast spindles, connectivity was moved towards the caudate region, the inferior parietal and paracentral lobules, and the inferior temporal gyrus. Taking together, our results provide new evidences of functional brain connectivity during sleep.

Title: Simultaneous measurements of the brainstem sleep-wake neuronal activity indicates non-discrete state transitions

Authors: *F. BAHARI, M. W. BILLARD, C. CURAY, J. KIMBUGWE, K. D. ALLOWAY, B. J. GLUCKMAN;
Pennsylvania State Univ., University Park, PA

Abstract: Sleep-wake states are thought to be driven by brainstem and hypothalamic circuits. The states are predominantly characterized from EEG and EMG and have been described as discrete states with fast-switching mechanisms. Models of underlying mechanisms of sleep-wake regulation attempt to reproduce these quantized transitions. To do so, these models often invoke discrete co-inhibitory dynamics analogous to electrical flip-flops.
Observations of switching mechanisms behind states transitions are derived predominantly from experiments with head-fixed or lightly anesthetized animals, or short recordings in sensory deprived novel environments. These conditions are abnormal and inherently dysregulate sleep-wake patterns.
To study sleep-wake transitions in normal conditions, we have obtained long-term continuous experimental single- and multi-unit measurements simultaneously from multiple of the hypothalamic and brainstem sleep-wake regulatory nuclei, along with cortical and hippocampal, activity and head acceleration, from freely behaving rats in their home-cages.
We categorized three main SOVs of REM, NREM, and Wake based on EEG rhythms, and head acceleration (Sunderam 2007): REM is characterized by a sharp spectral peak in the theta band of hippocampal activity and an absence of accelerometer activity except for brief muscle twitches. NREM is characterized by high amplitude, slow oscillations resulting in high delta band power in cortical activity and an absence of accelerometer activity. Wake is characterized by either low or high-power accelerometer activity indicating small or large head-movement respectively.
We found that transitions between these states are not discrete. We characterized a significantly long intermediate state between NREM and REM with no accelerometer activity and no clear spectral peak at delta or theta frequencies. The coarse-grained activity of the cell groups match the patterns of discrete state transitions. But on finer scale the firing rates of the REM-ON neurons did not reflect and/or predict occurrence of the intermediate state.
We report the first network analysis of the sleep-wake regulatory system derived from simultaneous measurements across multiple cell groups involved in sleep-wake regulation, in freely behaving rats. Our findings suggest that state transitions are governed by fluid interactions across multiple mechanisms rather than discrete on-or-off switches. This questions the conventional discrete definition of sleep-wake states used to investigate sleep-wake regulation in normal or diseased brain.

Title: Aberrant homeostatic sleep processes following exposure to chronic social defeat stress

Authors: *B. M. RADWAN[1], G. JANSEN[2], A. YANEZ[1], S. HAMMAMI[1], S. DEMAS[3], R. KHALIL[3], D. CHAUDHURY[1];
[1]Biol. Dept., New York Univ. Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Dept. of Physiology, Develop. and Neurosci., Univ. of Cambridge, Cambridge, United Kingdom; [3]Dept. of Biology, Chem. and Envrn. Sci., American Univ. of Sharjah, Sharjah, United Arab Emirates

Abstract: Increased stress of modern life negatively impacts sleep in the global population. Sleep and mood are closely related as sleep loss was shown to negatively affect mood. However, how chronic stress affects sleep regulation and sleep homeostasis is still poorly understood. Here, we hypothesize that the homeostatic mechanisms of sleep that signal sleep need, and restore brain stability, are aberrant in individuals exposed to chronic social defeat stress (CSD). Adult C57BL/6 mice were implanted for electroencephalogram recordings (EEG) and then exposed to a 15-day CSD protocol. They were classified as either susceptible or resilient to stress based on their social interaction and sucrose preference scores following CSD. Subsequently, the EEG was measured across a 24-h post-stress baseline, followed by a 4-h sleep deprivation (SD), and then a 8-h sleep recovery period. To further investigate how the brains of stress-naïve versus stress-exposed individuals respond to prolonged wake experience/SD, and how it recovers during sleep, we profiled gene expression by performing RNA sequencing analysis. Additionally, the differences in synaptic density and morphology via Golgi staining following SD and recovery sleep were assessed in the stress-susceptible and stress-resilient mice in order to investigate "synaptic renormalization" or downscaling during recovery sleep. Moreover, the change in the frequency and the amplitude of the miniature EPSCs (mEPSCs) recorded from the mPFC slices was examined in the stress-exposed and stress-naïve mice to explore the homeostatic depotentiation of synapses due to sleep compared to SD. We report that mice susceptible to stress exhibited increased and lasting rapid eye movement (REM) sleep rebound response following 4-h SD, whereas REM sleep occurrence in mice resilient to stress returned to the control value at a faster rate. Furthermore, stress-exposed mice display deficient non-rapid eye movement (NREM) sleep response compared to stress-naïve individuals. Our preliminary data showed that the spine density in the cortical neurons in the medial prefrontal cortex (mPFC) in stress-naïve mice was lower after 4-h recovery period compared to the stress-susceptible mice. The amplitude of mEPSCs in the stress-suceptible mice is higher than in the stress-resilient and stress-naïve mice following both SD and sleep demonstrating a deficient depotentiation mechanism of the synapses. Our data provide evidence that the homeostatic sleep processes are altered in stress-susceptible mice and that the synaptic downscaling during sleep might be deficient due to stress.

Title: Deep-brain imaging of lateral hypothalamic vGAT neurons during sleep

Authors: C. BLANCO-CENTURION[1], S. LUO[1], A. VIDAL-ORTIZ[2], Y. SUN[1], M. LIU[1], ***P. J. SHIROMANI**[2,1];

Abstract: An important goal in neuroscience is to map the circuits in the brain that are activated in response to specific behaviors, including sleep. We use microendoscopy to monitor activity in neurons that contain the vesicular GABA transporter (vGAT) and considered to be GABAergic. The vGAT neurons are a distinct population juxtapositioned with the neurons that contain orexin or melanin-concentrating hormone (MCH) in the lateral hypothalamus (LH). The activity of the LH vGAT neurons in sleep is unknown. Here, we find that they are maximally active in active waking and REM sleep. In vGAT-cre mice, rAAV-DIO-GCaMP6m was delivered stereotaxially to the LH (isofluorane anesthesia) and a GRIN lens, together with EEG and EMG electrodes were implanted. Three weeks later a baseplate was inserted (isofluorane) that allowed a miniscope (INSCOPIX) to be attached. After adaptation to the miniscope, sleep was recorded and vGAT fluorescent neurons were imaged. Thirty-eight neurons were extracted (PCA-ICA analysis; Mosaic software) from vGAT-cre mice (n=3; female; GCaMP6M). The average Ca2+ fluorescence was significantly higher during both active waking and REM sleep compared to quiet waking (QW), NREM or REM transition [$F(4,175)=14.05$; $P=0.001$; Mixed Model SPSS25]. The fluorescence in NREM was the lowest compared to the other states [$P=0.001$]. In REM sleep, the fluorescence was event-dependent and synchronized between neurons. During active waking, fluorescence was elevated during walking or grooming behavior. We found that vGAT neurons were very active during purposeful behaviors such as walking and grooming, and during REM sleep when there is muscle atonia. We contrast the activity of vGAT neurons with

the MCH neurons (Blanco etal, J Neuroscience, 2019) which were preferentially active during REM sleep. Mapping activity of neurons and glia during active waking and sleep will yield a sleep connectome.

Abstract: Patients with rapid eye movement (REM) sleep behavior disorder (RBD) display dream enactment during REM sleep. It has been recently suggested that, in addition to REM sleep alterations, NREM sleep and wake functions may also be impaired. We thus investigated topographical differences in neuronal activity between RBD patients and controls using high density electroencephalography (hdEEG) recordings in both REM and NREM sleep.
9 RBD patients underwent a regular sleep polysomnography coupled with 256 channel hdEEG. They were matched (sex and age) to 9 non-medicated controls and 9 controls with similar psychiatric conditions and medications. EEG data from N2-3 NREM and REM sleep were 1-40 Hz filtered and average-referenced. Independent component analysis was applied to remove physiological noise. Power densities of each classical EEG frequency band, absolute and subject-normalized EEG topographies, and overnight decline in delta and theta power were compared between groups. Tests were thresholded at corrected $p<.05$ (using nonparametric threshold-free cluster enhancement).
Non-medicated controls had relatively less N1 and tonic REM sleep, a shorter REM sleep latency and a faster alpha peak frequency than both patients and medicated controls (ANOVA $p<.05$). No difference in sleep architecture was found between patients and medicated controls. All three groups had similar sleep efficiency and periodic leg movement- and apnea-related

measures. Topographical analyses for REM sleep revealed marginal differences between groups. Compared to both control groups, however, patients displayed less reduction in beta power in centro-occipital regions in phasic compared to tonic REM sleep. During NREM sleep, patients showed a smaller overnight decrease in delta and theta power compared to both control groups. They also showed decreased occipital normalized alpha power compared to both control groups. Differences in sleep architecture between patients and non-medicated controls are likely related to medication effects, given they do not survive analysis with medicated controls. Compared to both control groups, patients display a reproducible decrease in attenuation of fast frequency brain activity in phasic compared to tonic REM sleep. This suggests a decreased depth of phasic REM sleep, which may be related to the occurrence of dream enactment. In addition, patients display impaired NREM sleep homeostasis compared to both control groups. This may reflect decreased cortical plasticity, possibly related to an impairment of the noradrenergic locus coeruleus, and may contribute to the non-motor symptoms of RBD and associated neurodegenerative diseases.

Title: Daily rhythm of orexin immunoreactivity and release in a diurnal rodent model of seasonal affective disorder

Authors: *A. MOODY[1], K. GEORGE[1], K. LINNING-DUFFY[1], J. LONSTEIN[2], L. YAN[2]; [1]Psychology, [2]Psychology and Neurosci. Program, Michigan State Univ., East Lansing, MI

Abstract: Orexin/hypocretin is a neuropeptide that has been implicated in many functions including sleep/wakefulness, energy expenditure, reward, mood and cognitive functions. Our previous work using diurnal Nile grass rats (*Arvicanthis niloticus*) has shown that there are fewer hypothalamic orexin-immunoreactivity (ir) cells in animals housed in a 12:12 hr light:dark (LD) cycle involving dim daylight intensity (50 lux, dimLD), in comparison to animals housed in bright daylight (1000 lux, brLD). Grass rats housed in dimLD also showed higher depression-like behaviors and spatial memory impairments compared to the animals in brLD, suggesting that the orexin system may serve as a link between daylight intensity and the behavioral changes. It has been reported in humans and nonhuman primates that orexin peptide is high during the day

and low at night in brain tissue or cerebrospinal fluid (CSF), suggesting a diurnal rhythm in peptide release. In the present study, we examined day/night fluctuation in the number, soma size, and optical intensity of orexin-ir cells in the hypothalamus of grass rats housed in dimLD or brLD for four weeks. Male and female grass rats were perfused at zeitgeber time (ZT, lights on is defined as ZT0) 2 and 14. Brains were processed to examine orexin-ir in the hypothalamus (n = 6-8/condition/sex/time point). The results revealed a significant day/night difference in the number, soma size and optical density of orexin-ir neurons, with more neurons, bigger soma size and greater density observed at ZT14 in both brLD and dimLD conditions. The higher orexin-ir at night is consistent with the high release of peptide during the day in diurnal species. Although a day/night fluctuation was observed in both brLD and dimLD groups, the amplitude was higher in brLD group, suggesting more peptide released during the day in brLD animals than in the dimLD group. To confirm this, the next experiment collected cisternal CSF in the late afternoon at ZT10 and measured orexin peptide A content using ELISA. Consistent with the higher amplitude of orexin-ir in the hypothalamus, CSF orexin A was also higher in brLD group compared to the dimLD group. The results suggest that in diurnal rodents, orexin peptides accumulate within the cell body at night, before being released during the day. Daylight intensity modulates the degree of orexin change in the hypothalamus and in CSF across a day.

Title: Too sad to sleep? Sleep patterns in a rodent SAD model analyzed by the piezoelectric system

Authors: *S. D. PHILLIPS[1], H. XIONG[1], K. DONOHUE[3], B. F. O'HARA[3], J. S. LONSTEIN[2], L. YAN[2];
[1]Psychology, [2]Psychology and Neurosci. Program, Michigan State Univ., East Lansing, MI; [3]Univ. of Kentucky, Lexington, KY

Abstract: Seasonal Affective disorder (SAD) is a major depressive disorder that occurs in the fall and winter months followed by remission in the spring and summer. The major symptoms include depressed mood, anxiety, cognitive impairments and sleep disturbance. To explore the underlying neuropathology, our lab has developed an animal model of SAD using the diurnal

Nile grass rat, *Arvicanthis niloticus.* Previous research from our lab has found that grass rats housed in a winter-like dim daylight condition show increased depressive-like behaviors and impaired spatial learning/memory compared to those housed in a summer-like bright daylight condition. These behavioral changes are accompanied by changes in the neuropeptide orexin, which has been implicated in regulating sleep/wakefulness and mood. Given the effects in behaviors and orexin, the present study investigated the extent to which sleep is affected in our SAD model, and the association between sleep disturbance and depressive behaviors. Male and female grass rats were housed in a 12 hr bright light (1,000 lux):12 hr dark (brLD) or 12 hr dim light (50 lux):12hr dark (dimLD) conditions (n=7-8/condition/sex). Sleep pattern were recorded and analyzed over four weeks using a piezoelectric motion sensor system. Following sleep recording, animals were tested for anxiety and depression-like behavior using the open field and forced swim test (FST). Analysis of sleep recording revealed a significant effect of daytime light intensity in male grass rats. Males housed in dimLD had a lower diurnal wake ratio and shorter sleep bout lengths at night compared to those in brLD. The peak wake time also appeared to be delayed, occurring toward the end of the day, in some of the dimLD animal in contrast to early morning peaks in all of brLD males. In females, the difference between brLD and dimLD group was not statistically significant. This may be due to a higher intergroup variability and/or limited sensitivity of the motion sensor because of a lighter body weight compared to males. We also confirmed again that animals housed in dimLD condition showed increased depression-like behaviors revealed by a shorter latency and longer duration of immobility during FST ($p<0.05$) in both males and females. Interestingly, males that showed a shorter sleep bout at night tend to have a shorter latency ($R=0.89$, $p = 0.001$) and longer duration ($R=-0.44$, $p = 0.23$), while females that showed a shorter sleep bout during the day tend to have a shorter latency ($R=0.77$, $p < 0.01$) and longer duration ($R=-0.7$, $p = 0.02$) of immobility during FST. These results will contribute to a better understanding of the interplay among depressed mood, sleep disturbance, and sex in SAD.

Title: Effect of closed-loop auditory stimulations on sleep homeostasis and delta waves dynamics

Authors: *K. EL KANBI[1], K. BENCHENANE[2];
[1]CNRS, Paris, France; [2]MOBS Team, Brain Plasticity Unit, UMR CNRS ESPCI, Paris, France

Abstract: Slow-wave-sleep is a critical phase for recovery. More precisely, slow oscillations coming from the rhythmic occurrence of delta waves - broad oscillations (~1Hz) observed in mammals - seem to be linked to the amount of time spent awake and are a widely used marker for sleep pressure. Studies have shown possible to manipulate these slow waves with auditory stimulations: enhancing slow waves would result in an improvement in sleep dependent memory task, whereas perturbing them impairs would have an negative effect on a sleep dependent visuo-motor task. After assessing the short-term effect of auditory stimulations on the cortical multi-unit activity during sleep in mice, we study the effect of impairing or enhancing delta waves with sounds on sleep homoeostasis and delta waves dynamics at a larger time scale

Title: *In vivo* cell specific characterization of AVP neurons in the mouse suprachiasmatic nucleus

Authors: *A. C. STOWIE[1], I. ELLIS[1], D. CAMACHO[1], M. BENVENISTE[2], A. J. DAVIDSON[1];
[1]Neurobio., [2]Neurosci. Inst., Morehouse Sch. of Med., Atlanta, GA

Abstract: Previous work has identified an important role for VIP expressing neurons in maintaining and resetting the phase of the mammalian master clock, the SCN *in vivo*. Conversely, though it is known that AVP expressing neurons in the mammalian SCN are important in determining the circadian network period, little is known about how these neurons behave in an intact neuronal network. In the present work, we have utilized miniaturized one-photon microscopy to characterize the calcium dynamics in AVP neurons of awake, behaving mice in constant darkness, a light/dark schedule, and during acute light exposure. In contrast with global SCN electrical activity measured by MUA, we found that only a relatively small proportion of SCN AVP neurons seem to display daily rhythms in both baseline fluorescence as well as spontaneous calcium events and with a subjective nighttime peak. Interestingly, when

present, these calcium events were high amplitude and last as long as 30 seconds. Further, we have not observed changes in baseline fluorescence or induction of calcium events in response to acute light exposure. Taken together, these data provide unexpected characteristics of neurons within the murine master clock which are thought to have an important role in synchronizing extra-SCN oscillators throughout the body.

Title: Implantable microimaging CMOS sensor for deep brain gene expression analysis in freely behaving mice

Authors: *J. OLOROCISIMO, J. BRIONES, R. REBUSI, Y. OHTA, M. HARUTA, K. SASAGAWA, Y. NAKAHATA, Y. BESSHO, J. OHTA;
Nara Inst. of Sci. and Technol., Ikoma, Japan

Abstract: The suprachiasmatic nucleus (SCN) is the main regulator of our circadian rhythm, and is dubbed as the body's "central clock". It controls the timing of numerous physiological processes in an organism such as the sleep-wake cycle, hormonal secretion, digestion, metabolism and even mood. The dysfunction of circadian rhythm has been implicated in a wide variety of diseases such as obesity, cancer, and depression. However, the causal mechanism has yet to be established.
In order to do this, there must be a method to observe and manipulate the SCN most especially *in vivo*. However, due to its deep brain location and small size, it has been difficult to observe and much more manipulate the SCN. Recent technology employed the use of implanted optical fibers to visualize luciferase reporter-based gene expression in the SCN, but this involves the use of huge photomultiplier tubes which are very expensive and difficult to handle.
In our study, we present a very lightweight and ultrasmall microimaging CMOS sensor that is safe to implant and inexpensive to manufacture. We tested the sensitivity and signal-noise ratio of our device compared to previous models, and found a remarkably improved performance. Furthermore, we added an alternating array of optical absorption filter on the device to reduce background noise. The new device showed: a higher sensitivity to small changes in light intensity; a better signal-noise ratio, as exhibited by a larger difference between signal and noise readings; and finally, a low fluctuation of temporal noise despite long exposure times. The improvement of these parameters was important because of the weak intensity of bioluminescent

reporters like luciferase.
The device can enable us to observe circadian gene expression in freely behaving *Bmal1-Luc* and *Per1-Luc* mice. This will allow for the analysis of both deep brain gene expression and organismal behavior at the same time and in the same individual. Furthermore, the device can be coupled with uLEDs for optogenetic manipulation. This can potentially be used to elucidate the relationship between neural activity, gene expression and behavior, and see how the interplay of these might lead to circadian dysfunction and its numerous implicated diseases.

Title: Characterization of SynGAP circadian expression within the murine suprachiasmatic nucleus

Authors: *S. ATEN[1], K. R. HOYT[2], K. OBRIETAN[3];
[1]Dept. of Neurosci., [2]Pharmaceutics and Pharmaceut. Chem., Ohio State Univ., Columbus, OH;
[3]Dept. of Neurosci., Ohio State Univ. Dept. of Neurosci., Columbus, OH

Abstract: Mammalian physiology is modulated by a complex, distributed, network of circadian timing systems. At the center of this organism-wide web of oscillators is the suprachiasmatic nucleus (SCN) of the hypothalamus. As the master clock, the SCN modulates the phasing of peripheral oscillator networks. In addition, the SCN serves as the sole conduit by which the 24 hr light cycle sets the phasing of the circadian timing system. One key effector of SCN timekeeping and light entrainment is the p44/42 mitogen-activated protein kinase (ERK/MAPK) cellular signaling pathway. Notably, the ERK/MAPK cascade is activated by a number of small-molecule GTPases—including Ras and Rap. Here, we analyzed the expression of SynGAP—a GTPase-activating protein that functions as a negative regulator of Ras and Rap signaling—within the murine SCN. Of note, SynGAP is known to be expressed mainly in the postsynaptic density of excitatory, glutamatergic, neuronal populations, where it couples NMDA-receptor activation to the suppression of Ras/ERK/MAPK signaling. Using a combination of immunohistochemical, cell culture, and Western blotting approaches, we show that SynGAP is highly expressed within the SCN. Specifically, double fluorescence-based immunolabeling revealed that SynGAP is expressed in GABAergic SCN neurons. Further, we show that SynGAP is enriched within the arginine vasopressin-positive neurons that form the shell region of the SCN—with lower levels of expression detected within the retinoreceptive SCN core region. In

addition, a significant circadian oscillatory expression pattern of SynGAP was detected in both the SCN shell and core regions—a finding that was not observed in animals with germline deletion of the core circadian-clock gene *BMAL1*, which renders animals arrhythmic. Finally, we found that a light pulse (15 min; 100 lux) during the early subjective night triggered an increase in SynGAP phosphorylation at Serine 1138—an event that has been shown to disrupt SynGAP signaling by triggering its dispersion from the synapse. These findings raise the prospect that, via its effects on MAPK signaling, SynGAP could function as a potent modulator of SCN clock timing and entrainment. Currently, we are in the process of characterizing the circadian and light entrainment phenotypes of *SYNGAP1* null and heterozygous animals.

Title: Somatostatin contributes to light-driven plasticity of circadian behavior and master clock function

Authors: *D. A. JOYE, M. ARZBECKER, T. INDA, A. WUORINEN, N. O'NEILL, A. TELEGA, E. HERFF, J. A. EVANS;
Biomed. Sci., Marquette Univ., Milwaukee, WI

Abstract: Daily rhythms in behavior and physiology are programmed by a master clock in the anterior hypothalamus known as the suprachiasmatic nucleus (SCN)—a neural network containing different types of neurons distinguished by peptide expression. Somatostatin (SST) is an inhibitory neuropeptide produced by a subclass of SCN neurons that form extensive connections with many different types of SCN neurons. Although this suggests that SST may influence SCN function, the specific role of SST signaling in the master clock remains unclear. Previous research has found that seasonal lighting conditions influence SST expression in the hypothalamus, but whether this likewise occurs in the SCN has not been examined. Here we test that long days increase the number of SCN somatostatin (SST) neurons and that SST signaling regulates circadian clock function. Using a genetic labeling approach, we find evidence that long days activate *de novo* somatostatin transcription in a reserve pool of SCN neurons. Further, loss of somatostatin alters circadian behavioral responses to long day photoperiods and other environmental lighting conditions. In line with these results, the SCN expresses receptors for

SST, with spatiotemporal variation in the pattern of SSTR expression that is distinct from that found for other SCN neuropeptides. Lastly, loss of somatostatin signaling markedly attenuates the ability of SCN neurons to resynchronize and return a synchronous state after exposure to long day photoperiods. Collectively, these results suggest that somatostatin signaling is an important SCN signal that contributes to light-driven plasticity of circadian behavior and master clock function. More broadly, this work identifies a novel peptidergic subclass that forms a critical circuit node required for clock network function, expanding our understanding of SCN circuitry.

Title: Circadian circuits underlying daily rhythms in corticosterone release

Authors: *J. R. JONES, E. D. HERZOG;
Washington Univ. in St. Louis, St. Louis, MO

Abstract: The circadian release of hormones at the optimal time of day is essential for normal behavior and physiology. Disruption of these rhythms due to disease or lifestyle is associated with numerous pathologies including affective and metabolic disorders. Understanding the neural circuits regulating the daily pattern of hormone production is therefore a fundamental problem in neuroscience. The timing of hormone release is controlled by the master circadian pacemaker, the suprachiasmatic nucleus (SCN). However, fundamentally, we do not know how the SCN regulates daily rhythms in different hormones that each peak at different times of day. Here, we address this problem by investigating the mechanisms underlying the circadian production of corticosterone. Specifically, we examined the interaction between vasoactive intestinal peptide (VIP)-producing neurons in the SCN and corticotropin-releasing hormone (CRH)-producing neurons in the paraventricular nucleus of the hypothalamus (PVN). We postulated that circadian signals from SCN VIP neurons to PVN CRH neurons influence rhythmic corticosterone production in the hypothalamic-pituitary-adrenal axis. We found that ex vivo, CRH neurons exhibit daily rhythms in intracellular calcium levels as measured by

GCaMP6s and core clock gene expression as measured by PER2::LUC. We also found that the majority of CRH neurons express the VIP receptor VPAC2R. Both PER2 expression and calcium transients in CRH neurons were induced after applying VIP to the ex vivo PVN slice. In vivo, we found that CRH neurons exhibited daily rhythms in calcium transients peaking either around midday or dusk. These results suggest the existence of subpopulations of circadian CRH neurons with distinct times of daily activity in the PVN. Finally, we found that in vivo optogenetic stimulation of SCN VIP neurons reduced the peak amplitude of circadian corticosterone release measured every 4 hours over 3 days. Together, these preliminary results indicate that the circadian regulation of corticosterone release depends on a daily inhibitory signal from SCN VIP neurons to circadian subpopulations of PVN CRH neurons. Title: Tonic and synaptic $GABA_A$ receptor-mediated currents in suprachiasmatic nucleus neurons

Authors: M. MOLDAVAN, O. CRAVETCHI, *C. N. ALLEN;
Oregon Inst. of Occup. Hlth. Sci., Oregon Hlth. Sci. Univ., Portland, OR

Abstract: $GABA_A$ receptor ($GABA_AR$)-mediated neurotransmission plays an important role in the function of suprachiasmatic nucleus (SCN). Despite the fact that $GABA_A$ receptor-mediated synaptic currents (GPSC) are well studied, the origin and parameters of the $GABA_AR$-mediated tonic current (Itonic) remain unexplored. Whole-cell patch clamp recordings from SCN neurons in rat brain slices were performed using a high $CsCl^-$ intracellular recording solution. Picrotoxin (50 µM) and the $GABA_AR$ inhibitors gabazine (10 µM) and bicuculline (20 µM), induced an outward shift of holding current (6.2 ± 1.4 pA, 9.1 ± 2.6 pA, and 9.5 ± 2.0 pA, respectively), which defined the magnitude of the Itonic. The Itonic amplitude increased proportionally to the spontaneous GPSC (sGPSC) frequency and the magnitude of synaptic charge transfer. TTX (1 µM) inhibited action potential dependent synaptic GABA release and reduced the Itonic 82.0 ± 4.0 %, which demonstrates the importance of GABA diffusing out of GABAergic synapses for Itonic activation. Circadian regulation of the tonic and $GABA_A$-mediated synaptic currents were analyzed. The root mean square noise (RMS) reflects the sum of the currents flowing through

individual extrasynaptic $GABA_A$ receptors ($GABA_ARs$). RMS increased during activation of extrasynaptic $GABA_ARs$ and decreased during their inhibition by bicuculline, gabazine and picrotoxin. Activation of presynaptic $GABA_B$ receptors inhibited the GABA release from synaptic terminals, decreased the sGPSC amplitude and frequency, and decreased the Itonic. The baseline current was not altered by activation of postsynaptic $GABA_B$ receptors nor the glycine receptor antagonist strychnine (1 μM). The equilibrium potential for Itonic was close to 0 mV, which was similar to the calculated Cl^- equilibrium potential, under our experimental conditions, and was the same as the equilibrium potential for the currents induced by GABA (50, 100 μM). The Itonic amplitude showed noticeable outward rectification at membrane potentials over the range of -70 mV to -10 mV then was linear at voltages greater than -10 mV. Expression of α4-, α5- and δ- $GABA_AR$ subunits in the SCN was shown using fluorescent microscopy and their contribution to Itonic was confirmed by application of the $GABA_AR$ agonist THIP and $GABA_AR$ inverse agonist L655,708. Thus, Itonic was mediated by extrasynaptic $GABA_ARs$, and was primarily activated by GABA diffusing out of GABAergic synapses.

Title: Colocalization of Na^+/Ca^{2+} exchanger NCX1 and L-type Ca^{2+} channel $Ca_V1.2$ with neuropeptides in the rat suprachiasmatic nucleus

Authors: Y.-S. CHEN, *R.-C. HUANG;
Dept. of Physiol. and Pharmacol., Chang Gung Univ. Col. of Med., Tao-Yuan, Taiwan

Abstract: The central clock in the suprachiasmatic nucleus (SCN) is composed of two oscillators with asymmetric mutual interaction. Light information entrains the gastrin-releasing peptide (GRP)- and vasoactive intestinal peptide (VIP)-containing neurons in the core or ventrolateral SCN oscillator, which in turn entrains the arginine vasopressin (AVP)-containing shell or dorsomedial SCN oscillator. In the rodent SCN, high K^+ solution produces Ca^{2+}-dependent release of dense-core vesicles as well as all three major neuropeptides, VIP, GRP, and AVP. In the rat SCN neurons, the Ca^{2+} response to high K^+-evoked depolarization is shaped by Ca^{2+} entering both L-type and non L-type Ca^{2+} channels and by Ca^{2+} clearance through the plasmalemmal Na^+/Ca^{2+} changer (NCX). The rat SCN expresses NCX1 and NCX2, but not

NCX3, with NCX1 distributed in the whole SCN and NCX2 restricted to the ventral SCN. The immunostaining results also indicated colocalization of NCX2 with VIP, GRP and VIP/GRP in the ventral SCN, but not with AVP in the dorsal SCN. In this study we used double and triple immunofluorescence staining to investigate the colocalization of NCX1 and CaV1.2 with neuropeptides (VIP, GRP, and AVP) and markers for major input pathways (vesicular glutamate transporter type 2 (vGluT2), serotonin transporter (SERT), and neuropeptide Y (NPY)) in the SCN prepared from Sprague-Dawley rats (23-25 days old; n = 12). Our results indicated high levels of colocalization of NCX1 with AVP and VIP, but not GRP, in particular, in puncta surrounding the soma and in varicosity-like swelling along the process. NCX1 is also found to colocalize with SERT and NPY, but not vGluT2. The colocalization pattern of NCX1 is consistent with our previous observation that NCX1 is distributed in the whole SCN, but with more intense NCX1 immunoreactivity in the ventral region that receives major inputs. Furthermore, triple staining of NCX1, CaV1.2 and VIP can be observed as puncta opposing the soma, and there is also triple staining of NCX1, CaV1.2 and SERT scattered as puncta in the ventral SCN, suggesting the involvement of NCX1 and CaV1.2 in the regulation of VIP and serotonin release. Together with our previous observation of more restricted localization of NCX2 with VIP, GRP, and VIP/GRP, the results suggest a differential role of NCX1 and NCX2 in the regulation of neuropeptide release in the SCN.

Title: Functional network of suprachiasmatic nucleus in the human brain using independent component optimization

Authors: B. KIM[1], Y. JUNG[2], J. BAE[2], H. KIM[2,1], M. BYUN[3], Y. LEE[3], *Y. SON[2,1], D. LEE[3]; [1]Gachon Advanced Inst. for Hlth. Sci. & Technol., Incheon, Korea, Republic of; [2]Gachon Univ., Incheon, Korea, Republic of; [3]Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract: Circadian rhythm is important in determining sleep-wake cycle and suprachiasmatic nucleus (SCN) plays a major role as a pacemaker in the brain. Recently, in the resting state functional magnetic resonance imaging (rsfMRI), several functional network have been found, but the sleep-wake cycle network has not been found yet. In this study, we postulate that the

SCN is the major component of the circadian rhythm and its network can be resolved from the rsfMRI signal by increasing the number of the components in the independent component analysis (ICA). The present study included normal adults(n=152, 77 males, 25-86 years) who participated in the Korean Brain Aging Study for the Early Diagnosis and Prediction of Alzheimer's disease (KBASE), which is an on-going prospective cohort study since 2014. All participants underwent 3D T1-weighted MRI scans with a 3T Biograph mMR (PET- MRI) scanner (Siemens; US). Each images were normalized with template image provide by SPM8. Based on the fact that the SCN is located in ventral side of hypothalamus and top of optic chiasm, the regions of interest (ROIs) were set as left (x=3 ,y=4, z=-12) and right SCN (x=-3 ,y=4, z=-12) on the averaged T1 image. ICA was used to decompose rsfMRI signal using functional connectivity toolbox (CONN). As the number of independent component (IC) was increased in the range of 20 to 70, the network having the maximum beta values within the SCN ROI was selected among all beta maps (Fig. 1a). In order to confirm its relevance to the circadian rhythm, correlation was performed between beta values of the SCN and sleep-wake parameters such as onset latency, efficiency, wake after sleep onset (WASO). As the result, the beta value of SCN reached the maximum when the number of ICs was 55(fig. 1b, red box). Onset latency (r: -0.366, p: 0.00001), WASO (r: -0.254, p: 0.001) and efficiency(r: 0.289, p: 0.0003) showed significance with right SCN (Fig. 1b). It is worthy of note that the correlation also reached maximum when the number of ICs was 55. In conclusion, the newly defined network from the rsfMRI may be associated with SCN, circadian rhythm, and sleep.

Title: Gene expression rhythms in the suprachiasmatic nucleus are changed during timed daily restricted feeding

Authors: *T. D. NIEPOKNY[1], A. RASTOGI[2], E. M. MINTZ[3];
[1]Dept. of Biol. Sciences, Sch. of Biomed. Sci., [2]Dept. of Biol. Sci., [3]Biol. Sciences, Biomed. Sciences, and Brain Hlth. Res. Inst., Kent State Univ., Kent, OH

Abstract: The suprachiasmatic nucleus (SCN) of the hypothalamus regulates circadian rhythms of physiology and behavior in mammals. The circadian clock mechanism in the SCN is normally entrained by the daily light/dark (LD) cycle. This regular activity rhythm can be modulated by regular, nonphotic events. In particular, animals respond to periods of restricted food access during the daytime by showing a period of food anticipatory activity, which is thought to represent signaling from a food entrainable oscillator. The response of the circadian clock in the SCN to restricted feeding appears to be both species and strain-specific. In mice, some inbred strains can entrain locomotor activity to normocaloric restricted feeding cycles in constant darkness, while others, such as the C57BL/6J strain, rarely do so. Previous research suggests that C57BL/6J mice do not experience a shift in clock gene expression in the SCN during normocaloric timed restricted feeding, while other brain regions do show changes in clock gene expression. However, such studies were limited and primarily looked at period gene expression. In this series of studies, we sought to measure expression levels of both clock and neuropeptide genes in the SCN of C57BL/6J female mice on a 4-hour daytime restricted feeding schedule. Mice were individually housed with a running wheel on a 12:12 LD cycle with food available ad libitum for two weeks. After entrainment, food restriction occurred from ZT6-ZT10 (daytime restricted feeding), ZT18-ZT22 (nighttime restricted feeding) or ad libitum for 14 days, upon which mice (n = 5 per timepoint per group) were sacrificed every four hours across the circadian cycle. RNA samples from SCN tissue punches were then reverse transcribed into cDNA for quantitative real-time PCR analysis of the clock and neuropeptide genes *Per1, Per2, Cry1, Cry2, Clock, Bmal1, AVP, VIP, Grp* and *Sst.* Analysis of rhythmic expression using JTK_Cycle revealed significant rhythmicity in *Per1*, *Per2*, and *Avp* under baseline ad/lib feeding conditions and nighttime restricted feeding. However, during daytime restricted feeding rhythmicity was also induced in *Clock*, *Bmal1*, and *Cry1*, with near significant rhythms also detected in *Cry2*, and *Grp*. The phase of *Per1, Per2*, and *Avp* was not substantially altered in daytime restricted feeding, but the phase of *Clock* and *Bmal1* appeared to shift such that they peaked shortly after the period genes. Rhythm amplitude was also increased in *Per2* during daytime restricted

feeding. These data suggest that changes in the phase relationship between clock genes may be associated with changes in locomotor activity patterns during timed restricted feeding.

Title: Regional specializations of arginine vasopressin neurons in the suprachiasmatic nucleus

Authors: *Y. CARBAJAL[1], R. HOLT[1], J. LESAUTER[2], R. SILVER[3];
[1]Neurosci., [2]Barnard Col., New York, NY; [3]Psychology, Columbia Univ., New York, NY

Abstract: Arginine Vasopressin (AVP-) expressing neurons form the major population of the ~20,000 neurons in the Suprachiasmatic Nucleus (SCN). They participate not only in inter-neuronal coupling which serves to synchronize oscillation, but also in the output signal that supports circadian rhythmicity in the rest of the brain and body. Dynamic analysis of SCN oscillation suggests a caudal to rostral wave of activation, pointing to the possibility of functional specializations in the network of these subregions of the nucleus. To explore this hypothesis, we analyzed AVP neurons and their efferents in the SCN. We found that the anterior and posterior populations differ importantly in morphology and projections. The posterior AVP neurons are larger in size than those lying in the anterior area. The majority of fibers of the posterior populations project dorsally and caudally while rostral neurons project rostrally towards the third ventricle. We conclude that there are distinct clusters of regionally specialized AVP neurons in the SCN. The implication of these findings is that these distinct populations differ in the signal they produce and in the targets that they reach.

Title: Integration of neuropeptide signaling sets the phase of the master circadian clock

Authors: *K. E. ROHR, J. A. EVANS;
Marquette Univ., Milwaukee, WI

Abstract: Daily rhythms in behavior and physiology are generated by the suprachiasmatic nucleus (SCN) of the anterior hypothalamus. Although intercellular signaling is known to be necessary for SCN function, the signaling mechanisms that sustain master clock function remain unclear. Like other hypothalamic nuclei, the SCN contains a variety of distinct cell types characterized by differences in neurotransmitter and neuropeptide expression. The SCN is typically subdivided into two spatially segregated compartments known as the shell and core, which contain arginine vasopressin (AVP) and vasoactive intestinal polypeptide (VIP) neurons, respectively. Although AVP has been viewed traditionally as an output signal, the SCN itself expresses AVP receptors (V1A and V1B). Despite being the first neuropeptide detected in the SCN, the role of V1 signaling in determining master clock function remains unclear. To gain a deeper mechanistic understanding of V1 signaling in the SCN, we used an *in vitro* bioluminescence assay to interrogate whether V1 receptor agonists reset the circadian clock a the molecular level. We find that V1 signaling shifts the molecular clock in the SCN in a time-dependent manner to elicit phase delays during subjective night, which is the time of highest V1A receptor expression. Interestingly, the magnitude of the resetting response differed by sex and varied across the anteroposterior axis of the SCN, indicating that there are dimorphic and regional differences in V1 receptor function. Further, V1 agonists failed to reset the SCN molecular clock in the absence of VIP, suggesting that AVP signaling interacts with VIP signaling to reset the master clock at either the cellular or network levels. Overall, this work reveals that AVP signaling acts in combination with other important SCN neuropeptides to modulate the emergent properties of the master clock network, which likely has implications for the daily regulation of behavior and physiology.

Title: Electrophysiological effects of secretin among distinct neural populations of subfornical organ

Authors: *F. ZHANG[1], L. ZHANG[2], W. YUNG[3], B. K. C. CHOW[1];
[1]Sch. of Biol. Sci., The Univ. of Hong Kong, Hong Kong, China; [2]GHM Inst. of CNS Regeneration, Jinan Univ., Guangzhou, China; [3]The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: In animal's brain, subfornical organ (SFO) is a circumventricular organ that lacks the normal blood-brain barrier, is an important sensor for circulating signal, and has been suggested to have an essential role in maintaining water homeostasis. Recent studies have shown that there are distinct neural populations in the SFO, and excitatory neurons may directly drive drinking behaviour. As the first hormone to be found, Secretin (SCT) is a classical gastrointestinal peptide hormone. In recent years, our laboratory discovered the osmoregulatory actions of SCT in which both acute and chronic intraventricular administration of SCT can significantly increase water intake in mice. Furthermore, SCT and SCT receptor (SCTR) were found to be highly expressed in SFO after water deprivation treatment through immunohistochemistry and *in situ* hybridization staining. However, it is still unclear how SCT acts on SFO neurons, the most upstream water homeostatic centre. In this study, we have recorded the effects of SCT in excitatory neurons (marked by neuronal nitric oxide synthase, nNOS) and inhibitory neurons (marked by glutamate decarboxylase 1, GAD67) of SFO by whole-cell patch-clamp. The population of neurons in SFO was identified by single-cell RT-PCR and electrophysiological properties. Immunofluorescence results showed that c-Fos expression in SFO^{SCTR} neurons was significantly up-regulated after 48 hours water deprivation. In addition, SFO^{nNOS} and SFO^{GAD67} neurons overlap with 61% and 21% of SFO^{SCTR} neurons, respectively. Current-clamp recordings demonstrated that bath-applied 300 nM SCT influences the excitability of the SFO^{nNOS} neurons by eliciting depolarizing (mean 5.38 ± 0.42 mV, 9 of 21 cells), effects which were concentration dependent and reversible. Meanwhile, only a few of SFO^{GAD67} neurons were depolarized by SCT (mean 6.34 ± 1.60 mV, 4 of 24 cells). Moreover, no significant SCT effects were observed in the SFO of the SCTR knockout mice. In line with the electrophysiological results, c-Fos expression in the SFO was found to be up-regulated after intraperitoneal injection of SCT (100 g/kg body weight) and most of it were expressed in SFO^{nNOS} neurons. Present results demonstrated that (1) SCTR was primarily localized on SFO^{nNOS} neurons; (2) circulating SCT can directly influence the excitability of distinct neural populations of the SFO. Based on these data, we hypothesize that up-elevated circulating SCT level during hyperosmolarity may induced water drinking behaviour by activating SFO^{nNOS} neurons. Overall, these data will help to establish a complete mechanistic role of SCT in water homeostasis.

Title: Sodium palatability in spontaneously hypertensive rats with angiotensin type 1 receptor blockade in the brain

Authors: E. D. PEREIRA JR, G. M. F. ANDRADE-FRANZÉ, ***J. V. MENANI**, L. A. DE LUCA JR, C. A. F. ANDRADE;
Dept. of Physiol. and Pathology, Dent. School, UNESP, Araraquara, SP, Brazil

Abstract: Excessive salt intake has been associated with the development or worsening of chronic diseases such as hypertension. Spontaneously hypertensive rats (SHR) have an increased preference and palatability for sodium when compared to normotensive strains. In the present study, we tested the changes in sodium appetite and palatability in 24 h water deprived SHR and normotensive rats with or without the blockade of angiotensin II (ANG II) type 1 receptors (AT-1r) centrally. Male SHR (n = 12) and normotensive Holtzman rats (HTZ, n = 10) with stainless steel guide cannulas implanted in the lateral ventricle (LV) and a polyethylene cannula implanted intra-orally (IO) were used. Rats with 24 h of water deprivation (WD) had access to only water during 2 h for partial rehydration (PR) (WD-PR protocol) before receiving LV injections of saline (1 µl) or losartan (100 ng/1 µl). Fifteen min after LV injections, hedonic and aversive orofacial motor responses to intra-oral infusions of 0.3 M NaCl (IO-NaCl, 1 ml/min) were recorded. Immediately after, rats were allowed to freely ingest 0.3 M NaCl and water for one hour (appetite test) and at the end of the test another IO-NaCl infusion was performed. Before sodium appetite test, SHR treated with saline into the LV showed increased number of hedonic (213 ± 30, vs. HTZ: 9 ± 3 reactions/min) and reduced aversive reactions (11 ± 6, vs. HTZ: 38 ± 5 reactions/min) in response to IO-NaCl. Losartan reduced the number of hedonic (34 ± 9), with no effect on aversive (17 ± 5) reactions in SHR. In the sodium appetite test, SHR treated with saline into the LV ingested more 0.3 M NaCl than HTZ (2.8 ± 0.4, vs. 0.8 ± 0.2 ml/100 g/h), an effect abolished by losartan (0.4 ± 0.2 ml/100 g/h). However, losartan did not change the number of hedonic (119 ± 21, vs. saline: 154 ± 28) or aversive (13 ± 5 vs. saline: 3 ± 1) reactions in SHR at the end of the sodium appetite test. The results show increased palatability and sodium intake in SHR submitted to WD-PR. They also suggest that central AT-1r is part of the mechanisms activated to increase sodium intake and palatability in SHR.

Abstract: Interoception, the process of sensing and integrating diverse bodily signals, is essential for regulating physiological homeostasis, cognition, and emotions. Studies in humans highlight the importance of insular cortex (InsCtx) for interoception, yet the underlying cellular activity patterns and circuit mechanisms remain unclear. Here, we performed microprism-based two-photon imaging of InsCtx across natural and artificial states of hunger and thirst. InsCtx neurons were driven by cues predicting food/water, but also showed gradual changes in ongoing activity reflecting physiological state transitions. In sated mice, artificial activation of hypothalamic neurons that drive hunger/thirst restored selective behavioral and InsCtx responses to food/water cues, but it did not restore InsCtx representations of physiological state. Food/water cues transiently shifted the pattern of InsCtx population activity towards representations of a future satiety state. Together with circuit-mapping experiments, these data suggest that InsCtx integrates visceral-sensory inputs regarding current physiological state, with hypothalamus-gated limbic inputs signaling upcoming ingestion of food/water, to compute a prediction future physiological state.

Title: AT_2 angiotensin receptor involved on sucrose intake induced by water deprivation

Authors: M. H. PAES, L. M. CARDOSO, ***L. B. DE OLIVEIRA**;
Biol. Sci., Fed. Univ. Ouro Preto - UFOP, Ouro Preto, Brazil

Abstract: Water deprivation generates endogenous production of angiotensin II, which is associated with water and sodium intake. However, recent studies have also shown an increase in sucrose intake after water deprivation followed by partial rehydration. Thus, this study aimed to verify the central involvement of angiotensin receptors on water deprivation-induced sucrose intake. Therefore, male Wistar rats weighing 300-330g were anesthetized with ketamine (80 mg/kg) and xylazine (7 mg/kg) and a stainless-steel cannula was implanted directed to the right lateral ventricle (LV) in animal's brain. During recovery period (five days), water, 2% sucrose solution and food were offered *ad libitum*. To the intake test, water and sucrose solution were removed for 24 hours. After this period, food was removed and the rats had free access to water (partial rehydration) for 2 hours (water intake was measured at 15, 30, 60, 90 and 120 minutes). At 105 minutes (after the beginning of water offer) the animals received central injection (1µL on LV) of vehicle, AT1 or AT2 angiotensin receptor antagonists (losartan 50nmol/µL or PD 123319 30nmol/µL, respectively). 15 minutes later, 2% sucrose solution was also offered to the animals. Water and sucrose intakes were measured at 135, 150, 180, 210 and 240 minutes. At the end of 4 hours, the animals received food, water and 2% sucrose solution *ad libitum*. Results are expressed as means±SEM. Two-way RMANOVA and pos test Tukey's were used for statistical analyses. Differences were considered significant at $p<0.05$. In the first two hours of experiment (before the central injections), a similar water intake among groups was observed, which corresponds to partial rehydration that occurred in response to water deprivation. After central injections, as expected, there was no significant water intake (vehicle 0.3 ± 0.3, losartan 0.1 ± 0.1 and PD123319 0.2 ± 0.2, $p>0.05$). Animals that received injection of vehicle or losartan ingested a higher amount of sucrose than animals receiving PD123319 injection (vehicle 6.1 ± 1.9, losartan 7.2 ± 1.4, PD123319 0.74 ± 0.79, $p=0.0001$). These results suggest that sucrose intake induced by water deprivation depends on AT2, but not AT1, receptor activation.

Title: Distinct neural circuits for food- and water-related presystemic regulation of vasopressin release

Authors: *A. KIM[1,2], J. C. MADARA[1], M. L. ANDERMANN[1,2], B. B. LOWELL[1,2];
[1]Div. of Endocrinology, Diabetes, and Metabolism, BIDMC, Boston, MA; [2]Program in Neurosci., Harvard Med. Sch., Boston, MA

Abstract: Vasopressin (VP), an antidiuretic hormone, is key for maintaining water balance. VP release is regulated by two temporally distinct signals: 1) slow systemic signals that convey systemic osmolality information, and 2) rapid 'presystemic' signals that anticipate future osmotic challenges. We recently demonstrated that VP neurons show bidirectional anticipatory presystemic responses to feeding and drinking. To find the source of presystemic regulation, we used rabies and ChR2-assisted circuit mapping to map afferents to neuroendocrine VP neurons. Major inputs to VP neurons come from the lamina terminalis (the SFO and MnPO/OVLT), A1/C1 neurons of ventrolateral medulla, and GABAergic neurons in the perinuclear zone (PNZ), an area surrounding supraoptic nucleus. Using fiber photometry, we found that SFO and MnPO/OVLT neurons, like VP neurons, are rapidly regulated by water-predicting cues and water intake. Inhibition of neurons in the MnPO/OVLT significantly attenuated the presystemic response of VP neurons to water cues and drinking while leaving the food response intact, suggesting that MnPO/OVLT acts as a gateway for water-related presystemic regulation but has no role in presystemic regulation by food. Food-related presystemic regulation is not mediated by A1/C1 neurons, PNZ^{GABA} neurons, nor release of gut hormones as blocking these pathways had no effect on VP response to feeding. Instead, we found that A1/C1 neurons mediate hypotension- and hypoglycemia-induced activation of VP neurons. We are in the process of identifying the source of food-related presystemic regulation. These results suggest VP neurons

are regulated by multiple distinct and dedicated circuits that carry presystemic and systemic information about physiological states of the body.

Title: Brattleboro rats are more sensitive to the glucagon-like peptide-1 receptor agonist, exendin-4

Authors: *D. J. BRAKEY, K. C. SCHATZ, M. J. PAUL, D. DANIELS;
State Univ. of New York at Buffalo, Buffalo, NY

Abstract: Long Evans rats that are homozygous for the Brattleboro mutation lack arginine vasopressin (AVP) and are a model of diabetes insipidus. To defend fluid homeostasis in the face of the lack of AVP, Brattleboro rats consume significantly more water than do wildtype (WT) controls. Despite this excessive water intake, food intake remains relatively normal. Given that activation of the glucagon-like peptide-1 (GLP-1) system decreases both food and water intakes, it suggests that the impact of endogenous GLP-1 on fluid intake is somehow overridden in the Brattleboro rat, while its role in food intake satiety is maintained. Accordingly, we aimed to use Brattleboro rats to better understand the neural mechanisms controlling water intake, separate from those that underlie food intake. As a first step toward this larger goal, we evaluated the response to a central injection of a GLP-1 receptor (GLP-1R) agonist in male and female WT and Brattleboro rats. Food and water intakes were measured 4, 12, and 24 hours post-injection. Evaluation of the timing of water intake between measures was inferred by lickometry. Results show that despite the strong need to consume water, Brattleboro rats were equally, if not more, sensitive to the GLP-1R agonist exendin-4. Most suppression occurred in the first 12 hours, but Brattleboro rats showed suppression that persisted into the last 12 hours of the test. Analysis of drinking microstructure indicated that the decrease in fluid intake caused by exendin-4 was primarily due to a reduction in burst size, which is thought to reflect orosensory components of the fluid. Additionally, sex differences in baseline food and water intakes were present in WT rats, but were detected in Brattleboro rats when controlling for body weight. Additional studies are underway to evaluate proglucagon and GLP-1R expression in brain regions associated with fluid regulation. Although these studies are incomplete, the results to date suggest that

Brattleboro rats provide a unique opportunity to examine the endogenous GLP-1 system and its control of fluid intake.

Title: Adult drinking behavior is altered by early life exclusive access to sucrose solution

Authors: *K. L. VOLCKO, D. J. BRAKEY, J. T. PRYZBYZ, D. DANIELS;
Psychology, Univ. at Buffalo SUNY, Buffalo, NY

Abstract: Proper fluid balance is critical for life. Severe dehydration is deadly, and modest dehydration can have deleterious consequences on physiology and cognitive function. Learning plays an important role in shaping the appetitive behaviors required for drinking. Children often forego drinking plain water and instead consume beverages such as milk or juice. What effect this may have on adult behavior remains an open question. To model aspects of the human condition, we bred Sprague-Dawley rats in a cage that prevented the pups from obtaining fluid other than from nursing. In one cohort, pups were weaned onto either tap water or a 5% sucrose solution, and given access to only that fluid for the next 8 weeks. In another cohort, pups were weaned onto either tap water or a 0.08 M saline solution, and given access to only that fluid for the next 8 weeks. We then measured intake of water or sucrose/saline after (a) a mild hypertonic saline (HS) injection, and (b) overnight fluid deprivation. We also performed subsequent sucrose/saline preference (two-bottle) tests after HS injection, then maintained all rats on water for one week and repeated the test. Experiments with the saline-maintained cohort are ongoing, but with the sucrose-maintained rats we found that rats maintained on sucrose drank less water than did rats maintained on water after a mild HS injection. After overnight fluid deprivation, rats maintained on sucrose drank less water and more sucrose in the first 10 min of the test, but intake by the end of the test was not different between the groups of rats. Although we observed a comparable number of licks across the whole test, microstructural differences in licking patterns were detected. Rats maintained on sucrose showed a stronger preference for sucrose, but group differences in preference were ameliorated after a week of drinking only water; however, differences in lick patterns for sucrose remained. These data provide evidence that adult drinking behavior is influenced by exclusively drinking sucrose early in life.

Title: Pre-locus coeruleus in rat and mouse

Authors: ***S. GASPARINI**, A. M. GORE, L. PELTEKIAN, J. C. GEERLING;
Neurol., Univ. of Iowa, Iowa City, IA

Abstract: We identified a unique population of neurons in the hindbrain tegmentum called the pre-locus coeruleus (pre-LC). Pre-LC neurons receive input from the nucleus of the solitary tract, express the neuronal activity marker c-Fos during sodium-deprivation, and express the transcription factor FoxP2. In rats, the pre-LC sits immediately rostral to the locus coeruleus (LC), but in mice the anatomic distinction between pre-LC and LC is more complex. Here we use molecular markers and anterograde axonal tracing to clarify and compare the location, identity, and distribution of pre-LC neurons in mice, relative to rats. First, we label the activity marker c-Fos and the transcription factor FoxP2 in the hindbrain of sodium-deprived rats to show their co-localized distribution, which defines the pre-LC. Next, in both sagittal and axial planes we compare the distribution of this FoxP2+ population with markers for surrounding catecholaminergic and cholinergic neurons. Then, in mice, we use chemogenetic activation of aldosterone-sensitive HSD2 neurons to drive Fos activation and identify the homologous distribution of pre-LC neurons. Combining this information with synaptophysin-mCherry axonal labeling, we find that pre-LC neurons receive dense afferent projections from the infralimbic cortex, arcuate AgRP neurons and paraventricular nucleus of the hypothalamus, and HSD2 neurons in the nucleus of the solitary tract. This information clarifies the location and distribution of pre-LC neurons in mice, providing a foundation for cell-type-specific studies of their properties and functions in the future. Pre-LC neurons receive appetitive and other homeostatic information from a wide range of brain regions (descending from cortex and hypothalamus and ascending from lower brainstem) and may influence behaviors including sodium appetite.

Title: Giot1 participates in the modulation of ingestive behavior

Authors: *A. R. TERRA DOS SANTOS[1], W. L. REIS[1], J. B. LIMA[1], J. T. DOMINGUES[1], L. D. DE ARAUJO[1], M. GREENWOOD[2], M. GREENWOOD[2], L. L. K. ELIAS[1], D. MURPHY[2], J. ANTUNES-RODRIGUES[1];
[1]Univ. of Sao Paulo, Ribeirao Preto, Brazil; [2]Univ. Bristol, Bristol, United Kingdom

Abstract: Gonadotropin inducible ovarian transcription factor 1 (*Giot1*) is a kruppel-type zinc finger protein induced by gonadotropin in teca cells of the ovary and also identified in the central nervous system areas related with hydromineral and energy homeostasis. Osmotic challenges induce simultaneously an increase in the *Giot1* and AVP mRNA expressions in the paraventricular nucleus (PVN). Our hypothesis is that Giot1 has a central role on the ingestive behavior, and it may underlie the E2 effects on energy homeostasis. To confirm this hypothesis, female Sprague-Dawley(200g) rats with free access to diet and fluids were maintained on metabolic cages. Water was offered during 8 days followed by water and 0.3M NaCl solution during 12 days. After these 20 days, animals were randomly assigned into the *Giot1* gene knockdown group and submitted to a bilateral microinjection of small hairpin RNA expressing lentiviral vector (shGiot1) into the PVN. shGFP lentivirus was used as control group (Scramble group). After recovery, the ingestive behavior was recorded during 20 days. The estrous cycle was verified daily along the experiment. This study was conducted following the "Guide for the Care and Use of Laboratory Animals" (NIH Publication nº85-23, 1996). The *Giot1* knockdown decreased the salt preference compared with the scramble group (63.4% ± 1.6, n=6 vs. 68.8% ± 2.0, n=6; *p*=0.04). On the other hand, the *Giot1* knockdown group had a higher food intake compared with the scramble group (12.4g ± 0.2, n= 6 vs. 10.2g ± 0.2, n= 6; *p*=0.0001), with no difference in the body weight (shGiot1: 252g ± 2.0, n= 6 vs. Scramble: 246g ± 2.3, n= 6; p=0,06). Radioimmunoassay analysis also revealed a differential hormonal response in AVP (Scramble: 1.0 pg/ml ± 0.01, n=6 vs. shGiot1: 0.6 pg/ml ± 0.1, n=6; p=0.05) and ANGII (Scramble: 31.8 pg/ml ± 9; n=6 vs. shGiot1: 14.8 ± 1.5, n=6; p=0.02) secretion. In a second set of experiments, after 21 days of bilateral microinjection of shGiot1 or shGFP into the PVN, female rats were water deprived (WD) for 48h. After that, water and 0.3M NaCl intake were

evaluated. shGiot1 animals had a decrease in 0.3M NaCl intake (2.7 ml/BW ± 0.2 vs. 3.5ml/BW ± 0.2; n=10; p=0.02), compared with scramble animals. These Giot1 effects were associated with a decrease in the plasma AVP of shGiot1 group compared to Scramble group (1.1 pg/ml ± 0.1 vs. 2.4 pg/ml ± 0.3; n=10; p=0.002) and ANGII (31.5 pg/ml ± 2.3 vs. 66 pg/ml ± 4,7; n=10; p=0.005) concentrations after WD. In conclusion, *Giot1* in the PVN is likely to participate in the regulation of ingestive behavior, modulating food intake as well as salt appetite. The mechanisms underlying these effects of Giot1 need to be further investigated. Support: FAPESP.

Title: Angiotensin II-responsive brain areas relay with structures involved in associative learning

Authors: *Q. E. CARROLL, D. DANIELS;
Psychology, Univ. at Buffalo - The State Univ. of Ne, Buffalo, NY

Abstract: Recent studies provide evidence for a role of associative learning in the enhanced response observed after daily injections of angiotensin II (AngII). Specifically, the findings suggest that an observed increased drinking response after daily AngII involves a strengthening of the association between the stimulus (AngII) and the response (drinking). This effect appears to be mediated in part, by NMDA receptor activation, a critical component in associative learning, and there is a rich literature demonstrating the importance of the hippocampus in associative learning. Although the neural pathways that connect drinking-related structures to areas involved in associative learning are poorly understood, we hypothesized the existence of a relay between the median preoptic nucleus (MnPO), a critical area for the drinking response to AngII, and the hippocampus. To test this hypothesis, we made injections of a retrograde tracer (CTb) into the hippocampus and made MnPO injections of an adeno-associated virus (AAV2/10) that is transported anterogradely and expresses mCherry under the CMV promoter. Retrogradely labeled cell bodies and anterogradely labeled fibers were found in several brain areas, but the most striking overlap of the two was in the paraventricular nucleus of the thalamus (PVT). This finding is consistent with the well-studied role of the PVT in learning and memory processes,

and offers a novel circuit by which Ang-II-related signals in the MnPO can access the hippocampus.

Title: The effects of MDMA on central circuits mediating fluid balance in rodents

Authors: *J. C. WYROSDIC, C. W. BOURQUE;
Neurol. & Neurosurg., McGill Univ. Hlth. Ctr., Montreal, QC, Canada

Abstract: Clinical data discloses a large increase in locomotor activity, and body temperature after MDMA ingestion, due to the context in which the drug is consumed and MDMA's amphetamine qualities. To examine the behavioral aspect and validate the rodent model of MDMA, C57 mice received a subcutaneous telemetry implantation which recorded activity, and body temperature every 120s for 9 consecutive days. The IP administration of MDMA at 15mg/kg, which is equivalent to a human "party" dose caused an increase in body temperature, as well as heightened locomotor activity during the light phase in comparison to the saline injected controls. These two behaviors also stayed elevated in the MDMA treated animals hours after the injection. Clinical data also proposes that MDMA increases water intake by inducing the sensation of thirst, and to promote fluid retention by the kidney. These effects account for the high incidence of cases of hyponatremia (low blood sodium and excel water in serum) in patients visiting hospital emergency departments as a result of experiencing headaches and dizziness (and other signs of hyponatremia) following ingestion of MDMA. Clinical as well as rodent studies also reveal an increase in serum vasopressin levels when MDMA is ingested or administered, which is likely a key factor in fluid retention. To investigate the neurophysiological mechanisms underlying these effects brain slices obtained from transgenic rodent brains (rats and mice) were prepared at a specific angle to preserve circuitry important for the regulation of thirst and vasopressin release. Whole cell current clamp recordings from identified vasopressin neurons revealed that a bath application of 10μm of MDMA causes an excitatory response; mediated by membrane depolarization. Moreover, a proportion of tonically active vasopressin neurons were observed to transition to a phasic firing pattern known to facilitate peptide release. These results suggest that MDMA can act directly on neurons controlling fluid balance thereby promoting hyponatremia.

Title: Anatomical organization of the subfornical organ

Authors: ***A.-I. HICKS**[1], S. KOBRINSKY[2], M. PRAGER-KHOUTORSKY[3];
[1]Physiol., [3]Ctr. for Res. in Neurosci., [2]McGill Univ., Montreal, QC, Canada

Abstract: The subfornical organ (SFO) is one of the brain's sensory circumventricular organs (CVOs), which are highly vascularized midline structures lacking a complete blood-brain barrier (BBB). CVOs are characterized by the presence of tanycytes, specialized glia-like cells lining the ventricular floor of the CVOs and interacting with fenestrated vasculature. Due to the lack of a complete BBB, SFO and other CVOs are unique sites where peripheral circulating factors can penetrate into the central nervous system, influencing neuronal activity and allowing brain cells to monitor blood-borne signals. This provides the brain with information from the periphery and contributes to the generation of centrally-mediated physiological responses to humoral feedback and physiological stressors. Accordingly, SFO plays a key role in the regulation of cardiovascular status, hydromineral balance, energy metabolism. SFO neurons express a variety of receptors for peripheral signals. Moreover, SFO neurons can be activated by numerous circulating molecules associated with fluid balance (e.g. angiotensin II, sodium, endothelin, vasopressin) and energy metabolism (e.g. leptin, ghrelin, glucose). While extensive studies have focused on the characterization of the SFO neurons and their roles in the regulation of cardiovascular and metabolic status, the contribution of non-neuronal cells to this regulation is unclear. In this study, we use histological techniques to characterize the anatomical organization of the SFO and to examine the location of non-neuronal cells, including tanycytes, astrocytes, ependymocytes, fenestrated and non-fenestrated vasculature, as well as neurons, within its confines.

Title: Gender-specific regulation of brain inflammation and metabolism by erythropoietin in mice

Authors: S. DEY[1], M. GASSMANN[2], *C. T. NOGUCHI[1];
[1]Mol. Med. Br., Natl. Inst. of Diabetes and Digestive and Kidney Dis., Bethesda, MD; [2]Inst. of Vet. Physiol., Univ. of Zurich, Zurich, Switzerland

Abstract: Diet-induced obesity (DIO) is closely linked with increase in hypothalamic inflammation, disruption of glucose homeostasis, and activation of the hypothalamic-pituitary-adrenal (HPA) axis. Erythropoietin (Epo) is known to regulate metabolism and has been shown to prevent inflammation in white adipose tissue (WAT) and improve insulin sensitivity and glucose tolerance. We hypothesized that Epo signaling in brain could regulate hypothalamic inflammation, maintain metabolic homeostasis, and prevent HPA axis activation in a high fat-diet (HFD)-fed mouse model of DIO. We examined a mouse model of chronic over-expression of transgenic human *EPO* in brain (*Tg21*). HFD-induced weight gain compared to WT mice was significantly lower in male *Tg21* mice only, and not in females. Immunofluorescent staining of the arcuate nucleus (ARC) region of hypothalamus showed increased inflammatory TNFα and activated microglia marker Iba1 expression with HFD-feeding in male and female WT and *Tg21* mice compared to regular-chow-diet (RCD)-fed mice, and a greater inflammatory response in male mice. Furthermore, only males showed lower TNFα and Iba1 in *Tg21* mice than wild type (WT) counterparts. Compared to RCD-fed mice, males also showed the number of cells staining for non-activated microglial marker P2Y12 decreased in HFD WT mice and increased in HFD *Tg21* mice. Similarly, CD169 positive macrophage (Mϕ) recruitment from periphery after HFD was increased in male WT mice and lower in male *Tg21* mice. These changes were not observed in female WT and *Tg21* mice, and female mice did not show any CD169 positive cells, suggesting no Mϕ recruitment. Only males showed HFD-feeding in WT mice increased phospho-Erk in the hypothalamus, Corticotropin-releasing hormone (CRH) expression, serum ACTH and corticosterone levels compared to HFD-fed *Tg21* mice. Interestingly, both male and female *Tg21* mice showed significantly improved glucose tolerance and insulin sensitivity, under both RCD and HFD. Serum Fgf21 was increased in *Tg21* mice on RCD and unchanged on HFD. HFD increased Fgf21 in WT mice only. Adiponectin, a cytokine produced in WAT by Fgf21 response, was lower in HFD-fed WT mice, suggesting Fgf21-resistance developing in WT mice

during DIO. In summary, our studies show that Epo over-expression in male and female mouse brain improved glucose homeostasis possibly through maintaining FGF21 sensitivity of WAT adiponectin production in DIO. We also provide evidence for gender-specific Epo regulation in brain to protect male mice against DIO associated brain inflammation and microglial cell activation in the hypothalamus, and activation of HPA axis.

Title: Dietary oleic acid modulates feeding behavior by controlling OEA response

Authors: *M. IGARASHI[1], K. IWASA[2], K. YOSHIKAWA[2], T. TSUDUKI[3], I. KIMURA[1]; [1]Tokyo Univ. of Agr. and Technol., Fuchu, Japan; [2]Saitama Med. Univ., Iruma, Japan; [3]Tohoku Univ., Sendai, Japan

Abstract: Gastrointestinal tract plays an important role in initiating hormonal and neuronal control for energy metabolism in responding to the nutrients. Previous studies in humans and rodents have suggested that obesity condition reduces levels of gut-derived peptide hormones such as cholecystokinin, and therefore leads to decreased satiety and overeating behavior. In addition to the peptide hormones, oleoylethanolamide (OEA), a derivative of dietary oleic acid, has been reported as a lipid-derived satiety factor in the gut. In this study, we investigated how dietary fat, especially dietary oleic acid, affects biosynthesis of OEA and feeding behavior in mice. Our study indicated that low levels of dietary oleic acid reduced jejunal OEA levels and increased food intake under low-fat diet condition. However, the low oleic acid diet did not affect body weight gain. These effects were not observed when mice were treated with capsaicin. Furthermore, infusion of lipids or oleic acid into upper gut stimulated jejunal OEA production in mice, associating with the reduction of substantial food intake. On the other hand, intestinal OEA production was reduced in the mice fed with a high fat diet that contains high levels of oleic acid, compared to low-fat diet (lab chow). Collectively, these findings suggest that imbalance between oleic acid and fat amount alters the intestinal OEA biosynthesis and satiety, suggesting that balanced dietary fat intake is important in controlling feeding behavior.

Title: Dietary interventions during reproductive period affects metabolic profile in dam's mice and the behavioral parameters of the offspring in a long-term

Authors: J. FISCH, V. FEISTAUER, A. A. ANDRADE, V. B. BOLLIS, C. K. S. OLIVEIRA, A. DE MOURA, R. P. GUEDES, ***A. G. BARSCHAK**, M. GIOVENARDI;

Abstract: Genetic and environmental factors related to maternal diet may predispose offspring to serious diseases. Mounting evidence has shown that maternal nutritional status may affect the progeny not only in a short-term but also in a long-term way, since some dysfunctions may appear only in the adulthood. However, consequences of a maternal diet intervention during gestation and lactation, and its association with caloric restriction after weaning on the progeny are not completely known. Besides, there is a lack of information regarding the impact of nutrition on maternal health. The present study analyzed the metabolic profile and maternal behavior of 30 female BALB/c mice. The animals were divided into three groups (10 per group) and received standard (CONT), hypercaloric (HD) or restrictive diet (RD) during mating, pregnancy and lactation. On the first postpartum day (PPD), the litters were standardized to 6 pups, which were weighted on PPD 3, 8, 12 and 21. Maternal care behavior was assessed by the pup retrieval test on the 7^{th} postnatal day (PND). We also investigate how the different maternal diets may affect the behavior of the female offspring that was also submitted to RD. The female offspring were divided into 6 groups (10 female per group) abbreviated accordingly maternal/offspring diets: CONT/CONT, CONT/RD, RD/CONT, RD/RD, HD/CONT, HD/RD. Around 70 days of age, the animals were submitted to the behavioral tests in the diestrus period. First, the animals were submitted to the open field test, one week later they were analyzed in the elevated plus maze and after another week of interval they were submitted to the novel object recognition test. We found a significant increase in triglycerides ($p=0.0004$) and leptin ($p=0.0007$) concentration of the HD dams group compared to CONT and RD. RD-fed mice exhibited an increase in the number of days necessary to become pregnant in comparison to the CONT group ($p=0.027$), but no differences among groups were found in the maternal care. Offspring from RD-fed dams exhibited a decrease in lateral area locomotion in the open field test ($p=0.001$). Evaluation of anxiety-like behavior and recognition memory showed no significant

difference among groups. In conclusion, HD promoted metabolic dysfunction in the dams and RD did not cause any harmful effect during reproductive period and lactation. The maternal diet, during gestation and lactation, influences behavior responses of the offspring in a long-term.

Title: Maternal consumption of sugar-sweetened beverages in pregnancy and lactation alters food preferences in the Wistar rat offspring

Authors: *D. OLIVO RAMIREZ, C. QUINTERO NARANJO, L. ROJAS ROSAS, G. LÓPEZ RODRÍGUEZ, M. GALVÁN;
Área Académica de Nutrición, Univ. Autónoma del Estado de Hidalgo, Pachuca, Hidalgo, Mexico

Abstract: Consumption of beverages sweetened with caloric-sweeteners is associated with obesity. Maternal diet can influence food preferences in the offspring. The aim of this study was to evaluate body weight, adipose tissue (AT) and food preferences in Wistar rat offspring exposed during pregnancy and lactation to sugar sweetened beverages. Dams of Wistar rats had access to a drink with caloric sweeteners (10% v/w); groups: sucrose (SU), high fructose corn syrup (HFCS) and dextrose (DEX) or water (control group) during pregnancy and lactation. Seven days after weaning, body weight was measured in the pups (n=8 per group). Six males and six females born of each group (CO, SU, HFCS and DEX) were evaluated with a two-choice diet test (standard diet: SD vs high fat diet: HFD) for 6 weeks (postnatal week 5 to 10); body weight and food consumption (Kcal) were measured every 48 hours. At the end of the test, gonadal, mesenteric and retroperitoneal adipose tissue were dissected and weighed. The data was processed with the statistical package SPSS v.16.0 Data are reported as mean ± SEM. Body weight were analyzed with a repeated measures ANOVA; HFD and SD intakes (Kcal/day) and % AT/body weight were analyzed using a one-way ANOVA; Tukey pos hoc test was used in both cases. Seven days after weaning, pups' body weight in CO group was significantly lower (48.80±1.46 g) than the pups of rest of the groups (SU: 69.79±1.47, HFCS: 65.34±1.28, DEX: 57.65±2.01 g: $p<0.05$ in all cases). During the two-choice diet test, males and females offspring

of the HFCS and DEX groups consumed significantly more Kcal per day from the HFD than the CO group (males: AF: 65.69±5.97, DEX: 63.17±3.93 vs CO: 43.95±4.35 Kcal/day; females: AF: 51.28±3.52, DEX: 61.40±3.60 vs CO: 38.88±3.07 Kcal/day). At the end of the food test, females with maternal exposition to caloric beverages were heavier than the CO group (SU: 198.66±6.07, HFCS:184.00±8.06, DEX:193.83±5.51 vs CO:163.33±3.81 g; ANOVA, $p<0.05$) and accumulated more percentage of AT/body weight (SU: 3.33±0.40, HFCS: 4.10±0.30, DEX: 3.81±0.40 vs CO: 2.13±0.16 %; ANOVA, $p<0.05$). The males of the experimental groups did not show differences in body weight, however, those exposed to caloric beverages during pregnancy and lactation accumulated more retroperitoneal AT compared to CO (SU:1.63±0.11, HFCS:1.32±0.12, DEX:1.40±0.10 y CO:0.87±0.10 %; ANOVA, $p<0.05$). These results suggest that the consumption of caloric sweeteners during pregnancy and lactation influences food preferences, body weight and accumulation of AT in the Wistar rat offspring, being these consequences more marked in females than in males.

Title: Estradiol-mediated protection from diet-induced obesity in female mice is associated with changes in gut microbiota

Authors: *K. D. ACHARYA[1], M. GRAHAM[1], H. NOH[2], S. SUK[2], R. FRIEDLINE[2], J. CHEN[3], J. KIM[2], M. TETEL[1];
[1]Wellesley Col., Wellesley, MA; [2]Univ. of Massachusetts Med. Sch., Worcester, MA; [3]Mayo Clin., Rochester, MN

Abstract: A decrease in estrogens in postmenopausal women increases their risk of adiposity and predisposes them to cardiovascular disease, type 2 diabetes, chronic inflammation, and cancer. Similarly, in female rodents, loss of estrogens by ovariectomy and high fat diet (HFD) feeding increases food intake, attenuates physical activity and causes obesity. In addition to estrogens, gut microbiota are also implicated in energy homeostasis. In the current study, we investigated if estrogens alter gut microbiota and if these changes are linked to estrogen-

mediated protection from obesity. Ovariectomized adult C57BL6/J mice received implants containing estradiol (E2; 50 µg) or vehicle (Veh) (n=6/group). Mice were fed a standard diet (SD) for the first two weeks and then fed a HFD for four weeks. Fresh fecal samples were collected during SD and HFD for 16S rRNA gene sequencing. Effects of E2 and HFD on longitudinal metabolic changes, including food intake, energy expenditure, and physical activity, were measured using metabolic cages. Plasma glucose, cytokines and hormones, including insulin, leptin, and resistin, were measured during SD and HFD. Insulin sensitivity and glucose metabolism were measured using hyperinsulinemic clamp in awake mice. Tissue-specific muscle glucose uptake and triglycerides were also measured. E2 treatment protected ovariectomized mice from HFD-induced obesity, primarily by increasing energy expenditure, physical activity, insulin sensitivity, and glucose utilization. Parallel changes in microbial communities were observed as an effect of both E2 and HFD. E2 increased the phylum Verrucomicrobia and its genus *Akkermansia,* implicated in mucin degradation and maintenance of healthy gut epithelial barrier. Veh mice showed greater abundances in the families Clostridiaceae (during both diets), and Erysipleotrichaceae and Streptococcaceae (during HFD only). HFD profoundly affected microbiota by reducing microbial richness and increasing evenness. HFD also increased multiple taxa, including *Bacteriodes* (phylum Bacteriodetes), *Clostridia* (phylum Firmicutes), and *Coriobacteria* (phylum Actinobacteria), which are linked to HFD-induced weight gain in humans. In summary, the current findings suggest that E2-mediated protection against diet-induced obesity and metabolic dysregulation are dependent on changes in gut microbiota. Currently, we are analyzing correlations between specific metabolic and microbial changes to understand how these factors could affect each other. These results may provide important insights in the development of potential microbial targets for the treatment of metabolic dysregulation in women.

Title: The role of CAPS1 RNA editing in energy homeostasis

Authors: *K. M. SHUMATE, R. B. EMESON;
Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: Calcium-dependent activator protein for secretion 1, CAPS1, is a SNARE accessory protein that functions to promote vesicle priming at the plasma membrane during regulated exocytosis. CAPS1 is primarily expressed in the central nervous system and in endocrine tissues, and pre-mRNA transcripts encoding CAPS1 are subject to an adenosine-to-inosine (A-to-I) RNA editing event near the carboxyl-terminal domain, resulting in a glutamate-to-glycine (E-to-G) alteration in the encoded protein. Previous studies from our lab demonstrated that edited CAPS1 enhances the rate of vesicle exocytosis, suggesting that CAPS1 RNA editing may play a role in regulating physiologic events that involve neurotransmitter or peptide hormone release. Using genetically-modified mice solely expressing CAPS1 protein isoforms encoded by edited or non-edited RNAs, we have examined the effects of CAPS1 RNA editing on energy homeostasis. Mice solely expressing the edited isoform of CAPS1 were lean compared to wild-type littermates due to a loss of both lean and fat body mass. No differences were found in circulating levels of plasma growth hormone, insulin-like growth factor-1, thyroid stimulating hormone or total thyroid hormone (T4) levels, suggesting that the observed decrease in body mass for edited CAPS1 animals was not due a dysregulated hormone release from the anterior pituitary, thyroid gland, or liver. Edited CAPS1 animals were hyperactive in both novel and home cage environments, when compared to wild-type littermates, and displayed an increased energy expenditure during the dark phase, but not during light phase. While edited CAPS1 animals showed no difference in total food intake compared to wild-type littermates, increased meal frequency and reduced meal size was observed. These results indicate that mice solely expressing edited CAPS1 may have a dysregulated energy homeostasis that is primarily driven by a hyperactivity-dependent increase in energy expenditure. The absence of a compensatory increase in food intake, along with alterations in meal patterning, may contribute to a chronic energy deficit leading to the observed decrease in body mass. By contrast, mice solely expressing the CAPS1 isoform encoded by the non-edited RNA also were assessed for locomotor, metabolic, and feeding phenotypes, yet no significant differences were found when compared to wild-type animals, suggesting a normal energy homeostasis. Together, these studies provide initial evidence of a modulatory role for CAPS1 RNA editing in the regulation of energy balance.

Title: High fat diet modifies the feeding behavior and induces brain, colon and liver alterations which is not exacerbates by E17

Authors: *D. DIAZ-URBINA[1], E. I. MEDINA REYES[2], N. L. DELGADO BUEN-ROSTRO[2], V. E. LÓPEZ ALONSO[1], R. E. ESCARTIN PÉREZ[1], J. M. MANCILLA DÍAZ[1], J. L. REYES[1], M. I. GONZALES[2], Y. I. CHIRINO LÓPEZ[2];

Abstract: High-fat diets not only modify the metabolism but also cause anxious symptomatology, producing increments of frequency and meal's size. Additionally, high-fat diets might be accompanied by the consumption of potentially risky food additives. Among these additives, food grade titanium dioxide (E171) has been related to tumor formation in the colon, which highlights its potential toxicity. After oral consumption, E171 is translocated to bloodstream reaching several tissues and crossing the blood-brain barrier may induce brain inflammation. The possibility that E171 may induce alterations in the brain raises the concern of exacerbation of the disturbances induced by high-fat diets, for instance, changes in satiety processing. Aim: To evaluate if oral consumption of E171 (5 mg/kg BW) modifies the satiety process and induce or exacerbate the alterations in brain, colon, spleen, and liver using a mice model feed with a high-fat diet during 16 weeks. POMC and AgRP gene expression was measured in the hypothalamus and was used as a marker of satiety. Methods: C57BL6 mice were divided into 4 groups as follows: a) Regular diet, b) regular diet + E171, c) high-fat diet and d) high-fat diet + E171, and they were maintained in the corresponding condition for 16 weeks. Body weight gain, and food and water intake were monitored weekly. In the last week of the study, the microstructure of feeding was analyzed during a 60-min period of continuous recording at the onset of the dark phase. The behavioral categories analyzed were meal size (g/min) and frequency, meal duration (s), latency for the first meal (s), local feeding rate, and inter-meal intervals. Next, mice were euthanized and brain, colon, spleen, and liver were extracted and mounted for histological analyses. Result: Both groups treated with E171 gradually decreased their weekly food intake compared to regular diet and regular diet + E171 groups. High-fat diet and high-fat diet + E171 groups gained up to 49% more body weight than mice with the regular diet and regular diet + E171. High-fat diet + E171 group consumed less food, had a reduction of the meal frequency and local feeding rate but increased the latency for the first meal and inter-meal intervals duration compared with the high-fat diet group. High-fat diet induced liver steatosis and colon adenomas, however high-fat diet + E171 did no exacerbate this effect. Conclusion: Oral intake of E171 did not exacerbate the high-fat diet effects on the colon (adenomas), liver (steatosis), and high-fat diet per se modified the feeding behavior in C57BL/6 male mice after 16 weeks

Title: Human umbilical derived mesenchymal stem cell transplant in adipose tissue improve fear conditioning memory in a diet-induced obese mouse model

Authors: *S. SAIEVA[1,3], B. KRISHNAN[1], N. ABATE[2], G. TAGLIALATELA[1];
[1]Neurol., [2]Intrnl. Med. - Div. of Endocrinol., Univ. of Texas Med. Br., Galveston, TX;
[3]Biomedicine, Neurosci. and Advanced Diagnostics, Univ. of Palermo, Palermo, Italy

Abstract: Insulin resistance characterizes Type 2 Diabetes mellitus (T2DM) as well as of Alzheimer's Disease (AD), particularly in CNS areas associated with cognitive performance, such as the hippocampus. A major risk factor for insulin resistance and T2D is adipose tissue (AT) dysfunction, which is mainly caused by obesity. High-caloric diets may lead to adipose tissue (AT)-insulin resistance, resulting in fatty acid spillover and ectopic fat deposition. Notably, high levels of FFA have been reported in AD patients; likewise, rodents fed with high-fat diets display peripheral insulin resistance, as well as hippocampal synaptic deficiencies with reduced insulin signaling and memory deficits. These observations suggest that improving peripheral insulin resistance may result in beneficial effects in CNS. Interestingly, the AT of T2DM/prediabetic patients show depletion of their mesenchymal stem cell (MSC) reservoirs, thus impairing adipocyte turnover and fat storage ability, thus suggesting that an exogenous delivery of mesenchymal stem cells directly in the adipose tissue could help in halting/reversing the insulin resistance and its systemic complications, including CNS deficits. To test this hypothesis, we transplanted human umbilical cord-derived mesenchymal stem cell in the epididymal adipose tissue of high-fat diet-induced obese (DIO) mice and tested their effect in both periphery and CNS. Along with a significant improvement of glycemia, we observed an improvement of freezing behavior in the contextual fear conditioning test in transplanted mice (accompanied by a tendential but not significant improvement in the cued environment). This memory benefit of the peripheral transplant, however, was not associated with any change in insulin receptor response in synaptosomes isolated from different areas of the brain, suggesting that further studies exploring diet-induced neuroinflammation and oxidative stress will be needed to fully explore the involved mechanisms. Nonetheless, these collective results suggest that retrieving the insulin signaling in periphery is also beneficial for CNS, thus potentially providing a novel viable therapeutic approach to treat obesity/T2DM-induced CNS deficits and possibly alleviate the impact of T2DM-related insulin resistance on clinical onset/progression of AD.

Title: Sensitivity to ghrelin is increased in female offspring of rat model of vertical sleeve gastrectomy

Authors: *R. A. SPANN, B. A. WELCH, B. E. GRAYSON;
Neurobio. and Anatom. Sci., Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Bariatric surgery is the most effective and durable means of treating obesity and its comorbidities. Women make up 80% of those receiving weight loss surgery and they experience improvements in fertility. Unfortunately, bariatric surgery in the context of pregnancy is associated with complications including intrauterine growth restriction (IUGR) and small for gestational age offspring (SGA). SGA offspring, then, have a greater risk for obesity in adulthood. The mechanism for this SGA-induced obesity is unknown. We have previously shown in a rat model of vertical sleeve gastrectomy (VSG), changes to ghrelin signaling, a stomach-derived hormone that increases appetite and induces growth hormone secretion. Pregnant VSG dams have a reduction in total and active circulating ghrelin compared to sham operated dams, and in placenta tissue, there is an increase in ghrelin O-aclytransferase (GOAT) mRNA expression in VSG dams, suggesting a drive to increase available ghrelin in the developing fetus. Here we hypothesize that postnatal VSG offspring will have an increased sensitivity to ghrelin compared to offspring of sham dams, in response to reduced *in utero* ghrelin. Exogenous ghrelin (100 ug/kg, IP) administered at postnatal day (PND) 14 to VSG and sham pups does not alter milk intake at all, consistent with the literature that postnatal week 2 pups do not respond to ghrelin. At PND21, male and female VSG offspring have an increase in mRNA expression for the ghrelin receptor (growth hormone secretagogue receptor) in the hypothalamus compared to sham offspring, and expression of GOAT is lower in females compared to males. Expression of other genes in the growth hormone system (growth hormone releasing hormone and growth hormone) are not altered. Plasma levels of total ghrelin at PND21 are also not different between VSG and sham pups. At PND112, one hour chow intake of female but not male VSG offspring given 100 ug/kg of exogenous ghrelin by IP injection is greater than sham offspring given exogenous ghrelin. These results indicate that maternal VSG surgery has an impact on ghrelin signaling in offspring and that as adults, female VSG offspring may be functionally more responsive to ghrelin. Future work will determine the contribution of ghrelin signaling to IUGR and SGA-induced obesity.

Title: The conundrum of gaining weight: Blame it on genetics?

Authors: *Z. YING[1], G. ZHANG[1], X. YANG[1], F. GOMEZ-PINILLA[1,2];
[1]Integrative Biol. and Physiol., UCLA, Los Angeles, CA; [2]Dept. of Neurosurg., UCLA Brain Injury Res. Ctr., Los Angeles, CA

Abstract: One of the most fascinating questions in biomedical research is why individuals react differently to the same challenge or treatment. Metabolic challenges are among the most powerful driving forces of biological adaptations, with long-lasting consequences on homeostatic control and disease stages. High fructose consumption is increasingly recognized as a risk factor for the escalating prevalence of metabolic syndrome, posing significant risk for type 2 diabetes, cardiovascular diseases, obesity, and non-alcoholic fatty liver disease. We systematically examined the metabolic parameters and tissue-specific gene regulation in response to fructose treatment in multiple inbred mouse strains C57BL/6J (B6), DBA/2J (DBA), and FVB/NJ (FVB) due to their divergence in genetic composition. DBA mice showed the highest susceptibility to gain adiposity and glucose intolerance. Elevated insulin was found in DBA and FVB mice, and cholesterol levels were uniquely elevated in B6 mice. The transcriptional profiles of liver, hypothalamus, and adipose tissues showed strain- and tissue-specific pathways altered by fructose, including fatty acid and cholesterol pathways for B6 and PPAR signaling for DBA in liver, and oxidative phosphorylation and eating behavior for B6 and protein processing for DBA in hypothalamus. Using network modeling, we predicted potential strain-specific key regulators of fructose response such as *Fgf21* (DBA), *Lss* (B6) in liver, and validated the regulatory action of *Fgf21* and *Lss* in primary hepatocytes. Our findings show that fructose elicits specific arrangements in the organization of genes and pathways in separate tissues across genetically diverse mice, which seem responsible for distinct metabolic functions across genetically diverse mice. Our results suggest that the interaction between dietary challenges and genetics influences systemic metabolism by engaging gene regulatory pathways that are tissue specific.

Title: Sex differences in the metabolic and cognitive outcomes of high fat diet preference and exercise in rats

Authors: *T. Y. YANG[1], Z. GAO[1], F. NAJERA[1], G. PETRUS[1], N.-C. LIANG[2];
[2]Psychology, [1]Univ. of Illinois-Urbana Champaign, Champaign, IL

Abstract: The modern obesogenic environment promotes overeating palatable, high fat (HF) foods and favors a sedentary lifestyle. Both factors work in combination to disrupt energy homeostasis and exacerbate the development of obesity. As a treatment intervention, exercise facilitates weight and fat loss to a greater extent in males than females. Using a two-diet choice (chow vs. HF) and wheel running (WR) paradigm, we have previously reported that running-induced HF diet avoidance is more common and persists longer in male than female rats. Given this, we hypothesized that sex differences in HF diet preference may predict sex-specific metabolic and cognitive outcomes of long-term HF feeding and that exercise would attenuate these HF-induced deficits. To test this hypothesis, rats underwent an oral glucose tolerance test before and after 6 weeks of WR and diet choice to assess the effects of HF feeding on glucose homeostasis. During the last week, rats were trained on the Barnes Maze and underwent tests of reversal learning to assess HF-mediated deficits in learning and cognitive flexibility. All sedentary (Sed) rats preferred the HF diet throughout the study. Female WR rats reversed running-induced HF diet avoidance ~3 weeks earlier than males. Following that reversal, WR females expressed higher whereas WR males maintained lower HF diet preference than their respective Sed controls. These sex differences in HF diet preference and adiposity were reflected in metabolic outcomes. Exercise suppressed weight gain and adiposity in males but not females. Only male WR rats showed improved glucose tolerance from that of their pre-HF feeding. These findings suggest that the ability for exercise improve energy metabolism and balance differs between the sexes. The interpretation of HF-induced deficits in cognitive flexibility was confounded by the finding that our Sprague-Dawley rats used a serial search strategy rather than spatial cues to locate the escape box on the Barnes Maze. Nevertheless, all rats learned to escape on the maze and on average, females had shorter latencies than males. Regardless of sex, WR rats had shorter latencies than Sed rats, which suggests that exercise may improve learning similarly for both sexes. Taken together, our results suggest that exercise may attenuate the

deleterious outcomes of HF feeding in a sex-dependent manner and highlights the importance of developing sex-specific treatment interventions for obesity.

Title: Access to snacks in female rats from weaning onward causes weight gain and signs of metabolic syndrome but does not alter hypothalamic POMC and NPY

Authors: H. R. ARCHER, R. A. CURTO, C. L. RODRIGUEZ, L. F. SMITH, M. A. SAMUEL, C. A. EASTERLIN, A. N. MINUTILLO, R. C. CLAWSON, K. A. BEZOLD, ***H. I'ANSON**; Biol., Washington & Lee Univ., Lexington, VA

Abstract: We have shown that snacking on healthy (HS) or unhealthy (US) snacks, in addition to chow, from weaning to adulthood causes weight gain, deposition of abdominal adipose tissue and symptoms of metabolic syndrome in a female rat model (*Phys. & Behav. 201:165-174, 2019).* Unlike high fat diet-induced obesity studies in adult human and animal models, HS and US rats experienced weight gain without an increase in daily caloric intake compared to control, chow-fed (CC) rats, suggesting that constant access to energy facilitated weight gain due to a change in feeding patterns rather than hyperphagia. Obesity and metabolic syndrome have been associated with hypothalamic neuronal injury and a decrease in proopiomelanocortin (POMC) cell number *(J. Clin. Invest. 122:153-162, 2012).* We therefore determined if snacking caused a similar decline in POMC cell neuron number in the hypothalamus of HS and US rats compared to CC rats. POMC neurons were visualized in the anterior hypothalamus (AH) and arcuate nucleus (ARC) of CC, HS and US female rats using immunocytochemistry. While there were similar significant POMC cell number differences across regions in all groups (AH and rostral, medial and caudal ARC; $P<0.0001$), there was no difference in total POMC cell number between snacking and control rats ($P=0.4$). These data suggest that development of metabolic syndrome due to snacking does not result in a decline in hypothalamic POMC neurons in our model. We next determined gene expression of POMC and Neuropeptide Y (NPY) within the hypothalamus using RT-qPCR since these neuron populations are considered critical components in regulating

energy balance. Relative gene expression analysis revealed similar expression patterns in both POMC and NPY between snacking and control rats (p=0.3 and 0.6, respectively). These data suggest that snacking from weaning does not cause inappropriate hypothalamic POMC and NPY neuron functioning, as has been demonstrated in adult animal studies. Further, because our rats show altered feeding behavior with both healthy and unhealthy snacking, but no increase in caloric intake, our findings indicate that the temporal effects of snacking and not the nutrient composition may alter metabolism if snacks are added to the diet from weaning onwards.

Title: Early hipercaloric diet exposure reduces brain BDNF content and impacts on episodic memory in Wistar rats

Authors: *K. BERTOLDI[1], R. P. PALAZZO[1], A. GREFENHAGEN[1], B. B. DA SILVA[1], L. C. F. DE MEIRELES[2], I. L. S. TORRES[1], I. R. SIQUEIRA[1];
[1]Univ. Federal Do Rio Grande Do Sul, Porto Alegre, Brazil; [2]Univ. Regional Integrada do Alto Uruguai e das Missões, Erechim, Brazil

Abstract: Exposure to hypercaloric caloric diets has been related to cognitive function impairment in the offspring at adulthood. However, the diet effects on early developmental phases and the neurochemical mechanisms involved needs more studies. It has been demonstrated that gestational exposure to hypercaloric diets may alter central BDNF levels as well as HDAC5 expression, moreover a relationship between HDAC5 levels and BDNF expression has been proposed. Our aim was to evaluate the effect of early exposure - gestational and lactational phases - to cafeteria diet on memory performance and eating behavior as well as HDAC5 and BDNF content in hippocampus and olfactory bulbs of male and female *Wistar* rats. The Institutional Committee for Animal Care and Use of the Hospital de Clínicas de Porto Alegre (GPPG/HCPA #160561) approved all procedures. Pregnant females were randomized in standard or cafeteria diet groups. The cafeteria diet group was exposed to diet in gestational and lactational phases. The offspring weight was evaluated in PND 2 and PND 21. The nest odor preference and eating behavior tests were performed in PND 7 and PND 20, respectively. Rats were decapitated 24 h after the eating behavior test (PND 22). Hippocampus and olfactory bulbs were dissected out and used to quantify HADC5 and BDNF contents by western blot. Animals

exposed to the cafeteria diet showed lower weight compared to standard diet animals only in PND 2 (p=0.013). Pups whose dams were exposed to cafeteria diet up to PND 7 showed the classic paradigm of conditioning, since they demonstrated reduced preference for the nest bedding compared to standard diet animals. The early exposure to hypercaloric diet increased the number of meals associated with a lower first inter-meal interval in both gender; moreover the total food consumption increased (p=0.009) which can suggest the diet impact on episodic memory of a meal in PND 20, without any impact on weight. Exposure to cafeteria diet reduces the BDNF content in olfactory bulb (p=0.002) and hippocampus (p=0.006). Additionally, we observed an increase in HDAC5 content in hippocampus (p=0.02), however, this increase was observed only in olfactory bulbs of female rats (p=0.005). It is possible to infer that lower BDNF levels in the olfactory bulb and hippocampus can reflect a worse episodic memory. Moreover, the reduced BDNF levels induced by our diet protocol might be related to an increase in HDAC5 content since this epigenetic marker has been associated with BDNF expression regulation.

Title: Hypercaloric-induced obesity is influenced by chronic stress and can be modulated by transcranial direct-current stimulation (tDCS) in male wistar rats

Authors: *D. J. STEIN[1,3], J. S. DE FREITAS[2], C. DE OLIVEIRA[2,4], I. C. MACEDO[5], I. L. S. TORRES[2,3];
[1]Med., [2]Pharmacol., Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Ctr. de Pesquisa Exptl., Hosp. de Clínicas de Porto Alegre, Porto Alegre, Brazil; [4]Faculdade São Francisco de Assis, Porto Alegre, Brazil; [5]Med., Univ. Federal do Pampa, Uruguaiana, Brazil

Abstract: Chronic stress and metabolic diseases are intricately associated and influence the escalating prevalence of obesity observed in humans in the past few decades. This medical condition has reached epidemic proportions, leading to a global public health issue. Associated with several comorbidities, obesity raises mortality rates in modern societies mainly because of

the lack of prevention and poor treatment options. In this study, we investigated the effects of bicephalic tDCS on hypercaloric-induced obesity in adult male Wistar rats (n = 80) that were or not exposed to restraint stress. Animals were randomly allocated to one of the following groups: standard diet + sham tDCS (SDS), standard diet + tDCS (SDT), standard diet + sham tDCS + stress (SDSS), standard diet + tDCS + stress (SDTS), hypercaloric diet + sham tDCS (HCDS), hypercaloric diet + tDCS (HCDT), hypercaloric diet + sham tDCS + stress (HCDSS), hypercaloric diet + tDCS + stress (HCDTS). Obese and control rats were evaluated for behaviors in the open-field and in the elevated plus-maze tests. Caloric intake, body weight gain, liver, adrenal and adipose tissue weight were measured. Additionally, central BDNF, NPY, IL-10, IL-1β, and TNF-α were evaluated at the end of the experimental protocol. Palatable food consumption test was performed in obese and control animals under fasting and feeding conditions. Hypercaloric diet rapidly increased weight gain and visceral fat mass. After 40 days of diet and stress, eight daily 20 min. sessions of 0.5 mA tDCS reduced weight gain only in obese rats while restraint stress has exacerbated this reduction. tDCS reduced BDNF and inflammatory markers in the cerebral cortex and decreased the amount of palatable food consumed under both fasting and feeding conditions. Restraint stress produced an anxiogenic effect only in control animals. These results suggest that bicephalic tDCS may change palatable food consumption and alter inflammatory parameters in the cortex, both influenced by stress and obesity.

Title: Maternal food restriction reduces cocaine and amphetamine regulated transcript (CART) neurons in the lateral hypothalamic area of aged rats

Authors: *C. M. MACHADO[1,3], M. G. MARTINS[2], I. Z. GUIATI[4], J. C. BITTENCOURT[5], J. C. HORTA, Jr.[1];
[1]Anat., [2]Physiol., Inst. of Biosci. of Botucatu, Botucatu, Brazil; [3]Faculdades Integradas de Bauru, Bauru, Brazil; [4]Basic Sci., Sch. of Dent., Araçatuba, Brazil; [5]Anat., Inst. of Biomed. Sci., Sao Paulo, Brazil

Abstract: Maternal nutrition during critical periods of individual development is essential, since nutrient deficiency during pregnancy and lactation causes significant changes in body weight, energy balance, food intake and neuropeptides expression. The cocaine and amphetamine regulated transcript (CART) is a neuropeptide widely expressed in the lateral hypothalamic area (LHA) that is involved in the regulation of energy balance and feeding behavior, in which CART plays an anorexigenic role. However, there is no information about the long-lasting effects of maternal food restriction on CART neurons in the LHA. Our aim was to analyze the number and distribution of CART neurons and their ultrastructure in the LHA of rats whose mothers were subjected to food restriction during pregnancy and lactation. After pregnancy confirmation, female Wistar rats were divided in two groups: control group (CG), ad libitum standard chow, and caloric restriction group (RG), 50% chow restriction compared to the control group during pregnancy and lactation. The male pups from both groups were divided into five age subgroups (n = 8): PND 21, 28, 50, 90 and 540. Biometric parameters, food intake and glycemia were also evaluated. Brains were processed for analysis of number, distribution and ultrastructure of CART neurons in the LHA, according to immunohistochemistry protocols for light (n=5) and transmission electron microscopy (n=3). The mapping and estimate of CART neurons in the LHA were performed using 3-D reconstruction and stereological study. Quantitative data were statistically analyzed ($p<0.05$). Our data indicated that maternal caloric restriction decreased body weight, body length, brain weight and visceral and retroperitoneal adipose tissues throughout life. No differences between groups were observed in the glucose metabolism and food efficiency, although the relative food intake was increased in RG. Stereological data have shown a decreased number of CART neurons in the LHA of RG540. LHA area and volume were smaller in RG in PND 21, 50 and 90. Changes were also observed in the distribution of CART neurons in RG540, with lower number of neurons in the perifornicial region and caudal sections of LHA. No ultrastructural alterations in CART neurons were caused by maternal caloric restriction during pregnancy and lactation. In conclusion, maternal food restriction during pregnancy and lactation changed biometric parameters in the offspring and their food intake. Furthermore, maternal undernutrition decreases CART neurons and their distribution in LHA of the aged rats, with no effects on this neuropeptide ultrastructure.

Title: Gestational exposure to high fat diet in mice alters hypothalamic MeCP2 expression in a sexually dimorphic way

Authors: S. BISHOP, J. FRAYRE, P. FRAYRE, C. MANI, M. J. MORRIS, ***E. NA**;
Texas Woman's Univ., Denton, TX

Abstract: Obesity is a worldwide epidemic that affects 650 million people globally. Obesity is a major risk factor for a number of different diseases such as cardiovascular disease, hypertension, diabetes, as well as some forms of cancer. Given the negative health consequences associated with obesity, it is considered to be one of the most serious public health challenges facing westernized societies. Particularly noteworthy is the scarcity of data regarding the sexually dimorphic effects of obesity on brain function, specifically areas of the brain relevant to food intake such as the hypothalamus. Methyl-Cp-G binding protein 2 (MeCP2) is a neuroepigenetic factor that has been associated with the neurodevelopmental disorder, Prader-Willi syndrome which is characterized by morbid obesity in children and in which there are mutations in *Mecp2* function. Past data have shown that disruption in MeCP2 function results in obesity in mice, thereby recapitulating the effects of MeCP2 dysfunction in Prader-Willi syndrome children. We are using a diet-induced obesity mouse model in order to assess the sexually dimorphic effect that gestational or postnatal exposure to high fat diet has on MeCP2 expression in the hypothalamus. Our current data suggest that gestational exposure to high fat diet significantly decreases MeCP2 protein expression in the hypothalamus of female mice, effects that are not seen when high fat diet is given to mice during adulthood. Moreover, these effects are seen specifically in a subregion of the hypothalamus known as the arcuate nucleus as demonstrated by immunohistochemical data. Interestingly, body weight appears to be more adversely affected by high fat diet during adulthood, suggesting that perhaps high fat diet exposure during adulthood may be affecting mechanisms independent of MeCP2 function. Collectively, our data demonstrate that there are developmentally sensitive periods in which MeCP2 expression can be influenced by high fat diet exposure in a sexually dimorphic manner.

Title: Dietary augmentation with monosodium glutamate: Behavioral and neurophysiological correlates in a rat model

Authors: *F. LI[1], E. P. WIERTELAK[2];
[1]Macalester Col., St. Paul, MN; [2]Neurosci., Macalester Col., Saint Paul, MN

Abstract: Monosodium glutamate (MSG) is a popular food additive in Chinese and Japanese culture as well as in the US. In the 1970s, the substance was accused of causing the "Chinese Restaurant Syndrome" (Kwok, NEJM, 1968) which was ultimately said to include such symptoms as headache, facial pressure, sweating, chest pain heartburn, and abdominal pain. Previous research examining animals exposed to MSG provided mixed conclusions on the potential effect of MSG-treated diets. However, to the best of our knowledge, the great majority each had used animals that have not reached maturation, or used a remarkably large amount of MSG, or injected the substance into the animal's system, all of which pose problems for reasonable interpretation. An observation of the Chinese and the Japanese diet have demonstrated no harmful effects in humans who include MSG as a part of their daily diet. The current study was designed to examine dietary supplementation analogous to human levels of consumption of MSG on a daily basis. Adult (140 days at onset of experimentation) male and female Sprague Dawley rats were given free access to foods containing 1% of MSG by weight. A sodium control group received foods containing the same level of sodium as the MSG-added diet. Food intake was monitored throughout the duration of the study. The animals were weight at the beginning and the end. An open can test was implemented to test anxiety levels. The animals were also tested on their spatial memory and learning ability in the Morris Water Maze. Two tail-flick tests were administered at different time points during the study to assess potential thermal nociceptive threshold differences. Reliably, no significant differences were found when comparing food intake, weight changes, anxiety level, spatial memory, and thermal nociceptive threshold. The results of this study do not support the contention that an MSG-treated diet can cause any cognitive deficits, altered pain response or abnormal weight changes. These data have implications for the inclusion of MSG in adult diets, providing support in favor of MSG supplementation in the elderly, recently reported to counter wasting syndromes. Glutamatergic mechanisms are discussed.

Title: Hypercaloric diet in juvenile rats induced adult overweight, decreased striatal and increased hypothalamic monoamines activities in adulthood

Authors: *N. MOREIRA[1], J. M. DACLÉ[1], P. R. SILVA[1], T. B. KIRSTEN[1], J. C. FLÓRIO[2], T. M. REIS-SILVA[1], A. C. S. SAMPAIO[1], M. C. GALVÃO[1], K. E. KIATAQUI[1], E. F. BONDAN[1], L. V. BONAMIN[1], M. M. BERNARDI[1];
[1]Paulista Univ., São Paulo, Brazil; [2]Univ. of São Paulo, São Paulo, Brazil

Abstract: Overweight and obese condition in juvenile age constitutes a major health problem that increases the risks for several diseases, including type 2 diabetes, cardiovascular disease, psychiatric disorders, endocrine and immune dysfunction. In this context, the present study investigated the long-term effects of feeding high-calorie diet (HD) on body weight during the juvenile period and monoamine levels in the adulthood of male rats. After weaning (postnatal day 23), the rats were randomly divided into two groups: high hypercaloric diet (HD group) or normocaloric diet (ND group) from postnatal day 23 to 65. After postnatal day 65 the diet was returned to balanced laboratory chow. The body weight gains in the juvenile period and in adulthood were assessed. The striatal and hypothalamic serotonin (5-HT), dopamine (DA) and noradrenaline (NOR) levels as well as its metabolites were assessed in postnatal day 90-95. For the statistical analysis was used the student t test, and the results were considered significant at $p < 0.05$. The results showed a significant increase in weight gain in the juvenile period ($p < 0.0001$) and adulthood ($p = 0.02$), decreased 5-HT ($p < 0.0001$) in the striatum, and increased DA ($p = 0.006$) and 5-HT ($p = 0.02$) in hypothalamus. NOR was not significantly different in the structures evaluated ($p > 0.05$). The present results show that hypercaloric diet intake during the juvenile period could be a strongest and earliest predictor of adulthood obesity, and revealed specific and permanent central neurochemical disturbances. Thus, as these neurochemical disorders are related to psychopathological disease, such as anxiety, depression and binge eating disorder, it is a topic that needs further investigation. Funding Source: This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoa de Nível Superior (CAPES; Finance Code 001), and from Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq; grant number 153494/2018-2).

Title: Effects of chronic central insulin infusion on food intake of offspring from mild hyperglycemic rats

Authors: *A. C. KISS[1,2], M. G. MARTINS[1,2], G. P. OLIVEIRA[1], A. G. CRUZ[1,2], B. C. WOODSIDE[3];
[1]Physiol., Sao Paulo State University, Campus Botucatu, Botucatu, Brazil; [2]Physiol., Univ. of São Paulo, São Paulo, Brazil; [3]Concordia Univ., Montreal, QC, Canada

Abstract: Changes on maternal metabolism, such as maternal diabetes, during pregnancy and lactation can influence the development of offspring central pathways regulating food intake. There is evidence that insulin acts on the brain reducing food intake of normo and hyperglycemic animals. However, it remains a question whether offspring of diabetic rats respond differently to central insulin administration. Therefore, the aim of the present study was to evaluate the effects of chronic central insulin infusion on food intake of offspring from mild hyperglycemic rats. At birth, female Sprague Dawley rats were assigned either to Control (subcutaneous (sc) citrate buffer; n=10) or STZ group (streptozotocin (STZ) -100 mg/kg- sc.; n=10). Rats were mated at 90 days old and delivered naturally around pregnancy day 22. The litters were culled to 6 pups, 3 females and 3 males. On postnatal day (PND) 75, four experimental groups were formed according to maternal metabolic state (Control or STZ) and treatment (saline or insulin): Control saline (n=10), Control insulin (n=10), STZ saline (n=10) and STZ insulin (n=10). Only one male offspring from each litter was used on each experimental group, thus the litter was the experimental unit. Food intake and body weight were followed up 7 days before and 7 days after surgery for implantation of a cannula in the lateral ventricle. The cannula was connected by a polyethylene tube to an osmotic pump (Alzet® model 2001), which released saline or 10 mU of insulin per day for 7 consecutive days. Food intake rate and body weight changes were calculated. The chronic central infusion of insulin reduced food intake and its anorectic effect was more pronounced in the offspring of rats with mild hyperglycemia. The present study shows that the presence of maternal hyperglycemia during pregnancy alters the development of brain circuits regulating food intake of the offspring.

Title: Knockout of SNAT10 (SLC38A10) in mice causes a lowered body weight in adolescent and adult mice, along with altered levels of amino acids in plasma, but do not give rise to a behavioural phenotype

Authors: *F. A. LINDBERG, K. NORDENANKAR, R. FREDRIKSSON;
Pharmaceut. Biosci., Uppsala Univ., Uppsala, Sweden

Abstract: Sodium-coupled neutral amino acids transporter 10 (SNAT10) is a member of the solute carrier (SLC) 38 family. The SLC38 family has eleven members, SLC38A1-11, and are amino acidtransporters. Our group has earlier established that SNAT10 is a bidirectional transporter of L-glutamine, L-glutamate, L-alanine and D-aspartate through *in vitro* studies.
In this exploratory study, a knockout mouse model of SNAT10 (KO) was investigated in order to understand the *in vivo* importance of this transporter. Mice were weighed three times per week between the age of three to seven weeks, and once per week when they reached adult age. KO mice were found to weigh less than control ($SNAT10^{+/+}$) mice, but $SNAT10^{+/-}$ mice were unaffected. Food intake was therefore measured in adult mice, but no differences were observed. Neither was there any difference in body size on embryonic day 15.5.
Plasma samples were collected from adult mice, and levels of amino acids were measured. Levels of glutamine and glutamic acid was found to be lower in the KO mice when compared with control mice. Plasma from $SNAT10^{+/-}$ mice were not tested.
The behavioural profile was studied in the Y-maze, open field, marble burying and the rotarod tests. Grip strength was also investigated. However, no behavioural phenotype was found in KO mice as compared with control mice.
In conclusion, the SNAT10 KO mouse was smaller than control, caused minor changes in plasma levels of glutamine and glutamic acid, but do not seem to give rise to a behavioural phenotype. The cause of the lowered body weight is from this study still unknown but could possibly be due to an affected mTOR pathway. However, this needs to be studied further.

Title: Hypertensive and arrhythmogenic effects of an energizing naturist supplement in young university students in the state of Hidalgo, Mexico

Authors: *J. ARIAS-RICO[1], O. A. JARAMILLO-MORALES[2], E. V. RAMIREZ-JIMENEZ[2], M. BAUTISTA-AVILA[3], E. RAMIREZ-MORENO[2], R. C. JIMENEZ-SANCHEZ[2], R. BARRERA-GALVEZ[2];
[1]Univ. Autonoma Del Estado De Hidalgo, Pachuca, Hgo., Mexico; [2]Univ. Autonoma del Estado de Hidalgo, Pachuca, Hgo., Mexico; [3]Univ. Autonoma del Estado de Hidalgo, Pachua, Hgo., Mexico

Abstract: Introduction: Currently, nutritional supplements are a group of commercially available products that are consumed as an addition to the usual diet. Its consumption without measure is justified by its natural origin, seeking mainly physical, aesthetic or miraculous ends, without in any case taking into account the possible harmful effects that its use can entail. On the other hand, beverages known as energizers are stimulant preparations, whose main composition is caffeine and carbohydrates (glucose, glucoronolactone, fructose or sucrose), accompanied by dietary supplements (taurine, vitamins, minerals) or plant extracts and additives acidulants (citric acid and sodium citrate It is very important to mention that these products are consumed in a large proportion in the adolescent population, mainly students, which belong to the youngest and most vulnerable segment of the population, in this sense, **the objective** of the present study was to evaluate the cardiovascular effects of nutritional supplements in healthy young university students of the Institute of Health Sciences of the state of Hidalgo. **Materials and methods**: We used a cross-sectional correlational experimental study that was carried out in a methodological plan divided into four phases, in which the subjects with a minimum risk were chosen to present a stress test following the Bruce protocol. . The population was constituted by young people between an age range of 18 - 24 years and a random sampling was carried out. For data analysis, the IBM SPSS Statistics 23 program was used, using descriptive statistics and to test the hypothesis the chi square was calculated. **Results**: Healthy young patients who consumed the nutritional supplement showed significant alterations in the type of recovery (Cardiac Frequency, Arterial Blood Pressure), QT and QTC figures of the electrocardiogram and in the duration of the bruce protocol phases compared to patients who received the placebo. **Conclusion:** Our data show for the first time that the consumption of dietary supplements generates cardiovascular alterations of great importance in healthy young people. However, more studies are needed in order to clarify a possible mechanism of action of these alterations.

Title: Identification of exercise-specific functional brain network and its exercise-intensity dependency

Authors: ***N. KUBOTA**, H. KASAHARA, S. AMEMIYA, T. NISHIJIMA, I. KITA; Tokyo Metropolitan Univ., Tokyo, Japan

Abstract: Accumulating evidence suggests that physical exercise has beneficial effects on psychological health via mediating activation of diverse brain regions involved in emotion. However, the exercise-specific functional brain network underlying the beneficial effects of exercise, and its exercise-intensity dependency remains unclear. Here, we tried to identify the exercise-specific functional brain networks using 30-min acute treadmill running at different intensities (HSR: high speed, 25 m/min; LSR: low speed, 15 m/min; SED: control, only sitting on the treadmill) in rats. According to previous study (Wheeler et al., 2013), we quantified neural activity across 28 brain regions involved in emotion and motor functions using c-Fos expression, and then visualized the functional connectivity of the brain regions based on correlation analysis and graph theory. The acute treadmill running enhanced c-Fos expression in several regions in a manner that depended on intensity, whereas c-Fos expression in the interfascicular part of dorsal raphe was significantly enhanced only by LSR. The matrices of inter-regional correlations for Fos expression showed less co-activation in acute exercise (both LSR and HSR) compared to that in SED. The functional networks obtained based on a scale-free degree distribution showed that the nod size and weight of the connection in functional network in LSR were different from those in HSR. In addition, we identified the structure of clusters and the region as hub in the network, using graph theory analysis with the modularity and the centrality of degree and betweenness respectively, and found that those parameters were different between LSR and HSR. These results suggest exercise-intensity dependency on functional networks recruited by acute exercise. Understanding the exercise-specific functional brain network recruited by acute exercise at various conditions, including intensity, duration, and type of exercise, may provide new insights into establishment of optical exercise regimens for psychological health.

Title: Activation of the lateral hypothalamus GABAergic neurons enhance hedonic value to nearest stimuli and promotes consummatory behavior

Authors: *D. A. GARCIA[1], J. LUIS ISLAS[2], A. I. HERNANDEZ-COSS[2], L. PURON SIERRA[2], R. GUTIERREZ[2];
[1]Inst. de Fisiologia Celular, UNAM, Ciudad de Mexico, Mexico; [2]Farmacologia, CINVESTAV, Ciudad de Mexico, Mexico

Abstract: Hedonic value or palatability is encoded by an unidentified population of LH neurons. It is known that photostimulation of LH GABAergic neurons promotes appetitive and consummatory behavior to different stimuli, regardless of their nutritional value. Also, the activation of these neurons induced approach behavior to the closest stimulus. We reasoned that activation of LH GABAergic neurons might increase the palatability of stimuli, thereby promoting the described behaviors. To test this idea, we placed sated mice that expressed ChR2 in GABAergic neurons (Vgat-ChR2) in an operant box with three ports, where they -concurrently- had access to 3% sucrose (left port), 18% sucrose (right port) or water (central port). We found that transgenic mice increased consumption of 18% sucrose in 5-min laser on blocks compared to 5-min off blocks. These results can be explained because mice spent more time near the 18% sucrose port, and thus during photostimulation (2s On 4s Off), they consume more 18% sucrose. To determine if this manipulation promoted the ingestion of the stimulus with the highest palatability or the nearest-although less palatable- one, the same animals were trained in a similar task, but this time the laser was activated when the mice made a head entry in the central port. All transgenic mice self-stimulated, but one group increased the water consumption over sucrose, and the other instead moved to consume 18% sucrose. Therefore, these inter-subjects variability shows activation of LH GABAergic neurons may modulate two components: proximity and palatability. Subsequently, in the same task, we replaced the water in the central port for either no solution (dry licks), quinine or airpuffs. The three conditions increased the number of head entries (self-stimulation), but the aversive stimuli (quinine and

airpuffs) decreased the number of licks in the central port. However, if photostimulation was delivered from head-entry to lick once the central sipper (i.e., the airpuff now were inescapable), the transgenic mice stopped self-stimulation. Thus, LH GABAergic neurons activation does not override aversive stimuli. Also, we put 18% sucrose in the central sipper, and transgenic mice drastically overconsum ed it. Finally, by using a brief access test, we confirmed that activation of LH GABAergic neurons increased the hedonic value of the less palatable stimulus: decreased the latency to start consumption and increased the lick rate of low palatable over the most palatable stimulus. We concluded that activation of LH GABAergic neurons could enhance the hedonic value of stimuli, thereby promoting approach consummatory behavior to the nearest stimuli.

Title: Opposite codification of sucrose palatability by GABAergic and glutamatergic lateral hypothalamus neurons

Authors: *A. HERNANDEZ-COSS[1], M. HERNANDEZ LUNA[2], R. GUTIERREZ[3];

Abstract: The increasing prevalence of overweight and obesity calls for a deeper understanding of the causes of such disorders. Arguably the most relevant cause for the energetic disbalance that leads to overweight and obesity is the overconsumption of sugar, due to its ubiquity in the food industry and the ease to consume it far beyond our physiological needs. In previous works using extracellular recordings, we investigated the Lateral Hypothalamic Area (LHA) in mice, an important node on the feeding circuit and found two distinct subpopulations of neurons that had different electrophysiological responses to the consumption of increasing concentrations of sucrose, one of these populations increased activity directly proportional to the sucrose intensity (i.e., concentration) and was found to be comprised of GABAergic neurons, the other was inversely proportional to sucrose intensity and was hypothesized as non-GABAergic. In this work we sought to identify if a functional difference between glutamatergic and GABAergic

neurons explained the heterogeneous response of LHA neurons to sucrose palatability. We achieved this using fiber photometry to measure the calcium activity of glutamatergic and GABAergic neurons separately in the LHA during a Brief Access Taste Test (BATT), in which 7 different stimuli were presented to the mice semi-randomly in 4 s windows. The stimuli were water, artificial saliva and different concentrations of sucrose (1.5, 3, 10, 18 and 32 wt/vol %). Calcium activity information was acquired from GCaMP6m fluorescent indicators expressed in either GABA or glutamatergic neurons in the LHA of freely moving animals and the lick rate and bout sizes were used as measures for palatability. We observed a common rise of calcium activity in both groups following the stimulus presentation compared to their baseline, and we found that GABAergic neuron activity was directly proportional to the palatability of the stimulus, while glutamatergic neuron activity was inversely proportional to it, decreasing its normalized fluorescence intensity as the sucrose concentration increased. Our findings shed light on the functional difference of these two subpopulations of neurons and how they might complement each other in the encoding of sucrose palatability.

Title: Nucleus accumbens and lateral hypothalamus neural responses during appetitive and consummatory behaviors in an instrumental task with solid and liquid rewards

Authors: *B. I. DURAN-SOSA, R. GUTIERREZ;
Farmacología, CINVESTAV, Mexico City, Mexico

Abstract: It is well known that Lateral Hypothalamus (LH) and Nucleus Accumbens (NAc) are two important nodes for feeding behavior and reward. The communication between these brain regions has been widely studied but, it hasn't been explored, neither directly compared, how they respond to the anticipation and consumption of solid vs. liquid food rewards with different hedonic values. To answer these questions, we designed a fixed ratio (FR4) task with alternated trials rewarded with food pellets or liquid sucrose that effectively separates appetitive and consummatory part of feeding behavior. C57BL/6J mice were required to press four times a lever to receive either a 20 mg chocolate pellet or a 2 s opportunity window to lick for sucrose (3µL/drop/lick), by pressing a different lever. At pellet rewarded trials, only the pellet associated lever was available, after the fourth press it was retracted and a pellet was delivered, then a sucrose trial would begin, by exposing the sucrose associated operandum. Since sight of food modulates other hypothalamic neurons (e.g., AgRP neurons) related with hunger and thirst, we also decided to test if seeing the pellet evoked the same responses in LH and NAc neurons. To this end, we included a condition during the pellet trials, giving a 50% chance of delivering the pellet right after the fourth lever press, thus the reward was visible as the subject was approaching the pellet port, while the other 50% trials the pellet was dropped at the port until the head entry. After training, subjects were implanted with a 16 microelectrode array in NAc or LH. We found that mice would press the pellet lever faster than the one rewarded with sucrose, suggesting the solid chocolate pellet has a greater hedonic value over liquid sucrose. Interestingly, mice would take longer to move towards the pellet port than to the sucrose port, which suggests that our condition at the pellet trials creates a feeling of uncertainty that delays the approach to the reward. Our recordings show very heterogenous modulations from both brain regions with task related neurons found in every epoch. We found a group of neurons that responded equally to both rewards, while others preferred to fire more for pellet or for sucrose rewards. Interestingly, NAc and LH have a group of neurons that modulate their firing rate in response to anticipation of the solid reward, increasing firing rate during the approach while the pellet was visible was the most common response. This suggests both regions encode information about hedonic value of pellets and sucrose rewards, right from the appetitive phase of feeding (lever presses), including the approach and during consummatory behavior.

Title: Central oxytocin signaling inhibits motivated responding for palatable food

Authors: *C. M. LIU, A. N. SUAREZ, R. A. FATEMI, E. E. NOBLE, S. E. KANOSKI; USC, Los Angeles, CA

Abstract: Central oxytocin signaling reduces food intake in humans and in experimental rodent models. However, the behavioral mechanisms through which these effects occur are poorly understood. Here we examined the effects of central oxytocin signaling in rodents on conditioned aspects of feeding behavior using behavioral procedures that require motivated responding to obtain palatable sweet-tasting foods. First, male Sprague-Dawley rats (n=12) were administered lateral intracerebroventricular (ICV) oxytocin (1μg/μl) or vehicle (within-subjects design) and tested in the differential reinforcement of low rates of responding (DRL) task, a procedure measuring food impulsivity that requires animals to refrain for 20 seconds from making an operant response for sucrose. Results revealed that ICV oxytocin significantly increased efficiency in the DRL task relative to vehicle treatment, suggesting that central oxytocin reduces impulsive responding for palatable food. We next examined the effects of central oxytocin on effort-based food-related decision making in a concurrent progressive ratio procedure that involves a choice between free consumption of bland food (standard rodent chow) vs. effort-based (lever pressing on a progressive ratio reinforcement schedule) consumption of palatable sucrose. We found that food-restricted rats (n=11; within-subjects design) that received ICV oxytocin decreased the ratio of sucrose calories consumed over total calories, thus reducing motivation to work for sucrose in the presence free chow. Lastly, we utilized the conditioned place preference procedure in order to study the effects of central oxytocin signaling on appetitive responding for palatable food (high fat, sucrose-enriched diet) in the absence of consumption and postingestive feedback. Results revealed that in comparison to vehicle-injected rats, rats that received ICV oxytocin (n=9/group; between-subjects design) immediately prior to a place preference test in which no food was available showed significantly reduced food seeking behavior as measured by the ratio of time spent in a context previously paired with palatable food vs. a context in which the rats had equivalent previous exposure, but without food access. These results indicate that central oxytocin alters conditioned food seeking behavior in the absence of immediate postingestive feedback. Collectively, these findings reveal that central oxytocin inhibits conditioned motivated behaviors directed towards acquiring palatable food, including food impulsivity, effort-based food-related decision making, and food seeking behavior in the absence of consumption.

Title: MCH neuron activity is sufficient for reward and reinforces feeding

Authors: I. AKLAN, ***N. S. ATASOY**, Y. YAVUZ, D. ATASOY;
Univ. of Iowa, Iowa City, IA

Abstract: Melanin Concentrating Hormone (MCH)-expressing neurons of lateral hypothalamus (LH) have long been implicated in regulation of energy homeostasis and reward. The role of MCH neuron electrical activity in short term modulation of appetite and reward has not been fully understood. Here we investigated short-term behavioral and physiological effects of MCH neuron activity manipulations. We used a combination of optogenetic and chemogenetic approaches in *Pmch-cre* transgenic mice to acutely stimulate or inhibit MCH neuronal activity, while probing food intake, locomotor activity, anxiety-like behaviors, glucose homeostasis and reward. MCH neuron activity is neither required nor sufficient for short-term control of appetite for chow food unless stimulation is temporally paired with consummatory period. While MCH neuronal activity does not affect short-term locomotor activity, its inhibition improves glucose tolerance and has mildly anxiolytic effect. Finally, using two different operant tasks we show that activation of MCH neurons alone is sufficient to induce reward. Collectively, these experiments confirm diverse behavioral and physiological functions of MCH neurons and suggest a direct role in reward function. Our results support a role for MCH neurons in reinforcement of ongoing consumption, rather than directly increasing the motivation to eat.

Title: Getting to the nitty-gritty: Probing the mechanism of interaction between ghrelin and endocannabinoid systems at ventral tegmental area dopamine neurons

Authors: *A. W. EDWARDS, L. HYLAND, M. J. CHEE, A. ABIZAID;
Neurosci., Carleton Univ., Ottawa, ON, Canada

Abstract: Ghrelin and endocannabinoids (eCBs) promote food intake by activating the growth hormone secretagogue receptor (GHSR) and cannabinoid receptor 1 (CB-1R), respectively. In the hypothalamus (HYP), ghrelin requires eCB signalling to promote food intake, as deletion or antagonism of CB-1Rs prevents ghrelin-induced feeding. Both GHSRs and CB-1Rs are also expressed in the ventral tegmental area (VTA) and GHSR activation stimulates dopaminergic (DA) neurons in this region to promote food motivation and consumption. Similar to what is seen in the HYP, global and intra-VTA CB-1R antagonism blunts the feeding motivation and food intake induced by intra-VTA ghrelin, thus it appears that ghrelin requires functional CB-1Rs to fully promote motivated feeding in the VTA. The mechanism by which CB-1R antagonism prevents the orexigenic effects of ghrelin in the VTA is not yet known, therefore we examined the mechanisms underlying the effect of ghrelin and its interaction with CB-1R activation on putative DA neurons. We performed whole cell patch-clamp recordings from GFP-labelled neurons that express tyrosine hydroxylase (TH) in the VTA of *TH-cre:L10-GFP* mouse brain slices and first confirmed the stimulatory effects of ghrelin on these putative VTA DA neurons. We found that bath application of ghrelin (500 nM) produced a 3-fold increase in action potential firing frequency by directly depolarizing these neurons; these effects reversed upon ghrelin washout. To test if ghrelin can also stimulate excitatory glutamatergic tone onto VTA DA cells, we recorded spontaneous excitatory postsynaptic current (sEPSC) events and showed that ghrelin also reversibly increased the frequency of sEPSCs in VTA DA neurons to approximately 3 times that of baseline. Thus, ghrelin can stimulate VTA DA neurons by promoting neuronal excitability and excitatory glutamatergic tone to this region. To determine if CB-1R antagonism can prevent ghrelin-mediated activation of VTA DA neurons, we pretreated slices with the CB-1R antagonist rimonabant (5 μM) to test if bath application of ghrelin would still increase the neuronal excitability of these cells. We found that the rimonabant pretreatment did not block ghrelin-mediated excitation of VTA DA neurons, suggesting CB-1R signalling is not essential for ghrelin to excite these cells. In summary, while ghrelin has a robust excitatory effect on VTA neurons, it does not appear to rely on CB-1R activation directly at VTA DA neurons. Studies are currently underway to test if presynaptic activation of CB-1Rs acts to modulate ghrelin-mediated excitation of VTA DA neurons.

Title: The role of glutamatergic transmission in melanin-concentrating hormone neurons in the lateral hypothalamus

Authors: *A. S. SANKHE[1], D. BORDELEAU[1], D. M. ALFONSO[1], G. WITTMANN[2], M. J. CHEE[1];
[1]Neurosci., Carleton Univ., Ottawa, ON, Canada; [2]The Div. of Endocrinology, Diabetes and Metabolism, Tufts Med. Ctr., Boston, MA

Abstract: Melanin-concentrating hormone (MCH) neurons are exclusively expressed within the lateral hypothalamic area. We and others have found that MCH neurons coexpress the vesicular glutamate transporter 2 (vGLUT2), thus in addition to MCH, these neurons can release glutamate. MCH has well-known roles in feeding and energy expenditure, but the relative contribution of glutamate to these roles remains unclear. MCH administration into the brain stimulates food intake and mice with MCH deletion become lean, hyperactive, and do not overeat a palatable high fat diet, which is normally seen in wildtype littermates. These findings indicate that MCH is an orexigenic neuropeptide that can regulate homeostatic and hedonic feeding. It has recently been shown that glutamate from MCH neurons may increase feeding and body weight, but the role of glutamate in hedonic feeding is not known. To study the role of glutamate release from MCH neurons, we crossed a *Mch-cre* mouse with a *Vglut2-flox* mouse to selectively delete vGLUT2 from MCH neurons in *Mch-Vglut2-KO* mice. We determined the colocalization of MCH immunoreactivity with *Vglut2* mRNA by *in situ* hybridization and found that *Vglut2* colocalizes with more than 90% of MCH neurons. Only 15% of MCH neurons expressed *Vglut2* in *Mch-Vglut2-KO* animals. *Mch-Vglut2-KO* mice had similar body weights to *Vglut2-flox* controls. There was also no difference in baseline ambulatory activity, but *Mch-Vglut2-KO* animals have reduced ambulatory activity in a novel environment, such as following a cage change. To determine the role of glutamate in feeding, we compared the food intake of *Mch-Vglut2-KO* and *Vglut2-flox* animals on a chow and then a 45% high fat diet (HFD). Both groups consumed the same amount of calories on a chow diet. Within 24 hours of switching to HFD, all animals become hyperphagic relative to their chow intake. Interestingly, *Mch-Vglut2-KO* animals consumed 25% more calories during this period than control animals. In summary, our findings suggest that glutamate, in contrast to MCH, may not alter baseline body weight,

ambulatory activity, or chow feeding; but context-dependent stimuli, like HFD, revealed differing roles between glutamate and MCH.

Title: Impact of protein appetite on the dopamine mesolimbic system

Authors: ***F. NANEIX**[1], G. CHIACCHIERINI[1], K. Z. PETERS[1], E. M. S. SNOEREN[2], J. E. MCCUTCHEON[1];
[1]Dept. of Neuroscience, Psychology and Behaviour, Univ. of Leicester, Leicester, United Kingdom; [2]Dept. of Psychology, UiT The Arctic Univ. of Norway, Tromso, Norway

Abstract: Maintenance of protein homeostasis is an essential process in the control of food intake as many amino acids cannot be synthetized *de novo*. However, the underlying neurobiological circuits remain poorly understood. Recently, our lab developed a model of protein appetite in which rats maintained on a low protein diet (5%; protein-restricted) present a strong conditioned preference for a flavored casein (milk protein) solution versus an isocaloric flavored maltodextrin (carbohydrate) solution. This protein preference is not observed in control, non-protein restricted, rats. Using viral expression of the calcium indicator GCaMP6s in ventral tegmental area (VTA) neurons and *in vivo* fiber photometry recordings, we first observed that protein preference was associated with elevated VTA activation during casein consumption, relative to maltodextrin. Moreover, protein preference and VTA responses were still observed when protein homeostasis was restored, suggesting long-lasting adaptations. By contrast, the switch to protein restricted state of control rats induced a rapid behavioral shift as well as changes in the VTA response to casein intake. Further experiments confirmed this rapid development of the protein preference as rats showed an almost immediate preference for casein, relative to maltodextrin, even without previous exposure to the solutions. Furthermore, using quinine adulteration of casein, we showed that, although protein appetite is associated with an initial increased palatability of casein, this does not seem to be essential for driving behavioral preference. Current experiments are investigating the specific involvement of dopamine

signaling in the nucleus accumbens by using the genetically encoded dopamine sensor, dLight1, in behaving rats and *ex vivo* fast scan voltammetry recordings in brain slices. Taken together our results highlight for the first time the involvement of mesolimbic circuits in behavioral processes underlying protein appetite.

Title: Opioid receptor-mediated physical dependence following sugar intake expressed in a model of withdrawal-suppressed behavior

Authors: *B. D. FISCHER, C. KROLL;
Cooper Med. Sch. of Rowan Univ., Camden, NJ

Abstract: Studies in animal models have suggested that sugar deprivation following excessive intake elicits opioid-like withdrawal. However, little has been done to investigate sugar induced physical dependence using established preclinical assays of opioid withdrawal. The present study used both a withdrawal jumping procedure and an operant procedure to assess further the development of opioid receptor-mediated physical dependence following excessive sucrose intake. These two endpoints were chosen to assess behaviors that are either elicited (withdrawal jumping) or suppressed (operant behavior) during naloxone-precipitated opioid withdrawal. C57BL/6 mice were given daily 14-hour access to a 10% sucrose solution in addition to water and food. Over a 28-day period, mice consumed an average (± SEM) of 2.3 ± 0.8 g of sucrose per day. Naloxone-precipitated opioid withdrawal experiments were conducted weekly. In the withdrawal jumping procedure, precipitated withdrawal was assessed in individual plexiglas observation cylinders. Jumping was measured for 5 minutes immediately following administration naloxone (1.0 mg/kg i.p.). In this procedure, naloxone failed to precipitate increased withdrawal jumping behavior in the mice self-administering sucrose. In the operant behavior procedure, mice were trained on a fixed-ratio schedule of reinforcement. In this procedure, naloxone (0.1-1.0 mg/kg, i.p.) produced dose- and time-dependent decreases in operant response rates following the 28-day period of sucrose self-administration. Parallel experiments were conducted in mice administered morphine (100 mg/kg, i.p.) twice daily for 6 days, in which naloxone precipitated withdrawal in both the withdrawal jumping and operant behavior procedures. Together, these findings raise the possibility that opioid receptor-mediated physical dependence following excessive sucrose consumption may be expressed in assays of

withdrawal-suppressed behaviors. Further, these data suggest that assays of withdrawal-suppressed behaviors may be useful for further study related to opioid receptor-mediated sugar dependence.

Title: The dopamine D4 receptor antagonist L-745,870 decreases body weight gain, food intake and food-reinforced behavior in rats exposed to an energy-dense diet

Authors: *R. ESCARTIN-PEREZ[1], R. CRUZ-TRUJILLO[2,3], F. CORTÉS-SALAZAR[1], D. DÍAZ-URBINA[1], J. SUÁREZ-ORTÍZ[1,2], A. HERNÁNDEZ-GUTIÉRREZ[3], V. LÓPEZ-ALONSO[1], J. MANCILLA-DÍAZ[1];
[1]División de Investigación y Posgrado, UNAM, FES Iztacala, México, Mexico; [2]Univ. Autónoma de Chiapas, Chiapas, Mexico; [3]Inst. Politécnico Nacional, Cdmx, Mexico

Abstract: The global obesity epidemic remains one of the major risk factors for the occurrence of a number of chronic diseases, including diabetes, cardiovascular diseases and different types of cancer. Recurrent over-consumption of energy-dense foods is a common feature of obese individuals and this phenomenon has been replicated in animal models of diet-induced obesity. Accordingly, it has been shown that energy-dense diets that are highly palatable induce activation of the brain reward circuit, a mechanism that explains in over-consumption of food in obese individuals and experimental animals. The finding that diet-induced obese mice overexpress the dopamine D4 receptor (D4r) mRNA in specific cerebral regions, including the ventral region of the lateral septum (LS), suggests a potential role of D4r receptors in the genesis and/or development of obesity induced by energy-dense diets. Consequently, alterations in the reward system associated with diet-induced obesity are potentially related to changes in the dopaminergic transmission mediated by presynaptic D4r of LS projections. This idea is supported by findings that showed regulatory inputs to the nucleus accumbens and the ventral tegmental area from the LS. Accordingly, we propose the hypothesis that the pharmacological blockade of D4r will prevent the development of excessive body weight gain in rats chronically exposed to an energy-dense diet and will decrease the motivation for palatable food. Thus, the aim of this study was to evaluate the effects of chronic administration (ip, daily administrations during 14 days) of the D4r selective antagonist, L-745,870 (1mg/kg), on body weight gain (g),

food consumption (g) and motivation for palatable food (breakpoints, 45 mg chocolate-flavored sucrose pellets, operant task) in male Sprague Dawley rats exposed to an energy-dense diet (high-fat diet, HF, 60% of calories from fats). The pharmacological treatment started after 52 days of exposure to the HF diet; adipose tissue, glucose, triglycerides, and cholesterol (total, LDL and HDL), as well as locomotor activity, were also measured. We found that chronic administration of L-745,870 prevented the increase of body weight gain, and decreased food consumption and breakpoints, as well as the abdominal adipose tissue accumulation and the serum glucose levels and triglycerides. We concluded that chronic systemic blockade of D4R may inhibit feeding behavior and motivation for palatable food, despite the subjects had access to the HF diet. Furthermore, accumulation of body weight gain and abdominal adipose tissue decreased, suggesting that D4r antagonist may be useful for the pharmacological treatment of obesity.

Title: Evolution of neural ensembles coding reward seeking and taking in the medial prefrontal cortex

Authors: *Y. ZHANG[1], G. BARBERA[1], B. LIANG[1], L. ZHANG[1], Y. LI[2], Y. SHAHAM[1], D.-T. LIN[1];
[1]NIDA/NIH, Baltimore, MD; [2]Dept. of Zoology and Physiology, Univ. of Wyoming, Laramie, WY

Abstract: Seeking natural rewards such as food is of fundamental importance for an individual's survival and well-being. The medial prefrontal cortex (mPFC) is critical for reward-seeking. However, it remains unclear how spatially and temporally organized neural activity in the mPFC codes reward seeking and taking. In this study, we employed a custom miniature fluorescence microscope (miniScope), to simultaneously track calcium activity from hundreds of neurons longitudinally at single cell resolution in the mPFC. We imaged mPFC neural activity in which mice learned to lever press for food reward, to reveal how neural ensembles that encode reward seeking and taking. We found that different subgroups of neurons showed increased activity

around distinct behavioral events (i.e. lever press/cue presentation as reward seeking, and food retrieval as reward taking). We also trained an artificial neural network using a machine-learning algorithm to predict the timing of lever pressing using neural activity and showed that the identified neural ensemble carried most behavioral relevant information. Together, our results reveal the evolution of dynamic neural ensembles in the mPFC that encode reward seeking and taking.

Title: Endocannabinoid modulation of chemosensation underlying altered food preferences in *C. elegans*

Authors: *A. LEVICHEV[1], S. FAUMONT[1], R. Z. BERNER[2], Z. PURCELL[2], S. R. LOCKERY[1];
[1]Inst. of Neurosci., [2]Univ. of Oregon, Eugene, OR

Abstract: The mammalian endocannabinoid system, comprised of the endocannabinoids AEA (N-arachidonoyl-ethanolamine) and 2-AG (2-Arachidonoylglycerol), their receptors, CB1 and CB2, and their metabolic enzymes, is thought to integrate internal energy state and sensory food cues to modulate feeding. For example, cannabinoids, acting on CB1, can increase preference for more palatable, calorically dense food: a response called *hedonic amplification*, colloquially known as “the munchies.” In mammals, cannabinoids can increase sensitivity to odors and sweet tastes, which may underlie amplification. We are developing *C. elegans*, an omnivorous bacterivore, as a model in which to investigate the neurophysiology of hedonic amplification. We found that exposure to AEA, an endogenous cannabinoid common to mammals and *C. elegans*, further increases the worm's preference for strongly preferred (more palatable) bacteria over weakly preferred (less palatable) bacteria, mimicking hedonic amplification in mammals. Furthermore, AEA acts bidirectionally, increasing consumption of strongly preferred bacteria while decreasing consumption of weakly preferred bacteria. We also found that deletion of the *C. elegans* CB1 ortholog, *npr-19*, eliminates hedonic amplification, which can be rescued by expression of wild type *npr-19* or human CB1, establishing a humanized worm for cannabinoid signaling studies. Deletion of the olfactory neuron AWC, which directs chemotaxis to food,

abolishes hedonic amplification. Consistent with this finding, calcium imaging revealed that AEA bidirectional modulates AWC activity, increasing its responses to strongly preferred food and decreasing its responses to weakly preferred food. In a GFP expression analysis, we found that *npr-19* is expressed ~21 neuron classes but, surprisingly, not in AWC. Although AEA's effect could be mediated by NPR-19-expressing neurons presynaptic to AWC, nearly complete elimination of fast synaptic transmission, via the mutation *unc-13(e51)*, had no effect on modulation. We are now testing the hypothesis that AEA modulates AWC by activating one or more NPR-19-expressing neurons that release a diffusible neuromodulator to which AWC is sensitive.

Title: Leptin receptor-expressing neurons in lateral hypothalamus regulates food-seeking behavior

Authors: *Y. LEE, D.-S. HA, J. PARK, H. SONG, H. CHOI;
Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: The symptom of eating disorders that is difficult to treat is a dissociation between food-seeking behavior and metabolic needs. The lateral hypothalamus (LHA) regulates various motivated behaviors including food intake. Among those subpopulations, LHA GABAergic neurons are known to be involved in modulation of food reward and consumption. Previous studies showed that activation of LHA GABAergic neurons enhance food intake and compulsive behaviors in mice. However, specified behavioral phenotypes and functions of the subset of LHA GABAergic neurons are unclear. Thus, our research aimed to identify the food-related behavioral phenotypes that are regulated by leptin receptor-expressing neurons in LHA. We performed food-seeking test, operant chamber test, overall chow and palatable food intake test and marble burying test. Interestingly, through behavior assays, we found that chemogenetic activation/inhibition of LHA leptin receptor neurons only modulate 'food-seeking' behavior. However, activation of LHA GABAergic neurons increased both food intake and compulsive behaviors without affecting food-seeking. These results suggest that food-seeking is independent from food intake, and LHA leptin receptor expressing neurons are specifically involved in food-seeking behavior that can be targeted to treat eating disorders.

Title: Enhanced incentive motivation, interactions between susceptibility to obesity and NAc CP-AMPAR mediated transmission

Authors: R. C. DERMAN, F. SANCHEZ CONDE, ***C. R. FERRARIO**;
The Univ. of Michigan, Ann Arbor, MI

Abstract: Stimuli paired with palatable foods (i.e., food cues) powerfully influence food-seeking behaviors. These incentive motivational responses to food cues rely on excitatory transmission in the nucleus accumbens (NAc) and can be influenced by individual susceptibility to obesity. For example, the magnitude of incentive motivational responses to food cues is stronger in obesity susceptible vs. obesity resistant rats prior to the development of obesity. Further, cue-triggered food-seeking in the form of Single Outcome Pavlovian-to-instrumental transfer (SO PIT) is mediated by NAc CP-AMPA receptors (CP-AMPAR) in selectively bred obesity-prone but not obesity-resistant rats. However, it's unclear whether the role of CP-AMPARs in this behavior generalizes to outbred rats identified as susceptible to diet induced obesity. Moreover, SO PIT does not distinguish between sensory specific vs. affective mechanisms of PIT. Thus, it is unclear which of these processes is enhanced in susceptible groups. Finally, how consumption of a sugary, fatty "junk food" diet alters motivational responses to food cues in susceptible vs. resistant populations remains unknown. We address these questions in 3 experiments. First, we show that in outbred rats, the degree to which NAc CP-AMPAR blockade attenuates SO PIT and conditioned approach is strongly correlated with subsequent weight. This suggests that the role for NAc CP-AMPARs in the expression of Pavlovian motivation may be unique to obesity susceptible individuals. Next, we show that the magnitude of General PIT is positively correlated with subsequent weight in outbred rats and that General PIT is stronger in selectively bred obesity-prone vs. obesity-resistant groups. These data suggest that affective mechanisms of PIT are enhanced in obesity susceptible populations. Finally, we show that basal expression of conditioned approach is stronger in obesity-prone vs. obesity-resistant rats, but "junk food" consumption enhances conditioned approach in both groups. These data suggest that that the neural alterations induced by "junk food" enhance incentive motivation, regardless of individual

susceptibility. Data overall reveal phenotypic enhancements in incentive motivation unique to obesity susceptible populations, and that junk-food enhances incentive motivation regardless of individual differences. This supports the idea that enhanced neurobehavioral responsivity to food cues found in humans is likely the result of phenotypic differences between those that are more vs. less vulnerable to diet-induced weight gain, and that "junk food" consumption alters the brain in ways that enhance incentive motivation.

Title: Input specific alterations in CP-AMPAR mediated transmission in the NAc core following junk-food diet consumption

Authors: *T. L. FETTERLY, C. R. FERRARIO;
Pharmacol., The Univ. of Michigan, Ann Arbor, MI

Abstract: Excitatory transmission within the nucleus accumbens (NAc) mediates cue-triggered motivation in the contexts of both food- and drug-seeking behavior. In humans, greater activation in the NAc in response to food cues has been observed in obesity-susceptible individuals, suggesting that there are differences in NAc function in obesity-susceptible vs. obesity-resistant populations. Work from our lab rats has found that incentive-motivational responses to food-cues are enhanced in obesity-susceptible rats as compared to obesity-resistant rats, and that this behavior is mediated by calcium permeable-AMPARs (CP-AMPARs) in the NAc. Furthermore, when placed on a sugary, fatty "junk-food" diet, a rapid and persistent increase in both NAc CP-AMPAR transmission and expression is observed in obesity-susceptible, but not obesity-resistant rats. While this demonstrates an alteration in glutamatergic transmission in the NAc following junk-food consumption, it does not provide information about which specific circuits are altered. The NAc receives glutamatergic input from several brain regions, including the medial prefrontal cortex (mPFC) and basolateral amygdala (BLA). Our current study utilizes an optogenetic strategy to dissect the contribution of the mPFC and BLA inputs to changes in NAc glutamatergic transmission following junk-food consumption (10 days)

in our selectively bred obesity-prone and obesity-resistant rat populations. Following stereotaxic injection of pAAV-CamKII-Chronos-GFP into either the mPFC or BLA, we prepared *ex vivo* brain slices containing the NAc and then recorded optically-evoked AMPA currents in medium spiny neurons using whole-cell patch-clamp electrophysiology. The contribution of CP-AMPARs to overall AMPA transmission was then determined using naspm (200 uM), a CP-AMPAR selective antagonist. Preliminary data show that junk-food increases CP-AMPAR transmission at mPFC inputs to the NAc in obesity-prone rats compared to chow fed controls. In contrast, CP-AMPAR mediated transmission at mPFC inputs was similar between obesity-resistant chow and junk-food groups. Studies examining effects in BLA inputs are ongoing. Additionally, basal differences in CP-AMPAR transmission at the mPFC and BLA inputs will be compared using control rats maintained on a standard chow diet. Combined, these studies identify specific circuits altered by junk-food consumption and will help design behavioral experiments connecting cue-triggered motivation to circuit-specific changes in glutamatergic transmission within the NAc.

Title: Effects of the estrous cycle and junk-food diet on nucleus accumbens core medium spiny neuron excitability

Authors: *Y. ALONSO CARABALLO[1], H. PAPACOSTAS QUINTANILLA[2], C. R. FERRARIO[3];
[1]Neurosci. Grad. Program, Univ. of Michigan, Michigan, MI; [2]Farmacobiologia, CINVESTAV, México DF, Mexico; [3]Pharmacol., The Univ. of Michigan, Ann Arbor, MI

Abstract: The nucleus accumbens (NAc) plays critical roles in motivated behaviors, including food-seeking in response to Pavlovian cues. We have found that selectively-bred male and female obesity-prone rats show stronger motivational responses to food-cues than obesity-

resistant rats. Consistent with this, in males, basal intrinsic excitability of medium spiny neurons (MSN) in the NAc core is enhanced in obesity-prone vs. obesity-resistant rats. However, it is unknown if similar differences exist in females and whether consumption of sugary, fatty "junk-food" alters MSN excitability. Whole-cell patch clamp recordings were conducted to examine MSN intrinsic excitability in female obesity-prone and obesity-resistant rats. Rats were given chow or 10 days of free access to "junk-food" followed by 1-2 days of "junk-food" deprivation prior to recording from MSNs. In chow fed controls, MSN intrinsic excitability was greater in female obesity-prone vs. obesity-resistant rats during metestrus/diestrus (M/D), but comparable during proestrus/estrus (P/E). This was due to cycle effects on excitability in obesity-prone but not obesity-resistant rats. Furthermore, junk-food reduced intrinsic excitability in female obesity-prone, but not obesity-resistant rats. Interestingly, this effect of junk-food was apparent during M/D, but not during P/E, suggesting dissociable mechanisms underlying cycle vs. food effects on excitability. These differences in MSN excitability between female obesity-prone and obesity-resistant rats are similar to the pattern found in male rats, with the addition of effects of the cycle on MSN excitability. These data suggest that enhanced basal excitability may contribute to stronger motivational responses to food-cues in obesity-prone vs. obesity-resistant populations. In addition, they reveal previously unidentified effects of the cycle on MSN excitability in the NAc core.

Title: Mu opioid receptors in the medial orbital cortex regulate licking microstructure and the expression of reward value

Authors: *S. R. WHITE, M. LAUBACH;
Ctr. for Behavioral Neurosci., American Univ., Washington, DC

Abstract: Abnormal sensitivity to reward underlies the development of drug dependence and addiction. Mu opioid receptors mediate the primary effects of opioid drugs and are prominent in

the frontal cortex. Only a few published studies have examined how these receptors contribute to the control of reward-guided behavior (e.g. Mena et al., 2013; Castro and Berridge, 2017). The medial orbital cortex is a key frontal region for processing of reward information. Reversible inactivation of this region eliminates incentive contrast effects and reduce measures of palatability (Parent et al., 2015). Neuronal activity in this area is modulated when rats initiate consummatory licking (Horst and Laubach, 2013) and encodes the value of liquid sucrose rewards (Amarante et al., 2017). It is not known how mu opioid receptor stimulation affects reward signaling in the medial orbital cortex. To investigate this issue, we tested rats in an incentive contrast licking task. Adult male rats were trained to lick on a contact-sensitive spout to receive access to liquid sucrose. Concentrations of sucrose alternated between relatively high (16%) and low (4%) over alternating 30 second periods. With training, rats learned to persistently lick when the higher value fluid was available and to suppress licking when the lower value fluid was available. Rats were implanted with bilateral drug cannulae targeting the medial orbital cortex and tested following infusions of the selective mu-opioid receptor agonist DAMGO (1μg/μL) and following reversible inactivation via the selective GABA-A receptor agonist muscimol. Effects of muscimol were similar to Parent et al. (2015): Rats showed reductions in the ratio of licks for high vs low concentrations of sucrose, reductions in the durations of their licking bouts especially when licking for the higher value fluid, and emitted more licking bouts. In a similar way, DAMGO reduced the durations of licking bouts and had a more dramatic effect on the number of bouts that were emitted: Rats emitted nearly three times as many bouts with DAMGO infused compared to vehicle. Effects of ratios of high and low value licks were dramatic and yet heterogeneous over rats. DAMGO had no effects on neither inter-lick intervals, total lick counts, nor the duration of task engagement. Together, these data suggest that opioid stimulation in the medial orbital cortex controls licking microstructure and the expression of reward value. We are currently examining the neuronal basis for these effects using chronic recording methods combined with intracortical pharmacology.

Title: Time matters: Effects of instantaneous fluid volume on reward signals in the rat medial frontal and orbitofrontal cortex

Authors: *L. M. AMARANTE[1], M. MITCHELL[2], J. WILSON[2], K. ALDENDERFER[3], J. NEWPORT[3], M. LAUBACH[1];
[1]Ctr. for Behavioral Neurosci., [2]Neurosci. Program, [3]Physics Dept., American Univ., Washington, DC

Abstract: The medial frontal cortex (MFC, also known as mPFC) and orbitofrontal cortex (OFC) are known to be involved in processing reward information across species. Previous studies (from our lab and others) have found reward related neural activity in both brain areas in rats that is time-locked to consummatory behavior. Specifically, our lab has found that the strength of phase locking to the rat's lick cycle encodes reward size, both for rewards that vary in nutrient concentration (Amarante et al., 2017) and fluid volume (Amarante, 2018 SfN abstract 688.04). Here, we investigated if these signals track differences in reward size based on the instantaneous volume of fluid that is delivered. Commercial lab equipment is not available to deliver precise fluid volumes on a microliter scale, and can only currently be done through either using different sized syringes from two different pumps, or through leaving a syringe pump running or solenoid valve open for different periods of time. As such, published studies of magnitude coding have confounded fluid volume with reward delivery time (e.g. Fiorillo et al., 2003; Bermudez and Schultz, 2010). To investigate this issue, we developed an open-source syringe pump control circuit using commonly available parts, a Teensy microcontroller, and custom written code. The syringe pump can deliver different volumes from one syringe over a common time epoch. The pump's functionality is achieved by changing the motor's velocity and acceleration. Using our device, we assessed how differences in reward magnitude are encoded by the rat MFC and OFC upon the immediate receipt of different fluid volumes. We found that lick-entrained neural activity in both MFC and OFC encoded the instantaneous volume of fluid delivery. Phase locking was stronger to licks for the large volume (30 uL) as opposed to a small volume (10 uL) over the same timescale (500 ms). A second series of experiments found stronger phase locking for licks that delivered a larger instantaneous volume of fluid (30 ul over 200 ms) compared to a smaller instantaneous volume (30 ul over 600 ms). Notably, the same total volume was delivered per fluid delivery, suggesting that the MFC and OFC are sensitive to instantaneous fluid volume. Our findings confirm extended properties of reward encoding in the rat frontal cortex and additionally suggest that classic studies of reward coding should be re-evaluated for effects of the duration of fluid delivery. That is, are these results reflecting the value or temporal information of the reward?

Title: Sex differences in motivation to consume sucrose following abstinence and environmental enrichment in Long-Evans rats

Authors: *J. W. GRIMM, F. SAUTER, D. MACDOUGALL, E. SPAULDING, S. GIADONE, K. STENSGAARD, M. HARDY;
Psychology, Western Washington Univ., Bellingham, WA

Abstract: Background and Rationale: There are clinically-significant sex differences in addiction behaviors including craving and relapse. We have previously observed robust sex differences in motivation to consume sucrose in adult Long-Evans rats.
Method: In the present study, motivation to consume 10% sucrose was assessed with lever press responding (0.2 mL per reinforcement) on the progressive ratio (PR) schedule in daily 3 h sessions for one week following either overnight (acute) or one month (chronic) environmental enrichment (EE). EE consisted of a large cage with 3 rats and novel toys. Controls were housed in standard single housing. Acute EE was provided immediately after initial training or after 29 days abstinence. Males and females were segregated by sex throughout the study.
Results: Females responded to higher break points during training and post-EE testing. For both sexes, there was an abstinence-dependent increase (incubation) of PR responding for sucrose in subjects tested after one month vs. one day of abstinence. Both acute and chronic EE decreased subsequent PR responding, but the persistence of the effect differed by sex and length of abstinence. For testing following one day of abstinence from sucrose, acute EE with males resulted in decreased responding for sucrose persisting 2 days. The effect persisted in females for 1 day. For testing starting after 29 days of abstinence from sucrose, acute EE with males resulted in decreased responding persisting 3 days. For females, the effect persisted 1 day. Chronic EE with males decreased their responding for 3 days but had no effect on responding by females.
Conclusion: These results replicate our previous findings of greater motivation to consume sucrose by females, demonstrate an incubation of PR responding for both sexes, and an overall more persistent anti-sucrose taking effect of EE with males.

Title: Fmri and satiety related hormones pre and post sleeve gastrectomy

Authors: S. ENAYET[1], S. BABOUMIAN[2], J. HO[1], ***M. ZHONG**[3], S. PANTAZATOS[4], O. CHINCHWADKAR[3], A. FLEET[3], A. GELIEBTER[2,5];
[1]Inst. of Human Nutrition, Columbia Univ. Med. Ctr., New York, NY; [2]Icahn Sch. of Med. at Mount Sinai, and St. Luke's Mount Sinai Hosp., New York, NY; [3]St. Luke's Mount Sinai Hosp., New York, NY; [4]Mol. Imaging and Neuropathology Div., New York State Psychiatric Inst. and Dept. of Psychiatry at Columbia Univ., New York, NY; [5]Touro Col. and Univ. Syst., New York, NY

Abstract: Bariatric surgery is currently the most effective long-term treatment for obesity. Besides gastric restriction, sleeve gastrectomy (SG) induces neuroendocrine changes, which may contribute to satiety. At 1 mo pre and 5 mo post intervention, we examined the effects of SG (n= 9), a low-calorie diet (n = 14), and no treatment (n = 16) on the satiety-related gut peptides GLP-1 and PYY before and after a standardized meal prior to fMRI. We also examined brain activation in response to high-energy dense (HED) vs low-energy-dense (LED) visual and auditory food stimuli. Postprandial PYY and GLP-1 both increased significantly following SG, but not following the low-calorie diet or no treatment ($p < 0.05$). The fMRI analysis was based on whole brain statistical maps, with a cluster extent threshold at $p < 0.05$ corrected. The SG group experienced greater brain activation in the dorsolateral prefrontal cortex (dlPFC) and lower activation in the parahippocampal (PHG)/fusiform region in response to HED vs LED stimuli as compared to the low-calorie diet or no treatment, suggesting that SG led to greater inhibitory control (dlPFC) over HED foods and reduced attention (PHG/fusiform) to HED foods. The postsurgical changes in postprandial PYY and GLP-1 may be contributing to the changes in brain responsivity to food cues.

Title: Brain substrates of hedonic hunger: Cortical-subcortical imbalance and the brain response to food cues

Authors: *J. ELKIND[1], A. R. CHILDRESS[4], P. S. REGIER[2], A. M. TEITELMAN[3], K. JAGANNATHAN[2];
[1]Univ. of Pennsylvania, Philadelphia PA, PA; [2]Dept. of Psychiatry, [3]Univ. of Pennsylvania, Philadelphia, PA; [4]Psychiatry, Univ. PENN Perelman Sch. Med., Philadelphia, PA

Abstract: Objective and Rationale: The brain plays an integral role in modulating hunger and regulating motivated behaviors related to eating. It has been found that people with increased sensitivity to environmental food cues are more likely to overeat and become obese. Therefore, it is important to understand the neural mechanisms underlying behavioral responses to food that may contribute to hedonic hunger and overeating. The purpose of this study was to examine the association of hedonic hunger, measured by power of food scale (PFS) scores, with the brain response to food cues in brain regions associated with motivation and reward. Determining the relationship between hedonic hunger and brain response to food cues may inform targeted behavioral interventions to address obesity treatment and prevention. We hypothesized that greater hedonic hunger would be associated with heightened response to food cues in reward regions of the brain.
Methods: This secondary analysis assessed female participants (n=52; initially recruited for a Behavior in Urban Female Risk Study), scanned with event-related BOLD fMRI. Brain response to presentations of 500 msec appetitive food cues (e.g., cheesecake, French fries) was correlated with PFS scores. Three contrasts were analyzed as a function of PFS scores: novel food cues, repeated food cues, and change in brain activity to repeated (vs. novel) food cues.
Results: The brain activity to novel food cues in cortical areas (medial/middle frontal gyrus, anterior cingulate gyrus) showed an inverse relationship with PFS scores ($p < 0.01$, $k > 200$). In addition, the change in brain activity to repeated (vs. novel) food cues in several reward-related regions (e.g., hippocampus, parahippocampus) was positively correlated with PFS scores ($p < 0.01$, $k > 200$).
Conclusions: Although the analyses did not fully support our hypothesis that heightened cue-reactive (e.g., mesolimbic) regions would correlate with higher PFSs, the results present an interesting dynamicGreater hedonic hunger was associated with . Added together, lower cortical activity to novel food cues to novel food cues and greater increasing change in change brain activity to repeated (vs. novel) food cues. of response from novel to repeated cues in cue-reactive regions in those with greater hedonic hungerThis suggests an a potential imbalance of top-down/bottom up processing of appetitive food cues that may reflect less a lack of control in desire to eat.

Title: Neuroimaging of the sensory and nutrient components of food rewards in humans

Authors: *P. A. KHORISANTONO[1], P. C. FLETCHER[2], I. S. FAROOQI[3], F. GRABENHORST[1];
[2]Dept. of Psychiatry, [1]Univ. of Cambridge, Cambridge, United Kingdom; [3]Wellcome Trust-MRC Inst. of Metabolic Sci., Addenbrooke's Hosp., Cambridge, United Kingdom

Abstract: Neural reward systems regulate eating behavior by detecting nutrients from sensory food properties and using this information to guide food valuation and choice. For example, fat, sugar and associated sensory characteristics, such as sweetness and texture, are particularly effective rewards that are implicated in obesity. Although oral-sensory food properties experienced during consumption critically shape eating behavior, human neuroimaging studies typically focus on valuations of visual food stimuli. Accordingly, it remains unclear how neural responses to oral food rewards derive from specific nutrients and sensory components. Moreover, although structures such as the orbitofrontal cortex, amygdala and hypothalamus are known to respond to oral food rewards, how these responses contribute to economic food valuations and real-life eating phenotypes is unknown. Here we address these questions by combining psychophysical and neuroimaging experiments with a subsequent real-life eating test. Non-obese healthy participants consumed well-defined liquid foods with various fat, sugar and protein contents during behavioral testing and fMRI scanning. We assessed the subjective economic value of the foods using a Becker-DeGroot-Marschak (BDM) auction in which participants placed bids to consume 250 ml of the offered liquids. Behavioral data indicate that economic valuations of orally delivered foods depended primarily on subjective sweetness (beta=0.358, $p<0.0001$) and thickness (beta=0.254, $p<0.0001$). Accordingly, across participants, the stimulus with the highest fat and sugar content consistently ranked highest in subjective value ($F(6,727)=30.33$, $p<0.0001$). By contrast, the stimulus with lowest fat and sugar content was valued the least, and stimuli with either low fat or low sugar content ranked in between. Substituting high fat content with either protein or a fat-free thickening agent approximated the reward value of high-fat stimuli. Analysis of neuroimaging data will show how these sensory and nutrient components elicit responses in neural reward and feeding systems. In turn, we will examine relationships between the nutrient-sensitivity of these neural systems and participants' real-life eating phenotypes as measured through a free-eating paradigm.

Title: Select innervation of target regions by individual arcuate nucleus proopiomelanocortin neurons

Authors: ***M. J. METZ**, S. T. HENTGES;
Colorado State Univ., Fort Collins, CO

Abstract: Proopiomelanocortin (POMC) neurons in the arcuate nucleus of the hypothalamus produce peptides, including the potent anorexigenic factor α-MSH and the endogenous opioid β-endorphin, and can also release the fast amino acid transmitters GABA and glutamate. This array of transmitters allows for POMC neurons to participate in diverse processes including analgesia, energy balance and reward. However, whether an individual POMC neuron, or a subset of POMC neurons, projects to unique downstream targets to mediate specific actions is not known. To begin to address this, retrograde-labeling agents were injected into distinct target sites of male and female mice to determine if individual POMC neurons innervated more than one target area. The results indicate that POMC neurons projecting to a particular brain region typically do not project to another injected target region simultaneously. POMC neurons have been characterized as a heterogeneous population based on a number of factors including differential responsiveness to regulatory factors such as serotonin, insulin and leptin. Thus, we characterized intrinsic electrical properties of POMC neurons projecting to known target sites and assessed their responsiveness to regulatory agents. Together, these results suggest that distinct subpopulations of POMC neurons may participate in select physiologic functions through unique projection patterns and pre- and post-synaptic regulation. This adds to evidence that POMC neurons should not be treated as a unified population of cells and that manipulating these cells in a subpopulation-specific manner will provide more reliable results in future studies. Studies aimed at determining whether specific subpopulations are activated by distinct physiologic states such as pleasure, pain or satiety are now warranted in order to better understand how POMC neurons contribute to these states.

Title: Hypothalamic microRNA-7 regulates energy homeostasis *in vivo*

Authors: *M. P. LAPIERRE, S. GODBERSEN, M. STOFFEL;
Inst. of Mol. Hlth. Sci., ETH Zürich, Zürich, Switzerland

Abstract: The hypothalamus, in particular the arcuate (ARC) and paraventricular (PVN) nuclei, play critical roles in the regulation of food intake, energy expenditure, and nutrient metabolism. MicroRNAs (miRs) modulate many biological processes by binding to the mRNA of target genes to repress their expression[1], and the inhibition of microRNA biogenesis in the hypothalamus causes obesity in mice[2]. Among the most highly enriched microRNAs in the ARC and PVN are the miR-7 family members, miR-7a1, miR-7a2, and miR-7b[3]. MiR-7 is known to protect against neuronal cell death in models of Parkinson's disease[4,5]; however, whether it affects hypothalamic neuron function remains unknown. We have observed upregulation of miR-7 in the hypothalamus of obese *ob/ob* mice and downregulation during fasting, suggesting that hypothalamic miR-7 may be involved in the regulation of energy homeostasis. To address this hypothesis, we ablated all three members of the miR-7 family via Cre-lox recombination in POMC-, AgRP-, LepR-, and SIM1-expressing neurons. We also used UBC-Cre-ERT2 to generate a global, tamoxifen-inducible miR-7 knockout mouse line. In each of these five models, we performed metabolic phenotyping (body weight; random-fed blood glucose; glucose and insulin tolerance tests) of both males and females fed a normal diet or high-fat diet, and we observed that loss of miR-7 in these different neuronal populations leads to varying degrees of diet-induced obesity. In order to understand the mechanism underlying the observed phenotypes, we will perform RNA sequencing to identify the regulated miR-7 target genes and other relevant genes. In addition, we are exploring the relationship between miR-7 and the circular RNA, Cdr1as, which acts as a "sponge" to sequester miR-7 via its numerous miR-7 binding sites[6,7]. We have found that these sites outnumber miR-7 by 50-fold in the hypothalamus, suggesting enormous capacity for miR-7 inhibition. We anticipate that the results of this study will expand our knowledge of hypothalamic pathways regulating energy homeostasis.

Title: PVN RGS2 is critical for the regulation of energy homeostasis

Authors: *Y. DENG, U. SINGH, K. SAITO, H. CUI;
Pharmacol., Univ. of Iowa, Iowa City, IA

Abstract: Obesity has become a major public health concern due to its high risk of developing life-threatening chronic diseases, such as hypertension and diabetes, and its prevalence has been increasing worldwide. While there is a consensus that the central nervous system (CNS) plays a crucial role in obesity, the underlying neural substrates mediating the dysregulation of energy balance remain incompletely understood. Accumulating evidence suggests that the paraventricular nucleus of hypothalamus (PVN) is a key intersection point that regulates energy homeostasis through multiple mechanisms. However, the detailed regulatory components involved in these alternations have not been thoroughly identified. Regulator of G protein signaling (RGS) proteins function as endogenous negative regulators of GPCR signaling. RGS2 is a member of the B/R4 family of RGS proteins with ubiquitous expression, and it is reported that *RGS2* knockout mice exhibit resistance to age-related weight gain, suggesting its involvement in the energy metabolism. Since the role of central RGS2 is largely unknown, we investigated the function of PVN RGS2 in the regulation of energy metabolism. Our RNAscope analyses revealed that RGS2 is highly expressed in PVN neurons, many of which also co-express melanocortin 4 receptor (MC4R), which is a G protein-coupled receptor (GPCR) known to be substantial for energy homeostasis. Thus, we hypothesized that PVN RGS2 is important for the regulation of whole-body energy balance. The expression of RGS2 within the PVN of $RGS2^{Flox}$ mice was disrupted through stereotaxic microinjection of AAV-Cre-GFP. Surprisingly, compared to their wild-type littermates, $RGS2^{Flox}$ animals exhibit significantly higher body weight while no difference is observed in food intake and resting metabolic rate (RMR). Body composition analysis by nuclear magnetic resonance (NMR) suggests that both fat mass and lean

mass are increased in *RGS2^{Flox}* mice. Additionally, PVN RGS2 deletion leads to elevated digestive efficiency in female *RGS2^{Flox}* mice, suggesting its potential role in the neuroendocrine regulation. Our results clearly state that PVN RGS2 deletion mice have distinct body weight phenotype compare to whole-body RGS2 knockout animals, indicating the divergence of central and peripheral RGS2 function in the regulation of energy homeostasis. Future studies will focus on the detailed mechanistic study aimed at understanding the potential modulatory role of RGS2 on different GPCRs in PVN neurons.

Title: Role of p75 in leptin signaling

Authors: J. C. RYU[1], Y. LIU[1], B. PODYMA[2], B. XU[4], A. D. GULER[2], C. DEPPMANN[3], *S. YOON[1];
[1]Ohio State Univ., Columbus, OH; [3]Biol., [2]Univ. of Virginia, Charlottesville, VA; [4]Dept. of Neurosci., Scripps Res. Inst. Florida, Jupiter, FL

Abstract: P75 was reported to influence metabolism, wherein its null mice remained lean without hypophasia, and do not develop insulin resistance even with high-fat diet (HFD). This effect was attributed in part to its role in white adipocytes. We found that p75 levels increased significantly with HFD in the hypothalamus, in particular in the arcuate nucleus, dorsomedial nucleus, and tanycytes of the medial eminence. Neurons in these nuclei are involved in feeding and energy expenditure in response to leptin. We thus asked whether p75 null mice are similarly recalcitrant to developing leptin resistance. P75 colocalizes with the leptin receptor in these neurons, and 70 and 40% of NPY/AgRP and POMC neurons, respectively, express p75 in the arcuate nucleus. We found that p75 null mice exhibited greater sensitivity to leptin than the wild type both with normal chow and 4 months of HFD feeding. Corollary to the phenotype, a greater number of neurons in p75 null mice express p-STAT3 in the arcuate and dorsomedial nuclei in response to leptin compared to the wild type. In line with these data, we found that p75 attenuates STAT3 activation, while enhancing ERK activation by leptin in 293T cells. The mechanism by which p75 influences leptin signaling appears to involve p75 interacting with the leptin receptor by sharing SHP2 as an adaptor in response to leptin. To investigate whether there

is a genetic interaction between p75 and leptin signaling, p75 null mice were then crossed with leptin-defective (ob/ob) and leptin receptor-defective (db/db) mice. To our surprise, ob/ob:$p75^{KO}$and db/db:$p75^{KO}$mice failed to eat, began losing weight beginning 7 weeks of age, and died of starvation by 15 weeks. These results suggest that p75 is necessary to control feeding in the absence of normal leptin signaling.

Title: Identification of leptin-sensitive raphe neuron projections to the hypothalamic nuclei

Authors: *N. D. MAXWELL[1], L. P. REAGAN[1,2], J. R. FADEL[1], F. Z. LOYO-ROSADO[1], C. A. GRILLO[1];

Abstract: Leptin is an adipocyte hormone that controls a myriad of homeostatic functions. Most notably, leptin acts on neurons in the hypothalamus through the leptin receptor-mediated JAK/STAT pathway to control energy homeostasis and appetite. Leptin has not only been shown to act on hypothalamic neurons, but also on other select areas of the brain such as the raphe nuclei, the primary source of serotonin (5-HT) in the brain. We are interested in studying the connections between raphe and hypothalamic nuclei and their ability to control food intake. Although these connections have been described anatomically, their functional roles remain to be elucidated. Our objectives are: (1) to define raphe neurons sensitive to leptin that send projections to the hypothalamic nuclei; and (2) to determine whether a population these neurons are serotonergic. In order to accomplish this goal, we injected fluorescently tagged cholera toxin-subunit-B (fCTB, a retrograde tracer) into the arcuate nucleus or the lateral hypothalamus (LH). One month following the tracer administration, the rats were injected with leptin into the lateral ventricle and perfused with paraformaldehyde 1 hour later. We hypothesize that there are leptin-sensitive serotonergic neurons in the raphe nucleus that send projections to different nuclei within the hypothalamus including the arcuate, as well as other phenotypes of neurons.

Immunohistochemistry and immunofluorescence were performed on these brain sections, primarily focusing on the raphe nucleus. In order to observe colocalization between our targets, we triple-labeled with antibodies against phosphorylated STAT3 (pSTAT3), a marker for leptin activated neurons, and tryptophan hydroxylase (TPH), a marker of serotonergic neurons along with the fCTB from the injection into the arcuate or LH. First, we show through the colocalization of fCTB and TPH in the raphe nucleus that serotonergic neurons do in fact project to the arcuate, and to a lesser extent the LH. More importantly, we observed that serotonergic and non-serotonergic raphe neurons that project to the arcuate nucleus are activated by leptin. These data support our hypothesis that there is an existing leptin-mediated raphe pathway projecting to the hypothalamus. We aim to characterize this pathway and tease apart the role that it may play in feeding behavior regulated by leptin.

Title: Ventromedial hypothalamus neuronal nitric oxide synthase expressing neurons project to the lateral hypothalamus

Authors: *P. SARKAR, H. WAJID, B. TRIAS, K. B. KNAPP, A. SINGH, V. H. ROUTH; Pharmacol, Physiol & Neurosci, RBHS: New Jersey Med. Sch., Newark, NJ

Abstract: A functional relationship with regard to energy balance exists between the lateral (LH) and ventromedial (VMH) hypothalamus. However, the anatomical correlate(s) underlying this functional relationship are not known. The VMH possesses glucose-inhibited (GI) neurons which increase their activity as glucose levels decline. We have shown that VMH GI neurons are critical for restoring euglycemia after insulin-induced hypoglycemia. This suggests that VMH GI neurons regulate glucose homeostasis. AMP-activated protein kinase (AMPK)-induced activation of neuronal nitric oxide synthase (nNOS) increases the activity of VMH GI neurons in low glucose. VMH AMPK activation also inhibits brown fat thermogenesis and white fat browning leading to decreased energy expenditure and weight gain. Estrogen promotes weight loss by inhibiting VMH AMPK. Bone morphogenetic protein 8B (BMP8B) mediates estrogen's thermogenic effect. The effect of BMP8B is dependent on activation of LH orexin neurons. We found that estrogen blunts activation of VMH nNOS-GI neurons in low glucose by inhibiting

AMPK. These data suggest that estrogen's thermogenic effect is due, in part, to inhibition of VMH nNOS-GI neurons. *Therefore, we hypothesize that VMH nNOS neurons which express BMP8B project to the LH.* This hypothesis was tested by injecting fluorescently labelled Retrobeads™ (retrograde tracer) into the LH of c57bl6 mice (8-12 weeks) to determine whether Retrobeads™ co-localized with VMH nNOS expressing neurons. Retrobeads™ were observed throughout the ventrolateral (vl), dorsomedial (dm), and central VMH. Retrobead™ labelling was found in subpopulations of both nNOS expressing and non-nNOS expressing cell bodies of the vl and dm VMH. In separate set of experiments, we used immunohistochemistry to determine whether nNOS and the BMP8B receptor, BMPR1a, co-localize in the VMH of mice. A larger percentage of vlVMH cells were BMPR+ (50.6±4.3% of total in males, n=4; 67.0±5.7% in females, n=4) than were nNOS+ (39.6±3% in males and 47.9±3.3% in females). BMPR1a was co-localized in 31.6±4.5% of nNOS+ vlVMH cells in male mice (n=4) vs. 55.6 ± 9.3% in females (n=4). Thus, some VMH nNOS expressing neurons project to the LH and some express BMPR1a. Moreover, this pathway appears to be sexually dimorphic. These data suggest that LH projecting nNOS neurons express BMPR1a. This observation supports our hypothesis and suggests that VMH nNOS-GI neurons may mediate some of estrogen's effects on energy homeostasis.

Title: Systematic analysis of high-spatial resolution mapping of hypothalamic markers involved in energy homeostasis regulation using Axiome neuroinformatics tools

Authors: *C. GARCIA-LUNA, G. SANCHEZ-WATTS, A. J. JOKIAHO, J. D. HAHN, A. G. WATTS;
Dept. Of Biol. Sciences, Dana and David Dornsife Col. of Letters, Arts and Sci., USC, Los Angeles, CA

Abstract: The hypothalamus plays a fundamental integrative role in energy balance to enact appropriate behavioral, autonomic and endocrine responses that change food intake and energy expenditure. Given the peptidergic heterogeneity of hypothalamic neurons and the variety of research models and analytical methods, it is a challenge to construct high-spatial resolution network models that identify key hypothalamic subregions and the spatial interaction between neuropeptides involved in the regulation of energy homeostasis in both health and disease. Neuroinformatics tools may be employed to assist understanding of the organization of neural circuits implicated in energy balance regulation. Here we have used Axiome (created by JDH): a suite of modular computational tools based on systematized and interactive Excel templates that facilitate rigorous entry and comparative analysis of brain data (currently tailored for use with the Swanson rat brain atlas). To identify hypothalamic regions that integrate peripheral and central signals in naïve or metabolic-challenged rats, we mapped (using Axiome C module) the regional locations of various neuronal markers onto sequential hypothalamic atlas levels. They include: the neuronal projection markers pseudorabies virus (PRV) and vascularly injected fast blue; chemical phenotypic markers (orexin; glucagon-like peptide 1 receptor [GLP1R] mRNA expression) from animals receiving PRV injections in the adrenal glands; and a neuronal activation marker (Fos) from animals subjected to slow- or rapid-onset hypoglycemia. Accurate mapping was achieved by referencing gray matter regions with dark field photomicrographs, together with the distribution of the norepinephrine synthetic enzyme, dopamine-beta hydroxylase. Some data used for mapping are previously published, but are now analyzed here using Axiome. By cross-referencing data from the different markers and metabolic conditions recorded in Axiome C, we identified the lateral hypothalamic area (LHA) juxtadorsomedial (LHAjd) and dorsal (LHAd) regions as important integrative and output nodes following rapid-onset hypoglycemia, and the dorsomedial hypothalamic nucleus (DMH) to slow-onset hypoglycemia. This identifies the LHAjd, LHAd and DMH as potential contributors to a hypothalamic output network that controls sympatho-adrenal output during hypoglycemia.

Title: Expression of ERα in hippocampus, amygdala, and hypothalamus during altered energy states are dependent on sex

Authors: *K. KROLICK[1], H. SHI[2], X. LIU[1];
[1]Miami Univ., OXFORD, OH; [2]Miami Univ., Oxford, OH

Abstract: Obesity and metabolic disturbances continue to be a top health concern. Estrogens are recognized for their neuroprotective and anorexigenic effects in males and females. Metabolic effects of estrogens primarily work through estrogen receptor alpha (ERα), which is differently expressed between the sexes not only in hypothalamic regions associated with controlling food intake but also in limbic regions that are not typically associated with feeding such as the hippocampus and amygdala. This could account for why estrogens differentially affect metabolic disturbances in two sexes depending on the brain region of injection. While researchers continue to elucidate the pathways responsible for estrogen's actions, it is surprising that no study has mapped the expression of ERα in extra-hypothalamic areas during different energy states between the sexes. We propose that ERα is expressed differently depending on (1) energy status of the animal, (2) sex of the animal, and (3) nuclei of brain regions. Two key extra-hypothalamic nuclei new to our understanding of regulation of feeding are the amygdala and hippocampus. Long-Evans rats were individually housed and separated into different treatment groups, reflective of different energy statuses seen in Western high-fat diet (HFD) and with HFD-induced obesity. Both short-term (4 days) and long-term (4 weeks) conditions of each treatment were used. Treatment groups are: normal rodent diet (chow; 3.003 kcal/g; 14% calories from fat); HFD (4.728 kcal/g; 45% calories from fat); HFD pair-fed (HFD-PF) which allows us to ascertain the effects of dietary fat as opposed to obesity; 24-hour fasting; and 30% chow-restricted . Chow and HFD had closely matched amounts of protein and carbohydrates, but quite different amounts of fat. Immunohistochemical staining of ERα was performed using monoclonal antibody (Santa Cruz, sc-514857) and ImmunoCruzTM mouse ABC Staining Systems (sc-2017). Photoshop was used to stitch together images taken using light microscopy and ImageJ was used to quantify the number of positive cells. Two-way ANOVA (dietary condition x sex) for each brain region of interest will be used with $P < 0.05$ considered statistically significant. The expression in different nuclei in each brain structure is quantified, as differences in ER expression may be overlooked in studies that do not take this into account. ERα is differently expressed in the amygdala and the hippocampus dependent on energy status and sex of the animal. Findings from this project will contribute to the cellular mechanisms responsible for sex differences in the role of estrogen in the extra-hypothalamic circuitry as it relates to energy metabolism.

Title: Functional mapping of the K_{ATP} channel-dependent central glucose regulatory circuit

Authors: Y. CHEN[1], ***H. TSAI**[2], S. YANG[1];
[1]Institue of Biomed. Sci., Taipei, Taiwan; [2]Inst. of Biomed. Sci., Taipei, Taiwan

Abstract: Glucose homeostasis involves processes that manage food intake, stable energy storage, and spending during times on different caloric states. Glucose, which conveys short-term fuel availability to the CNS, acts on the hypothalamic neurons to modulate the physiological responses that control energy homeostasis. However, the anatomic distribution of glucose-excited neurons and their function in energy homeostasis remained poorly understood. We use activity-dependent genetic labeling to characterize neurons activated by transient hyperglycemia. Our preliminary results showed that this transient hyperglycemia labeled the neurons in the paraventricular nucleus (PVN), dorsomedial nucleus (DMH), lateral nucleus (LH), arcuate nucleus (ARC) and ventromedial nucleus (VMH). Since earlier studies have shown that the ATP-sensitive potassium channel (K_{ATP}) is crucial for glucose sensing in the hypothalamus, we examined whether the mice lacking functional K_{ATP} channels may alter the anatomical distribution of the activity-labeled neurons in the basomedial hypothalamus. We found that mice lacking K_{ATP} channels had a similar amount of glucose-labeled neurons as the wild-type control mice (PBS injected) in the DMH, LH, VMH, and ARC, indicating that neurons lacking functional K_{ATP} channels can not sense glucose. Our RNA *in situ* hybridization results showed that the mRNA of KCNJ11, the Kir6.2 coding gene, was wildly expressed in hypothalamus with the highest levels in VMH and LH. Furthermore, we also noticed that a large portion of the activity-labeled neurons co-expressed KCNJ11 in the LH and VMH. Delivering Kir6.2-rAAV into the basomedial hypothalamus rescued the glucose intolerance in mice lacking functional K_{ATP} channels. In conclusion, our results highlighted the potential importance of the neuronal circuits that utilize K_{ATP} channel to regulate glucose homeostasis.

Title: Sexually dimorphic expression of melanocortin 3 receptors in neural circuits that link control of metabolism with reproductive state

Authors: *M. N. BEDENBAUGH[1], P. R. SWEENEY[2], K.-Y. YAM[1], R. D. CONE[2,3], R. B. SIMERLY[1];
[1]Vanderbilt Univ., Nashville, TN; [2]Life Sci. Inst., [3]Univ. of Michigan, Ann Arbor, MI

Abstract: The physiological systems regulating reproduction and metabolism must communicate with each other in order to maintain homeostasis. While it is clearly evident that reproduction and energy balance are closely intertwined, the neural circuits integrating these two processes are poorly understood. Recent functional data suggests the melanocortin 3 receptor (MC3R) mediates the exchange of information between reproductive and metabolic state. Additionally, females exhibit uniquely aberrant metabolic and reproductive phenotypes after deletion of MC3R. However, the cellular identity of MC3R-expressing neurons has not been determined in males and females, nor have their central circuits been defined. Here, we have begun to neurochemically define and map MC3R expression using RNAScope, immunohistochemistry, axonal labeling, tissue clearing and lightsheet microscopy. Using MC3R-GFP mice, we have found that MC3R is expressed in brain regions known to play a role in the control of reproductive and metabolic state, including the anteroventral periventricular nucleus (AVPV), arcuate nucleus (ARH), paraventricular nucleus of the thalamus (PVT), ventral tegmental area (VTA), and discrete regions of the caudal brainstem. The AVPV contains three times as many MC3R neurons in females compared with males, and MC3R is expressed in a majority of both AgRP and POMC neurons in the ARH, but to a significantly greater extent in males. MC3R is also coexpressed with kisspeptin neurons and ESR1 in both the AVPV and ARH. The projections of MC3R neurons, visualized through genetically targeted axonal labels, extend to a surprising variety of functional neuronal systems that include circuits known to control body weight, gonadotropin secretion, motivated behavior and reward. Taken together, these results suggest that MC3R signaling functions differently in males and females to regulate circuits involved in the coordination of reproductive and metabolic state, and may explain the unique roles for MC3R females.

Title: Dorsal raphe nucleus GABA neurons regulating energy balance

Authors: *V. M. BHAVE[1], M. SCHNEEBERGER[2], T. D. BANERJEE[1], L. PAROLARI[2], P. WANG[2], J. FRIEDMAN[2], A. NECTOW[1];
[1]Dept. of Neurosci., Princeton Univ., Princeton, NJ; [2]The Rockefeller Univ., New York, NY

Abstract: The central regulation of energy balance is critical for survival. The processes responsible for energy homeostasis are regulated at both the autonomic and behavioral levels. These processes are thought to be regulated by neurons within the hypothalamus and brainstem. However, the cell types and circuits within the brainstem regulating these processes are less well understood. We have recently identified a population of inhibitory, GABAergic neurons—within the dorsal raphe nucleus (DRN) of the mouse brainstem—that are critical for regulating energy intake and expenditure. In particular, we have found that these so-called "DRN Vgat" neurons are activated by food deprivation and ambient warmth, two signals critical for conveying an animal's internal and external environments. Here, we demonstrate that these neurons exhibit vast projections that ascend divergently into the forebrain (to structures such as the bed nucleus of the stria terminalis, the dorsomedial hypothalamus, and the medial preoptic area). DRN Vgat also exhibit projections that descend to the raphe pallidus (within the medulla) and ultimately to interscapular brown adipose tissue (iBAT). Optogenetic and chemogenetic modulation of these projections demonstrates a divergent pattern of regulation, with respect to both feeding and different types of thermogenesis. Together, this work establishes DRN Vgat neurons as a critical node embedded within the extended circuitry mediating energy homeostasis.

Title: Regulation of food intake and thermogenesis by the dorsal raphe nucleus

Authors: *T. DAS BANERJEE[1], V. M. BHAVE[1], M. SCHNEEBERGER PANE[2], A. R. NECTOW[1];
[1]Princeton Univ., Princeton, NJ; [2]Mol. Genet., The Rockefeller Univ., New York, NY

Abstract: In mammals, energy balance is tightly regulated and changes in metabolic state result in compensatory effects on both food intake and energy expenditure. We have recently identified and characterized the dorsal raphe nucleus (DRN) as a novel node in the extended neural circuitry regulating energy homeostasis. Previous pharmacological and electrophysiological studies have suggested a role for the DRN in controlling food intake and other aspects of energy balance, but the specific cell types mediating these effects were not well understood. We have recently reported that DRN neurons expressing the vesicular transporters Vgat and VGLUT3 play a role in controlling food intake and body weight. These so-called DRN^{Vgat} and DRN^{VGLUT3} neurons are anatomically distinct, and reciprocally regulate food intake such that activation of DRN^{Vgat} neurons increases feeding while activation of DRN^{Vglut3} suppresses feeding. Optogenetic modulation of $DRNV^{GLUT3}$ neurons bidirectionally affected food intake in a reciprocal fashion to that of DRN^{Vgat} neurons. Here we show that DRN^{Vgat} neurons, but not DRN^{VGLUT3} neurons, are activated by an increase in ambient temperature suggesting a possible role of DRN^{Vgat} neurons in regulating body temperature, independently of DRN glutamatergic activity. We further demonstrate that chemogenetic modulation of the DRN^{Vgat} neurons potently regulates energy expenditure through changes in both thermogenesis and locomotion. Interestingly, while optical activation of DRN^{VGLUT3} neurons significantly increases acute locomotor activity, inhibition of these neurons has no effect on movement. Collectively, these studies establish the DRN as an important node in regulation of energy expenditure.

Abstract: Obesity is an alarming chronic health crisis that currently affects 39.8% of the adult population in the United States. An important driver of obesity is overconsumption of highly-palatable food, including high-fat food, beyond nutritional energy requirements. Homeostatic feeding is regulated by the paraventricular nucleus of the hypothalamus (PVN), which functions to integrate central and peripheral signals about energy balance. A subset of PVN neurons project to the nucleus accumbens (NAc). The NAc is closely associated with hedonic feeding, and administration of glutamate (Glu) antagonists in the NAc increases intake of high-fat food. To date, the role of the PVN→NAc pathway in mediating intake of high-fat food remains unknown. **Therefore, we hypothesized that the PVN→NAc pathway modulates Glu to control intake of high-fat food.** The goal of these studies was to determine the structural, functional and behavioral significance of the PVN→NAc pathway on intake of high-fat food. We used viral tracing techniques coupled with immunohistochemistry to characterize neurons in the PVN→NAc pathway. Our results indicate that PVN→NAc neurons are localized to parvocellular regions of the PVN, and co-localize with vesicular glutamate transporter 1 presynaptically in the NAc. Next, we quantified neurotransmitter release from PVN→NAc neurons in real time using microdialysis with on-line capillary electrophoresis and laser-induced fluorescence. Pharmacogenetic stimulation of PVN→NAc neurons using the hM3D DREADD resulted in robust and sustained Glu release in the NAc. We also used hM3D to determine the behavioral significance of the PVN→NAc pathway on intake of high-fat food. We observed a decrease in intake of high-fat food upon pharmacogenetic stimulation of PVN→NAc, which is consistent with increased Glu release. Overall, glutamatergic PVN→NAc transmission plays a regulatory role in intake of high-fat food, and represents a novel target that will critically advance efforts to improve treatment outcomes in obesity and metabolic dysregulation.

Title: Hypothalamic OPN5 regulates thermogenesis in mammals

Authors: *K. X. ZHANG[1,2], B. A. UPTON[1,2], S. P. D'SOUZA[1,2], C. J. MADDEN[3], S. KERNODLE[4], A. J. HOLT[5], S. VEMARAJU[2], G. NAYAK[2], S. F. MORRISON[3], R. J. SEELEY[4], A. SWEENEY[5], R. A. LANG[1,2];

Abstract: The thermogenic potential of brown adipose tissue (BAT) is a promising therapeutic target in the treatment of obesity and metabolic disorders. The preoptic area (POA) is a region in the anterior hypothalamus responsible for autonomic thermoregulation by means of modulating BAT activity through sympathetic nerve activity (SNA). Neurons in the POA express opsin-5 (OPN5), an atypical opsin found in various extraretinal tissues and known to respond to near-UV wavelengths with a lambda-max of 380 nm. OPN5 has previously been shown to regulate seasonal breeding behavior in birds. Loss of OPN5 in mice have been demonstrated to impair circadian photoentrainment. We have also shown OPN5 to be required in retinal ganglion cells for *in vivo* entrainment of a retina circadian clock independent of the suprachiasmatic nucleus. To date, no other physiological role for mammalian OPN5 has been proposed. The same POA neurons that express OPN5 also engage the central thermoregulatory circuit that modulates BAT activity. Using a genetically targeted glycoprotein-deleted rabies virus injected into the POA, we identified labeled neurons in the rostral raphe pallidus (rRPa), the lateral parabrachial nucleus (LPB), and the dorsomedial hypothalamus (DMH), all nuclei known to participate in central BAT thermoregulation. *Opn5*$^{-/-}$ mice better defend their core body temperature during acute 4°C challenge. Our results indicate this effect to be due to increased BAT thermogenesis and not heat retention or pyrexia. Furthermore, BAT thermogenesis target gene transcripts (*Ucp-1*, *Prdm16*, *Pgc-1a*) were elevated in these cold stressed *Opn5*$^{-/-}$ animals. To demonstrate the importance of OPN5's near-UV light sensing function in cold defense, C57BL/6J mice reared from E16.5 without 380 nm light phenocopy *Opn5*$^{-/-}$ animals when acutely cold challenged. Direct 380 nm photostimulation of the POA also blunted BAT thermogenesis, showing that hypothalamic OPN5 can respond acutely to near-UV light. We also found that *Opn5*$^{-/-}$ mice consume more food and have a higher total daily energy expenditure than controls. Our results suggest a mechanism where near-UV sensitive hypothalamic OPN5 neurons regulate BAT thermogenesis directly, proposing that the mammalian autonomic thermoregulatory apparatus is light responsive.

Title: Tachykinin-1-expressing neurons in the parasubthalamic nucleus (PSTN) signal food availability and suppress food consumption

Authors: O. BARNHILL, J. SPERBER, F. GULAMALI, J. KIM, T. LEGAN, *M. CARTER; Williams Col., Williamstown, MA

Abstract: The motivation to eat depends on the relative balance of activity in orexigenic and anorexigenic neuronal populations. Previous studies implicate neurons in the parasubthalamic nucleus (PSTN), a small population of neurons in the posteriorlateral hypothalamus, as potentially regulating appetite, but the role of these neurons in food intake behavior has not been characterized. Here, we report that PSTN neurons can be subdivided into populations of neurons that express tachykinin 1 (Tac1) or corticotropin releasing hormone (CRH). Tac1 PSTN neurons, but not CRH PSTN neurons, increase expression of Fos, an indirect marker of neuronal activation, during a meal or after administration of anorexigenic hormones. *In vivo* fiber photometry recordings show that Tac1 PSTN neurons become active during the consumption of food in hungry mice, but only when food is accessible. Optogenetic or chemogenetic stimulation of Tac1 PSTN neurons decreases food intake while chemogenetic inhibition of Tac1 PSTN neurons increases food intake. Tac1 PSTN neurons project to the external lateral parabrachial nucleus and nucleus of the solitary tract, two brain areas that contain anorexigenic neuronal populations, suggesting a potential mechanism for their suppression of food intake. Taken together, these results demonstrate that Tac1 PSTN neurons signal food availability and negatively regulate food intake behavior.

Title: Leptin suppresses GLP-1 innervation to the paraventricular nucleus of the hypothalamus and impairs postsynaptic signaling

Authors: *J. E. BIDDINGER[1], R. M. LAZARENKO[1], M. M. SCOTT[2], R. B. SIMERLY[1]; [1]Vanderbilt Univ., Nashville, TN; [2]Dept. of Pharmacol., Univ. of Virginia, Charlottesville, VA

Abstract: The nucleus of the solitary tract (NTS) is critical for the central integration of signals from visceral organs and is the first central target of vagal afferents that signal nutritional status from gut to brain. The NTS contains preproglucagon (PPG) neurons that send direct projections containing glucagon-like peptide-1 (GLP-1) to the paraventricular nucleus of the hypothalamus (PVH), which regulates a variety of homeostatic physiological responses. Nearly all GLP-1 neurons express leptin receptors and are directly responsive to leptin in neonatal mice, as well as in adulthood. Leptin functions during development to impact the organization of intra-hypothalamic metabolic circuitry, but whether it specifies brainstem-hypothalamic connections is unknown. To address this question, we used PPG-cre mice to target a fusion protein of synaptophysin and tdTomato to PPG neurons in order to visualize neuronal projections in leptin-deficient *Lep$^{ob/ob}$* mice. In contrast to development of projections from the arcuate nucleus to the PVH, projections from PPG neurons show an increase in the PVH of *Lep$^{ob/ob}$* mice compared with controls, with no change in numbers of PPG neurons. Moreover, a similar increase in PVH innervation is seen in mice with disrupted leptin receptor expression (*LepRbTB* mice). Crossing *LepRbTB* and PPG-cre mice, resulted in mice with LepRb signaling restored in PPG neurons on an otherwise null LepRb background. GLP-1 innervation of the PVH was rescued to wt levels in these mice, suggesting a cell-autonomous action of LepRb on development of GLP-1 projections to the PVH. The increase in PVH innervation observed in *Lep$^{ob/ob}$* mice is also reflected in the ability of visceral sensory information to activate PVH neurons, as evidenced by an increase in cFos labeling in the PVH of mice that received i.p. injections of cholecystokinin, and this action also appears to be controlled by the cell autonomous action of leptin on PPG neurons. Because PPG neurons are glutamatergic, we recorded mEPSCs from PVH neurons that express GLP-1 receptors (GLP-1 R) by using whole-cell patch recordings in PVH slices derived from GLP-1 R-cre:tdTomato mice. An increase in mEPSC frequency was observed in *Lep$^{ob/ob}$* mice, compared with wt mice, with no change in mEPSC amplitude, suggesting increased excitatory neurotransmission in GLP-1 R neurons in the absence of leptin. Together, these findings indicate

that leptin acts during development to suppress the representation of excitatory afferents from PPG neurons, thereby diminishing the impact of visceral sensory information on GLP-1 receptor neurons in the PVH.

Title: The hypothalamic chemoarchitecture project, year 5: High-spatial resolution atlas-based mapping of neuronal populations expressing melanin concentrating hormone, hypocretin/orexin, and calbindin in the hypothalamus of the adult male rat

Authors: A. MARTINEZ[1], V. I. NAVARRO[1], K. ARIAS[1], J. BARNETT[1], A. CARREON[1], B. CASTANEDA[1], M. FLORES[1], J. MAGADAN[1], D. HEREDIA[1], J. HOOPER[1], T. LOPEZ[1], A. LOZANO[1], S. [1]HHMI/UTEP PERSIST Program: Brain Mapping and Connectomics Lab., [2]Dept. of Biol. Sci., Univ. of Texas at El Paso, El Paso, TX

Abstract: Hypothalamic circuits contribute to bodily homeostasis, in part, through signals encoded by neuropeptides. Although previous work reports localization of hypothalamic neuropeptides in the rat, their spatial distributions are not understood in the context of a rigorously defined, hierarchically organized set of gray matter regions in a digital, open access atlas reference space. The research presented here is the latest installment of an ongoing hypothalamic mapping project that has been carried out by four previous cohorts of undergraduate students in “Brain Mapping & Connectomics”, an HHMI-funded laboratory course at the University of Texas at El Paso. Students were taught how to map neuropeptide distributions across levels 24-29 of a rat brain atlas (LW Swanson, 2004, *Brain Maps: Structure of the Rat Brain, 3rd edition*). Melanin-concentrating hormone (MCH) and hypocretin/orexin (H/O) contribute to the regulation of sleep-wake cycles and hunger and emotional states. In contrast, the intracellular macromolecule calbindin (CalB) binds calcium to control neuronal firing, and is often used as a biomarker to mark neurons. To better understand the spatial

distributions of MCH, H/O, and CalB, students used fluorescence immunohistochemistry (IF) and Nissl-staining techniques to localize their chemoarchitectonic patterns.
Initial mapping shows that, consistent with previous reports, there are sparse MCH immunoreactive (ir) cell bodies at anterior levels of the hypothalamus, while at more caudal levels they are prominently found throughout the ZI and scattered across the AHN and LHAd (refer to Swanson, 2004; for explanation of abbreviations). MCH-ir axonal fibers were mostly concentrated ventromedially in the ZI, ARH, subdivisions of the TU, and ME. H/O-ir cell bodies were only present in the LHAd, ZI, and perifornical LHA at caudal hypothalamic levels. While H/O-ir fibers were found throughout the hypothalamus, they were dense in the PVi, ARH, TUsv, perifornical LHA and the internuclear regions. CalB-ir showed a high density of cell bodies within the ARH, SO, ME, TUsv, VMH, DMHa, and internuclear regions. The similarities in the density and distribution of the three (neuro)peptides mapped here indicate possible interactions among them.
While many of the peptide distributions noted have been characterized before, the high-resolution atlas-based mapping of cell bodies and/or fibers immunoreactive for MCH, H/O, and CalB in the hypothalamus is unique. These maps generated by freshman-level students will further our understanding of hypothalamic chemoarchitecture and could provide novel insights about hypothalamic structural organization.

Title: High-spatial resolution atlas-based mapping of chemoarchitecture within the forebrain: Selected studies of the bed nuclei of terminal stria and the ventral tegmental area

Authors: *K. T. LORENZANA, E. J. PEREZ, K. J. GALVAN, K. A. S. BURNETT, B. E. PINALES, A. M. KHAN;
Dept. of Biol. Sci., The Univ. of Texas at El Paso, El Paso, TX

Abstract: The bed nuclei of terminal stria (BST) and the ventral tegmental area (VTA) contain neurons that participate in a variety of functions, including autonomic responses and emotional control; and the control of behaviors that involve feeding, reward and anxiety. In order to begin identifying the contributions of specific chemical signals to the array of functions served by these structures, we conducted a high-spatial resolution mapping analysis to identify the chemical phenotypes of neurons and axonal fibers in these regions. Using multi-fluorescence histochemical techniques, we labeled tissue using antibodies directed against Agouti-related peptide (AgRP), α-melanocyte stimulating hormone (αMSH), neuropeptide Y (NPY), cocaine amphetamine regulated transcript (CART), and tyrosine hydroxylase (TH). Nissl-stained tissue sections from an adjacent series were used as a reference to determine cytoarchitectonic boundaries for the fluorescently-labeled immunostaining patterns. Plane-of-section analysis was carefully performed to facilitate mapping of the chemoarchitecture within a standardized rat brain atlas (L. W. Swanson, 2018, *Brain Maps 4.0, J Comp Neurol*). We plotted the distributions of these immunoreactivities (ir) onto digital atlas templates to create maps of these diverse neuronal populations in relation to the subregions of the BST and VTA. We determined that Swanson Atlas Levels 16-23 contain distinct distributions of each chemical marker within BST subregions. The dorsomedial and ventral nuclei of the BST displayed high densities of AgRP-, NPY-, αMSH-, and CART-ir fibers. The anteromedial and anterolateral areas of the BST displayed moderate numbers of immunoreactive fibers. Areas in the BST with low immunoreactive elements included the principal and oval nuclei. TH-ir fibers were distributed sparsely within the same BST subregions displaying expression of fibers for AgRP, αMSH, NPY, and CART. Further (confocal) analysis will provide information on the putative interactions. At the level of the VTA, CART-ir neurons and fibers were evident; with many of these fibers displaying co-expression with αMSH. Together, these data contribute to our ongoing effort to create an atlas-based compendium of chemoarchitecture to aid future efforts to target specific chemical systems within functional studies of these regions.

Title: Distribution of neurons and/or fibers expressing cocaine and amphetamine regulated transcript, dopamine beta-hydroxylase, and alpha-melanocyte stimulating hormone within the hypothalamus: Chemoarchitectural mapping using a standardized rat brain atlas

Authors: K. A. S. BURNETT, *B. E. PINALES, E. J. PEREZ, K. T. LORENZANA, K. J. GALVAN, A. M. KHAN;
Dept. of Biol. Sci., Univ. of Texas at El Paso, El Paso, TX

Abstract: Connections to the lateral hypothalamic area (LHA) are important for feeding control. However, the contribution of several key regions that send signals to the LHA have yet to be chemoarchitecturally defined or systematically mapped within a standardized reference framework. Here, we provide a chemoarchitectural analysis of neurons and fibers that are immunopositive for cocaine amphetamine regulated transcript (CART), dopamine beta hydroxylase (DBH), and α-melanocyte stimulating hormone (αMSH) in the hypothalamus of the male rat. Using a Nissl-stained, adjacent series of tissue sections to establish cytoarchitectural boundaries, we represent the distributions of CART-, DBH-, and αMSH-immunoreactive (ir) cell bodies and/or fibers onto vector-formatted templates represented in a standardized rat brain atlas (L.W. Swanson, 2018, *Brain Maps 4.0, J Comp Neurol*). Dense CART- and DBH-ir fibers were observed within the periventricular nucleus, along the third ventricle and extending to the dorsomedial hypothalamic nucleus (DMH), and also in the LHA, encompassing areas surrounding the fornix. CART-ir cell bodies were found within the same vicinity of both fiber systems. Dense αMSH-ir fibers were observed within the boundaries of the medial preoptic nucleus, and in the paraventricular, periventricular, dorsomedial and arcuate hypothalamic nuclei. Expression of moderate to sparse immunoreactive fibers was noted within the lateral hypothalamic area. αMSH-ir fibers were also apparent, though sparse, in the suprachiasmatic, anterior and ventromedial hypothalamic nuclei. This work contributes to our ongoing effort to map the precise locations of chemoarchitectural elements within the rat hypothalamus using a high-spatial resolution series of standardized atlas templates. We anticipate that this work could provide valuable information to streamline the targeting of experimental probes to these complex systems.

Title: Distribution of beta-klotho mRNA within the brain

Authors: *B. S. BONO, M. J. CHEE;
Neurosci., Carleton Univ., Ottawa, ON, Canada

Abstract: Fibroblast growth factor 21 (FGF21) is an endocrine factor that facilitates energy homeostasis by promoting insulin sensitivity, glucose consumption, and the browning of white adipose tissue. FGF21 is synthesized primarily by the liver, pancreas, and adipose tissue but exerts its effects on multiple organs including the brain. Central action of FGF21 stimulates thermogenesis via the sympathetic nervous system, regulates circadian rhythm, and decreases taste preference for sucrose. However, the brain regions that support the actions of FGF21 are not clearly defined. FGF21 has a low affinity to FGF receptors and thus activation of the obligate co-receptor β-Klotho (Klb) is required for FGF21 action. In order to determine the sites of FGF21 action, we analyzed the distribution of *Klb* mRNA. We performed *in situ* hybridization using RNAscope technology to stain for *Klb* throughout the rostro-caudal axis of two male wildtype mice. We amplified *Klb* hybridization using the tyramine signal amplification system and then labelled it with Cyanine 3. *Klb* hybridization signal appeared as punctate red fluorescent "dots." In order to quantify *Klb* expression we obtained confocal photomicrographs and counted the number of dots that colocalized with 4′,6-diamidino-2-phenylindole (DAPI) stained soma. There was a widespread distribution of *Klb* throughout the brain, most notably in the hypothalamus, hippocampus, and the cerebral cortex. Within the hypothalamus, the suprachiasmatic nucleus (SCN) contained the greatest *Klb* hybridization signals (>4 dots) compared to all regions analyzed; this expression was limited to the dorsal medial part of the SCN. The periventricular nucleus, paraventricular nucleus, ventromedial nucleus, and dorsomedial nucleus had lesser but notable *Klb* hybridization (1–2 dots). Within the hippocampus *Klb* hybridization was localized to the pyramidal cell layer but had differential expression throughout the Cornu Ammonis (CA). The CA2 had the highest level of hybridization (3–4 dots), followed by CA3 (2–3 dots), and then the dentate gyrus and CA1 (1–2 dots). The hybridization of *Klb* in the cerebral cortex was heterogenous. For instance, there was selective hybridization in the cingulate cortex, motor cortex, and the retrosplenial cortex, but not in the medial prefrontal cortex (3–4 dots). In summary these findings are consistent with the known roles of FGF21. Hypothalamic *Klb* expression correlates with the known effects of FGF21 in the

regulation of energy expenditure and circadian rhythms. Meanwhile hippocampal and cortical *Klb* expression may implicate a role of FGF21 that integrates cognitive processes during feeding.

Title: Effect of melanin concentrating hormone on neuronal excitability and synaptic input to the lateral septum

Authors: *M. A. PAYANT, D. P. SPENCER, M. J. CHEE;
Carleton Univ., Ottawa, ON, Canada

Abstract: Melanin concentrating hormone (MCH) is a neuropeptide produced exclusively by neurons in the lateral hypothalamic area and plays important roles in feeding, energy balance, and motivated behaviour. However, the target sites of MCH action are not well defined. Projections from MCH neurons are widespread throughout the brain and we found that the lateral septum (LS) has the densest accumulation of MCH nerve terminals. These terminals release glutamate to directly innervate the LS, an area also known to regulate food intake. The LS is thus a prospective area that may mediate the roles of MCH, however it is not known if or how MCH regulates LS neurons. In order to assess the role of MCH within the LS, we determined the distribution of MCH receptor (MCHR1) expression in this region and investigated the electrophysiological effects of MCH on LS neurons. In order to map the distribution of MCHR1 in the LS, we performed *in situ* hybridization for *Mchr1* mRNA using RNAscope technology. Throughout the LS, the most prevalent expression of *Mchr1* mRNA localized to the intermediate part of the LS (LSI). *Mchr1* expression emerges in the posterior region of the dorsal and ventral parts of the LS, but remained lower than the expression seen in the LSI. We prepared acute brain slices containing the LS from male or female wildtype mice and performed whole cell patch clamp recordings of LS neurons to determine the effect of MCH on cell excitability and synaptic activity. Bath application of MCH (3 µM) suppressed action potential firing and directly hyperpolarized LS neurons by 5 mV. The inhibitory effect of MCH was reversible with the washout of MCH and is consistent with the intracellular coupling of MCHR1 to G_i proteins. We then determined if MCH also inhibits GABAergic and glutamatergic inputs to the LS. MCH

application produced a reversible rightward shift in the distribution of inter-event intervals between spontaneous inhibitory postsynaptic current (sIPSC) events thus decreasing the frequency of GABAergic activity to the neuron; this corresponded with a leftward shift in the distribution of sIPSC amplitudes. Glutamatergic events at LS neurons were relatively infrequent (<0.4 Hz) and we did not detect an effect of MCH application on these excitatory inputs. In summary, the LS expresses MCHR1, and MCH can inhibit the neuronal activity and GABAergic input to LS neurons. Elucidating the mechanisms underlying MCH effects in the LS will contribute to our knowledge of this novel neurocircuit that may support the role of MCH in the regulation of energy balance and motivation.

Abstract: Glucose metabolism is crucial for proper brain function. Indeed, inadequate brain glucose can result in cognitive impairments, unconsciousness and even death. Given the importance of maintaining optimal glucose levels, glucoregulatory behavioral (e.g. increased food seeking/feeding) and physiological responses (e.g. decreased insulin and increased corticosterone secretion) are in place to support glucose homeostasis. Based on previous research, catecholaminergic neurons within the ventrolateral medulla (VLM) are potently activated by glucoprivation and thought to support both behavioral and physiological responses to glucoprivic state. However, how this neuronal subpopulation contributes to these processes is unclear. Here, using a combination of fiber photometry, optogenetics, and whole cell patch-

clamp we investigated the circuit mechanism for glucoprivation-induced food seeking/intake. The results gathered from this investigation demonstrate that a forebrain projection of VLM catecholaminergic neurons drives glucoprivation-induced feeding behavior. Notably, optogenetic stimulation of these forebrain projection is sufficient to drive feeding behavior in well-fed mice. These results unveil a circuit and cellular mechanism by which VLM catecholaminergic neurons orchestrate glucoprivation-induced feeding.

Title: Linking impaired neural network oscillations in hypothalamus and hippocampus to the hypocretinergic system in high-fat diet-induced obesity in mice

Abstract: Prolonged intake of high-fat diet (HFD) can lead to obesity but also to structural and functional brain alterations including neuronal inflammation and injury, neurotransmission changes, and certain behavioral and cognitive deficits. Accordingly, evidence suggests that brain regions such as the hypothalamus, which is involved in feeding control, and hippocampus, involved in cognitive functions, might be particularly vulnerable to HFD. In this study, we explored neural network oscillatory activity in these regions in C57BL/6 mice fed with HFD for 10-12 weeks and age-matched mice being on regular chow diet (ND). To better understand the role of hypocretin (Hcrt) neurons, which are exclusively localized in the lateral hypothalamus (LH) and widely projected throughout the brain, in HFD-induced effects we expressed stimulatory DREADD receptor hM3Dq in LH Hcrt neurons in the subset of HFD mice (HFD-DREADD). Local field potentials were recorded in vivo from LH and CA1 area of hippocampus under urethane anesthesia. In the LH, spontaneous gamma oscillation power was significantly higher in HFD mice compared to ND controls. Acute chemogenetic activation of LH Hcrt neurons in HFD-DREADD mice with clozapine-N-oxide (CNO) decreased gamma power to the

level of ND mice. On the contrary, injection of CNO in HFD mice without DREADD receptors (HFD-CNO) itself did not affect elevated gamma power. The same trend of increased spontaneous gamma oscillation in HFD and HFD-CNO comparing to ND and HFD-DREADD mice was observed in the hippocampus. However, opposite results were obtained for the power of elicited hippocampal theta oscillation induced by high-frequency brainstem stimulation. The quantitative input-output analysis between the groups showed a significant difference in theta power but not peak frequency in response to varying stimulation intensities. Post-hoc comparisons revealed a significant decrease in theta power in HFD and HFD-CNO when compared to ND and HFD-DREADD mice, although the phase-amplitude coupling between hippocampal theta and gamma elicited oscillations did not differ between the groups. These results imply that HFD has detrimental effects on Hcrt neurons, which weakened activity induces excitatory/inhibitory imbalance in hypothalamic and hippocampal neural networks thus affecting interoceptive awareness.

Title: Altered spatiotemporal dynamics of stimulus-evoked neural responses in clinical depression: An MEG study

Authors: V. POGHOSYAN[1], F. ALDOSARY[2], F. ALMOHAMMED[1], T. ALOTAIBI[1], B. ALQADHEEB[1], R. ALDOSARI[1];

Abstract: Neurobiological underpinnings of major depressive disorder (MDD) are not yet well understood. In this ongoing exploratory study, we use magnetoencephalography (MEG) to address this issue. Here we report initial results from 15 drug-free patients with MDD and 15 matched healthy controls. MEG signals were recorded using 306-channel MEGIN system, while subjects viewed pleasant, unpleasant and neutral pictures, presented in random order. Data were analyzed based on Brainstorm (http://neuroimage.usc.edu/brainstorm), using advanced source analysis tools and rigorous statistical methods. Between-group comparison of valence-independent event-related neural activity identified an MDD-affected network of brain regions, involving predominantly right hemisphere frontal, parietal and mesial temporal areas (fig. 1).

The earliest and largest change was identified within right intraparietal sulcus (IPS), as a profound hypoactivity in patients, with an onset at 55 ms (fig. 2). Table 1 shows latencies and sequence of affected responses within the identified network. Valence-related neural activity in MDD is described elsewhere (see the abstract by Poghosyan et al. “Altered spatiotemporal dynamics of emotional neural processing in clinical depression: an MEG study”). The present report provides evidence of altered neural processing in MDD, affecting predominantly right hemisphere frontal, parietal and mesial temporal areas, largely consistent with earlier fMRI findings. Our results add the crucial timing information for these regions and reveal the precise dynamics and sequence of aberrant brain responses in MDD. Further, they stress the pivotal role of right IPS in MDD.

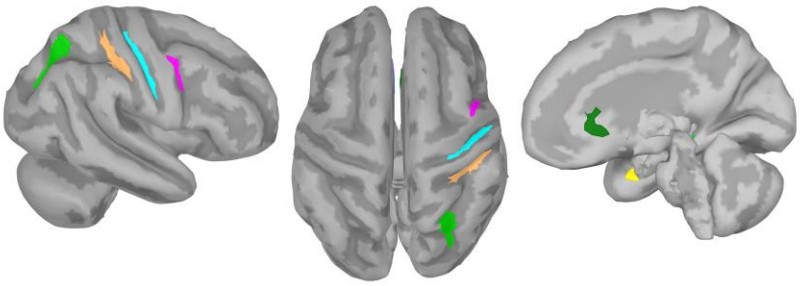

Figure 1. MDD-affected network of brain regions in visual stimulus processing. Key right hemisphere cortical areas showing differential activity between patients and controls are marked on the cortical surface. Lateral, top and medial views are shown.

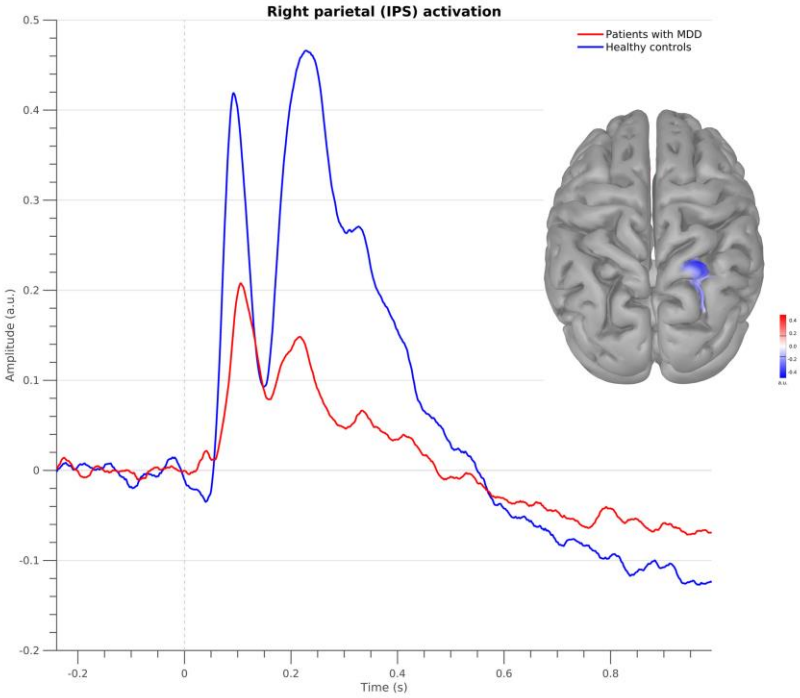

Figure 2. Right parietal (IPS) activation time course in reponse to visual stimuli in patients with MDD (red) and healthy controls (blue). The inset shows the localization of MDD-affected hypoactivation from which the region of interest was defined.

Key ROIs showing differential activity between patients and controls in visual stimulus processing

ROI name	Direction of group differences	Start time (ms)	End time (ms)	Direction of group differences	Start time (ms)	End time (ms)
Right intraparietal sulcus (**R IPS**)	C > P	55	560			
Right inf. precentral gyrus (**R inf. preCG**)	C > P	115	600			
Right central sulcus (**R CS**)	C > P	125	560			
Right postcentral gyrus (**R postCG**)	C > P	170	550			
Right mesial temporal cortex (**R MTC**,entorhinal cortex, parahippocampal gyrus etc.)	P > C	65	800			
Right rostral anterior cingulate cortex (**R rACC**)	P > C	100	650			
Left mesial temporal cortex (**L MTC**, entorhinal cortex, parahippocampal gyrus etc.)	C > P	65	145	P > C	230	575
Left rostral anterior cingulate cortex (**L rACC**)	P > C	100	620	C > P	620	1000

C > P, stronger activity in controls; P > C, stronger activity in patients

Abstract: Major depressive disorder (MDD) is characterized by distorted emotional processing. In this ongoing exploratory study, we use magnetoencephalography (MEG) to examine neural correlates of emotional processing and its variations in MDD. Here we report initial results from 15 drug-free patients and 15 matched healthy controls. MEG signals were recorded using 306-channel MEGIN system, while subjects viewed pleasant, unpleasant and neutral pictures. Data were analyzed based on Brainstorm (http://neuroimage.usc.edu/brainstorm), using advanced source analysis tools for deep brain activity, including amygdala, and statistical methods. Group differences in valence-related patterns of neural responses were identified predominantly within bilateral prefrontal cortex, anterior temporal cortex, insular cortex, posterior lateral sulcus and amygdala (fig. 1 and table 1). The earliest and most notable difference was found in right amygdala (fig. 2 and 3): In patients, it differentiated emotional and neutral pictures in 90-140 ms and 250-450 ms time ranges, with significantly stronger response to emotional pictures. Later, from 450 ms onward, right amygdala distinguished negative from positive and neutral pictures, exhibiting sustained elevated activity in response to negative pictures. Such late-latency, negative valence-related, sustained activity was found also in right orbitofrontal, ventrolateral prefrontal and insular cortices. No such effect was evident in controls. The present report provides evidence of altered emotional neural processing in MDD, revealing the precise temporal dynamics of key brain regions often implicated in emotional processing.

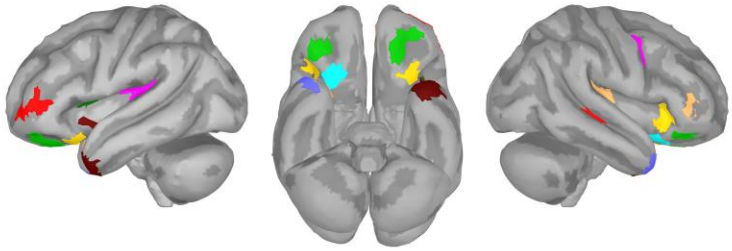

Figure 1. MDD-affected network of brain regions in emotional processing. Key cortical areas showing differential activity between patients and controls are marked on the cortical surface. Left, bottom and right views are shown, respectively.

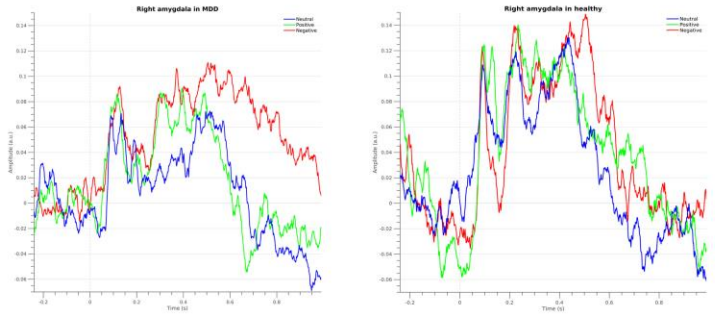

Figure 2. Right amygdala activation time course in response to neutral (blue), positive (green) and negative (red) pictures, in a) patients with MDD and b) healthy controls.

Title: The effect of ketamine on cortico-striatal circuitry in depressed and healthy individuals

Authors: *A. MKRTCHIAN[1], J. W. EVANS[1], J. P. ROISER[2], C. A. ZARATE, Jr.[1]; [1]Exptl. Therapeut. & Pathophysiology Br., Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Inst. of Cognitive Neurosci., Univ. Col. London, London, United Kingdom

Abstract: A sub-anesthetic dose of ketamine can improve depressive symptoms within hours in treatment-resistant depressed (TRD) patients. These improvements occur specifically in symptom-clusters related to lack of motivation or pleasure capacity, even over and above general depressive symptoms. However, the precise neural circuits driving these effects remain unclear. Here we examine if ketamine affects cortico-striatal circuitry, which is well established in driving goal-directed behavior, in TRD patients and healthy controls.

Data were drawn from a double-blind, placebo-controlled, crossover trial of ketamine (0.5mg/kg), including 33 TRD patients and 25 healthy controls. Resting-state functional magnetic resonance imaging data were acquired at 3T, two days following ketamine and placebo infusions. Seed-based functional connectivity was examined using four seed regions in the striatum, reflecting functional subdivisions that are connected with different cortical regions involved in affective, cognitive and motor processes. Linear mixed-effects models were conducted at the group level in AFNI. Correction for multiple comparisons was achieved using an initial threshold of $p<0.005$, and a minimum cluster size of 46 voxels resulting in family-wise error-correction at $p<0.05$.

In patients, ketamine increased functional connectivity between the ventral striatum and the dorsolateral prefrontal cortex (dlPFC); the dorsal caudate and the ventrolateral PFC (vlPFC); the dorsal caudal putamen and the anterior cingulate cortex (ACC); and the ventral rostral putamen and the orbitofrontal cortex (OFC; all F-contrasts). By contrast, ketamine decreased connectivity in these circuits in healthy controls compared with placebo. Mean connectivity parameters were also examined in a control region (primary visual cortex), which did not demonstrate similar connectivity changes.

These results suggest that ketamine affects the fronto-striatal neural circuitry in cognitive and affective-associated frontal regions. However, there was a differential pattern of response beween healthy individuals and TRD patients, such that cortico-striatal functional connectivity was enhanced in patients but decreased in healthy individuals following ketamine. Our control analysis suggested that this was not a global brain pattern but instead restricted to the PFC. These findings support a homeostasis model of ketamine's neural effects that might be particularly relevant for the shift in motivational symptoms following ketamine, considering the crucial role that the cortico-striatal circuit plays in goal-directed behavior.

Title: Correlation between decrease of neuronal noise and depressive symptom severity

Authors: *S. YUN, B. JEONG;
KAIST, Daejeon, Korea, Republic of

Abstract: Object: Recent studies have shown that neuronal noise is not just noise, so changes in neuronal noise in the pathologic state are also of interest. The recently developed Refined composite multiscale permutation entropy (RCMPE) overcomes the limitations of existing signal variability indicators such as Multiscale Entropy (MSE). We used RCMPE to investigate the relationship between symptom severity and neuronal noise in depression.
Methods: Resting state electroencephalography (EEG) was measured by the University of Arizona. The depressed group was selected for people with a BDI score of 12 or higher, and a total of 44 people were selected. Measurement of EEG was made with a 64 channel Neuroscan. Multi-scale (2ms~40ms) time-series data was obtained through coarse-gaining procedure and RCMPE was calculated in each epoch (2s). The epoched RCMPE was averaged according to each channel and time scale. Correlation coefficients between RCMPE and BDI scores in each group were calculated using Pearson's correlation. Multiple comparison test was performed by cluster permutation test. The cluster defining thresholds were set at 0.01. The cluster alpha level was set at p-value 0.025 and permutation n=5000.

Result: In the depressed group, the two clusters showed a significant correlation with the BDI score. The 1st cluster was located in the frontal area between 2ms and 10ms, and the cluster p-value was 0.0236. The 2nd cluster was located in the Lt. parietal area on the temporal scale of 2ms to 12ms, and the cluster p-value was 0.0244. In the Healthy control group, no significant clusters were found.
Conclusion: In the depressed group, there was a negative correlation between the severity of depressive symptoms and the neuronal noise. In particular, topologically, a decrease of neuronal noise in the frontal area and the Lt. parietal area were associated with severity of depression in depressive group.

Abstract: Brain-Computer interface (BCI) systems permits to gain control of different brain signals. Most of BCI studies have been built upon the idea that a patient can learn by practice to generate a healthy brain-state. However, due to the inherent altered brain functioning, patients could have difficulties finding a healthy pattern of brain signals being guided by the feedback of their own brain activity. The two aims of the present study were: to train depressive patients to achieve a healthy emotional brain-state, aided by a BCI system asociated to a “subject-independent (or population-based) classifier” of emotional states, created from a set of EEG data coming from healthy individuals, and to explore the use of this system as a potential clinical and

neuroscientific tool.A subject-independent pattern-based classifer (SIC) of brain states (based on EEG signals and support vector machine, SVM) was created, with information coming from 19 healthy individuals during positive emotional states. This classifer was asociated to a BCI system to train 4 subjects with depressive symptoms, trained to “match” a healthy brain state. Patients participated in 3 days of BCI training. Each day consisted of 5 training runs with 4 blocks of brain-self regulation (during positive emotional imagery), interspersed with 4 blocks of rest (20s each block). Self regulation blocks were visually guided by the result of the classifier to receive the information of the similary of her brain state compared with the one provided by the classifer in real-time (updated every 1 second). Clinical changes were evaluated blinded by Beck and Hamilton scales.Patients were able to reproduce the brain patterns of the original group of healthy subjects, as reflected for classifications acuracies of the SIC (SVM-outputs) above chance [Figure 1]. Mood modifications towards the alliviation of depressive symptoms were observed on different degrees. These results represent a step forward towards the automatic recognition of brain
states in combination with Brain-Computer Interfaces, as a potential clinical and neuroscientific tool.

Figure 1. SVM output of a two representative training runs. The data samples are plotted on the x-axis against the SVM values on the y-axis. The letters ′H′ and ′M′ represent the blocks of self-inducted happines and motor imaginery respectively, separated by vertical dashed lines. The short red lines represent the mean SVM value during the condition at this time. The green line shows the overall mean of the SVM output values.

Title: Temporal independent EEG microstates from simultaneous EEG and fMRI measurements and implications for 'big data'

Authors: *J. H. TANG[1], H. YUAN[1], Y. CHEN[1], M. PAULUS[2], J. BODURKA[2];
[1]Univ. of Oklahoma, Norman, OK; [2]Laureate Inst. for Brain Research, Tulsa, OK

Abstract: Simultaneous electroencephalography (EEG) and functional Magnetic Resonance Imaging (fMRI) data provide a unique opportunity to measure brain spatio-temporal neural activity at a high temporal and spatial resolution [1-3]. However, EEG recorded simultaneously with fMRI contains many artefacts and is difficult to analyze. These EEG artifacts are difficult to suppress during time-consuming and labor-intensive manual preprocessing. In the era of 'big data' for neuroimaging, large EEG-fMRI datasets aim to streamline and automate EEG preprocessing and analysis [4,5]. For our preliminary analysis, 20 datasets were derived from T-1000 [6]. The manual preprocessing method involved BrainVision Analyzer 2.0 to remove Ballistic Cardiogram (BCG) and Gradient Artifacts (GA), while EEGLAB was used to denoise and perform Independent Component Analysis (ICA). The automatic correction method coded for GA, BCG artifacts and ICA reconstruction in MATLAB [4,5]. Temporal independent EEG microstates (EEG-ms) [2] were derived and compared based on two preprocessing approaches. In addition, we assessed EEG-ms associated with salience network and their differences among healthy and mood and anxiety (MA) subjects. We compared and benchmarked an automatic EEG preprocessing pipeline with manual preprocessing for the purpose to derive EEG-ms from resting state EEG-fMRI data in healthy and MA subjects. The automatic pipeline was capable to successfully extract EEG-ms. Temporal quantitative measures of EEG-ms associated with the salience network differentiated between the healthy and MA groups. Specifically, the occurrence rate of EEG-ms associated with salience network was significantly lower in the MA individuals than that in the healthy control. The measures of anxiety state (i.e. State-Trait Anxiety Inventory scores) were negatively correlated with the occurrence rate of the salience-network-associated EEG-ms ($p<0.05$). The group-level differences associated with anxiety in the salience network are in line with previous research [3]. We have confirmed the proposed feasibility of the automatic EEG preprocessing for the EEG-fMRI brain neuroimaging data to streamline and produce EEG features extraction from large data sets. Further, we independently validated

exemplar EEG features originally discovered in a different cohort with high-density EEG-fMRI measurements [2,3]. Using EEG-ms microstates, we differentiated changes between healthy and MA participants. Importantly, automated EEG-preprocessing provides a strong incentive for conducting simultaneous EEG-fMRI of the whole brain spatio-temporal neuronal activity.

Title: Neural prediction of anxiety and depression when processing negative emotion

Authors: *S. KIM[1], Y. ZOH[1], S. M. GORKA[3], K. L. PHAN[3], W.-Y. AHN[2];
[2]Dept. of Psychology, [1]Seoul Natl. Univ., Seoul, Korea, Republic of; [3]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Aberrant neural activation, when processing negative emotion, is a major feature of Major Depressive Disorder (MDD) and Anxiety Disorder (AD). While existing literature suggests that there exist both common and distinct patterns of fMRI responses in MDD and AD, it is a limitation that most studies used univariate analysis (general linear modeling), and multivariate patterns among brain regions are often neglected. Here, we aimed to identify multivariate patterns of fMRI response when processing emotional stimuli that will predict individuals' level of depression and anxiety. To achieve the goal, we applied a machine learning approach (elastic net) to fMRI data from clinical populations with multiple diagnoses. Participants included 99 patients with primary diagnoses of MDD, social anxiety disorder, or generalized anxiety disorder, and additional 37 healthy controls. They completed the emotional facial matching task inside the MRI scanner. The participants' levels of depression and anxiety were measured with the Hamilton Depression Scale (HAM-D) and Hamilton Anxiety Scale (HAM-A), respectively. Preliminary results suggest that angry faces generate neural responses that are predictive of both HAM-D and HAM-A, and we found common regions predicting both HAM-D and HAM-A in the insula, the anterior cingulate cortex, and the middle temporal gyrus. These results highlight the importance of transdiagnostic and quantitative approaches in characterizing the neural underpinnings of psychiatric disorders.

Title: Cross-sectional analysis of plasma cytokines and brain structure in untreated major depressive disorder

Authors: *G. GRYGLEWSKI[1], R. SEIGER[1], Z. KÖRNYEI[2], P. MICHENTHALER[1], L. RISCHKA[1], M. B. REED[1], L. SILBERBAUER[1], G. M. GODBERSEN[1], J. UNTERHOLZNER[1], A. KOMOROWSKI[1], É. MIKICS[3], A. DENES[2], R. LANZENBERGER[1];
[1]Dept. of Psychiatry and Psychotherapy, Med. Univ. of Vienna, Vienna, Austria; [2]Lab. of Neuroimmunology, [3]Lab. of Translational Behavioral Neurosci., Inst. of Exptl. Med., Budapest, Hungary

Abstract: Accumulating evidence suggests the involvement of the immune system in major depressive disorder which affects brain circuits involved in emotion processing and cognition. We analysed cross-sectional data collected from 41 patients (19 female, aged 29.6±10.6 years) suffering from an acute episode of unipolar major depression and 53 healthy controls (31 female, aged 28.3±8.8 years). Patients were free from antidepressant treatment for 3 months prior to inclusion and had a Hamilton Rating Scale for Depression ($HAM\text{-}D_{17}$) score ≥ 18. T1 weighted structural magnetic resonance imaging (MRI) was acquired on a 3T hybrid PET/MR scanner using a MPRAGE sequence (TE/TR=4.21ms/2000ms) and plasma concentrations of 20 cytokines were measured using cytometric bead arrays. MRI data was reconstructed using FreeSurfer 6.0 to obtain the volumes of bilateral amygdalae and hippocampi. Independent t-tests were used to test differences in cytokine concentrations between groups. Spearman correlation coefficients were calculated to assess the association of cytokines with volumes of brain regions. In depressed patients, higher concentrations of P-selectin (CD62P, 95%-CI=[22.6, 150.7], p=0.009) and interleukin 1 receptor, type I (CD121a, 95%-CI=[4.6, 65.8], p=0.03) were observed. Furthermore, correlations of interleukin 4 concentrations with the volumes of the bilateral amygdalae and hippocampi were found (Spearman's rho: 0.36 (right amygdala and hippocampus, p<0.01), 0.31 (left hippocampus, p=0.01), 0.29 (left amygdala, p=0.03)). This association was unaffected by correction for total intracranial volume, and persisted in the right amygdala if only the patient group was considered (Spearman's rho=0.50, p=0.02). We further analysed the associations of interleukin 4 with the volume of the subfields of the hippocampi and the nuclei of the amygdalae. Correlations were observed in the right basal nucleus, right corticoamygdaloid transition area, right cornu ammonis (CA)1, right parasubiculum, left

parasubiculum and the molecular layer and CA4 field of the left hippocampal head (all $p<0.01$). Interestingly, these correlations were higher in the patient group and absent in the group of healthy participants. These results substantiate the involvement of immune processes in the pathophysiology of depression and pinpoint the associations of specific mediators in plasma with alterations in the highly plastic gray matter structures of the hippocampoamygdalar complex.

Title: Precision psychiatry: Development of methodology for personalized therapeutic brain stimulation

Authors: *R. CASH[1], L. COCCHI[2], P. FITZGERALD[3], A. ZALESKY[4];
[1]Melbourne Neuropsychiatry Ctr. & Dept. of Biomed. Engineering, The Univ. of Melbourne, Melbourne, Australia; [2]Clin. Brain Networks Group, QIMR Berghofer, Brisbane, Australia; [3]Monash Alfred Psychiatry Res. Ctr. & Epworth Healthcare, Melbourne, Australia; [4]Melbourne Neuropsychiatry Ctr., Melbourne, Australia

Abstract: Introduction: Repetitive transcranial magnetic stimulation (rTMS) of the dorsolateral prefrontal cortex (DLPFC) is a promising antidepressant therapy. We recently provided some of the strongest evidence to date that treatment response is predicted by the strength of the functional connectivity (FC) between the subgenual cingulate cortex (SGC) at the precise DLPFC stimulation site. Prospective identification of the optimal site based on brain connectivity offers a promising means to enhance rTMS clinical response. Here we address a critical gap for clinical translation of personalised rTMS and develop new methodologies to reliably pinpoint the optimal DLPFC stimulation site on a single subject basis. **Methods**: A variety of computational methods were developed based on thresholding approaches, clustering algorithms, scanning procedures and e-field modelling. The accuracy with which these could pinpoint the optimal DLPFC site (based on SGC connectivity) across repeated scans (i.e. test-retest reliability) was tested. In addition, the influence of smoothing and acquisition time on reliability estimates was evaluated. We utilised existing scan data from the healthy individuals in the human connectome project (n=1000) and a depression cohort (n=25). Test-retest reliability was defined by the median distance between coordinates identified across successive scans.

Inter-individual variation was measured as the median distance between coordinates across all individuals. **Results**: Initial results indicate substantial distortion of the SGC FC map with smoothing kernels of greater than 6mm FWHM diameter, causing shifts in the estimated optimal coordinate. While this work is still ongoing and outcomes are likely to improve, our methodology currently demonstrates that the optimal stimulation site can be reliably estimated within a distance of ~19mm across repeated scans, whilst preserving inter-individual variation. Methodologies will be compared in detail. **Discussion**: These data indicate the feasibility and reproducibility for meaningful identification of individually optimised stimulation coordinates. This methodology is critical for translation of empirical knowledge into better clinical outcomes and will facilitate research on personalised precision rTMS in cognitive & psychiatric disorders.

Title: Machine learning identifies large-scale reward-related activity modulated by dopaminergic enhancement in major depression

Authors: *Y. LIU[1], R. ADMON[2], E. L. BELLEAU[3,5], R. H. KAISER[6], R. CLEGG[3], M. BELTZER[3], F. GOER[3], G. VITALIANO[4,5], P. AHAMMAD[1], D. A. PIZZAGALLI[3,5]; [1]Blackthorn Therapeut., San Francisco, CA; [2]Dept. of Psychology, Univ. of Haifa, Haifa, Israel; [4]Brain Imaging Ctr., [3]McLean Hosp., Belmont, MA; [5]Dept. of Psychiatry, Harvard Med. Sch., Boston, MA; [6]Dept. of Psychology and Neurosci., Univ. of Colorado, Boulder, CO

Abstract: *Objective*: Theoretical models have emphasized systems-level abnormalities in Major Depressive Disorder (MDD). Towards unbiased yet rigorous evaluations of pathophysiological mechanisms underlying MDD, it is critically important to develop data-driven approaches that harness whole-brain data to classify MDD and evaluate possible normalizing effects of targeted interventions. Here, using an experimental therapeutics approach coupled with machine-learning we investigated the effect of a pharmacological challenge aiming to enhance dopaminergic signaling on whole-brain's response to reward-related stimuli in MDD.
Method: Using a double-blind placebo-controlled design, functional magnetic resonance imaging

(fMRI) data from 31 unmedicated MDD participants receiving a single dose of 50 mg amisulpride ($MDD_{Amisulpride}$), 26 MDD participants receiving placebo ($MDD_{Placebo}$), and 28 healthy controls receiving placebo ($HC_{Placebo}$) were analyzed. An importance-guided machine learning technique for model selection was used on whole-brain fMRI data probing reward anticipation and consumption to identify features linked to MDD ($MDD_{Placebo}$ vs. $HC_{Placebo}$) and dopaminergic enhancement ($MDD_{Amisulpride}$ vs. $MDD_{Placebo}$).
Results: Highly predictive classification models emerged that distinguished $MDD_{Placebo}$ from $HC_{Placebo}$ (AUC=0.87) and $MDD_{Placebo}$ from $MDD_{Amisulpride}$ (AUC=0.89). Although reward-related striatal activation was identified as among the most predictive features, the best models based on whole-brain features were significantly better relative to models trained using striatal features only. Examining the top features in our models indicated that, in MDD, enhanced dopaminergic signaling restored abnormal activation and connectivity in a widespread network of regions.
Conclusions: These findings provide new insights into the pharmacological mechanism of antidepressants at the system level in addressing reward processing deficits among depressed individuals.

Title: Beneficial effects of physical activity/exercise on mood regulation

Authors: *B. POPE, L. WEGMAN-POINTS, A. ZOBEL, S. SAICHELLAPPA, L.-L. YUAN; Physiol. and Pharmacol., Des Moines Univ., Des Moines, IA

Abstract: Emerging evidence suggests physical activity/exercise exerts beneficial effects on many normal physiological and psychological processes ranging from cardiovascular function to cognition to mood regulation. Furthermore, exercise also serves as a potential protective factor to counteract the effects of stress and aging. On the basis of human and rodent studies, various cellular and molecular mechanisms have been proposed to underlie those positive influences including metabolic pathways, neurotrophic factors, and neurotransmitter systems. However, acute exercise, defined as a single bout of physical activity, has received less attention in its beneficial effects on mood regulation, yet a better understanding of acute exercise would contribute to the mechanistic studies of chronic exercise. We investigated the effects of acute exercise on the central nervous system by profiling molecular changes taking place in in brain regions responsible for mood regulation, particularly in the medial prefrontal cortex (mPFC), the most commonly reported area to undergo improvement by exercise. Rats were subject to 30 min acute treadmill running, and brain tissue was collected one-hour post-exercise. Prior to acute exercise, both control and experimental groups received 4 days of treadmill training at a low running speed followed by 4 days of rest in order to minimize potential stress impact. A phospho-antibody based, mid-throughput profiling analysis of mPFC tissue revealed a list of protein candidates that were either up-or downregulated by an acute bout of exercise. Majority of the positive hits fell into three categories, 1) synaptic markers such as postsynaptic glutamate receptors and proteins involved in presynaptic release machinery; 2) markers for Neurogenesis; and 3) signaling molecules such as protein kinases and phosphatases. Those molecular events in the mPFC induced by acute exercise showed some similarity to that of fast-acting antidepressant ketamine, raising a question whether fast-acting antidepressant ketamine may act through signaling and metabolic pathways that overlap with those activated by physical activity. Further studies are currently underway to assess the potential of harnessing the positive effects of movement to treat depression.

Title: Characterizing the KEOPS complex in the DLPFC in depression

Authors: *M. E. ABEL[1], S. M. O'DONOVAN[1], E. BENTEA[2], K. ALGANEM[1], R. E. MCCULLUMSMITH[1];
[1]Univ. of Toledo, Toledo, OH; [2]Dept. of Psychiatry, Univ. of Cincinnati, Cincinnati, OH

Abstract: Major Depressive Disorder (MDD) affects approximately 20% of the world population and is an economic burden worldwide. The treatments that are currently available have varying efficacy. 10-30% of people with MDD do not improve with antidepressant treatment, or show a partial response that is associated with side effects such as functional impairment and a high rate of relapse. A greater understanding of the underlying neurobiology of MDD is necessary to develop new, efficacious treatments.
Telomeres protect the ends of chromosomes and are essential for preserving genome stability. Previous studies have shown that subjects with MDD have shortened telomere lengths. Shortened telomere length is associated with chronic stress, a major contributing factor to the symptoms of depression. Meta-analysis has identified a positive correlation between shortened length and depression. In addition, depression severity is also significantly associated with telomere length.
The KEOPS (Kinase, Endopeptidase and Other Proteins of small Size) complex is a highly conserved eukaryotic complex involved in maintaining telomere length. The role of the KEOPS complex in MDD is yet to be elucidated. However, dysregulation of an active component of KEOPS, P53 related protein kinase (PRPK) has been identified in the DLPFC in MDD.
We hypothesize that the KEOPS complex is dysregulated in subjects with MDD and that this dysregulation leads to shortened telomere length in subjects with MDD.
We measure gene expression changes in the components of the KEOPS complex, KAE1, TP53RK (PRPK), CGI121, PCC1 and GON7 in the DLPFC of depressed subjects and healthy controls using qPCR. Changes in protein expression will be assayed by western immunoblot. Telomere length will be measured with a telomere assay. Overall, we will measure the changes in the components of the KEOPS complex in the DLPFC in MDD and healthy controls.
Key Words: postmortem, depression, (kinase) MDD, KEOPS complex, telomere length

Title: Model-based identification of optimal stimulation protocols for treating intractable depression with subcallosal cingulate deep brain stimulation

Authors: *B. HOWELL[1], A. C. WATERS[2], K. CHOI[2], A. VEERAKUMAR[3], M. O. OBATUSIN[2], H. S. MAYBERG[2], C. C. MCINTYRE[1];
[1]Case Western Reserve Univ., Cleveland, OH; [2]Mount Sinai Hlth. Syst., New York City, NY; [3]Emory Univ., Atlanta, GA

Abstract: *Objective and rationale*. Deep brain stimulation (DBS) of the subcallosal cingulate (SCC) is an evolving strategy for individuals with intractable depression. Good, long-term outcomes coincides with placing the active contact within the confluence of four pathways (i.e., forceps minor (FM), cingulum bundle (CB), uncinate fasciculus, and frontal connections to the thalamus and/or striatum), inspiring a "connectomic" approach for targeting; but this model-based strategy was not deployed in SCC DBS' pivotal clinical trial, which may have contributed to suboptimal outcomes. Within the target confluence, our recent theoretical findings point to FM and the CBs being the most probable therapeutic targets, and this exploratory study's objective was to pilot a model-based strategy for optimizing stimulation protocols for activating the target pathways in three subjects.
Methods. We optimized stimulation protocols for SCC DBS using connectomic models of DBS that combined medical imaging and tractography with biophysical modeling. Out of 1065 programmable settings (i.e., electrode configurations and pulse widths), we identified three selective settings that maximally activated each pathway in isolation, and two energy-efficient settings (i.e., one per lead) that used minimal energy to activate the same proportion of pathways as the clinical setting. Subsequently, we used EEG to explore how evoked potentials generated by optimal settings differed from those evoked by the subject's therapeutic setting.
Results. Selective and energy-efficient settings differed by subject and hemisphere. FM-selective

settings produced a bilateral response with positive voltage deflections that began in the orbitofrontal cortex and propagated to the posterior cortex via the central midline, but compared to therapeutic responses, posterior features were more distributed and longer-lasting. CB-selective settings produced a lateralized response with no marked midline or posterior features. Energy-efficient settings evoked responses most similar to those of the therapeutic settings. *Conclusions.* There is likely no universal stimulation protocol for SCC DBS, and our results demonstrate there are opportunities to enhance the pathway-specificity and energy-efficiency of this therapy. Model-based design improved surgical positioning for SCC DBS, improving outcomes, and when paired with optimization, connectomic modeling can systematically identify settings that confirm target engagement and improve battery life, which may have clinical impact and simplify device programming for future clinical trials.

Title: Electrophysiological features of subcallosal cingulate cortex in patients with treatment-resistant depression

Authors: *S. ALAGAPAN[1], V. TIRUVADI[1,2], M. ESLAMPANAH SENDI[1,2], A. WATERS[3], A. VEERAKUMAR[2], M. OBATUSIN[3], A. CROWELL[2], P. RIVA POSSE[2], R. J. BUTERA[1], H. S. MAYBERG[3], C. ROZELL[1];

Abstract: Subcallosal cingulate cortex white matter (SCCwm) has been identified as an effective deep brain stimulation (DBS) target for treatment-resistant depression (TRD) [1]. Insights on electrophysiological features that are engaged by DBS, leading to symptom improvement, will enable closed-loop and adaptive stimulation strategies. We aim to identify electrophysiological markers that reflect target engagement and track treatment response using implanted pulse generators that also possess local field potential (LFP) recording capabilities (Activa PC+S, Medtronic, MN, USA). Patients generally experience a decrease in symptom severity post-surgery, briefly for a few days, followed by an increase that stabilizes by the time stimulation is

turned on. We hypothesize this decrease to be due to outlasting effects of stimulating the SCCwm during intra-operative assessments [2]. To test this hypothesis, we tracked changes in LFP spectral features during this period of no stimulation (chronic LFP). We compared the chronic LFP spectral features with those recorded right after stimulation of therapy target in an in-lab experiment (post-stimulation LFP).LFPs were acquired daily from 10 patients in the 4-week period between implantation of DBS leads and commencement of therapeutic stimulation. LFPs were acquired in differential configuration from 2 contacts on either side of stimulation contact in each hemisphere as 15 second segments every 3 - 4 hours. Power spectral densities (PSDs) were computed using a multi-taper FFT approach. Logistic regression and random forest classifiers with nested hold-one-subject-out cross-validation was used for multivariate comparison of PSD. PSDs exhibited peaks between 6 and 10 Hz in both hemispheres. Spectral power in delta and theta frequency bands decreased over the 4 weeks while power in alpha and beta bands increased. In the comparison between chronic LFP and post-stimulation LFP, we observed that the performance of the classifiers was at chance level 1 week post-surgery (AUROC = 0.54 ±0.21) while the performance was higher 4 weeks post-surgery (AUROC = 0.77 ±0.10, One-way ANOVA, $p = 0.02$), indicating that the effects of intra-operative stimulation did indeed persist beyond surgery. Additionally, we found the feature importance for beta band in both hemispheres increased with time.The results suggest activity in the beta frequency band may be a marker of symptom severity and potentially serve as a feedback signal for control of stimulation.

Abstract: Large-scale monitoring of activity from different brain regions and during realistic behaviors is now possible in many organisms with nervous systems of different levels of complexity, e.g., larval zebrafish, rodents, nonhuman primates, and humans. Such data provides a rich opportunity to uncover the mechanisms linking neural dynamics and behavior in both normal and disease states. These data are often high dimensional and thus challenging for traditional statistical methods. Principled theory in combination with advanced data analysis is therefore crucial to understand these data and derive mechanisms from them. Here, a new class of multi-region recurrent neural network (RNN) models is developed, constrained from the outset by data spanning multisite neural dynamics and time-varying behavior. The data-inspired multi-region RNNs are then reverse-engineered to infer brain-wide interactions and circuit mechanisms, not accessible from measurements alone. We extend previous work to multi-region RNNs based on two different datasets: 1) densely sampled, cellular-resolution imaging from over 20000 neurons in larval zebrafish as they transition to immobility after a minutes-long behavioral challenge, and 2) sparsely sampled, local field potentials (LFPs) and 256-channel electroencephalograms (EEGs) in patients undergoing DBS for depression, particularly those with concomitant motor deficits. We focus on the period between stimulation off and on in an hours-long, acute protocol. By analyzing these models, we determine whether, and which, circuit mechanisms inferred from smaller, highly sampled nervous systems (zebrafish) scale in a conserved manner to a larger, more complex, and sparsely sampled nervous system (human patients), as well as mechanisms that are divergent. To do this, we first analyze the full multi-region RNN dynamics and the essential low-dimensional features of those population dynamics extracted through state-space analyses, and compare them with analogous measures from data. Second, we analyze the connectivity matrices of the multi-region RNN models fit to data and infer the within- and across-region directed interactions responsible for observed dynamics and behavior. This approach provides a novel and viable alternative for the inference of directed interactions linking neural activity and behavior from different types of data, outperforming correlation-based analyses and also valuable for large brains beyond the scope of connectomics. This approach of building and analyzing data-inspired multi-region RNN models can be used to infer brain-wide circuit mechanisms mediating both adaptive and maladaptive states.

Title: Reinforcement learning makes distinct contributions to predict anhedonia in adults with depression after behavioral activation therapy

Authors: *J. K. GOLLAN[1], T. KAHNT[2], G. ABITANTE[1], J. DEARCANGELIS[1], Q. J. HUYS[3];
[1]Psychiatry and Behavioral Sci., [2]Dept. of Neurol., Northwestern Univ., Chicago, IL; [3]Div. of Psychiatry and Max Planck UCL Ctr. for Computat. Psychiatry and Ageing Res., London, United Kingdom

Abstract: Anhedonia may explain treatment resistance to behavioral psychotherapies. Anhedonia is explained by diminished reward sensitivity and impaired reinforcement learning, sub-constructs of the positive valence system domain of NIMH's Research Domain Criteria (RDoC; Insel et al., 2010). The behavioral properties of reinforcement learning and their status as predictors of therapy response are not well characterized. This experimental prospective, longitudinal study aimed to identify behavioral features of reinforcement learning linked with anhedonia in participants with depression and test how reinforcement learning predicts anhedonia severity after nine weeks of behavioral activation psychotherapy. Our approach was to measure Pavlovian and instrumental learning using an orthogonalized go/no-go task (Guitart-Masip et al., 2012b) and build computational models from this behavioral data. The task separates action from valence and allows us to collect data on learning performance. Adults (n=13) were enrolled, with scores $\geq$ 24 on the Inventory of Depressive Symptomatology, Self-Report (IDS-SR)(Rush et al., 1986) and depression diagnoses on the Mini-International Neuropsychiatric Interview (MINI 7.0.2)(Sheehan et al., 1998). Anhedonia was measured using items 19 and 21 on the IDS-SR. Using ANOVAS to compare learning accuracy, i.e., mean percentage of correct responses, results reveal preferential learning to seek reward (go to win) and withhold from loss (no-go to avoid). Task performance was well explained by a computational model, which includes a parameter for associative reinforcement learning (Rescorla-Wagner component), Pavlovian 'go' bias, Pavlovian (go to win) bias, Pavlovian (no-go to avoid loss) bias. Importantly, reinforcement learning at baseline predicted anhedonia status at end of treatment. These results advance computational approaches to define reinforcement learning that may develop targeted treatments for anhedonia.

Title: Oscillatory mechanisms of electroconvulsive therapy (ECT) for major depressive disorder (MDD)

Authors: *S. E. SMITH[1], V. MA[2,7], M. JACOBSON[9], D. PRINTZ[3,8], B. VOYTEK[1,4,5,6], M. SOLTANI[3,10];
[1]Dept. of Cognitive Sci., [3]Dept. of Psychiatry, [4]Halıcıoğlu Data Sci. Inst., [5]Neurosciences Grad. Program, [6]Kavli Inst. for Brain and Mind, [2]Univ. of California San Diego, La Jolla, CA; [8]Psychiatry, [7]VA San Diego Hlth. Syst., San Diego, CA; [9]Clin. Psychology, [10]Psychiatry and Family Med., Univ. of California San Diego Hlth. Syst., San Diego, CA

Abstract: Patients with psychotic and mood disorders, including Major Depressive Disorder (MDD), are typically treated with therapy and medication. In cases of otherwise treatment-resistant MDD, electroconvulsive therapy (ECT) can be highly efficacious. However, despite its efficacy, the neural mechanism(s) by which ECT results in beneficial outcomes for MDD has not yet been identified. MDD has been attributed to states of pathological hemispheric imbalance in slow frequency power, with abnormally-elevated alpha (8-12 Hz) oscillation power often localized to left frontal cortical regions (Henriques & Davidson, 1990).
Here, we evaluated the electrophysiological signatures of the effects of ECT on neural oscillations in the theta (3-8 Hz) and alpha (8-12Hz) bands in a unique dataset of clinical MDD patients receiving ECT treatment. In this study, resting-state electroencephalography (EEG) data and clinical ratings (MADRS, QIDS, C-SSRS) were collected from MDD patients intermittently over a 12-session ECT treatment. Data was collected before and after the first, fourth, eighth, and twelfth ECT sessions, to permit analysis of the short-term effects within a single session, and long-term effects over the course of treatment. In addition to assessing the feasibility of this collection regime, we characterize these data in the frequency domain using measures of oscillatory power and aperiodic activity.
Preliminary results show that there are hemispheric differences in slow frequency oscillatory power in MDD patients that are altered by ECT at a single-treatment scale. Over the course of treatment, the size of this hemispheric effect is greater for late sessions than early sessions. In more exploratory analyses, we evaluated oscillatory dynamics in the time domain. We propose that MDD might be characterized by pathologically overcoupled neural firing in frontal cortical

regions, with ECT acting to disrupt overcoupling by introducing high-frequency activity into the neuronal network (McIntyre et al., 2004). In the time domain, we quantify this phenomenon using measures of oscillatory waveform shape and find that at a short-term scale, ECT produces a smoothing effect on sharply-peaked slow-frequency oscillations, similar to the proposed action by which deep brain stimulation aids in ameliorating the motor symptoms of Parkinson's disease.

Title: Genetically encoded biosensors for rapidly acting antidepressants (RAADs) inside neurons

Authors: *K. BERA[1], A. KAMAJAYA[1], A. L. NICHOLS[1], A. V. SHIVANGE[1,2], P. M. BORDEN[2], B. N. COHEN[1], A. K. MUTHUSAMY[1], J. H. JEON[1], T. CHIN[1], J. S. MARVIN[2], C. H. KIM[1], J. H. WANG[1], P. DESHPANDE[1], L. L. LOOGER[2], H. A. LESTER[1];
[1]Caltech, Pasadena, CA; [2]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: Rapidly acting antidepressants (RAADs) partially relieve depression in < 1 day, then continue this relief for several days. This onset is 10- to 100-fold folder faster than serotonin and norepinephrine reuptake inhibitors (SSRIs and SNRIs). Some RAADs are ketamine enantiomers (R-Ket/S-Ket), metabolites [(2R, 6R)-HNK/(2S, 6S)-HNK], or analogs such as radafaxine. Other RAADs, such as scopolamine (Scop) is best known as a muscarinic antagonist and structurally unrelated to ketamine. The mechanism(s) of RAAD action are largely unknown at levels ranging from the molecular target, the signaling pathway, the cell types, or the circuits. It is important to detect and quantify the RAADs inside subcellular regions of living neurons.
Therefore, we develop the "**i**ntensity-based **RAAD**-**S**e**n**sing **F**luorescent **R**eporter" [iRAADSnFR] genetically encoded biosensor family for RAADs. This biosensor family structurally resemble a previously published nicotine biosensor: a fusion between a mutated periplasmic binding protein OpuBC, interdomain likers, and circularly permuted GFP. Mutants are tested with computational docking models, site-saturation mutagenesis, high-throughput fluorescence screens on bacterial lysates, and fluorescence measurements with purified proteins.

We have mutated residues at the binding site, for sensitivity to RAADs. In solution, iS-KetSnFR responds to S-Ket with EC_{50} of ~ 7 μM, and with maximal fluorescence increases ($\Delta F/F_0$) of ~ 3.8; iR-KetSnFR displays EC_{50} = ~ 22 μM and $\Delta F/F_0$ = 2.5; iScopSnFR displays EC_{50} = ~ 7 μM and $\Delta F/F_0$ = 3.5.
We add additional sequences that target the sensors either to the plasma membrane (PM) or to the endoplasmic reticulum (ER). Fluorescence microscopy shows that, at the low μM concentrations appropriate to the antidepressant action, S-ketamine enters and leave the endoplasmic reticulum within a few seconds and attains extracellular levels. We hope to expand the family to sense other RAADs and within other organelles.

Abstract: Depression is a common neuropsychiatric disorder. The available pharmacotherapy is ineffective for a substantial proportion of patients and has numerous side effects. Therefore, finding safer drugs for the management of depression is of paramount importance. The present study was aimed to evaluate the anti-depressant like effects of quercetin 4'-O-glucoside (QG) in mouse model of unpredictable chronic mild stress (UCMS) induced depression. Animals were subjected to various stress paradigms to induce depression like behaviour and were treated with QG for 21 days. Behavioural tests (forced swim test, sucrose preference test and open field test) as well as brain oxidative stress, monoamine oxidase A (MAO-A) and serotonin levels were determined to measure the anti-depressant like effects of QG. Treatment of UCMS- exposed mice with QG (10 and 20 mg/kg) improved UCMS induced behaviour anomalies and restored brain biochemical parameters (oxidative stress, MAO-A activity and serotonin levels). QG was

found effective in treating stress induced depression in animals via prevention of brain oxidative stress and restoring serotonin levels by inhibiting MAO-A activity. Thus, QG could be developed as a potential antidepressant drug.

Title: *In vitro* and *in vivo* characterization of group II mGlu receptor negative allosteric modulators as an alternative to ketamine for depression

Authors: D. J. SHEFFLER[1], M. B. BICAKCI[2], A. ANTWAN[2], N. PRAKASH[2], E. M. STANDARD[1], G. VELICELEBI[1], R. A. GADIENT[1], J. H. HUTCHINSON[1], D. R. PANICKAR[1], A. S. LIMPERT[1], N. D. P. COSFORD[1], *A. DER-AVAKIAN[2];

[2]Psychiatry, Univ. of California San Diego, La Jolla, CA

Abstract: The noncompetitive N-methyl-D-aspartate (NMDA) glutamate receptor antagonist ketamine produces rapid antidepressant effects in patients with major depressive disorder (MDD), which has led to the recent FDA approval of intranasal (S)-ketamine (Spravato, Esketamine) for the treatment of patients with treatment-resistant depression (TRD) in conjunction with an oral anti-depressant. Group II metabotropic glutamate receptor ($mGlu_{2/3}$) antagonists produce many of the same downstream molecular and preclinical behavioral effects as ketamine, suggesting that $mGlu_{2/3}$ may be targeted for antidepressant treatment without producing the undesirable effects of ketamine. However, a recent Phase II clinical trial with decoglurant (RG1578, RO4995819), a non-selective $mGlu_{2/3}$ negative allosteric modulator (NAM), failed to show efficacy in depression as an adjunctive to selective serotonin reuptake inhibitors (SSRIs). In order to better understand the factors that may have contributed to this clinical trial failure, we evaluated the *in vitro* pharmacological and *in vivo* pharmacokinetic, neurophysiological, and behavioral properties of ketamine, decoglurant, and new $mGlu_{2/3}$-selective NAMs in male Wistar rats. Ketamine suppressed frontal slow-wave delta (0-4 Hz) oscillations, enhanced frontal high-frequency gamma (30-100 Hz) oscillations, and decreased immobility in the forced swim test (FST) both immediately and one week after drug administration. Conversely, decoglurant failed to produce the same frontal EEG effects as

ketamine and failed to produce a persistent antidepressant-like effect in the FST. Moreover, the plasma concentration of decoglurant remained elevated near peak levels for at least 24 h after drug administration. Compared to decoglurant, new $mGlu_{2/3}$-selective NAMs showed greater potency for $mGlu_{2/3}$, greater plasma and brain concentrations after systemic administration, and much more rapid plasma clearance. The new $mGlu_{2/3}$-selective NAMs also produced similar frontal EEG effects and persistent antidepressant-like effects in the FST as compared to ketamine. Thus, decoglurant failed to produce ketamine-like pharmacokinetic, neurophysiological and behavioral effects in rats, which may partly explain its lack of efficacy in depression. Moreover, our results suggest that targeting $mGlu_{2/3}$ holds promise for the development of effective, fast-acting antidepressant treatments.

Title: Antidepressant effect of ketamine and (2R,6R)-hydroxynorketamine requires activation of cap-dependent mRNA translation initiation

Authors: *A. AGUILAR VALLES[1], E. MATTA CAMACHO[1], A. SKALEKA[2], M. ESLAMIZADE[2], D. DE GREGORIO[3], G. GOBBI[3], J.-C. LACAILLE[4], N. SONENBERG[2]; [1]Neurosci., Carleton Univ., Ottawa, ON, Canada; [2]Biochem., [3]Psychiatry, McGill Univ., Montreal, QC, Canada; [4]Univ. De Montreal, Montreal, QC, Canada

Abstract: BACKGROUND AND AIM: The fast-acting antidepressant drug ketamine and its metabolite (2R, 6R)-hydroxynorketamine (HNK) activate the mammalian target of rapamycin (mTOR) signaling pathway, which is required for the antidepressant effect of ketamine. mTOR regulates many cellular functions, including mRNA translation (also known as protein synthesis) through phosphorylation and inactivation of the eukaryotic initiation factor 4E (eIF4E) binding proteins (4E-BPs), leading to the activation of eIF4E and mRNA translation initiation. There are two alternative hypotheses on the cellular targets of ketamine, one suggesting that it directly targets excitatory neurons while another suggests that it indirectly activates these neurons by

inactivating inhibitory interneurons. We sought to determine whether 4E-BPs were required for the antidepressant effect of ketamine and HNK, and whether this pathway is activated in excitatory or inhibitory neurons. METHODS: To determine whether the 4E-BP/eIF4E axis is required for the antidepressant effect of ketamine and HNK, *Eif4ebp1* or *Eif4ebp2* knockout (KO) mice were treated with ketamine (IP, 10 mg/kg) or HNK (IP, 20 mg/kg) and their antidepressant effect (1 h) was determined in the forced swim test (FST) and novelty suppressed feeding (NSF). To determine whether 4E-BPs are required in a specific cell type, we used conditional *Eif4ebp1* or *Eif4ebp2* KO mice in excitatory (Camk2a positive) or inhibitory (Gad2 positive) neurons treated with either ketamine, HNK or fluoxetine (IP, 3 mg/kg). RESULTS: Neither drug affected the immobility in the FST of *Eif4ebp1*$^{-/-}$ or *Eif4ebp2*$^{-/-}$ mice, but, as expected, they reduced it in wildtype mice. In addition, the effect of ketamine on NSF (reduced latency to feed in a new environment) was absent in *Eif4ebp2*$^{-/-}$ and *Eif4ebp1*$^{-/-}$ mice. Mice lacking either *Eif4ebp1* or *Eif4ebp2* in Camk2a+ cells, were resistant to the antidepressant effects of ketamine and HNK, but responded normally to an acute injection fluoxetine. Conditional KO mice in Gad2+ cells were also resistant to the effects of ketamine, HNK and fluoxetine. Furthermore, *Eif4ebp2-/-* mice in Gad2+ cells displayed reduced immobility in the FST without any antidepressant treatment, suggesting a more preponderant role for 4E-BP2 in Gad2+ neurons in the response to antidepressant drugs. CONCLUSIONS: Overall, these results indicate that activation of cap-dependent translation is required in both excitatory and inhibitory neurons for the antidepressant effect of ketamine and HNK.

Title: Development of an optimized biosensor for the visualization of the selective serotonin reuptake inhibitor fluoxetine in the endoplasmic reticulum of live cells

Authors: *L. LUEBBERT[1,2], A. L. NICHOLS[1], P. M. BORDEN[3], A. V. SHIVANGE[1,3], J. H. WANG[1], A. K. MUTHUSAMY[1], J. S. MARVIN[3], L. L. LOOGER[3], H. A. LESTER[1,3]; [1]Biol. and Biol. Engin., Caltech, Pasadena, CA; [2]Inst. of Biol., Leiden Univ., Leiden, Netherlands; [3]Janelia Res. Campus, Howard Hughes Med. Inst., Ashburn, VA

Abstract: Major depressive disorder (MDD), more commonly known as depression, is a severe mood disorder and one of the most common illnesses worldwide. Depression is often treated with selective serotonin reuptake inhibitors (SSRIs), which lead to the elevation of extracellular serotonin concentrations. That SSRIs bind to the serotonin transporter (SERT) on the plasma membrane (PM) is indisputable. However, SSRIs typically require 2-6 weeks before a response to treatment can be observed, and the processes that occur during this delay remain elusive. We wish to test the hypothesis that SSRI-SERT interactions within organelles play a role, especially within the endoplasmic reticulum (ER) and *cis*-Golgi. As a first step, one must directly test, quantify, and temporally resolve the entry of SSRIs into organelles. We are developing and applying genetically encoded fluorescent biosensors to study the subcellular pharmacokinetics of SSRIs. OpuBC, a monomeric bacterial periplasmic binding protein (PBP), has previously been mutated to bind nicotine at a site between two domains. We insert circularly permuted "superfolder" GFP (cpGFP), flanked by several residue linkers, near the OpuBC interdomain hinge regions. By applying directed evolution to optimize the sensing of drugs, we have achieved the goal of $\Delta F/F_0 \approx 1$ at 1 μM for the fluoxetine-biosensor pair. We call this "**i**ntensity-based **Fluoxetine**-**S**e**n**sing **F**luorescent **R**eporter" (iFluoxetineSnFR). Targeting and retention sequences direct the constructs to the ER or the PM of mammalian clonal lines and cultured neurons. Live-cell video imaging shows that, after we jump [fluoxetine] (increase or decrease) near cells, the drug appears in the ER within < 10 s but takes up to 10 times longer to leave. Responses are robust, even at the steady state [fluoxetine] in the brain of a patient. These results resemble those for our existing biosensor iEscitalopramSnFR. The two SSRIs enter the lumen of the ER at concentrations similar to those detected on the extracellular surface of the plasma membrane, seconds after the SSRI enters the extracellular space. These experiments provide first evidence for the existence and relevance of SSRI inside-out drug action. It may be possible to develop other iDrugSnFRs for other SSRIs and for other organelles. We hope that further application of these tools will encourage investigators to study the initial steps in the pathway of SSRI intracellular pharmacokinetics, allowing elucidation of the role "inside-out" neuropharmacology plays in therapy for major depressive disorder.

Abstract: Introduction: Children with fetal alcohol spectrum disorder (FASD) exhibit cognitive, behavioral, and other neuropsychological problems, and are at higher risk of developing depression. Many women who used alcohol (EtOH) during pregnancy also suffer from comorbid depression, and both EtOH abuse and depression in the mother might influence the fetal development of metabolic pathways implicated in childhood depression, *i.e.*, the serotonergic (5-HT) and dopaminergic (DA) pathways. In order to determine whether EtOH-exposed fetal brains have biochemical abnormalities predictive of depression, we have used an available biobank of fetal brain tissues. Molecular mechanisms of EtOH neurotoxicity are relatively unexplored in human fetal brain; we interrogated the role of the serotonergic and dopaminergic systems. Serotonergic signal transmission may be a target for therapies to reduce FAS. Previously we reported a neuroprotective role against EtOH toxicity for pDING phosphatase (from medicinal plant St. John's wort). Now we interrogate the roles of endogenous pDING, serotonin (5-HT) transporter (SERT) and 5-HT receptor in the neurotoxicity mediated by EtOH.
Methods: Fetal brains were collected according IRB approved protocol. The EtOH exposed group (N=6) was compared with controls matched for gestational age, fetal gender. pDING levels were assessed in total brain, synaptosomes, and blood. Transcriptomic microarrays were applied to human cells induced by human DING protein. mRNA was quantified by qRT-PCR. Expression of 84 human genes associated with DA and 5-HT pathways, and biomarkers of depressive disorders (BDNF, GDNF) in fetal tissues were analyzed.
Results: EtOH exposure upregulated DA (D3 and D5) and 5-HT receptors (HTRB, HTR5A and HTR6) ~ 5-fold, while HTR4 was down-regulated 4-fold. EtOH increased DA transporter gene expression 2-80 fold, and down-regulated 5-HT transporter (SERT) gene expression. EtOH exposure reduced also pDING 5.2-fold in blood. Transcriptomics profiles revealed several upstream regulators, including 5-HT1A that was inhibited >100-fold by stress conditions, while pDING upregulated 5-HT1A 5-fold.
Conclusions: pDING is expressed in human brain and blood. pDING increased survival of EtOH-exposed cells and rescues the expression of HTR1A, which is strongly suppressed by stress conditions. pDING binds to SERT in human brain cells. The findings suggest potential

mechanisms for the increased rates of FAS in children of women who experience EtOH use and/or depression during pregnancy, and an important neuroprotective role for pDING in FASD.

Title: Small conductance calcium-activated potassium channels (SKCs) as novel targets for the development of antidepressants

Authors: ***M. G. NASHED**[1], F. R. BAMBICO[2], I. GREIG[3], D. NGUYEN[2], H. LAU[2], J. ZHANG[2], D. OLEINICHENKO[2], M. BILLYARD[2], J. N. NOBREGA[2];
[1]Ctr. For Addiction and Mental Hlth., Toronto, ON, Canada; [2]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada; [3]Univ. of Aberdeen, Aberdeen, United Kingdom

Abstract: Background: The antidepressant effects of ketamine and scopolamine (SCP) have recently been described. Despite divergent upstream pharmacological action, recent evidence suggests a downstream convergence point involving small conductance calcium-activated potassium channels (SKCs), which directly regulate neuronal activity and plasticity.
Methods: Fisher344 rats (n=5-6/group) underwent chronic unpredictable stress (CUS), and the effects of SCP and SCP+EBIO on behaviours were assessed. Brain-wide [^{125}I]apamin autoradiography was performed on CUS rats. SK3 knockout mice (WT=10, Hom=12) underwent behavioural testing. Three novel SKC antagonists were assessed in forced swim test (FST) following intracerebroventricular (ic.v.) infusion in Sprague Dawley rats (n=7-8/group). Results were corrected for multiple comparisons where appropriate.
Results: SCP (4 µg/kg, i.v.) reversed CUS-induced reduction of sucrose preference (P=0.003), and CUS-induced prolongation of feeding latency in the novelty-supressed feeding test (P=0.001). Co-administration of the SKC positive modulator EBIO (4 mg/kg, i.v.) abrogated the effects of SCP. CUS increased [^{125}I]apamin binding of SKCs in the CA1 (P=0.04) and prelimbic cortex (P=0.006). SK3 knockout did not produce effects in the elevated plus maze (EPM), but produced a trend towards decreased hyponeophagia in the novelty-induced hypophagia test (NIHT) (p=0.07), and reduced passive behaviour in the FST (P=0.048). All three novel SKC antagonists (10 ng, ic.v.) reduced passive behaviour in the FST (P<0.001).
Conclusion: Small molecules targeting SKCs offer a promising new avenue for the development

of antidepressants, which may circumvent the addiction liability and adverse effects associated with ketamine and scopolamine.

Title: Activating transcription factor 4(ATF4)-dependent activation of the human tryptophan hydroxylase 2 gene is mediated through binding to a CCAAT/enhancer-binding protein(C/EBP)-ATF composite site in its promoter

Authors: *H. MATSUI[1], **Y. NAWA**[2], H. KANEKO[2], M. TSUBONOYA[2], T. HIROI[2], R. TAKAHASHI[3];
[1]Dept Mol Behav Neurosci, St. Marianna Univ. Grad Sch. Med., Kawasaki, Japan; [2]Inst. RI Res, St. Marianna Univ. Grad Sch. Med., Kawasaki, Japan; [3]Dept Biochem, Fac Pharm Sci, Toho Univ., Funabashi, Japan

Abstract: Tryptophan hydroxylase 2(TPH2) plays a critical role in the regulation of 5-HT neurotransmission and is thus a promising therapeutic target for the treatment of neuropsychiatric disorders. The mechanism by which the human TPH2 (hTPH2) gene expression is activated still remains an open question. Activating transcription factor 4 (ATF4), a member of CREB/ATF transcription factor family of basic-region leucine zipper proteins, has been implicated in integrated stress response, synaptic plasticity, learning and memory, circadian rhythm, and behavior. ATF4 can form a homodimer, and heterodimers with CCAAT/enhancer-binding proteins (C/EBPs). ATF4-C/EBP heterodimers bind to DNA sequences called C/EBP-ATF composite site to regulate target gene expression. Bioinformatics analysis (JASPAR database) revealed one potential ATF4 binding site near the transcription start site of the hTPH2 gene (-53/-46, 5'-TTGCATCA-3') that is identical to the consensus C/EBP-ATF composite site. However, functions of this composite site still remain undetermined. In this study, we examined how the hTPH2 promoter activity changes by ATF4 and C/EBPs. A 2-kb promoter region of the hTPH2 gene (-1850/+141) was cloned into pGL4-Basic and then, its 5'-untranslated region (+10/+121; a region containing potential repression elements) was deleted to yield TPH2-100. Promoter activities were assessed by transfections into RN46A cells**,** a *cell* line derived from rat raphe neurons. Quantitative real-time RT-PCR analysis revealed the expression of *Atf2*, *Atf3*, *Atf4*, *Cebpa*, *Cebpb*, *Cebpg*, *Cebpd* and *Cebpe* genes in RN46A cells. Overexpression studies

demonstrated that among ATFs tested, ATF4 was the most potent in activating the hTPH2 promoter. This activation was further enhanced by co-expression of each of the five C/EBPs. Curiously, C/EBPG which lacks all known activation domains also further enhanced the effects of ATF4. The C/EBP-ATF composite site mutations negated the effects of ATF4. A dominant negative ATF4 blocked the effects of ATF4. Functional analysis of N-terminal and internal deletion mutants indicated that ATF4 (aa 1-124) is critical for activation. Moreover, co-expression of endogenous inhibitor proteins, tribbles pseudokinase 3 or taxilin γ attenuated the effects of ATF4. Finally, we found that the treatment with BDNF activated the hTPH2 promoter. BDNF has been reported to increase ATF4 levels. Thus, we speculated that BDNF activates the hTPH2 promoter, possibly via modulation of ATF4 functions. Altogether, these results imply that ATF4 plays a pivotal role in regulating the hTPH2 gene expression, and itself undergoes complex regulation at multiple levels.

Title: Inhibition of K_{ATP}channel activity in brown fat reduces high fat diet-induced depression

Authors: *Y.-Y. KUO[1], P.-C. CHEN[2];
[1]Inst. of Basic Med. Sci., Natl. Cheng Kung Univ., Tainin, Taiwan; [2]Dept. of Physiol., Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: Clinical researches indicate the highly correlation between obesity and depression. Depressed patients show symptoms such as anhedonia, which caused by dysregulation of mesolimbic dopamine (DA) system that is the projections of dopaminergic (DAnergic) neurons from the ventral tagmental area to the nucleus accumbens (NAc). Several studies indicate that ATP sensitive potassium channels (K_{ATP}) regulate the firing rate of DAnergic neurons. To ask if ATP-sensitive potassium (K_{ATP}) channels act as a metabolic sensor that link metabolic disorders to depression in the mesolimibic DA system, we established high fat diet (HFD)-fed obese mice model. These mice displayed type II diabetic characteristics and importantly depressive symptoms evaluated by sucrose preference test and forced-swim test. The analysis of catecholamine was shown lower levels of serotonin and DAnergic activities in the NAc of HFD than Chow-fed mice. Previous report indicated the activity of brown adipose tissue (BAT) might

be related to mood control. Hence, HFD induced depression mice were implanted by mini-osmic pump containing K_{ATP}channel blocker (glibenclamide) into the interscapular BAT. Our results showed two weeks of glibenclamide treatment improves glucose homeostasis, insulin sensitivity, the blood triglyceride concentration as well as reduces depressive symptoms. Additionally, the NAc of HFD with glibenclaminde infusion presents higher amount serotonin and DAnergic activity as compared to HFD mice which further support the behavioral assessments. Collectively, our data suggest that inhibition of K_{ATP}channel activity in the BAT not only improves metabolic abnormalities but also depressive symptoms.

Title: Characterization of NV-5138, the first selective brain mTORC1 activator

Authors: *E. GIAIME, S. SENGUPTA, S. HAHM, G. P. VLASUK, E. SAIAH;
Navitor Pharmaceuticals Inc, Cambridge, MA

Abstract: The mechanistic target of rapamycin complex 1 (mTORC1) has been linked to several important chronic medical conditions many of which are associated with advancing age. A variety of inputs including the amino acid leucine are required for full mTORC1 activation. The cytoplasmic proteins Sestrin1 and Sestrin2 specifically bind to the multiprotein complex GATOR2 and communicate leucine sufficiency to the mTORC1 pathway activation complex. Here we present *in situ* hybridization data showing the specific expression of Sestrin1 and Sestrin2 mRNA in neurons. We also present data showing that NV-5138 activates mTORC1 both *in vitro* and *in vivo*. NV-5138 transiently activates mTORC1 in several peripheral tissues. In contrast to orally administered leucine, NV-5138 uniquely activates mTORC1 in different regions of the brain. Finally, we show that a transient activation of mTORC1 in neurons can induce synaptic protein synthesis as well as spine formation in prefrontal cortex and hippocampus up to three days after dosing. NV-5138 is the first selective orally available mTORC1 activator targeting an amino acid sensor that is brain penetrant and will permit the exploration in areas of unmet medical need including neuropsychiatric conditions and cognition which have been linked to the activation status of mTORC1.

Sci., Hiroshima Univ., Hiroshima, Japan; [5]Dept. of Neuropsychiatry, Fac. of Life Sci., Kumamoto Univ., Kumamoto, Japan

Abstract: Background: Lysophosphatidic acid (LPA) is a bioactive phospholipid that acts as an extracellular signaling molecule through six different G-protein-coupled receptors (LPA1-6). LPA has many roles in the central nervous system that influence brain development, function, and behavior. In this study, we examined the distribution of all LPA receptors in adult mouse brain. Among LPA receptors, LPA1 is crucial for LPA-induced learning and emotional behavior and an antidepressant effect (Kajitani et al. 2016), indicating that LPA1 may be a potential therapeutic target for neuropsychiatric disorders. However, the cellular localization of LPA1 is not completely understood. Identification of LPA1 expressing cells is essential for drug discovery research. We evaluated the cellular localization of LPA1 in the brain using LPA1 heterozygous mice that integrate a lacZ reporter-tagged deletion allele. **Method:** Adult wild type C57BL/6J and LPA1 heterozygous mice were used in this study. All animal experiments were approved by the animal research ethics committee of NHO Kure Medical Center. Total RNA was extracted from nine brain regions (olfactory bulb, frontal cortex, striatum, hippocampus, thalamus, hypothalamus, mid brain, hind brain and cerebellum). The mRNA expression changes were examined by real-time PCR. Cellular localization of LacZ in LPA1 heterozygous mice brain was evaluated by double fluorescent immunostaining of antibodies against β-galactosidase (LacZ) and each cell markers (CD31, GFAP, Iba1, NeuN, Olig2 and S100β). **Results:** The mRNA expression of all LPA receptors was detected in adult mouse brain. LPA1, 2, 3, 5 and 6 mRNAs were abundantly expressed in the brain stem (hypothalamus, mid or hind brain). LPA4 mRNA was abundantly expressed in the olfactory bulb. In LPA1 heterozygous mice, mRNA

expression of LPA1 was strongly correlated with that of LacZ, indicating that LacZ can be alternatively used to examine LPA1 cellular localization. Fluorescent immunostaining revealed that the majority of LacZ-positive cells were Olig2-positive oligodendrocytes. Most S100β-positive ependymal cells expressed LacZ. The remaining LacZ-positive cells were GFAP-positive astrocytes and CD31-positive vascular endothelial cells. Neuron and microglia hardly expressed LacZ. **Conclusion:** Almost all LPA receptors were abundantly expressed in the brain stem. Especially in LPA1, oligodendrocytes could be involved in the distribution of LPA1 in the brain. Astrocytes, ependymal cells and vascular endothelial cells also expressed LPA1. These findings could be useful in the development of drugs targeting LPA1.

Title: Psychoactive properties of BNN27 in both sexes - A novel neurosteroid derivate

Authors: *M. G. SOTIROPOULOS[1], N. KOKRAS[1], C. DIOLI[1], R. PARAVATOU[1], I. CHARALAMPOPOULOS[2], A. G. GRAVANIS[2], C. DALLA[1];

[2]Dept. of Pharmacol., Sch. of Medicine, Univ. of Crete, Crete, Greece

Abstract: Dehydroepiandrosterone (DHEA), a potent neuroactive neurosteroid, is synthetized in the brain, as well as in peripheral tissues and glands, like the adrenals. Neurosteroids and DHEA in particular, play a role in neurodegeneration and neural protection, but they are metabolized in androgens, estrogens or other active metabolites. A synthetic analogue of DHEA, named BNN27 ((20R)-3β,21-dihydroxy-17R,20-epoxy-5-pregnene), has been developed. Although the neurotrophic actions of BNN27 have been studied, its potential anxiolytic or antidepressant properties have not been investigated. Male and female adult Wistar rats were treated with BNN27 (10, 30, 90 mg/kg, i.p.) or vehicle (DMSO 100%) and were subjected to a series of behavioral tests. Horizontal and vertical activity, and time spent in the center of the arena were measured in the open field. Total number of transitions and per cent of time spent into the illuminated compartment were measured in the Light/Dark Box. Time spent and entries in the open arms were measured in the Elevated Plus Maze. Immobility, swimming, climbing and head shake behaviors were measured in the two-day Forced Swim Test (FST). Specifically, rats were subjected to a 15min pretest FST session, thereafter all rats received three injections of BNN27 or vehicle at 1, 19, 23 hrs after the pretest session and one hour later they were subjected to the

second 5min FST test session. Three weeks later, all rats had again one single injection of either BNN27 or vehicle, were killed, hippocampus and prefrontal cortex were collected for biogenic monoamine and aminoacid assays using HPLC-ED, and trunk blood was collected for hormone measurements. Our results showed that at 30min post-injection, BNN27 has a marked impact on spontaneous motor activity of male and female rats. Specifically, both male and female rats displayed lower horizontal and vertical activity when injected with progressively higher doses of BNN27. The highest BNN dose resulted in a clear suppression of motor activity in the open field. The statistical analysis, using a two-way ANOVA, revealed that BNN27 increases the levels of glutamine in the area of the hippocampus, irrespectively of the dosage and the sex of the animals. Furthermore, the levels of glutamate in the areas of the hippocampus and the prefrontal cortex were higher in males than in females. BNN27 treatment seems to influence the levels of glutamine and thus indirectly, the glutamatergic system in the hippocampus. This finding may be linked with the possible capacity of BNN27 to improve cognitive function in neurodegenerative disorders. Our results further show that BNN27 has psychotropic properties in male and female rats.

Title: *In vivo* anxiolytic and antidepressant activity of LCGA-17, a new peptide modulator of GABAergic system

Authors: *A. MALYSHEV, I. DORONIN, V. PAVSHINTCEV, V. GEDZUN, I. SUKHANOVA, E. RAZUMKINA, M. LOVAT, A. KUCHUMOV, G. BABKIN;
Lactocore, Inc., Plymouth, MI

Abstract: Background: New concepts of pharmacotherapy in psychiatry highlight increasing potential for peptides in treating mood disorders. LCGA-17 is a novel tetrapeptide discovered using docking procedures from proprietary peptide library and characterized as potential GABA-A receptor positive allosteric modulator. The GABAergic system plays an important role in normal functioning of corticolimbic circuits and regulation of hippocampal neurogenesis and neural maturation, which are now established as cellular substrates of many treatments. LCGA-17 could provide prominent anxiolytic and antidepressant effect by enhancing GABA-A receptors activity.
Objective: Investigate dose-dependent LCGA-17 efficacy in depressive/anxiety models in

comparison with benzodiazepine, and the role of GABA-A receptor in mediating the peptide's activity.
Methods: Three doses of the LCGA-17 (1, 10, 20 mg/kg) were studied after a single i.p. injection in BALB/C mice (n=13 per group) using elevated plus maze (EPM) and forced swim (FS) tests, with diazepam (0.75 mg/kg) as a positive control. The most efficient dose was chosen for co-administration with bicuculline (5 mg/kg), a competitive GABA-A receptor antagonist, to be compared with the peptide alone in a new set of animals using the same behavioral methods.
Results: EPM test revealed a significant increase in time on open arms after 20 mg/kg dose injection of LCGA-17 and improvement in complex "anxiety index" parameter in all 3 doses of the peptide comparing to control group. Anxiolytic-like activity was dose-dependent and comparable to diazepam. But unlike diazepam, LCGA-17 also showed an ability to decrease behavioral despair in FS test by significantly reducing immobility time at all 3 peptide doses and increasing climbing time at 20 mg/kg. EPM and FS tests were subsequently used to compare the efficacy of the peptide alone (at 20 mg/kg) and in combination with bicuculline. It has been observed that bicuculline completely abolished peptide's effects while the peptide alone had reproducibly shown high activity in both tests, pointing to a strong connection of the peptide's activity with GABA-A receptor.
Conclusion: Novel peptide LCGA-17 showed dose-dependent anxiolytic-like and antidepressant-like activity in vivo, with no reduction in locomotor activity, or any other common psychotomimetic side effect. Bicuculline-dependent type of activity suggests LCGA-17 is likely a GABAergic system modulator. Further experiments using chronic stress models are in progress to develop this promising peptide as a potential treatment of mood disorders.

Title: (*2R,6R*)-hydroxynorketamine acts through a synapse-specific presynaptic mechanism to rapidly potentiate hippocampal glutamatergic transmission

Authors: *L. M. RIGGS[1], Y. ARACAVA[2], P. ZANOS[3], J. FISCHELL[4], E. X. ALBUQUERQUE[5], E. F. R. PEREIRA[5], S. M. THOMPSON[6], T. D. GOULD[7];

Care Sys, Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Preclinical studies indicate that (*2R,6R*)-hydroxynorketamine (HNK) retains the rapid and sustained antidepressant-like actions of ketamine, but is spared its dissociative-like properties and abuse potential. While (*2R,6R*)-HNK is thought to exert its antidepressant-like effects by potentiating α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR)-mediated synaptic transmission, its acute mechanism of action is unknown. Here, the acute synaptic effects of (*2R,6R*)-HNK were examined by recording field excitatory postsynaptic potentials (fEPSPs) and miniature excitatory postsynaptic currents (mEPSCs) in rat hippocampal slices. (*2R,6R*)-HNK bath application caused a rapid and persistent potentiation of AMPAR-mediated Schaffer collateral (SC)-CA1 fEPSPs in slices derived from male and female rats. The (*2R,6R*)-HNK-induced potentiation occurred independent of *N*-methyl-D-aspartate receptor (NMDAR) activity, was accompanied by a concentration-dependent decrease in paired pulse ratios, was occluded by raising glutamate release probability, and was blocked by presynaptic calcium channel inhibition. Additionally, in the presence of tetrodotoxin, (*2R,6R*)-HNK increased the frequency, but not amplitude, of mEPSC events, confirming a presynaptic site of action that is independent of glutamatergic network disinhibition. A dual extracellular recording configuration revealed that the presynaptic effects of (*2R,6R*)-HNK were synapse-selective, occurring in CA1-projecting SC terminals, but not in CA1-projecting temporoammonic terminals. Overall, we found that (*2R,6R*)-HNK enhances excitatory synaptic transmission in the hippocampus through a concentration-dependent, NMDAR-independent, and synapse-selective increase in glutamate release probability with no direct actions on AMPAR function. The current study provides novel insight regarding (*2R,6R*)-HNK's acute mechanism of action, and reveals that non-canonical presynaptic forms of synaptic plasticity can be engaged by compounds with rapid-acting antidepressant potential. These findings represent an important step toward identifying novel antidepressant drug mechanisms that may possess superior efficacy, safety, and tolerability than those currently available.

Title: Crosstalk between lysophosphatidic acid and cannabinoid receptor signalling in the regulation of antidepressant activation of MAP kinases in hippocampal neurons

Authors: *M. C. OLIANAS[1], S. DEDONI[2], P. ONALI[3];
[1]Univ. of Cagliari, Cagliari, Italy; [2]Univ. of Cagliari, Dept Biomed. Sci., Cagliari, Italy; [3]Univ. of Cagliari, Dept.Biomedical Sci., Monserrato, Italy

Abstract: Accumulating evidence indicates that lysophosphatidic acid (LPA) signalling participates in the regulation of neuroprotection and emotional behaviour. Moreover, we have previously reported that in neuronal and glial cells activation of the LPA_1 receptor mediates MAP kinase activation and pro-survival effects of different classes of antidepressants. The cannabinoid system has also been implicated in the pathogenesis of depression and anxiety through the modulation of multiple neurotransmitter pathways. However, there is little information on whether lysophospatidic acid and cannabinoid systems interact in the regulation of neuronal responses to antidepressants. In the present study we report that in HT22 mouse hippocampal neurons the endocannabinoid anandamide stimulated ERK1/2 phosphorylation, which was blocked by the selective CB_1 receptor antagonist rimonabant. The stimulatory effect of anandamide was mimicked by the cannabinoid receptor agonist WIN55,212-2. Both LPA and the tricyclic antidepressant amitriptyline induced a rapid increase of ERK1/2 phosphorylation , which was blocked by LPA_1 receptor antagonists but insensitive to rimonabant. The exposure of HT22 hippocampal cells to either anandamide or WIN55,212-2 potentiated the stimulation of ERK1/2 induced by either LPA or amitriptyline. The potentiation was prevented by cell pre-treatment with rimonabant. These data provide the first evidence for the occurrence in hippocampal neurons of a functional interaction between endogenously expressed CB_1 and LPA_1

receptors in the control of intracellular signalling. This interaction appears to set the gain of MAP kinase activation in response to endogenous lipids and antidepressants.

Title: Demonstration of high affinity, reversible JNJ-42226314 binding by monoacylglycerol lipase in brain homogenates and via autoradiography using [^{3}H]SAR-127303

Authors: *S. W. SUTTON, B. LORD, T. W. LOVENBERG, P. BONAVENTURE; Janssen Res. & Development, L.L.C., San Diego, CA

Abstract: Cannabis Sativa has been used for many generations to treat a variety of ailments including pain and depression. However, tetrahydrocannabinols and other cannabinoids are long lived agonists that have undesirable effects such as memory impairment and hyperphagia. Plant cannabinoids engage 2 cannabinoid receptors (CB1R and CB2R), which have endogenous cannabinoid ligands in mammals (2-arachidonoyl glycerol and anandamide). Monoacylglycerol lipase (MGLL; Navia-Poldanius et al, 2012) is the key serine hydrolase catabolizing 2-arachidonoyl glycerol (2-AG), a full agonist of both cannabinoid receptors. MGLL inhibitors offer a strategy to transiently increase local levels of the endocannabinoid 2-AG by inhibiting its degradation, optimally avoiding the undesirable cannabinoid effects. SAR-127303, a selective covalent inhibitor of MGLL and ABHD6, has been shown to be a suitable tracer for imaging MGLL in the brain (Wang et al., 2016). We have used [^{3}H]SAR-127303 in enzyme binding assays to describe the high affinity and reversible binding of MGLL inhibitor JNJ-42226314. When using this tracer for in vitro binding one can show compounds' affinity and selectivity with regard to serine hydrolase ABHD6. The relative amount of MGLL binding competed by selective MGLL inhibitors as opposed to selective ABHD6 inhibitors confirms an excess of MGLL binding sites compared to ABHD6 sites in native brain tissue. The small fraction of binding from ABHD6 sites can also be seen in binding of this tracer using samples from MGLL knockout mouse brain tissue. Jump dilution with a tracer solution further shows the reversibility of JNJ-42226314 and its K_{off}. In vitro autoradiography experiments using native rodent, simian and human brain samples further show the brain distribution of MGLL.

Title: An instructive role for eukaryotic elongation factor 2 kinase in rapid antidepressant action

Authors: *K. SUZUKI, E. T. KAVALALI, L. M. MONTEGGIA;
Dept. of Pharmacology, Vanderbilt Brain Institute, Vanderbilt Univ., Nashville, TN

Abstract: Major depressive disorder is one of the most prevalent mental illnesses. Traditional antidepressants, which target the monoamine system, are commonly for the treatment of depression but typically take several weeks to exert a clinical effect, with a sizable fraction of the patient population failing to respond to treatment. There has been a major unmet need for the development of pharmacological therapies that can quickly and effectively alleviate symptoms associated with depression. Ketamine is a noncompetitive glutamatergic N-methyl-D-aspartate receptor (NMDAR) antagonist with rapid and sustained antidepressant efficacy for patients with treatment-resistant major depressive disorder. We previously showed that ketamine blocks NMDARs activated by spontaneous glutamate release that couple to eukaryotic elongation factor 2 kinase (eEF2K) signaling, which is essential for the rapid antidepressant action of ketamine in mouse models. When eEF2K phosphorylates its only known target, eukaryotic elongation factor 2 (eEF2), it impairs ribosomal translocation and slows the elongation phase of protein synthesis. Conversely, when eEF2K is inhibited the result is desupression of protein translation. Our hypothesis is that ketamine block of resting NMDAR activity in hippocampus suppresses eEF2K activity and regulates protein synthesis including brain-derived neurotrophic factor (BDNF) and α-amino-3-hydroxy-5-methylisoxazole-4-propinic acid receptors (AMPARs) to trigger a novel form of homeostatic plasticity that is necessary for rapid antidepressant effects. While our work proposes a specific intracellular signaling pathway necessary for rapid antidepressant action, there is little known regarding eEF2K in neurons. We examined eEF2 phosphorylation in hippocampal neurons with respect to specific localization of eEF2K in neuronal subcompartments. We observed high levels of phosphorylated eEF2 in dendrites and spines suggesting eEF2K functions at postsynaptic sites. In addition, to elucidate the impact of eEF2K inhibition on synaptic function, we performed whole cell voltage patch clamp experiments in

hippocampal neurons. Data will be presented showing that eEF2K plays a key role in setting synaptic efficacy which may provide critical insight into the molecular mechanisms important for rapid antidepressant action.

Title: Sex differences in the development of anxiodepressive-like behavior in mice with chronic pain

Authors: *A. M. CARDENAS, E. DIMITROV;
RFUMS, North Chicago, IL

Abstract: Gender differences in pain perception and response to analgesics are well established. The prevalence of chronic pain is higher among women and women are more likely to report widespread pain. However, studies in both, humans and rodents, suggest that females show increased resilience to the development of pain-associated behavioral phenotype. Women in pain clinics have higher physical activity levels and experience less mood disturbances than men. Females do not develop place-conditioned hypersensitivity, while males are readily conditioned by pain experience. Female rodents are less susceptible to develop chronic pain after stress and do not show contextual memory impairment after prolonged periods of pain. The neurotransmitter norepinephrine (NE) is an essential modulator of both pain and mood, and the sexually dimorphic locus ceruleus (LC) is the main source of NE to the forebrain. NE is also a factor for maintenance of the hippocampal neurogenesis, which is vital not only for memory processing, but also for the modulation of anxiety and stress response. We investigated the possible contribution of LC activity to the sex differences in the development of pain phenotype in mice. Mice of both sexes were subjected to neuropathic pain for 45 days. The male mice showed decreased thermal and mechanical thresholds, increased anxiodepressive-like behavior and suppressed hippocampal neurogenesis as measured by the reduced number of doublecortin (DCX) neurons in the hippocampus. The thermal and mechanical thresholds decreased in female mice as well, but the females did not manifest any heightened anxiodepressive-like behavior or changes in DCX expression even after 45 days of pain. We also evaluated the protein levels of dopamine-β-hydroxylase (DBH) in tissue samples from the pons in mice with and without pain. Increased protein levels of DBH were found in females with pain, but not in male mice with

pain. Next, we used a chemogenetic approach to inhibit the LC projections to the ventral hippocampus in female mice with chronic pain. Clozapine N-oxide (CNO) was added to the drinking water of mice in which the projection neurons from LC to hippocampus were transfected by inhibitory AAV-DREADD-Gi virus. The experimental group developed anxiodepressive-like behavior after only 14 days of CNO treatment. The CNO treated group also showed significant decrease of hippocampal DCX expression. Together, the results of our experiments show that the resilience of female mice to the development of pain-associated anxiodepressive-like behavior relies on intact hippocampal neurogenesis, which is very likely supported by increased norepinephrine release from an overactive LC.

Title: Effects of serotonin1A receptor agonist on doxorubicin and cyclophosphamide-induced anxiety-like behavior in rats

Authors: *Y. KITAMURA[1], Y. NAKAMURA[2], Y. SUMIYOSHI[2], N. NAITO[2], Y. WADA[2], I. MIYAZAKI[3], M. ASANUMA[3], T. SENDO[1];
[1]Dept. of Pharm., Okayama Univ. Hosp., Okayama, Japan; [2]Dept. of Clin. Pharm., Okayama Univ., Okayama, Japan; [3]Dept. of Med. Neurobio., Okayama Univ. Grad. Sch., Okayama, Japan

Abstract: We previously reported that combination treatment with doxorubicin and cyclophosphamide (chemotherapy) produced anxiety-like behavior and significantly increased the frequency of (±)-DOI (a serotonin $(5\text{-HT})_{2A}$ receptor agonist)-induced wet-dog shakes in rats. Chemotherapy-induced anxiety-like behavior is mediated by the hyperfunctioning of the 5-HT_{2A} receptor subtype. On the other hand, several studies have suggested that there are functional interactions between 5-HT_{2A} receptors and 5-HT_{1A} receptors. In the present study, we focused on the effects of a 5-HT_{1A} receptor agonist on doxorubicin and cyclophosphamide-induced anxiety-like behavior in rats. [METHODS] Rats were intraperitoneally injected with doxorubicin (5 mg/kg) and cyclophosphamide (50 mg/kg) once a week for 2 weeks. We assessed anxiety-like behavior using the light-dark test. We also evaluated the frequencies of DOI-induced wet-dog shakes (5-HT_{2A} receptor function) and the 8-OH-DPAT-induced flat body posture (5-HT_{1A} receptor function). [RESULTS] Combination treatment with doxorubicin and cyclophosphamide significantly increased the number of DOI-induced wet-dog shakes, but did not affect the

frequency of the 8-OH-DPAT-induced flat body posture. The number of DOI-induced wet-dog shakes was significantly decreased by 8-OH-DPAT treatment. Anxiety-like behavior was significantly inhibited by mirtazapine, a 5-HT_{2A} receptor antagonist/5-HT_{1A} receptor agonist, and tandospirone, a partial 5-HT_{1A} receptor agonist, but not fluoxetine, a selective serotonin reuptake inhibitor. [DISCUSSION and CONCLUSION] These results suggest that 5-HT_{1A} receptor agonists could be used to inhibit doxorubicin and cyclophosphamide-induced anxiety-like behavior.

Title: Effects of chronic and acute inhibition of cannabinoid CB2 receptor on anxiety levels and oxytocin activity

Authors: L. RODRÍGUEZ, P. MUNOZ, A. RAMOS, V. ENCARNACION, E. OLMEDO, F. GONZALEZ, W. NORZÉ, *C. S. MALDONADO-VLAAR;
Biol., Univ. Puerto Rico, San Juan, PR

Abstract: Oxytocin (OT) has been tested as a potential therapeutic agent in the treatment of various behaviors related to cocaine addiction. Previous work in our laboratory demonstrated that OT has anxiolytic effects and the ability to reduce cue-induced cocaine seeking behavior. Many studies revealed a cross-talk between the endocannabinoid system and the OT system. Our objective was to assess: (1) behavioral effects of chronic and acute inhibition of the CB2 receptor (AM630) in adult male Sprague-Dawley rats, (2) changes produced in the expression of CB2, TRPV1 and OT receptors within the amygdala, median raphe nucleus and hypothalamus. We expect that chronic treatment with AM630 will increase anxiety behavior and acute administration will have an anxiolytic effect. A separate group of animals received twice daily injections of AM630 (3mg/kg i.p.) or vehicle for 5 days. On the 6^{th} day they were tested on the elevated plus maze (EPM). In addition, another group of animals received a single dose of AM630 (3mg/kg i.p.) or vehicle before testing on the EPM. Preliminary results show that when administered chronically systemic blockade of CB2 receptor had a tendency to increase anxiety behavior in male animals. Further biochemical studies will examine cross talk between OT and

the endocannabinoid system as mediators of possible mechanisms responsible for regulating anxiety behavior involving OT.

Title: Class II human leukocyte antigen expression influences behavioral manifestations of mild food allergy in mice

Authors: *D. L. GERMUNDSON, N. A. SMITH, K. NAGAMOTO-COMBS;
Pathology, Univ. of North Dakota Sch. of Med. and Hlth. Sci., Grand Forks, ND

Abstract: Food allergy has been implicated in triggering or exacerbating symptoms of anxiety, depression, attention-deficit hyperactivity disorder, and autism. However, food allergy as a cause of behavioral manifestations has been debated due to inconsistencies in human cohort studies. A factor of such inconsistencies may be variations in class II human leukocyte antigen (HLA-II), which is essential in antigen recognition and presentation for adaptive immunity. HLA-II is highly polymorphic, and it is well-established that specific HLA-II haplotypes increase susceptibilities to various diseases. As HLA-II variants have unique affinities to an antigen, we hypothesized that behavioral manifestations of food allergy would depend on the HLA-II variant expressed. To test this hypothesis, we used three strains of transgenic mice expressing an allelic variant of HLA-II, DR3, DR15, or DQ8. We previously demonstrated that sensitization of C57BL/6 mice to cow's milk whey proteins resulted in anxiety-like behavior without anaphylaxis. Based on this mouse model, we sensitized 4-week-old male and female mice to a major cow's milk allergen, beta-lactoglobulin (BLG), for 5 weeks followed by a BLG challenge. Clinical symptoms, such as itching and swelling, were monitored, and changes in body temperature were recorded at 30 min post-challenge. Sensitized DR3 mice showed moderate clinical responses with perioral redness and swelling, while DQ8 and DR15 mice exhibited occasional ear scratching. One day post-challenge, locomotion, anxiety-like behavior, and spatial memory were tested with open-field activity monitoring and cross maze test. No significant

behavioral changes were observed in sensitized DR3 and DQ8 mice. In contrast, BLG-sensitized DR15 mice displayed behavioral alterations in a sex-dependent manner. The mobility of sensitized male mice decreased compared to their sham counterparts, while sensitized females showed decreased spatial memory. This data establishes that variations in HLA-II differentially influence both physical and behavioral manifestations of non-anaphylactic food allergy. More importantly, our findings support a screening strategy to identify individuals with increased susceptibility to behavioral manifestations of mild or undiagnosed food allergy.

Title: Anxiolytic effects of full-spectrum cannabidiol-rich hemp extracts in mice

Authors: J. WAGNER[1], R. ARVILA[1], M. BROOKS[1], H. WEBSTER[1], K. REID[1], F. MCGUINNESS[1], F. GAVIN[1], T. HARYU[2], B. PREDOVICH[2], ***J. S. KAPLAN**[1]; [1]Western Washington Univ., Bellingham, WA; [2]Prelabs, LLC, Lehigh Acres, FL

Abstract: Cannabidiol (CBD) is a non-intoxicating cannabinoid that has been shown to have anxiolytic properties. There is a vast number of CBD products available to potential users, yet many pre-clinical empirical assessments of CBD's efficacy are limited by the use of isolated or synthetically-derived CBD, cannabis-derived CBD, or only assess acute exposure. Synthetic and isolated forms of CBD are practically non-existent in the current marketplace, and many individuals cannot legally access cannabis-derived CBD. Consequently, many are turning to hemp-based extracts for chronic treatment of anxiety. Here, we tested the dose-dependent anxiolytic effects of a full-spectrum CBD oil from a commercially-available hemp source in mice using the elevated plus maze assay. We observed that after one week of twice daily i.p. injections of 5 mg/kg of CBD in hemp oil, mice showed reduced anxiety-like behavior compared to vehicle-treated mice as measured by the ratio of time spent in the open arms compared to the closed arms. These anxiolytic effects were lost at higher doses of 20 mg/kg and 100 mg/kg, consistent with previous studies showing an inverted-U dose-response curve for CBD's anxiolytic properties. Our findings support CBD's anxiolytic benefits at low-to-moderate doses and confirm that they persist after repeated exposures of a full-spectrum hemp oil. Our follow-up experiments will assess different full spectrum hemp-derived CBD oils with varying minor cannabinoid and terpene compositions. These comparisons will provide important insight into the roles of terpenes and other cannabinoids in modulating the therapeutic efficacy of cannabis-based treatment of anxiety. Additionally, we will present our immunohistochemistry results

where we assessed the impact of hemp oil exposure on cannabinoid type I receptor expression profiles. Together, our work demonstrates the importance of dose, even from full-spectrum hemp extracts, in CBD's anxiolytic properties and they shed light on the role of terpenes and minor cannabinoids in these anxiolytic effects.

Title: Anxiolytic properties of Matcha in mice: Contribution of dopamine D1 receptor- and serotonin 5-HT_{1A} receptor-mediated mechanisms

Authors: *Y. KURAUCHI[1], H. PRASAD DEVKOTA[2], K. HORI[2], Y. NISHIHARA[1], T. SEKI[1], H. KATSUKI[1];

Abstract: Matcha tea is a traditional drink in Japan. In recent years, the term Matcha is becoming popular worldwide, because it is also used as a dietary supplement or flavoring ingredient in snacks. Matcha is the finely ground powder of specially cultivated tea plant leaves (*Camellia sinensis*), and is thought to be beneficial for brain functions; however, only a few scientific studies have shown the effects of Matcha tea powder on psychiatric behavior. Here, we evaluate the anxiolytic activity of Matcha tea powder in mice, using the elevated plus maze test. Oral administration of Matcha tea powder and ethanol extract (CSE) of Matcha tea powder exerted anxiolytic effects. Among the fractions of CSE, the ethyl acetate and hexane fractions (CSEE and CSEH, respectively) exerted anxiolytic effects. Notably, the water fraction of CSE (CSEW) synergistically enhanced the anxiolytic effects of CSEE, although CSEW itself did not show anxiolytic properties. Moreover, SCH23390, a dopamine D1 receptor blocker, and WAY100135, an antagonist of the serotonin (5-hydroxytryptamine: 5-$HT)_{1A}$ receptor, prevented Matcha tea powder and CSEE from exerting their anxiolytic effects. These results suggest that Matcha tea powder exerts anxiolytic effect through the activation of the dopaminergic and serotonergic systems.

Title: Neurotherapeutic effects of closed-loop stimulation in an NHP model of anxiety

Authors: S. R. SANTACRUZ[1], ***E. L. ZIPPI**[2], J. M. CARMENA[2,3];
[1]Biomed. Engin., Univ. of Texas at Austin, Austin, TX; [2]Helen Wills Neurosci. Inst., [3]Electrical Engin. and Computer Sci., Univ. of California, Berkeley, Berkeley, CA

Abstract: The prefrontal cortex is known to be involved in emotional regulation. In order to demonstrate a functional link between mood state and neural state, we used a proxy for an acute anxiety animal model in the nonhuman primate (NHP). Two NHP subjects were trained in an eight-target center-out task which consisted of three blocks. During the first block, baseline physiology and behavior was established. At the beginning of the second block, beta-carbolines, a type of benzodiazepine inverse agonist, were administered to induce an acute anxiety-like state. Finally, in the third block a treatment was administered to the subjects in the form of either closed-loop stimulation or midazolam, a known anxiolytic drug in the class of benzodiazepines. Using biomarkers of mood state changes discovered during this behavior, we designed closed-loop microstimulation protocols to mediate these changes and restore the subjects to a baseline, non-anxious state. We applied unilateral microstimulation to prefrontal cortical sites to modulate the response evoked from the beta-carbolines administered in the second block. We found that microstimulation was able to restore neural features to baseline levels and generate a profound anxiolytic physiological response.

Title: Cannabidiol effects on defensive responses and compulsive-like behaviors in rats considering the influence of sex and estral cycle

Authors: *D. FABRIS[1], K. GENARO[2], W. A. PRADO[3], J. S. CRIPPA[3], A. R. DE OLIVEIRA[1];
[1]Psychology, Federal Univ. of Sao Carlos (UFSCar), Sao Carlos, Brazil; [2]Univ. of California, Irvine, CA; [3]Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: The endocannabinoid signaling system (eCBs) regulates various physiological processes and is considered a potential pharmaceutical target for modulating emotional responses. Cannabidiol (CBD), a phytocannabinoid, enhances the action of eCBs and has an anxiolytic effect in several animal models. Although there are important differences in prevalence, severity and symptomatology in the expression of emotional disorders between men and women, preclinical research is performed predominantly in males. Few studies consider the influence of sex and the impact of fluctuations of female gonadal hormones on the expression of emotions and the effects of drugs used in the treatment of mental disorders. The present study evaluated the effects of CBD on defensive and compulsive-like behaviors in rats, considering the influence of sex and estrous cycle phases. Male and female (proestrus and late diestrus) Wistar rats (n=6-11) received intraperitoneal administration of CBD at doses of 0.0, 0.3, 3.0 or 30 mg/kg. In the sequence, distinct groups had their behavioral responses analyzed in the elevated plus-maze (EPM), open field, marble burying, nestlet shredding and spontaneous alternation tests. Males that received 3.0 mg/kg CBD showed increased number (1-way ANOVA, $F(3,33)=3.27$; $p<0.05$) and duration ($F(3,33)=3.04$; $p<0.05$) of visits to the open arms of the EPM, indicative of an anxiolytic effect. No significant effect was observed for any of the other tests. Females receiving 0.3 mg/kg CBD during late diestrus, but not during proestrus, showed the same increase in the exploratory response of the open arms of the EPM (number of visits: $F(3,29)=3.45$; $p<0.05$; duration: $F(3,29)=4.03$; $p<0.05$). Again, no significant effect was observed for the other tests. The results indicate that sensitivity to CBD seems to be dependent on the type of defensive/compulsive response assessed and differ according to gender and phase of the estrous cycle.

Title: Anxiety-like behavior is differentially induced in C57BL/6J and BALB/cJ mice as a form of non-anaphylactic response to cow's milk allergy

Authors: ***N. A. SMITH**, D. L. GERMUNDSON, K. NAGAMOTO-COMBS;
Univ. of North Dakota Sch. of Med. and Hlth. Sci., Grand Forks, ND

Abstract: Neuropsychiatric disorders such as depression, attention deficit hyperactivity disorder, and autism spectrum disorder are a major public health concern. Though a large proportion of research focuses on development of behavior modulating pharmaceuticals, the complex etiology underlying these disorders requires further investigation. It is well-documented that the immune system influences behavior. For example, food allergy is often reported to be comorbid with various neuropsychiatric disorders. However, this observation is not universal to all allergic individuals. We therefore hypothesized that some individuals are predisposed to behavioral manifestation of food allergy due to specific biases in their immune responses. Because the type of T helper cell (Th) activated upon allergen exposure is a major determinant of hypersensitivity reactions, we used two strains of mice with distinct Th1- or Th2-biased responses and assessed whether allergen sensitization would induce differential behavioral responses upon allergen challenge. Starting at 4-weeks of age, Th1-biased C57BL/6J and Th2-biased BALB/cJ male and female mice were sensitized with a major cow's milk allergen, β-Lactoglobulin (BLG), for 5 weeks. Sex- and strain-matched sham-treated mice were used as controls. On the 6th week, all mice were challenged with BLG, and their symptom score and body temperature were recorded at 30 min post-challenge. In BALB/cJ mice, sensitized male and female scored higher in our symptom scale and showed greater degrees of hypothermia compared to their respective sham groups. One day after the challenge, male BALB/c mice additionally showed decreased activity and increased anxiety-like behavior with open field activity monitoring and elevated zero maze test, respectively. Sensitized male C57BL/6J mice also displayed anxiety-like behavior despite showing no observable signs of anaphylaxis upon challenge, indicating that allergy-induced behavioral changes can manifest without anaphylaxis. Females did not show behavioral changes, demonstrating a sex-specific response to the allergen challenge. These results suggest that sex

and genetic background of an individual can differentially affect behavioral changes caused by food allergy.

Title: Therapeutic potential of a single administration of the anticonvulsivant pregabalin in extinguishing contextual aversive memory and inducing anxiolytic-like responses in diabetic animals

Authors: *A. P. FARIAS WALTRICK, A. H. B. DE LIMA SILVA, J. MENEZES ZANOVELI;
Pharmacol., Federal Univ. of Paraná, Curitiba, Brazil

Abstract: Diabetes mellitus (DM) is a chronic metabolic disorder highly associated with several psychopathologies such as anxiety disorders and stress-related disorders (*i.e.* the post-traumatic stress disorder). A major challenge for patients suffering from DM and their comorbidities is treatment, as there is a high prevalence of patients resistant and/or refractory to first-line medications. Thus, evidence suggests that anticonvulsant drugs such as pregabalin may be a good alternative in those cases. Pregabalin acts by selectively binding to the α2δ subunit of calcium-dependent voltage channels. The channel undergoes a conformational change that reduces the influx of calcium at the nerve terminals, decreasing, for example, the release of excitatory neurotransmitters such as glutamate. There are almost no studies investigating cognitive impairments related to fear anxiety in diabetic (DBT) rats. Therefore, the present study aimed to investigate the effect of pregabalin (0, 30 and 100 mg/kg, i.p.) on the freezing time in normoglycemic (NGL) and DBT rats submitted to the contextual fear conditioning protocol. The freezing time was evaluated in 3 sessions (S1, S2, and S3) without unconditioned stimulus presentation, with S2 occurring 24 hours after S1 and S3 occurring a week after S2. Shortly after S3, the animals were also submitted to the elevated plus maze test to evaluate anxiety parameters and/or sensitization of fear response. Our data show that DBT animals have greater difficulty in extinguishing a contextual aversive memory (S2), which is longer (S3) in relation to NGL. In addition, DBT animals presented an increased anxiety-like response than NGLs. Interestingly, we verified that a single injection of the drug was able to accelerate the extinction of aversive memory and to induce the anxiolytic-like effect. All these effects present a long-lasting duration (7 days after pregabalin injection). Finally, the data showed the importance of studying the pathophysiology of this overconsolidation of enduring aversive memory associated with

increased anxiety in DBT rats, and the importance of studies on new alternative treatments. To conclude, pregabalin seems to have therapeutic potential for such cases of more pronounced aversive responses associated with aversive memory.

Title: Different types of stress affect rodent's performance in attentional set-shifting task

Authors: *S. MA, Y. ZUO;
UC Santa Cruz, Santa Cruz, CA

Abstract: As the pace of modern life accelerates, stress becomes more and more prevalent. Many studies have shown that stress can lead to various mental and physical health conditions and is a risk factor for many psychiatric disorders such as depression, anxiety, sleep disorders and post-traumatic stress disorder. Among different brain areas, the prefrontal cortex (PFC) is the most sensitive to the stress exposure. The PFC is responsible for cognitive and executive functions. In rodents, PFC consists of two major subregions: medial prefrontal cortex (mPFC) and orbital frontal cortex (OFC). To evaluate PFC-mediated cognitive flexibility - a core executive function, we used attentional set-shifting task (AST). Previous lesion experiments show mPFC is responsible for extradimensional shift (EDS), which requires the subject to alter their response strategy and focus on previously irrelevant information to solve the new set of problems. On the other side, OFC is responsible for reversal, which requires the subject to change their response to previous non-rewarded information. In this study, we subjected mice to two modes of stress common in our daily life: restraint stress (RS, 2h of physical restraint repeated daily) and unpredictable stress (US, daily exposure to varying mild stressors). Our work finds that mice undergoing RS before AST exhibit impairment of EDS only; while mice subjected to US were impaired in both reversal and EDS. We are currently studying how distinct brain circuits are affected by different modes of stress to lead to altered mPFC and OFC functions.

Title: Robust and replicable measurement for prepulse inhibition of the acoustic startle response

Authors: E. A. MILLER[1], D. B. KASTNER[2], M. N. GRZYBOWSKI[3], M. R. DWINELL[3], A. M. GEURTS[3], *L. M. FRANK[4];

Abstract: Measuring animal behavior in the context of experimental manipulation is critical for modeling and understanding neuro-psychiatric disease. Prepulse inhibition of the acoustic startle response (PPI) is a behavioral paradigm used extensively for this purpose, but the results of PPI studies are often inconsistent. As a result, the utility of this metric remains uncertain. Here we deconstruct the phenomenon of PPI. We first confirm several limitations of the traditional PPI metric, including that the underlying startle response has a non-Gaussian distribution and that the traditional PPI metric changes with different stimulus conditions. We then develop a novel model that reveals PPI to be a combination of the previously appreciated scaling of the startle response, as well as a scaling of sound perception. Using our model, we find no evidence for differences in PPI in a rat model of Fragile-X Syndrome (FXS) compared to wild-type controls. These results in the rat provide a reliable methodology that could be used to clarify inconsistent PPI results in mice and humans. In addition, we find robust differences between wild-type male and female rats. Our model allows us to understand the nature of these differences, and we find that both the startle-scaling and sound-scaling components of PPI are a function of the baseline startle response. Males and females differ specifically in the startle-scaling, but not the sound-scaling, component of PPI. These findings establish a robust experimental and analytical approach that has the potential to provide a consistent biomarker of brain function.

Title: Ethologically based behavioural and neurochemical characterisation of mice with loss of dysbindin-1A

Authors: *C. M. O'TUATHAIGH[1], L. DESBONNET[3], C. PAYNE[4], E. PETIT[4], R. COX[4], S. LOFTUS[2], G. CLARKE[2], O. TIGHE[4], S. WILSON[5], B. P. KIRBY[4], T. DINAN[2], J. L. WADDINGTON[6];
[1]Med. Educ. Unit, Sch. of Med., [2]Univ. Col. Cork, Cork, Ireland; [3]Natl. Univ. of Ireland Galway, Galway, Ireland; [4]Royal Col. of Surgeons in Ireland, Dublin, Ireland; [5]GlaxoSmithKline, Stevenage, United Kingdom; [6]Royal Col. of Surgeons In Ireland, Dublin, Ireland

Abstract: Dysbindin-1 is implicated in several domains implicated in schizophrenia including cognition, glutamate and dopamine neurotransmission. Selective knockout of dysbindin-1A (dys-1A$^{-/-}$), the most abundant and widely expressed isoform in the brain, is associated with working memory deficits. Using an ethologically based approach, the following behavioural phenotypes were examined in dys-1A$^{-/-}$ mice: exploratory activity, social interaction, anxiety, problem-solving ability. The ethogram of initial exploration in dys-1A$^{-/-}$mice was characterised by increased sniffing and rearing seated behaviour; over subsequent habituation, sniffing and rearing to wall were increased, with reduced stillness behaviour. In a test of dyadic social interaction with an unfamiliar C57Bl6 in a novel environment, male dys-1A$^{-/-}$mice showed increase latency to engage in investigative social behaviour relative to wildtype mice. No genotypic differences were observed in frequency of agonistic behaviours. Marble burying behaviour was unaffected in dys-1A$^{-/-}$ mice. Using the puzzle box test to measure general problem-solving performance, no effect of genotype was observed across nine trials of increasing complexity. Levels of monoamines and their metabolites were measured in the striatum, hippocampus, and prefrontal cortex using high-performance liquid chromatography [HPLC] with electrochemical detection. Dys-1A$^{-/-}$ demonstrated a marginal increase in dopamine

levels in the hippocampus, and lower levels of 5-HT in ratio to its metabolite (5-HIAA) in the prefrontal cortex. These studies elaborate the behavioural phenotype of dys-1A$^{-/-}$ mice, revealing genotype-related differences in non-social and social exploratory behaviours and habituation of exploration in a novel environment, as well as subtle changes in dopamine and 5-HT activity in schizophrenia-relevant brain areas.

Title: Binge eating disorder - Role of accumbal cocaine- and amphetamine-regulated transcript and orexin as well as impulsivity traits in a rat model

Authors: *J. S. SCHULLER, M. KOCH;
Neuropharm., Univ. Bremen, Bremen, Germany

Abstract: Binge eating disorder (BED) is the most prevalent eating disorder affecting approximately 2-5 % of the adult population and is often associated with obesity. Furthermore, it is often co-morbid with anxiety, mood or substance abuse disorder. BED is characterized by compulsive episodes of excessive consumption of highly palatable food (binges) together with strong feelings of guilt and loss of control. [1]
BED is conceptualized as an impulsive/compulsive disorder with altered reward sensitivity and food-related attentional biases. [2] In the current study we not only investigate possible correlations between BED and impulsivity in rats but also the neuronal basis of BED using an animal model of the disease. Basis of the experimental set-up is the hypothesis that eating disorders including BED result from disturbances in neural circuits underlying impulse control and reward processing.
The involvement of the nucleus accumbens (NAc) in impulse control and in pathological feeding behavior have been studied extensively both in animals and humans. [3] However, the underlying neurotransmitter systems still need to be further elucidated. Several neuropeptides (e.g. the group of orexins or cocaine- and amphetamine-regulated transcript (CART)) and neurotransmitters (e.g. dopamine) which are involved in the natural feeding behavior are candidates to play an important role in BED.
We here investigate the role of two neuropeptides in a rat model of BED considering impulsivity

traits. For this purpose, male Lister Hooded rats were screened for impulsivity using a well-established impulse control paradigm (5-choice serial reaction time task) and subsequently tested in a paradigm for BED (limited access model). Preliminary findings suggest that antagonizing the orexin 1-receptor in the NAc shell region differentially affects the binge eating behavior in high-impulsive rats compared to both low-impulsive and control animals, while CART-antibodies did not reveal such effects. These findings suggest orexin dysregulation being involved in BED.

Title: Cortical serotonergic dysregulation in Gunn rat: A model for congenital hyperbilirubinemia

Authors: *A. OH-NISHI[1], S. MIURA[2], K. TSUCHIE[2], R. ARAUCHI[2], T. MIYAOKA[2], M. INAGAKI[2];
[1]Fac. of Medicine, Dept. of Immune-neuropsychiatry, Shimane Univ., Izumo, Japan; [2]Fac. of Medicine, Dept. of Psychiatry, Shimane Univ., Iuzmo, Japan

Abstract: [Introduction]It has been reported that Jaundice or neonatal hyperbilirubinemia increase the risk of Attention Deficit Hyperactivity Disorder (ADHD) (Wei 2015), although the molecular mechanisms are not yet well understood. Several reports show the Gunn rat, which is an animal model of congenital Jaundice, has hyperactivity similar to ADHD (Hayashida 2009, Tsuchie 2013, Stanford 2015). It is well understood that cortical serotonin have important role for cognitive functions including attention. In this study, we investigated cortical serotonin neurotransmission in the Gunn rat.[Methods]The amounts of serotonin and its metabolites in the cortical region of the Gunn rats were measured by high performance liquid chromatograph, furthermore, serotonergic neurons in the dorsal raphe nucleus were visualized by immunohistochemistry. The hyperactivity in the Gunn rats were confirmed by open field test.[Results]There were significantly higher serotonin and its metabolite at the frontal cortex and hippocampus in the Gunn rats compared to the control rats. The immunohistochemistry showed

that the number of TPH positive cells was increasing in dorsal raphe nucleus of Gunn rats. Moreover, we demonstrated that serotonergic neuronal intervention improves a behavioral abnormality in the Gunn rats.[Conclusion]The serotonergic dysfunctions in the cortical regions seem to play an important role in neonatal hyeprbilirubinaemia associated abnormal behaviors. Our study suggests that intervention with abnormal serotonergic transmission may improve symptom of neonatal hyeprbilirubinaemia associated ADHD.

Title: Role of microRNAs in impulsive behavior in rats: Implication for impulse control disorders associated with Parkinson's disease

Authors: *T. DUFOURD, D. MALLET, C. CARCENAC, S. BOULET, S. CARNICELLA; Grenoble Inst. of Neurosciences - INSERM U1216, Grenoble, France

Abstract: Parkinson’s disease (PD) has long been considered as a pure motor disorder. However, a plethora of non-motor manifestations may occur, ranging from apathy to impulse control disorders (ICDs), and are now considered as disabling as the motor symptoms. These neuropsychiatric disorders are two major comorbid syndromes of PD, and dopamine replacement therapy used to treat the motor symptoms is often associated with ICDs, that include pathological gambling, hypersexuality and compulsive shopping. These behavioral addictions, occurring in 10 to 14 % of PD patients under dopaminergic medications, completely mask the overall motor benefits of the treatment. Unfortunately, it remains unknown why only a portion of these patients will develop these symptoms and thereby, relevant and efficient management of this syndrome is lacking. Recently, several studies have linked dysregulations of microRNAs with PD or psychiatric disorders. These molecules are small non coding RNA playing a pivotal role in the translation of RNA messenger into proteins. However, no one has investigated yet the implication of these molecules in the neuropsychiatric symptoms associated with PD. We therefore investigate the potential implication of microRNAs in the development of ICDs. Some

factors of vulnerability to develop those ICDs have been identified, such as impulsivity trait and dopaminergic treatment use. We used here a behavioral approach with a delay discounting task, a task that allow to assess a form of impulsivity tightly linked to ICDs. After separating rats according to their impulsivity level, we then assessed the effect of pramipexole, a dopaminergic treatment known to induce ICDs in PD patients, in the development of impulsive behavior and looked at microRNA expression profile. Finally, by using high-throughput microRNA sequencing, we identified in tissues of selected brain regions and in plasma from rats, specific microRNAs associated with impulsivity traits and modified by a dopaminergic treatment. A causal validation is ongoing to disentangle the implication of these microRNAs in the development of impulsivity, by using an overexpressing strategy in order to mimic the dysregulations induced by pramipexole in the striatum and assess the effect of this molecular manipulation on the behavior of rodents according to their impulsive level. These findings may lead to the identification of potential new biomarkers that could be useful for the identification of patients under medication vulnerable to ICDs. Also, the microRNAs identified will be good candidates for the development of innovative therapeutic strategies, leading to a better caretaking of these patients.

Title: Prenatal tetrahydrocannabinol exposure causes strong reductions in omega-3 fatty acid levels in mesocorticolimbic brain circuits: Implications for increased neuropsychiatric vulnerability

Authors: *T. D. JUNG[1], M. CHANG KIT[1], K. YEUNG[1], D. HARDY[1], W. J. RUSHLOW[2], S. R. LAVIOLETTE[1];
[2]Dept of Anat. and Cell Biol., [1]Western Univ., London, ON, Canada

Abstract: Acute or chronic exposure to tetrahydrocannabinol (THC), the primary psychotropic component of cannabis, is known to induce schizophrenia-like symptoms in humans and other animals. The developing brain is particularly sensitive to the effects of THC. While adolescent

exposure to THC has been shown to increase the risk of schizophrenia, little is known about how pre-natal THC exposure may impact brain development and neuropsychiatric risk. This is particularly concerning given that increasing numbers of pregnant women are consuming cannabis to alleviate pregnancy-related symptoms. Dysregulated dopamine (DA) signaling is strongly implicated in schizophrenia. Interestingly, omega-3 fatty acid supplementation has been shown to improve schizophrenia symptoms and delay schizophrenia onset. In addition, schizophrenia has been linked to decreased omega-3 fatty acid levels in neurons. Considering that omega-3 deficiency is linked to aberrant dopaminergic signalling, we hypothesized that pre-natal exposure to THC might alter levels of omega-3 fatty acids in schizophrenia-related neural circuits, including the nucleus accumbens (NAc), prefrontal cortex (PFC), and hippocampus (HIPP). Accordingly, we examined the levels of docosahexaenoic acid (DHA), an essential omega-3 fatty acid that is abundant in the brain, following prenatal exposure to THC. In this study, pregnant Sprague Dawley rats received daily intraperitoneal THC or vehicle injections from gestational day 6 to 22. The brains of pups were collected and frozen at 3 weeks and 6 months of age. Matrix-assisted laser desorption/ionization (MALDI) imaging mass spectrometry (IMS) was used to obtain the DHA peak intensities in the PFC (prelimbic and infralimbic), NAc and HIPP (ventral subiculum and CA1). Remarkably, our findings reveal for the first time, a substantial loss of DHA in the observed brain regions of THC treated rats, demonstrating that prenatal THC exposure can strongly reduce omega-3 fatty acid levels in neural regions implicated in schizophrenia. These findings are also the first evidence to suggest that chronic prenatal THC exposure can increase vulnerability to a schizophrenia-related phenotype by functional modulation of neural omega-3 fatty acid expression.

Title: Cocaine drives schizophrenia-like behaviors via reduced neuronal activity in the nucleus accumbens

Authors: *S. HAM[1], H.-I. IM[2];
[1]Korea Inst. of Sci. and Technol., Seoul, Korea, Republic of; [2]Ctr. For Neurosci., Korea Inst. of Sci. & Technol., Seoul, Korea, Republic of

Abstract: Schizophrenia (SCZ) is a complicated disorder with abnormal symptoms in various categories: positive, negative, and cognitive symptoms. Although specific cause of SCZ has been not elucidated until now, many researchers have believed that genetic factors are involved in these symptoms based on numerous genomic studies. However, development of SCZ-like behaviors also can be provoked by a number of environmental factors at adulthood. As one of environmental stimuli, some drugs such as cocaine can induce schizophrenic behaviors. Despite of obvious SCZ-like symptoms by these drugs, drug-induced SCZ models have been mainly studied about reliability and validity as an animal model of SCZ. The purpose of this study is to make a cocaine-induced schizophrenia (CIS) model with reliability and validity, and to explore important genes of CIS. First, we used cocaine to induce schizophrenic symptoms into young adult C57BL/6 male mice, which is a dopamine reuptake inhibitor. We successfully established CIS mouse model with three categories of symptoms. Subsequently we checked whole brain changes with immunostaining of neuronal activity related protein, ribosomal protein S6. Interestingly we found that reduced intensity of that through whole brain, and we observed that most altered region was nucleus accumbens, where neurons receive major dopaminergic inputs from substantia nigra and ventral tegmental area. In addition, we observed decreased number of spike within nucleus accumbens with microelectrode array. Finally, to study the effects of the environmental factor on schizophrenia, by performing RNA sequencing, we found that expression changes of several genes in the nucleus accumbens of the CIS model. These findings suggest that SCZ-like behaviors induced by cocaine may be mediated via reduced neuronal activity of neurons within nucleus accumbens. This brain dysfunction maybe resulted from changes of genes such as miR-5126, miR-3473g, LCAM2, and ZAR1L. As a result, this new model is reliable and valid as a SCZ model, and the neurological change could be used in the study of SCZ in the future.

Title: Neuroprotective effect of low field magnetic stimulation in cuprizone-induced demyelinated mice

Authors: *Z. SUN, Z. ZHANG, Y. HE, J. YANG;
Beijing Anding Hosp., Beijing, China

Abstract: Myelination of axons by oligodendrocytes is essential for proper physiological function, and white matter and myelin sheath integrity are disrupted in schizophrenia. To date, non-invasive magnetic brain stimulation is a promising new therapeutic approach in neuropsychiatric diseases. In particular, deep-brain reachable low field magnetic stimulation (DMS), could alleviate cognitive impairment and depressive-like behaviors in animal models. In this study, we sought to assess the effects of DMS on myelin sheath damage and schizophrenia-like behaviors in the cuprizone-induced demyelination mouse model. Mice were fed cuprizone (copper ion chelating agent, 0.2% w/w mixed with food) for 6 weeks to induce demyelination. During these 6 weeks, mice were stimulated with either sham, high-frequency (HFS, gamma Hz) DMS for 20 minutes or quetiapine (a common kind of antipsychotics) each day. Behavioral tests were conducted 24 h after the final DMS session. The expression of oligoastrocyte was examined by immunohistochemistry and the expression of neuregulin-1/ErbB4 in the prefrontal cortex was measured with Western blotting. Six weeks of HFS and quetiapine significantly alleviated schizophrenia-like behaviors in cuprizone mice, including improved nesting, social interaction and sensorimotor gating. In addition, both HFS and quetiapine repaired the myelin sheath and increased the expression of PDGFR α (marker of oligodendrocyte precursor cells). However, no significant difference was found in the therapeutic effect between HFS and quetiapine. Furthermore, the expression of neuregulin-1 and its receptor ErbB4, in the prefrontal cortex of demyelinated mice. Our findings showed that DMS is a potential effective neuromodulation technique for the treatment of schizophrenia, and indicated the neuroprotective effect of DMS on oligoastrocyte. The mechanism underlying these therapeutic effects might involve the neuregulin-1/ErbB4 signaling.

Title: Age-dependent effects of dentate gyrus inhibition on hippocampal pathology and psychosis-like behaviors in mice

Authors: *D. SCOTT[1], C. A. TAMMINGA[2];
[1]Psychiatry, UT Southwestern, Dallas, TX; [2]Univ. of Texas Southwestern Med. Ctr. at Dallas, Dallas, TX

Abstract: Although psychosis is the defining and the most recognizable symptom domain in schizophrenia, the biological mechanisms underlying psychosis remains unknown. Analysis of post-mortem human brain and *in vivo* human imaging studies in schizophrenia have detected abnormalities within hippocampal subfields: decreased GluN1 within the dentate gyrus (DG), along with increased synaptic plasticity markers in CA3 and increased *in vivo* basal activity within CA3/CA1 which correlates with psychosis severity. We have previously demonstrated in mice that CA3 hyperactivity is sufficient to induce psychosis-like behaviors. However, the mechanism underlying the induction of this hippocampal hyperactivity remains unclear. We hypothesize that decreasing DG granule cell activity in mice would result in a replication of both the brain pathology associated with psychosis, i.e., increased basal activity and synaptic markers in CA3, and a psychosis-like behavioral phenotype. Moreover, as psychosis tends to emerge during adolescence, we believe adolescent, as opposed to adult mice, will be particularly susceptible to the hippocampal dysfunction. To address this, we infused male adult and adolescent C57BL6/J mice (n >6/group) with AAVs containing either DREADDs or a control virus to specifically inhibit DG granule cells. Following surgery, we chronically treated mice with the DREADD ligand Compound 21, assessed basal activity in the hippocampal subfields through expression of cFos, measured synaptic markers with Western blotting, and performed behavioral analysis, utilizing paradigms associated with a psychosis-like phenotype in mice: prepulse inhibition, fear conditioning, and social memory. Scientific rigor was ensured by repeating each experiment in multiple cohorts of mice, and analyses were performed using automated methodology when possible, to eliminate experimental bias. Results suggest that decreasing DG activity increases hippocampal activity regardless of age, but adolescent mice show molecular alterations at the MF-CA3 synapse, as well as a psychosis-like behavioral phenotype. These results suggest a critical period during which DG dysfunction can cause pathological and behavioral effects suggestive of psychiatric illness.

Title: Possible mild mitochondrial uncoupling and normal leak activity, with increased striatal complex I-II oxygen consumption in males in a murine, juvenile, two hit model of schizophrenia

Authors: O. HUBERT[1], C. MAURICE-GELINAS[1], P. SARRET[3], ***S. GRIGNON**[2]; [1]Pharmacology/Physiology & Psychiatry, [2]Psychiatry & Pharmacology/Physiology, Univ. De

Sherbrooke, Sherbrooke, QC, Canada; [3]Pharmacology/Physiology, Philippe Sarret, Sherbrooke, QC, Canada

Abstract: Schizophrenia is a chronic disorder involving among others, mitochondrial abnormalities. We have previously shown an increase in complex I and complex II-induced respiratory activity (IRA) in a murine, juvenile, two hit (maternal immune activation + adolescent restraint stress) model of schizophrenia (THMS). To gain further mechanistic insight, we present here the results of the concomitant determination of ATP levels and the expression levels of proteins relevant to mitochondrial function, including uncoupling proteins (UCP) 2 and 4. The tryptophan metabolite and NMDAR antagonist, kynurenic acid, provides an interesting connection between inflammatory/oxidative status and neurochemical function and is increased in schizophrenia. Hence, we also report on the effects of 1 methyl-DL-tryptophan (1MT), an inhibitor of the kynurenine rate-limiting indoleamine 2,3-dioxygenase. Methods Mitochondrial O_2 consumption and ATP production were measured from mitochondria isolated from the striatum with MitoXpress and Invitrogen kits, respectively. Control or THMS mice were treated with vehicle or 1MT. Leak activity (glutamate-malate (G-M) + succinate (S) + ADP + oligomycin), complex I (G-M + ADP) and complex II (G-M+ S + rotenone + ADP) IRA and ATP production were measured. Results In line with our previous results, we confirmed *an increase in complex I+II IRA in the THMS male striatum (+46%; p<0.05)*. ATP production was not significantly different in the THMS. *The ATP/ (O_2 consumption) ratio for complex I+II IRA was decreased by 34.2% (p=0.02) in THMS mice*. 1MT was devoid of significant effects in the male striatum under our conditions, on O_2 consumption and ATP production. Complex I+II IRA and ATP production in the presence of oligomycin (leak activity) did not differ between the two groups. OXPHOS proteins, UCP2 and UCP4 levels were unchanged. Discussion We confirmed a robust increase in complex I-II IRA in the striatum in male THMS mice, without a parallel increase in ATP production, which is compatible with the pattern of "mild uncoupling" elicited, among others, by UCP proteins; however, UCP2 and UCP4 levels were unchanged. Further work addressing other proteins involved in mitochondrial uncoupling (UCP5, ANT) and the post-translational modulation of UCPs, might provide further mechanistical insights.

Title: Chronic psychosocial stress during pregnancy affects maternal behavior and neuroendocrine function and modulates hypothalamic CRH signaling pathway

Authors: *S. ZOUBOVSKY[1], S. HOSEUS[1], J. SCHULKIN[2], L. MUGLIA[3];
[1]Univ. of Cincinnati, Cincinnati, OH; [2]Dept. of Neurosci., Univ. of Washington, Seattle, WA;
[3]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Postpartum depression (PPD) affects up to 20% of women and exerts adverse consequences on mother and child. Stress and abnormalities in neuroendocrine function have been associated with PPD. Here, we measured effects of chronic psychosocial stress during pregnancy (CGS) on maternal behavior and postpartum hypothalamic-pituitary-adrenal (HPA) axis regulation. From gestational day 6.5 to 17.5, pregnant C57Bl/6 female mice were exposed to a novel chronic stress paradigm consisting of variable psychosocial stressors and were assessed from postpartum day 2 to 7 for behavioral alterations as well as circadian and acute stress associated glucocorticoid (CORT) response. mRNA changes in molecular regulators of the HPA axis were measured in 1 mm punches of the hypothalamic paraventricular nucleus (PVN) via qPCR. Offspring were also assessed for behavioral changes at postnatal day 28. After undergoing CGS during pregnancy, mice exhibited deficits in maternal care, a depressive-like phenotype, and anxiety. Abnormalities in the activity of the maternal HPA axis were measured as seen by a flattening of the circadian rhythm of CORT secretion, CORT hypersecretion following 20 minutes of restraint stress, and increased adrenal gland weights. These changes were associated with an upregulation of PVN corticotropin releasing hormone (CRH) mRNA and decreased CRH receptor 1 compared to non-stressed control dams, while vasopressin and oxytocin levels remained undisturbed. Furthermore, PVN glucocorticoid receptor (GR) and progesterone receptor (PR) mRNA were downregulated, and FKBP5 mRNA, a co-chaperone known to negatively orchestrate GR/PR transcriptional activity, was increased during the peripartum period. Behavioral alterations were also observed in CGS female offspring only, including a decrease in time spent immobile and in frequency of immobility episodes in the forced swim test, suggesting an impulsivity-like phenotype. These results implicate maternal hypothalamic changes in GR/PR signaling pathway as putative regulators of postpartum changes in CRH after stress and in maternal affective dysregulation. They further suggest sex-specific differences in alterations in neurodevelopment after exposure to elevated maternal CORT levels due to CGS. Transcriptional profiles in brain regions known to play essential roles in mood regulation are currently being generated in order to gain better insight into the neurobiological pathways that become dysregulated following CGS. Furthermore, sex-specific differences in placental metabolism and fetal exposure to CORT are being investigated.

Title: Olanzapine and clozapine differentially influence behavior in GluN1 DG-specific KO mice

Authors: *F. DYBOWSKI[1], C. A. TAMMINGA[2];
[1]Psychiatry, UT Southwestern Med. Ctr., Dallas, TX; [2]Psychiatry, Univ. of Texas Southwestern Med. Ctr. at Dallas, Dallas, TX

Abstract: Psychosis, a predominant symptom domain of schizophrenia, has been characterized in human *in vivo* imaging and post-mortem studies by decreased hippocampal GluN1 expression in dentate gyrus (DG), CA3 subfield hyperactivity and increased synaptic plasticity markers. Thorny excrescences (TE) constituting the mossy fiber-CA3 synaptic connections have been deemed a tunable gain control of excitatory input and were found increased in post-mortem studies. We hypothesize that drug treatment may reverse the CA3 subfield hyperactivity and abnormal TE morphology, which could lead to reversal of psychosis-like behavioral phenotypes. In order to test that, we administered clozapine and olanzapine to male GluN1 DG-specific knock-out (at least 4 months old) mice. As a measurable output, we looked at the morphology of TEs and performed a battery of behavioral tests with N>8/group. The behavioral test battery consisted of open field test, object location and recognition memory, social recognition memory, pre-pulse inhibition, contextual and cued fear conditioning. Golgi-Cox staining or AAV-GFP infusion was used to analyze the morphology of TEs and measure their total area. We have found that clozapine and olanzapine have different influence on behaviors listed above. These experiments, which are still ongoing, will provide a broad perspective regarding the antipsychotic mechanism underlying current pharmacotherapies and may suggest novel targets for emerging drugs.

Title: Novel insights into purinergic P2X4-dopamine D2 receptor interaction in regulation of sensorimotor gating and underlying signaling molecules: A potential mechanism underlying psychiatric disorders

Authors: *S. KHOJA[1], L. ASATRYAN[2], M. W. JAKOWEC[3], D. L. DAVIES[4];
[1]Titus Family Dept. of Clin. Pharm., [2]Sch. of Pharm., [3]Neurol., [4]Titus Family Dept of Clin. Pharm., USC, Los Angeles, CA

Abstract: Sensorimotor gating is the process of filtering out trivial sensory information from salient ones in order to efficiently navigate in a stimulus-laden environment. Sensorimotor gating deficits have been linked to psychiatric disorders characterized by cognitive deficits including schizophrenia, bipolar disorder and autism. Current anti-psychotics have shown limited effectiveness in treating patients with cognitive deficits. Considering that sensorimotor gating deficiencies could be a predisposing factor to poor cognitive functioning, elucidation of mechanisms of sensorimotor gating could lead to identification of novel drug targets for treatment of cognitive deficits. To this end, we have reported a role for purinergic P2X4 receptors (P2X4Rs) in sensorimotor gating using prepulse inhibition (PPI) of acoustic startle reflex as an operational measure. P2X4Rs are ion channels gated by adenosine-5'-triphosphate (ATP) in the brain. Positive modulation of P2X4Rs by ivermectin (IVM) induced deficits in PPI in a P2X4R-dependent manner. Additionally, P2X4R knockout (KO) mice exhibited PPI deficits that were restored upon dopamine (DA) D2 receptor antagonism, supporting a role for DA D2 receptors in P2X4R-mediated PPI disruption. However, unrecognized compensatory changes induced by gene deficiency may undermine this novel interaction. To pharmacologically investigate the P2X4-D2 interaction, we tested the effects of the D2 receptor antagonist, raclopride (3 mg/kg) and the D2 agonist, quinpirole (0.1mg/kg) in regulation of IVM-mediated effects on PPI. From a mechanistic standpoint, we tested the effects of raclopride on phosphorylation of signaling proteins underlying PPI regulation including dopamine and cyclic-AMP regulated phosphoprotein of 32kDa (DARPP-32), Ca^{2+}/calmodulin kinase II (CaMKII) and neuronal nitric oxide synthase (nNOS) in the ventral striatum, a critical brain region underlying PPI function. We found that raclopride significantly reversed IVM-mediated PPI disruption whereas quinpirole synergistically augmented the PPI disruptive effects of IVM. At the molecular level, raclopride significantly blocked IVM-mediated increase in DARPP-32 phosphorylation and decrease in CaMKII phosphorylation, thus providing a mechanistic explanation for changes at the behavioral level. Collectively, these findings suggest that P2X4Rs- D2 receptor interaction is important for normal PPI functioning and that disruption of this interaction could lead to gating deficits which can result in fragmentation of cognitive behavior.

Title: Modulation of brain networks by continuous theta burst stimulation in Mal de Debarquement syndrome

Authors: *Y. CHEN[1], D. GLEGHORN[3], B. DOUDICAN[3], Y.-H. CHA[3], L. DING[2], H. YUAN[4];
[2]Stephenson Sch. of Biomed. Engin., [1]Univ. of Oklahoma, Norman, OK; [3]Laureate Inst. of Brain Res., tulsa, OK; [4]Stephenson Sch. of Biomed. Engin., Norman, OK

Abstract: Repetitive transcranial magnetic stimulation (rTMS) has been increasingly explored in treating many neuropsychiatric conditions. However, the response is heterogeneous across patients, mainly due to limited understanding about the mechanisms of rTMS. Our research has been focusing on optimizing rTMS treatment for a balance disorder called Mal de Debarquement Syndrome (MdDS), a motion perception disorder caused by entrainment to background oscillating motion. Our previous work based on functional magnetic resonance imaging (fMRI) and electroencephalography (EEG) have both revealed the important role of the default mode network (DMN) related to treatment responses. Using prior fMRI and EEG data that suggested targeting of the posterior DMN, we used a rapid form of rTMS called continuous theta burst stimulation (cTBS) as a potentially more efficient method to desynchronize the posterior DMN. Targets included the occipital cortex, cerebellar vermis, and lateral cerebellar hemispheres. In this study, independent component analysis (ICA) was run on concatenated clean EEG sources. The derived EEG connectivity maps were then compared with the clinical score changes after cTBS. As a result, the DMN was identified in the EEG connectivity maps of the participants (n = 24). We confirmed that a decrease of symptoms in positive responders was associated with a decrease in connectivity within the DMN as measured by EEG. Furthermore, baseline

connectivity was negatively correlated with symptom changes in positive responders in both the left and right parietal lobules (i.e., higher baseline connectivity, better clinical response). Our results confirmed the significant contribution of DMN nodes in MdDS and TMS treatment mechanisms. Moreover, the cTBS protocol applied in this study took much less time and yielded larger treatment magnitudes than a prior 1Hz-10Hz rTMS protocol over the dorsolateral prefrontal cortex. This study suggests that baseline brain imaging with EEG holds promise in the development of more effective stimulation protocols for patients.

Title: The effect of traumatic brain injury on p300 amplitudes in impulsive vs. non impulsive antisocial personality disorder

Authors: *A. PEREZ CORTEZ[1], R. A. SCHUG[2];
[1]Dept. of Psychology, [2]Sch. of Criminology, Criminal Justice, and Emergency Mgmt., California State University, Long Beach, Long Beach, CA

Abstract: A predominant symptom of antisocial personality disorder (ASPD) is impulsivity, frequently associated with deleterious effects upon individuals and society. Reactive crime as a result of impulsive and reckless behavior has been identified as a large portion of convictions for people with ASPD. Few attempts have been made to validate diagnostic measures with more objective data from methodologies such as neuropsychological and electroencephalography (EEG) measures. Impulsive behavior may be attributed to impairments in the orbitofrontal region and measured using electrodes FP1 and FP2. Moreover, it may be that not all individuals with ASPD display impulsivity, raising the question of possible impulsive variants marked by deficits in orbitofrontal functioning as indicated by reduced performance on neuropsychological and EEG measures. The present study sought to identify a potential impulsive subtype of ASPD (ASPD-I) and substantiate traditional diagnostic measures with neuropsychological performance data. Adult males (n = 60) recruited from a large-city rescue mission were evaluated for ASPD using the Structured Clinical Interview for DSM-5 Personality Disorders (SCID-5-PD). To empirically assess for impulsive behaviors, a composite z-score of combined scores from Porteus Maze Test, Iowa Gambling Task, and a Go/No-Go Task was computed and used to assign

participant cases into quartiles, transforming a continuous variable into categorical as a way to evaluate a range within our sample. A 2 (ASPD: Absent, Present) x4 (Quartile groups for Impulsivity) between-subjects ANCOVA was used to examine average amplitudes at frontal lobe sites while controlling for number of past traumatic brain injuries (TBI). Main effects for ASPD and impulsivity were found on several electrode sites, while the simple effect of impulsivity for the ASPD present condition supported our hypothesis for physiological variance in impulsivity within ASPD. In some electrode sites, a curvilinear relationship was found where the most impulsive people in the sample were not found to be different from controls, but those in the middle two groups were significantly different from controls. Because TBI was a significant covariate for only one electrode site, it may not have influenced brain activity as an anatomical barrier despite previous literature suggesting otherwise. Understanding the variability within this disorder may assist in identifying a more functional form of ASPD that has been overlooked in previous research. Future research should explore psychosocial factors that influence magnitude differences of impulsive presence.

Title: miR-19b is increased in peripheral blood of schizophenic patients and affects proliferation and survival of hippocampal neural progenitor cells

Authors: *S. BOKU[1], T. HORAI[2], S. OKAZAKI[2], I. OTSUKA[2], K. MOURI[2], A. HISHIMOTO[2];
[2]Dept. of Psychiatry, [1]Kobe Univ. Grad. Sch. of Med., Kobe, Japan

Abstract: MicroRNAs (miRNAs) have been investigated in neurodevelopmental and psychiatric disorders including schizophrenia (SZ). Previous studies showed miRNAs dysregulation in postmortem brain tissues and peripheral blood of SZ patients. These suggest that miRNAs may play a role in the pathophysiology of SZ and that miRNAs may be a potential biomarker of SZ. Previous studies also showed that miRNAs regulate neurogenesis and that neurogenesis is involved in the pathophysiology of SZ. In addition, a recent study showed that miR-19a and 19b, which are enriched in neural progenitor cells (NPC) in adult hippocampus, are increased in human NPC derived from induced pluripotent stem cell (iPSC) derived from SZ patients. However, it remains unclear whether the expression of miR-19a and 19b are altered in peripheral blood of SZ patients and how miR-19a and 19b affects neurogenesis. To elucidate them, first we examined the levels of miR-19a and 19b in peripheral blood of SZ patients with quantitative RT-

PCR and showed that the level of miR-19b, but not miR-19a, was significantly higher in peripheral blood of SZ patients than that of healthy controls. Next, we examined the involvement of miR-19b in proliferation and survival of mouse neonatal mice hippocampus-derived NPC with BrdU assay and TUNEL assay. The knockdown of miR-19b significantly increased both proliferation and survival of neonatal mice hippocampus-derived NPC. These results suggest that the level of miR-19b in peripheral blood can be a potential biomarker of schizophrenia and that the higher level of miR-19b may increase vulnerability of SZ via attenuating proliferation and/or survival of hippocampal NPC.

Center, Univ. of Southern California, Los Angeles, CA

Abstract: Strong biological markers of psychiatric disorders have not yet been identified. A genetics-first approach that starts with a known etiology may provide insights disrupted biological pathways contributing to complex psychiatric phenotypes, guiding better nosology and future treatments. 22q11.2 deletion syndrome (22q11DS) is among the strongest genetic risk factors for schizophrenia. One in four 22q11DS patients develop schizophrenia, and 60% meet criteria for a neuropsychiatric disorder including autism, anxiety, mood disorders, and/or ADHD. Here we present the largest study of subcortical structure in 22q11DS, comparing patterns of effects across the largest harmonized psychiatric neuroimaging studies ever conducted.

T1-weighted brain MRI scans were acquired at 14 scan sites (22q11DS=533, HC=330), including a subset of matched 22q11DS subjects with psychotic disorder (22q+Psy=64) and without (22q-Psy=64). Gross volume (FreeSurfer 5.3) and two shape metrics quantifying local thickness and surface area were computed bilaterally for the hippocampus, amygdala, thalamus, caudate, putamen, pallidum, and accumbens. Multiple linear regressions were fit for all measures, adjusting for age, age^2, sex, scan site, and intracranial volume, and corrected for multiple comparisons. Spearman rank correlations of effect sizes were used to compare subcortical effects across psychiatric disorders.

The 22q11DS group showed significant alterations in most subcortical structures, with shape analysis revealing complex subfield changes. 22q+Psy subjects generally had lower volumes compared with 22q-Psy. 22q+Psy effects significantly overlapped with alterations in several neuropsychiatric disorders including schizophrenia, major depression, bipolar, and obsessive compulsive disorder (Figure 1).

The significant convergence of effects with other large-scale psychiatric studies, including generally larger effect sizes in 22q11DS and 22q+Psy, lends further support to a genetics-first approach as a powerful avenue to studying mechanisms of psychiatric illness.

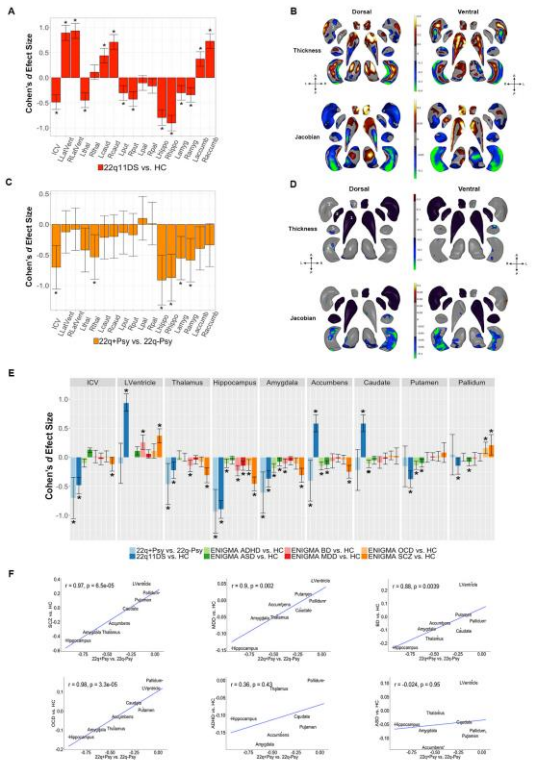

Figure 1. A. Cohen's *d* effect sizes (with 95% confidence intervals) plotted for 22q11DS vs. HC gross volumetric comparison. An asterisk (*) indicates significant group difference after correction for multiple comparisons. FDR corrected P-values<0.05 were considered significant. Models were adjusted for age, age*age, sex, ICV, and scan site. Abbreviations: *L/R*, left/right; *LatVent*, lateral ventricle; *thal*, thalamus; *caud*, caudate; *put*, putamen; *pal*, pallidum; *hippo*, hippocampus; *amyg*, amygdala; *accumb*, accumbens; *ICV*, intracranial volume. **B.** 22q11DS vs. HC shape analysis with regression coefficients plotted in regions passing correction for multiple comparisons (FDR q<0.05). Blue/green colors indicate negative coefficients, or regions of lower thickness (i.e., local radial distance) or Jacobian (i.e., local surface area contraction) measures in 22q11DS compared to HC. Red/yellow colors indicate positive coefficients, or regions of greater thickness or Jacobian values in 22q11DS comared to HC. The top row includes local thickness results; the bottom row includes Jacobian (surface area dilation/contraction) results. Dorsal and ventral views of the structures are provided: A, anterior; P, posterior; L, left; R, right. 1. Caudate; 2. Putamen; 3. Globus Pallidus; 4. Hippocampus; 5. Amygdala; 6. Thalamus; 7. Nucleus Accumbens. Gray regions indicate areas of no significant difference after correction for multiple comparisons. **C.** Cohen's *d* effect sizes (with 95% confidence intervals) plotted for 22q+Psy vs. 22q-Psy gross volumetric comparison. Asterisk (*) indicates significant group difference after correction for multiple comparisons. Models were adjusted for age, age*age, sex, and scan site. **D.** Shape analysis comparing 22q+Psy vs. 22q-Psy with regression coefficient values plotted in regions passing correction for multiple comparisons (q<0.05) with same color scheme as in part B. Black structures are those for which no vertexwise test was significant after correction for multiple comparisons. **E.** Gross volume case-control Cohen's *d* effect size estimates from the ENIGMA schizophrenia (N=4,568; van Erp 2016), major depressive disorder (N=8,927; Schmaal 2016), bipolar disorder (N=4,304; Hibar 2016), obsessive compulsive disorder (N=2,967; Boedhoe 2016), autism spectrum disorders (N=3,222; van Rooij 2018), and attention deficit hyperactivity disorder (N=3242; Hoogman 2017) Working Group Studies, which all used harmonized processing and analysis methods to the current 22q11DS study. Significant case-control differences are indicated by (*), including 95% confidence intervals from original study publication. Note that the ENIGMA ADHD group did not assess lateral ventricle volume in their subcortical study. **F.** Spearman rank correlations between 22q+Psy vs. 22q-Psy gross volume effect size estimates and those from other ENIGMA working groups (8 ROIs: lateral ventricle, amygdala, hippocampus, thalamus, caudate, putamen, pallidum, and nucleus accumbens). Significant correlations were found between 22q+Psy and the ENIGMA schizophrenia, major depressive disorder, bipolar disorder, and obsessive compulsive disorder Working Group Studies.

Title: Brain response on game craving according to personal preference for games

Authors: *J. HA[1,2], L. KIM[1];
[1]Ctr. for Bionics, Korea Inst. of Sci. and Technol., Seoul, Korea, Republic of; [2]Dept. of Biomed. Engin., Univ. of Hanyang, Seoul, Korea, Republic of

Abstract: Nowadays, Internet gaming disorder (IGD) is very popular issues especially for adolescents. The fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) published by the American Psychiatric Association in 2013 says that IGD is a condition for further study. Recent studies have demonstrated that neurofeedback training helps addiction patients to improve mental health and control cravings. Accordingly, the effective way to induce craving is very important for the study on game craving. However, most of previous studies did not consider subjects' preference of games presented as stimuli that could affect to craving response. In this study, we hypothesized that there will be difference of brain activity between preferred and non-preferred gameplay videos when subjects are exposed to the videos. We compared self-reported craving score and electroencephalogram (EEG) pattern between preferred and non-preferred gameplay video for both IGD and healthy control (HC) groups. We recruited a total of 62 adolescent/late-adolescent males (age: 19.31 +- 2.51 years) participate in our experiment. All participants were classified into IGD and HC group according to the score of Korea version of Young's Internet addiction test (Y-IAT-K) (Young et al.,1998; Kim et al., 2003). The IGD group were 21 young adults (Y-IAT-K score > 60) and the HC group were 20 young adults (Y-IAT-K score < 40). We measured EEG of all participants while they were watching preferred and non-preferred gameplay videos. After each videos were over, they conducted self-assessment to report the level of game craving. Craving scores for preferred gameplay videos were significantly higher than non-preferred gameplay video in the IGD, but not in the HC. For the brain activity, the IGD group for preferred gameplay video exhibited significantly increased relative delta power and decreased alpha/beta power on anterior and posterior area of the brain compared to non-preferred gameplay video. However, there was no change on the same band and area in the HC group. Previous studies discussed that increase of

low frequency band power of EEG and decrease of high frequency band power in anterior and posterior areas was relevant to craving (Liu et al., 1998; Kim et al., 2003; Reid et al., 2006). In this study, we found that the preference of games presented as stimuli has a strong influence on both self-reported craving score and EEG pattern. These results indicate that that preferred games could be stimuli to elicit game craving more effectively than non-preferred games in the IGD group.

[1]State Key Lab. of Cognitive Neurosci. and Learning & IDG/McGovern Inst. for Brain Research, Beijing Normal Univ., Beijing, China; [2]Peking Univ. Sixth Hospital/ Inst. of Mental Hlth., Beijing, China

Abstract: Attention-deficit/hyperactivity disorder (ADHD) is a brain disorder marked by an ongoing pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development. As an emerging portable and non-invasive technology, functional near-infrared spectroscopy (fNIRS) has been applied to a number of brain neuroimaging studies, but little is known whether brain differences between ADHD and healthy control (HC) can be found by resting-state fNIRS imaging. The aims of the present study were to explore: 1) whether there are differences between ADHD and HC in brain functional connectivity (FC) and network efficiency. 2) whether there is relationship between the brain FC and network efficiency and clinical characteristics in ADHD. In the present study, we calculated FC, global and local network efficiency based on binary brain networks and compared group differences between 30

ADHD boys and 30 age-matched HC using network-based statistics. We found that the mean FC pattern of ADHD children exhibited lower values than that of HC and more specifically, ADHD showed decreased FC values in almost all brain functional networks, especially in frontoparietal and visual network. At network level, global efficiency of ADHD was significantly lower than that of HC while at nodal level, some nodes were found to have increased nodal efficiency but some were just the opposite in ADHD group. We also found that the changes of FC values negatively correlated with the inattention and hyperactivity/impulsivity symptoms in ADHD ($p<0.05$), suggesting the occurrence and development of disease is accompanied by a reduction in brain FC. These results may benefit a lot for finding biomarkers for ADHD children, and fNIRS may become an assistant for ADHD diagnosis.

Title: Elevation of complement pathway-related transcripts in midbrain in schizophrenia cases who display cytokine-related high inflammation profiles

Authors: T. D. PURVES-TYSON[1,2], ***D. A. ROTHMOND**[1], K. ROBINSON[1], C. SHANNON WEICKERT[1,2];
[1]Schizophrenia Res. Lab., Neurosci. Res. Australia, Randwick, Australia; [2]Sch. of Psychiatry, Univ. of New South Wales, Randwick, Australia

Abstract: Introduction: Neuroinflammation contributes to the pathophysiology of schizophrenia and the complement system has been implicated. In ~50% of people with schizophrenia, pro-inflammatory cytokine transcripts are elevated in postmortem midbrain. It is unknown whether molecular measures of the complement system are changed near dopamine cell bodies in the midbrain in schizophrenia. We hypothesised that gene expression of complement initiator C1qA, effectors C3 and C4, and regulators decay-accelerating factor (DAF/CD55) and MAC-IP (membrane attack complex-inhibitory protein /CD59), will be elevated in the midbrain in schizophrenia cases exhibiting high inflammation. Methods: C1qA, C3, C4, DAF and MAC-IP mRNAs were examined by qRT-PCR in the midbrain from 28 schizophrenia cases and 29 healthy controls. Three diagnosis/inflammatory subgroups (controls/low inflammation

schizophrenia/low inflammation, schizophrenia/high inflammation) were previously defined using cluster analysis of pro-inflammatory transcripts. Student's t-tests or ANCOVA, with demographic variables as covariates when required, were used to detect diagnostic differences and differences between inflammation/diagnosis subgroups. Spearman's correlations were used to determine relationships between illness duration, antipsychotics, immune cell gene expression and complement gene expression. Results: C1qA, C3, C4 and MAC-IP mRNAs were increased between 37%-107% in the schizophrenia/high inflammation subgroup compared to both low inflammation subgroups ($F>5.51$, $p<0.05$), while DAF mRNA was unchanged ($p>0.05$). No transcript correlated with illness duration but C1qA, C3 and C4 mRNA positively correlated with daily CPZ equivalents ($Rho>0.44$, $p<0.05$). Complement gene expression was strongly and positively correlated with gene expression of markers of microglia (AIF), astrocytes (GFAP) and macrophages (CD163) in schizophrenia cases. Conclusions: Increased complement cascade synthesis may be a component of the state of increased inflammation in some schizophrenia cases and contribute to midbrain pathophysiology. Increased complement transcripts correlate with glial cells, including microglia and astrocytes, and one immune cell marker for macrophages. Increased MAC-IP supports that resident neurons or cells in midbrain may be attempting to protect themselves against increased complement activity. While the role of antipsychotics in complement activation cannot be ruled out, the increased antipsychotics in those patients with higher inflammation and complement could also indicate a more symptomatic patient requiring higher treatment doses.

Title: Transcranial direct current stimulation reduced food craving and nucleus accumbens response to high calorie food cues among individuals with obesity

Authors: M. LEE[1], K. LEE[2], J.-C. KIM[1], H.-M. BAEK[3], *H. CHOI[1];
[1]Dept. of Anat., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of; [2]Dept. of Psychiatry, Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of; [3]Korea Basic Sci. Inst., Ochang, Korea, Republic of

Abstract: Previous studies have reported that individuals with obesity tend to be more sensitive to reward stimuli such as high calories foods. Obese people also show greater reward-related circuit response to food pictures because they may be more rewarded by food cues. Transcranial

direct current stimulation (tDCS) is a neuromodulation technique that shown to be effective to reduce food craving and consumption. The present study aimed to investigate the tDCS effects on neural and behavioral response involved in eating. Method: Fourteen obese adults participated in this study (4 female, BMI=29.63±1.16, age=29.53±12.65). This study employed a single-blind sham-controlled within subjects crossover design in which all participants received real and sham tDCS. An intersession interval was at least two weeks for avoiding any carryover effects due to stimulation. Visual analogue scales (1-10 score) related to food craving were measured before and after tDCS session, respectively. All participants were scanned while they were viewing 100(50 high-calories food/50 low-calories food) picture stimuli during an fMRI assessment. ROI analysis was conducted using a pre-determined region of interest (ROI), especially the nucleus accumbens(NAcc) implicated in reward and motivation processing. Parameter estimates of the high vs. low contrast image were extracted from the NAcc ROI. Paired t-tests on behavioral ratings (e.g., fullness) and neural activation (i.e., NAcc response to high-calories vs low-calories food pictures) were used to compare the real vs. sham tDCS sessions. Results:There were statistically significant differences in the fullness score ($t(10)=2.246$, $p<0.05$) between real and sham stimulation. Food preference score for high calorie-food that acquired in scanner was not different between real and sham tDCS condition($t(13)=-1.309$, p=,213). RoI analysis revealed that left accumbens area activity for high-calories food is greater after the sham tDCS session than real session ($t(12)=-2.555$, $p=.025$). However, there was statistical correlation with right NAcc activation and food preference rating for each of food cues($r=.592$, $p<.05$). Conclusion: Brain stimulation with tDCS modulated eating behaviors and NAcc activation. Our study implies that the brain stimulation with tDCS represents a promising option for treating obesity in humans by modulation of neural circuits associated with reward and motivation in response to food cues.

Title: Forests and brain health: Emerging benefits

Authors: *S. A. MASINO;
Trinity Col., Hartford, CT

Abstract: Forests are essential. They emerged more than 300 million years ago and are incredibly resilient - they have recovered from catastrophic volcanic eruptions, ice ages, and meteor strikes. Forests offer exercise, solace, medicines and biodiversity; new species, potentially the source of new medicines, are still being discovered. Furthermore, natural climate solutions are essential in mitigating climate change and the biggest potential for additional negative carbon emissions lies in forest-based sequestration. To this end, proforestation is a purposeful policy that maximizes natural climate solutions by growing existing forests to take full advantage of many ecosystem values - biological carbon sequestration, flood resilience, biodiversity, and health - including brain health. Unlike more common forest-based strategies to combat climate change, i.e. afforestation and reforestation, proforestation does not require significant additional land, time, money or labor to yield immediate and lasting benefits to the planet and to people. The brain health benefits of proforestation are expected to increase significantly in the coming decades, and the National Health Service has a motto “growing forests for health.” With this in mind, the positive impact of forests on brain health cannot be overlooked: we face increasing costs for disorders ranging from Alzheimer’s disease to addiction. Lifestyle modifications are effective and successful, and forests offer co-benefits of exercise, mindfulness, stress reduction and more - naturally. Here we review recent quantitative research on benefits in healthy people and special populations, such as U.S. veterans and at risk teens, and identify strategies for combining proforestation with brain health benefits in communities across the country. In the U.S. one option is the Old Growth Forest Network, a national network of more than 90 protected native forests in 22 states. Future research should focus on gaps in understanding and on identifying more intact protected forests across the landscape to optimize forest-based brain health benefits and benefit current and future generations.

Center, Univ. of Maryland Sch. of Med., Catonsville, MD; [9]Dept. of Psychiatry, Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Despite progress from large genome-wide association study (GWAS) consortia, common risk variants for schizophrenia (SCZ) have proven difficult to follow up for biological and clinical translation, primarily due to their small effects. The discovery of rare variants with large effects on neuropsychiatric disease risk has gained momentum through sequencing studies. The first gene implicated and replicated by exome sequencing in SCZ is a chromatin remodeling gene called SET Domain Containing 1A (*SETD1A*). Many distinct rare loss-of-function and missense variants in *SETD1A* collectively confer substantial risk for SCZ. SETD1A is a histone methyltransferase, responsible for methylation of lysine 4 on the histone 3 tail (H3K4me3), an important marker of active promoters and enhancers. However, the mechanisms by which *SETD1A* variants lead to SCZ risk are unknown. Here, we integrated multiple cutting-edge technologies to trace molecular, cellular, neurodevelopmental, neuroimaging, and neurocognitive consequences of rare *SETD1A* variants. Our analyses of publicly available and newly generated RNA-seq and single-cell RNA-seq data from the developing and adult human cortex revealed that *SETD1A* is most highly expressed during mid-fetal brain development, specifically in radial glia, the neural stem cells (NSCs) that give rise to cortical excitatory neurons (ENs). CRISPR/Cas9 knockout of *SETD1A* in human embryonic stem cells (hESCs) revealed increased apoptosis and decreased proliferation. RNA-seq analysis of *SETD1A* knockout hESC-derived NSCs revealed that *SETD1A* is required for the expression of a gene module that *in vivo* is expressed in proliferative NSCs early in brain development. We hypothesized that *SETD1A* variants cause decreased proliferation of radial glia *in vivo*, which would result in reduced numbers of cortical ENs. Consistent with the hypothesis, data from the UK Biobank and Amish Connectome Project revealed that protein-coding variants in *SETD1A* are associated with decreased cortical thickness, a well-known deficit in SCZ cases, as well as deficits in cognition. Overall, our results suggest a critical role for *SETD1A* in the development of the human cortex and support a causal path from gene to brain to behavior underlying SCZ risk.

Title: Alteration in resting-state functional connectivity of the anterior cingulate cortex in individuals with greater lifetime history of aggression

Authors: M. GOTRA[1], *S. KEEDY[2], J. WREN-JARVIS[2], R. LEE[2], E. F. COCCARO[3]; [1]Psychology, Rosalind Franklin Univ. of Med. and Sci., North Chicago, IL; [3]Psychiatry and Behavioral Neurosci., [2]Univ. of Chicago, Chicago, IL

Abstract: Background: Aggression and impulsivity have been associated with structural and neurochemical properties of the anterior cingulate cortex (ACC), as well as the amygdala and orbito-frontal cortex. However, no prior work has assessed functional connectivity of these brain areas at rest in relation to aggression. In the present study, we aimed to address this gap, beginning with a focus on the ACC, a node of the default mode network, the most robustly identifiable network in resting state functional magnetic resonance imaging (fMRI) studies. **Methods:** Resting state fMRI and structural T1 weighted images were collected on subjects who were also assessed with the Lifetime History of Aggression (LHA) scale, a commonly used measure of trait aggression. Subjects included those diagnosed with intermittent explosive disorder (IED; n=22) and healthy controls (n=23), allowing for a wide range of LHA scores for the analysis. Mean age was 34.8 years (59% female) for the IED group and 29.6 years (52% female) for healthy controls. Following standard preprocessing, seed-based connectivity maps, with ACC as the seed, were calculated using the CONN toolbox. Regression analyses were conducted using these connectivity maps and scores from the LHA, controlling for age and sex. Significant results were identified at $p < 0.0125$, corrected for multiple comparisons. **Results:** Greater LHA scores were associated with significantly reduced connectivity between the ACC and several other brain regions (no increased connectivity was identified). These regions included the posterior cingulate cortex (PCC), precuneus, a cluster at the left temporo-parietal-occipital junction (angular gyrus, superior occipital cortex, posterior supramarginal gyrus), and the left thalamus. **Conclusion:** Participants with more life history of aggression had weaker connectivity between the ACC and brain regions responsible for sensory and social processing.

Additionally, greater aggression was associated with weaker connectivity in the ACC to the PCC and precuneus, key components of the default mode network. These results suggest that increased lifetime aggression, which characterizes those diagnosed with IED, is associated with dysfunction in key networks associated with stimuli saliency and self-relevant processing, in line with prior studies and expanding the body of knowledge to include alterations detectable in the resting state.

Title: Sensitivity, biases and multisensory integration in the visual and haptic perception of elliptical shapes in patients with anorexia nervosa

Authors: *G. RISSO[1,2], R. M. MARTONI[3], G. CALZONE[3], L. BELLODI[3,4], G. BAUD-BOVY[1,5];
[1]Robotics Brain and Cognitive Sci., Italian Inst. of Technol., Genoa, Italy; [2]Universita' degli studi di Genova, Genoa, Italy; [3]I.R.C.C.S. San Raffaele-Turro, Milan, Italy, Milano, Italy; [4]Fac. of Psychology, [5]Univ. Vita-Salute San Raffaele, Milan, Italy

Abstract: A key feature of Anorexia Nervosa (AN) is a distorted perception of the body shape. Recent studies on Eating Disorders (EDs) showed that AN patients exhibit various sensory and perceptual deficits in the visual and tactile modalities. In this study, we investigated visuo-haptic integration in AN patients using Helbig and Banks (2007)'s paradigm, which allows one to assess the weight given to each sensory modality and whether the two sensory modalities are integrated optimally. The study included three groups of participants: a Healthy Control (HC) group (N=18), a restricting type AN group (N=10), and an intermediate group of individuals with body concerns (assessed with the Body Shape Questionnaire) showing psychological features commonly associated with ED (assessed with the Eating Disorders Inventory 2), with normal BMI and no diagnosis. The stimuli consisted in high-relief ellipses with variable axes lengths. For each participant, we measured the Point of Subjective Equality (PSE), i.e. the eccentricity of the ellipses that were perceived as circular, and the discrimination threshold (DL) between vertically and horizontally elongated ellipses in a haptic condition, a visual condition and three bimodal conditions where the visual and haptic cues could be consistent or not. We found that AN patients discriminated elliptical shapes less precisely than the other groups and that they perceived ellipses as more horizontally elongated than the HCs with the intermediate

group in the middle. Our results confirm that haptic and visual information is optimally integrated in the control group. For the two other groups, the evidence is compatible with the optimal integration and best modality hypotheses. The increase DLs provide support for the idea that the restricted diet of individuals might impair normal function of peripheral sensory apparatus but they do not explain the observed biases when judging the shape of the ellipses. To our knowledge, this is the first study that demonstrates a bias in the perception of the shapes that do not represent body parts in AN.

Title: Neural correlates of emotion regulation in adults with ADHD

Authors: *J. J. CAPELLA[1], Y. HUNG[1], S. D. HOULIHAN[1], R. HOAGLAND[1], M. UCHIDA[2], S. GAILLARD[1], J. D. GABRIELI[1], J. BIEDERMAN[2];
[1]Dept Brain/Cognit Sci., MIT, Cambridge, MA; [2]Massachusetts Gen. Hosp., Boston, MA

Abstract: Attention-Deficit/Hyperactivity Disorder (ADHD) is a lifelong neurobehavioral disorder conventionally characterized by inattentive, hyperactive, and impulsive behaviors. One symptom set, poor emotion regulation (ER), an executive function deficit in regulating negative emotions, has received increasing attention in recent ADHD research. Deficits in ER can lead to significant impairments in the ability to handle daily life stress, resulting in irritability, low frustration tolerance, and emotional outbursts. However, little is known about the neural mechanism and behavioral manifestation of ER in ADHD, particularly for adults. Using multi-modal neuroimaging methods and rigorous behavioral assessments, we aim to provide a neural profile of ER in adults with ADHD. Specifically, we explored the relationship between ER, working memory, and mindfulness in 33 adults with ADHD and healthy age-matched controls. Participants (mean age = 28.0, *SD*=6.9) completed measurements of working memory (CANTAB Spatial Working Memory Task) and mindfulness (Cognitive and Affective Mindfulness Scale, Mindful Attention Awareness Scale, and others). In a functional magnetic resonance imaging (fMRI) session, participants were instructed to actively alter their perception of negative stimuli from the IAPS image set. We obtained functional (fMRI and resting fMRI) and structural (T1 and diffusion tensor imaging) data to provide a full neural profile of ER in

ADHD. Pilot publications and preliminary results indicate activation in the medial and lateral prefrontal cortex (including the anterior cingulate cortex) during reappraisal, as well as an attenuated amygdala response. We hypothesize that this amygdala downregulation is attenuated in participants with ADHD, and other regions may be recruited as compensatory mechanisms. Characterizing the neural response to emotional reappraisal strategies can lead to a better understanding of emotion regulation and its relationship with other functional impairments associated with ADHD. By providing a full neural profile of emotional dysregulation in adults with ADHD, we hope to provide insights for improved clinical assessments and treatment. Understanding the neural mechanisms and behavioral manifestations of ER could lead to improvements in psychotherapy interventions for adults with ADHD, with the ultimate goal of improving the quality of life for this population.

Title: High rates of temporal discounting among individuals with heightened dissociative symptomatology

Authors: *J. C. BASSO, M. K. SATYAL, A. METPALLY, W. K. BICKEL;
Virginia Tech. Univ., Roanoke, VA

Abstract: Dissociative disorders are characterized by an involuntary escaping of reality, whereby the individual feels detached or disconnected from their thoughts, identity, consciousness, or memory. The prevalence of these dissociative states is quite common (approximately 50% of adults in the United States report at least one or more depersonalization/derealization episode in their lifetime); however, the diagnosable disorder occurs in only 2% of the population. Dissociative states often develop in response to traumatic events, with positive associations occurring between symptom levels and number of adverse childhood experiences, especially emotional abuse and neglect. Delay discounting measures the process by which the value of a reward declines as a function of its delay from the present. A high discounting rate indicates an excessive preference for immediately available rewards, and a disregard for future, potentially negative consequences. Individuals with a high rate of discounting show a propensity for a variety of maladaptive health behaviors including drug and

alcohol use, unhealthy eating, physical inactivity, and irresponsible spending. Limited previous research has examined the relationship between discounting rates and affective states, and no studies to date have tested the hypothesis that steeper discounting is related to higher levels of disassociation. Data was collected via Amazon Mechanical Turk from n=221 adults (ages 18 to 45). A 5-trial adjusting delay discounting task was used to assess discounting rate, and the Cambridge Depersonalization Scale was used to assess level of dissociative symptomatology. As hypothesized, higher rates of discounting were associated with greater levels of depersonalization ($r(221)=0.163$, $p=0.007$). This effect was seen across all subscales including anomalous body experience ($r(221)=0.185$, $p=0.003$), emotional numbing ($r(221)=0.156$, $p=0.010$), anomalous subjective recall ($r(221)=0.120$, $p=0.037$), and alienation from surroundings ($r(221)=0.139$, $p=0.019$). Probability discounting, a negative behavioral control, did not show any such associations with dissociative state ($r(221)=0.055$, $p=0.419$). These results suggest that temporal discounting may be one of the psychological mechanisms through which dissociative states operate.

Title: Graph theory analysis of multimodal neuroimaging data in high-functioning adults with autism spectrum disorder

Authors: *R. AYUB[1], R. FLORES[2], L. FUNG[2], M. SAGGAR[2];
[1]Bioengineering, [2]Psychiatry and Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: Complex behavioral abnormalities in Autism Spectrum Disorder (ASD) suggest a disruption in the underlying brain networks. An important question that remains open is whether this disruption is caused by changes in structural connectivity, functional connectivity, or a combination of both. Past neuroimaging studies have found alterations in functional and structural connectivity in subjects with ASD, but they have primarily focused on one neuroimaging modality at a time. It is a well-known fact that both structural and functional connections work together to facilitate cognitive processes, therefore more combined neuroimaging studies are needed for an integrated understanding of brain connectivity. Here, we

conducted a multimodal neuroimaging investigation of high-functioning adults with ASD and age-matched typically developing (TD) controls. Functional networks were created from subjects' (n = 16 ASD, n = 15 TD) resting state functional MRI (rs-fMRI) data by thresholding the ROI correlation matrix at various levels of graph density. Structural networks were similarly created from subjects' (n = 28 ASD, n = 28 TD) tractograms derived from diffusion weighted imaging (DWI) data. Communities in the functional and structural connectome were assigned based on known large-scale resting state networks. We found that TD adults exhibited greater modularity in their functional connectomes than adults with ASD across all graph density thresholds. Interestingly, the structural connectomes showed no statistically significant difference in this same metric. There were no statistically significant differences in the clustering coefficient, global efficiency, and characteristic path length in either the functional or structural connectomes. Our preliminary results suggest that reduced modularity in the functional connectome may suggest a topological reorganization of functional networks in adults with ASD. Lack of group differences in the structural connectome suggest that functional data may be more indicative of changes in brain connectivity in adults with ASD.

Title: OPRM1 genotype-dependent opioid-ethanol interactions in male rhesus monkeys

Authors: J. S. OVERTON, T. PAREEK, J. E. COOK, R. ANTONYRAJ, *D. M. PLATT; Univ. of Mississippi Med. Ctr., Jackson, MS

Abstract: Opiate and alcohol addictions separately are widespread public health problems that are associated with individual differences in opioid neurotransmission. A single nucleotide polymorphism, A118G, in the human mu opioid receptor gene (OPRM1) may change the way in which the endogenous opioid system mediates reward via the mesolimbic circuitry. The 118G variant is linked to higher levels of alcohol-induced euphoria and an increased risk of opiate and alcohol addiction when compared to the A118 variant. A similar polymorphism in rhesus monkeys (C77G) mirrors the human mutation and its corresponding physiological and behavioral phenotypes. There is growing evidence that opioids frequently are co-abused with alcohol and that this polydrug abuse can increase lethality of the individual drugs, as well as

decrease the effectiveness of opioid maintenance therapy. However, the extent to which OPRM1 genotype influences the drug interaction remains unknown. In the present study, male rhesus monkeys genotyped for the C77G polymorphism (N's: 4 C/C; 4 G/G) were given limited, daily, concurrent access to 4% w/v ethanol solution and water under a fixed-ratio schedule. Once daily ethanol intake was stable, monkeys received pretreatments of saline, morphine (0.03-0.3 mg/kg) or fentanyl (0.001-0.01 mg/kg) prior to the session. Compared to vehicle (saline), both opioids failed to enhance ethanol drinking in C/C animals and even suppressed intake at their highest doses. In G/G animals, morphine appeared to enhance ethanol drinking, while fentanyl did not alter consumption. The results indicate a clear effect of genotype in that C/C animals were more sensitive to the suppressing effects of opioids compared to G/G animals. To the extent that the decreases reflect non-specific behavioral effects, this result suggests that these drug combinations would have more severe side effects in A118-carrying humans. In the G/G animals, the results indicate a clear effect of drug on modulation of ethanol consumption. Although the reasons underlying the observed differences are not clear, they could reflect differences in drug efficacy, duration of action, or signaling bias.

Title: A model of chronic voluntary oral oxycodone self-administration in female and male rats

Authors: *G. ZANNI[1], M. J. DESALLE[1], H. M. DETSCH[1], G. KHABIB[1], S. J. SIMMONS[1], A. A. DOUGHER[1], G. A. BARR[1,2], A. J. EISCH[1,3];

Abstract: The opioid abuse epidemic poses major challenges for health and socioeconomic systems. The increased prescription of opioids - such as oxycodone - has fueled diversion of

these medications, increasing the number of people who have access to these highly-addictive drugs. For optimal translational relevance, a preclinical model that recapitulates key aspects of prescription opioid abuse in humans is needed. Here we present a novel oral oxycodone self-administration paradigm in rats that results in voluntary intake, long-term opioid exposure, and measurable levels of dependence and motivation to take drug. Adult male and female Long-Evans rats were given unlimited, home cage access to two bottles: for Control rats, both bottles contained water; for Experimental rats, one bottle contained water with Oxycodone. Virtually all Experimental rats voluntarily drank oxycodone (targeted daily dose: 10 mg/kg/day) and escalated their intake over 22 weeks. Females self-administered twice as much oxycodone as males, leading to greater levels of oxycodone in blood, and engaged in more gnawing behavior. Given the continuous access to oxycodone, it is perhaps not surprising that female and male rats showed no signs of spontaneous withdrawal. However, precipitated withdrawal (naloxone 1 mg/kg) revealed high levels of dependence in both sexes in the total withdrawal score, as well as in individual behaviors, such as burrowing, teeth chattering, high walking, diarrhea, and weight loss (e.g. 4x decrease in females and 2x in males compared to their respective Controls). To assess the motivation to drink oxycodone, citric acid at ascendant concentrations (1, 3, and 5 mM) suppressed the intake of oxycodone (Experimental rats) and the intake of water (Control rats); however Experimental rats returned to pre-citric acid preference levels whereas Controls rats did not. Thus, our model reproduces in female and male rats many of the features of human oxycodone abuse, and provides a paradigm for both understanding mechanisms that mediate long-term voluntary drug use and for exploring potential treatment options.

Title: Balanced opioids provide excellent analgesia and reduced side effects

Authors: *J. L. WHISTLER[1], L. HE[3], S. W. GOODING[2], A. GAUR[1];
[2]Ctr. for Neurosci., [1]Univ. of California Davis, Davis, CA; [3]Unversisty of California Davis, Davis, CA

Abstract: There remains an ongoing debate as to whether “biased” or balanced” agonists at the mu opioid receptor (MOR) will produce analgesics with reduced side effects. Endorphins and enkephalins, the endogenous ligands at the MOR are balanced agonists at the MOR, signaling to G-protein and effectively engaging beta-arrestins. On the other hand, morphine and all its derivatives are significantly biased for G protein signaling. Here we demonstrate that a modified MOR that signals in a “balanced” way to both G-protein and arrestin produces excellent analgesia, reduced analgesic tolerance, reduced physical and affective dependence, reduced ability to promote compulsive drug seeking behavior, and reduced effects on cognitive flexibility after long term abstinence in knock in mice expressing this altered receptor. We also demonstrate that MOR engagement with arrestin does not increase opioid-induced respiratory depression. Taken together these data suggest that “balanced” opioid agonists with a lack of signaling bias that mirrors that of the endogenous ligands could provide excellent analgesia, no increase in respiratory effects and reduced abuse liability.

Title: Per2 influences locomotor sensitization and reward effects against morphine through dopamine transporter and opioid receptor activities in mesolimbic pathways

Authors: *M. KIM, C. BOTANAS, R. CUSTODIO, L. SAYSON, A. ABIERO, H. LEE, J. CHEONG, H. KIM;
Uimyung Reasearch Inst. For Neurosci., Seoul, Korea, Republic of

Abstract: Complex interactions between endogenous and exogenous factors have been proposed to explain the mechanism underlying drug addiction. The genetics underlying circadian rhythms are representations of endogenous factors that influence addiction. Previously, we found that *Per2*-knockout mice and *Per2*-overexpressed mice showed different response towards the rewarding effects of methamphetamine through dopaminergic system in the striatum. Thus, the goal of this study is to investigate the role of *Per2* in drug addiction. We observed locomotor sensitization responses to morphine administration and rewarding effects through a conditioned place preference (CPP) test in *Per2*- knockout (KO) and overexpressed (OE) mice. In addition,

the withdrawal signs were assessed on the 1st withdrawal day after 7 days repeated treatments of morphine. We also investigated the expression levels of opioid receptors (kappa, mu and delta) and dopamine-related genes (DRD1, DRD2, DAT, and TH) in VTA, striatum (NAc), and PFC using qPCR, western blot, and immunofluorescence. *Per2*- KO mice showed increased locomotor sensitization and rewarding effects of morphine compared to WT mice, whereas *Per2*-OE mice showed the opposite. In addition, the results of withdrawal signs were consistent with the behavioral changes in *Per2* KO, OE and WT mice. Moreover, *Per2*-KO mice showed higher expression levels of mu and delta opioid receptors in VTA and lower DAT level in striatum (NAc) than WT mice, while the opposite results were observed in *Per2*- OE mice. Taken together, *Per2* expression level may influence the addictive effects of morphine through mu and delta opioid receptors in VTA and DAT activities in striatum of mice.

Title: Next-gen sequencing of RiboTag mRNA from striatal microglia identifies gene sets associated with morphine escalation and naloxone precipitated withdrawal

Authors: *K. COFFEY, A. J. LESIAK, R. MARX, E. K. VO, J. F. NEUMAIER; Psychiatry and Behavioral Sci., Univ. of Washington, Seattle, WA

Abstract: Many facets of opioid dependence contribute to the clinical and social crisis that we are now facing. In addition to the loss of control over drug use that accompanies extensive exposure to opioids, the severity of withdrawal is a major barrier that stops individuals who would like to discontinue opioids from detoxing. Furthermore, these symptoms can precipitate relapse to drug taking in order to alleviate withdrawal. In this experiment we investigated the contribution of microglia to morphine exposure and naloxone precipitated withdrawal. To accomplish this, we utilized RiboTag, a technique which allows for isolation and analysis of RNA that is actively undergoing translation in a specified set of cells. We used male and female transgenic CX3CR1-Cre/RiboTag mice that express HA-tagged rpl22 exclusively in resident microglia. These mice were administered a rapidly escalating, tolerance inducing, non-contingent morphine schedule (versus saline) followed by naloxone-precipitated withdrawal (versus saline), then at 4 hours after naloxone (or saline) we sacrificed the mice and

immunopurified the ribosome-associated RNA from microglia and then analyzed the RNAs undergoing translation using RNAseq. While there are many individual genes that are differentially expressed during morphine exposure and withdrawal, this report focuses on gene set level changes. Gene set enrichment analysis (GSEA) revealed decreases in genes related to neuronal projection guidance, and increases in genes related to aberrant protein folding after escalated morphine exposure. These results suggest escalated morphine exposure forces microglia to reduce some of their healthy-state roles, like aiding neuronal projections, and increase their role dealing with aberrantly folded proteins. During naloxone precipitated withdrawal, microglia massively increase expression of phosphodiesterases. These changes to the translatome of microglia only represent a very narrow window in time, so a second wave of animals will be run to be sacrificed at varying time points after withdrawal. Animals will be sacrificed at 0, 2, 8, and 24 hours after naloxone precipitated withdrawal, and changes to genes of interest will be quantified using RT-qPCR and in-situ hybridization. Careful analysis of these genes should provide new mechanistic understanding of how microglia respond to opioid withdrawal and could lead to the identification of novel target genes or gene sets for promoting adaptive microglial responses and inhibiting detrimental microglia responses.

Title: Genetic differences in nicotine withdrawal-induced learning deficits and nicotine metabolism across inbred mouse strains

Authors: *S. M. MOONEY-LEBER[1], L. R. SEEMILLER[1], L. R. GOLDBERG[1], P. SMITH[2], Y. TIAN[3], A. PATTERSON[3], G. PELTZ[4], T. J. GOULD[1];
[1]Biobehavioral Hlth., [2]Huck Inst. for the Life Sci., [3]Vet. and Biomed. Sci., Penn State Univ., University Park, PA; [4]Anesthesiology, Perioperative, and Pain Med., Stanford Univ., Palo Alto, CA

Abstract: Nicotine withdrawal produces cognitive deficits and changes in affect, which are associated with an inability to quit. Human studies have shown that these deficits are highly heritable, yet the underlying genetic variants have not been identified. Our lab has previously demonstrated that nicotine withdrawal in mice produces cognitive deficits in fear conditioning.

Here we utilized a comprehensive mouse inbred strain panel to assess the genetic variation associated with nicotine-evoked cognitive deficits. Male mice from 21 inbred strains (C57BL/6J, BALB/cJ, CBA/J, FVB/NJ, NOD/ShiLtJ, A/J, C3H/HeJ, DBA/2J, AKR/J, DBA/1J, 129S1/SvlmJ, SJL/J, SWR/J, LP/J, BTBR T+ ltpr3tf/J, NZB/BINJ, SM/J, MA/MyJ, 129S4/SvJaeJ, 129S8/SvEvNimrJ,129-Elite) received either chronic saline or nicotine (12.6 or 18 mg/kg per day for 12 days) via osmotic minipump, and then were tested for learning deficits using hippocampal-dependent contextual fear conditioning. We identified a significant effect of strain ($F_{17, 465}$ = 73.678, p = 0.0001), and a strain by treatment interaction ($F_{34, 465}$= 1.544, p = 0.028). Moreover, we found deficits in fear conditioning after chronic nicotine in NZB/BINJ (at 12.6 mg/kg/day) and C57BL/6J (at 18 mg/kg/day). Interestingly, we found enhancement of fear conditioning in AKR/J and SJL/J at after chronic treatment with 12.6 and 18 mg/kg/day, both of which could be maladaptive responses. In addition, due to the known role of nicotine metabolism in mediating withdrawal severity, we assessed nicotine metabolism in male C57BL/6J and NOD/ShiLtJ mice by collecting urine and serum after acute nicotine treatment (1 mg/kg). Nicotine metabolites were quantified using liquid chromatography-mass spectrometry (LC-MS), and metabolism-related genes were identified using sequences from Sanger Institute Mouse Genomes Project. C57BL/6J and NOD/ShiLtJ strains had notable differences in nicotine metabolite levels, and non-synonymous mutations were found in *Cyp2f2*, *Aox1*, and *Cyp3a44*. These data demonstrate markedly different responses to nicotine in commonly used inbred mouse strains and provide a foundation for future study of genetic variants underlying cognitive deficits during nicotine withdrawal.

Title: Behavioral response in cocaine-sensitized female rats is related to lower GABA levels in the medial prefrontal cortex

Authors: *L. FREESE[1], M. FRAGA DE SOUZA[1], G. CALETTI[4], M. S. NIN[1,4,6], G. K. CURY[2], V. F. PERES[1], R. GOMEZ[4,5], H. M. T. BARROS[1,3];

Biológicas: Farmacologia e Terapêutica, [5]Dpto de Farmacologia, Univ. Federal do Rio Grande do Sul - UFRGS, Porto Alegre, Brazil; [6]Ctr. Universitário Metodista IPA, Porto Alegre, Brazil

Abstract: Cocaine sensitization is greater in female than in male rats and we found that estradiol enhances this behavioral response (Souza et al, 2014). Here, we investigated the *in vivo* changes in extracellular GABA, glutamate and taurine levels after cocaine sensitization in the medial prefrontal cortex (mPFC) of gonadal intact (SHAM) or ovariectomized (OVX) female rats. Adult (±90 post-natal day (PND)) female Wistar rats were bilaterally ovariectomized or sham-operated and randomly assigned to control (CTR), acute (ACT) or repeated (RPT) cocaine administration (15 mg/kg, i.p.) groups, following the classical model of sensitization. After a 10-day wash-out period and 7 days from stereotaxic surgery to implant a guide-canulae in the mPFC, the ACT and RPT groups received a challenge dose of cocaine (15 mg/kg, i.p.). Locomotion was monitored and microdialysis was conducted over 2.5 h to determine extracellular GABA, glutamate and taurine levels. The major finding is that SHAM-RPT group demonstrated behavioral sensitization, and correspondingly did not show a peak of GABA efflux at 30 min At the same time, OVX-RPT rats did not show sensitization and showed a peak of GABA efflux at 30 min. The sham group did show a delayed and permanent increase in GABA efflux and this effect was not mechanistically related to the behavioral response. Acute and repeated cocaine administration increased taurine at 60 min in SHAM and OVX, respectively. In addition, changes in glutamate were measured, and the delayed increase levels only in the ACT-OVX group were observed. The current data do not support a role for a cocaine-mediated stimulation of excitatory transmission within the mPFC via glutamate in the development of behavior sensitization in female rats. Thus, this aspect still needs to be better elucidated. The decrease in GABA levels in the mPFC of SHAM rats was related to a suppression of cocaine sensitization behavior and this effect seems to be dependent of estrogen. The taurine response in the OVX-RPT showed a later and shorter direction of changes, similar to the GABA. The gender difference of the neurobiological basis for the cocaine sensitization is still poorly characterized and these data are the first to typify the levels of some important neurotransmitters in sensitized-female rats.

Title: Effects of environmental enrichment on behavioral measures of sensation/novelty seeking in inbred Fischer 344 and Lewis rats

Authors: *K. ISHIWARI[1], O. POLESSKAYA[2], A. A. PALMER[2], J. B. RICHARDS[1];
[1]Pharmacol. & Toxicology, Univ. at Buffalo, Buffalo, NY; [2]Psychiatry, UCSD, La Jolla, CA

Abstract: Sensation/novelty seeking (SNS) is a heritable trait and a vulnerability factor for drug abuse. Inbred Fischer 344 (F344) and Lewis (LEW) rats have been used as a model of genetic vulnerability to drug abuse, based on their innate differences in sensitivity to the reinforcing effects of drugs of abuse and responsiveness to stress. We previously observed robust differences between the two strains for two behavioral measures of SNS, locomotor response to novelty and light reinforcement tests [1]. Environmental enrichment produces a variety of beneficial neurobehavioral effects in animal models of neuropsychiatric disorders including drug abuse. The present study examined the effects of environmental enrichment during adolescence on the two behavioral measures of SNS in adult male F344 and LEW rats. Starting on about postnatal day 30, male F344 and LEW rats were housed either in pairs in standard plastic laboratory cages or in groups of 16 in a complex environment consisting of a large multi-level cage filled with pet toys. After six weeks of differential housing, the four groups (2 strains × 2 housing conditions, n=16 each) were compared for their performance on locomotor response to novelty and light reinforcement tests. In the former, rats were tested for locomotor activity for 36 min in dark plastic chambers equipped with an infrared motion-sensor system. Unlike our previous finding, we found no significant strain differences in standard-housed rats in the total distance traveled or rearing, while locomotor activity was significantly reduced in both F344 and Lewis rats reared in the complex environment compared to their standard-housed counterparts. In the light reinforcement test, following six daily habituation sessions in dark chambers, rats were tested for snout poke responding for light onset in six 18-min daily sessions. In accordance with our previous finding, standard-housed F344 rats responded for light significantly more than standard-housed LEW rats, while both F344 and LEW rats reared in the complex environment responded for light significantly less than their standard-housed counterparts, with no difference between enriched F344 and enriched LEW rats. Thus, our results indicated that environmental enrichment attenuated SNS phenotypes and obliterated differences between the two inbred strains observed in standard-housed animals, suggesting that complex rearing environments can buffer against the genetic risk for drug abuse.

Title: Behavioral effects of repeated intermittent ethanol access and withdrawal on male and female rats selectively bred for high immobility in the forced swim test

Authors: *F. B. ALMEIDA[1,2], L. M. B. DA COSTA[2], N. HEIDRICH[1,2], A. R. FONSECA[2], P. R. FERNANDES[1,2], F. F. S. DA SILVA[1,2], L. FREESE[1,2], M. S. NIN[4,5,2], H. M. T. BARROS[1,3]; [1]PPG Ciências da Saúde: Farmacologia e Toxicologia, [2]Lab. Neuropsicofarmacologia, [3]Depto. Farmacociências, UFCSPA, Porto Alegre, Brazil; [4]Ctr. Universitário Metodista do IPA, Porto Alegre, Brazil; [5]PPG Ciências Biológicas: Farmacologia e Terapêutica, UFRGS, Porto Alegre, Brazil

Abstract: Alcohol abuse is associated with psychiatric disorders such as depression, though the mechanisms by which these conditions are linked remain incompletely elucidated. One hypothesis is that individuals with a higher individual susceptibility (i.e. genetic construct) to develop depression would be at higher risk of alcohol abuse. The acute ethanol (EtOH) withdrawal produces behavioral manifestations that can be modeled in animals. The main objective of this study was to evaluate behavioral changes during acute periods of abstinence at low doses of EtOH in male and female rats selectively bred to present high depressive-like behaviors, with an EtOH forced diet model. Forty-two adult (PND 40) Wistar rats (males and females) from a high immobility line previously developed in our laboratory (Almeida *et al*., 2018) were submitted to EtOH self-administration from a forced diet (Sustagen® meal) for 21 continuous days (induction phase), where half the rats received an EtOH-containing solution (8% v/v) and the other half received an isocaloric control solution. After this period, the EtOH animals were submitted to intermittent 24 h cycles switching between withdrawal (control solution was offered) and EtOH availability [repeated intermittent EtOH access (RIEA) phase] (Costa *et al*., 2015) for 14 days. In the last day of withdrawal, the forced swim test (FST) was performed after 6 hours without access to EtOH. We observed that that EtOH-exposed rats of both sexes initially consumed more solution than control rats, but this was normalized towards the end of the induction phase. During the RIEA phase, males and females consumed more solution in EtOH re-exposure days in comparison to EtOH withdrawal days and control rats. Partial data analysis of FST behaviors using a Two-Way ANOVA showed a suggestive result regarding EtOH exposure ($P = 0.067$) where EtOH-receiving rats showed a lower immobility

duration than controls. We obtained very similar results in male and female rats regarding EtOH intake and behaviors in the FST, indicating that gender differences are not relevant in this particular model. There seemed to be a line effect due to the very robust increase in EtOH-containing solution intake during re-exposure days, a parameter that was only modestly increased in previously studied *wild-type* rats. The reduction in FST immobility was probably caused by an acute effect of EtOH and likely not related to antidepressant action. Our results support the hypothesis that there are overlapping internal factors that contribute to the development of disorders such as alcohol abuse and depression, resulting in similar outcomes in both sexes.

Title: Effects of Ibogaine, synthetic indole molecules and environmental enrichment on cocaine-conditioned place preference

Authors: *N. HEIDRICH[1], T. F. BIF[2], C. FEDDERN[2], I. A. DA SILVA[2], S. GOLBSPAN[4], A. R. FONSECA[2], F. B. ALMEIDA[1], P. R. FERNANDES[1], M. N. G. BIAJOLI[3], L. FREESE[1], H. M. T. BARROS[1,3];
[1]PPG Ciências da Saúde, [2]Laboratório de Neuropsicofarmacologia, [3]Dpto Farmacociências, Univ. Federal de Ciências da Saúde de Porto Alegre - UFCSPA, Porto Alegre, Brazil; [4]Laboratório de Neuropsicofarmacologia, Univ. Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil

Abstract: We recently found that, besides having a protective role in animal models of addiction, the environmental enrichment (EE) has a neuroprotective effect to cocaine exposure (Freese et al, 2018). Pharmacologically, indole molecules have been growing in interest as treatment for drug addiction. Here, we aim to verify whether the protective effects of EE and treatment with indole molecules, naturally occurring (ibogaine) and synthetic (SS7 and SS12), affect preference for cocaine in male and female rats in the conditioned preference place protocol (CPP). Wistar albino male (n=56) and female (n=51) rats on postnatal day (PND) 21 were

allocated in: standard housing (SH) or enriched housing (EH, n=10/cage), made of polycarbonate transparent cages (80x40x50) with 2 floors and diversified objects rearranged 3x/week). At PND 50, a classical CPP was initiated. Treatments were administered on day PND 62 at morning, around 5 hours before testing: vehicle (VEH: DMSO 80% + saline 20%); ibogaine (IBO): 40 mg/kg; indole molecules SS7 and SS12: 10 mg/kg. Vaginal smear cytology was done daily to verify the female estral cycle. Experiments followed the guidelines of the International Laboratory Animal Science Council and were approved by UFCSPA's Ethics Committee for Research (#233/18). The results are presented as mean±SEM. The estrous cycle distribution of female rats in the CPP day test was: diestrus=46%, metestrus=18%, proestrus=16% and estrus=20%. In the VEH, we found that the EH seem to be able to decrease the time spent (seconds) in the cocaine chamber in males (VEH/SH = 478±55 - VEH/EH=441±73) and females (VEH/SH = 394±57 - VEH/EH=312±52) compared to the vehicle. In male rats, without considering the ambient factor, we found that IBO and SS12 decreased the cocaine chamber time spent in 12% and 30%, respectively. In the female rats, both IBO and SS12 treatment reduced the time in relation to the vehicle by 6%. In the other hand, SS7 treatment had no effect in the male and increased the cocaine chamber time spent in 12% in the female rats. This partial results show promising results for treatment with the SS12 syntetic molecule, in contrast to what happens with the SS7 molecule, that shows an increase in the cocaine chamber time spent. Treatment with the IBO appears to be stable, as expected. These data are innovative because they test the effect of new molecules developed here. We expect to show more robust analysis as we complete our set of experiments.

Title: The effects of caffeine on alcohol oral self-administration behavior and pre-frontal cortex DANA damage in rats

Authors: P. R. FERNANDES[1], C. FEDDERN[1], A. STEIMETZ[2], M. M. VIEIRA DA CUNHA[1], D. J. DE MOURA[1], J. SAFFI[2], L. FREESE[1], ***H. M. BARROS**[1];
[1]Pharmacosciences, [2]UFCSPA, Porto Alegre, Brazil

Abstract: Caffeine and alcohol are some of the most widespread self-administered psychoactive substances, and are known to be extensively co-administered. However, little is known about to which the degree they may mutually change each other's consumption and effects. We aimed to investigate the alcohol, caffeine and alcohol+ caffeine oral self-administration behavior and the DNA damage index (DI) in the prefrontal cortex (PFC). Thirty-two Wistar male rats (± 200 g, 55-65 days old were randomly allocated to sucrose 2% (S), caffeine (0.25 mg/ml) (C), alcohol (10% v/v) (A) or alcohol+ caffeine (10% v/v + 0.25 mg/ml)(A+C). All drugs were prepared in sucrose at 2%. During 7 days, the rats were trained to self-administer sucrose 2% using a FR1 schedule . On day 8, the self-administration of S, C, A, A+C began, lasting for 21 days (FR1, 1 hour/day). The Forced Swim Test (FST) was performed 1 day before the self-administration training and 24 hours after the last self-administration session. Experiments followed international guidelines and were approved by UFCSPA's Ethics Committee for Research (#214/17). The results are presented as mean±sem liquid consumption (ml/kg) . There was no significant difference between the S (54.53 ±0.73 ml/kg) and C (52.62 ±0.44 ml/kg). Consumption of A (31.33 ±0.65 ml/kg) was lower than the S and the C. Consumption of the A+C (28.34 ±0.56 ml/kg) was lower than S, C, A . In the FST test, C presented significantly increased immobility in comparison with all other groups. The A+C group presented significantly less immobility than the other groups. The DI for double-strand breaks was significantly higher in the A group compared with the C and A+C. The major findings of this study are that there is decreased alcohol consumption and less DNA damage when alcohol is co-administered with caffeine. There is great variability in studies results on the effects of caffeine upon alcohol consumption, probably the other studies use the forced administration, which can produce significant behavioral changes. The self-administration model used here has a greater translational validity than other studies and showed that a low dose of caffeine might be protective towards alcohol self-administration and DNA damage in prefrontal cortex cells.

Title: Correlations between subunits of GABAA and NMDA receptors in chronic alcohol treated or withdrawal and the effect of taurine in the hippocampus of rats

Authors: *R. GOMEZ[1], A. W. HANSEN[1], F. B. ALMEIDA[2], L. F. PAULA[1], N. A. NIETIEDT[1], R. R. PULCINELLI[1], S. BANDIERA[1], L. D. IZOLAN[1], M. S. NIN[3], H. M. T. BARROS[2];

Abstract: Chronic use of alcohol and its withdrawal impair the balance between GABAergic and glutamatergic systems. A better comprehension of the different roles of $GABA_AR$ and NMDAR subunits could be helpful to define new strategies to counteract the deleterious effects observed during alcohol withdrawal. Taurine, a sulfonated amino acid, has been proposed to attenuate alcohol withdrawal symptoms due to its neuromodulatory properties. In this study, we evaluated the correlations between $GABA_AR$ and NMDAR subunits expression in the hippocampus of rats chronically treated with alcohol or in alcohol withdrawal, and the effects of taurine treatment on these parameters. Rats received alcohol (2 g/kg) or water by oral gavage (control), twice a day, for 28 days. From day 29 to 33, withdrawal rats received water instead of alcohol and all groups were reallocated to receive 100 mg/kg taurine or saline intraperitoneally, once a day. On day 34, rats were euthanized and the hippocampus was dissected for the measurement of $GABA_A$ (α1, α4, δ, and γ2) and NMDA (GluN2A and GluN2B) receptor subunits mRNA expression by RT qPCR. Though inter-group, absolute levels of $GABA_A$ and NMDA receptor subunits expression did not change in the hippocampus of rats, we found a positive intra-group correlation among the δ $GABA_A$ and the GluN2A and GluN2B NMDA receptor subunits in control rats. These correlations were not present in chronic alcohol-treated rats and withdrawal restored only the correlation between δ and GluN2A. Taurine treatment induced the co-expression of α1 and γ2 $GABA_AR$ subunits in both control and alcohol-treated rats. In alcohol-treated rats, taurine also induced the co-expression of α1 $GABA_A$ and GluN2A NMDA receptor subunits. Taurine did not restore any correlations in alcohol withdrawal rats and extinguished the one between GluN2A and δ subunits. Thus, taurine or alcohol withdrawal did not restore the co-expression between $GABA_A$ and NMDA receptor subunits showed in control rats, but taurine increased the α1 and γ2 $GABA_AR$ co-expression, likely making $GABA_ARs$ more sensitive to GABA neurotransmission.

Title: Characterization of a post-dependent phenotype of alcohol use disorder

Authors: *S. G. QUADIR[1], C. D. ROHL[2], A. ZEABI[1], P. COTTONE[2], V. SABINO[3]; [1]Pharmacol. & Exptl. Therapeut., [2]Dept. of Pharmacol. & Exptl. Therapeut., [3]Pharmacol. and Exptl. Therapeut., Boston Univ. Sch. of Med., Boston, MA

Abstract: Alcohol Use Disorder (AUD) is a chronic relapsing condition characterized by compulsive, uncontrolled consumption of alcohol. AUD is also characterized by impairments in decision making, driven by dysregulation of prefronto-cortical regions, including the anterior cingulate cortex (ACC) and the medial prefrontal cortex (mPFC). The overall goal of this research was to characterize the post-dependent phenotype resulting from the exposure to chronic intermittent ethanol (CIE) vapor in rats. In particular, we assessed the effects of chronic alcohol exposure on cognitive tasks and pain sensitivity during both acute and protracted withdrawal. We found that rats in protracted withdrawal exhibit increased impulsive action compared to their air-exposed counterparts. On the other hand, post-dependent rats showed no differences in cognitive set shifting. Furthermore, we found a robust effect of CIE on mechanical sensitivity during acute withdrawal, as measured through the von Frey test. This effect persisted into two weeks withdrawal. Alongside, we found CIE rats exhibit increased sensitivity to thermal stimuli, as measured through the Hargreaves test. Current studies are underway to elucidate the neurobiological mechanisms underlying this aberrant phenotype, with a particular focus on sigma-1 receptor (Sig-1R) and N-methyl-D-Aspartate (NMDA) activity, whose expression we found to be significantly elevated in the ACC during withdrawal from CIE. Additional studies will examine how Sig-1Rs in the ACC are involved in behaviors amplified during the post-dependent state.

Title: Modulation of emotional and neurogenic deficits elicited in three models of sucrose dependence

Authors: *K. BEECHER, A. JACQUES, S. ALI, N. CHAAYA, A. BELMER, S. BARTLETT; Queensland Univ. of Technol., Brisbane, Australia

Abstract: Obesity has become a major public health concern around the globe, costing Australia an excess of $56.6 billion dollars per year. Recent research suggests that the overconsumption of sugar changes the molecular signalling pathways and brain circuitry similar to other drugs of abuse, which may ultimately contribute to the development of obesity. Many studies suggest sugar-withdrawn rats exhibit both anxious and depressive-like symptoms. However, there is limited research into the emotional affect and neurogenic deficits of sugar-withdrawn mice. Consequently, a model of sugar overconsumption in mice needs to be established. Three mouse models were examined: chronic restricted access to low sucrose concentration (Drinking-in-the-Dark, 5% sucrose solution), chronic restricted access to high sucrose concentration (Drinking-in-the-Dark, 25% sucrose solution) and chronic unlimited access to high sucrose concentration (*ad libitum* access, 25% sucrose solution). To test whether sucrose elicits withdrawal-induced emotional deficits in these 3 different models, the following anxiety/depression paradigms were utilised: marble burying, elevated-plus-maze, open-field, forced swimming test, and novelty supressed feeding test. To investigate the role of sucrose-induced neurogenic deficits, we systemically administered three injections of EdU (50 mg/kg) over 2 weeks (days 0, 7, 14). Each stage of neurogenesis in the dentate gyrus of the hippocampus was quantified in Neurolucida 360 (stage 1: EdU/GFAP+/Nestin+; stage 2: EdU/Nestin+/GFAP-; stage 3: EdU/PSA-NCAM+/DCX+; stage 4: EdU/calretinin+/NeuN+ and stage 4: EdU/calbindin+/NeuN+). Distribution of the different markers within EdU-immunoreactive cell populations were compared between the models of sugar overconsumption. Our results show that the concentration of, and accessibility to, sugar solution produce differential effects on locomotor activity, anxiety, impulsivity, aggressiveness, neurogenesis and weight gain, suggesting that sugar dependence involves particular neural circuits in a complex mechanism.

Title: Sugar and expression of neuronal nicotinic receptors in the nucleus accumbens

Authors: *S. ALI, K. BEECHER, A. JACQUES, N. CHAAYA, A. BELMER, S. E. BARTLETT;
Queensland Univ. of Technol., Brisbane, Australia

Abstract: It has been estimated that obesity can cause $87.7 billion in additional costs on the healthcare system. Health Survey 2011-2012 showed that children and adolescents (2-18 years) attain 40% of their daily energy intake consumed from high sugar/fat containing foods and beverages. There is evidence to show that high sugar/fat containing food and beverage intake leads to a higher risk for metabolic diseases and neurological disorders. Recent research suggests sugar changes the molecular signaling pathways and brain circuitry in a similar manner to alcohol and nicotine. Nicotinic receptors are an essential target for driving addictive behaviors; however, it has never been proven due to a lack of effective compounds. We expect to classify the role of neuronal nicotinic acetylcholine receptors (nAChRs) located in the nucleus accumbens (NAc) in the overconsumption of sucrose (5% w/v), glucose (5% w/v) and fructose (5% w/v). We have modeled long-term (12-week) voluntary binge-like sugar consumption in mice using the drinking-in-the-dark paradigm. Long-term sugar consuming mice were systemically injected with nAChRs subtype specific antagonists and agonists using Latin square design. Similarly, nAChRs subtypes agonists were microinfused specifically into the NAc. Preliminary data indicates nAChRs subtypes antagonists and agonists differentially modulates sugar consumption. We expect to identify the specific nAChR subunits and brain subregions (NAc core or shell) involved in sugar overconsumption to enable the development of more specific and novel therapeutics for the prevention, management and treatment of obesity resulting from the overconsumption of sugar.

Title: Increased sensation seeking behavior is associated with caudate volumes in male adolescent marijuana users

Authors: *P. SUBRAMANIAM, E. MCGLADE, D. A. YURGELUN-TODD;
Univ. of Utah, Salt Lake City, UT

Abstract: Marijuana (MJ) is one of the most commonly used drugs among adolescents with an estimated 1.6 million adolescents between the ages of 12 to 17 reporting past month MJ use. Chronic MJ use has been associated with altered neurodevelopmental and behavioral processes that can persist into adulthood. Increased sensation seeking behavior has been suggested as a risk factor for the initiation and use of alcohol and illicit substances including MJ. Studies examining the neural correlates of sensation seeking behavior have shown alterations in regions associated with reward processing including striatal regions. While these regions have been shown to be altered in MJ users, few studies have examined the relationship between adolescent MJ use, sensation seeking behavior and the underlying neurobiology involved. Therefore, we hypothesized that increased sensation seeking behavior would be observed in adolescent MJ users which would be associated with striatal brain regions involved in reward processing. 19 MJ users and 16 non-using controls (HC) were included in the analysis. All participants were male and completed a high-resolution magnetic resonance imaging (MRI) scan on a 3 Tesla Siemens Trio scanner. Participants also completed a structured diagnostic interview (SCID) and clinical assessments including the sensation seeking scale (SSS), a 40-item questionnaire that assesses four different components - Thrill and Adventure Seeking (TA), Disinhibition (DIS), Experience Seeking (ES) and Boredom Susceptibility (BS). Volumetric segmentation of structural MRI brain images was performed using FreeSurfer and data for striatal regions were extracted for statistical analysis. MJ-using adolescents reported significantly higher scores on the DIS ($p<0.001$), ES ($p<0.001$), and BS ($p=0.024$) subscales of the SSS as well as on total SSS ($p<0.001$). Findings showed a significant inverse correlation between the right caudate volume ($R= -0.460$, $p = 0.050$) and total caudate volume ($R = -0.462$; $p = 0.046$) with the BS subscale in the MJ group. No significant between group differences were demonstrated for caudate volumes and no significant correlations were observed between the SSS and caudate volumes in the HC group. Our results showing increased sensation seeking behavior and the negative relationship observed between caudate volumes and BS subscale suggest altered reward processing in

adolescent MJ users. Additional studies evaluating the relationship between subcortical brain regions, sensation seeking behavior and MJ use especially in adolescents are critical to differentiate potential risk factors and/or neurotoxic effects associated with MJ use.

Title: Sex-related differences in subjective, but not neural, cue-elicited craving response in heavy cannabis users

Authors: *S. PRASHAD, R. P. HAMMONDS, A. L. WIESE, A. L. MILLIGAN, F. M. FILBEY;
Ctr. for BrainHealth, Univ. of Texas at Dallas, Richardson, TX

Abstract: Previous research has found sex-related differences in factors that affect efficacy of treatments, including continued use, development of cannabis use disorder (CUD), and relapse. As such, studies indicate that female cannabis users progress more quickly than male users through the milestones of CUD, likely due to an increased craving response in female users. While studies have reported sex-related differences in subjective craving, differences in neural response and the relative contributions of neural and behavioral response remain unclear. We examined sex-related differences in neural and behavioral response to cannabis cues and other cannabis use measures in 112 heavy cannabis users (54 females). We used principal component (PC) analysis to determine the relative contributions of neural and behavioral response and cannabis use measures. We also conducted an exploratory analysis to examine whether menstrual cycle phases underlie any sex-related differences. We found that PC1, which accounts for the most variance in the dataset, was correlated with neural response to cannabis cues and there were no differences between males and females ($p = 0.091$). PC2, which accounts for the second-most variance, was correlated with subjective craving such that females exhibited increased subjective craving relative to males ($p = 0.005$). The exploratory analysis indicated that females in the follicular phase contributed to the sex-related difference in subjective craving, suggesting an important role of menstrual cycle phase. We also found that CUD symptoms correlated with both PC1 and PC2, corroborating the relationship between craving and CUD severity. These results suggest a nuanced relationship between neural and subjective craving

response and CUD that differ between sexes. Accounting for these differences will increase efficacy of treatments and interventions through personalized approaches.

Title: Sex differences in endocannabinoid system adaptations to noradrenergic depletion in the murine locus coeruleus

Authors: *E. J. VAN BOCKSTAELE[1], J. A. ROSS[2], M. URQUHART[2], S. A. THOMAS[3], K. MACKIE[4], B. A. REYES[5];
[1]Pharmacol. and Physiol., Drexel Univ. Col. Of Med., Philadelphia, PA; [2]Pharmacol. and Physiol., Drexel Univ. Col. of Med., Philadelphia, PA; [3]Systems Pharmacol. and Translational Therapeut., Univ. of Pennsylvania, Philadelphia, PA; [4]Psychological and Brain Sci., Indiana Univ., Bloomington, IN; [5]Pharmacol. & Physiol., Drexel Univ., Philadelphia, PA

Abstract: The locus coeruleus (LC)-norepinephrine (NE) system is highly responsive to stress-related stimuli, and the dysregulation of the coeruleo-cortical pathway has been implicated in several stress-related psychiatric disorders. The LC is a nucleus on which the endogenous cannabinoid (eCB) and NE systems converge. The eCB system plays a significant role in modulating the stress response, in part by modulating the LC. The eCB synthetic enzyme, diacylglycerol lipase-α (DGL-α), is a key enzyme in the biosynthesis of 2-arachidonoylglycerol (2-AG), the primary eCB that is degraded by monoacylglycerol lipase (MGL). Anandamide (AEA) is a second eCB that is degraded by fatty acid amide hydrolase (FAAH). Here, we investigated expression levels of DGL-α, MGL and FAAH in the LC of a mouse model that is NE deficient due to knock out (KO) of the enzyme Dopamine-β-Hydroxylase (DβH-KO). DGL-α expression was significantly increased in the LC of both male and female DβH-KO mice ($P < 0.05$) when compared to WT, while MGL and FAAH were not altered in male or female DβH KO groups compared to WT controls. This suggests overall increased eCB tone in DβH KO mice in both sexes. A pharmacological lesion by intraperitoneal injection of N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine hydrochloride (DSP-4) was used as a second approach to induce NE depletion in male and female rats. Results showed that in the LC, DGL-α expression was significantly increased in male DSP-4-treated rats ($P < 0.05$) when compared to saline-treated

controls, and a similar trend was observed in DSP-4 treated female rats. While there were no observed differences between groups for MGL expression, FAAH was found to be significantly decreased in DSP-4 treated males and significantly increased in DSP-4 treated females. Additionally, immunoelectron microscopy revealed the presence of FAAH in tyrosine hydroxylase (TH)-immunoreactive (ir) somatodendritic processes of the LC in naïve male rats. Preliminary semi-quantitative analysis shows that approximately 51% (307/592) of TH-ir LC somatodendritic processes are also FAAH-ir. Of the TH- and FAAH-ir somatodendritic profiles, 24% (146/307) formed, potentially inhibitory, symmetric synaptic contacts. Excitatory synapses, identified morphologically by an asymmetric cleft, occurred 11% (67/307), while undefined synapses accounted for 30% (178/307) of the total FAAH and TH-ir profiles. Taken together, the findings indicate that the eCB and NE systems have important reciprocal roles in regulating each other, and further, infer that therapeutics aimed at the eCB system for the treatment of various stress-related neurological disorders may have a direct effect on LC neurons.

Title: Sex differences on the developmental effects of chronic inhaled marijuana: A multimodal MRI study

Authors: *J. R. COLEMAN, Jr[1], A. KNUDSEN[1], I. ALKISLAR[1], M. ATHANASSIOU[3], X. CAI[1], D. MADULARU[4], A. MAKRIYANNIS[2], P. P. KULKARNI[1], C. F. FERRIS[1];
[1]Ctr. for Translational NeuroImaging, [2]Ctr. Drug Discovery, Northeastern Univ., Boston, MA; [3]McGill Univ., Montreal, QC, Canada; [4]Psychiatry, McGill Univ., Verdun, QC, Canada

Abstract: As it is the case worldwide, marijuana (cannabis) use in the United States and Canada is highly prevalent and societal views of its use are changing rapidly, as are the policies that govern the legality of its recreational and medical use. With the recent wave of legalization efforts in both the US and Canada, it is critical that more clinically translatable research is conducted so that we may better understand this drug's long-term effects on the central nervous system. The aim of this study was to assess any sex-based effects of chronic inhalation (PND 23 - PND 51) of vaporized cannabis on brain structure and function in male and female mice using non-invasive multimodal magnetic resonance imaging (MRI) and behavioral assays. Dried, pulverized cannabis plant matter (9.7% THC) or placebo (0.0% THC) was vaporized and inhaled by mice during 30-minute full-immersion exposure sessions, for 28 consecutive days.

Approximately 48 hours after the last exposure, subjects (N=32) were scanned for functional coupling across integrated neural circuits using resting state BOLD functional connectivity, alterations in gray matter microarchitecture using diffusion-weighted imaging with quantitative anisotropy and brain structure using voxel-based morphometry. MRI scans were performed again approximately 3 months post-exposure. All images for each modality were registered to a 3D MRI Mouse Atlas with 140 segmented and annotated brain areas used to generate an unbiased computational analysis of all data. Novel-object recognition (NOR) was conducted to assess recognition memory function. MRI data shows differences in the changes to male and female brain structure and function in areas associated with reward, addiction, and sensory perception, while behavior data shows deficits in recognition memory in males, but not in females. Data are being analyzed to see if these effects last for months in mice (decades in humans). Results from this study demonstrate that sex-based differences in both quantitative MRI measures and qualitative behavioral data exist between males and females following chronic cannabis exposure.

Abstract: As it is the case worldwide, marijuana (cannabis) use in the United States and Canada is highly prevalent and societal views of its use are changing rapidly, as are the policies that

govern the legality of its recreational and medical use. With the recent wave of legalization efforts in both the US and Canada, it is critical that more clinically translatable research is conducted so that we may better understand this drug's long-term effects on the central nervous system. The aim of this study was to assess any effects of chronic inhalation of vaporized cannabis on brain structure and function in adult female mice using non-invasive multimodal magnetic resonance imaging (MRI). Dried, pulverized cannabis plant matter containing 9% THC (n = 10) was vaporized and inhaled by the mice during exposure sessions lasting 30 minutes, for 21 consecutive days. Marijuana plant with less than 0.1% THC (n = 10) was used for placebo. Approximately 48 hours after the last exposure, mice underwent imaging sessions during which resting-state functional MRI, diffusion-weighted, and voxel-based morphometry scans were collected. All images for each modality were registered to a 3D MRI Mouse Atlas with 140 segmented and annotated brain areas used to generate an unbiased computational analysis of all data. The neuroradiological data show changes in several integrated neural circuits including the accumbens/ventral striatum. (Supported by NIH/5TL4GM118974).

Title: Cannabinoid (THC) exposure during adolescence has enduring effects on hippocampal plasticity and learning in females

Authors: *B. M. COX[1], J. QUINTIANILLA[1], A. A. LE[1], M. AMANI[1], S. V. MAHLER[2], C. M. GALL[1], G. LYNCH[1];
[1]Anat. and Neurobio., [2]Neurobio. and Behavior, Univ. of California Irvine, Irvine, CA

Abstract: Marijuana is the most common illicit drug abused during adolescence, a critical period in brain development. Correlational studies in humans have shown adolescent cannabis use to be associated with cognitive deficits, including deficits in episodic memory, a fundamental component of human cognition. Episodic memory is a complex form of information processing

which involves the acquisition of information into a narrative about what happened, where particular features occurred, and the order in which they appeared ('what', 'where', and 'when'). We have shown that each of these basic elements of an episode involve distinct regions of the hippocampal system. Using behavioral paradigms designed to assess the different components of episodic memory, as well as hippocampal field CA1 dependent object location memory we examined the effects of THC administered daily for 2 weeks during adolescence to both male and female rats and then tested behavior in adulthood. The results point to sex-specific effects of adolescent THC exposure on episodic memory, specifically with females, but not males, exhibiting decreased cognitive abilities on tasks that dependent on hippocampus. Future studies will examine synaptic plasticity in subregions of the hippocampus to help elucidate whether the THC treatments influence hippocampal circuitry in different ways in males and females.

Title: Effects of oral delta-9-tetrahydrocannibinol (THC) consumption on motor activity and anxiety-like behavior in adolescent and adult Sprague-Dawley rats of both sexes

Authors: A. R. BANKS[1], A. P. CHAMBERS[1], E. R. CARLSON[1], K. A. HAMBLEN[1], L. N. CARNEVALE[2], A. DAS[2,3], N.-C. LIANG[1,3], *J. M. GULLEY[1,3];

Abstract: Exposure to cannabis and its primary psychoactive component delta-9-tetrahydrocannabinol (THC) may induce changes in neural circuitry that in turn lead to adverse consequences on behavior. Previous studies in rodents have shown that intraperitoneal or subcutaneous administration of THC has the potential to produce an anxiogenic effect and reduce locomotor activity, but it is unclear if this also occurs following volitional THC exposure. Moreover, most of the studies to date have not investigated the impact of age and sex on the psychoactive effects of THC. In the current study, we allowed male and female rats (n=12/group) to voluntarily consume THC (3.0, 5.0, and 10.0 mg/kg; p.o.) by providing them access to THC-impregnated crackers starting on either P36 for adolescent-onset groups or P80 for adult-onset groups. Locomotor activity in an open-field arena (OFA) was assessed 90 min after rats in these

groups ingested these doses or in control rats given crackers impregnated with sesame oil vehicle. Behavior in an elevated plus maze (EPM) was assessed in a fourth test performed 90 min after rats were given a vehicle or 10 mg/kg THC cracker. Immediately after the conclusion of the EPM test, rats were sacrificed and trunk blood and brains were collected for subsequent analysis of THC and its metabolites using LC-MS/MS. Preliminary results suggest THC induced a dose- dependent decrease in locomotor activity in the OFA, with males exhibiting a relatively greater effect than females. In the EPM, exposure to THC induced a decrease in exploration of open arms with males showing a heightened sensitivity to these effects compared to females. These preliminary findings suggest that rats will voluntarily consume THC via the oral route of administration and at doses that lead to significant effects on locomotor activity and anxiety-like behavior. Moreover, these effects appear to be dependent on sex as males exhibited a relatively greater sensitivity to the effects of THC compared to females.

Title: Sleep disturbances in mice during chronic THC administration and abstinence

Authors: *A. KESNER, K. P. ABRAHAO, M. J. PAVA, D. M. LOVINGER;
NIAAA, Rockville, MD

Abstract: The diagnosis of cannabis withdrawal is contentious because reliable, objective measures of withdrawal from delta-9-tetrahydrocannabinol (THC), the major psychoactive ingredient in cannabis derivatives, have been difficult to observe. Typically, in laboratory animal studies withdrawal symptoms are elicited by treatment with a cannabinoid type 1 receptor antagonist, which does not mimic the normal course of withdrawal in human cannabis users. A known consequence of chronic cannabis usage in humans is altered sleep, particularly disputed non-rapid eye movement (NREM) sleep. We sought to determine if cannabis withdrawal-induced changes in sleep can be modeled in rodents using electrocorticogram and electromyogram recordings from chronically implanted mice combined with our fully automated sleep analysis system to score sleep before, during and after chronic injection of either THC or vehicle control. The first THC injection augmented total time spent in non-rapid eye movement (NREM) sleep, but this effect was significantly attenuated following the last injection in the

chronic treatment regimen. Measurements obtained over six days following cessation of THC treatment revealed that time spent in NREM sleep was reduced largely because of a decrease in NREM bout duration. Additionally, rapid eye movement (REM) sleep was reduced on the first day of acute THC administration and was enhanced 6 days following treatment. The augmentation in REM during the abstinence phase of the experiment could be due to an increase in the number of REM bouts, and this effect persisted throughout the 6 days of abstinence. None of these changes were observed in controls. Paradoxically, the power of delta oscillations (0-4 Hz) was no different between THC and controls during the first day of abstinence, but THC mice displayed markedly less delta power by the last day of abstinence. This suggests that impairment of processes contributing to slow oscillations in the cortex gradually begins to manifest over recovery from chronic THC exposure. To assess the effects of extended abstinence from chronic THC treatment, 48 hr recordings were obtained from these mice after 77 days of abstinence. We observed an augmentation of NREM sleep time following extended abstinence from chronic THC, and a reduction in delta power during NREM. These findings indicate a chronic THC regimen can produce overt withdrawal symptoms, and in addition, extended abstinence from chronic THC may reveal allostatic processes that emerge during the recovery from acute withdrawal. We also studied whether our observed sleep effects contribute to behavioral abnormalities. This work was supported by NIAAA DICBR.

Title: Stress and delta-9-tetrahydrocannibinol exposure in adulthood leads to disinhibited behavior on anxiety related and social tasks

Authors: E. KATAQUAPIT, B. REIMER, G. CAMPBELL, R. SIRISKA, T. FOWLER, A. BROUILLETTE, A. STILLAR, *A. C. W. WEEKS;
Nipissing Univ., North Bay, ON, Canada

Abstract: Cannabis research continues to be important due to increasing legalization worldwide and uncertainties around potential benefits and/or dangers of consumption. There are also questions around the differences between acute and chronic effects of cannabis and its constituents at various stages of development in both humans and animal models. This study

considered the interaction of chronic stress and repeated delta-9-tetrahydrocannibinol (THC) administration on the subsequent learning and behavior of adult rats. Specifically, forty male Wistar rats were equally and randomly allocated to one of four treatment groups: Stress-THC, No Stress-THC, Stress-Vehicle, and No-Stress-Vehicle. Initially, half of the adult rats (post-natal day (PND) 70) were exposed to a chronic mild stress (CMS) paradigm for 14 days. The CMS paradigm consisted of cage tilts, random light/dark changes, and social isolation. Locomotor activity and anxiety levels were assessed in an open field on PND 84 after the CMS housing was concluded. On PND 85, rats began daily intraperitoneal injections of vehicle or THC for ten consecutive days. The THC doses were incremental at 2.5, 5.0 and then 10.0 mg/kg for 4, 3 and 3 days respectively. Following a six-day drug-free period, anxiety related and exploratory behaviours were measured using an elevated zero maze. The next day, social behaviors were assessed using an interaction task where novel pairs of rats were observed together. Finally, a water maze task was completed over four days to assess spatial learning and memory. Results from the open field test confirmed that the CMS procedures produced the expected changes in anxiety related behavior. There was also a main effect of stress in the social interaction task where rats that received CMS showed a significant increase in social interaction with novel conspecifics. In the elevated zero maze, CMS and THC interacted to produce significant differences. Specifically, the stress/drug group spent more time in the open areas of the maze compared to the stress/no drug group. No changes were observed for the water maze task. When compared to an earlier study that considered adolescent aged animals, the current experiment found that while adult rats present a unique pattern of changes, they have roughly the same amount of behavioral disruption. These results suggest that exposure to CMS and THC, while not impairing spatial memory, interact to produce disinhibited behavior and/or reduced anxiety.

Title: Preservation of analgesic activity of cannabis sativa after dopamine receptor antagonist in Wistar rats

Authors: *A. ALHASSAN[1], A. S. ISA[2], A. MUHAMMAD[2], M. I. A. SALEH[2];
[2]Human Physiol., [1]Ahmadu Bello Univ. Zaria, Zaria, Nigeria

Abstract: Background
Cannabis sativa is a drug of abuse for centuries. However, evidence indicate that *Cannabis sativa* possesses therapeutic potentials, some of which includes, analgesic, antiemetic, anti-spastic, neuroprotective, and anti-inflammatory actions, and it is has also been reported to be effective in certain psychiatric diseases. Nevertheless, the medicinal use of cannabis have been limited mainly by their undesirable psychotropic effects especially addiction. Addiction has been associated with activation of the dopamine pathway, thus blocking the dopamine pathway may mitigate the psychotropic effect of cannabis but the question is, if the beneficial effect will be retained after this blockade.
Aim and Objectives : This study investigated the analgesic potential of cannabis in rats given a dopamine antagonist (haloperidol).
Materials and Methods: Twenty Wistar albino rats were randomly divided into four groups. Group 1 (control) received 1 ml/kg normal saline, group 2 received haloperidol only (1mg/kg), group 3 and 4 received 100 mg/kg cannabis sativa and cannabis sativa (100 mg/kg) + haloperidol (1 mg/kg) respectively. Assessment of mechanical pain threshold was done using the Randall-Selitto analgesiometer.
Results and Conclusion: The results obtained from this study showed that pain threshold for the cannabis sativa was significantly higher ($p < 0.05$) when compared to the control and haloperidol group. Similar result was also recorded for the group that received cannabis sativa and haloperidol. These confirmed the analgesic potential of cannabis sativa. It also indicated that cannabis sativa retained its analgesic activity after administration of haloperidol.
In conclusion, it may suggested that if the psychotropic effect of cannabis sativa is inhibited the analgesic activity remains intact.
Key words**:** Pain, dopamine, haloperidol

Title: Optogenetic dissection of dopamine-related neural mechanisms underlying cannabis reward versus aversion

Authors: *C. J. JORDAN[1], B. A. HUMBURG[1], Y. HE[1], X. HAN[1], G.-H. BI[1], E. L. GARDNER[1], X.-Q. XIE[2], Z.-X. XI[1];
[1]Natl. Inst. on Drug Abuse, Baltimore, MD; [2]2.Department of Pharmaceut. Sci. and Computat. Chem. Genomics Screening Ctr., Sch. of Pharmacy, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Cannabinoids can exert both hedonic and aversive effects. While some human users report euphoria following cannabis use, others report anxiety, and animal studies suggest cannabis is minimally reinforcing or dysphoric. However, the neural mechanisms underlying cannabinoids' paradoxical effects are poorly understood. In the past, cannabis reward has been attributed to agonist activity at brain CB_1 receptors (CB_1R) on GABA inputs in the ventral tegmental area (VTA), which disinhibits VTA dopamine (DA) neurons. In contrast, we recently reported that Δ^9-THC produces aversive effects by activation of CB_1R on VTA glutamate neurons. In addition to acting on CB_1R, many cannabinoids also exert activity at brain CB_2R on VTA DA neurons. Therefore, we hypothesized that the net rewarding vs. aversive effects of cannabinoids depend upon the balance of cannabinoid activity at multiple cell type-specific receptor mechanisms. To test this hypothesis, we used optogenetic and transgenic approaches to express light-sensitive channelrhodopsin (ChR2) in VTA DA neurons using DAT-cre mice. Optical stimulation of VTA DA neurons induced robust optical intracranial self-stimulation (oICSS) behavior in a frequency-dependent manner, indicating that increased DA is rewarding. Strikingly, responding for oICSS was significantly enhanced by systemic administration of XLR-11, a new synthetic cannabinoid, suggesting that XLR-11 is rewarding by itself likely through activation of CB_1R, and therefore pretreatment produced additive or synergistic effects with optical brain-stimulation reward. In contrast, pretreatment with other mixed CB_1R/CB_2R agonists (Δ^9-THC, WIN55,212-2) or selective CB_2R agonists (Xie2-64 and 2-49) inhibited oICSS maintained by optical stimulation of VTA DA neurons. Taken together, these findings support our hypothesis that the relative activity of cannabinoids at CB_1R vs. CB_2R may account for rewarding vs. aversive effects of cannabis. Cannabinoids that are selective for CB_1R may exert primarily rewarding effects, whereas cannabinoids selective for CB_2R may exert primarily dysphoric effects. Mixed CB_1R/CB_2R agonists may exert either rewarding or aversive effects, depending upon their receptor binding affinities and cellular distributions of CB_1R/CB_2R in different subjects.

Title: Pathway-specific modulation of lateral habenula GABAergic inputs by acute and chronic cannabinoids

Authors: *E.-K. HWANG, C. R. LUPICA;
Electrophysiology Res. Section, NIDA IRP, NIH, Baltimore, MD

Abstract: The lateral habenula (LHb) is a brain region implicated in coordinating behavioral responses to punishment, omission of reward, and other negative environmental stimuli. Moreover, LHb neurons increase their activity during behavioral avoidance and in depression-like states. LHb output is largely glutamatergic and the activity of these neurons is strongly controlled by several inhibitory GABAergic afferents. However, how these individual GABAergic inputs are organized to control LHb activity is poorly understood. Here we examine characteristics of two external sources of LHb inhibition arising from the ventral tegmental area (VTA) and nucleus accumbens shell (NAcs), brain areas mediating motivation and reward. Using selective optogenetic activation in rat brain slices, we find that the NAcs and VTA both send monosynaptic GABAergic inputs to the medial LHb, and this inhibits these cells. However, in vitro whole-cell recordings also revealed notable differences in these projections regarding the strength of the inhibition, probability of GABA release, the expression of synaptic plasticity, and sensitivity to modulation by cannabinoids. Thus, only NAcs the inputs to LHb were inhibited by CB1 receptor agonists, and these inhibitory inputs were significantly weakened after chronic exposure to Δ^9-THC (5 mg/kg, 2 weeks), a psychoactive constituent of cannabis and agonist of CB1 and CB2 receptors. Moreover, the inhibition of NAcs GABAergic inhibitory inputs to the LHb by the cannabinoid agonist WIN55,212-2 was significantly reduced following Δ^9-THC exposure, indicating cross-tolerance to Δ^9-THC at these NAcs-LHb GABAergic synapses. These results demonstrate pathway-specific differences in GABAergic control of LHb output, and that cannabinoids differentially controls this inhibition. We hypothesize that the selective modulation NAcs input to the LHb by Δ^9-THC may relate to the amotivational and aversive effects of Δ^9-THC noted in humans and animals in models of reward and addiction.

Title: Differential effects of cannabidiol and a novel cannabidiol analog on oxycodone place preference and analgesia in mice; an opioid abuse deterrent with analgesic properties

Authors: *H. M. HARRIS[1], W. GUL[2], M. ELSOHLY[2,3], K. J. SUFKA[4,5,2];
[1]Dept. of Biomolecular Sci., [2]Res. Inst. of Pharmaceut. Sci., [3]Dept. of Pharmaceutics, Univ. of Mississippi, University, MS; [4]Dept. of Psychology, Univ. of Mississippi, Oxford, MS; [5]Dept. of Psychology, Univ. of Mississippi, University, MS

Abstract: This study sought to compare cannabidiol to a cannabidiol analog, CBD-VHS, and its ability to attenuate oxycodone reward without affecting its analgesic effects. In Experiment 1) Mice were enrolled in the conditioned place preference paradigm and received either saline or oxycodone in combination with one of four doses of cannabidiol or CBD-VHS using 3 sets of drug-/no drug-conditioning trials. Experiment 2) sought to determine whether a dose of cannabidiol or CBD-VHS that blocked opioid reward administered alone or in combination with a sub-analgesic or analgesic doses of oxycodone would affect nociceptive processes on the hotplate and abdominal writhing assays. Results from this study demonstrated CBD-VHS can attenuate the rewarding effects of oxycodone place preference at 8.0 mg/kg and is void of rewarding or aversive properties. Cannabidiol however, did not attenuate oxycodone reward at any dose and produced condition place aversion at 10.0 mg/kg. CBD-VHS alone, but not cannabidiol, produced antinociceptive effects in both nociceptive assays and was most effective when compared to oxycodone against thermal nociception. Interestingly, there was a differential interaction of cannabidiol and CBD-VHS in combination with oxycodone across the two nociceptive assays. CBD-VHS+oxycodone produced subadditive responses on the hotplate assay. Enhanced nociception was observed in the abdominal writhing assay with the administration of cannabidiol or CBD-VHS in combination with sub-analgesic and analgesic doses of oxycodone. These data demonstrate CBD-VHS is superior to cannabidiol in blocking opioid reward, producing analgesia in inflammatory assays, and enhances opioid analgesia in a model of inflammation. These findings suggest CBD-VHS could prove useful in pain management and addiction treatment settings.

Title: Development of a mouse model to study the effects of adolescent vaping of Δ-9-tetrahydrocannabinol (THC)

Authors: *T. M. PATTEN[1], A. DREIER[2], E. A. HELLER[1], M. DE BIASI[2];
[1]Dept. of Systems Pharmacol. and Translational Therapeut., [2]Dept. of Psychiatry, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cannabis is the most frequently used illicit drug in the world with highest consumption occurring in economically developed countries like the United States, especially among adolescents and young adults. Increased legality of cannabis, and therefore availability, has occurred alongside a widespread popularization of electronic cigarettes (e-cigs) among youth. E-cigs often contain nicotine, but cannabis and other substances can be used in conjunction with these devices. Recent data from the National Youth Tobacco Survey (NYTS) show that nearly 1 in 11 students had used cannabis in e-cigarettes in 2016. Thus, it is increasingly important to establish preclinical models to study cannabis "vaping" in adolescence and to understand its potential effects on the developing brain. The present study utilized an e-cig machine to deliver vaporized e-liquid containing Δ-9-tetrahydrocannabinol (THC) to adolescent C57/BL6J mice of both sexes. Subcutaneous body temperature was measured before and after an acute exposure to either THC vapor or to vehicle control vapor using implantable programmable temperature transponders. The same animals were also tested in the open field arena for locomotor activity 30 minutes after acute e-cig vapor exposure. 24-h after acute exposure to THC or vehicle vapor, tissue was collected from brain regions relevant to reward processing for analysis of post translational histone modifications. A subset of mice was sacrificed immediately after vapor exposure and serum THC concentrations were measured using enzyme-linked immunosorbent assay (ELISA). Adolescent C57/BL6J mice of both sexes exposed to THC via e-cigarette vapor showed dose-dependent changes in physiological endpoints (e.g. subcutaneous body temperature and locomotor activity) compared to controls. Molecular analyses determined the histone expression pattern in THC-exposed compared to vehicle-exposed animals. By using commercially-available products, this study establishes a highly translational method to study THC vaping in adolescents, which is a rising epidemiological concern. In addition, this research could increase our understanding of the effect of THC exposures on the adolescent epigenome.

Title: Intravenous self-administration of Δ^9-tetrahydrocannabinol by adolescent rats alters reinstatement and working memory behaviors in adulthood

Authors: *S. J. STRINGFIELD[1,2,3], M. M. TORREGROSSA[1,2,3];
[1]Psychiatry, [2]Translational Neurosci. Program, [3]Ctr. for the Neural Basis of Cognition, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Adolescence is a period of brain development that often coincides with initiation of drug use, including Δ^9-tetrahydrocannabinol (THC), the primary psychoactive component of marijuana. This exposure can alter development on a neuronal and molecular level, leading to deficits in learning and memory and enhancements in addiction-associated behaviors. Using a novel intravenous THC self-administration model, we hypothesized that chronic exposure to THC at voluntarily self-administered doses would result in enhanced drug-seeking behaviors and altered performance on a cognitively taxing working memory task. Adolescent male and female Sprague-Dawley rats operantly self-administered escalating doses of THC, reaching a final dose of 30μg/kg/infusion (moderate dose) or 100μg/kg/infusion (high dose) over 20 days (PND 32-51). Next, lever pressing was extinguished during 9 days of lever extinction training (PND 52-60). Rats were tested for cue reinstatement and incubation of THC-seeking after 10 (PND 61) and 30 (PND 81) days of abstinence. Concurrently during abstinence, rats were trained on the delayed-match-to-sample working memory task. During this task, rats learned to nose poke into one of 5 illuminated sample ports to receive a sucrose pellet reward. After responding into a specific sample port, a variable delay period (0-24s) elapsed before the originally sampled port and 2 adjacent ports were illuminated. If the originally sampled port was correctly chosen, the rat received a sucrose pellet reward. We found that male and female adolescent rats self-administered both moderate and high doses of THC. All animals showed reinstatement and incubation of THC-seeking during abstinence, but female rats demonstrated increased incubation compared to males. Additionally, sex differences arose in the effect of high dose THC exposure on working memory task performance, with females showing reduced performance and males

showing enhanced performance. Thus, intravenous THC self-administration produced measurable, dose-dependent effects on cognitive tasks and addiction-associated behaviors. Ongoing studies continue to investigate putative sex- or brain region-specific differences in neuronal activity and protein expression that may mediate these effects.

Title: Toxicity of cannabidiol in neuroblastoma and neuroprogenitor stem cells

Authors: *M. L. QUINTELLA[1], S. A. ROMARIZ[3], B. M. LONGO[2];
[1]Neurophysiol., [2]Univ. Federal de São Paulo, São Paulo, Brazil; [3]Univ. Federal De São Paulo, São Paulo, Brazil

Abstract: Cannabidiol (CBD) is the second most common phytocannabinoid in the Cannabis Sativa, and recent evidence suggests great therapeutic potential, specially in the field of epilepsy. CBD has been shown to reduce neuronal lesion in central nervous system diseases. Our objective was, therefore, to observe any change in the viability of precursor and differentiated cells exposed to CBD. In order to do so, we quantified the cell viability of undifferentiated and differentiated neuroblastoma (N2a) and differentiated neuroprogenitor stem cells (NPC) with MTT assay. We also observed the capacity of undifferentiated NPCs to form collonies. N2a Cells were deprived of fetal bovine serum and exposed to retinoic acid to differentiate, and after 48 hours of exposure to CBD, fixated with paraformaldehyde. NPCs were fixated after 24 hours of differentiation. Neurosphere growth was used to asses viability of undifferentiated cells. Cell viability tests have shown a dose-specific neurotoxicity in N2a and in NPC. The use of CBD in concentrations equal to or higher than 50 µM inhibit growth of undifferentiated N2a cells ($p<0.001$), equal or higher than 1 µM are toxic to differentiated N2a cells; and doses as low as 5µM are toxic to both differentiated ($p<0.0001$)and undifferentiated NPCs. We conclude that despite the evidence of therapeutical properties of CBD, it is important to emphasize the need to analyse the safety and optimal dose of CBD.

Title: Independent subspaces for working memory and motor preparation in the lateral prefrontal cortex

Authors: *C. TANG[1], R. HERIKSTAD[2], C. LIBEDINSKY[1,2,3], S.-C. YEN[2,4];
[1]Inst. of Mol. and Cell Biol., Singapore, Singapore; [2]Singapore Inst. for Neurotechnology, Natl. Univ. of Singapore, Singapore, Singapore; [3]Dept. of Psychology, Natl. Univ. of Singapore, Singapore, Singapore; [4]Dept. of Electrical and Computer Engineering, Natl. Univ. of Singapore, Singapore, Singapore

Abstract: The lateral prefrontal cortex (LPFC) encodes and integrates multiple types of information, resulting in mixed selectivity in LPFC cells and a high-dimensional representational space. It is not clear what mechanisms are used by downstream regions to read out information from mixed-selective responses in the LPFC. One possibility is to have low-dimensional information subspaces, which allow independent readout of different types of information with minimal interference with information in other subspaces. Here we demonstrate the existence of two independent information subspaces in the LPFC network: one that encoded spatial working memory information, and another that encoded movement preparation information. We identified the two subspaces by decomposing the population firing pattern into two sub-patterns with the lowest possible mutual information (0.076 bits). The two sub-patterns defined two subspaces: one subspace was consistent with working memory, since it maintained working memory information throughout the trial in a relatively stable manner; another subspace was consistent with a motor preparation, since information in this subspace emerged after distractor presentation, and the activity correlated highly with pre-saccadic movement execution signals (more than 50% of the cells showed significant correlation). The contribution of individual cells to the two subspaces were highly correlated ($r=0.69$, $p<0.01$), corroborating the multiplexing roles of mixed-selective cells. The two subspaces efficiently reduced the dimensionality of information from 226 to only 7 dimensions without significant loss of decodable information (85.9±5.6% and 87.4±0.8% for memory in Delay 1 in full space and subspace, 76.7±7.8% and 77.7±1.9% for preparation in Delay 2 in full space and subspace). Error trial responses projected into the two subspaces deviated significantly from those in correct trials (decoding performance dropped from 87.4±0.8% to 36.1±2.9% for memory in Delay 1; from 77.7±1.9% to 43.5±1.9%

for preparation in Delay 2), which indicated that the subspaces were behaviourally relevant. We also found low interference between the two subspaces - the superimposition of the response from one subspace weakly affected the decoding performance in the other subspace (memory decoding dropped from 70.2±1.7% to 51.9±1.6% when preparation activity was added in Delay 2; preparation decoding dropped from 77.7±1.9% to 62.1±1.4% when memory activity was added in Delay 2). Our results suggest that the LPFC may be able to use subspace representations to encode different forms of information within the same neuronal population.

Title: Functional specialization of primate lateral prefrontal subregions for spatial working memory

Authors: *P. K. TAN[1], S.-C. YEN[1,2], C. LIBEDINSKY[1,3,4];
[1]Singapore Inst. for Neurotechnology, [2]Dept. of Electrical and Computer Engin., [3]Dept. of Psychology, Natl. Univ. of Singapore, Singapore, Singapore; [4]Inst. of Mol. and Cell Biol., Agency for Science, Technol. and Res., Singapore, Singapore

Abstract: The lateral prefrontal cortex (LPFC) plays a role in the maintenance of working memory. Recent work has suggested that dorsal regions are spatially selective during working memory tasks and that such selectivity decreases in an anterior-posterior gradient. However, it is unclear if such predictions hold in the context of a spatial working memory task with an intervening distractor. Here we characterize functional specialization of the LPFC by quantifying the distribution of classical and mixed selective neurons, selectivity strength, percentage explained variance and cross-temporal decoding performance of subregions of the LPFC. We recorded the activity of single neurons in the LPFC of two monkeys. The microelectrode arrays covered the dorsal and ventral area 8 (frontal eye field), dorsal and ventral area 9/46 (posterior LPFC), dorsal and ventral area 46 (anterior LPFC), area 8B (dorsal to the posterior LPFC) and area 6DR (anterior premotor cortex). The monkeys performed a visually guided delayed saccade task with an interfering distractor. Using cross-temporal decoding, we show that the majority of target location information was found in the ventral posterior LPFC, and this information displayed a marked code morphing (Parthasarathy et al., 2017). Furthermore, we found that the large majority of neurons with nonlinear mixed selectivity reside in the ventral posterior LPFC.

In contrast, the dorsal anterior LPFC displayed almost no memory information, no code morphing, and no neurons with nonlinear mixed selectivity. Our results suggest that an anterior-posterior and dorsal-ventral gradient of spatial selectivity does exist. However, unlike previous reports, we found stronger spatial representations in the ventral compared to the dorsal LPFC.

Title: Dopamine neurons of ventral tegmental area modulate working memory performance and the associated neuronal activity in medial prefrontal cortex

Authors: *C. GE[1,2], Z. CHEN[1], H. FAN[1], C. LI[1];
[1]Inst. of Neuroscience,Sibs, CAS, Shanghai, China; [2]Univ. of Chinese Acad. of Sci., Beijing, China

Abstract: The dopamine neurons in ventral tegmental area is important in modulating many brain functions, including working memory, the ability of active maintenance and manipulation of information during a delay period of seconds. However, the mechanism underling behavioral modulation of WM by dopamine neurons is unclear, especially during learning phase. To tackle this problem, we trained mice to perform an olfactory WM task while performing optogenetic and electrophysiological recording experiments. Activation of VTA dopamine neurons and the

dopamine terminals in mPFC during delay period of learning phase improved behavioral performance, whereas suppression dopamine neurons during delay period impaired performance. Consistent with behavioral modulation, bidirectional optogenetic manipulation of dopamine neurons bidirectionally modulated the signal-to-noise ratio and coding ability of mPFC neurons. Using dopamine sensor, we also observed the dynamic changes of dopamine in mPFC during earlier-delay and decision-making/reward periods. Therefore, changes in neuronal activity in mPFC is associated with modulation in VTA dopamine neurons in WM task.

Title: A sensitive period in the postnatal development of prefrontal cortical function and behavior

Authors: *L. J. BENOIT[1], S. BENICH[3], E. TEBOUL[4], E. HOLT[4], S. E. CANETTA[2], C. KELLENDONK[2];
[1]Dept. of Neurobio. and Behavior, [2]Div. of Mol. Therapeut., Columbia Univ., New York, NY; [3]Barnard Col., New York, NY; [4]New York State Psychiatric Inst., New York, NY

Abstract: Sensitive periods denote time windows during which certain brain regions are more susceptible to transient perturbations, which can result in persistent changes in circuitry. These periods have been well characterized in sensory systems, such as the visual system, which integrates excitatory inputs from the two eyes in a competitive activity-dependent manner during the sensitive period. A similar process may exist in the medial prefrontal cortex (mPFC), a structure implicated in many psychiatric disorders and cognitive functions. However, because the mPFC does not receive direct sensory input, it has been difficult to study the role that incoming excitatory input during development plays in the maturation of mPFC circuitry and subsequent cognitive behaviors.
To address this question, we developed an approach in mice using a combination of viral vectors, genetics, and the inhibitory DREADD, hM4DGi, whereby we can transiently modulate one of the main sources of excitatory input to the mPFC, from the mediodorsal nucleus of the thalamus (MD). By virally expressing hM4DGi in the early postnatal MD, we can transiently decrease excitatory input from this structure during defined time windows by administering the ligand for

hM4DGi, clozapine-N-oxide. We have initially chosen to manipulate MD excitability during adolescence, a period during which mPFC circuitry is continuing to mature and one that is conceived as a vulnerable period in the progression of psychiatric disorders. As a comparison, we also transiently manipulate MD excitability in adulthood. Forty days following the end of the adolescent or adult manipulation, we test for persistent effects on mPFC circuitry and behavior. Our data show that transient perturbation of the MD during adolescence (P20-50) results in persistent deficits in the acquisition of an mPFC-dependent task in adulthood. In parallel, we demonstrate long-term decreases in the frequency of excitatory inputs in the mPFC in adulthood following adolescent manipulation using slice electrophysiology. However, the same manipulation during adulthood (P90-120) did not result in persistent behavioral impairments. These data indicate a temporally restricted "sensitive period" during adolescence when perturbations to incoming excitatory input can have persistent effects on mPFC circuitry and behavior. This study represents an important step in furthering our understanding of the mechanisms governing mPFC maturation and may offer insights into processes involved in developing a psychiatric disorder.

Title: Topographic and learning-related patterns of prefrontal neuronal activity during credit assignment

Authors: *E. LEE[1,3], W. F. ASAAD[1,3,4,2];
[1]Neurosci., [2]Neurosurg., Brown Univ., Providence, RI; [3]Carney Inst. for Brain Sci., Providence, RI; [4]Norman Prince Neurosciences Inst., Providence, RI

Abstract: The ability to link effects with their causes is fundamental to learning. One aspect of this is credit assignment, in which the outcome of a choice must be attributed to some earlier event or experience. We trained two monkeys to perform a credit assignment (CA) task in which they learned to attribute a choice outcome to one of several earlier options. The particular option, a visual cue, that deserved credit varied across different blocks of trials. Performance on this task was compared to a simple delayed-match-to-sample (DMS) task in which no credit assignment

was necessary to perform subsequent trials correctly. We implanted large arrays of independently-moveable electrodes over the lateral prefrontal cortex in each animal (96 electrodes in one, 128 in the other). We observed differences in neuronal population activity between early (initial learning) and late (well-learned) trials in the CA task and these differences varied according to the region of the lateral prefrontal cortex. Furthermore, we observed differences between the CA and DMS tasks, particularly with respect to "ramping" activity at the end of the delay period prior to the choice. This ramping activity also varied topographically across the prefrontal cortex.

Title: Delay-period activity of medial prefrontal cortex is critical for working memory specific in learning of both sensory and motor oriented tasks

Authors: *J. YAO[1,2], R. HOU[1], Z. HAN[1], X. ZHANG[1], C. T. LI[1];
[1]Inst. of Neurosci., Shanghai, China; [2]Univ. of Chinese Acad. of Sci., Beijing, China

Abstract: Working memory (WM) that involves a brief period of memory maintenance known as the delay period plays a quite important role in our daily life. The maintained information can be either sensory or motor in nature. Our previous work has demonstrated that the delay-period

activity of medial prefrontal cortex (mPFC) is critical for a sensory-oriented WM task specifically during learning, but not well-trained, phase. It is unclear whether this specific involvement of mPFC in learning depends on the task type. Here we trained mice to perform either a sensory-oriented WM task, a delayed paired association (DPA) task, or a motor-oriented WM task, a delayed response task (DRT). We then optogenetically suppressed activity of mPFC excitatory neurons during the delay period in learning and well-trained phases of the two tasks. Behavioral performance was impaired during the learning phase but not after the mice were well trained for both tasks. To investigate the neural correlates of mPFC in both tasks, we performed extracellular recording during a rule-switching task, in which mice need to switch between DPA and DRT task in a block design. In this task, the sensory stimuli to be maintained were the same, but the rule was switched between blocks. We found that the coding ability of mPFC population neurons was increased along learning process of both tasks. We did not observe learning-related modulation in coding ability of WM information for the DPA and DRT tasks. Thus, delay-period activity of mPFC is critical for information maintenance specifically during learning of both sensory- and motor-oriented WM tasks.

Title: Loss of glutamate signaling from the centromedian-parafascicular thalamus to dorsal striatum impairs working memory and cognition in non-human primates

Authors: *G. J. MASILAMONI[1], R. RICHARDSON[3], Y. SMITH[2], J. BACHEVALIER[4]; [2]Dept. of Neurol., [1]Yerkes Natl. Primate Res. Center, UDALL Ctr. of Excellence for Parkinson's Dis., Atlanta, GA; [4]Dept. of Psychology, [3]Yerkes Natl. Primate Res. Ctr., Atlanta, GA

Abstract: The circuit involving projections from the centromedian-parafascicular (CM/PF) thalamus to the dorsal striatum plays an essential role in the acquisition and execution of discrimination learning in rodents (Bradfield et al., 2013, Front. Syst. Neurosci. 7:51). CM/PF neurons profoundly degenerate early in the course of neurodegenerative diseases such as Parkinson's disease (PD), raising the possibility that degeneration of the CM/PF-striatal system contributes to early cognitive deficits in PD patients (Smith et al., 2014, Front. Systems Neurosci 8:5). However, the exact role of this thalamostriatal pathway in learning and other cognitive

processes is not well established in primates. To address this question, a highly efficient retrograde gene transfer vector encoding the recombinant immunotoxin (IT) receptor was injected into the dorsolateral striatum (putamen/caudate) in one adult female rhesus monkey to express the receptor in neurons innervating the striatum. IT treatment into the CM/PF of the vector-injected animal caused a selective elimination of neurons in the CM/PF-derived thalamostriatal pathway (Kato et al., 2011, J Neurosci. 31:17169). This experimental animal and a control monkey were tested both pre- and post-surgery in a task measuring attentional set shifting and behavioral inhibition (Intradimensional/extradimensional shifting). Our preliminary data indicate that, as compared to the control animal, the CM/PF-lesioned monkey failed to remember the extradimensional shift task it learned prior the lesion, making more errors to re-learn the task and showing a severe impairment in reversal learning. Both animals were then tested in a working memory task (Spatial Delayed Response) and again the CM/PF-lesioned monkey showed a significant deficit as compared to the control monkey. Yet, the elimination of this pathway did not influence spontaneous locomotion and motor skill learning that are mediated by the dorsal striatum. These preliminary data suggest that removing the excitatory input from CM/PF to the dorsal striatum may result in an enduring deficit in learning-related plasticity.

Title: Adaptive coding of multiplexed information in primate lateral prefrontal cortex

Authors: *F.-K. CHIANG[1], J. D. WALLIS[2], E. L. RICH[1];
[1]Nash Dept. of Neurosci. and The Friedman Brain Inst., Icahn Sch. of Med. at Mount Sinai, New York, NY; [2]Dept. of Psychology and Helen Wills Neurosci. Inst., UC Berkeley, Berkeley, CA

Abstract: Mixed-selectivity allows prefrontal neurons to represent high-dimensional cognitive information and adapt executive functions flexibly. Such mixed neural codes not only increase representational capacity in cognitive tasks, by encoding the information efficiently, but may also optimize metabolic costs. Therefore, changes in cognitive task demands may influence the degree of mixed-selectivity. We've recently shown that neural activity in lateral prefrontal cortex

(LPFC) encodes the spatial and sequential information required to perform a visuospatial working memory (WM) task, and the strength of spatial tuning is modulated by behavioral strategies. However, little is known about how these neural ensembles multiplex information in different behavioral strategies. To assess this, we re-analyzed data from two monkeys performing a spatial self-ordered search task with six identical visual targets. The subjects were required to saccade to each target, one at a time in any order, returning their eyes to the center after each target. Therefore, they had to use WM to keep track of which targets had been visited and prepare for next target selection. Blocks of 40 trials with the same target configuration enable us to quantify behavioral strategies. Target color within a trial was the same, but it changed to indicate the onset of a new trial. We used linear discriminant analysis (LDA) to categorically decode information about target location or saccade order from ensembles of LPFC neurons. Target locations were more accurately decoded than saccade orders, and the accuracy of the decoder to predict saccade orders increased when subjects performed more stereotyped selection. To determine how each neuron contributed to the ensemble, we iteratively removed one neuron at a time, analogous to a lesion process, in order of contribution to the decoder. We found that the accuracy of decoding sequential information from the most informative half of neuronal ensembles was similar to that of the entire population. To test how size of the optimal ensemble changes with behavioral strategies, we systematically varied the number of neurons to create decoders based on the most informative units or ensembles. We found that the size of optimal neural ensembles for decoding spatial or order information, but not target color, increased with stereotyped strategies, suggestive of a less efficient neural code. Overall, these results indicate that efficient coding of multiplexed information in LPFC is affected by the behavioral strategy selected by the animal, and can be achieved by relatively small neuronal ensembles.

Title: Cell type specific impairment of naturalistic spatial working memory coding by ketamine in primate lateral prefrontal cortex

Authors: *M. ROUSSY[1], M. KHAKI[1], N. MORTAZAVI[1], A. J. SACHS[2], L. PALANIYAPPAN[1], J. C. MARTINEZ-TRUJILLO[3];

[1]Univ. of Western Ontario, London, ON, Canada; [2]Ottawa Hosp. Res. Inst., Ottawa, ON, Canada; [3]Dept. of Physiol. and Pharmacol. and Psychiatry, Brain and Mind Institute, Univ. of Western On, London, ON, Canada

Abstract: Through its role as a N-methyl-D-aspartate acid receptor (NMDAR) antagonist, ketamine has been shown to induce schizophrenia like symptoms including impairments in spatial working memory (WM). Computational models propose that NMDAR play a fundamental role in maintaining WM encoding in the prefrontal cortex; however, experimental evidence supporting this in primates is scarce (Wang, 2013). Moreover, how NMDAR antagonism affects information coding in individual neurons and neuronal populations that support naturalistic use of WM remains unclear.

To investigate this issue, we trained two rhesus macaques to perform a spatial WM task in a virtual environment. During a trial, a visual cue appears in 1 of 9 possible locations in a virtual arena. Subjects had to remember the cue location during a 2 second delay period. They were then required to navigate to the cued location using a joystick. Neural recordings were performed on both subjects using two 96 channel multi-electrode arrays located in the lateral prefrontal cortex (areas 8Ad/v).

Here we demonstrate that intramuscular administration of ketamine in non-human primates produce short lasting (~1 hour) impairments in performance during a spatial WM task in a virtual environment that mimics naturalistic settings. This corresponds to a transient loss in the tuning of lateral prefrontal cortex neurons that is required to encode remembered locations in the environment. Narrow spiking (putative) parvalbumin interneurons lose their tuning by decreasing their responses to preferred remembered locations. Contrastingly, broad spiking neurons (primarily putative pyramidal neurons) loss their tuning by increasing their responses to all remembered locations. These effects caused a reduction in the ability of prefrontal neuronal populations to encode mnemonic representations of space.

Our results show that low doses of ketamine produce transient WM impairments during a virtual task that mimics realistic use of WM by reducing the ability of prefrontal neuronal populations to produce reliable memory representations. Results may also reflect mechanisms underlying WM deficits in individuals with schizophrenia.

Abstract: Retaining behaviorally relevant information in the face of distraction is a distinctive feature of working memory. Previous studies have shown that the prefrontal cortex (PFC) is able to resist distracting inputs, but the implementation at the single neuron and neuronal population level remains unknown. Relevant information could be carried over using the same code, or there might be a reorganization of code after distraction. Here, we use population analyses with retained links to individual neurons to explore the basis of resistance to distraction in working memory. We analyzed acute extracellular recordings of 726 single units acquired in 78 sessions from the lateral PFC of two rhesus monkeys performing a delayed match-to-numerosity task with distractors. Linear discriminant analysis (LDA) classifiers were cross-temporally trained and tested (100 ms steps, 100 ms FWHM) on either the sample (task-relevant) or distracting numerosity to investigate the persistence and transfer of working memory representations. Examination of discriminant subspaces showed that the decision boundary was mostly captured by the first component. We found that sample information could be robustly decoded from the PFC population even after distraction. Notably, however, the code did not transfer from the first to the second memory delay (preceding and following the distractor, respectively). We selected the dominant sample coding neurons (largest projection onto the first component) in both delay periods. The populations did not overlap. The dominant first delay neurons coded sample information early and persistently until the distractor was presented, but did not continue into the second delay. Instead, they switched to encoding the distractor. Conversely, distractor information was low in the dominant second delay population. Neurons in this group started to represent the sample numerosity late in the first delay, just prior to distraction. Robust cross-stimulus decoding (trained on sample, tested on distractor) confirmed that the task-relevant and distracting stimuli partly shared memory codes and thus competed for the same cognitive resources. In contrast to the dominant neurons, the remaining population exhibited less accurate and more dynamic coding of sample information. Interestingly, this population's code readily transferred from the first to the second memory delay. Together, these findings suggest complementary contributions of distinct subgroups of PFC neurons to working memory maintenance and resistance to distractors, warranting further investigations into their cellular identity and connectivity patterns.

Title: Reference frames for spatial working memory in dorsal and ventral lateral prefrontal cortices of macaques

Authors: *R. LUNA[1,2], M. P. ROUSSY[1,2], A. J. SACHS[4], S. TREUE[5], J. C. MARTINEZ-TRUJILLO[1,2,3];
[1]Physiol. and Pharmacol., [2]Robarts Res. Inst., [3]Brain and Mind Inst., Univ. of Western Ontario, London, ON, Canada; [4]Brain and Mind Res. Inst., Univ. of Ottawa, Ottawa, ON, Canada; [5]German Primate Ctr., Goettingen, Germany

Abstract: Single neurons of the Lateral Prefrontal Cortex (LPFC) of macaques can encode spatial working memory (WM) signals. Nevertheless, it is not clear whether this mechanism retains spatial information in different frames of reference. Here we explored this question using an Oculomotor-Delayed Response (ODR) task, which allowed us to dissociate the memorized spatial locations between two frames of reference (i. e., retino-centered or screen-centered). We trained two rhesus monkeys to fixate a dot that appeared at one of sixteen possible positions on the stimulation screen. Then a cue stimulus transiently appeared at a different position during 1000ms. The animals kept looking at the fixation dot for another 1000ms (WM delay) and upon its extinction they made a saccade to the memorized target location. Liquid reward was delivered for correct responses. We recorded the activity of single-unit cells in the LPFC using two multi-electrode arrays (contact area of 16mm2, 10x10 electrodes) implanted in the dorsal (dLPFC) and ventral (vLPFC) gyri surrounding the Principal sulcus and anterior to the Arcuate sulcus (areas 8A and 9/46, respectively). Next, we computed the average firing rate during the WM delay for all units and decoded their spatial selectivity. The systematic variations in the initial fixation position allowed us to decode the remembered, cued locations relative to the fixation point (retino-topic reference frame) as well as relative to the stimulation screen (spatio-topic reference frame). We recorded 83 and 142 units in the dLPFC and vLPFC areas, respectively. We found that 17% of dLPFC units and 15% of vLPFC units encoded the remembered location in the retinotopic reference frame. Notably, 11% of dLPFC units along with 13% of vLPFC units encoded the remembered location in the spatiotopic reference frame. Our results show that LPFC encodes spatial working memory in both retinotopic and spatiotopic frames of reference, with a slight dominance of the former. Interestingly, they also show that dLPFC contains a larger

proportion of neurons tuned for the retinotopic frame, but a lower proportion tuned for the spatiotopic frame, compared to vLPFC.

Title: Blockade of connexin43 hemichannels impairs working memory and excitatory synaptic transmission in the prefrontal cortex of rats

Authors: *X. TAO, Z. LIU, X. ZHANG;
Inst. of Brain Sci., Shanghai, China

Abstract: The gap junction is essential for the communication between astrocytes and neuron by various connexins , which allows the rapidly exchange of biological information between cells, playing a key role in coordinating the synaptic functions. Cx43 hemichannels (Cx43 HCs) is highly expressed in the central nervous system and have been demonsrated to modualate syanptic plasticity and hippocampal spatial memory. However, whether Cx43 HCs of medial prefrontal cortex involves in synaptic transmission and working memory in the medial prefrontal cortex of rats still remains unclear . To this end, we made use of Gap27, a specific hemichannels blocker for Cx43 HCs,is bilaterally infused Gap27 into the prelimbic (PrL) area of the mPFC followed by the test of working memory in a T maze.Furthermore, we examined the effects of Gap27 on synaptic transmission using whole-cell patch-clamp in acute prefrontal cortex slices. Our results demonstratethat prefrontal cortex Cx43 HCsblockade significantly impair the working memory and synaptic transmission, implying that Cx43 HCs in prefrontal cortex play an important role in prefrontal cortex working memory and synaptic transmission.

Title: High channel count electrophysiological recordings in prefrontal cortex in a novel spatial memory task

Authors: *C. BÖHM[1], A. K. LEE[2];
[1]Janelia Res. Campus, Ashburn, VA; [2]HHMI Janelia Res. Campus, Ashburn, VA

Abstract: Past research on spatial working memory has largely focused on simple tasks with a binary choice, such as the T-maze. In these tasks, the animal can memorize the location of the goal or the route to the goal from the start location. In addition, such tasks tend to result in stereotyped behaviors for each goal that may themselves produce goal-associated neural correlates. Thus, the animal's strategy to solve the task and the interpretation of neural correlates can be ambiguous. We have devised a novel spatial memory task where rats are required to flexibly encode three spatially distinct goals on a trial-by-trial basis. The goals can be reached via multiple routes, one of which is available in each trial. Knowledge of the available route is only gained after a delay period in which the animal has to perform a nose poke in one of three randomly chosen start positions. This design forces the animal to memorize the spatial location of the goal instead of planning a route from start position to goal position. This allows us to dissociate between neural correlates of route planning and goal representation. In such cognitively demanding tasks a large population of neurons in several brain regions, including prefrontal areas, are expected to be required to coordinate their activity and encode task-relevant variables and rules. Sampling a sufficiently large number of neurons at high temporal accuracy poses a challenge to current electrophysiological recording technology. Here we have employed Neuropixels probes, a new type of high channel count silicon probe featuring nearly a thousand recording sites along a single 10 mm shank, of which 384 can be recorded simultaneously. The shank spans multiple task-relevant brain regions including anterior cingulate cortex, prelimbic cortex and infralimbic cortex. This technology has allowed us to record activity from 100-200 frontal cortical neurons simultaneously in freely behaving rats performing a complex spatial working memory task. The high number of neurons also facilitates single trial analysis, which is highly relevant since the working memory content must be updated from trial to trial and be instantly accessible. We have found that current spatial location at the start or goal positions can be clearly and unambiguously decoded by the combined firing rates of multiple neurons over a range of timescales, from hundreds of milliseconds to seconds. The intended goal location while

the rat is performing the nose poke is not linearly separable in this form. Ongoing analysis is focused on other biologically plausible forms of representation, such as sequences of neural activity or coordinated ensemble activity.

Title: Linking selective pharmacological suppression of HCN1 to synaptic integration, prefrontal cortical function and working memory

Authors: *E. HARDE[1], M. WEBER[1], J. WELLBOURNE-WOOD[1], P. SCHOENENBERGER[1], M. PAINA[2], J.-F. ROLLAND[2], M. CHERNYSHEVA[3], B. KOC[1], R. REDONDO[1], J. WAMSTEEKER CUSULIN[1], F. HELMCHEN[3], E. O'CONNOR[1], B. HALL[1];

Abstract: HCN channels regulate neuronal excitability, dendritic integration of synaptic inputs, and contribute to synaptic plasticity. HCN1 channels are highly expressed in brain regions associated with cognition including medial prefrontal cortex (mPFC) and hippocampus. Genetic suppression of HCN1 improves working memory by increasing signal-to-noise ratio in mPFC circuits, which suggests that pharmacological suppression of HCN1 channels would have beneficial effect on cognition. Pharmacological characterization to gain insight into the role of HCN channels has largely relied upon antagonism using ZD7288. However, this compound is not HCN isoform selective, it affects other channels, and is not suitable for *in vivo* studies. Here, we have further characterized a tool compound (J&J12e) that has 150-fold higher potency than ZD7288. Using automated and manual patch clamp, we demonstrated fast onset of channel block by J&J12e and observed an 8-fold higher potency for HCN1 over HCN2. J&J12e slowed activation kinetics of HCN1-mediated I_h current in HEK293 cells as well as in brain slices, suggesting an allosteric channel blocking mechanism. In brain slices, J&J12e suppressed HCN-mediated sag response and improved synaptic integration through increased summation of evoked or artificial EPSPs. Additionally, J&J12e showed activity on HCN1 when co-expressed with TRIP8b, on tandem HCN1/HCN2 channels, and on both rat and human isoforms. In contrast to ZD7288, J&J12e passes the blood-brain barrier and is therefore suitable for use *in vivo*. We performed EEG recordings in freely moving rats and found that J&J12e increased power in the gamma frequency range. Using miniaturized microscopes to gain single cell resolution *in vivo*, we show that J&J12e modulates activity of a subset of mPFC neurons. Since

mPFC is critical for working memory, we assessed the compound in behavioral tests including TUNL and T-maze alteration task. Our results indicate that selective, pharmacological inhibition of HCN1 has potential to provide cognitive enhancement through its actions of promoting synaptic integration in brain circuits critical to support working memory.

Title: High fat diet evokes exaggerated neuroinflammation in prefrontal cortex and impairments in working spatial memory in aged rats

Authors: B. M. GONZALEZ OLMO[1], J. M. JOHNSON[1], ***R. M. BARRIENTOS**[1,2,3,4];
[1]Inst. for Behavioral Med. Res., [2]Dept of Psychiatry and Behavioral Hlth., [3]Chronic Brain Injury, Discovery Themes Initiative, [4]Dept of Neurosci., The Ohio State Univ., Columbus, OH

Abstract: World-wide consumption of saturated fats and refined sugars has dramatically increased across all age groups, including older adults. Not surprisingly, these statistics are highly correlated with the escalating obesity rates in this population. This is concerning because of the well-known associations between obesity and cognitive declines, and aging and vulnerable cognitive function. Because obesity is a complex disease with many comorbidities (making the study of underlying mechanisms difficult and confounded), we employ a short-term diet manipulation protocol. We have previously demonstrated that short-term consumption of a high-fat diet (HFD) among aged rats evokes an exaggerated neuroinflammatory response in the hippocampus and amygdala, causing precipitous memory consolidation impairments of contextual, cued-fear, and reference spatial memory. Here, we explore the effects of HFD in aging on prefrontal cortex function and neuroimmune phenotype. Young adult (3 months old) and aged (24 months old) F344xBNF1 rats were assigned to either chow or HFD for one week. Proinflammatory cytokine levels in the prefrontal cortex were significantly elevated in HFD-fed aged rats compared to HFD-fed young adult rats. In a separate cohort of rats, working spatial memory was assessed using the Morris water maze. In accordance with the neuroimmune data,

HFD-fed aged rats exhibited significantly longer latencies to reach the platform than controls, indicating impaired working memory function. These findings suggest that short-term HFD consumption in the aged rat is sufficient to evoke widespread memory impairments that may be a result of robust neuroinflammatory responses in key memory-mediating brain regions.

Abstract: Spatial working memory (SWM) is a central cognitive process during which the hippocampus and prefrontal cortex (PFC) encode and maintain spatial information for subsequent decision making. This occurs during ongoing computations relating to spatial position, recall of long-term memory, attention, etc. We recorded single units, in both hippocampus and PFC, to define how neural dynamics associated with intermittently presented task parameters relate to continuing oscillatory activity in control rats and those with a brain malformation. Neurons that encode task parameters are those that are well-modulated in time and incorporated into a functional network between regions. Our results implicate a model in which ongoing oscillatory coordination among neurons in the hippocampal-PFC network defines a functional network that is poised to receive sensory inputs that are integrated and multiplexed as working memory. These dynamics are systematically altered in disease and may provide potential targets for stimulation-based therapies.

Title: Maternal skewing of the active X chromosome via Xist deletion induces cognitive deficits in young and aging female mice

Authors: *S. ABDULAI-SAIKU[1], D. WANG[1], B. PANNING[2], D. B. DUBAL[1];
[1]Dept. of Neurol., [2]Dept. of Biochem. and Biophysics, Univ. of California San Francisco, San Francisco, CA

Abstract: The X chromosome is enriched for cognition-related genes. Female mammals have two X chromosomes per cell, one of maternal and one of paternal origin. In development, one X is randomly inactivated by *Xist*, a long noncoding RNA. Thus, females are mosaics; they express the maternal X in roughly half of their cells and the paternal X in the other half. Mosaicism of the active X confers epigenetic diversity since the parent-of-origin governs differences in X gene expression. Interestingly, due largely to the randomness of X inactivation, the ratio of maternal to paternal X expression is skewed in many females. We wondered whether diversity of the active X chromosome's parent-of-origin contributes to cognition. To test this, we generated transgenic mice with a skewed X chromosome inactivation pattern by deleting *Xist* from the maternal X chromosome (XIST mice). This genetic manipulation renders only the maternal X active. In XIST mice and their non-transgenic (NTG) litter-mate controls, we assessed learning, memory and behavior using the Morris Water Maze, interactive place avoidance test, open field and elevated plus maze. We found that female XIST mice were cognitively impaired in the spatial memory tasks measured in the water maze, place avoidance, and the open field, compared to NTG controls. Importantly, pain perception, locomotion and anxiety were equivalent between NTG and XIST females. Select impairments extended to and increased in aging female XIST mice. Thus, maternal skewing of the active X chromosome via *Xist* deletion in female mice impaired cognition – and this worsened with some measures in aging. Since mice were inbred, all X's were genetically identical. Therefore, differences between XIST and NTG mice can be attributed to epigenetic X effects resulting from maternal X origin and/ or *Xist* deletion. Further understanding of how X chromosome skewing influences epigenetics, gene expression, and cognition may offer new insights into new therapeutic targets for cognitive impairment across the lifespan and in aging.

Title: Longevity factor klotho attenuates cognitive and synaptic deficits related to Parkinson's disease

Authors: *A. J. MORENO[1], N. LUTHRA[1], J. LIN[1], L. BROESTL[1], A. BÉTOURNÉ[1], R. SEHGAL[1], D. WANG[1], S. E. LESNÉ[2], C. TANNER[1], J. OSTREM[1], D. B. DUBAL[1]; [1]Neurol., Univ. of California San Francisco, San Francisco, CA; [2]Dept. of Neurosci. and Inst. for Translational Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Cognitive impairment from Parkinson's disease (PD) is a major challenge with no effective medical treatments. Klotho is a pleiotropic protein that, with transgenic elevation, extends lifespan, enhances cognition, increases synaptic plasticity, and counters cognitive deficits related to Alzheimer's disease (AD). In humans, a genetic variant of *KLOTHO,* in the form of KL-VS heterozygosity, increases klotho levels and associates with better healthspan, enhanced executive cognition, and attenuated emergence of certain AD biomarkers. Here, we investigated whether transgenic klotho elevation in mice attenuates deficits related to PD – and whether genetic variation of *KLOTHO* in humans associates with measures of resilience in PD. In our mouse studies, we crossed transgenic mice expressing the wildtype human alpha-synuclein (hSYN) with transgenic mice overexpressing klotho. We measured mortality, spatial and working memory, motor functions, synaptic plasticity, and pathogenic protein levels in littermates using multiple cohorts of mice. In our human studies, we measured baseline cognition and CSF biomarkers in healthy controls (HC) and PD subjects, based on KL-VS status, in the Parkinson's Progression Markers Initiative (PPMI) study. We found that klotho overexpression decreased hSYN-induced mortality in mice. Further, hSYN impaired working and spatial memory and motor functions – and klotho attenuated these cognitive, but not motor, deficits. Klotho overexpression also decreased hSYN-induced synaptic impairments, measured by long-

term potentiation, an effect mediated by a subunit of the NMDA receptor, GluN2B. Biochemical studies showed that klotho decreased total hippocampal levels of the human alpha-synuclein protein, but not other pathogenic proteins. In human PD, KL-VS heterozygotes exhibited better baseline semantic and phonemic fluency across several cognitive tests. While PD subjects as a group showed decreased CSF alpha-synuclein levels, KL-VS heterozygotes showed no changes between HC and PD. Together, these data provide evidence that klotho can counteract cognitive deficits related to PD, possibly by decreasing alpha-synuclein levels – and these findings may be relevant to human PD. Further study of klotho and alpha-synuclein may open new therapeutic pathways to combat cognitive dysfunction in PD and other neurodegenerative diseases.

Title: The X chromosome factor Kdm6a confers sex-based resilience against Alzheimer's disease-related deficits

Authors: *E. J. DAVIS[1], S. ABDULAI-SAIKU[2], A. J. MORENO[2], L. W. BONHAM[3], G. M. WILLIAMS[4], D. WANG[2], A. P. ARNOLD[6], B. PANNING[5], J. S. YOKOYAMA[3], D. B. DUBAL[2];

Abstract: Biologic sex influences Alzheimer's disease (AD) - with differing vulnerabilities in men and women. More women suffer from AD, largely due to their longevity since they live to advanced ages when AD risk is highest. In contrast, men with the disease die faster in populations worldwide, indicating a male-disadvantage. We have previously shown that a second X chromosome increases resilience to aging and AD-related deficits using genetic manipulations of gonads and sex chromosomes in male and female hAPP mice and in mouse primary neurons. Here, we sought to investigate how a second X chromosome can confer resilience against AD-related deficits using a mouse model of AD, primary neurons, and a human population representing the spectrum of AD. While XY and XX organisms express only one active X due to X chromosome inactivation (XCI), a few factors escape XCI and thus are higher in females compared to males. One of these genes, *Kdm6a*, escapes in both mice and humans and is a histone demethylase linked to cognitive functions. We thus determined whether higher levels of *Kdm6a* - as found in the XX brain - could counter AD-related vulnerability in the XY brain. We first confirmed the presence of a second X chromosome increased levels of *Kdm6a* in mouse hippocampus; it did so in a manner that was independent of gonadal phenotype or the Y chromosome. We then used lentiviral vectors in mice to modulate *Kdm6a* expression *in vivo* and *in vitro.* Overexpression of *Kdm6a* in the hippocampus of XY hAPP mice to higher levels observed in XX hAPP mice attenuated spatial learning and memory deficits in the Morris water maze. Similarly, overexpression of *Kdm6a* in XY primary neurons decreased Aβ toxicity *in vitro*. Furthermore, knockdown of *Kdm6a* in XX neurons to levels observed in XY neurons worsened Aβ toxicity *in vitro*. Finally, we found that in parallel with female mice, *KDM6A* was also elevated in the brains of women - and that *KDM6A* genetic variation causing higher RNA levels in humans was associated with cognitive resilience. Our findings reveal a role for the baseline XCI escapee *Kdm6a* in countering AD-related deficits. Further understanding of how the second X chromosome confers resilience, and specifically of *Kdm6a*'s downstream mechanisms, could lead to novel therapies for treating AD in both men and women.

Abstract: The brain performs computation in the network of populations of neurons. Organizing principles of such populations are well studied in the sensory and motor cortices. It remains, however, unclear in the association cortex such as the prefrontal cortex (PFC) important for higher-level cognition. Several studies suggested columnar organizations in the PFC neural activity during working memory, which is a cognitive system temporally holding information for processing and a hallmark of PFC functions. However, fine functional structures have never been visualized in the PFC.
Two adult rhesus monkeys were trained to perform the standard oculomotor delayed response (ODR) task where they had to remember a spatial position. Neural activity was measured using a calcium sensor, GCaMP6s, which was expressed in PFC neurons by injecting an adeno-associated virus vector into multiple sites around the principal sulcus of the PFC in the left hemisphere. While performing the task, calcium signals were imaged from neurons in the superficial layers. We found that functional clustering of neurons was absent in examined 8 sites

near the principal sulcus in two monkeys. One exception was a cluster located near the caudolateral end of the principal sulcus. In this cluster, approximately 40% of neurons had sustained activity representing spatial information while the monkey was remembering an instructed spatial location. The activity of nearby neurons represented similar spatial positions. At more rostral 8 sites, only a minority of neurons (~10%) encoded spatial information and those neurons were located sparsely.
Thus, PFC neurons with similar functional properties were clustered at the caudoralteral site, but not at other rostral sites, suggesting that columnar organizations do not exist ubiquitously in the dorsolateral PFC as a processing unit for spatial working memory.

Title: A role for double-strand DNA breaks in epigenetic-mediated transcriptional control during memory reconsolidation

Authors: *S. V NAVABPOUR[1], J. ROGERS[2], T. MCFADDEN[3], S. A. ORSI[4], T. J. JAROME[5];
[1]Translational Biology, Medicine, and Hlth., [2]Biol. Sci., [3]Animal and Poutlry Sci., [4]Biochem., [5]Translational Biology, Medicine, and Health, Animal and Poultry Sciences, Sch. of Neurosci., Virginia Tech., Blacksburg, VA

Abstract: Consolidation is a process that stabilizes acquired memories in cells and requires increased transcription regulation via epigenetic mechanisms. Numerous studies have revealed that following retrieval, a previously consolidated memory is destabilized and requires increased transcriptional regulation in order to be restablized, a process called reconsolidation. Previously, it was reported that global and gene-specific histone H3 lysine-4 trimethylation (H3K4me3), an indicator of active transcription in cells, is increased in the area CA1 of the dorsal hippocampus one hour after the retrieval of a contextual fear memory and was critical for the reconsolidation process (Webb et al. 2017). However, it is currently unknown how this epigenetic mark is regulated following memory retrieval. Recently, it has been shown that neuronal activity triggers double-strand DNA breaks (DSB) in some early-response genes (Madabhushi et al. 2015). However, little is known about the role of DSB *in vivo* and whether DSB occur following the

retrieval of a memory remains equivocal. Here, using chromatin immunoprecipitation (ChIP) analyses, we report a significant overlap between DSB and H3K4me3 in area CA1 during the reconsolidation of a contextual fear memory. We found an increase in phosphorylation of histone H2A.X at serine 139 (H2A.X(p139)), a marker of DSBs, in the *Npas4*, but not *c-Fos*, promoter region 5 minutes after retrieval, which returned to baseline by 15 minutes, indicating a potential role of DSB in the transcription of some, but not all, critical memory permissive genes. While previous reports found an increase of H3K4me3 in the transcription start site (TSS) region of *Npas4* one hour after retrieval, we observed an increase in H3K4me3 levels in the *Npas4* promoter, but not TSS, region 5 minutes after the retrieval, with no change at *c-Fos* promoter or coding regions. This suggests that H3K4me3 may initially start in the *Npas4* promoter region and move into the coding region as the reconsolidation process progresses. Additionally, the significant overlap between H2A.X(pS139) and H3K4me3 at the *Npas4* promoter suggest that DSBs may be critically involved in increased epigenetic-mediated transcriptional regulation necessary for memory reconsolidation. Consistent with this, our preliminary results show that siRNA-mediated knockdown of topoisomerase II β, the enzyme responsible for DSB, in area CA1 prior to retrieval impairs memory, suggesting the indispensable role of DSB in the memory reconsolidation process. Collectively, our data propose a novel mechanism for memory reconsolidation through the increase of gene transcription via DSB early on after memory retrieval.

Title: Evidence that muscarinic receptor activation destabilizes object memories via a mechanism involving CaMKII and synaptic protein degradation

Authors: *C. E. WIDEMAN[1], S. D. CREIGHTON[1], K. H. JARDINE[1], K. PEDENKO[1], V. THAYALAN[1], K. A. MITCHNICK[1], B. E. KALISCH[2], W. S. MESSER, Jr[3], B. D. WINTERS[1]; [1]Psychology and Collaborative Neurosci. Program, [2]Mol. and Cell. Biol., Univ. of Guelph, Guelph, ON, Canada; [3]Pharmacol. and Exptl. Therapeut. and Medicinal and Biol. Chem., Univ. of Toledo, Toledo, OH

Abstract: The storage of long-term memory is more dynamic than once believed. Reminder cues can trigger consolidated long-term memories to destabilize, rendering them labile and necessitating protein synthesis-dependent reconsolidation. It has been postulated that the content of long-term memories can be updated when in this labile state. However, not all memories destabilize following reactivation. Our previous work has shown that novel contextual information at the time of reactivation can destabilize otherwise resistant object memories and that this process depends on acetylcholine (ACh) activity at M_1 muscarinic receptors in perirhinal cortex (PRh). Accordingly, pharmacological activation of M_1 receptors can also promote object memory destabilization in the absence of novelty. Both novelty- and M_1-induced object memory destabilization require activation of the ubiquitin proteasome system (UPS). The UPS is critical for regulating turnover of synaptic proteins, and this may reflect a mechanism by which memories physically destabilize at the synaptic level. Calcium calmodulin-dependent protein kinase II (CaMKII) is implicated in proteasome activation. Consistent with this, here we show that CaMKII in PRh is required for both novelty- and M_1-induced object memory destabilization, indicating a mechanism through which M_1 receptors likely activate the UPS for destabilization. We also provide molecular evidence for UPS activation following reactivation with novelty. We observed a reduction in Shank 3, a synaptic scaffold protein, in PRh of rats reactivated with novelty, suggesting that synaptic protein degradation may underlie novelty-induced object memory destabilization. The results of the current study therefore build on our previous work implicating the molecular pathway by which ACh can lead to memory destabilization. Together these findings suggest a novel role for ACh in long-term memory maintenance, whereby muscarinic signaling promotes memory destabilization when new information is present during reactivation. This mechanism is likely important for adaptive long-term memory updating over time.

Title: Triggering reconsolidation of an ethanol conditioned place preference (CPP) memory: The role of reactivation`s length and dopaminergic receptors

Authors: *F. Z. BOOS[1], C. A. FAVORETTO[1], F. C. CRUZ[2], I. M. QUADROS[1];
[1]Psychobiology, [2]Pharmacol., Univ. Federal de Sao Paulo, Sao Paulo, Brazil

Abstract: Following retrieval, memory can enter into a labile state (destabilization) and be updated through the reconsolidation process. It has been suggested that occurrence of a prediction error during retrieval is important to induce destabilization, which involves dopamine (DA) signaling. In the CPP literature, reactivation sessions successful to induce destabilization are conducted in a drug-free state. Importantly, studies suggest that DA can be either increased by contextual cues related to the drug, or decreased by prediction error in case the drug was absent. In this study, our goal was to investigate the involvement of D1R in the destabilization of a CPP memory. Therefore, we conditioned mice to CPP with ethanol and later reactivated memory by allowing them to freely explore the contexts in a drug-free state for 5 or 10min. Immediately after, animals receive the protein synthesis inhibitor cicloheximide (CHX) to block reconsolidation, or vehicle (VEH). Next, to assess the D1R involvement in memory destabilization, the same protocol we repeated but the D1R antagonist SCH23390, D1R agonist SKF38393, or VEH i.p. was administered 30min pre-reactivation. We found that CHX disrupted reconsolidation when injected after the 10min reactivation session, but not after the 5min one. In the second experiment, SCH and SKF treatments did not affect recall, and the 10min session unexpectedly decreased preference in most of the groups during test, including VEH-VEH, suggesting that extinction took place. These preliminary results indicate that the CPP memory is not destabilized by a 5min reexposure, but reconsolidation is triggered following a longer 10 min session. However, a 10min reactivation may be in between the time window effective to induce reconsolidation and extinction, and additional studies will be required to infer the role of D1R in destabilization.

Title: cAMP mediates the impact of sleep deprivation on memory and synaptic plasticity

Authors: *E. WALSH[1,3], M. S. SHETTY[1,3], K. DIBA[4], T. ABEL[1,3,2];
[1]Dept. of Mol. Physiol. and Biophysics, [2]Dept. of Pharmacol., Univ. of Iowa, Iowa City, IA;
[3]Iowa Neurosci. Inst., Iowa City, IA; [4]Dept of Anesthesiol., Univ. of Michigan, Ann Arbor, MI

Abstract: We spend nearly one-third of our life asleep, yet the biological reasons for this state have not been identified. Sleep facilitates memory storage, and sleep loss leads to impairments in memory. Memory for tasks that involve the hippocampus, a brain region that mediates memory for facts and events, is particularly sensitive to sleep loss. Within the hippocampus sleep loss leads to deficits in synaptic plasticity, decreased dendritic spine density, and decreased protein synthesis. Previous work in our lab found that the reduction of cyclic AMP (cAMP) that occurs as a result of sleep deprivation may mediate those memory deficits, and that rescue of cAMP in the hippocampus of sleep-deprived mice is sufficient to prevent them. Our hypothesis is that cAMP not only acts as a mediator for the cognitive outcomes of sleep deprivation, but also for the observed changes in hippocampal plasticity. By expressing the *Drosophila* G-protein coupled octopamine receptor (OAR) in excitatory hippocampal neurons, we are able to selectively increase cAMP levels in those neurons during a five-consecutive hour sleep deprivation period. Immediately following sleep deprivation, hippocampal slices were prepared for electrophysiological recordings. We found that cAMP rescue during the five-hour deprivation period prevents deficits in 4-train long-term potentiation (LTP), a long lasting (late) form of LTP. This finding demonstrates that cAMP mediates not only the hippocampal-memory effects of sleep deprivation, but also some of the changes in hippocampal synaptic plasticity. Future work will focus on the effect of cAMP rescue on other forms of LTP, and on the effects of cAMP rescue on dendritic spine density in the hippocampus.

Title: The involvement of the hippocampal Rac1 activity in protein synthesis-induced transient amnesia

Authors: *L. LV[1], Y. ZHONG[2];
[1]Tsinghua Univ., Beijing, China; [2]Tsinghua Univ., Beijing City, China

Abstract: Memory consolidation is the process that depends on de novo protein synthesis for the stabilization of a long-term memory (LTM). During the process, memory is susceptible to disruption, such as protein synthesis inhibition, resulting in persistent retrograde amnesia. However, thecurrent study reveals that the protein synthesis inhibitor-induced impaired contextual fear memory can spontaneously recoverwith time, which correlates with the levels of Rac1 activity in hippocampal excitatory neurons. A single injection of the protein synthesis inhibitor, either anisomycin or cycloheximide, following single-trial contextual fear conditioning caused transient retrograde amnesia as reflected with a spontaneous recovery of the memory at day 7 after training. By virally expressing the inhibitory DREADDs (designer receptors exclusively activated by designer drugs), hM4Di, we first identified the reversibility of protein synthesis induced amnesiawithin hippocampus, but not mPFC. Since Rac1-dependent active forgetting is involved in dynamic memory maintenance, we were interested in studying whether hippocampal Rac1 activity play roles in the reversibility of protein synthesis-induced amnesia**.** Unexpectedly, we found that a single injection of the protein synthesis inhibitors causes an increase of hippocampal Rac1 activity at day 1 after training. And such increased Rac1 activity returned to the basal level at day 7 after training, accompanying with spontaneously recovery of memory under amnesia. Our data suggest that the reversibility of amnesia correlates with hippocampal Rac1 activity.

Title: A "synaptic tag and capture"-like mechanism (probably) does not underlie the consolidation of second-order fear

Authors: *D. M. LEIDL[1], B. P. LAY[2], R. F. WESTBROOK[1], N. M. HOLMES[1];
[1]Sch. of Psychology, Univ. of New South Wales, Sydney, Australia; [2]Concordia Univ., Montreal, QC, Canada

Abstract: The present experiments originated in our recent findings (Lay et al, 2018) that consolidation of a second-order fear memory requires neuronal activity, but not de novo protein synthesis, in the basolateral amygdala complex (BLA). They tested the hypothesis that proteins synthesized in the BLA to consolidate first-order conditioned fear are exploited to consolidate second-order conditioned fear, similar to “synaptic tag and capture” (STC) identified in brain

slice electrophysiology studies. They did so by reducing the interval between S1-shock pairings (1st order) and S2-S1 parings (2nd order) from 48 hours to a few minutes. We reasoned that, if an STC-like mechanism underlies the consolidation of second-order conditioned fear, then blocking protein synthesis in the BLA during or after first-order conditioning should simultaneously disrupt consolidation of both first- and second-order conditioned fear. We found no evidence to support this hypothesis. Instead we consistently disrupted fear to the first-order S1 but left intact fear to the second-order S2. These results confirm that consolidation of first-order conditioned fear requires de novo protein synthesis in the BLA. They additionally show that consolidation of second-order conditioned fear does not involve an STC-like exploitation of proteins in the BLA.

Title: Differential effect of moderate and intense training on expression in phosphorylated CREB protein in dorsal hippocampus

Authors: *A. C. MEDINA, H. I. GUILLERMO, P. C. BELLO-MEDINA, G. L. QUIRARTE, R. A. PRADO-ALCALÁ;
Neurobiologia Conductual y Cognitiva. Inst. de Neurobiologia-UNAM, Queretaro, Mexico

Abstract: Phosphorylation of cAMP response element-binding (pCREB) is related to memory consolidation as this molecule participates in gen transcriptional activity in many brain neurons, which is important for synaptic plasticity. There is experimental evidence showing that the mechanism involved in the formation of long-term memory change when subjects are given intense training; in this condition amnestic treatments do not impede memory consolidation. Because the hippocampus has an important role in the memory consolidation, the objective of this study was to determine if amount of pCREB positive neurons in the dentate gyrus (DG) and Ammon's Horn CA1 and CA3 differ in moderate training from intense training. Independent groups of rats were trained in a one-trial step-through inhibitory avoidance task using different intensities of foot-shock (0.0, 1.0, and 3.0 mA). We also studied a group of rats that received the higher foot-shock (3.0 mA) without training and a naive group. Their brains were dissected 1 h after training. pCREB detection was made using an immunohistochemical technique. The results

showed that moderate training induced an increase in the amount of positive pCREB neurons in CA1 and DG, as compared with the naïve group. Intense training induced an increase in positive pCREB neurons in all hippocampal regions, and this increase was greater in CA3. We conclude that positive pCREB neurons in CA1 are involved in memory consolidation of moderate training, while positive pCREB neurons in GD, CA3, and CA1 are implicated in memory consolidation of intense emotional experiences. Title: Effects of exercise on memory performance and hippocampal gene expression

Authors: *A. A. KEISER[1], C. W. BUTLER[2], E. A. KRAMÁR[1], D. P. MATHEOS[1], N. C. BERCHTOLD[2], S. CHEN[3], M. SAMAD[3], C. MAGNAN[3], P. BALDI[3], C. W. COTMAN[2], M. A. WOOD[1];
[1]Neurobio. & Behavior, [2]Neurol., [3]Inst. for Genomics and Bioinformatics, Sch. of Information and Computer Sci., Univ. of California, Irvine, Irvine, CA

Abstract: A growing body of evidence suggests that exercise is capable of improving cognitive function and reducing the risk of cognitive decline associated with aging and Alzheimer's disease (AD). Our labs have previously demonstrated that in males, exercise enables hippocampal-dependent learning in conditions that are normally subthreshold for encoding and memory formation, and depends on hippocampal induction of brain-derived neurotrophic factor (BDNF) as a key mechanism. In male mice with prior exercise experience, only a brief exercise period is required to reactivate the increase of BDNF in the hippocampus, suggesting that there exists a 'molecular memory' for the prior exercise experience that facilitates subsequent learning. However, the underlying mechanisms that mediate the molecular memory are currently unknown. We hypothesize that an epigenetic molecular memory of exercise as a previous experience primes specific genes for subsequent activation upon new learning, resulting in facilitated memory formation. In this study, we used RNA-sequencing to begin to define the

molecular and epigenetic signature underlying exercise-enhanced learning in the hippocampus. The behavioral approach involved examining different periods of initial exercise (0-3 weeks), a sedentary delay period (0-2 weeks), and a second short exercise period (2 days), followed by 3 min subthreshold training in an object location memory task. This allowed us to identify exercise parameters that led to the formation of robust long-term memory for object location, even though animals were given a subthreshold training period. Those parameters were then used to examine hippocampal long-term potentiation (LTP), a form of synaptic plasticity thought to underlie memory. We also used the same parameters to examine gene expression using RNA sequencing during memory consolidation period, one hour after training. Our results indicate that 2 weeks of exercise is sufficient to engage robust memory and LTP, even after one week of sedentary delay. We have also begun to examine how these parameters may be similar or different in females, as well as gene expression profiles engaged in the female hippocampus following exercise and subthreshold training in the object-location memory task. We are also beginning to understand how epigenetic mechanisms may be involved in establishing a molecular memory of exercise and facilitating gene expression during learning. Together, these studies begin to elucidate how a previous experience such as exercise is encoded at a molecular level to facilitate memory.

Abstract: The beneficial effects of exercise on cognition are well established; however specific exercise parameters regarding the frequency and duration of physical activity that provide optimal cognitive health have not been well defined. Here, we explore the effects of the duration of exercise and sedentary periods on long-term Object Location Memory (OLM) in mice. We

use a weak object location training paradigm that is sub-threshold for memory formation in sedentary controls, to demonstrate that exercise enables long-term memories to form. We show that 14- and 21-days of running wheel access enables mice to discriminate between familiar and novel object locations after a 24 hour delay, while 2- or 7-days running wheel access provides insufficient exercise for such memory enhancement. Exercise-induced cognitive enhancement then exhibits considerable decay following 3 days of sedentary behavior. However, exercise-induced cognitive enhancement can be reactivated by an additional period of just 2 days exercise, previously shown to be insufficient to induce cognitive enhancement on its own. The reactivating period of exercise is capable of enhancing memory after 3- or 7-days of sedentary behavior, but not 14 days. These data suggest a type of "molecular memory" for the exercise stimulus, in that once exercise duration reaches a certain threshold, it establishes a temporal window during which subsequent low-level exercise can capitalize on the neurobiological adaptations induced by the initial period of exercise, enabling it to maintain the benefits on cognitive function. These findings provide important information regarding the temporal aspects of exercise-induced cognitive enhancement.

Title: IGF2 receptor is required for memory consolidation in the hippocampus

Authors: *X.-W. YU, K. PANDEY, C. M. ALBERINI;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Previous work from our laboratory showed that insulin-like growth factor II (IGF2) is crucial for memory formation. Additionally, supplying IGF2 when the animal is learning, immediately after the learning event, or during memory retrieval enhances memory retention and prevents forgetting. These memory-enhancing effects of IGF2 require its high-affinity receptor, the IGF2 receptor (IGF2R). IGF2R is also known as the cation-independent mannose-6-phosphate receptor, and has been largely studied for its role in sorting proteins to the endosomal and lysosomal compartments. However, the role of IGF2R in memory formation is not yet understood. Here, we used injections of a functionally-blocking IGF2R antibody into hippocampus of rats, and neuron-specific IGF2R knockdown in the hippocampus of mice, to

examine the role of IGF2R in memory consolidation. We found that blocking IGF2R impaired memory consolidation in rats during a limited temporal window. However, we observed no impact on memory encoding, expression, or retrieval. There were also no differences in locomotion or anxiety levels. Similar data were found in mice with IGF2R knocked down in hippocampal neurons. Blockade of IGF2R in rats also prevented the training-induced increase in *de novo* protein translation, measured using the surface sensing of translation (SUnSET) technique. We conclude that hippocampal IGF2R is upstream of training-induced translation of proteins, and is required for memory consolidation.

Title: Episodic memory formation in infant rat requires hippocampal regeneration of reduced glutathione

Authors: *B. BESSIÈRES, E. CRUZ, C. M. ALBERINI;
Ctr. For Neural Sci., New York, NY

Abstract: The ability to form and remember long-term memories differs across developmental ages. Episodic memories formed in infant rat (post-natal day 17 - PN17) appear to be rapidly forgotten, a phenomenon found in rodents as in humans and believed to be associated to infantile amnesia, the inability of adults to remember early life experiences. By contrast, juvenile PN24 rats are able to form and express long-term memories. The formation of episodic memories requires the hippocampus, a region metabolically activated by episodic learning. The metabolic energy requirements of the brain are higher during post-natal development than in adulthood, suggesting that different metabolic regulatory mechanisms may underlie the formation of memory during development. However, very little is known about how learning regulates the metabolic responses across developmental ages. To begin filling this knowledge gap we determined how the hippocampal metabolome changes over the course of post-natal developmental ages and in response to learning. Untargeted metabolomic profiling of the rat hippocampus were carried out at PN1, PN7, PN17, PN24 and PN80 (young adult) in untrained condition and 1h after a single inhibitory avoidance (IA) training at PN17, PN24 and PN80.

Statistical and pathway analyses indicated that the hippocampus undergoes significant metabolic changes over development in all classes of metabolites, with the highest diversity and quantity of metabolites measured at PN24. Furthermore, most of the changes associated with learning were observed at PN17 with 54 metabolites significantly downregulated by comparison with the age-matched untrained rats. Among the 20 top-ranked metabolites downregulated, a large proportion are involved in the cellular defenses against oxidative stress, including the reduced glutathione (GSH), which is the most abundant antioxidant in the mammalian brain. We demonstrated that IA learning at PN17, but not at PN24, induces a fast and long-lasting increase in the activity of the hippocampal glutathione reductase (GR), an enzyme involved in the regeneration of GSH from its oxidized form. Using selective pharmacological inactivation of the GR upon IA learning, we then showed that the hippocampal GR-dependent regeneration of GSH is necessary for the formation of long-term memory in infant (PN17) but not in juvenile (PN24) rats. Taken together, our results provide new insights on metabolic regulations occurring in the hippocampus over development and after learning, and identify the glutathione-mediated antioxidant defense as a critical metabolic pathway for memory formation during infancy.

Title: Translation-dependent macroautophagy is required for long-term memory formation

Authors: *K. PANDEY, X.-W. YU, A. STEINMETZ, C. ALBERINI;
Ctr. for Neural Sci., New York Univ., New York City, NY

Abstract: Long-lasting memories, which store information for days, months and up to a lifetime, require wave/s of *de novo* translation, which has been extensively investigated in many species and different types of memories. Learning-induced *de novo* translation implies that mechanisms that rebalance protein levels, like protein degradation, must occur in order to control protein accumulation and maintain protein homeostasis. Although protein degradation mechanisms have been implicated in learning and memory, its regulation remains unknown. Here we show that episodic learning in rats significantly increases both the levels of proteins involved in autophagy and lysosomal degradation (macroautophagy), including beclin-1, LC3-II, p62 and LAMP1, and the autophagic flux in their dorsal hippocampus. The increases in macroautophagy proteins upon learning is not accompanied by changes in their mRNA levels, but depend on *de novo* translation

and Arc/Arg3.1. Similarly, autophagic flux requires translation and Arc/Arg3.1. In agreement with this translation requirement, learning increases the recruitment of beclin-1, LC3-II, p62 and LAMP1 mRNAs to the actively translating ribosomes. Finally, pharmacological or targeted molecular disruption of the learning-induced macroautophagy proteins impairs long-term memory, while leaving the short-term memory intact. We conclude that learning-induced *de novo* translation and Arc are required for the induction of macroautophagy, which is critical for long-term memory formation.

Title: Hippocampal PFKFB3 glycolytic activity is required for memory formation during early development

Authors: *E. CRUZ, B. BESSIÈRES, C. M. ALBERINI;
New York Univ. Ctr. for Neural Sci., New York, NY

Abstract: Glucose is the major source of energy production in the brain, and energy consumption in the brain peaks during late childhood. How glucose metabolism is regulated in juvenile compared to adult brains, particularly in response to learning, remains to be determined. Here we compared the juvenile and adult hippocampi following episodic learning in rats to determine neuronal and/or astrocytic regulations of glucose metabolism. We assessed the expression regulation, in untrained conditions and following learning of 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase-3 (PFKFB3), a key glycolytic-promoting enzyme that catalyzes the production of fructose-2,6-bisphosphate (F2,6BP), a positive allosteric effector of 6-phosphofructo-1-kinase (PFK1), the rate-limiting enzyme of glycolysis. We chose to study PFKFB3 during learning because up-regulation of this enzyme in neurons results in the activation of glycolysis, a metabolic pathway that we found to be up-regulated during learning in development but not adults. Furthermore, because PFKFB3 is degraded by the E3 ubiquitin ligase anaphase-promoting complex/cyclosome-cadherin1 (APC/C-Cdh1), we also assessed the levels of this degrading enzyme. We found that, compared to adult, the juvenile hippocampus, at postnatal day 24 (PN24) has significantly higher basal levels of PFKFB3 and lower levels of

APC/C-Cdh1 in both astrocytes and neurons. Furthermore, inhibitory avoidance learning at PN24 significantly up-regulates PFKFB3 and down-regulates APC/C-Cdh1 in both cell types, suggesting high PFKFB3-mediated glycolytic activity induced by learning during early development. Finally, using molecular interference and pharmacological inhibition, we found that PFKFB3 is required for memory consolidation in juveniles, but not adult rats. Collectively, our findings suggest that, compared to adult, the juvenile brain recruits differential mechanisms of glycolysis regulation to support the consolidation of early-life memories.

Title: Mutation of the HERC 1 ubiquitin ligase impairs learning and sinaptic plasticity in the lateral amygdala

Authors: *J. NEGRETE-DIAZ[1], E. JUAREZ-CORTES[2], H. AGUILAR-ZAVALA[2], J. ARMENGOL[3], E. PEREZ-VILLEGAS[3], A. RODRÍGUEZ-MORENO[3];
[2]Enfermería Clínica, [1]Univ. de Guanajuato, Celaya, Mexico; [3]Univ. Pablo de Olavide, Sevilla, Spain

Abstract: Long-term potentiation (LTP), expressed as an increase in synaptic strength, is considered an excellent approach to explain the cellular and molecular bases of learning and memory. *Tambaleante* mouse (*tbl*/*tbl)* presents a spontaneous mutation in the E3 ubiquitin ligase protein (HERC1), present a loss of Purkinje cells and suffers an ataxic syndrome. Given that the presence of a mutation in HERC1 in humans correlates with cognitive deficits, we investigated here whether *tbl*/*tbl* mice show alterations in learning, short-term synaptic plasticity (STP) and long-term potentiation (LTP). Field excitatory postsynaptic potentials (fEPSP) were obtained from slices from control and *tambaleante* mice containing the amygdala, stimulating the cortical afferents (external capsule) or the thalamic afferents (internal capsule) and recording from the lateral or basolateral amygdala, respectively. After 10 minutes of basal stimulation at 0.2 Hz, a

theta burst stimulation protocol was applied to induce LTP consisting in: 10 trains of 4 stimuli of 100 microseconds duration, at 100 Hz, with an interval inter stimulus of 10 ms and with 200 ms between trains; this protocol was repeated 5 times every 5 seconds, to return immediately to the basal stimulation for 1 hour. We analyzed the slope and amplitude of the maximum peak of the fEPSP, and the magnitude of LTP after 1 hour of recording post protocol stimulation. The tbl/tbl mice perform worse than wild-type animals in the passive avoidance test, and histologically, the tbl/tbl mice have more immature forms of dendritic spines. Also, we observed a decrease in STP and LTP could not be detected in these mutant mice. These results suggest that the cognitive deterioration presented by individuals carrying a mutation in HERC1 might be due in part to a decrease in synaptic strength and it could involve an alteration to the ubiquitin-proteasome pathway.

Title: Modulating social-emotional control by synchronizing rhythmic brain circuits

Authors: *B. BRAMSON[1], I. TONI[2], K. ROELOFS[3];
[1]Donders Ctr. For Cognitive Neuroimaging, Nijmegen, Netherlands; [2]Donders Inst., Nijmegen, Netherlands; [3]Donders Ctr. for Cognitive Neuroimaging, Nijmegen, Netherlands

Abstract: Regulating social-emotional behaviour depends on prefrontal control over downstream areas such as the amygdala, parietal- and motor cortex (Volman et al., 2011), and is implemented through phase-amplitude coupling between prefrontal theta- and sensorimotor gamma-band rhythms (Bramson et al., 2018). This study tests the possibility of altering the regulation of social-emotional behaviour by manipulating phase-amplitude coupling between prefrontal and sensorimotor cortex. We do that using dual-site phase-coupled transcranial alternating current stimulation (tACS). Forty-one human participants performed a social approach-avoidance task while brain activity was measured with fMRI, and both right anterior prefrontal (aPFC) as well as left sensorimotor (SMC) cortex were focally stimulated with tACS. Participants had to approach angry- and avoid happy faces in affect-incongruent task conditions,

requiring control over prepotent social-emotional behaviour (namely avoid-angry and approach-happy in affect-congruent conditions). During task performance, participants were concurrently stimulated over two sets of ring electrodes (100 mm Ø, 1 mA peak-to-peak, in blocks of 60 sec): theta-band (6 Hz) tACS over the aPFC, and gamma-band (75 Hz) tACS over SMC. There were three stimulation conditions. The power envelope of the SMC gamma-band stimulation was tapered by a 6 Hz sine wave locked to either the peaks (in-phase) or the troughs (anti-phase) of the aPFC theta-band stimulation. In the third stimulation condition (sham), the electric current at both rings was reduced to zero after 10 sec. tACS (verum vs sham conditions) increased task-related BOLD-signal in areas proximate to the stimulation and involved in social-emotional regulation. Facilitation of aPFC-SMC connectivity (in-phase vs anti-phase tACS) led to changes in task-related BOLD-signal over aPFC and SMC in stimulation locations that scaled with reduced behavioural costs (faster reaction times) during social-emotional regulation. Disruption of aPFC-SMC connectivity (anti-phase vs in-phase tACS) led to increased task-related BOLD-signal over left aPFC and posterior parietal cortex (PPC), contralateral to the stimulated aPFC region. Left aPFC scaled with reduced behavioural costs (reduction in error rates) during social-emotional regulation, possibly reflecting a compensatory mechanism. Together, these findings provide novel insights into active and potentially compensatory mechanisms coupling regulatory prefrontal signals with fronto-parietal areas implementing social-emotional actions.

Title: Higher order theta harmonics account for the detection of slow gamma

Authors: ***A. P. MAURER**[1], Y. ZHOU[2], Y. QIN[2], J. P. KENNEDY[1], N. M. DICOLA[1], S. N. BURKE[1], A. SHEREMET[3];

Abstract: The debate over the origins and function of oscillations in the hippocampal local field potential has a long history dating back approximately 80 years (Gerard, Marshall, & Saul, 1936;

Jung & Kornmüller, 1938; Renshaw, Forbes, & Morison, 1940). Recently, the application of different decomposition algorithms to local field potential data have further kindled different interpretations regarding whether or not individual frequency bands of the power spectrum independently support distinct cognitive functions. The current study compared the results of different decomposition algorithms as implemented in contemporary literature to a synthetic time-series dataset. A simple of benchmark test was developed in which a synthetic 8-Hz oscillation along with harmonics up to 32 Hz was placed against a pink noise background to construct time-series data with known parameters. This synthetic time series was then run through a Fourier decomposition, Wavelet as described by Colgin et al. (2009), and ensemble empirical mode decomposition (EEMD) as described by Lopes-dos-Santos et al. (2018). A significant discrepancy across these methods was apparent. While Fourier maintains fidelity with the synthetic trace, resolving all of the harmonics, the wavelet decomposition resulted in a convolution of the harmonics erroneously distributing energy across a broad 25-50Hz range. EEMD failed to remove all of the harmonics of theta and also resulted in a convolution giving the impression of multiple low gamma bands. As this simple benchmark assessment challenges a long-standing dogma in the field, “slow gamma” as a dominant oscillation, we encourage others to test this for themselves.
Nevertheless, we present the results in defense of the idea that the identification of slow gamma as a dominant rhythm is an artifact of not carefully selecting the appropriate analytical parameters. We proceed to demonstrate that studies prior to the discovery of slow gamma, sensitive enough to detect the presence of slow gamma, made no such conclusion. While it has been argued that Fourier cannot be used to identify non-stationary signals, we demonstrate that Fourier is readily able to detect gamma (50-120 Hz) and ripple oscillations from CA1 recordings. Multiple suggestions are presented in order to facilitate spectral analyses moving forward.

Title: Nonlinear interaction of theta and theta harmonics between hippocampus and medial entorhinal cortex

Authors: *Y. Z. ZHOU, Y. QIN, K. JACK, B. SARA, A. SHEREMET, M. ANDREW;
Univ. of Florida, GAINESVILLE, FL

Abstract: The hippocampal theta rhythm, believed to support various behaviors including navigation through physical and mnemonic space, has been intensively studied for over 80 years. It was acknowledged early on that the theta rhythm exhibits significant deviations from a sinusoid (John D Green & Petsche, 1961; Stumpf, 1965). This nonlinearity is expressed as second and higher order harmonics that appear as a function of velocity (Sheremet et al., 2016). Moreover, the theta rhythm along with harmonics are also detected in medial entorhinal cortex (Zheng et al., 2015). As the medial entorhinal cortex provides strong afferent input into the hippocampus and also receives CA1 inputs, we sought to determine the relationship between theta and its harmonics between the MEC and across lamina of the hippocampus. Therefore, F344-BN F1 rats from Charles River were implanted with two 32-site silicon probes which for simultaneous recording across CA1 lamina and the dorso-ventral axis of the MEC. Rats were trained to perform a spatial delay alternation task. Standard power spectrum analysis was performed, reconfirming the existence of theta harmonics in MEC which extended upwards of 24 Hz. Therefore, coupling within the MEC was investigated via bispectral analysis while MEC versus hippocampal lamina was conducted with cross-bicoherence. A nonlinear phasing coupling index is introduced to estimate and compare the strength of cross frequency coupling within MEC and cross regions (MEC to HPC). Preliminary analysis result indicates the MEC theta harmonics has stronger nonlinear phase coupling with HPC theta compared with the coupling with MEC theta. If this observation is true, then the harmonics observed in MEC might be generated in and propagated from HPC rather than generated locally.

Title: Theta in the visual cortex

Authors: *J. P. KENNEDY[1], Y. ZHOU[2], Y. QIN[2], S. N. BURKE[3], A. SHEREMET[4], A. P. MAURER[5];
[2]Civil & Coastal Eng., [3]Neurosci., [4]Engin. Sch. for Sustainable Infrastructure and Envrn. (ESSIE), [5]Evelyn F. McKnight Brain Inst., [1]Univ. of Florida, Gainesville, FL

Abstract: It is widely accepted that the coordination of activity between brain regions is critical to the execution of complex behavior. While the precise mechanisms underlying this coordination are not understood, there is significant evidence that it is accomplished via oscillations in the local field potential (LFP). One of the most prominent examples of this is the 4-12Hz theta oscillation. Specifically, the larger reentrant circuits of the brain may provide the anatomical basis for rhythmic entrainment at theta frequency between the hippocampus and cortex (Edelman, 1987). However, the nature of cortical theta is still a matter of debate. Some have proposed that cortical theta is volume conducted from the hippocampus (Winson, 1974; Bland and Whishaw, 1976; Gerbrandt et al., 1978; Sirota et al., 2008; Senzai et al., 2019), generated locally (Zold and Shuler, 2015), or some combination of the two (Holsheimer et al., 1979; Leung and Borst, 1987). While Sirota and colleagues emphasized that theta in the cortex could be due to the superposition of two or more current sources, it was also noted that neocortical neuron firing and the local gamma oscillation can be entrained by hippocampal theta frequency. An instance of cortical gamma bursts at the theta frequency, when spectrally decomposed will be expressed as having both theta and gamma. Therefore, issues surrounding cortical theta may be one of semantics, attempting to divide a pacemaker from a current generator. Furthermore, while theta in the cortex may be volume conducted, it does not necessarily mean that volume conducted theta is without a physiological influence. We sought to revisit cortical LFP entrainment relative to the hippocampal theta rhythm, investigating the nature of cross-regional interactions and current generation. Four f344xBN hybrid rats were implanted with two single-shank 64 channel silicon probes in the dorsal hippocampus and visual cortex. Notably, spectral decomposition revealed theta and harmonics in the visual cortex. Furthermore, there was power-power coupling as well as phase-phase coupling between the theta and gamma (50-120 Hz) within the visual cortex. The results were reconfirmed using mouse data generously provided by the Buzsaki laboratory (Senzai et al., 2019). Therefore, as gamma is considered to be local and yet is modulated at theta frequency, these results offer preliminary support that the cortical circuitry can provide the ion current to bias the LFP to express theta locally.

Title: Bursting activity propagation within homogeneous and isotropic population of neurons

Authors: *Y. QIN, A. SHEREMET, A. MAURER;
Univ. of Florida, Gainesville, FL

Abstract: The mammalian brain is characterized by laminar organizations formed by a variety of neuronal types. While the basic physiology behind an action potential is well understood, cognition occurs as a function of activity across a population. Therefore, it is necessary to know how activity may propagate across a lamina of neurons. Working under the assumption of stochastic synaptic connections, we propose a model which uses a time continuous governing equation of population activity. By introducing a state variable, the mean potential energy, to describe the time evolution of populations we can formulate the equations from an energy perspective. Thus the concept of energy conservation and energy flux can be applied to allow the distribution of energy among neurons to be considered. We use this model to resolve continuous energy transfer of population. Importantly, this model could be applied to networks with single or multiple types of neurons, both homogeneous and in-homogeneous, both isotropic or non-isotropic. Elementary analysis on the model reveals different mechanisms to support waves and energy propagation in isotropic networks. During our theoretical work, two types of propagating waves were identified which are a consequence of different mechanisms: refractory waves and interactive waves. Theoretical analysis indicates the existence of different wave regimes, that might have biological implications. Whether these regimes represent realistic conditions depends on the configuration of connections.

Title: The role of frontal midline theta in reasoning accuracy and conflict detection

Authors: *A. WEIL, C. CARABALLO, E. BREWINGTON, C. JAYCOX, M. HASLAM, K. MEHRTENS, J. NGO;
Psychology, Washington Col., Chestertown, MD

Abstract: The neuroscience of judgment and reasoning is still in its infancy, and as such little is known about the neural correlates of individual differences in reasoning ability. Reasoning ability is classically defined as being able to inhibit intuitive responses in favor of more logical answers. For example, in a joint-probability problem a participant might read a description of

Damien, who is from Texas, and feels that he truly embodies what it means to be a Texan. Participants are then asked which of the following two events is more likely: (1) Damien is a ballet dance instructor, or (2) Damien knows how to ride a horse and is a ballet dance instructor. Most participants choose option two, despite it being logically impossible for two events to be more likely than one. These errors in judgment have historically been attributed to participants' inability to detect the conflict between an intuitive and logical response. However, recent work suggests that people may be able to implicitly detect this conflict between logic and intuition, providing a new way to characterize individual differences in reasoning ability. In this study we investigated how individual differences in conflict detection and reasoning accuracy relate to frontal midline theta activity. Frontal midline theta is a frequency band (4-7 Hz) of neural oscillatory activity generated by the medial frontal cortex that has been implicated as a general mechanism of cognitive control. As such, we hypothesize that differences in frontal midline theta power may underlie observed individual differences in reasoning accuracy and the ability to detect a conflict between logical and intuitive responses. Participants reasoned through joint-probability and base rate problems in which half of the problems presented a conflict between logical and intuition, and half did not. Neural data were collected using an ANT Neuro 32-channel electroencephalography net, and power spectrum density was extracted using custom Matlab scripts. Replicating previous work, accuracy was lower on conflicting problems compared to non-conflicting problems for both joint-probability and base rate problems. Most participants were conflict detectors, as evidenced by lower confidence and longer reaction times to incorrect conflicting problems compared to correct control problems. Electrophysiological data suggest that more effortful reasoning processes are reflected in greater frontal midline theta power, providing the foundation for future work on the role of frontal midline theta in judgment and reasoning tasks.

Abstract: Altered neural dynamics in medial prefrontal cortex (mPFC) and hippocampus may contribute to cognitive impairments in the complex chromosomal disorder, Down Syndrome (DS). Here, we demonstrate non-overlapping behavioural differences associated with distinct abnormalities in hippocampal and mPFC electrophysiology during a canonical spatial memory task in three partially trisomic mouse models of DS (Dp1Tyb, Dp10Yey, Dp17Yey) that together cover all regions of homology with human chromosome 21 (Hsa21). Dp1Tyb mice showed slower decision-making (unrelated to the gene dose of *DYRK1A*, which has been implicated in DS cognitive dysfunction) and altered theta dynamics (reduced frequency, increased hippocampal-mPFC coherence, increased modulation of hippocampal high gamma); Dp10Yey mice showed impaired alternation performance and reduced theta modulation of hippocampal low gamma; while Dp17Yey mice were no different from wildtype mice. These results link specific hippocampal and mPFC circuit dysfunctions to cognitive deficits in DS models and, importantly, map them to discrete regions of Hsa21.

Title: Selective disruption of hippocampal sharp-wave ripples leads to impaired object-place recognition memory

Authors: *S. DUTTA[1], A. K. FELDMAN[1], C. KEMERE[1,2];
[1]Rice Univ., Houston, TX; [2]Baylor Col. of Med., Houston, TX

Abstract: Rodents have an innate curiosity to explore novel contexts and objects resulting in them spending more time with novel objects and locations as opposed to familiar ones. Extensive work through lesion studies has demonstrated this novelty preference to be hippocampally dependent via novel object test (NOT) paradigms. More recent work has correlated hippocampal CA1 signatures, such as fast-gamma oscillations, to be of importance in NOT object-place recognition memories and demonstrated predictable changes in other transient hippocampal events, such as sharp-wave ripples (SWRs). Specifically, SWRs have been shown to increase after encoding of novel objects and general novelty in the test; however, the concomitant spiking activity has not been correlated with object-place pairings leading us to question the role of these events in encoding objects and place. To interrogate the role of SWRs in encoding novelty, we selectively modulate of SWR activity using our previously engineered closed-loop, open-source SWR detection system during various NOT paradigms. Preliminary results indicate that suppression of SWR activity during object encoding and post encoding sleep sessions impair object-place recognition memory of familiar objects in novel locations but not of novel objects in novel locations. We look to further understand the role of SWRs along with its co-occurring neural activity that would lead to such a deficit in recognition memory by selectively interacting with different subsets of high frequency oscillations and further investigating the modulation of concomitant neural firing patterns. Altogether, our preliminary findings suggest SWRs play a role in object-place pairing consolidation as opposed to simply broadcasting the presence of novelty.

Title: A metabolic function of the hippocampal sharp-wave ripple

Authors: *D. TINGLEY[1], K. MCCLAIN[1], G. BUZSAKI[2];
[1]NYU Neurosci. Inst., New York, NY; [2]New York University, Sch. of Med., New York, NY

Abstract: The hippocampal sharp-wave ripple (SPW-R) is a 40-150 millisecond event that consists of synchronized spiking from approximately 10-20% of hippocampal pyramidal neurons. These events primarily occur during consummatory behaviors and NREM sleep. The physiological role of SPW-Rs is typically discussed in connection with memory consolidation and action planning, requiring SPW-R spiking content to be communicated to the neocortex. However, several subcortical areas are also recipient and respondent to SPW-R-related synchronous hippocampal activity.
We took an iterative anatomical approach to examine where these population bursts may be transmitted. By looking for the densest anatomical efferents of the hippocampus, we find that the lateral septum is a major recipient of hippocampal projections. In turn, we find that the main efferent projection of the lateral septum is to the hypothalamus. Others have reported that hypothalamic nuclei project heavily to brainstem nuclei, including those that give rise to vagal efferents that innervate the pancreas. Thus, there exists a dense multisynaptic pathway from the CA1 neuron population to insulin-producing beta cells of the pancreas.
To examine whether these anatomical connections are utilized for a physiological function, we simultaneously recorded SPW-Rs in hippocampal CA1 while also monitoring interstitial glucose concentrations in freely behaving rats. We find that SPW-R occurrence reliably predicts a small but consistent decrease in systemic glucose concentrations 2-5 minutes into the future. Preliminary analyses suggest this relationship is not state (sleep vs wake) or movement dependent. Additionally, we find that short duration SPW-Rs, and bursts of SPW-Rs are more strongly correlated with future decreases in glucose concentrations.
Finally, we find that this correlation between SPW-Rs and glucose fluctuations is stronger when food is provided ad libitum, or during meal intake, than during fasting. We propose that these data support the hypothesis that the SPW-R, occurring primarily during periods immediately preceding metabolic changes (i.e. food intake), is a multi-modal signal that is capable of directly influencing the metabolic state of the organism.

Title: Inferring long-term changes in spike transmission while accounting for time-varying network drive

Authors: *R. HUSZAR[1], S. A. MCKENZIE[2], G. BUZSAKI[3];
[1]New York Univ., New York, NY; [2]NYUMC, New York, NY; [3]New York University, Sch. of Med., New York, NY

Abstract: The storage of information in neural circuits depends on long-lasting modifications of synaptic strengths. However, while many techniques exist to simultaneously record from large numbers of neurons, the tools for large-scale monitoring of synaptic dynamics in freely moving animals are still lacking. Recently, it was demonstrated that fine timescale spiking synchrony can be used to infer monosynaptically connected E and I cells in vivo (English et al., 2017). Here, we consider the reliability of pairwise spiking synchrony (referred to as spike transmission probability) as a proxy measure of synaptic strength (Csicsvari et al., 1998). First, we demonstrate that these estimates of synaptic strength are confounded by measures of instantaneous network drive. More specifically, hippocampal theta phase, ripples and multiunit activity all correlate with spike transmission probability. Furthermore, changes in spike transmission correlate with both changes in pre- and postsynaptic firing rates. In order to regress out the time-varying contribution of different network states to postsynaptic spiking, we make use of a generalized linear model that also includes the influence of presynaptic spikes as one of its regressors. With this statistical framework in hand, we decouple slow changes in synaptic coupling while accounting for changes in postsynaptic rate that unfold at a broad range of timescales. We validate the model on simulated data with known ground truth, and use it to explore synaptic dynamics in extracellular CA1 datasets in both rats and mice involving different stimulation protocols (i.e., on-track stimulation, PV-interneuron stimulation triggered on presynaptic events).

Title: Sleep dynamics in the dorsal hippocampus and amygdala

Authors: B. KHOUADER[1], I. INEMA[2], G. BUZSAKI[3], *G. GIRARDEAU[1];
[1]Inst. Du Fer-à-Moulin - Inserm, Paris, France; [2]McGill Univ., Montreal, QC, Canada; [3]New York University, Sch. of Med., New York, NY

Abstract: Sleep is a physiological state of reduced vigilance and alertness known to be important for brain homeostasis, memory consolidation and emotional regulation. During sleep, the brain cycle trough two main stages: Non-REM sleep (also called slow-wave sleep) and REM sleep. The neuronal dynamics of REM and Non-REM sleep have been extensively studied, notably in the hippocampus and neocortex, in link with homeostasis and plastic processes related to memory consolidation. The amygdala is a critical brain region for the processing of emotions. However, the sleep dynamics of the amygdala are comparatively understudied, despite a hypothesized role for both REM and Non-REM sleep in emotional memory consolidation. Here, using large-scale recording of LFPs and neuronal assemblies in the hippocampus and basolateral amygdala (BLA) of freely moving rats, we extensively describe the dynamics of neuronal firing in the BLA at transitions between states (Wakefulness/REM/Non-REM), and within REM-sleep. In addition, we analyze how local (BLA) and hippocampal theta oscillations during REM-sleep influence activity in the amygdala. Preliminary results indicate increased firing rates of both pyramidal neurons and interneurons in the BLA at Non-REM to REM transitions, leading to a change in the excitatory/inhibitory balance. Moreover, subsets of BLA neurons are modulated by hippocampal theta oscillation during REM-sleep. Unique firing patterns in the BLA during REM and Non-REM sleep might underlie the specific roles of these two sleep stages in emotional regulation and memory.

Title: Long-duration spontaneous and optogenetically prolonged hippocampal sharp wave ripples improve memory

Authors: *A. FERNANDEZ-RUIZ[1], A. OLIVA[2,1], E. F. OLIVEIRA[3,1], F. ROCHA-ALMEIDA[4,1], G. BUZSAKI[1];

Abstract: Hippocampal sharp-wave ripples (SPW-Rs) are highly synchronous network activity patterns. They have been hypothesized to serve as a mechanism to replay previous experiences for memory consolidation and planning of future actions. Most works supporting this framework have been correlational. Although several studies have demonstrated that electrical perturbation of SPW-Rs results in memory deficits, the mechanisms by which such perturbation works are unknown. Furthermore, improvement of memory by manipulating ripples could not be achieved to date. The duration of ripples and associated neuronal sequences show a skewed distribution with a minority of long duration events. We found that the incidence of long duration ripples is increased in various situations demanding learning and memory in rats. Furthermore, correct versus error trials in spatial memory tasks could be predicted from the length of the SPW-Rs. Based on these observations, we hypothesized that prolongation of spontaneously occurring ripples by closed-loop optogenetic stimulation would enhance spatial memory performance. We then combined silicon probe recordings with optogenetic activation of hippocampal pyramidal neurons in rats performing a spatial working memory task. Prolongation of spontaneously occurring ripples by closed-loop optogenetic stimulation, but not randomly induced ripples, increased working memory performance. The neuronal content of randomly induced ripples was similar to short duration spontaneous ripples and contained little spatial information. The spike content of the optogenetically prolonged ripples was biased by the ongoing, naturally initiated neuronal sequences. Prolonged ripples recruited new neurons that represented either the left or right arm of the M-shape maze. Thus, neurons are not randomly recruited by light but constrained by the ongoing network activity. We concluded that long-duration hippocampal SPW-Rs with neuronal sequences replaying large parts of planned routes are critical for memory.

Title: Firing rate heterogeneity during spontaneous activity reflects a balanced neuronal “ground state”

Authors: *D. LEVENSTEIN[1], J. GORNET[2], M. VALERO[3], J. M. RINZEL[4], G. BUZSAKI[5]; [1]NYU, New York City, NY; [2]New York Univ., Brooklyn, NY; [3]NYU Neurosci. Inst., New York, NY; [4]Ctr. Neural Sci., New York Univ. Ctr. for Neural Sci., New York, NY; [5]New York University, Sch. of Med., New York, NY

Abstract: Even within a given cell type, neurons show heterogeneous activity patterns. For example, heterogeneous responses to experimenter-imposed stimuli are frequently studied. However, heterogeneity is also seen in activity not obviously related to stimulus tuning, such as the mean firing rate during "spontaneous" activity (sFR). In theory, sFR heterogeneity might come from variability in 1) intrinsic neuronal properties, 2) network properties, or 3) the environmental frequency of tuned stimuli. However, the relative contributions of these effects are not known. To further characterize sFR heterogeneity, we analyzed the statistics of inter-spike intervals (ISIs) from multiple brain regions in freely behaving rats and their relationship to network activity and behavior.

Regardless of region, we found that forebrain excitatory neurons spend the majority of time in a neuronal "ground state": a low rate mode with irregular ~0.5-5s ISIs that was the main determinant of a neuron's sFR. In vivo experiments with synaptic blockers revealed that ground state activity relies on network input, as the absence of synaptic drive resulted in either silence or regular spiking in neocortical neurons. Comparison with the firing statistics of fluctuation-driven integrate and fire units revealed that the ground state ISIs are consistent with a balanced regime in which sFR heterogeneity emerges from variation in the incoming excitatory/inhibitory ratio, which can be replicated in a network in which each neuron self-balances at a unique firing rate with inhibitory STDP.

While the firing frequency of each neuron was bounded from below by a ground state common among regions, each neuron could fire up to ~100 Hz in "activated states": region and state - specific patterns of ISIs <300ms. Spiking during activated states tended to be more regular, reflecting suprathreshold spiking or coupling to oscillations, and could be evoked by tuned behavior/stimuli.

Together, these results reveal a picture of the activity of individual neurons in the mammalian forebrain in which neurons homeostatically tune the ratio of incoming excitatory and inhibitory synaptic weights to maintain a cell-specific low rate of activity. Balanced input from ongoing brain activity results in a ground state of fluctuation-driven spiking. On top of this ground state, region- and state-specific activated states can be evoked by synchronous or unbalanced inputs that emerge during spontaneous activity or the presence of tuned stimuli.

Title: Parametric model of hippocampal place cell activity applied to assess speed modulation of firing rates

Authors: *K. MCCLAIN[1], D. J. HEEGER[2], G. BUZSAKI[3];
[1]NYU Neurosci. Inst., New York, NY; [2]Dept Psychol & Ctr. Neural Sci., New York Univ., New York, NY; [3]New York University, Sch. of Med., New York, NY

Abstract: Hippocampal place cells have been studied for their encoding of a rodent's position in the environment. Two features of place cell activity contain spatial information: 1) the firing rate increases dramatically in a roughly Gaussian pattern centered on a particular location and 2) the phase of spiking within the theta oscillation precesses with respect to position. It has been suggested that rate and phase codes are independent: spike phase codes for position and firing rate for speed. We explore the implications of these overlapping codes in a novel parametric model for place field activity. This model has three primary utilities: 1) generating realistic place cell simulation data, 2) parametrically characterizing place fields to compare across cells, time and condition, 3) conceptualizing a framework for principled hypothesis testing to identify additional sources of variability in place cell data. We model the firing rate of a place cell as a multiplication of parameterized tuning curves with respect to position and theta phase. We model spiking as a Poisson process of this time varying firing rate, and fit to data with maximum likelihood optimization. We apply the model to understanding the influence of running speed on place cell firing rates. Using simulation, we identify an implicit role of speed, as firing rate variability increases at high speeds due to interaction between the two spatial codes. We also investigate the explicit role that speed may play. In real place field data recorded from rats running on a linear track, we observe a heterogeneous distribution of speed modulation across place cells, including some that are inhibited at high speeds. To disambiguate explicit speed dependence from statistical anomaly, we compare how well our real data is captured by speed dependent variations of our model vs. the speed-independent null model.

Title: Physiological and network properties of down state-active neurons in neocortex

Authors: *M. VALERO, G. BUZSÁKI;
NYU Neurosci. Inst., New York, NY

Abstract: During non-rapid eye movement (NREM) sleep, the neocortex alternates between periods of spiking (UP states) and synchronous hyperpolarization (DOWN states), which defined a dominant ‘slow oscillation’ (1-3 Hz) in the local field potential (LFP). This two-state behaviour is believed to arise from a combination of neuron intrinsic and network properties. Nonetheless, UP state transitions are organized both at the cortical column as well as the ensemble level, providing a scale-free subtract for memory management and homeostasis.It is generally assumed that during DOWN states all pyramidal cells and interneurons are silent. How the transition from DOWN to UP state occurs is not well understood. Recently, we described a small population of V1 layer 6 neurons that displayed a strong inverse correlation with the activity of the simultaneously recorded principal cells and interneurons, particularly evident during non-REM sleep. In this project, we aim to asses the cellular identity and physiological function of the “DOWN state-active” neurons. We combined focal optogenetic stimulation with extracellular silicon probe recording across multiple cortical regions in genetically modified mouse lines, including PV-Cre::Ai32, Sst-Cre::Ai32 and Ht3a(BAC)-Cre::Ai32, which together account for the majority of neocortical GABAergic neurons. We found that DOWN state-active neurons define a specific subtype of putative interneurons of the layer 6 (6.25% of all interneurons for the same layer) present in the several neocortical regions investigated. In general, they show a wide regular spiking autocorrelogram (peaking at 40ms), moderate firing rates (2-6 Hz) during NREM and quiet waking and are virtually silent during REM sleep. That activity profile correlates with their pattern of connectivity, strongly inhibited by at least some subpopulation of PV+ and SSt+ interneurons. Futures experiment with specific optogenetic manipulation of the DOWN state-

active neurons aim to disclose their physiological function, as well as their role in controlling UP and DOWN dynamics.

Title: Altered cell assembly dynamics in the hippocampus by focal cooling of the medial septum

Authors: *P. C. PETERSEN, G. BUZSAKI;
NYU Neurosci., New York Univ., New York, NY

Abstract: The hippocampal theta rhythm coordinates spike timing of neurons across multiple structures of the limbic regions. Lesions and pharmacological inactivation of medial septum (MS) result in disappearance of theta and impairment of learning and memory. In the presence of theta oscillations, place fields generate a space-time compressed representation of the environment. We have performed local thermal perturbation of the MS to perturb theta oscillations. We implanted silicon probes in CA1 in the hippocampus and a cooling probe (silver rod in MS, connected to device on the head) in rats. The animals were trained to perform a side alternation task on a figure eight maze, with ongoing cooling sessions, allowing for us to study the effects on spatial neuronal activity in the hippocampus and performing behavioral quantification. Cooling of MS decreased the frequency of theta oscillation by ~2Hz and its power during spatial navigation, and we observed a linear relationship between measured temperature and theta frequency. Cooling also degraded memory performance and we sought out to understand the physiological basis of the impairment. The oscillation frequency of place cells also decreased, proportional to the theta LFP change, thereby maintaining spike phase precession relationship. Both interneurons and pyramidal cells decreased their rate, yet the place field sizes did not change. The space-time compression was also altered, as we observed a slower progression of place cell sequences.Our results reveal that delicate timing changes, such as slowing the sequences of gamma-packaged place cell assemblies, affecting the entire hippocampus, and likely related structures, is sufficient to impair memory mechanisms in the hippocampus. We hypothesize that the impairment results from the inability of downstream structures to correctly read out the temporally altered hippocampal messages.

Title: Uncovering representations of spatially distributed rodent hippocampal LFPs

Authors: *L. CAO[1,4], G. BUZSÁKI[1], Z. S. SHEN[1,2,3];
[1]Neurosci. Inst., [2]Dept. of Psychiatry, [3]Dept. of Neurosci. and Physiol., New York Univ., New York, NY; [4]Dept. of Physics, East China Normal Univ., Shanghai, China

Abstract: Rodent hippocampal place cells are well known to have the localized spatial tuning property, and population spike activities from place cell assemblies provide a readout of the animal's spatial location. However, direct use of spike information for population decoding appears challenging due to practical issues of spike sorting, unit classification and instability etc. In contrast, hippocampal local field potentials (LFPs) consist of local subthreshold activities reliably represent neuron assembly activity around the recording site, serving as an alternative and robust information carrier for animal's spatial information representation. To date, however, representations of spatial distributed hippocampal LFPs are not well studied. Previously, researchers have succeeded in decoding rodent's position during navigation based on features extracted from spatially distributed hippocampal LFPs (Agarwal et al., 2014).
Here we employed several supervised and unsupervised methods to investigate representations of rodent hippocampal LFPs when the animal is freely foraging in multiple environments (linear, circular and T mazes) and during the offline state (quiet wakefulness and slow wave sleep). Multiple LFP features (e.g., theta phase, gamma amplitude, and ultra-high frequency amplitude or multiunit activity) are thoroughly examined. We found that spatially distributed theta phase features across silicon probe channels provides a robust and reliable readout of the animal's position during running. Furthermore, unclustered, spatially distributed signals at ultra-high frequency (>300 Hz-5 kHz) allowed a readout of replay content during hippocampal sharp-wave ripple (SPW-R) events, as revealed by Bayesian decoding of virtual track positions. We used a leave-one-out method to investigate the representational contribution of each shank during running and SPW-R events, and found that the magnitude of position prediction from theta and SPW-R signals co-varied with electrode position. We also applied several unsupervised learning methods (such as independent component analysis and dictionary learning) to optimize and visualize the spatially localized LFP features.

Our preliminary results reveal the potential representational power of unclustered, spatially distributed hippocampal LFPs. This approach is useful for an efficient decoding strategy for closed-loop brain-machine interface applications. Further studies of such population representations may provide hints for the animal's planned choices.

Title: Monitoring hippocampo-neocortical interactions using widefield calcium imaging and electrophysiology in behaving mice

Authors: *R. A. SWANSON[1], S. MOUSAVI[2], J. BASU[3], G. BUZSAKI[4];
[1]New York Univ., New York, NY; [2]Neurosci., Fordham Univ., New York, NY; [3]Dept. of Neurosci. and Physiol., Neurosci. Institute, New York Univ. Sch., New York, NY; [4]New York University, Sch. of Med., New York, NY

Abstract: Hippocampal sharp-wave ripple (SPW-R) coupled modulation of neural activity is observed throughout the neocortical mantel during periods of quiescence and non-REM sleep (Buzsaki 2015; Logothetis 2012). However, how this dynamic coupling is spontaneously achieved across spatial and temporal scales in the absence of coordinating sensory input is unknown. The anatomy of hippocampal projections suggests a broad yet systematic topographical communication with neocortical areas. Hippocampal connectivity with the forebrain varies along its longitudinal axis. Furthermore, SPW-Rs are high frequency oscillations that travel along this axis and may occur either locally or globally. This suggests a mechanism whereby SPW-Rs that emerge from the dorsal, intermediate, and ventral segments of the CA1 region may broadcast different content to their downstream targets at the same or different times. The extent to which this transfer occurs has been difficult to investigate, however, due to the spatial limitations of extracellular physiology and the temporal limitations of the BOLD signal. In this study, we present the development of widefield imaging of a dorsal cortical hemisphere, combined with high-density silicon probe recordings in the hippocampus and retrosplenial cortex. This preparation allows us to assess the functional relationship between topographic propagation of SPW-Rs in the hippocampus and functional activation of neocortex. Results, to date, indicate a robust topographic response to dorsal hippocampal SPW-Rs, that vary as a function of both duration and amplitude of SPW-R.

Title: The effect of sustained inhibition on the generation of hippocampal oscillations

Authors: *S. ROGERS, M. VALERO, G. BUZSAKI;
NYU Neurosci. Inst., New York, NY

Abstract: The role of inhibition in the generation and maintenance of physiological oscillations has been the subject of controversy. Inhibitory interneurons are believed to play critical roles in both synchronizing networks and gating activity that comes through a circuit. Therefore, they have been studied in the context of both epileptic and normal physiological conditions. Of particular interest is the role of inhibition in the trisynaptic loop of the hippocampus, largely responsible for the process of generating sharp wave ripples, which are involved in memory consolidation, and in the generation of epileptiform activity. In the present study, we expressed an excitatory designer receptor exclusively activated by designer drug (Gq-DREADD) in the inhibitory interneurons of the CA1 region of the hippocampus. By activating these interneurons with clozapine n-oxide (CNO), we studied the effect of sustained inhibition on cell firing rates and the generation and maintenance of hippocampal oscillations. We have found that with CNO-mediated activation of interneurons, pyramidal cell firing dramatically reduces, while interneuronal firing both increases and reduces in a complex manner. Furthermore, we found that the system is still able to generate oscillations such as ripples (150-200 Hz), gamma (40 -100 Hz), and theta (5-8 Hz), all oscillations involved in encoding and transmitting information. Interestingly, ripple and gamma power are reduced as predicted by previous studies, while theta is largely conserved. Lastly we have found that a cell's spike firing pattern is largely retained, despite the overall change in firing rate. For example, if a pyramidal cell increases its firing rate during a ripple, this preference for firing during ripples is retained even in the presence of increased inhibition. We also found that the phase modulation of spikes to the theta oscillation is also conserved, despite drastic reductions in overall cell firing. This suggests that increasing inhibition chronically reduces firing rate of pyramidal cells but allows them to retain basic characteristic features.

Title: Bimodal representation of information in the hippocampal theta oscillation during reward-associated navigation

Authors: *M. WANG, B. E. PFEIFFER;
Neurosci., UT Southwestern Med. Ctr., Dallas, TX

Abstract: Successful navigation requires accurate encoding of the current location as well as prediction of future outcomes based on prior behavior, and hippocampal place cells are believed to play a central role in these processes. During active exploration, place cells display “phase precession” with respect to the ongoing 4-12 Hz theta rhythm, firing at progressively earlier phases of theta as the rat traverses a cell’s place field. Across large populations of place cells, phase precession is hypothesized to produce theta sequences, temporally organized sequences of neural firing which encode short virtual trajectories. Current models suggest that the theta rhythm may temporally discretize theta sequences into retrospective and prospective segments to alternately facilitate encoding and prediction, but little evidence exists to directly support this hypothesis. Here, we show that during navigation in a memory-dependent, but not a memory-independent task, a large percentage (~34%) of hippocampal CA1 cells display a bimodal relationship with the theta oscillation. While unimodal neurons preferentially fire at the trough of theta, bimodal neurons fire prominently at both the trough and peak of theta. In addition, bimodal neurons alternately display both canonical phase precession (at the trough of theta) and, surprisingly, phase procession (at the peak of theta). At a population level, bimodal neurons contribute to two distinct forms of theta sequences which arise consecutively within the same theta oscillation: a prospective sequence encoding a trajectory in the same direction as the animal’s movement, and a retrospective sequence encoding a trajectory in the opposite direction. Firing within the prospective vs. retrospective sequence is independently modulated, indicating that bimodal place cells may be driven by two distinct sources of theta-frequency input that are phase offset by approximately 180°. During REM, around 30% of unimodal and 50% of bimodal cells shift their preferred firing phase from the major to minor peak, suggesting that bimodal neurons may be selectively sensitive to input from layer III entorhinal cortex. Finally, we observe stronger firing in retrospective, but not prospective, sequences as rats approach goal

locations, implicating this novel process in successful memory retrieval and behavioral performance.

Title: Correlates of behavioral flexibility within the frontal cortex of the macaque during categorization

Authors: *R. LOONIS, E. K. MILLER;
Picower Inst. for Memory and Learning, MIT, Cambridge, MA

Abstract: The capacity to organize sensory and abstract information into categories is a hallmark of cognition. However, excessive adherence to any categorization rule also reflects a failure of cognition, and moderating this tendency is a cognitive capacity known as behavioral flexibility. Ever since the days of Phineas Gauge, the frontal cortices are thought to be central in maintaining flexibility and alternating between behaviorally relevant rules. We trained two rhesus macaques on a dot-pattern categorization task (Posner & Keele, 1968), and recorded concurrently from a wide swath of frontal cortex (pre-arcuate, ventrolateral, and dorsolateral prefrontal cortex). During the test phase of this categorization task, monkeys were allowed to freely view exemplars of two categories, and subsequently choose the exemplar that matched the sample category by maintaining fixation on it for 700 ms. We found that the monkeys' behavior improved with the number of views they made investigating the test exemplars. Correlated with this behavioral improvement, we found a decrease in beta band power within the local field potential during the delay preceding the test phase on trials in which the animal proceeded to view both test exemplars before committing to a choice, as opposed to making a decision based on a single view. In other words, maintaining an “open” mind regarding the correct category resulted in improved performance, and decreased beta band modulation corresponded with this improvement. We also found that the pattern of delay period spike rates on multi-electrode arrays (i.e. how the activities of different groups of neurons increased or decreased together) were distinct between those trials in which the animal would investigate both test exemplars rather then just one. Overall, these results suggest that these frontal circuits play an important

role in maintaining flexible representations of the category identity, and that excess beta band modulations could lead to inflexible behavioral states.

Title: Prefrontal oscillations modulate the propagation of neuronal activity required for working memory

Authors: *J. SHERFEY[1], S. ARDID[2], N. J. KOPELL[3], E. K. MILLER[4], M. E. HASSELMO[1]; [1]Psychological and Brain Sci., [2]Dept. of Mathematics & Statistics, [3]Boston Univ., Boston, MA; [4]Picower Inst. Learning Memory, Massachusetts Inst. Technol., Cambridge, MA

Abstract: Cognition involves using attended information (e.g., stimuli, rules, responses), maintained in working memory (WM), to guide action. During a cognitive task, a correct response requires flexible, selective gating so that only the appropriate information flows at the proper time. Much evidence suggests that WM information is encoded in the firing rates of populations of neurons in prefrontal cortex (PFC). At the same time, many experiments have demonstrated separate, task-related modulation of oscillatory dynamics in PFC networks. In this work, we used biophysically-detailed modeling to explore the hypothesis that network oscillations, leveraging lateral inhibition, can independently gate responses to rate-coded items in working memory. Consistent with recent data, we modeled the superficial layers of PFC as a WM buffer that stores task-relevant information and the deep layers of PFC as an output gate that governs which information in the WM buffer is propagated downstream to guide action. We investigated two models of the WM buffer: a "classic" model where attractor dynamics generate persistent spiking, and another model motivated by recent findings that WM does not involve persistent spiking but instead involves bursts of beta- and gamma-frequency oscillatory dynamics. In the latter, short-term synaptic plasticity allows maintenance of working memory between intermittent bursts of activity. In both cases, we found that whichever WM item induced a response in the output gate with the shortest period between spike volleys would be most reliably propagated through the output gate. Furthermore, the output gate exhibited network resonance capable of selectively relaying items with resonant oscillatory modulation. We found

that network resonance can be flexibly tuned by varying principal cell excitability. In our PFC model, these dynamics reveal how population rate-coded items embedded in superficial beta and gamma oscillations can be alternately relayed by tuning network resonance in the deep layers of PFC depending on task demands. Our ongoing modeling work explores how gating, mediated by resonance and lateral inhibition, interacts with task-related beta and gamma bursts to govern response in delayed match to sample and contextual association tasks.

Title: Are oscillatory correlates of working memory preserved across cortex?

Authors: *M. LUNDQVIST, A. M. BASTOS, E. K. MILLER;
Picower Inst. of Learning and Memory, Massachussetts Inst. of Technol., Cambridge, MA

Abstract: We have recently found that in prefrontal (PFC) bursts of oscillations in beta (15-35 Hz) and gamma (45-100 Hz) have distinct functional correlates. They were anti-correlated over time and across recording sites. Gamma bursts increased at sites and times where and when information was expressed in spiking; beta showed the opposite. This suggested that interactions between gamma and beta could regulate the expression of information by PFC neurons.
We hypothized that these phenomenon are prevalent across cortex. This idea has support from noninvasive recordings from the occipital cortex in humans, albeit at lower frequencies, alpha (8-12 Hz) and lower beta (12-14 Hz). This difference in oscillatory frequency could be due to differences between species, tasks, cortical regions or recording methods. In addition, the lack of direct access to neural activity in human studies makes oscillatory correlates harder to interpetrate.
To bring clarity to these questions we recorded from multiple electrodes in three cortical areas (V4, parietal cortex and PFC) of rhesus macaques during a working memory task. We analyzed local field-potentials and multi-unit activity in tandem. We found a similar functional relationship between alpha/beta and gamma in all cortical areas. Alpha/beta bursting was suppressed during encoding and retention of information, and anti-correlated with spiking

actvitiy and gamma bursting across time and sites. In all areas, suppression of beta and elevation of gamma was greater at sites where spiking carried information.
However, there were several trends as the cortical hierarchy was ascended from sensory to prefrontal cortex: 1. A gradual increase in the peak frequencies within both the alpha/beta and gamma bands. 2. The alpha/beta and gamma bursts gradually decreased in duration. 3. During memory retention, the gamma burst rate was higher (and the beta burst rate lower) in higher cortical areas. Our findings suggest that alpha/beta gamma interactions are preserved across cortex and may play a general role in regulating expression of information by cortical neurons. Further, the briefer but greater number of gamma bursts during memory retention may serve two roles. The shorter gamma events could help higher cortex segregate different sensory inputs (carried by different bursts) while the greater rate of memory-related gamma bursting could better retain thoose inputs across time.

Title: Bilateral transfer of working memory traces in prefrontal cortex

Authors: ***S. L. BRINCAT**[1], J. A. DONOGHUE[2], M. LUNDQVIST[1], M. K. MAHNKE[3], E. K. MILLER[4];

Abstract: There is evidence that visual working memory (WM) storage is independent in the right and left visual hemifields. Yet somehow WM seems seamless when eye movements shift a remembered location between hemifields. We studied how WM is integrated across the visual hemifields by recording neural activity bilaterally from 256 PFC sites in monkeys performing a change detection task. A central sample object was presented while monkeys fixated to the left or right of it. Following a WM delay, a test object was shown. Subjects had to respond to it only if it changed from the sample. In half the trials, subjects made an instructed saccade in the middle of the delay to the opposite side, shifting the retinotopic location of the remembered object to the other visual hemifield. In the other half, they remained fixated through the delay, keeping the

remembered location constant.
As expected, in no-saccade trials the PFC representation was biased toward contralateral retinotopic locations—decoding the item held in WM from delay activity spike rates in each hemisphere was much more accurate following contralateral than ipsilateral samples. Consistent with a role in suppression, LFP beta-band power had the opposite pattern—stronger for ipsilateral samples. When a saccade shifted the remembered location, decoding accuracy in the "receiver" hemisphere, which shifted from ipsilateral to contralateral, increased to nearly the level of a constant contralateral trace. The "sender" hemisphere, which shifted from contralateral to ipsilateral, faded to the level of a constant ipsilateral trace. Beta power showed inverted dynamics—the receiver decreased and sender increased. A simple model consistent with the data is that inter-hemispheric transfer of a WM trace activates the same ensemble that would encode a constant trace at the same location. This predicts that a decoder trained on constant contralateral trials would generalize to explain post-transfer activity in the receiver. This was not the case—post-transfer cross-decoding accuracy was at baseline levels whether the decoder was trained on delay or sample-period activity in no-saccade trials. At the time of WM trace transfer—but not at analogous time points in no-saccade trials—LFPs transiently synchronized between PFC hemispheres at gamma frequencies. These results provide evidence for transfer of a working memory trace across prefrontal hemispheres during midline-crossing saccades, suggest inter-hemispheric gamma oscillations may mediate the transfer, and show that the transferred WM trace activates a distinct neural ensemble from a remembered visual object at the same location.

Title: A recurrent spiking network model operating on the boundary between asynchronous and oscillatory states explains synchronous (0-lag) spiking deficits observed in primate prefrontal cortex following NMDAR synaptic blockade

Authors: D. A. CROWE[1], M. V. CHAFEE[2], ***B. AMIRIKIAN**[3];

Abstract: Schizophrenia involves malfunction of prefrontal circuits, but due to our limited ability to study the function of neurons in the living human brain we have limited understanding of how the disease alters the function of neurons to produce symptoms and cognitive deficits. This is critical because learning how the disease alters the function of the brain at the cell level is the best first step toward identifying treatments that could potentially restore neuronal and therefore network function in the disease. Resolving prefrontal circuit malfunction at a cellular level requires animal and computational models. Here we report a convergence between them that could be relevant to the pathogenesis of schizophrenia.
We recently reported (Neuron 102:21-26. 2018) that blocking NMDAR in monkeys (1) reduces the frequency with which neurons in prefrontal circuits tended to fire action potentials at the same time (0-lag synchronous spiking) while (2) also chronically reducing the number of neuron pairs that exhibited significant effective coupling. Here we explore whether key features of the spike timing dynamics of prefrontal circuits can be explained by a recurrent network model accounting for GABA, AMPA and NMDA synaptic currents. Using mean field approximation (e.g., Renart et al., 2003) describing asynchronous network state and conditions for emergence of network oscillations (Brunel & Wang, 2003) we derived synaptic conductance parameters for a network operating on a boundary between asynchronous and oscillatory states. Simulations of network dynamics with these parameters revealed that the degree of network synchrony measured by the population average 0-lag spike correlation in this regime could be effectively controlled by modulation of recurrent NMDAR conductance and external AMPA currents. Particularly, the model exhibits an increase in 0-lag spike synchrony with a small increase in external currents, similar to the increase we observed in the primate PFC in probe relative to delay periods. Moreover, population 0-lag correlation is reduced following reduction of NMDAR synaptic conductance in the model, replicating a key feature of the primate PFC under drug condition. These results suggest that PFC circuits could be operating on the boundary between asynchronous and synchronous regimes that allows them to switch easily between stationary and oscillatory dynamics. This, in turn, provides a potential control mechanism for behavioral regulation of 0-lag spike synchrony in the brain.

Abstract: Anxiolytics are widely prescribed for psychiatric conditions such as generalized anxiety and various disorders associated with fear. It has been reported that some of these anxiolytics have adverse effects on learning and memory. In the current research we investigated the effect of commonly used anxiolytics in the radial arm maze. We also attempted to understand the electrophysiological effects associated with these anxiolytics on cognition. Chlordiazepoxide, gabapentin and buspirone were chosen for evaluating its effects on learning and memory. The doses chosen were such that anxiolytic effects would be observed. Following treatment, rats were subjected to elevated plus maze. Doses which showed anxiolytic effects were further assessed in the radial arm maze. The anxiolytics were dosed following habituation to the radial arm maze and prior to initiation of trial. It was observed that chlordiazepoxide and gabapentin exhibited cognitive dulling properties but not to the same extent, while buspirone had almost no effect on cognition. To further investigate the effect on cognition, the rats were subjected to EEG spectral analysis. It was observed that chlordiazepoxide and gabapentin modulated spectral bands in the range of 4-8 Hz and 25-50 Hz indicating the modulations in theta and gamma bands which are suggestive of changes on learning and memory.

Title: Memory function after rTMS in aged rats depends on cognitive status

Authors: M. WEILER, H. M. STARNES, P. MORENO-CASTILLA, E. L. R. MELENDEZ, K. C. STIEGER, *J. M. LONG, P. R. RAPP;
NIH, Baltimore, MD

Abstract: Repetitive transcranial magnetic stimulation (rTMS) is an FDA-approved procedure for the treatment of depression, and there is increasing interest in its potential application for other neurological conditions. rTMS can cause either a lasting increase or decrease in cortical excitability; however, identical stimulation patterns may not affect all individuals equally since the effects of rTMS also depend on the baseline excitability of the brain. Aging is associated with shifts in neuronal excitatory/inhibitory balance in specific cortical circuits, and the degree of cognitive impairment in aged humans and animal models has been related to disruptions in this balance.

In order to test the possibility that aging and cognitive integrity influence the behavioral response to stimulation, we evaluated rTMS effects on recognition memory in a rat model of cognitive aging where aged Long-Evans rats were classified as Aged-Impaired (AI) or Aged-Unimpaired (AU) according to their performance in the Morris water maze. We applied intermittent Theta Burst Stimulation under isoflurane anesthesia to 8 young (plus 9 young sham), 4 AU (plus 4 AU sham) and 8 AI (plus 6 AI sham) rats. Cognitive effects were evaluated using a spontaneous odor recognition memory task, relying on rats' innate preference for novelty. rTMS was delivered immediately after the sample odor presentation (i.e., during consolidation) and memory was tested 24 hr later.

Behavioral variability was substantial in stimulated rats, and comparisons between rTMS conditions (stimulated vs. sham) were not statistically significant. The pattern of memory performance within conditions, however, differed dramatically as a function of cognitive status. Specifically, Y and AU sham rats displayed highly reliable odor recognition memory, exploring novel odors significantly above chance, whereas sham treated AI rats displayed no retention. Stimulated Y rats also demonstrated significant memory, although scores were more variable than in sham controls. In stark contrast, the AU stimulated group displayed no significant retention, and rTMS treated AI rats exhibited robust retention relative to chance, comparable in magnitude to Y animals. These results support the view that rTMS may be an effective therapeutic in the treatment of cognitive disorders of aging. However, individual differences in neurocognitive status can critically dictate the response to rTMS, and accordingly, protocols with documented efficacy in young adults might have unexpected outcomes in the context of Alzheimer's pathogenesis or other neurodegenerative conditions.

Title: Stress vulnerability correlates with shorter lifespan and early cognitive impairments

Authors: *M. BAIRACHNAYA[1], A. SHNAYDER[1], A. SHEININ[2], I. MICHAELEVSKI[1], A. PINHASOV[1];
[1]Integrative Brain Sci. Ctr. - Ariel, Mol. Biol., Ariel Univ., Ariel, Israel; [2]Sagol Sch. of Neurosci., Tel-Aviv University, Tel-Aviv. Israel, Tel-Aviv, Israel

Abstract: Lack of adaptation to social stress may lead to deterioration of physiological functions and contribute to aging augmentation, age-related diseases and cognitive impairments. In the current study, we used a mouse model of social interactions with inherited traits of dominance (Dom) and submissiveness (Sub), exhibiting resilience or sensitivity to stress respectively, to assess their lifespan, physiological parameters and cognitive abilities. We found that the lifespan markedly differed between Sub and Dom both in males (n=30 for Dom, n=29 for Sub), and females (n=10 per strain). Both male and female Sub animals showed marked hypoglycemia, slow weight gain and decreased skin surface temperature from early life stages. Furthermore, aged Sub mice had overt splenomegaly and significant upregulation of proinflammatory interleukins IL-1b and IL-6 in serum. Animals cognitive performance was evaluated in different age groups (3, 6 and 9-month old) simultaneously with electroencephalography (EEG) monitoring during novel object recognition (NOR) test. Sub mice exhibited a marked cognitive decline from an early age, been accompanied with alterations in frequency bands reflected in significantly lower power in delta (1-4 Hz), theta (4-8 Hz) and low gamma (20-40 Hz) in hippocampus during novel object exploration. Taken together our data reveal that inherent sensitivity to stress determines the predisposition to the accelerated aging and early age cognitive decline correlated with power alterations of frequency bands.

Title: Three year change in cognition, motor function and stress reactivity in aging marmosets (callithrix jacchus)

Authors: E. S. ROTHWELL, K. P. WORKMAN, ***A. LACREUSE**;
Psychological and Brain Sci., Univ. of Massachusetts, Amherst, MA

Abstract: The literature regarding sex differences in healthy aging is mixed, however women are more susceptible to age-related dementia such as Alzheimer's disease. Longitudinal studies in animal models with high translational value are needed to clarify the nature of the difference in susceptibility to age-related decline. Marmosets are an ideal animal model to study sex differences in aging as they have a naturally short lifespan as well as sophisticated cognitive abilities and rich social lives. We studied a cohort of male (n = 13) and female (n= 14) marmosets from middle age (mean age ~5 at study entry) and followed them longitudinally for 3 years. We evaluated sex differences in age-related changes in cognitive performance, motor skills and stress reactivity. Each year, marmosets were tested on a reversal learning task with three pairs of stimuli, a fine motor task requiring them to grasp small rewards from two staircase apparatus and a social separation task to elicit stress responses. Overall, both sexes improved their cognitive performance across the 3 years of testing, but the practice effect was greater in males than in females. Both sexes exhibited slower motor function with increasing age, but females tended to be faster than males. In the social separation task, stress reactivity, as assessed by agitated locomotion, declined across the 3 years of testing in females but remained stable in males. Together, these findings show that sex influences age-related changes in cognition, motor function and stress reactivity. In addition, high variability in aging patterns suggests that some individuals may follow a trajectory characteristic of pathological aging.

Title: Behavioral comparison of the C57Bl/6 inbred mouse strain and the CB6F1 hybrid line

Authors: *K. CORDER, S. N. AUSTAD;
Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: The majority of basic biomedical research is conducted using genetically defined, inbred mouse strains. The C57Bl/6 mouse strain is the most widely used genetic background in current rodent research. The rationale for using inbred strains is that because all individuals are genetically identical, phenotypic variation will be minimized allowing more statistically

powerful experiments. However, both theoretical and empirical evidence suggest that F_1 hybrids allow for potentially greater resilience in response to the inevitable stresses of laboratory environments. F_1 hybrids between two inbred strains, which are also all genetically identical, are also heterozygous at every locus at which the parental strains differed. Thus F_1 hybrids may actually make for more powerful experimental results. The purpose of this study is to characterize the differences in both the mean and variability in performance in response to induced stresses in C57Bl/6 mice and the CB6F1 hybrid line. The CB6F1 mouse strain (C57BL/6 x BALB/c) is predicted to show better performance with reduced variability in physical performance, cognitive behavior, and resilience following physiological stress challenges. These results address the issue of whether neurological experiments are more powerful when performed with inbred mice or with F_1 hybrids. To access whether sex plays a role in these experimental paradigms, both males and females were evaluated.

Title: The role of PDE11A4 in age-related decline of social memories

Authors: *K. PILARZYK, N. S. PATEL, A. J. SMITH, M. P. KELLY;
Univ. of South Carolina- Sch. of Med., Columbia, SC

Abstract: Associative memories (aMEMs) are more susceptible to age-related cognitive decline than are recognition memories (rMEMs) for reasons that are not well understood. Age-related increases in phosphodiesterase 11A (PDE11A), an enzyme that breaks down cAMP/cGMP and regulates social behaviors, may be a fundamental mechanism underlying age-related cognitive decline of aMEMs. PDE11A4 is almost exclusively expressed in the ventral hippocampal formation, a brain region key to many types of aMEMs. Previous studies have suggested that cAMP and cGMP signaling are decreased in the aging and demented HIPP which is consistent with our recent observations of aging and dementia-related increases in HIPP PDE11A4

expression, more specifically with a selective increase in the membrane compartment of the VHIPP. Additionally, we have seen significantly elevated PDE11A4 in hippocampus of demented vs. non-demented aged humans with a history of TBI. Therefore, we hypothesized that age-related increases in HIPP PDE11A4 occur in a compartmentalized manner and impair social associative long-term memories (aLTMs). To test this hypothesis, we utilized 1) a genetic deletion of PDE11A4 through a KO mouse, 2) a stereotactic approach to mimic-TBI with overexpression of PDE11A4, and 3) a lentiviral construct (targeting the 'GAF-B' binding domain) that preferentially shifts PDE11A4 from the membrane to the cytosol to reduce expression of PDE11A4. We found that PDE11A KO mice are protected against age-related cognitive decline as old KO mice show robust aLTM for STFP on par with that of young PDE11A WT mice, while old PDE11A WT mice are severely impaired. Further, we showed that the protective effect of PDE11A deletion is reversible by acutely overexpressing PDE11A4 in the hippocampus of PDE11A KO mice. Lastly, we expressed the isolated GAF-B domain to the HIPP of old PDE11A WT mice to disrupt PDE11A4 homodimerization and found it is sufficient to reverse age-related decline of social aLTMs. Together, these data suggest that reversal/mimicry of age-related increases in PDE11A4 expression in the adult hippocampus is sufficient to rescue/cause deficits in social aLTMs.

Title: Age, experience, and neurobehavioral domain: Effects of environmental enrichment and social isolation on brain and behavior in middle-aged and aged rats

Authors: *M. ROJAS-CARVAJAL[1], K. RAMÍREZ[2], A. SEQUEIRA-CORDERO[3], J. FORNAGUERA[4], J. C. BRENES[5];
[1]Neurosci. Res. Ctr., Univ. of Costa Rica, Montes de Oca, San José, Costa Rica; [2]Fac. of Dent., [3]Inst. for Hlth. Res., [4]Neurosci. Res. Ctr., [5]Univ. of Costa Rica, Montes de Oca, Costa Rica

Abstract: In rats, environmental enrichment (EE) is a form of physical-social stimulation used for modeling the impact of optimal developmental conditions on animal's phenotype. When implemented during early life, EE improves animal's cognitive skills, reduces anxiety-like traits, and promotes different forms of brain plasticity. Conversely, young animals raised on

impoverished conditions like social isolation (SI), developed poor cognitive skills and increased the reactivity to stress. The sensitive windows for neurobehavioral plasticity become narrower as organisms grow up. It is somewhat unclear, however, to which extent positive or negative experiences throughout adulthood are still able to benefit or compromise behavioral, emotional, and cognitive domains and neural plasticity. To this aim, middle-aged (120 PND) and aged (330 PND) Wistar rats (n=8 per age/group) were reared in EE (large cage filled with ethologically relevant stimuli; group housed), SH (standard housing in polycarbonate cage; 4 per cage), and SI (individually housed in stainless-steel cages) during two months. Afterwards, risk-assessment behaviors (i.e., defensiveness) and novelty habituation (i.e., kinetics of locomotion, rearing, and grooming) were measured in two, consecutive open-field tests. We found that EE reduced risk-assessment behaviors and improved habituation in both age groups, but only middle-aged rats showed an increasing in complex forms of grooming. In SH and SI rats, those behaviors were strongly modulated by age rather than by housing conditions. After the OFT, latencies to scape in the Barnes maze test (i.e., spatial memory) were measured. There, EE also improved spatial memory especially in aged rats, whereas SI caused no particular impairments on this parameter. After testing, we analyzed the expression of different genes closely related to functional and structural neural plasticity (BDNF, GluA1, GluA2, NR2B, CFL1, p250GAP, DNMT3A) in the medial prefrontal cortex (mPFC), the nucleus accumbens (NAcc), and the ventral and dorsal hippocampus (HPC). We found that SI changed the gene expression of the glutamate receptors subunits (e.g., NR2B, GluA1, and GluA2) in the dorsal HPC and NAcc. DNMT3A expression increased especially in the ventral HPC of aged SI rats. The main effect of aging on gene expression resembled the pattern observed in SI rats. In general, the effect of EE and SI conditions dissociated between the behavioral and molecular phenotype they induced and between the two age periods, with SI affecting almost all genes in one brain region or another.

Title: The common marmoset (Callithrix jacchus) as a model for age-related cognitive decline

Authors: *C. GLAVIS-BLOOM, Z. W. DAVIS, J. H. REYNOLDS;
Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: The number one risk factor for Alzheimer's disease is aging. However, it is unclear what aspects of aging contribute to disease vulnerability. The common marmoset (*Callithrix jacchus*) is the shortest-lived anthropoid primate, and their short (~10 year) lifespan offers an opportunity to investigate age-related cognitive decline longitudinally. For this purpose, we are evaluating the performance of marmosets on tasks previously demonstrated to reveal age-related cognitive decline in humans. One of these, the Delayed Recognition Span Task (DRST), is a paradigm that evaluates working memory capacity. The DRST is dependent on the function and integrity of the hippocampus and prefrontal cortex in humans and macaque monkeys (Jeneson et al 2010; Bor et al 2006; Beason-Held et al 1999). Performance on the DRST has also been found to decline with age in both humans and macaque monkeys (Mazurek et al 2015; Maylor et al 2006; Moss et al 1997; Herndon et al 1997). The task begins with a single visual stimulus presented on a touch screen. When selected, a juice reward is delivered. Following a delay (blank screen), the first item and a new item appear simultaneously. If the new item is selected, the monkey receives another reward. New items are continually added until the subject incorrectly selects a previously selected item, or correctly selects the 9th new item, concluding the sequence. Each sequence of trials makes up a "span", and the number of items correctly identified as novel is defined as the "span length" for that trial. The distribution of span lengths provides a measure of memory capacity. Our results show that adult marmosets are amenable to touch screen cognitive testing in their home cages and are highly motivated to participate without food or water restriction. They quickly learn to interact with a touch screen for liquid rewards, and progressively improve performance on the DRST, completing more spans of longer lengths with training. The span length distribution can be changed by extending the delay, requiring monkeys to remember items for longer periods of time. We find that monkeys reliably complete sequences lasting upwards of two minutes, despite their skittish nature and freedom to disengage at any time.

Title: Illuminating the neurobiological intersection between sleep and cognitive aging

Authors: *C. MYRUM, M. E. STELZNER, J. B. HUNT, J. M. LONG, P. R. RAPP;
Natl. Inst. of Health: NIA, Baltimore, MD

Abstract: Scores of studies in humans indicate that age-related changes in sleep duration and quality are powerful mediators of the neurobiological effects that contribute to increased risk of Alzheimer's disease and cognitive impairment later in life. However, the molecular pathways underlying this relationship are largely unknown. To address this issue, we first examined whether sleep is coupled to age-related cognitive outcome in a rat model of normal cognitive aging. Aged Long-Evans rats were tested in a hippocampus-dependent version of the Morris water maze, where we observed considerable inter-individual variability among aged animals, mimicking the increased variability observed in human aging. To record sleep, rats were implanted with multichannel electrodes and cortical local field potentials were recorded via electroencephalogram (EEG) for 24 hr. A quantitative spectral algorithm was used to quantify the number of transitions (sleep architecture) and the amount of time spent in rapid eye movement (REM) sleep, non-REM sleep, and awake. A notable preliminary finding from EEG data was that, while the amount of REM sleep did not differ between adult and aged animals as a whole ($p=0.20$), aged rats with memory impairment exhibited significantly more REM than aged rats with intact memory ($p=0.008$) and adult rats ($p=0.03$) during the dark (wake) period. Capitalizing on our ability to link age-related cognitive status with age-related changes in sleep, we then examined potential mediators of this relationship. We began by quantifying expression of Arc—a protein that is essential for long-term memory formation, dysregulated in cognitive aging, and upregulated during REM sleep. In adult rats, we found that Arc expression peaked after 3-4 bouts of REM across the hippocampus, most prominently in the CA1 subregion ($p=0.03$). Initial analyses showed that three bouts of REM induced significantly less hippocampal Arc expression among aged rats than in adult rats. However, expression failed to differ across cognitive impaired and unimpaired aged rats. Ongoing experiments aim to examine additional aspects of REM-induced Arc expression in aging, including potential changes in synaptic dynamics and Arc+ neuronal ensemble reactivation during post-behavior sleep.

Title: Impact of high-fat diet and aging on cognitive function: Relation with glial fibrillary acidic protein levels

Authors: *L. AYALA-GUERRERO[1,2], F. BERMUDEZ-RATTONI[1], K. GUZMAN-RAMOS[3]; [1]Neurociencias Cognitivas, Inst. De Fisiología Celular, Ciudad de México, Mexico; [2]Posgrado en Ciencias Biológicas, UNAM, Ciudad de México, Mexico; [3]Ciencias de la Salud, Univ. Autónoma Metropolitana, Lerma, Mexico

Abstract: The chronic intake of a high-caloric diet and a sedentary lifestyle are causing two major health problems in the world, obesity and overweight. Along with the peripheric consequences of such states, are the increased risk to suffer cognitive impairment or dementia. Another important factor for the development of cognitive impairment is old age, and even though aging is a natural process that implies a decline of cognitive function, the presence of metabolic diseases such as diabetes, metabolic syndrome, obesity or overweight on elderly population, increased by 1.29-fold the risk to develop mild cognitive impairment or dementia. It is most likely that peripheric metabolic dysfunctions lead to central nervous damage, causing cognitive decline. Both, aging and metabolic disorders are associated with the production of oxidative stress in the brain and neuroinflammation, which is considered the main culprit of the development of such cognitive deterioration. Astrocytes are the most abundant cells in the brain and respond to any type of brain insult through astrogliosis.

One characteristic of astrogliosis is the increase in glial fibrillary acidic protein (GFAP), which is a major cytoskeleton protein of astrocytes, which is essential for the formation, growing and proliferation of astrocytes. It has been reported that astrogliosis increase during aging and after exposure to a high-fat diet in young mice, so it is possible that GFAP would be a good biomarker of central injury and aid us to predict the beginning of cognitive decline.

To test this hypothesis, we first analyzed the cognitive performance and expression of GFAP on the dorsal hippocampus (HIP) and the insular cortex (IC) of male and female C57BL/6 mice of 5 (n=9), 10 (n=15), 15 (n=12), and 19 (n=10) months. Then, we analyzed the same parameters from C57BL/6 mice of 5 (n=7) and 10 (n=12) months exposed for 5 months to a diet composed of 10% fructose and 60% caloric intake of fat. We found a progressive decline of cognitive function in memory dependent of tasks such as object recognition memory and Morris's water maze in normal aging. In addition, we found a progressive increase in the immunoreactivity of GFAP in HIP and IC. Conversely, high-fat/fructose diet in adult mice induces increased weight, central adiposity, glucose intolerance, causes mild cognitive impairment and increases immunoreactivity of GFAP in HIP and IC as the older untreated mouse. These results indicate that GFAP may be a molecular correlate of cognitive performance decline that could be used as a biomarker for brain damage.

Title: A new method for discriminating normal versus slow learners in a large population of aged mice

Authors: C. DUFFAU[1], S. HADZIBEGOVIC[1], V. ANDELKOVIC[1], I. LAGROYE[2], B. BONTEMPI[1], ***O. NICOLE**[1];
[1]CNRS, Univ. Bordeaux, UMR-CNRS5293, Bordeaux, France; [2]UMR 5218 Lab. de l'Intégration, du Matériau au Système (IMS), Bordeaux, France

Abstract: Cognitive disabilities that occur with age represent a growing and expensive health problem. Normal aging is associated with a progressive cognitive decline, particularly in memory functions. In rodents, this decline has been shown in different learning and memory paradigms requiring navigation though space. However, consistent with what is observed in the human population, alteration of cognitive functions is extremely variable within cohorts of animals. Building upon the analysis of a comprehensive set of observations derived from a large population (n = 111) of aged (22 month-old) mice submitted to spatial discrimination testing in an 8-arm radial maze, we generated a categorization index that provides a continuous, graded measure, of the severity of age-related impairment in spatial memory and enables to identify mice with the greatest learning difficulties. Mice were required to locate the 3 constantly baited arms of the radial maze. Reference memory training consisted in 8 equivalent blocks of six trials separated by a 1 day interval. Each trial started with all 8 arms opened and terminated when the mouse entered the third baited arm and returned to the central platform of the maze. The number of total errors (i.e., entries into nonbaited arms and repeated visits to baited arms) decreased significantly over the 8 training blocks in aged and young animals, both groups achieving the same level of task mastery after 8 days of training. However, close analysis of the slope of their learning curves revealed that young mice learned the position of the three baited arms faster than aged mice. To capture this differential speed of spatial learning into a reliable and discriminative memory performance index, we first normalized the performance of each mouse with respect to its number of errors committed the first day of training, then calculated when an exponential fit crossed the 50% best performance level achieved by each individual upon completion of training (lower asymptote), and finally created best fit individual psychometric curves. This method of analysis enabled to clearly isolate two populations of aged mice, one with a memory

performance similar to that of young mice (normal learners) and another exhibiting a reduced speed of learning (categorized as slow learners). Thus, the performance index generated may serve as a valuable categorization tool to discriminate normal versus slow learners within cohorts of aged animals. It should be potentially useful in conjunction with other behavioral or neurofunctional measures in correlational studies aimed at investigating individual differences during the course of the aging process.

Title: Successful trajectories in aging: Reserve and resilience in RatS (STARRRS) building a resource of longitudinal data for the study of neurocognitive reserve in aging

Authors: *C. BANUELOS, J. M. LONG, K. FISHBEIN, R. A. MCDEVITT, K. PERDUE, R. SPENCER, P. R. RAPP;
Natl. Inst. on Aging, NIH, Baltimore, MD

Abstract: Normal aging in humans and animals is associated with increased variability in cognitive function, with some individuals, despite exhibiting typical neurobiological consequences of aging, showing preserved cognition and others showing substantial impairment. The underlying mechanisms that mediate these divergent cognitive trajectories remains largely unknown. Accordingly, and in response to the recommendations of the 2017 Cognitive Aging Summit III, the Intramural Research Program of the National Institute on Aging is launching a major resource initiative to support the longitudinal study of neurocognitive reserve and resilience in rats. This resource is intended to generate an open database of longitudinal phenotypic data, neuroimaging scans, tissues, and other samples for distribution, utilizing a validated Long Evans rat model that features reliable individual differences in neurocognitive outcomes with age. A key design goal is to maximize the value of the resource to the research community. Our presentation will outline initial design concepts, infrastructure, and other project support with the aim of defining anticipated capabilities and soliciting further input from the interested scientific community. In brief, male and female rats will be followed from youth to approximately 24 months of age with state-of-the-art technologies to assess brain structure and

function non-invasively and with dynamic phenotypic measurements. Neuroimaging infrastructure will include a Bruker Biospec® 9.4T/20cm MRI with CryoProbe™ technology and spectroscopic capabilities. A variety of behavioral assessments will be available, including home cage activity, digitized gait analysis, water maze, olfactory discrimination, elevated plus maze, operant testing, open field activity and others. Periodic longitudinal sampling of biological materials (blood, feces, vaginal smears) and physiologic measures (body weight, temperature) will be available, in addition to terminal samples for post mortem analysis in relation to cognitive outcomes. Input from an NIH Request for Information (https://grants.nih.gov/grants/guide/notice-files/NOT-AG-19-017.html), and a focused work group at the September 2019 "Workshop on Research Definitions for Reserve and Resilience in Cognitive Aging and Dementia" (https://reserveandresilience.com/) will be presented.

Title: Intranasal insulin enhances spatial memory and intrinsic excitability of aging hippocampal neurons by altering expression of Ca^{2+}-dependent K^+ channels and of calcium-sensors for Ca^{2+}-dependent K^+ channels

Authors: *N. R. TANDON[1], L. T. THOMPSON[2];
[1]Biol. Sci., [2]Behavioral & Brain Sci., Univ. of Texas at Dallas, Richardson, TX

Abstract: The elderly population (age 65 and over) is estimated to double in number by year 2050. This will increase the socioeconomic burden associated with cognitive decline population associated with normal aging, pathological aging caused by Alzheimer's disease (AD) and other dementias, and with diabetes mellitus. While many pharmacological treatments have shown promise in ameliorating age-related cognitive decline, they have unfortunate side effects. Intranasal insulin has proven to improve cognitive deficits in clinical trials with AD and MCI patients, with few reported side effects. Maimaiti et al. (2013) showed cognitive improvement in aging rats treated with intranasal insulin. They also showed insulin-dependent decreases in the amplitude and duration of post burst afterhyperpolarizations (AHPs), which are significantly

increased in aging hippocampus leading to reduced intrinsic excitability. However, the molecular or cellular targets of insulin in hippocampal neurons that leads to insulin-dependent decrease in AHP in aged rats are yet unknown. Our objectives were to study the effects of insulin: 1. on hippocampal-dependent spatial and working memory consolidation and 2. on proteins involved in Ca^{2+}-dependent intrinsic excitability−the SK2 channel proteins underlying the mAHP, and the Ca^{2+}sensors calmodulin and hippocalcin respectively for the mAHP and sAHP.Young (4-6 mo) and old (20-24 mo) FBNs rats were used and handled daily for 7 d before treatment began. Subsets from each cohort were treated either with intranasal saline or with intranasal insulin (2 IU, Humalog) for 21 d. Morris water maze and spontaneous alternation tasks were performed to assess behavior. Hippocampal slices were collected from each group and were either stimulated with aCSF or with insulin-aCSF (24nM) for 10 min, then processed and analyzed using western blotting to assess protein expression. Our results show improved learning and spatial memory consolidation in both aging and young rats treated with intranasal insulin; the effect was larger and more significant in aging rats. Our western blot results show significant decreases in hippocalcin protein expression in aged hippocampal slices stimulated with insulin, while no significant effect of insulin was seen on hippocalcin expression in young tissue. Insulin stimulation altered expression of SK2 and calmodulin in both aging and young hippocampus; but the difference was not significant. Insulin appears to have age-related cognition and excitability enhancing effects that suggest potential future clinical benefits.

Title: Linking an increased afterhyperpolarization to cognitive deficits in a mouse model of aging

Authors: *S. J. MOORE[1], V. A. CAZARES[2], G. G. MURPHY[2];
[1]Mol. and Behavioral Neurosci. Inst., [2]MBNI/Physiology, Univ. of Michigan, Ann Arbor, MI

Abstract: Cognitive impairments in the aged population are generally associated with neurodegenerative disorders like Alzheimer's disease, but in fact, they often occur in the absence of overt pathology. As the aged population continues to expand in the coming decades, more and more people will be affected by age-related decreases in cognitive function, which degrade an individual's ability to function independently and adversely impact the quality of life. It can be

difficult to study the “normal” (i.e. non-pathological) aging process in a laboratory setting because of the long time frame required (typically 2-3 years in mice) and the paucity of genetic models of aging. Previous work in rodents has shown that aging is associated with an up-regulation of L-type voltage-gated calcium channel (LVGCCs), which is correlated with age-related memory impairments in hippocampus-dependent learning and memory tasks. Thus, we generated a novel transgenic mouse line which over-expresses the LVGCC, CaV1.3, as a mouse model of normal aging (Krueger et al., BBR, 2017). Our recent work shows that this mouse model recapitulates age-related cognitive deficits, such as a decrease in learning and memory performance assayed by the Morris water maze, as well as age-related changes in neuronal physiology, including an increase in the amplitude of the post-burst afterhyperpolarization (AHP) assayed by whole-cell current-clamp recordings in CA1 pyramidal neurons. Several earlier studies found that an increase in the AHP was accompanied by a decrease in neuronal excitability (i.e. action potential firing); these findings led to the hypothesis that decreased excitability represented the cellular mechanism underlying the observed deficits in learning and memory. Interestingly, in our experiments, firing rate was unchanged, even when the AHP was significantly increased, suggesting that decreased neuronal excitability is not necessary, and may not be sufficient, to account for age-related changes in cognitive function. We are now examining other potential mechanistic links between the AHP and deficits in learning and memory, including AHP-mediated modulation of the phase response curve (PRC), a measure of the timing of action potential firing relative to the timing of input throughout the phasic oscillations of a neuron, which reflects complex interactions between diverse intrinsic conductances that lead to spike generation. Taken together, our studies may further elucidate the cellular mechanisms that contribute to changes in neuronal function that occur with age, and identify potential therapeutic targets aimed at ameliorating age-related cognitive decline.

Title: Changes to the structure and function of layer 3 pyramidal neurons and the effects of curcumin intervention in the prefrontal cortex of aging monkeys

Authors: *W. W. CHANG[1], M. MEDALLA[1], T. L. MOORE[1], D. L. ROSENE[1], D. PATHAK[1], V. TURNBULL[1], J. GOODLIFFE[1], T. GUILLAMON-VIVANCOS[2], J. I. LUEBKE[1];

Abstract: A significant proportion of humans and non-human primates exhibit declines in working memory during normal aging. While the neural bases of these age-related changes in cognition are poorly understood, they have been associated with a number of sub-lethal changes to the structural and functional properties of neurons in prefrontal regions that are key mediators of working memory. For example, layer 3 (L3) pyramidal neurons in *in vitro* slices of the dorsolateral prefrontal cortex (dlPFC, area 46) of aged rhesus monkeys exhibit significantly increased input resistance (Rn) and action potential (AP) firing rates compared to neurons in young subjects (Chang et al., 2005). Furthermore, these neurons exhibit a significant decrease in dendritic spine density with age (Coskren et al., 2015). What is not yet understood is the time-course of the development of these neuronal alterations during the aging process and whether they can be ameliorated by the powerful anti-oxidant and anti-inflammatory agent curcumin. To address these questions, we compared the structural and functional properties of L3 pyramidal neurons in slices prepared from the dlPFC of behaviorally characterized rhesus monkeys between the ages of 8 and 29 years of age using *in vitro* whole-cell patch clamp recordings and high-resolution digital neuronal reconstructions. In these animals, performance on the delayed recognition span-spatial task (DRST-spatial)—a measure of spatial working memory—declined linearly with age ($p<0.02$). Interestingly, neurons began to exhibit reduced spine density as well as hyperexcitability in middle-age but to a lesser extent than what we have previously reported in aged subjects. Furthermore, Rn declined linearly with age ($p<0.003$), AP firing rates increased linearly with age ($p<0.005$), and spine density was reduced with age ($p<0.01$). Long-term (~2 years) dietary curcumin treatment led to greater improvements on the DRST-spatial task across repeated testing ($p<0.03$); but did not reverse the age-related alterations to neuronal properties, as excitability and spine density in neurons from subjects that received curcumin (n=8) did not differ from those of the untreated animals (n=5). These results suggest that significant changes to the structure and function of neurons that may contribute to cognitive deficits occur early during the aging process, and that while dietary curcumin mitigates cognitive deficits, it does not reverse or delay age-related changes in neuronal properties.

Title: Exercise mitigates chemotherapy-induced cognitive impairment

Authors: *K. GILLEY[1], G. SULLENS[1], M. J. SEKERES[2];
[1]Psychology and Neurosci., [2]Psychology & Neurosci., Baylor Univ., Waco, TX

Abstract: Chemotherapy-induced cognitive impairment (CICI) is commonly reported by human breast cancer patients, generally involving disruptions of memory and executive functioning. We use a pre-clinical model to determine if long term exposure to cardiovascular exercise (running) may protect against the development of CICI symptoms in a transgenic breast cancer mouse model. Previous pre-clinical studies have shown that post-treatment exercise reduces memory dysfunction and increases rates of hippocampal neurogenesis in rodents. Voluntary running throughout middle-age provides protective effects on neurogenesis, BDNF expression, and cognition into older age for female mice. In rodents, running after chemotherapy reduces CICI severity. Neural regions typically associated with CICI in memory and executive functioning include, respectively, the hippocampus and frontal lobe. To assess cognition and hippocampal and frontal lobe function in transgenic tumorigenic mice and in wild type controls, mice were given a pre-treatment and post-treatment behavioral test battery including spatial water maze, novel object recognition, context fear conditioning, and conditional associative learning. Behavioral tests indicate that tumorigenic subjects have reduced cognitive functioning with some savings in the fear conditioning and spatial water maze tasks for mice who engaged in pre-treatment running. We additionally observed larger tumor volume for mice who engaged in pre-treatment running, suggesting that long-term exercise may enhance rates of tumor growth in animals genetically predisposed to developing cancer.

Baltimore, MD; [3]Magnetic Resonance Imaging and Spectroscopy Section, [4]Cognitive Neurosci. and Psychopharmacology Section, NIH, Natl. Inst. on Drug Abuse, Baltimore, MD

Abstract: Cognitive aging varies tremendously across individuals, with some people remaining cognitively intact while others experience substantial decline, even in the absence of disease. Such decline is often accompanied by regionally specific reductions in brain volume. However, the co-occurrence of neurodegenerative disease in humans can obscure changes in brain volume attributable to normal aging, distinct from pathological processes. In order to define regional brain aging associated with individual differences in memory, we used a standardized neuropsychological test, delayed non-matching to sample (DNMS), to asses visual recognition memory in young adult (mean = 10.2 years, n = 6) and aged (25.5 years, n = 10) rhesus monkeys, which do not suffer spontaneous neurodegenerative disease with age. Volumetric T1-weighted MRI scans were acquired from anesthetized animals on a Siemens Trio 3T scanner and analyzed by voxel-based morphometry (SPM12 with DARTEL implemented in MATLAB, oriented and masked to the D99-SL macaque atlas). We demonstrate that brain regional volumes significantly correlated with acquisition and memory performance on DNMS are distinctly different in young adult and aged rhesus monkeys. Faster task acquisition (i.e., fewer trials to criterion) inversely correlated with larger medial temporal lobe (hippocampus, amygdala, entorhinal cortex, perirhinal cortex, inferotemporal area) volume in the young, whereas larger prefrontal regions (orbital, ventrolateral, and dorsolateral prefrontal areas) correlated with fewer trials to reach criterion in aged monkeys. When the memory demands of the procedure were increased by imposing longer retention intervals, average recognition accuracy in young positively correlated with medial temporal lobe, cingulate cortex and cerebellar (lobule IV, lobule V, crus I and crus II) volumes. In contrast, average performance across delays in the aged brain positively correlated with prefrontal, striatum and insula volumes. These results suggest that the pattern of regional volumes coupled with DNMS performance are distinct in young adult and aged monkeys. The data from young monkeys are consistent with lesion and functional MRI findings implicating the medial temporal lobe and prefrontal cortex in visual recognition memory. Interestingly, our results also introduce the cerebellum as potentially important for medial temporal lobe-dependent memory. Overall, these findings support the perspective that the aged primate brain can display substantial structural reorganization, potentially supporting significant compensatory or adaptive functional capacity in the cognitive trajectory of aging.

Title: Sex differences in the effect of voluntary exercise on cognitive flexibility in older mice

Authors: *D. ISLAS-PRECIADO[1], M. IBRAHIM[2], N. BLACK[1], C. K. BARHA[3], T. LIU-AMBROSE[3], L. A. GALEA[2];
[1]Djavad Mowafaghian Ctr. from Brain Hlth., [2]Dept. of Psychology, Djavad Mowafaghian Ctr. for Brain Hlth., [3]Dept. of Physical Therapy, Djavad Mowafaghian Ctr. from Brain Hlth., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Although studies show that aerobic training (AT) promotes memory and executive functions, a large degree of variation still exists in AT efficacy on cognition among older adults. Evidence suggests there may be a sex difference in cognitive response to AT such that women benefit more so than men (Barha et al., 2018). This sex difference may be related to the ability of AT to influence sex and stress hormones, perhaps via adrenal gland production of steroid and stress hormones. Cortisol levels are increased in older age and are linked to poorer cognition and smaller prefrontal cortex (PFC) (Stomby et al., 2016). These effects are more pronounced in women (Otte et al., 2005). Cognitive flexibility (CF) is a higher order PFC-dependent executive function that comprises the ability to control and direct behaviour to cope with novelty and facilitate adaptation (Banich et al.2009). Interestingly, CF is one of the first cognitive spheres affected in aging and dementia. Therefore, identifying potential therapies to improve cognition and the underlying mechanisms is imperative. Here, we explored whether AT could be an effective intervention to ameliorate CF in older males and females by using the 'visual discrimination and reversal' paradigm in Saksida-Bussey touchscreen chambers. C57BL/6J male and female mice aged 12-13 months were randomly assigned to either sedentary control or AT group. AT animals were given free access to running wheels for 2 weeks, and then food-restricted to 90-95% of their free-feeding body weight to increase motivation for task completion. Exposure to running wheels remained over the course of cognitive assessment. Preliminary data show that AT females learned to discriminate the stimulus faster than control females and males. In addition, AT females needed fewer sessions to reach criteria for reversal than males. These findings suggest greater AT efficacy in females despite no differences between sexes in average of total distance ran. Analyses to evaluate neurogenesis, stress, and sex hormones are ongoing. Our data suggest that voluntary running for 80 days in middle-aged mice improves cognitive flexibility more effectively in females than in males.

Title: Detection of age-specific decline in cognitive and motor performance in baboons using CANTAB and object retreival task with barrier detour

Authors: G. CHOUDHURY, ***M. DAADI**;
Texas Biomed, Southwest Natl. Primate Res., San Antonio, TX

Abstract: Aging brain cells is one of the major underlying pathophysiological processes contributing to the progressive decline in motor skills and cognitive functions. The difference in performances observed between young and old test subjects across species highlights the effects of aging on brain functions; however, the specific age in an individual's lifespan whereby a precipitous decline in brain functions begins is unknown. This inflection point in age-related decline is important for the physiological understanding of normal cell longevity and senescence and for timing therapeutic interventions. Nonhuman primates (NHP) are phylogenetically close to humans and share many similarities, including age related decline in neural and immune functions thus complex human-like behavioral endpoints may be measured. In the present study we integrated three clinically relevant outcome measures to investigate the effect of age on cognition, motor function and diurnal activity in older baboons. We used the Object Retrieval Task with Barrier-Detour (ORTBD), Cambridge Neuropsychological Test Automated Battery (CANTAB) and actigraphy to investigate age-related decline in cognition, motor skills, and diurnal / nocturnal activities, respectively. The data show significant age-related decline in movement planning, learning novel tasks, in simple discrimination tasks and in motivation. These results suggest that baboons may offer a model of dementia and early cognitive decline.

Title: Bidirectional coupling of grid cell and place cells as a mechanism for robust spatial representation across multiple maps

Authors: *H. AGMON[1], Y. BURAK[2];
[1]ELSC, Hebrew Univ. of Jerusalem, Jerusalem, Israel; [2]Edmond and Lily Safra Ctr. for Brain Sci., Hebrew Univ., Jerusalem, Israel

Abstract: Grid cells and place cells play an important role in spatial encoding. Grid cells in the medial entorhinal cortex have multiple periodically spaced firing fields that form a hexagonal lattice and are largely similar between environments. Hence, they are considered as reasonable candidates to be associated with path integration. Hippocampal place cells, on the other hand, typically display at most a single environment specific receptive field, and are associated with contextual memory since they exhibit 'global remapping', drastically changing their firing field between environments. In the past decade many experimental and theoretical studies examined the influence that grid cells and place cells might have on one another. Studies have demonstrated correlated phenomena between activities of grid cells and place cells under various manipulations, yet the exact mechanism and functional relationship between grid cells and place cells and its significance to encoding of spatial location is still unclear. Some studies have suggested that grid firing patterns are the main determinant of place cell firing while other studies have challenged this view arguing that grid fields are formed as a result of place cell input. Overall, studies so far were primarily concerned with uni-directional manipulations and their implications, namely, they dealt either only with the effects and emergence of grid cells from place cells inputs or vice versa. Instead of treating grid cells and place cells as two separate populations in successive stages of a processing hierarchy, we develop in this work a detailed computational attractor model with mutual interacting connections between grid cells and place cells and demonstrate the functional significance of such coupling. In this framework grid cell and place cell activities serve as complementary and interacting representations that work in combination to support the reliable coding of large-scale space over multiple environments.

Title: Impaired spatial representation in hippocampal entorhinal circuit of knock in Alzheimer's model

Authors: *H. JUN[1], S. SOMA[1], A. REDDY[1], T. SAITO[2], T. C. SAIDO[2], K. M. IGARASHI[1,3,4]; [1]Anat. and Neurobio., Univ. of California Irvine Sch. of Med., Irvine, CA; [2]RIKEN Ctr. For Brain Sci., Wako, Japan; [3]Ctr. for Neurobio. of Learning and Memory, [4]Inst. for Memory Impairments and Neurolog. Disorders, Univ. of California Irvine, Irvine, CA

Abstract: Alzheimer's disease (AD) is a progressive neurological disorder that debilitates our mind and memory. AD patients show impairments in multiple dimensions of memory including spatial memory and navigation, which causes wandering behavioral symptoms. Despite significant advances made in uncovering molecular and cellular mechanisms behind AD pathology, a limited number of studies have been performed to investigate changes that occur in the brain circuits of AD. By understanding what type of neuronal activities are lost and demonstrating the relationship between the dysfunctional neural network and cognitive deficits, we may be able to develop novel therapies targeted to reactivate these activities in AD patients. We focus on the circuit comprised of the entorhinal cortex (EC) and the hippocampus involved in memory formation and retrieval. Histological and imaging studies in AD patients and animal models have shown that the EC is a primary site of atrophy and activity loss in the early phases of AD. However, it is still unclear what type of activity is lost in the EC of AD patients, or even in AD mouse models. Using a novel amyloid precursor protein (APP) knock-in mouse model (Saito et al., Nat Neurosci 2014), we found that grid cells, a cell type harboring spatial memory-related activity in the medial entorhinal cortex (MEC), are impaired in APP knock-in mice. Place cells, another spatially-tuned neurons in the hippocampus, are also impaired. Our results provide evidence to demonstrate that the entorhinal-hippocampal spatial representation is impaired in the AD mouse model.

Title: Replay as wavefronts and theta sequences as bump oscillations in a grid cell attractor network

Authors: *L. KANG, M. R. DEWEESE;
Redwood Ctr. for Theoretical Neurosci., Univ. of California, Berkeley, Berkeley, CA

Abstract: Grid cells and place cells fire in sequences that represent rapid trajectories in space. During locomotion, theta sequences encode sweeps in position starting slightly behind the animal and ending ahead of it. During quiescence and slow wave sleep, bouts of synchronized activity represent long trajectories called replays, which are well-established in place cells and have been recently reported in grid cells. Theta sequences and replay are hypothesized to facilitate many cognitive functions, but their underlying mechanisms are unknown. A leading mechanism proposed for grid cell formation is the continuous attractor network. We demonstrate that it naturally produces theta sequences and replay as distinct consequences of modulating external input. Driving inhibitory interneurons at the theta frequency causes attractor bumps to oscillate in speed and size, which gives rise to theta sequences and phase precession, respectively. Decreasing input drive to all neurons produces traveling wavefronts of activity that are decoded as replays.

Title: Neural activity in the central complex of the crickets during phonotaxis

Authors: ***K. KAI**[1], H. SHIDARA[1], N. ANDO[2,3], H. OGAWA[1];
[1]Dept. of Biol. Science, Fac. of Sci., Hokkaido Univ., Sapporo, Japan; [2]Res. Ctr. for Advanced Sci. and Technol., The Univ. of Tokyo, Tokyo, Japan; [3]Dept. of Systems Life Engin., Maebashi Inst. of Technol., Maebashi, Japan

Abstract: Animals navigate themselves to a specific location such as feeding place, nest, and mating partners. For orienting to the desired goal, animals integrate multiple information about the goal location from surroundings and proprioceptive signals caused by self-movement in the specific brain region to encode the current heading and to produce proper steering commands. Many studies in insect suggested that the central complex (CX), a medial region in the brain, is the center of goal-directed behavior. A group of neurons in the CX is sensitive to the polarized-light, the essential cue for homing behavior in desert ants and honeybees. Neural activity recorded from the CX of cockroaches are related to walking speed and angular velocity. Furthermore, Calcium imaging in *Drosophila* CX revealed that the population vector of ellipsoid body (EB), the lower unit of CX, encodes the animal's angular velocity as well as its head-direction. However, at least in insect, few researches have investigated the neural mechanisms underlying the ethologically-meaningful orientation. Female crickets approach to the singing male by hearing its calling song, called phonotaxis. It is well-known that the auditory system of the cricket shows directional responses to the calling song and that magnitude of steering toward the sound source depends on the sound location, suggesting that directional information of sensory cue will be processed for making motor command in the brain. Then, using the cricket phonotaxis as a model, we explored neural mechanism encoding the goal direction and relevant steering commands in the cricket brain. We performed intracellular recording from the CX of female cricket during walking under the auditory VR environment. We found that a subset of the tangential neurons in the EB encoded the head direction in darkness. No CX neuron, so far, responded to the calling song. These results imply that the directional information of sound source by-passes the CX and that the CX tracks the internal heading based on self-motion during phonotaxis.

Title: Presubicular layer 3 neurons receive convergent input from anterior thalamus and retrosplenial cortex

Authors: L. RICHEVAUX[1], L. SCHENBERG[1], M. NASSAR[2], C. MAUTHE[1], I. COHEN[3], M. BERANECK[1], ***D. FRICKER**[1];

[1]Descartes Univ., [2]Collège de France, CNRS, Paris, France; [3]INSERM U1130 / CNRS UMR8246 / UPMC, Paris, France

Abstract: The presubiculum is a key structure for spatial orientation coding, located between the hippocampus and the entorhinal cortex. It is part of the brain wide head direction circuit, and its neurons are sensitive to an animals' head direction. The presubiculum is well positioned to integrate vestibular sensory input and visual landmark information, conveyed via the anterior thalamic nuclei and the retrosplenial cortex, respectively. Here we investigated the functional connectivity between these two afferent regions and the presubiculum, using anatomical tracing, optogenetics and electrophysiological patch clamp recordings in mouse brain slices. Retrograde tracing experiments with retrobeads or AAV2retro showed that neurons in the anterior thalamus and in the retrosplenial cortex provide major inputs to the presubiculum. Using anterograde viral vectors, Channelrhodopsin-2 fused to a fluorescent reporter protein was expressed in the anterior thalamus or the retrosplenial cortex, in order to specifically stimulate with light transfected axons in the presubiculum. As previously reported, we found that thalamic axons innervated the superficial layers of the presubiculum, and mono-synaptically excited principal neurons of layer 3, upon blue LED stimulation (onset latencies, 2.5 ± 1.0 ms). Retrosplenial axons also ramified in the superficial layers of the dorsal presubiculum and thus overlapped with thalamic inputs. Following photostimulation of retrosplenial axons, we recorded excitatory postsynaptic events from principal neurons of presubicular layer 3. These EPSPs had monosynaptic latencies of 3.2 ± 1.2 ms. Both thalamic and retrosplenial light-evoked events persisted in the presence of TTX and 4-AP. The intrinsic properties of postsynaptic presubicular neurons were similar, suggesting that thalamic and retrosplenial inputs target a same population of neurons. To directly investigate the convergence of thalamic and retrosplenial inputs onto single layer 3 neurons, we injected two different viral vectors to express blue and red shifted channelrhodopsins, Chronos and Chrimson, in the thalamus and the retrosplenial cortex, respectively. Calibration experiments indicated that axons originating form either region may be stimulated largely independently, when using brief pulses of 470 nm (0.5 ms) or 627 nm (2 ms) light and within a range of low light intensities (up to 0.5 mW). Combined, double wavelength optical stimulation experiments will help our understanding of multisensory information processing in single neurons in the presubiculum.

Title: Multimodal encoding of navigation variables in the anterior limbic system

Authors: *J. LAURENS[1], A. ABREGO[1], H. CHAM[1], Y. YU[1], N. ROTDEM[1], J. AARSE[2], D. DICKMAN[1], D. E. ANGELAKI[2];
[1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The brain's navigation system integrates egocentric sensory information to create a sense of position in allocentric space. Here we used a multimodal model (Hardcastle et al. 2017) to systematically assess how neurons throughout the navigation circuit encode an array of egocentric, allocentric and internal variables. We recorded neuronal activity in the murine anterior thalamic nuclei (ATN; antero-dorsal, antero-ventral and latero-dorsal; 6 animals, n=281 neurons), retrosplenial cortex (RSC; 4 animals, n=180 neurons) and anterior hippocampus (3 animals, n=112 neurons), as well as in the cingulum fiber bundle (5 animals, n=380 neurons) and the white matter regions surrounding the hippocampus (6 animals, n=267 neurons), while animals foraged in a circular arena.
As expected, we identified well-known cell types, such as head direction cells (45% of ATN cells) and hippocampal place and speed cells (19% and 20% of hippocampal cells, respectively). In addition, our approach revealed that 12% of ATN neurons encode the animal's allocentric position, similar to place cells, and that half of ATN neurons respond in phase with LFP in the theta band (4-12Hz). In line with other recent studies, we also found that a large fraction (45%) of RSC neurons, as well as some (9%) hippocampal neurons, encode the egocentric position of the arena's boundary.
We observed that tetrodes could readily record spiking activity in the cingulum fibers bundle and in white matter surrounding the hippocampus. These spikes typically had short durations (<0.33ms trough to peak), typical of axonal spikes. Cingulum units were recorded at the level of the anterior RSC, where the cingulum likely conveys predominantly ATN and RSC connections. We found that the population activity closely resembled a combination of ATN and RSC responses, in equal proportions, suggesting that navigational variables represented in these regions travel through the cingulum to reach other regions. Fibers traveling through the white matter in the vicinity of the hippocampus carried a mixture of navigation variables.
Our results draw a new picture of the information encoded and projected by the anterior thalamus and retrosplenial cortex, and offer new insights on navigational variables represented in the hippocampus and its vicinity. They also stress the importance of using unbiased multimodal models to assess population responses in navigation areas of the brain.

Title: Neural correlates of locomotion, cues, and context in the interactions between hippocampus and lateral septum

Authors: *H. S. WIRTSHAFTER[1], M. A. WILSON[2];
[2]Picower Inst. Learn/Memory, [1]MIT, Cambridge, MA

Abstract: The lateral septum (LS) has been implicated in anxiety and fear modulation, and may regulate interactions between the hippocampus (HPC) and regions that mediate goal directed behavior. In this study, we simultaneously record from cells in the LS and the HPC during navigation and conditioning tasks. We identify a speed and acceleration spiking code in the LS that does not map to states of motivation or anticipation. We also identify an overlapping population of LS cells that change firing to cue and reward during conditioning. These cells display sharp wave ripple and theta modulation, spatial firing fields, and responses similar to the HPC during conditioning. These HPC-associated cells are not disproportionately speed or acceleration modulated, suggesting that these movement correlates are not hippocampally derived. This suggests a role for the LS in evaluating movement-dependent changes in context that can be used to guide task-relevant behavior.

Title: A novel function of the thalamic reticular nucleus in the spatial navigation system

Authors: G. VANTOMME, Z. ROVÓ, G. KATSIOUDI, E. BÉARD, V. PERRENOUD, L. M. J. FERNANDEZ, *A. LUTHI;
Fundamental Neurosciences, Univ. of Lausanne, Lausanne, Switzerland

Abstract: The thalamic reticular nucleus (TRN) exerts inhibitory control over thalamo-cortical loops throughout all vigilance states. However, much of its portions, in particular the connectivity of its anterior, non-sensory sectors, are still largely unexplored. Through antero- and retrograde tracing and cellular electrophysiology, we identified the dorsal presubiculum (dPreS) and the anterior thalamic nuclei (ATN) as part of a thalamo-cortical loop involving the non-sensory TRN in mice. The dPreS, which is part of the parahippocampal formation, and the ATN are two key structures for spatial navigation. Presubicular excitatory glutamatergic synapses formed on TRN and ATN are part of a feedforward circuit through which TRN-mediated inhibition generates large burst-mediated inhibitory synaptic currents. Both synaptic pathways showed little depression when activated repeatedly, enabling persistent membrane depolarization and repeated firing of their postsynaptic targets. To explore the role of TRN in the spatial navigation system, we (1) recorded anterodorsal thalamic neurons from freely behaving mice and (2) combined a Morris Watermaze task with specific chemogenetic silencing of the non-sensory TRN. (1) The width of the tuning curve of head-direction neurons in the anterodorsal nucleus was broadened upon chemogenetic silencing of TRN neurons (n=8, p=0.04). Moreover, half of the head-direction neurons (n=4/10) showed action potential discharge patterns consistent with feedforward inhibitory responses upon light activation of the dPreS. These data suggest that feedback projections from the dPreS to the ATN recruit the TRN to sharpen the tuning of thalamic head-direction neurons. (2) Silencing of non-sensory TRN did not show any strong learning impairment in the watermaze task. Careful analysis of probe sessions at the end of the training period revealed that TRN silencing caused mice (n=11) to swim persistently in the area of the target quadrant unlike control mice (n=13), which investigated the rest of the maze after an initial period in the target quadrant (p=0.015). These data suggest that the non-sensory TRN participates in spatial orientation in the watermaze and guides an appropriate behavioral response that is, in this case, enlarging the exploration area.

Title: Hippocampus, medial prefrontal cortex and nucleus reuniens neuronal patterns predict behavior during a working memory task

Authors: *A. F. VICENTE[1], W. CLAWSON[2], A. GHESTEM[1], C. BERNARD[3], P. P. QUILICHINI[4];
[1]Aix-Marseille Univ., Marseille, France; [2]Aix-Marseille Univ. - Inst. de Neuroscien, Marseille, France; [3]INSERM U1106, Marseille Cedex 05, France; [4]INSERM U1106 INS, Marseille, France

Abstract: A dialogue between hippocampus (HPC) and medial prefrontal cortex (mPFC) in spatial working memory has been previously shown. Although HPC sends projections to mPFC, there are no return projections from mPFC to HPC. Nucleus reuniens (NR) is a good candidate to influence the interaction between HPC and mPFC due to its reciprocal projections to both brain areas. Furthermore, recent studies found an alteration in working memory performance following the inactivation of NR. In order to get a better understanding of the role of NR in working memory and its interactions with HPC and mPFC, we recorded simultaneously multi-unit activity and local field potentials in the 3 areas with silicon probes while Long-Evans rats performed a delayed-non-match to position task on a T-maze. We classified trajectories in 4 types of trials: left sample, right sample, left choice and right choice, depending on whether the rat entered in the left or right arm, and whether the trial was a sample (non-working memory dependent) or a choice (working memory dependent). We compared the original spikes trains with surrogate spikes trains created by shuffling left sample and right samples trials, and left choice and right choice trials. This procedure allowed us to identify neurons discharging differentially for right, left, sample and choice trials, and to detect the maze segments where discharge was different. Most neurons in the 3 areas differentiated between left and right, or sample and choice trials before the animal entered in the left or right arm, indicating that neuronal discharge predicts left/right and sample/choice trajectories. Additionally, we will analyze if neuronal discharge also predicts behavior during inter-trial periods. Further analyses will examine if these neurons are phase-locked to the ongoing hippocampal oscillation.

Title: Representation of space in the goldfish brain

Authors: *E. VINEPINSKY, L. COHEN, O. BEN-SHAHAR, O. DONCHIN, R. SEGEV; Ben Gurion Univ., Beer Sheva, Israel

Abstract: Navigation is one of the fundamental cognitive capability found in many animals across all of the animal kingdom, and specifically fish. This ability is important for finding food, shelter and mates in order to survive. However, almost nothing is known about the neural representation of space in the brain of animals outside the mammalian class. Goldfish, which is part of the largest vertebrate class, the bony fish, also have the cognitive ability to navigate using allocentric and egocentric cues. Furthermore, the lateral pallium in the goldfish brain is a possible homolog of the mammalian hippocampal formation and associated with allocentric navigation. Using a novel wireless recording system, we measured the activity of single cells in the lateral pallium in a freely swimming fish while it explores essentially two-dimensional environment. We report evidence for representation of space in the form of cells that were active in specific locations in the environment. Those cells resemble cell types which are found in the mammalian hippocampal formation and believed to be the building blocks which drive the navigation system. Our study sheds light on how spatial information is encoded in the fish brain and whether the mechanisms of the neural navigation system are preserved across evolution.

Title: The nucleus prepositus of mouse encodes eye-related information during passive and active head movement

Authors: *H. CHANG[1,2], S. ZHU[1], K. E. CULLEN[3];
[1]Johns Hopkins Univ., Baltimore, MD; [2]McGill Univ., Montreal, MD, Canada; [3]Dept. of Biomed. Engin., The Johns Hopkins Univ., Baltimore, MD

Abstract: The vestibular system plays a crucial role in our everyday life as it ensures gaze and postural stabilization and the sense of self-motion by detecting the head motion in space. To maintain a stable representation of spatial orientation, visual and non-visual signals such as vestibular and proprioceptive signals are required. It has been proposed that the nucleus prepositus hypoglossi (NPH) and the supragenual nucleus (SGN) in brainstem relay vestibular information from the vestibular system to head direction (HD) network. The prevailing view based on experiments in rodents is that this pathway produces a 'neural compass' of the head's direction relative to space that is vital for navigation. However, the NPH has also been long-known to comprise the oculomotor integrator which plays an essential role in eye movement control by holding the eye at an eccentric position in orbit after the saccade. Further, a recent study in non-human primates (Dale & Cullen, 2013), established that neurons in the NPH predominantly encode eye-related rather than head-related movement signals during both passively-generated and voluntary head movements. To date, however, it remains unknown whether neurons in the NPH of rodents encode eye-related and/or head-related movement signals. We hypothesized that NPH neurons in mouse, as in primate, preferentially encode eye-related rather than head-related signals during voluntary movement. To test this hypothesis, we performed in vivo recording of NPH neurons in mouse during passive and active head movement while simultaneously measuring eye movements. To measure mouse eye movement during active head movements, we used an AMR magnetic field sensor, which measured the location of a magnet implanted in the eye in orbit. During passive movements, we recorded the activity of NPH neurons during head-retrained behavioral protocols (Medrea & Cullen, 2013) including vestibular-ocular reflex (VOR), visuo-vestibular conflict (VORC), optokinetic reflex (OKR) and changes in static eye position (SEP) to dissociate eye and head movement sensitivities. The recording was also made during voluntary head movements. Notably, the mice were trained to make voluntary head movements to the left and right in response to an auditory tone. Our preliminary single unit recording experiments indicate that indeed consistent in the non-human primate model, neurons in the NPH of mice primarily output eye-related information during both passive and active head movement and function to stabilize gaze.

Title: Mechanistic models of place cell statistics in large environments

Authors: *M. Y. YIM[1], T. TAILLEFUMIER[1,2], I. R. FIETE[3];
[1]Dept. of Neurosci., [2]Dept. of Mathematics, The Univ. of Texas at Austin, Austin, TX; [3]Dept. of Brain and Cognitive Sci., MIT, Boston, MA

Abstract: In large environments, hippocampal place cells individually exhibit multiple stable firing fields, with great diversity in the number of fields expressed across cells. Moreover, the likelihood of a cell expressing a field persists across environments. We seek to understand the factors that could explain the placement of fields and their statistics across place cells. The existence and relative stability of place fields even in parts of the environment that lack detailed external local spatial cues suggests that they are informed by motion integration, presumably derived from entorhinal grid cell inputs. We thus investigated the degree to which grid cells, with their spatially periodic responses, might account for the statistics of place fields within and across cells. First, at the single-cell level, how much flexibility is there in the placement of multiple fields with grid cell input alone? We answer this question by computing the number of possible field arrangements for a place cell, and deriving stringent theoretical bounds for the distance over which arbitrary field arrangements are realizable. We found that only a very small fraction of possible field arrangements are achievable in large spaces, and that the range over which all field arrangements are possible is a miniscule fraction of the unique coding range afforded by grid cells, suggesting that place fields are either primarily driven by non-grid cues that derive from local external spatial cues, or that they fall in highly constrained arrangements when they are driven by grid cell inputs. Second, we studied the influence of grid cell inputs on the statistics of downstream place cells in population models with a variety of learned or random connections, to model the distribution of place cell firing propensities and generate predictions about the signatures of grid cell-driven responses. In all model variants, if the firing threshold (excitability) across place cells is similar, then grid cell inputs but not spatially localized inputs reproduce the distribution of place cell firing propensities. In all model variants, the predicted spatial frequencies associated with grid cell firing are overrepresented in the power spectral density of the place field distribution in both 1D and 2D environments, even after we include a range of spatially localized input and noise levels. Our theoretical study thus provides numerous

testable predictions for information flow from grid cells to place cells in individual hippocampal subregions.

Abstract: Grid cells in the medial entorhinal cortex have spatially periodic firing fields that are important for spatial navigation and may contribute to cognitive processes more generally. Grid cells have been categorized according to whether their firing fields are modulated by heading direction: conjunctive grid cells are active at particular locations when animals move in the cell's preferred direction; in contrast pure grid cells do not fire preferentially in a preferred movement direction. We investigated whether firing of grid cells is nevertheless direction-dependent. We recorded extracellular neuronal activity with tetrodes from the medial entorhinal cortex of mice (n= 16, 8 females and 8 males, mean age = 10.6 weeks SD=1.7 weeks) that explored a 1 meter square empty open field arena with a polarizing cue on one wall. We performed automated spike sorting using MountainSort (Chung et al. 2017, Neuron 95 (6): 1381-1394) and identified spatially selective cells including head-direction cells, pure and conjunctive grid cells. We found that the distribution of directions in which pure grid cells were active differed significantly from the animal's heading direction (n = 29 / 29 pure grid cells) indicating that grid firing is direction-dependent. To test whether the head-direction selective firing is a result of different head-direction preferences in individual grid fields, we analysed directional firing in individual fields. We found that individual firing fields of pure grid cells have head-direction selective firing. We repeated this analysis on data from rats (Sargolini et al. 2006, Science 312 (5774): 758-62) and found similar results. Our results suggest that the firing properties of pure grid cells depend on head-direction. This finding has implications for theorized functions and mechanistic models of the grid system.

Abstract: The ability to rapidly escape to shelter when confronted with predatory threat is essential for survival. In mice, exposure to imminent threats elicits shelter-directed flight that is preceded by a fast head-orientation movement towards the shelter position. This head movement is extremely accurate, and can be implemented without sight of the shelter, by relying exclusively on memory. While orienting to shelter is done instinctively by the animal, it is a computationally challenging action, as it requires mapping the current position with respect to the memorised shelter location, onto an appropriate egocentric head rotation movement.
In this work we have investigated the neural basis of orienting the head to shelter during escape, using behavioural assays, projection- and cell type- specific chemogenetics, and single unit recordings in freely moving mice. Consistent with the known role of the superior colliculus in the control of egocentric saccades and head-rotation movements, we found that inactivation of the lateral superior colliculus (lSC) impairs orientation to shelter. Using monosynaptic retrograde rabies tracing, we identified the retrosplenial cortex (RSC) as a lSC input projection well-positioned to provide allocentric and head-direction information to the lSC. In agreement, chemogenetic inactivation of this projection introduced large errors in head orientation to shelter, and caused animals to escape in random directions. Furthermore, silicon probe recordings revealed neurons in both RSC and lSC that encode the angular offset between the animal's

current position and the shelter. We are currently combining single unit recordings with chemogenetic inactivation of lSC-projecting RSC neurons, to test the model that the lSC receives shelter-vector angle information from the RSC to generate shelter-orienting movements. Preliminary data suggest that RSC inactivation selectively disrupts the mapping of head-orienting actions onto allocentric space, while leaving sensory-driven egocentric orientation intact. These results advance our understanding of escape behaviour, and may provide general principles for the computation of goal-directed actions.

Title: Evidence against the attractor network hypothesis for grid cell activity in entorhinal cortex

Authors: *M. B. STEMMLER;
Ludwig-Maximilians-Universität Munich, Martinsried-Planegg, Germany

Abstract: Grid cells in medial entorhinal cortex (mEC) are organized into distinct modules; within each module, the spatial firing fields of grid cells form a common hexagonal lattice with a fixed spacing between fields, a fixed orientation, and a fixed shear [1,2]. Within one module, the firing fields measured for any particular grid cell reflects a rigid translation of this common lattice. Theoretical models propose that these features result from a single attractor state of network activity [3-5]; as the animal moves through space, the attractor state simultaneously moves through mEC.
Yet the firing fields are far from uniform, as the peak firing rate within each field varies considerably [6,7]. We show that these variations obey a long-range spatial structure: a slowly varying envelope across space modulates the firing rates from firing field to firing field. Interestingly, such behavior is uncommon in attractor networks, which typically exhibit stable hexagonal patterns. Only in a narrow parameter regime can an Eckhaus instability with long-range spatial variation in field amplitudes occur, just before the activity pattern in the network changes from hexagons to stripes [8]. Evidence suggests that the spatial variation in firing fields in grid cells is not of this type, which argues against the theory that grid cells' activity arises through dynamical self-organization in a continuous attractor network.

Title: Distance codes in the medial entorhinal cortex during goal directed navigation

Authors: *S. A. TENNANT[1], H. STEVENS[1], W. YANG[1], K. Z. GERLEI[1], J. HUA[1], H. CLARK[1], E. R. WOOD[1], M. F. NOLAN[1,2];

Abstract: Successful navigation relies on accurate estimates of location. This can be achieved using landmarks or by path integration, where location is inferred from the direction and distance travelled relative to a known start point. Within the entorhinal cortex, grid, head direction, speed and border cells encode information that could be used to estimate location. It is not known whether these are the only codes used to represent location, or whether during specific behavioural tasks additional codes emerge to support goal directed navigation. To address this, we recorded with tetrodes from neurons in the medial entorhinal cortex (MEC) whilst wild-type mice engaged in a spatial memory task that can be used to assay path integration and cue-dependent navigation (Tennant et al. 2018, Cell Reports 22, 1313-1324). In this task mice are

trained to locate a reward zone marked with a visual cue within a virtual linear track. Use of path integration strategies can be tested in trials in which the reward zone is unmarked. We found a subset of neurons in the MEC that had distinct and striking patterns of activity whilst animals moved along the track. These neurons linearly increased or decreased their firing rate as a function of distance to or from the reward zone or boundaries of the track. Thus, these neurons provides a read out of position relative to salient track features. In a subset of neurons distance codes were present only on trials where the animal successfully completed the task, suggesting these representations may underlie successful task performance. Together these data support the idea that neurons in the MEC encode distances using a linear code that may support self-localisation in learned behaviours.

Title: A novel somatosensory spatial navigation system outside the hippocampal formation

Authors: X. LONG[1], ***S.-J. ZHANG**[2];
[1]Dept. of Neurosurg., Xinqiao Hosp., Chongqing, China; [2]Dept. of Neurosurgery, Xinqiao Hosp., Army Med. Univ., Chongqing, China

Abstract: The hippocampal-parahippocampal network has long been regarded as the central hub for the brain's spatial navigation system. Decades of research on the brain's spatial representation for position, orientation, border/boundary, speed and distance have intensively explored the hippocampal formation, revealing many functionally specialized yet different types of spatial cells, including place cells, head-direction cells, border/boundary-vector cells, speed cells, conjunctive cells and grid cells. Nevertheless, studies from patients with large medial temporal lobe lesions suggest that the hippocampal formation is not essential for space memory, indicating that spatial navigation might be computed with another still unknown representation system outside the medial temporal lobe structures. Such an extra-hippocampal navigational system has never been identified, however. To search for another possibly existed spatial navigation system outside the hippocampal formation, we implanted microdrives into the

primary somatosensory cortex of adult Long-Evans male rats and recorded neuronal activity and local field potential of individual somatosensory cells in two-dimensional opening environment. Surprisingly, we found the existence, in the rat somatosensory cortex, of a novel “all-in-one” spatial navigational system, which contained the full spectrum of all distinct spatial cell types including place cell, head-direction cell, boundary-vector/border cell, conjunctive cell, speed cell and grid cell. All recorded somatosensory spatial cells, from freely behaving rats with microelectrodes, showed similar firing characteristics to those detected previously in the canonical hippocampal-parahippocampal structures. Whisker-trimmed rats still remained similar spatial firing properties, eliminating the possibility that our detected different somatosensory spatial cell types were reflected by sensory responses typical to the primary somatosensory cortex. Additionally, a series of control experiments including running on the raised platform without walls, no food chasing and in darkness confirmed both specificity and consistency of similar functionally distinct somatosensory spatial cell types to those previously identified in the classical hippocampal formation. This newly detected somatosensory navigational system extends the classical theory of a cognitive map about space beyond two discrete hippocampal-entorhinal regions into another single highly hierarchical neocortical domain, providing possible alternative and sophisticated computational algorithms for spatial memory and cognitive mapping.

Title: A model for the processing of temporal relationships in navigation using phase coding

Authors: *E. PARRA BARRERO, S. CHENG;
Inst. for Neural Computation, Ruhr Univ. Bochum, Bochum, Germany

Abstract: Mammals are notable for their capacity to display flexible behavior and deal with changing contingencies. In order to do this, they need to be able to learn, represent and operate on the temporal relationships that link different states to the actions that lead from one state to another. A good case of study for this phenomenon is spatial navigation. In particular, we focus on the temporal relationships linking positions and movements, which are thought to be encoded within the grid cell network in the medial entorhinal cortex. We propose a model for the processing of these temporal relationships in which path integration, prediction of future positions, movement planning and inference of past states can all be accomplished by pattern completion in a network capable of representing positions and movements corresponding to the

recent past, present and future. We hypothesize that the temporal dimension is represented in the brain by the phase of firing relative to the theta oscillation. We test our hypotheses in two ways. First, we develop and simulate neural network implementations of our model and apply them to a simple navigation task in order to fully flesh out the model and arrive at new testable predictions. Secondly, we analyze whether experimental findings on phase coding are consistent with our model. To do so, we develop a parametric phenomenological model of phase coding to generate spikes under different coding assumptions. The model's spikes are then analyzed in the same way as experimental data, thus allowing for direct comparisons. Our results expose a contradiction in experimental findings that has gone unnoticed so far. Some studies indicate that activity in different phases of the theta oscillation reflect positions that lie a certain distance ahead of or behind the animal's current position, while other results imply phase coding for positions that were or will be reached a certain time interval in the past or the future, respectively. Overall, our work sheds light onto the nature and functional role of phase coding and suggests a novel paradigm for representing and reasoning about temporal relationships in the mammalian brain.

Title: Speed cells in the somatosensory cortex

Authors: *X. LONG[1], S.-J. ZHANG[2];
[1]Dept. of Neurosurg., Xinqiao Hosp., Chongqing, China; [2]Dept. of Neurosurgery, Xinqiao Hosp., Army Med. Univ., Chongqing, China

Abstract: Grid cells were proposed to function as path integrators, which continuously update, based on its directional and speed information, the internal representation of the animal’s relative location within the environment. The generation of regularly periodical grid cell firing is currently modeled with either oscillatory interference or continuous attractor network but both models require speed signal. Although speed cells are present not only in the medial entorhinal cortex (Kropff et al., 2015, Hinman et al., 2016, Pérez-Escobar et al., 2016, Ye et al., 2018) but also in the hippocampus (Góis and Tort, 2018), whether speed cells are encoded for path integration computations outside the hippocampal formation remains elusive. We recently

identified a novel “all-in-one” spatial navigational system in the somatosensory cortex (Long and Zhang, bioRxiv, https://doi.org/10.1101/473090, 2018), which contains the full spectrum of all distinct spatial cell types including place cell, head-direction cell, boundary-vector/border cell, conjunctive cell, and grid cells within the single somatosensory area. To search for possibly existed somatosensory speed cells, we implanted microdrives into the primary somatosensory cortex of adult Long-Evans male rats, recorded neuronal activities and local field potentials of individual somatosensory cells and performed a series of computational analyses with different approaches. Accordingly, we found that the instantaneous firing rate of a distinct subpopulation of somatosensory neurons was linearly correlated with running speed, and those somatosensory speed cells also intermingled with other distinct spatial cell types but had little overlapping with other spatially modulated cells in the somatosensory cortex. Specifically, somatosensory speed cells were encoded mainly by fast-spiking GABAergic interneurons as well as by excitatory pyramidal neurons. Moreover, speed score for fast-spiking interneurons was significantly higher than that of excitatory principal cells in the somatosensory cortex, consistent with the similar findings in the medial entorhinal cortex (Kropff et al., 2015, Ye et al., 2018). In the meantime, a subset of somatosensory speed cells showed a negative correlation with running speed. Furthermore, a proportion of somatosensory speed cells also exhibited theta rhythmicity. How somatosensory speed cells contributed to a possible parallel or independent somatosensory spatial navigation system outside the hippocampal formation awaits further investigation.

Title: Phase coding of spatial trajectories by lateral septum neurons

Authors: *H. T. BLAIR[1], A. G. HOWE[2], G. BLAIR[3], R. M. DE GUZMAN[4];
[2]NSIDP/Psychology, [3]Psychology, [1]UCLA, Los Angeles, CA; [4]SUNY Albany, Albany, NY

Abstract: The lateral septum (LS) is a major subcortical output target of the dorsal hippocampus. It has recently been reported that LS contains neurons which precess in phase against hippocampal theta rhythm, in such a way that they encode a rat’s position along navigational trajectories (Tingley & Buzsaki, Neuron 98:1229, 2018). To further investigate this phase coding phenomenon, we recorded theta-modulated neurons (n=136) from LS while male Long-Evans rats (n=3) foraged randomly for sucrose pellets in a circular arena. During 41

recording sessions lasting 2-3 hours, rats spent a majority of their time (>70%) foraging along thigmotaxic trajectories near the cylinder walls. We analyzed whether the theta phase offset between pairs of simultaneously recorded neurons encoded the rat's position during clockwise (CW) or counterclockwise (CCW) laps around the arena. 565 unique pairs of theta-modulated cells were identified, with some pairs held across multiple sessions. To analyze phase coding, each neuron's spike train was converted into continuous waveform referred to as the *pseudo LFP*, which tracked the cell's theta rhythmicity in time. The instantaneous phase offset between two theta-modulated neurons was measured as the circular difference between the phases of their pseudo LFPs. We found that 20% (114/565) of the cell pairs precessed in phase against one another during CW or CCW laps around the arena, with a preferred slope of 1 theta cycle/lap. About 2/3 of these pairs precessed against one another only during one foraging direction (e.g., CW), and became phase locked to one another in the opposite direction (e.g., CCW). For the remaining 1/3 of precessing pairs, one cell precessed against the other during laps in either direction, but no cell was ever observed to pre-cess against its partner in one direction, and pro-cess against its partner in the other. 18% (101/565) of cell pairs were rigidly phase locked to one another at all times. Based upon our analyses, we classified LS units into two types: 1) phase locking units (32%; 43/136) that exhibited strong theta rhythimicity and high firing rates, and were rigidly phase locked to one another at uniformly distributed offsets, and 2) phase shifting units (22%; 30/136) that precessed against phase locking units with a preferred slope of 1 cycle/lap.

Title: Optogenetics-assisted characterization of parvalbumin-expressing interneuron activity in the dentate gyrus of freely behaving mice

Authors: L. F. COBAR ZELAYA, K. LIT, *A. TASHIRO;
Nanyang Technological Univ., Singapore, Singapore

Abstract: Expression of a Ca^{2+} binding protein, parvalbumin, defines a subtype of inhibitory interneurons. These parvalbumin-expressing (PV^{+}) interneurons mostly consist of basket cells, which target the soma of granule, mossy and other basket cells, and axo-axonic cells, which innervate the axon initial segments of granule cells. Thereby these interneurons control the

generation of action potentials in their postsynaptic neurons. The activity of PV interneurons in the dentate gyrus has not been investigated in freely behaving rodents during exploration.
To identify PV^+ interneuron activity in extracellular unit recording, we used an optogenetics-assisted approach. We delivered light into the dentate gyrus of transgenic mice expressing channelrhodopsin-2 in PV^+ interneurons and used light-induced spikes as a marker for PV^+ interneuron activity. With this method, we successfully identified cells which exhibited a statistically significant increase in firing after light stimulation. The majority of these cells fired with short latency after light delivery (2.8-6.5 ms) and high response reliability (>99%), which supports that these light-responsive cells are PV^+ interneurons directly activated by light, as opposed to their postsynaptic neurons activated through synapses. During exploration under physiological conditions (without light stimulation), these cells showed typical features of putative interneurons in classical electrophysiological classification: high firing rate (25-40 Hz), frequent occurrence of short inter-spike intervals (~10 ms) and modulation by theta oscillations. We also identified cells which did not show light-induced spikes. Many of these cells seemed to show reduced firing in ~30-ms period following light stimulation, although reduction was often obscure due to low background firing rate. This inhibitory effect suggests that these cells are postsynaptic neurons inhibited by PV^+ interneurons. During animal's exploration, some of these cells showed features of classical putative interneurons while others were putative principal cells. Some putative interneurons had similar characteristics to light-responsive cells, but others were a distinct type dominated by longer inter-spike intervals (>20 ms). Some of putative principal cells showed stable place cell activity.
Our results indicate that PV^+ interneurons show a subtype of putative interneuron activity classically identified in freely behaving rodents. Their inhibitory control over other PV^+ interneurons and principal cells agrees with known synaptic targets of PV^+ interneurons in the dentate gyrus.

Title: Orienting in a visual world: An intact cortical visual pathway is necessary for landmark anchoring of rat postsubicular head direction cells

Authors: *J. S. STREET, K. J. JEFFERY;
Inst. of Behavioural Neurosci., Univ. Col. London, London, United Kingdom

Abstract: In solving navigational tasks, rats must integrate rich visual scenes into their cognitive map so as to align their representations of space with the world. These spatial representations in the brain include head direction (HD) cells, which encode the azimuth bearing an animal faces in an environment, and provide a likely neural substrate for a 'sense of direction'. Although HD cell activity is maintained using vestibular information, visual information can be used to reorient cell activity through 'landmark anchoring' to prominent cues.
Which features within a visual scene are integrated into the HD signal, and through what pathway does this information enter the HD system? Do the cortical and subcortical visual pathways perform different roles in processing landmarks? We hypothesised that, if the HD system receives information solely from the cortical pathway, anchoring would be impaired if this pathway was disrupted.
We present HD cells recorded from the postsubiculum of rats with lesions of the lateral geniculate nucleus, a key relay nucleus of the cortical visual pathway, but an intact subcortical pathway. Rats foraged in a cylinder with two large visual cues attached to the walls at 180 degrees apart. The symmetry of the cue configuration enabled testing of detection and discrimination of different cue cards: high-contrast, patterned, and control cues. The cylinder was rotated between trials to test for landmark anchoring.
For all cue configurations tested, landmark anchoring was impaired in HD cells recorded from lesioned animals compared with HD cells from animals with sham lesions. This effect was graded, with residual weak cue control observed to high-contrast cues in lesion HD cells, whereas no cue control was observed to patterned cues.
These results indicate that an intact cortical visual pathway is necessary for the accurate integration of landmark information into the HD system, and may also underlie visual information flow into other areas of the spatial navigation network. Future work may target striate and extrastriate visual cortex to test how these areas process cue-relevant information and contribute to its integration into abstract representations of space.

Title: Scalable landmark-relative path integration sequences in mouse retrosplenial cortex

Authors: D. MAO[1], V. BONIN[2], ***B. L. MCNAUGHTON**[3];
[1]Baylor Col. of Med., Houston, TX; [2]Imec NERF, Leuven, Belgium; [3]The Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Retrosplenial cortex (RSC) neuronal populations exhibit sequential activity that tiles the entire track space relative to reward events. We used cellular calcium imaging in RSC of mice moving in a linear virtual reality-treadmill environment, to study how the integration of locomotion, visual flow, and visual landmarks may give rise to these RSC population sequences. A prominent population showed sparse firing sequences that were anchored to the visual virtual environment whose boundaries were associated with reward delivery. This sequential activity required active movement through the environment. Importantly, the same sequences scaled proportionally with the gain between locomotion and visual motion such that they predominantly tracked reward-relative distance based on locomotion-updated visual flow but not locomotion per se. A separate population also tracked the distance from multiple visual landmarks in a rate-dependent manner. These results suggest that RSC integrates external sensory cues with internal self-motion representations to create a distance code relative to various salient inputs.

Title: Testing a two-component model of path integration in *Drosophila*

Authors: *D. TURNER-EVANS[1], S.-Y. TAKEMURA[1], S. ALI[1], K. JENSEN[2], A. SHERIDAN[1], T. PATERSON[1], H. J. HABERKERN[1], T. WOLFF[1], C. CHRISTOFOROU[1], C. MANAGAN[1], R. RAY[1], J. S. LAURITZEN[1], D. BOCK[3], S. PLAZA[1], V. JAYARAMAN[1];
[1]Janelia Res. Campus, HHMI, Ashburn, VA; [2]Cambridge Univ., Cambridge, United Kingdom; [3]Univ. of Vermont, Burlington, VT

Abstract: For over 20 years, a two-component model has been invoked to explain the neural mechanisms of path integration in invertebrates (Hartmann and Wehner, 1995). A circularly connected group of neurons form a ring attractor, with each individual neuron coding for a particular heading, while a second population of neurons integrates distance traveled. Heading and distance are then combined in a homing vector that can be read out downstream to lead the animal back to its nest.
A central region of the insect brain, known as the central complex, has long been implicated in navigation behaviors and, recently, has been suggested to host both a ring attractor (Kim*, Rouault*, et al, 2017) and anatomy that would enable distance estimation for path integration (Stone et al., 2017). We are now using a combination of experimental techniques to test and expand upon the two-component model of path integration in *Drosophila melanogaster*.
In a large, collaborative effort, we reconstructed connections between central complex neurons using two, independent adult fly brains that were imaged using electron microscopy. We also used RNA sequencing and fluorescence *in situ* hybridization to identify the constituent neurotransmitters and receptors. Guided by the connectivity data, we built anatomically accurate firing rate models to explore the potential roles of the neuron types in navigational computations. Predictions about activity correlates of the different neuron classes were then tested with two-photon calcium imaging in behaving animals while functional roles of these classes were probed with opto- and thermogenetic perturbation during behavior.
We found connectivity, anatomical structure, and physiology that were broadly consistent with existing models while also identifying newfound complexity. For example, hyper-local recurrent connections may help to maintain a memory of the animal's heading even in the absence of localizing sensory cues. Additionally, a class of interneurons functions as a hub in the network, passing heading information downstream to be combined with forward velocity, the integration of which may lead to a homing vector. Our preliminary findings suggest that the two-component model provides a suitable framework to test the mechanisms underlying path integration yet doesn't capture all of the functionalities of the actual biological circuit.

Title: Hippocampal encoding of space during navigation of an acoustically defined virtual environment

Authors: *S. GAO[1], A. BANTA[2], J. DE GEE[2], Z. MRIDHA[2], W. ZHANG[2], C. KEMERE[1,2], M. J. MCGINLEY[2];
[1]Electrical and Computer Engin., Rice Univ., Houston, TX; [2]Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Remembering and navigating environments is of great importance for humans and animals alike. Spatial navigation in animal models has traditionally been studied using only visual cues, particularly in virtual reality settings. However, auditory cues play an important role in navigation for animals, especially when the visual system cannot detect objects or prey, such as in the dark. It is thus surprising that only few navigation studies have incorporated auditory cues, and none that we are aware of have used exclusively auditory landmarks. Here, we have developed a virtual reality platform for mice aimed to bridge the gap in understanding how the auditory system and the hippocampus interact to use auditory spatial cues for memory-guided navigation. We ask whether the animals can navigate a virtual environment that lacks any visual spatial information, and instead is defined by sparse acoustic landmarks.
The virtual environment is composed of a repeating sequence of three acoustic landmarks, separated by three silent zones. Within one of the silent zones there is a hidden reward location. Head-fixed mice traverse the virtual environment by walking on a cylindrical treadmill. Animals learn the spatial environment, as shown by robust anticipatory licking when approaching the hidden reward location. In ongoing experiments, we are performing high-channel (128) electrophysiology in hippocampal CA1 to examine the mechanisms of hippocampal coding. We use an automated spike sorting algorithm to extract large number of units (e.g. 50) from each recording. We have identified units that exhibit place-cell characteristics: spatial selectivity and place-fields distributed along the virtual track.
Our results suggest that memory-guided navigation is possible with exclusively acoustic landmarks. Our virtual environment paradigm provides the first evidence of a place map derived from purely auditory landmarks and provides a foundation for study of hippocampal-cortical interactions during navigation of acoustically defined virtual spaces.

Title: Retrosplenial 'bi-directional' cells become tetra-directional in a fourfold-symmetric environment

Authors: *N. ZHANG, K. JEFFERY;
Univ. Col. London, London, United Kingdom

Abstract: Head direction (HD) cells signal direction, and together represent a global sense of direction. An unusual sub-type termed bi-directional (BD) cells has been discovered in dysgranular retrosplenial cortex (RSC). BD cells fire when a rat faces either of two opposite directions in an environment having 180° rotational symmetry. In this 2-box, two connected visually identical boxes are oriented in opposing directions so that when the rat moves from one box to the other, the visual cues reverse. We asked whether the BD pattern emerges from the environment or is intrinsic to the cells. To test this, we changed the overall rotational symmetry of the environment, to either infinite (circular) or fourfold (90° rotations). If a BD pattern is seen in all environments, it is likely to be an intrinsic property of the cells; otherwise it might be environmentally driven. We first recorded RSC neurons in rats foraging in circular arenas, before and after 2-box trials. All HD cells (n=50), as expected, remained unidirectional regardless of environments. BD cells (n=70) showed mixed responses in circular arenas: 1. Half of the BD cells either became inactive or lost directional anchoring; 2. Some of the other half had a singular pattern; and 3. A small subset maintained a BD firing pattern, possibly due to previous 2-box experiences. The general absence of a BD pattern in the circular arena suggests that the pattern is highly specific to the 2-box and derives from the environment structure. Then in a 4-box (four connected visually-same boxes, each rotated 90° relative to its neighbours), we found tetra-directional (TD) cells (n=16) that were directionally tuned to four directions, producing an overall ‘clover’ pattern. One subset of TD cells, showed a singular tuning pattern in each box and shifted directions by 90° between boxes. A second population, intriguingly maintained a fourfold pattern even within single boxes, possibly receiving feedback from HD cells. We conclude that the properties of these multi-directional cells arise from the environment structure. Extending from bi-directionality, the phenomenon of tetra-directionality provides new insights regarding the underlying computational mechanism of coupling between visual inputs and global heading in RSC.

Title: The stabilization of the medial entorhinal cortex representation of a novel environment requires normal NMDA receptor function

Authors: *O. M. CHADNEY, B. R. KANTER, C. LYKKEN, N. Z. BORGESIUS, K. ASUMBISA, C. G. KENTROS;
Kavli Inst. for Systems Neurosci., NTNU, Trondheim, Norway

Abstract: The medial entorhinal cortex (MEC) processes spatial information used to shape a stable representation of self-location in downstream place cells, enabling accurate navigation. Indeed, the MEC encodes features such as direction by head direction cells (HD), and location and distance by grid cells, border cells, and nongrid spatial cells.
In response to environmental change, HD cells rotate their preferred firing direction, grid cells shift and rotate or reshuffle firing rates across fields, spatial cells reorganise their firing patterns, whilst downstream place cells “remap”, thus defining a unique neural representation of space. The cellular mechanism underlying spatial memory is thought to involve N-methyl-D-aspartate receptor (NMDAR)-dependent plasticity. Interestingly, place cell remapping in rats exposed to novelty does not require NMDARs, but long-term stabilization of those firing patterns does. It is still unknown whether spatial representations upstream in the MEC also rely on NMDAR-dependent plasticity.
Here, we addressed this question by recording single units in mouse MEC and pharmacologically blocking NMDARs using (±)-3-(2-carboxypiperazin-4-yl)propyl-1-phosphoric acid (CPP). MEC activity was recorded while mice explored a familiar environment (F1), after which they received an injection of either CPP or saline. One hour post-injection, they were re-introduced to the familiar environment (F2) before being exposed to a novel environment (N1). After a 6-12 hour delay, once the drug no longer had an effect, mice were re-exposed to both environments, allowing us to monitor the stability of newly formed maps in N2 whilst checking cell stability in F3.
First, our results show that the presence of CPP does not prevent remapping of HD and spatial cells when exposed to a novel environment (N1). Second, in mice having received a CPP injection prior to N1, both HD and spatial cells remap by coherent rotation of directional tuning and changes in positional firing patterns, respectively, when re-exposed to the novel environment in N2. In contrast, in mice having undergone a saline injection, firing properties were

consistently maintained from N1 to N2. In agreement with previous work on hippocampal place cells, our findings suggest a critical role of NMDAR-dependent plasticity in the consolidation of novel MEC spatial and directional representations that may be required to stabilize hippocampal firing patterns following remapping.

Title: Hippocampal correlates of optimal route planning during open field foraging

Authors: *B. J. JACKSON, D. H. GIRE;
Psychology, Univ. of Washington, Seattle, WA

Abstract: Brains have evolved to efficiently solve complex real-world optimization problems such as finding the shortest routes while searching for food. During these searches animals rapidly identify constraints of the problems they face and adaptively employ appropriate cognitive strategies and heuristics to solve these problems, resulting in solutions that while not always optimal, are quickly and efficiently implemented. Previous research in our lab has shown that rats are able to adaptively shift cognitive resources between sensory and memory systems during semi-naturalistic foraging to optimize performance under uncertainty. In these experiments we found evidence that rats often employ a "nearest-neighbor" heuristic when searching for food across multiple possible locations. That is, they proceed first to the nearest likely location of food and iteratively execute this strategy until all pellets have been found. In the present study we directly test the limits of the heuristics that rats employ when solving a particularly difficult, foraging-based optimization scenario, the probabilistic "traveling salesman" problem. In this scenario, rats are trained to search for food pellets across 6-9 possible locations within a large (2.5m x 1m) foraging area, creating as many as 362,880 possible paths to collecting all of the pellets. Rats search without visual cues and must rely only on local cues to detect the pellets, such as whisker contact or olfaction. This forces them to plan foraging routes without reliable distal guidance cues. We used a computer-controlled pellet placement system to create distributions in which nearest-neighbor searches were either optimal or sub-optimal.

Under these conditions we find that rats perform significantly worse on trials in which a nearest-neighbor search is sub-optimal ($p = 0.0017$, Wilcoxon rank-sum test, n=12 rats), suggesting that they may employ this relatively simple heuristic. To further test this, we have created distributions in which a nearest-neighbor search would be strongly sub-optimal. Using these more challenging distributions we will test whether rats routinely use the nearest-neighbor heuristic or whether they shift to perform more complex, multi-step path planning when it is advantageous. We will investigate the neural correlates of route planning by recording from the hippocampus during this more challenging optimization problem. We predict that theta and gamma power and coherence across the hippocampus will vary as a function of the complexity of the route planning for a given path.

Title: Subiculum firing fields shift systematically to differentiate similar route shapes distributed across environmental locations

Authors: *R. J. PLACE[1], D. A. NITZ[2];
[1]Cognitive Sci., UCSD, La Jolla, CA; [2]Univ. of California San Diego, La Jolla, CA

Abstract: Recent findings reveal the subiculum (SUB) represents networks of intersecting paths with multiple activity fields, such that single neurons spike as rats navigate features shared across spatially distinct routes. These spiking patterns have been shown to track topographic structures, including the animal's axis of travel within an environment or its relative distance traversed along routes with common framework [1,2]. This signal could serve to extract common components across path structures or link multiple routes distributed across environmental space. To expand upon these results, we performed electrophysiological recordings in SUB as rats traversed a series of interconnected paths. This novel task required rats to navigate learned routes defined amongst a network of three path axes that intersect to form a triangular grid. For each trial, the rat was cued to start at any 1 of 12 positions along the network's perimeter, with each starting location dictating the given trial's rewarded route. The distribution of turn degrees and relative edge sizes was preserved across routes, but the route's orientation and absolute length depended upon the starting position. This path arrangement allowed us to test neuron spiking responses driven by room space (e.g. environmental location and orientation) versus route space

(e.g. path structures and scale).
We observed here that SUB neurons exhibited multiple firing fields within the complete path network, such that single neuron activity mapped individual route spaces by their relative relationship to the environment's perimeter. Neural ensemble analysis revealed that similar routes with different lengths, were systematically mapped along the same scale of room coordinates. This signal suggests SUB activity could serve to link individual paths within a network by defining single path substructure relative to its environmental position. In contrast to CA1 neurons, which often display singular spatially tuned activity fields, these findings highlight SUB's unique position to transform information between CA1 and cortical areas, including retrosplenial (RSC) and posterior parietal cortex (PPC), for which spiking patterns have been found to represent multiple spatial and movement features during route navigation [3,4].

Title: Spatial view cells and the primate retrosplenial cortex

Authors: *A. S. MITCHELL, S. MASON, E. LOMI, B. PERRY;
Univ. of Oxford, Oxford, United Kingdom

Abstract: In primates and humans, the retrosplenial cortex is part of the default mode network, a collection of cortical brain structures that form a principal neural network, which is particularly activated when at 'rest' during neuroimaging. In addition, damage to the retrosplenial cortex disrupts the retention of previously acquired object-in-place scene discriminations in primates, and in humans, causes topographic disorientation and difficulties navigating, even in familiar surroundings. In the current study, retrosplenial cortex function was assessed across multiple sessions while recording from multi-channel stereotrodes temporarily inserted into the retrosplenial cortex of two male rhesus macaque monkeys. During electrophysiological recordings, the monkeys were positioned vertically in their primate chair and rotated clockwise and counter-clockwise within their familiar research lab environment. The room was full of

various allocentric cues. ‘Spatial view cells’, which respond when the monkey looks at a certain part of the allocentric environment, were analysed. Neuronal recordings were also collected and analysed when the monkeys were at ‘rest’. We report on differences in retrosplenial neuronal responses during active viewing compared to periods of 'rest'.

Title: Functional connectivity during action recognition modulated by top-down goals

Authors: ***X. ZHOU**[1], D. STEHR[2], P. HWU[2], J. A. PYLES[3], E. D. GROSSMAN[1]; [1]Cognitive Sci., [2]Univ. of California Irvine, Irvine, CA; [3]Dept. of Psychology, Ctr. for the Neural Basis of Cognition, Carnegie Mellon Univ., Pittsburgh, PA

Abstract: The posterior superior temporal sulcus (pSTS) is a key component of action observation network (AON) and a putative input into mirror neuron system (MNS). The pSTS is engaged in perceiving faces and actions, detecting cues that signal animacy and agency, and interpreting these events as goal-directed behaviors. In human, neural activity on the pSTS reflects both perceptual and non-perceptual features, including task instructions during action observation (Grafton, 2009), current demands in the tasks (Tavares et al., 2008; Morris et al., 2008), and the extent to which actions are congruent with current expectation (Jastorff et al., 2011; Shultz et al., 2011; Wyk et al., 2009). We therefore propose that the pSTS encodes sensory cues in the context of expectations as constructed by the observer, with the implication that these top-down influences derive from higher levels of processing in action understanding originating from the prefrontal cortex. To test this hypothesis, we computed functional connectivity between bilateral STS, inferior frontal gyrus (IFG), the lateral occipital complex (LOTC), and hMT+ when participants viewed actions under three different task instructions: attend to the action, attend to the actor’s identity or attend to the actor’s goal. We found that when participants were instructed to direct attention to actions as opposed to the identity of the actor, functional connectivity increased between IFG and pSTS, and between IFG and hMT+. The same was true when observers were instructed to direct attention to action goals. We conclude that functional connectivity within the action observation network in strengthened when observers direct to features that promote action understanding, implicating IFG as a mechanism by which inference in action understanding may shape perceptual encoding.

Title: Top-down attention guidance shapes action encoding in the pSTS

Authors: ***D. A. STEHR**[1], X. ZHOU[1], P. HWU[1], J. A. PYLES[2], E. D. GROSSMAN[1]; [1]Dept. of Cognitive Sci., Univ. of California, Irvine, Irvine, CA; [2]Dept. of Psychology, Ctr. for the Neural Basis of Cognition, Carnegie Mellon Univ., Pittsburgh, PA

Abstract: The posterior superior temporal sulcus is a key brain region within the action observation network linked to the perceptual encoding of visual events that promote the understanding of actions and their goals. Mounting evidence reveals that the univariate BOLD response in pSTS is strongly influenced by top down attention during action observation (Tavares et al., 2007; Jastoff et al., 2011). This implies that top-down attentional guidance shapes feature-tuning in the pSTS during action encoding. To test this hypothesis, we evaluated the impact of top down modulatory signals on the multivariate spatial activation patterns in the pSTS while participants viewed avatars performing two actions (jumping or crouching) under three different task instructions (attend to action, attend to goal, attend to identity). For each of these tasks, support vector machine (SVM) classifiers were trained to predict the action class from trial-specific spatial patterns of beta estimates within the pSTS during action viewing. Action decoding was evaluated by mean classification accuracy using leave-one-run out cross-validation. Results showed that the ability to decode the action's class from multivoxel activity patterns varied with the attentional demands placed on the participant. The action's class was more easily decoded when participants attended to the action itself or its expected goal compared to when they attended to the identity of the avatar. This finding is evidence that attention to action features or their goals sharpens neural tuning in the pSTS. Our results support the hypothesis that the pSTS serves as an interstitial zone mediating top down goal-directed signals and bottom-up perceptual cues.

Title: Distinct neural mechanisms of speech imagery differentially modulate auditory perception

Authors: *O. MA[1,2], X. TIAN[2,3];
[1]East China Normal Univ., Shanghai, China; [2]NYU-ECNU Inst. of Brain and Cognitive Sci., Shanghai, China; [3]New York Univ. Shanghai, Shanghai, China

Abstract: The neural representation can be induced without external stimulation in top-down processes, such as mental imagery. The previous study found that imagined speaking (AI) and imagined hearing (HI) modulated perceptual neural responses in different directions, suggesting motor-to-sensory transformation and memory retrieval as two possible neural pathways for internally activating auditory representation (Tian & Poeppel, 2013). However, the functional characteristics of this top-down process are unclear. We hypothesized that motor-to-sensory transformation could evoke more precise representation than memory retrieval. We built a neural network model and conducted a behavioral and fMRI experiment to test this hypothesis. In the neural network, precision and its top-down function were modeled as the modulation of connection strength between layers. The simulation captured previous MEG imagery repetition effects. Moreover, we tested this model's novel prediction -- two types of speech imagery would affect hearing differently - by conducting a behavioral imagery-adaptation experiment (19 participants, 9 males, the average age of 22.58). Participants judged the /ba/-/da/ continuum auditory stimuli after they either performed AI or HI. The psychometric curve showed positive shifts toward the preceding imagined syllables, but the shift was more prominent after AI than HI, quantitatively in line with the prediction generated by the model. To further investigate the neural origins that lead to auditory representation with different degrees of precision, we conducted an fMRI experiments (25 participants, 13 males, the average age of 21.28). Participants were asked to watch silent videos that contained moving objects, while either imagined speaking sentences about the events (AI condition) or imagined hearing the objects' sounds that cannot easily be mimicked by human articulation (HI condition). The univariate and

region-of-interest (ROI) analyses revealed that auditory cortex was activated in both imagery conditions and AI induced greater activity in the superior temporal gyrus compared to HI. Moreover, the speech production system (including the precentral cortex and inferior frontal gyrus) and memory retrieval network (including the inferior parietal cortex and precuneus) were preferentially activated in AI and HI, respectively. These consistent simulations, behavioral and neuroimaging results support our hypothesis that distinct neural mechanisms of speech imagery can internally generate auditory representation with different degrees of precision and differentially influence auditory perception.

Title: Neural tracking of speech mental imagery: Evidence from magnetoencephalography and intracranial electroencephalogram

Authors: *L. LU[1,2], J. SHENG[2], J.-H. GAO[1,2];
[1]PKU-IDG/McGovern Inst. for Brain Res., [2]Ctr. for MRI Res., Peking Univ., Beijing, China

Abstract: Mental imagery is the unique subjective experience when our brain internally creates representations in absence of external stimulations. Although many neuroimaging studies have reported distributed neural networks that can be activated by speech mental imagery, the neural dynamics of speech mental imagery have been mostly overlooked. Therefore, it is necessary to establish a neurophysiological model of speech mental imagery to elucidate the spectral-temporal features of imagery-induced neural activities. To address this issue, we applied a unique frequency-tagging method to experimentally isolate the top-down process of speech mental imagery from bottom-up sensory-driven activities, and concurrently tracked the neural processing time-scale corresponding to the two processes. A total of twenty young adults (12 males, 24.6 ± 3.6 yrs) participated in the magnetoencephalography (MEG) experiment in which they received an imagery block with the task to internally count in groups following a sequence of sounds and a baseline block with the same auditory stimulation but without the task. As a result, significant spectral peaks were observed at the imagery-rate and stimulus-rate frequencies that were precisely tagged ($p < 0.001$). Further, minimum L1-norm source estimation for the significant frequency bins revealed isolated brain networks activated at the imagery-rate frequency, including the left central-frontal lobe, the left inferior occipital lobe and the right

inferior parietal lobule. In contrast, more extensive brain regions in the auditory temporal cortex were activated at the stimulus-rate frequency. The MEG results were replicated by stereotactic electroencephalogram (sEEG) data recorded from five subjects (two males, 27.6 ± 12.0 yrs) with implantation of intracranial electrodes who performed the same task. Our study for the first time tracked the neural processing time-scale induced by speech mental imagery and uncovered a disassociated neural network underlies the dynamic construction of speech mental imagery independent of auditory sensory perception.

Title: Prior expectations bias early visual processing: A magnetoencephalography study

Authors: G. TURNER, F. AITKEN, ***P. KOK**;
Wellcome Ctr. for Human Neuroimaging, Univ. Col. London, London, United Kingdom

Abstract: Perception can be cast as a process of inference, wherein external sensory inputs are combined with our prior knowledge and expectations. In line with this, many recent studies have found that prior expectations can influence processing in the visual cortex. However, very little is known regarding the temporal dynamics of the integration of sensory inputs with prior expectations. For instance, recent work suggests that expectations may set up pre-stimulus templates of expected stimuli in visual cortex, which can then bias the processing of external sensory inputs from the moment they arrive. Alternatively, it has been suggested that early stages of sensory processing are free from modulations by expectations, and only later, during perceptual decision-making, do prior expectations exert their influence. In the current study, we dissociated between these hypotheses by exposing human participants (N=22) to auditory cues that predicted the likely direction of upcoming noisy moving dot patterns while recording neural activity with millisecond resolution using magnetoencephalography (MEG). First, we found that participants' perceptual reports of the moving dot directions were biased towards the direction predicted by the auditory cues. To investigate whether prior expectations led to early modulations of sensory processing, we used inverted encoding models to decode the direction of moving dot patterns from the MEG signal in time-resolved manner. Strikingly, this approach revealed that the auditory cues affected the motion direction represented in the MEG signal as early as 150 ms after onset of the moving dots patterns. Furthermore, this early neural modulation was related to perceptual effects of expectation: participants with a stronger perceptual bias towards the predicted direction also revealed a stronger reflection of the predicted direction in the early MEG signal. In fact, for these participants, the motion direction decoded from the MEG signal correlated more strongly with the motion direction they reported perceiving than with the motion direction actually presented on the screen. This correlation between neural decoding and perception already emerged prior to onset of the moving dots (~-150 ms), suggesting that the pre-stimulus state of visual cortex influences how we process sensory inputs, and thereby partly determines perception. Together, these results suggest that

prior expectations can modulate sensory processing at very early stages, making expectation a fundamental component of the neural calculations underlying the contents of our perception.

Title: Human brain network involved in auditory deviance detection: Evidence from intracranial EEG recordings

Authors: *A. O. BLENKMANN[1], A.-K. SOLBAKK[2], S. LESKE[1], J. LUBELL[3], A. LLORENS[4], S. COLLAVINI[5], I. FUNDERUD[1], P. G. LARSSON[7], J. IVANOVIC[7], T. BEKINSCHTEIN[8], S. KOCHEN[6], R. T. KNIGHT[9], T. ENDESTAD[1];
[1]Univ. of Oslo, Oslo, Norway; [2]Univ. of Oslo, Bekkestua, Norway; [3]Univerty of Aarhus, Aarhus, Denmark; [4]Dept. of Psychology, Helen Wills Neurosci. Institute, UC Berkeley, Berkeley, CA; [5]Conicet, Buenos Aires, Argentina; [6]Conicet, Capital Federal, Argentina; [7]Oslo Univ. Hosp., Oslo, Norway; [8]Univ. of Cambridge, Cambridge, United Kingdom; [9]Univ. of California Berkeley, Berkeley, CA

Abstract: The neural network underlying human auditory deviance detection is not fully understood. To address this, we recorded intracranial EEG from 22 adult patients with drug resistant epilepsy undergoing presurgical monitoring who had depth electrodes implanted in all brain lobes (1193 channels in total). Patients passively heard a stream of bilaterally presented tones while reading. We used the Optimum-1 paradigm, that consisted of 300 standard tones interleaved with 300 randomly presented deviant tones per block. Patients completed between 3 to 10 blocks. Deviant tones differed from standards in: 1) intensity (louder or softer), 2) frequency (higher or lower), 3) sound source location (right or left), 4) a shorter duration, or 5) a silent gap in the middle of the tone (Näätänen et al., 2004). Electrode coordinates were obtained from coregistered MRI and CT images using iElectrodes toolbox (Blenkmann et al., 2017). Channels were bipolar referenced and high frequency band activity (HFA) analytic amplitude signal was obtained using the Hilbert transform (75-145 Hz).
Compared to the baseline period, significant HFA responses to tones in general were observed in 31% of the channels.
We used an ANOVA to quantify the HFA response variance across trials that could be explained

by the different factors of the stimuli: Intensity, Laterality, Frequency, Duration and Gap. We estimated the amount of explained variance by using ω2 (Siegel et al., 2015). Eighteen % of the channels showed a significant increase of the condition-specific explained variance. Some channels showed condition-specific activations to one particular deviant, while others showed activations to a combination of two or more deviants.
The channels showing responses to tones in general and condition-specific effects were mostly observed bilaterally in temporal cortex. Frontal, anterior cingulate, and parietal cortices were also involved to a lesser extent. Our results, in line with the predictive coding framework, reveal that a distributed brain network is involved in auditory processing and deviance detection.

Title: Local parts lost itself in the whole: A MEG study

Authors: *L. LIU, H. LUO;
Peking Univ., Beijing, China

Abstract: Grouping local parts into coherent shapes is a central function in vision. It has been suggested to be a generative process that feedback signals carry predictions and feedforward signals represent prediction errors. Although recent fMRI studies provide evidence supporting the predictive coding hypothesis in illusory shape perception, the neuronal temporal dynamics underlying this generative process remains largely unknown. To address the issue, we recorded magnetoencephalography (MEG) signals while human subjects were presented with three Pac-Man figures, the combination of which is either or not able to induce an illusory shape perception (‘Kanizsa triangle’), corresponding to grouping and ungrouping conditions respectively. Critically, here we employed a novel information theoretic measure, which is called Partial

Information Decomposition technique (PID), combine with randomly modulated the luminance of each Pac-Man to extract neuronal response specific for each of the three Pac-Man figures. First, the PID responses for grouping condition showed decreased activities compared to the ungrouping condition, consistent with predictive coding account. Second, the PID responses which represent three Pac-Man figures in grouping condition showed an early enhancement in illusory shape location. Specifically, within 0-100 ms, the PID responses for three Pac-Man figures increase was originated in regions of V1 that have a receptive field on the illusory shape, within 100-200 ms, the PID responses inhibition was found to arise from regions of V1 that have the receptive field on three Pac-Man figures. We propose that the representation of local parts in illusory shape perception consists of two stages: an early one that quickly encodes updated prediction about the new illusory shape and a late one that represents decreased prediction error that performs inhibition in individual local parts.

Title: A representational similarity analysis examining scene categorization in the brain

Authors: *E. M. AMINOFF, A. YOUNG;
Fordham Univ., Bronx, NY

Abstract: There are multiple goals achieved in visual recognition: some consist of recognizing a specific stimulus, and others consist of recognizing the category of the stimulus (e.g., Toto vs. dog). When processing a visual scene, which brain regions mediate the processing of the general category (e.g., office), rather than the specific exemplar (e.g., my office)? How does the answer to this question elucidate the mechanisms underlying scene perception? To answer these questions, we used the BOLD5000 dataset (Chang et al., 2019) to investigate similarities in fMRI voxel activity for when participants viewed the same exact scene, compared to when they viewed a scene of the same category. We examined five visual processing regions, three of which are considered scene processing regions: the parahippocampal place area (PPA), the retrosplenial complex (RSC), and the occipital place area (OPA). In addition, we examined an early visual region and the lateral occipital complex (LOC). The logic was if a region exhibited the same extent of similarity when a scene was repeated to when a different exemplar of the same category was presented, we concluded that region processed the scene with respect to the

generalized scene category rather than the specifics of the stimulus itself. Preliminary results demonstrated the right hemisphere RSC showed this pattern of results. In addition, the LOC demonstrated a sensitivity to the categorical processing of scenes, presumably due to the object recognition entailed. All other regions showed a greater similarity for when the same stimulus was repeated compared to when the category was repeated. We discuss these results in a contextual associative framework of scene processing and representation.

Title: Fear conditioning to imagined percepts and its relationship to standard visual conditioning

Authors: *L. M. BURLEIGH[1], J. OWENS-FRENCH[1], F. CHAISSON[1], A.-B. MADDEN[2], X. JIANG[1], L. RAGGIO[1], S. G. GREENING[1];
[1]Louisiana State Univ., Baton Rouge, LA; [2]Texas State Univ., Austin, TX

Abstract: Mental images can provoke intense emotional states (Holmes & Matthews, 2010). Imagery and perception have common neural and physiological mechanisms, including activation of the early visual areas (Albers et al., 2013). We tested the prediction that individuals can acquire fear to imagined percepts and if this fear transfers to viewing percepts, using fMRI and self-reported measures to determine participants' fear. The participants completed a task in which they viewed and imagined two stimuli, and were fear conditioned when imagining the CS+. Participants are only told that mild electrical stimulation will be paired with one of the stimuli, but not which stimulus, viewed or imagined. Participants completed 6 runs of each task after completing 6 runs of a habituation form of each task. Behaviorally, participants report greater fear when imagining the CS+ than imagining the CS-. When acquiring fear to an imagined stimulus, we found significant activation in the right insula. These findings are consistent with previous literature indicating that this region is involved in processes related to emotional memory, autonomic arousal, and emotion-related motivation. Behaviorally, participants also report greater fear when viewing the CS+ than when viewing the CS-, though neither is ever paired with shock. When fear is generalized from an imagined precept to a viewed one (i.e., CS+ view > CS- view), we found no significant activation. We can conclude that participants generalize the fear acquired when imagining the stimulus to viewing the stimulus, though no underlying neural mechanisms were uncovered. Finally, participants also show a

similar level of self-reported fear to fear conditioning acquired to imagining a stimulus as to when fear is acquired to viewing a stimulus. We found insular cortex and precentral gyrus activation when investigating the similarities between these processes. These results indicate that humans can fear condition to imagined percepts, which involves activation of anterior insula; that this fear conditioning generalizes to instances of viewing the conditioned percept; and that differential conditioning to both imagined and viewed percepts produced a similar magnitude of subjective fear along with activation of the right anterior insula.

Title: Fear extinction via mental imagery

Authors: *X. JIANG[1], R. L. LANDRY[1], P. M. MIZELL[1], H. J. CRULL[2], L. M. BURLEIGH[1], S. M. SALTZMANN[1], S. G. GREENING[1];
[1]Psychology, [2]Biol. Sci., Louisiana State Univ., Baton Rouge, LA

Abstract: Mental imagery is the perceptual-like experience of previously perceived stimuli without sensory input from external stimuli. It plays an important role in various affective conditions, in relation to both their symptom presentations (e.g., flashbacks in post-traumatic stress disorder) and clinical treatments (e.g., imaginal exposure therapy). Although widely used, this assumption of interactions between mental imagery and emotion is not well researched. The current study was designed to assess the relationship between mental imagery and emotion. Specifically, whether fear conditioned perceptual images can undergo extinction via exposure to their mental imagery. This is a two-day study with day 1 as the screener and day 2 as the functional magnetic resonance imaging (fMRI) day. In day 1, participants completed fear conditioning while their skin conductance responses (SCRs) were recorded. Two English letters were selected as the conditioned stimuli (CS) and electrical stimulation was used as the unconditioned stimulus (US). The US was adjusted for each participant so that it was "uncomfortable but not painful." One of the CS's was paired with the US (CS+) and the other one was not (CS-). In day 1, 49 out of the 147 participants collected exhibited SCR evidence of fear acquisition (i.e., greater SCR for the CS+ than CS-) and 26 of them completed day 2. Three English letters were selected for day 2, which was composed to three study phases. First, the fear

acquisition phase in which two of these letters were paired with shock (CS+) while a third letter was not (CS-); second, the first extinction phase involving exposure to mental images of one of the CS+'s (CS+I) and the CS-; third, the second extinction phase involving the viewing of all three letters.
The anterior insula (aIn) and anterior cingulate cortex (ACC) were selected as regions-of-interest (ROIs) using a separate functional localizer task during which participants viewed fearful and neutral images selected from the International Affective Picture System and the Nencki Affective Picture System. Following acquisition, there were significantly greater activations in left aIn and bilateral ACC and self-reported fear for the perceptual images of both CS+'s than CS- ($p < 0.05$ with Bonferroni correction). These preliminary findings provide evidence that fear conditioning took place in the current sample. A completed sample with analyses on the fMRI, SCR, and self-report data across all three experimental phases (acquisition, extinction 1, and extinction 2) will be presented in the poster.

Title: Internal distraction in emotion regulation: Efficacy and neural mechanisms of imagined distractors

Authors: *T. D. ROBINSON[1], L. GREGOIRE[2], K. JACKSON[1], S. GREENING[1];
[1]Louisiana State Univ., Baton Rouge, LA; [2]Texas A&M Univ., College Station, TX

Abstract: This study aimed to both verify the effectiveness and examine the neural underpinnings of internally generated distracters in the regulation of negative emotional stimuli. Distraction has well-established regulatory effects on affect and other regulatory techniques such as reappraisal appear underpinned by mechanisms of internal distraction. We tested the prediction that an internally generated distracter would reduce the effects of a negative stimulus as effectively as an externally presented distracter, and that neural activity would show this effect in emotion processing regions of interest. Participants were fear conditioned to one of two neutral face stimuli (CS+ vs. CS-) prior to viewing a series of composite face/distracter images (i.e., places: houses and buildings). During viewing, they were instructed to attend to either the face, (CS+ or CS-), or the place, which involved either attending to an external visual distracter

or to an internally generated (imagined) distracter. Likert-ratings revealed that the internal distracter paradigm lowers reported fear with the same effectiveness as the traditional external visual distracter. Emotional processing, evidenced by elevated fMRI BOLD activity in the anterior insula (aIn), was significantly different between CS+ and CS- faces during the attend face conditions, but not when distracting either externally or internally, which reflect by a significant interaction. This indicates that both the external and internal distraction tasks counteract the effects of the fear stimulus. Analysis of the parahippocampal place area (PPA) indicated elevated activity during both attend and imagine distracter tasks. To test the prediction that PPA activity was related to the observed changes in fear, correlational comparison of the differences in activity between attend minus distract CS+ was compared to aIn activity and self-reported fear. Higher PPA activity correlated with greater reductions in aIn activity and greater decreases in self-reported fear. These findings not only support the hypothesis that the internal distraction paradigm effectively reduces the effects of the fear stimulus, but also suggests that the regulatory effect is directly related to visualization of the imagined distracter stimulus.

Title: Decoding prestimulus EEG alpha activity reveals expectancy in the direction of stimulus changes

Authors: *B.-K. MIN[1,3], **J. KIM**[2], D. PANTAZIS[3], H. KIM[2];
[1]Dept. of Brain and Cognitive Engin., [2]Inst. for Brain and Cognitive Engin., Korea Univ., Seoul, Korea, Republic of; [3]McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: Since prestimulus EEG alpha activity is considered to convey prestimulus top-down processing, we investigated whether expectancy of upcoming stimulation can be decoded from prestimulus alpha oscillations under a changing direction paradigm. EEG was measured from 24 participants performing the changing direction task, which included expected and unexpected conditions, depending on whether a sequence of annulus-shaped stimuli expanded/contracted in

an ordered or random manner. Prestimulus alpha power (500 ms prestimulus to stimulus onset) was estimated by band-pass filtering the EEG signals in alpha band and applying a Hilbert transform. The expected condition yielded significantly shorter reaction times than the unexpected condition ($t(23) = -10.928$, $p < 0.001$; expected 246.3 ms, unexpected 384.2 ms), indicating more efficient preparation for upcoming stimuli during the expected sequence in the direction of changes. Using the prestimulus alpha power, the decoding performance between expected and unexpected sequences was significantly higher than chance level ($t(23) = 8.546$, $p < 0.001$). The maximum of decoding accuracy (86.7%) in the prestimulus period was observed just before stimulus onset. In the expected sequence, the prestimulus alpha power of the second inter-stimulus interval (ISI) was significantly higher than that of the first ISI, which was also used for prediction of the next stimulus type with a high accuracy of 70.0% ($t(23) = 2.622$, $p < 0.05$). Taken together, our results provide evidence that ongoing alpha activity encodes top-down information about the expected changes of upcoming visual stimuli.

Title: Testing the reproducibility of tDCS effect: Modulating beauty perception by brain stimulation

Authors: *K. TAKAHASHI, Y. YOTSUMOTO;
Dept. of Life Sci., The Univ. of Tokyo, Tokyo, Japan

Abstract: Transcranial direct current stimulation (tDCS) has been used in a large number of neuroscientific studies as a promising tool to test the causal relationship between brain areas of interest and behavior. However, its reproducibility is now questioned due to failures in replication reported by recent studies. In the present study, we focus on tDCS effect on one cognitive domain, beauty perception. To date, modulation of beauty perception by tDCS has been shown in the two studies: Cattaneo et al. (2014) and Nakamura & Kawabata (2015). While Cattaneo et al. reported increase of beauty perception following anodal tDCS over the prefrontal cortex, Nakamura & Kawabata (2015) showed the opposite outcome resulted by cathodal tDCS over the same brain area. Here, we aimed to replicate their studies and to investigate tDCS effect

on beauty perception with the parameters they used: (1) cathodal stimulation over the medial prefrontal cortex (mPFC) (Nakamura & Kawabata, 2015); (2) anodal stimulation over the left dorsolateral prefrontal cortex (lDLPFC) (Cattaneo et al., 2014). Also, besides attempting to replicate those studies, we performed more focal anodal stimulation targeting the orbitofrontal cortex (OFC) to explore an optimal stimulation site for modulating beauty perception (3). Participants rated the subjectively perceived beauty of images before and after tDCS. Furthermore, we divided images according to the obtained rating scores in our preliminary study: high, middle- high, middle-low and low image clusters. To exclude confounding factors such as stimuli attributions or individual preference, we examined the effect of tDCS on beauty perception in each image cluster separately. The results showed no strong effect of tDCS with the same parameters as of previous studies on beauty rating scores in any image cluster. Likewise, anodal stimulation over the OFC, the current simulation software derived parameter, did not lead to change in scores. In sum, we were not able to replicate the findings of previous tDCS studies. More focal stimulation (tDCS over the OFC) also failed to modulate beauty perception. These results provide evidence concerning the recent reproducibility issue of tDCS effect and might suggest the possible inflation of its effect on human cognition.

Title: Intracranial electrophysiological correlates of binocular rivalry in the human brain

Authors: *V. RANGARAJAN[1], D. KING-STEPHENS[3], K. D. LAXER[3], P. WEBER[3], J. LIN[4], E. F. CHANG[5], K. AUGUSTE[5,6], R. T. KNIGHT[1,2];
[1]Psychology, [2]Helen Wills Neurosci. Inst., Univ. of California, Berkeley, Berkeley, CA; [3]California Pacific Med. Ctr., San Francisco, CA; [4]Clin. Neurol., Univ. of California, Irvine, Irvine, CA; [5]Div. of Neurolog. Surgery, Univ. of California, San Francisco, San Francisco, CA; [6]UCSF Benioff Children's Hosp., Oakland and San Francisco, CA

Abstract: Binocular rivalry is a striking form of multistable perception where different images are presented concurrently to each eye and conscious perception alternates between the images. This provides a unique opportunity to disentangle conscious perception and sensory processing since perception alternates between the two possible percepts, while the sensory input remains

static. Electrophysiological and neuroimaging work in humans and nonhuman primates indicate that local competitive interactions between neuronal populations in visual areas under "top-down" influences from fronto-parietal (F-P) regions support binocular rivalry.
This study leveraged intracranial recordings in patients with refractory epilepsy to study how F-P regions support rapid shifts in conscious perception during binocular rivalry. Subjects (n=5) were implanted with intracranial electrodes over frontal, parietal, and occipito-temporal cortices. Subjects participated in 2 experiments. Experiment 1 was a category localizer in which subjects saw faces, houses, words, bodies, and scrambled images and were instructed to press a button when a scrambled image appeared (odd-ball paradigm). Experiment 2 was a face/house binocular rivalry paradigm in which red/blue stimuli were presented independently, but simultaneously to each eye. Subjects reported when a perceptual switch occurred during 2 main conditions: the rivalry condition in which perceptual switches were endogenous or self-driven and the replay condition in which switches were exogenously or externally controlled.
We first identified face- and house-selective electrodes in ventral temporal cortex (Exp 1), primarily located anatomically over the fusiform and parahippocampal gryi, respectively. We then examined the profile of responses during rivalry (Exp 2). Behaviorally, subjects reported subjective alternations between percepts every 2-6 seconds. We found that high-frequency broadband activity (HFB: 70-150 Hz) was significantly active above baseline during 3 main temporal response windows: (i) at the onset of stimulus presentation, and (ii) preceding or (iii) time-locked to the perceptual switch. Electrodes time-locked to the onset were located primarily in ventral occipito-temporal cortices and corresponded with the category-selective electrodes identified in Exp 1; In contrast, electrodes preceding or time-locked to the perceptual switch were primarily located in lateral frontal and parietal regions. We found that subregions of the F-P attention network support endogenous rivalry and contrasted their response patterns with the neural responses during replay.

Title: COALIA: A virtual human brain model of EEG for consciousness research

Authors: *P. BENQUET[1], J. MODOLO[2], S. BENSAID[2], I. MERLET[2], F. WENDLING[3]; [1]INSERM U1099 -LTSI, Rennes, France; [2]INSERM U1099, Rennes, France; [3]INSERM U1099 LTSI, Rennes Cedex, France

Abstract: Understanding the origin of the main physiological processes involved in consciousness is a major challenge of contemporary neuroscience, with crucial implications for the study of Disorders of Consciousness (DOC). One possibility of integrating the main results from the experimental literature into a cohesive framework, while accounting for nonlinear brain dynamics, is the use of physiologically-inspired computational models. In this study, we present a physiologically-grounded computational model, attempting to account for the main micro-circuits identified in the human cortex, while including the specificities of each neuronal type. More specifically, the model accounts for thalamo-cortical (vertical) regulation of cortico-cortical (horizontal) connectivity, which is a central mechanism for brain information integration and processing. The distinct neuronal assemblies communicate through feedforward and feedback excitatory and inhibitory synaptic connections implemented in a template brain accounting for long-range connectome. The EEG generated by this physiologically-based simulated brain is validated through comparison with brain rhythms recorded in humans in two states of consciousness (wakefulness, sleep). Using the model, it is possible to reproduce the local disynaptic disinhibition of basket cells (fast GABAergic inhibition) and glutamatergic pyramidal neurons through long-range activation of VIP interneurons that induced inhibition of SST interneurons. The model (COALIA) predicts that the strength and dynamics of the thalamic output on the cortex control the local and long-range cortical processing of information. Furthermore, the model reproduces and explains clinical results regarding the complexity of transcranial magnetic stimulation TMS-evoked EEG responses in DOC patients and healthy volunteers, through a modulation of thalamo-cortical connectivity that governs the level of cortico-cortical communication. This new model provides a quantitative framework to accelerate the study of the physiological mechanisms involved in the emergence, maintenance and disruption (sleep, anesthesia, DOC) of consciousness.

Title: Cognitive processing of viewers while watching different styles of editing in media contents

Authors: *A. GRUART[1], C. ANDREU-SANCHEZ[2], M. A. MARTIN-PASCUAL[2], J. M. DELGADO-GARCIA[1];
[1]Pablo De Olavide Univ., Seville, Spain; [2]Autonomous Univ., Barcelona, Spain

Abstract: How brain manages the perception of the audiovisual content is something that started to be developed in the 1950s. Studies about cognitive processing of media content are of interest since we have found some differences between different types of audiovisual editing. In the present study, we asked what the cognitive processing of the spectators would be while they observe editing cuts in audiovisual narratives and if there would be differences when inserting them in different editing styles. We presented two videos with the same narrative, content, and duration, but different style of edition to 36 subjects (aged 25-56). One stimulus was a movie with 33 shots and an average shot length (ASL) of 5.9 s, with a classical style of edition, based on the Hollywood-style, with smooth transitions among shots, clear presentation of the visual information, and a great continuity. The other stimulus was a movie with 79 shots and an ASL of 2.4 s, based on MTV-videoclips style, very discontinuous, chaotic, and fast. Continuous EEG was recorded and event-related potentials (ERPs) and the spontaneous eyeblink rate (SBR) were analyzed. We found that cuts decrease spectators' SBR during the following second to their end in a significant way ($t_{(35)} = -2.719$, $p = 0.01$, Student's paired t test). This significant decrease was obtained in the Hollywood-style movie, but not in the MTV-style movie. We computed ERPs associate to cuts from 500 ms before the cut to 1000 ms after it and found that as the time after the cut progresses, a spread of potential goes from the occipital area to the frontal area. We also found significant differences in the potential of brain responses to the different styles of edition studied here. While cuts inserted in a Hollywood-style movie evoked larger ERPs in the medial, and mostly, in the frontal areas, those inserted in an MTV-style movie evoked a larger ERP activation in the occipital area. According to our results, cuts manage viewers' attention. A cognitive process of visual perception of media content is reset after each cut. This is coherent with previous studies of visual perception of any visual stimulus change. However, the style of edition for presenting cuts is very important. Clear and continuous presentation of the content has a lower impact on the visual cortex but a greater effect on higher areas involved in conscious processing. The opposite happens in the case of more chaotic audiovisuals, video clip type. These results can be applied to create media works able to manage viewers' attention and cognitive processing.

Title: Response characteristics of one's own voice in the human auditory cortex

Authors: *T. HOSAKA, Y. YOTSUMOTO;
The Univ. of Tokyo, Tokyo, Japan

Abstract: It is strange to hear the recorded version of one's own voice. Recorded voice is perceived differently from the actively spoken voice (own voice) because the pathways of these two types of vocal sounds to our hair cells are different. Most studies that investigated neural mechanisms of voice recognition compared neural activities while the participant listened to their own voice with those while the participant listened to others' voices. However, humans show keen sensitivity when it comes to the perception of their own voices, and they are able to detect not only the differences between themselves and others but also the slight modulations of their own voices. Here, we examined the neural mechanisms underlying such sensitive perception of one's own voice. Our experiment consisted of three sessions. First, we recorded the participants' voices, and their voices were processed using five different filters that were used to simulate the participants' own voices in earlier studies. In the second session, the participants rated the similarity of the presented voice to their own. In the third session, the participants rated the presented voice again while they underwent functional magnetic resonance imaging (fMRI). The behavioral results from the second and the third sessions indicated that the filters induced a range of responses with regard to the likelihood of perception of one's own voice. We first calculated the contrast between the voices that were judged to be the least like the participants' own voice and the voices that were judged to be the most similar to their own from the fMRI data. The contrast revealed that the bilateral superior temporal gyrus showed greater activation while listening to the voice least similar to the participant's own voice and was activated to a lesser degree while listening to the voice most similar to their own. The superior temporal gyrus is known to be involved in the identification of a person by their voice and in long-term neural sharpening. With neural sharpening, the stimuli that are more typical for an object elicit reduced neural responses. Our results indicated that the superior temporal gyrus showed neural sharpening on presentation of voices and showed decreased activation to their own voice. To

summarize, we showed that the superior temporal gyrus is involved in detecting slight modulations of one's own voice and in self-recognition.

Title: Shared frequency-specific coding between auditory perception and auditory imagery revealed by multi-voxel pattern analysis

Authors: *S. KATSUI, Y. YOTSUMOTO;
The Univ. of Tokyo, Tokyo, Japan

Abstract: Human auditory cortex has tonotopic representation because of which the spatial activity pattern depends on the frequency of the sounds. On the other hand, it is also known that human auditory cortex responds to top-down processing such as auditory imagery. Visual imagery activates the early sensory cortex in a manner similar to visual perception, but the mechanism of auditory imagery and its relationship with auditory perception remains largely unknown. The present study examined whether an activated pattern in the primary auditory cortex can be used to distinguish not only the frequency of sounds heard but also that of imagined sounds. In this experiment, we used functional magnetic resonance imaging (fMRI) to measure the neural activations during listening and imagining of three different pure tones. In addition to a conventional univariate mapping method, we applied multi-voxel pattern analysis (MVPA) for the purpose of dealing with the difficulty of detecting cortical representation in the primary auditory cortex. A support vector machine (SVM) was used for the classification of multivariate analysis. The accuracy of intra-subject classification was compared with a chance level, to judge whether the different tones could be distinguished using the activated pattern. The results indicated that the classification was successful for both perception and imagery. This result suggested that the spatial pattern of activation in the human primary auditory cortex contains information regarding the frequency of imagined sounds as well as that of heard sounds. Moreover, cross-classification between perception and imagery was also successful, indicating similar activation patterns between perception and imagery. Our findings imply that the top-down process for auditory imagery and the bottom-up process for auditory perception partially

share neural mechanisms in the primary auditory cortex. Our results further suggest that auditory imagery and its processing are comparable to those in the visual domain.

Title: The effect of distorted temporal-spatial visual feedback on robot hand illusion

Authors: *Y. IOKA, S. SHIMADA;
Grad. Sch. of Sci. and Technol., Meiji Univ., Kanagawa, Japan

Abstract: We can make a distinction between our own body and others through self-body recognition. Robot Hand Illusion (RoHI) is an illusion regarding visuo-motor integration on a fake hand, which is relevant to both the sense of ownership and the sense of agency. A previous study investigated how delayed visual feedback influences self-body recognition in RoHI when participants use a data glove and manipulate a virtual hand projected on a monitor. As a result, the sense of agency was induced in less than 490ms delay conditions and the sense of ownership was induced in less than 190ms delay. In this study, we investigated how RoHI is induced when virtual hand's position and palm direction are distorted from the participant's hand posture, with visual feedback delay. Sixteen healthy right-handed participants (mean age 21.6 ± SD 1.1; 6 females) took part in this study. Participants conducted 12 sessions. In each session, participants make hand opening and closing movements with a sensor glove for 30s and watched the movement of a virtual hand which was projected on a monitor. The visual feedback delay was inserted in 3 conditions (100ms, 300ms, 500ms). Virtual hand's posture were altered in 4 conditions (Forward-Obverse: FO, Forward-Reverse: FR, Opposite-Obverse: OO, Opposite-Reverse: OR): Forward means that virtual hand's position is anatomically correct to the participant's torso, while Opposite means that it is rotated 180°. Obverse means that virtual hand's palm direction is the same as the participant's hand, while Reverse means that it is reversed. After each session, participants answered questionnaires associated with self-body recognition. We found the sense of ownership was induced only in the FO-100 (FO, 100ms delayed) condition (t-test, $t(15) = 2.7$, $p < 0.01$), and it was significantly decreased to less than zero in the 300ms delayed and 500ms delayed conditions (FR-300, $t(15) = -4.0$, $p < 0.001$; OO-300, $t(15) = -5.2$, $p < 0.001$; OR-300, $t(15) = -3.4$, $p < 0.005$; FO-500, $t(15) = -5.4$, $p < 0.001$; FR-500, $t(15) = -5.3$, $p < 0.001$; OO-500, $t(15) = -7.2$, $p < 0.001$; OR-500, $t(15) = -6.8$, $p < 0.001$). The sense of agency was induced in the 100ms delayed conditions, the FO-300 and the OR-300 conditions (FO-100, $t(15) = 8.7$, $p < 0.001$; FO-300, $t(15) = 3.4$, $p < 0.05$; FR-100, $t(15)$

= 5.6, $p < 0.001$; OO-100, $t(15) = 14.6$, $p < 0.001$; OR-100, $t(15) = 5.0$, $p < 0.001$; OR-300, $t(15) = 3.1$, $p < 0.005$). These findings indicate the sense of ownership is decreased when virtual hand's position and/or direction is greatly different from the participant's real hand posture. In contrast, the sense of agency can be induced by visuo-motor integration even if the posture is not matched.

Title: Consistency and strength of grapheme-color associations may be separable aspects of synesthetic experience: Evidence from an individualized implicit association test

Authors: N. STEINER[1], M. MARTINEZ[2], *S. A. LACEY[3], L. NYGAARD[1], K. SATHIAN[4]; [1]Emory Univ., Atlanta, GA; [2]Rowan Sch. of Osteo. Med., Stratford, NJ; [3]Penn State Col. of Med., Hershey, PA; [4]Dept. of Neurol., Milton S. Hershey Med. Ctr. & Penn State COM, Hershey, PA

Abstract: Synesthesia is a phenomenon in which experiences in one sensory or cognitive domain are accompanied by involuntary experiences in a second domain. Grapheme-color synesthesia, in which seeing a particular letter or number induces a secondary experience of color, is the most common form. Such synesthetic associations are characterized by their arbitrary (there is no obvious connection between the letters and colors) and idiosyncratic (different synesthetes may experience different colors for the same letter) nature. The Synesthesia Battery (SB: Eagleman et al., J Neurosci Meth, 2007) measures the consistency with which individuals choose the same color for the same grapheme and returns a standardized score: < 1 indicates a genuine synesthete, > 2 indicates a non-synesthete, 1 - 2 indicates that synesthetic status cannot be unambiguously determined. However, the SB does not measure the strength of synesthetic associations. Using the Implicit Association Test (IAT: Greenwald et al., J Pers Soc Psychol, 1998), we have previously shown that synesthetes have greater sensitivity to some crossmodal correspondences than non-synesthetes (Lacey et al., Eur J Neurosci, 2016). Here, we used the IAT to measure association strength. In the IAT, two stimuli are associated with the same response key. A single stimulus is presented on each trial and participants make speeded responses, which are faster when the key associations are congruent and slower when

incongruent, i.e., there is a congruency effect (Parise & Spence, Exp Brain Res 2012). Grapheme-color synesthetes (n =18) completed the SB and an individualized IAT in which two response keys were associated with a grapheme and its correct synesthetic color for congruent trials (e.g., A + red, B + green) or its incorrect color for incongruent trials (i.e., A + green, B + red). Age- and gender-matched non-synesthetic controls (n = 18) also completed the IAT, using the grapheme-color associations of their matched synesthete. We expected that synesthetes would have larger IAT congruency magnitudes than non-synesthetes. For synesthetes, a positive correlation between SB scores and congruency magnitudes would indicate that strong associations are also consistent. However, while congruency magnitudes were larger for synesthetes than non-synesthetes, strength (IAT magnitudes) was uncorrelated with consistency (whether SB scores or Euclidean distances in RGB color space). We conclude that the consistency and strength of associations may be separable aspects of synesthetic experience.

Title: Brain tissue electrical conductivity estimation for epilepsy diagnosis

Authors: ***F. WENDLING**[1], A. CARVALLO[1], P. BENQUET[1], S. LAGARDE[2], F. BARTOLOMEI[2], J. MODOLO[1];
[1]Inserm, Rennes, France; [2]CHU Timone, Marseille, France

Abstract: Rationale. Many studies reported the potential clinical value of electrical conductivity in the field of oncology and muscular diseases. In contrast, there were only few attempts to evaluate the potential clinical/diagnostic value of electrical conductivity to characterize brain tissue in neurological disorders. In the context of epilepsy, bioelectrical impedance and conductivity have been reported as possible indicators of brain tissue epileptogenicity, but conflicting data has limited their use for diagnosis. Objective: We developed a low-intensity pulsed stimulation method providing a fast and reliable estimation of brain tissue electrical conductivity, to identify potential changes in conductivity due to underlying pathophysiological processes induced by epilepsy. Methods: Using the quasi-static approximation of Maxwell equations, we derived an analytical model of the electric field generated by intracerebral stereotactic-EEG (SEEG) electrodes used for pre-surgical evaluation of patients with drug-resistant epilepsy. We coupled this electric field model with a model of the electrode-electrolyte interface to provide an explicit analytical expression of brain tissue conductivity based on the

recorded brain tissue response to pulse stimulation. Results: We validated our biophysical model using i) saline solutions calibrated in electrical conductivity, ii) rat brain tissue, and iii) electrophysiological data recorded from epileptic patients during SEEG exploration (n=7). Estimated conductivity values in saline solutions and post-mortem rat brains were close to actual values (typically < 1% error). More importantly, in patients, conductivity values were significantly different between healthy and epileptogenic regions, as assessed by the analysis of locally-generated epileptiform markers observed in SEEG signals. Conclusion: This new model-based method offers a fast and reliable estimation of brain tissue electrical conductivity while correcting for electrode-electrolyte interface effects. Significance: This method outperforms standard bio-impedance measurements since it provides absolute (not relative) changes in brain tissue conductivity. Novel diagnostic applications can be envisioned based on quantified differences in electrical conductivity between healthy and hyper-excitable regions.

Title: Neurofunctional relevance of genome-wide supported neuroticism loci

Authors: *V. FREYTAG[1,3], V. VUKOJEVIC[1,3,4], D. COYNEL[2,3], A. HECK[1,3,4], E. LOOS[2,3], P. DEMOUGIN[3,5], C. VOGLER[1,3,4], A. MILNIK[1,3,4], D. DE QUERVAIN[2,3,4], A. PAPASSOTIROPOULOS[1,3,4,5];

Abstract: Neuroticism is a heritable personality trait, genetically related to mental disorders such as anxiety and major depression. The study of its genetic basis is hence proposed as a means to gain insights into the biological underpinnings of these etiologically intractable illnesses. Recently, a large-scale study in more than 329,000 UK Biobank participants reported 116 independent variants influencing neuroticism as measured by a well-established self-report questionnaire that includes items related to negative emotionality such as feelings of worry, guilt, loneliness, irritability, and nervousness. Yet, the nature of this phenotypic assessment limits our ability to link the discovered genetic loci with tractable biological mechanisms involved in physiological and pathological conditions.
In this study, we investigated the relevance of these genome-wide supported findings by

imposing on the reported variants a layer of functional measurements of neuroticism-related neural circuitry. Specifically, a total of N=1,389 healthy young adults underwent genotyping assessment and an emotional processing task. A polygenic score (PRS) derived from the 116 reported neuroticism loci was subsequently tested for association with negative emotion processing-related fMRI activation at candidate regions previously reported as linked to neuroticism. This revealed a significant association between the neuroticism PRS and thalamic activation, adjusted for age and sex effects (p = 1.3e-03). Single-marker analysis further allowed the identification of one single-nucleotide polymorphsim, rs6773869, located within *PLCL2* - encoding for phospholipase C like 2 - significantly associated with thalamic activation (p = 1e-04). In a subsample of n=568 participants, this locus was also identified as a methylation quantitative trait locus (mQTL), as it correlated with whole-blood methylation levels of two distinct CpGs, intronic to *PLCL2*. Finally, rs6773869 also showed significant association with whole-blood expression levels of *PLCL2* in a subsample of n=403 subjects.
Altogether, capitalizing on large-scale GWAS for neuroticism and neurofunctional correlates of neuroticism, we identified a genetic marker associated with emotional processing activity in a thalamic region. Exploratory molecular traits analysis also suggest that this locus is likely functional.

Title: Neural habituation enhances novelty detection: An EEG study of rapidly presented words

Authors: *L. P. L. JACOB, D. E. HUBER;
Univ. of Massachusetts Amherst, Amherst, MA

Abstract: Huber and O'Reilly (2003) proposed that neural habituation serves an important function in perceptual processing, separating the current object from recently viewed objects that would otherwise blend with the current object. However, neural habituation comes at a cost, producing repetition deficits. Prior work confirmed the predicted transition from repetition benefits to deficits with increasing prime duration, but the concomitant prediction of enhanced

novelty detection was not tested. The current study examined this prediction with a same/different word priming task, using SVM classification of EEG data, ERP analyses focused on the N400, and an artificial neural network implementing the habituation theory, which was fit to the behavioral data to provide a priori predictions of the full-trial ERP waveforms. Subjects made same/different judgements to a test word in relation to an immediately preceding briefly presented target word; neural habituation was manipulated by varying the duration of the preceding prime word. With increased prime duration, correct "different" responses increased, evidencing enhanced novelty detection, and P100/N170 amplitudes to repeated targets decreased, evidencing neural habituation. A between-subject SVM classifier predicted trial-by-trial behavior with 66.34% accuracy on held-out data, with greatest predictive power at a time and topographic pattern consistent with the N400. The neural habituation model was augmented with a working memory layer, and a second experiment used response-locked ERPs to confirm the model's predictions regarding decision processes. These results support the hypothesis that synaptic depression enhances novelty detection, and the auxiliary assumption that the N400 reflects the encoding of new content into working memory.

Title: Approach biases in cannabis and pornography users

Authors: *S. M. SKLENARIK[1], K. JENKINS[1], M. FERNANDEZ[1], R. LIVOTI[1], S. PELLEGRINO[1], E. BULKLEY[1], A. PURINS[1], K. MILLER[1], E. LECKY[1], M. MOURMOURAS[1], M. GOLA[2], M. POTENZA[3], R. ASTUR[1];
[1]Univ. of Connecticut, Storrs, CT; [2]Univ. of California, San Diego, CA; [3]Yale Univ., New Haven, CT

Abstract: Addicted individuals often demonstrate relatively automatic action tendencies in response to addiction-related stimuli, whereby they approach rather than avoid addictive stimuli. For instance, Wiers et al. (2011) found that alcohol-dependent individuals are quicker to approach and slower to avoid pictures of alcohol compared to neutral stimuli; this approach bias is not present in people without problematic drinking behaviors. Importantly, studies indicate that such cognitive biases can be manipulated to decrease problematic behavior and improve treatment outcome (Wiers et al., 2013). The purpose of the current studies was to replicate this approach bias effect in individuals at risk for problematic cannabis use and problematic pornography use using computerized Approach-Avoidance Tasks (AAT).

65 undergraduates (20 male, 45 female) who reported using cannabis in the past 6 months were recruited from the University of Connecticut for a 30-minute study assessing cognitive biases for cannabis pictures. 224 additional undergraduates (58 male, 166 female) who reported using pornography were recruited for 30-minute studies measuring cognitive biases for erotic pictures. All participants completed questionnaires assessing cannabis and pornography use. Participants then completed the AAT, which differed only in the type of addictive stimuli presented (i.e. cannabis or erotic images). Using a standard gaming joystick, participants were instructed to pull a joystick in response to an irrelevant property of the pictorial stimuli (e.g., vertical orientation of the picture) and push in response to the opposite property (e.g., horizontal orientation). Pulling the joystick caused the images to enlarge as if moving closer (simulating approach movement), and pushing caused the images to shrink as if moving away (avoidance). Median reaction times were analyzed to calculate a cognitive bias score.
A one-sample T-test showed that there was no approach bias for the cannabis images (approach bias = 5.69 ms, SD= 68.7 ms, $t(64) = 0.67$, *ns*) compared to neutral images, although cannabis use was significantly positively correlated with pornography use, depression, and online gaming. However, males showed a significant approach bias of 81.81 ms (SD = 93.07) for the erotic images, $t(57) = 6.69$, $p < 0.001$, compared to the neutral images; males with problematic pornography use showed more than double this approach bias. Females showed a much weaker approach bias for erotic stimuli. Both clinical implications and intervention studies using a cognitive retraining paradigm to reverse approach biases and decrease problematic behaviors are discussed.

Title: The neural correlates of navarasa. Essence of 9 emotions

Authors: *R. P. REDDY, J. RAJESWARAN;
Clin. Psychology, NIMHANS, Bangalore, India

Abstract: The aim of the study was to compare the neural correlates of Navarasa (9 emotions) with Mental Health Professionals versus other professionals (n=6). All were screened on Mini-

International Neuropsychiatric Interview (MINI), Standard Progressive Matrices, Interpersonal Reactivity Index (Davis,1980), Questionnaire of Cognitive and Affective Empathy (Renate at al, 2011), Emotional Quotient (Chadda) Social Stories Questionnaire (Autism Research Centre, 2002), Faux Pas Recognition Test (Simon Baron- Cohen, 1998).
fMRI Design: Navarasa Face Paradigms (9 emotions- Śṛngāram:Love, Hāsyam: Happiness, Raudram: Anger, Kāruṇyam: Compassion, Bībhatsam: Disgust, Bhayānakam: Fear, Vīram: Brave, Adbhutam: Amazement). fMRI scanning: MRI scanning was conducted in a 3 Tesla Siemens Magnetom Skyra scanner. Anatomical scan was acquired with a T1 MPRAGE sequence, with FOV w240mm, slice thickness 0.9mm, slices per slab176, voxel size 0.9*0.9*0.9mm. fMRI was acquired with an EPI sequence. The FOV was 192mm, slice thickness 4mm, slices obtained 36, voxel size 3*3*4mm, matrix 64*64, TR 4 seconds, TE .03 seconds (E prime 1.1 / Block design paradigm/ Statistical Parametric Mapping on MATLAB). Preprocessing consisted of Realignment, Normalization and Smoothing. The first level analysis was General Linear Model with Family Wise Error (FWE), $p<0.05$. One sample t test was used in the 2nd level analysis without FWE & $p<0.001$
Results: When compared to MHP and OP there was nil significant statistical difference between the groups on behavioral data. Navarasa task activated medial, superior frontal gyrus, left inferior parietal lobule, right precuneus, right angular gyrus, left occipital, right fusiform, superior temporal gyrus, left cingulate gyrus, bilateral posterior cingulate, bilateral cingulate, and Bilateral cerebellum.
The total number of participants for the study is 60, analysis of the same is underway.

Title: Long-term piano training alters the functional connectivity of the core networks

Authors: *Y.-C. LIAO[1], C.-J. YANG[1,2], T.-Y. HONG[1,2], H.-T. YU[3], L.-F. CHEN[1], J.-C. HSIEH[1,2,4];
[1]Natl. Yang-Ming Univ., Inst. of Brain Sci., Taipei, Taiwan; [2]Integrated Brain Res. Unit, Taipei, Taiwan; [3]Taipei Natl. Univ. of the Arts, Grad. Inst. of Arts and Humanities Eduction, Taipei, Taiwan; [4]Brain Res. Ctr., Taipei, Taiwan

Abstract: Music performance is one of the most facinating creative behaviors (Heroux, 2016). Playing piano mandates a divergent contemplation one the musical storyline and the semantic context (Heroux, 2016). Pervious studies on general creativity have posited the interplay of the default mode network (DMN) and the executive control network (ECN) as pivotal for creativity (Beaty, et al, 2015; Heinonen, et al, 2016). The DMN is engaged in mind-wandering (Mason, et al, 2007), future thinking (Schacter, et al, 2012), and mental simulation (Bucker, et al. 2007). The ECN participates in working memory, attention, and relational integration (Beauty, et al, 2016). In this study, we specifically investigated the consolidated crosstalks in terms of functional connectivity (FC) between the DMN and ECN in university students majored in piano. We hypothesized that long-term piano training may be associated with heightgened FC between DMN and ECN. Thirty-three piano students (PIANISTs) and thirty-six age-matched non-musical controls (CONs) were enrolled. We utilized the resting-state functional magnetic resonance images (rs-fMRIs) to unveil the DMN- and ECN-seeded FCs. Abbreviated Torrance Test for Adults (ATTA) questionnaire to assess the general creativity. Behaviouraly, there were no significant differences in ATTA scores between two groups. PIANISTs showed hyperconnectivity of DMN-ECN FCs than CONs. DMN and ECN together play an important role in creativity. Performing music entails internal imagery and feeling to produce musical expressions as rooted in personal experience and memories as well as empathetic appreciation of the composer‘s musical ideas. Our data are indicative of the neurological underpinning of the core processing of musical creativity. Absence of ATTA findings may indicate that musical training would not substantially alter the general creativity. Pianist’s performing creativity is manifested via musical items rather than non-musical ones. The highgtened DMN-ECN FCs can serve as neural underpinnings of expressional creativity of music performance.

Title: Cyclic consolidation of human motor memory

Authors: *S. J. HUSSAIN[1], M. K. VOLLMER[1], G. NORATO[1], C. ZRENNER[2], E. R. BUCH[1], U. ZIEMANN[3], L. G. COHEN[1];

[1]NIH, Bethesda, MD; [2]Ctr. for Neurol., Univ. Hosp. Tübingen, Tuebingen, Germany; [3]Eberhard Karls Univ., Tübingen, Germany

Abstract: Fluctuations in cognitive function are a fundamental property of the human brain. These fluctuations parallel brain oscillations, with cognitive and sensory abilities being enhanced during optimal oscillatory phases. We recently demonstrated that output from the human motor cortex (M1) is increased during trough compared to peak phases of sensorimotor mu (8-12 Hz) rhythms and that this relationship depends on mu power (Hussain et al. 2018). However, whether human motor learning exhibits cyclic fluctuations and if so, the neural mechanisms causing them, is not known. We reasoned that if the mu rhythm cyclically modulates the motor cortical (M1) mechanisms underlying skill consolidation, then disrupting M1 activity during different mu phases after skill learning should differentially impair consolidation. Healthy adults practiced a novel explicit motor sequence learning task on Day 1. Immediately after practice, we transiently and repeatedly disrupted M1 activity using sensorimotor oscillatory phase-dependent closed-loop transcranial magnetic stimulation (closed-loop TMS) during either mu peak phases (N=17) or mu trough phases (N=17). We first confirmed the accuracy of the real-time EEG analysis algorithm required for closed-loop TMS delivery, showing that it accurately targeted mu peak and trough phases ($p<0.001$ for both). We then evaluated Day 1 acquisition (online learning) and overnight consolidation (offline learning) of the new motor skill. As expected, day 1 training led to comparable skill acquisition in both groups (online learning; main effect of LEARNING STAGE only, $p<0.001$). Subjects in both groups showed significant overnight performance improvements, reflecting consolidation (offline learning; main effect of LEARNING STAGE, $p<0.001$). However, disruption of M1 activity produced different effects depending on whether it was delivered during mu peaks or troughs (LEARNING STAGE x GROUP interaction, $p=0.001$). Disrupting M1 activity during mu peaks resulted in poorer overnight consolidation compared to disrupting M1 activity during mu troughs. Corticospinal excitability and mu power measurements during closed-loop TMS did not explain differences in consolidation between groups. We therefore conclude that neural mechanisms of stable skill learning operate cyclically to produce successful consolidation.

Title: Neural representation of the memory of errors

Authors: *R. QUENTIN[1], E. R. BUCH[1], I. ITURRATE[1], L. CLAUDINO[1], M. K. VOLLMER[1], J. STIMELY[1], M. VERNET[2], L. G. COHEN[1];
[1]Human Cortical Physiol. and Neurorehabilitation Section, NINDS, Bethesda, MD; [2]Lab. of Brain and Cognition, NIMH/NIH/DHHS, Bethesda, MD

Abstract: Background. We continuously use information from our previous errors to improve performance and learn. Computational models proposed how could this information contribute to improve future performance [1,2] but the neural representation of this memory of errors has not been identified [2]. Methods. To address this question, we recorded magnetoencephalographic (MEG) activity in thirty-two healthy volunteers while they performed a visuomotor adaptation learning task. The experimental design required subjects to adapt to a stable -30° or +30° visual feedback perturbation (*motor adaptation task*) and to observe a similar feedback in the absence of motor movement (*observation task*). We used multivariate pattern analysis (MVPA) to decode from the MEG brain activity the visuomotor adaptation error signal in each trial, defined as the distance in radian between the target and the visual feedback. We predicted that the brain would maintain a memory of the previous error until the following trial. Results. All subjects learned to adapt to the perturbation during the *motor adaptation task.* In both conditions, MVPA decoded a brief signal time-locked to the presentation of the visual feedback. Subsequently, the error signal was decoded over several seconds until the onset of the following trial only during the *motor adaptation task*. Decoding in the 500 ms time window preceding the onset of each trial further identified the error signal in the *motor adaptation task* but not in the control *observation task*. Time-frequency analyses showed that the error signal was decoded in different frequency bands of neural activity. Conclusions. During motor learning, the brain encodes and maintains a neural representation of the memory of errors, conceivably to correct errors in future movement. These results reveal a neural substrate of the maintenance of previous error during human motor learning.

Title: Neural replay during wakeful rest predicts skill learning

Authors: *E. R. BUCH, L. M. CLAUDINO, M. BÖNSTRUP, R. QUENTIN, L. G. COHEN; Human Cortical Physiol. and Neurorehabilitation Section, NINDS, Bethesda, MD

Abstract: Background: Motor skills are acquired and consolidated through online (during practice) and offline (in between practice sessions) processes. In animal models, offline learning is linked to neural replay events (Ramanathan et al., 2015). In humans, it is not known if wakeful replay exists in the context of skill learning. Methods: To address this question, we studied data previously acquired (Bonstrup et al., 2019) in 28 subjects who practiced a novel task that involved repetitive typing of a 5-item numeric sequence as fast and accurately as possible with their non-dominant, left hand. Task training consisted of 36 alternating practice and rest intervals (10 seconds each) lasting a total of 12 minutes (Day 1). 26 subjects returned for a retest session the following day (Day 2). Online skill learning was measured as the change in tapping speed (count/s) of correct sequences between the beginning and end of training on Day 1, while overnight offline learning was defined as the difference in tapping speed between retest on Day 2 and the end of Day 1 training. Simultaneous 275-channel magnetoencephalography (MEG) recordings were obtained on Day 1 to assess resting-state and task-induced MEG dynamics immediately before, during and after Day 1 training. Support vector machine (SVM) classifiers were constructed for individual key-press events during practice and then used to identify 25-2500ms duration neural replays of the trained sequence during wakeful rest. Accuracy remained stable along the experiment. Results: Subjects on average displayed significant online (0.613±0.049 [mean±SEM]; t_{27}=12.49, p<1x10-12) and offline (0.205±0.025 ; t_{25}=8.21, p<1x10-8) improvement in correct sequence speed. Replay events were identified during wakeful rest in the 12-min practice period and after the end of practice, but not before practice. The duration at which peak replay rates occurred in most subjects was 75 or 100ms. The rate of 75-500ms duration neural replay events in rest intervals during the 12min practice period correlated with online (r = 0.41-0.49; p<0.03), and at 375-500ms for overnight offline (r = 0.48-53; p < 0.01, FDR corrected) learning for individual subjects. Conclusions: Human neural replay during wakeful rest intervals while practicing a new task predicts early skill learning.

Title: Sensorimotor mu phase-dependency of self-paced movement initiation

Authors: M. K. VOLLMER[1], S. J. HUSSAIN[2], R. QUENTIN[1], I. ITURRATE[1], *L. G. COHEN[1];

Abstract: Human brain function exhibits cyclic fluctuations that parallel endogenous brain rhythms, with cognitive and sensory abilities being increased during specific optimal phases (VanRullen 2016). Whether human motor behavior, specifically timing of movement initiation, exhibits such fluctuations is not known. One brain rhythm that could feasibly produce these fluctuations is the sensorimotor mu (8-12 Hz) rhythm, which originates from synchronous post-synaptic potentials of sensorimotor cortical pyramidal cells (Pineda 2005). Given that voluntary movements are initiated when M1 activity reaches an excitatory threshold (Hanes and Schall 1996), we reasoned that this threshold could be differently reached during different mu rhythm phases. To investigate this possibility, we evaluated whether voluntary self-paced finger movements are preferentially initiated during an optimal mu rhythm phase in 20 healthy adults. We first determined each subjects' cortex-to-muscle latency (CML) as the onset latency of motor-evoked potentials in the left first dorsal interosseous (L. FDI) muscle. Then, subjects completed a self-paced movement initiation task during which they viewed a series of pictures on a computer screen while EMG was recorded from the left first dorsal interosseous (FDI) muscle. Subjects viewed each picture for as long as they desired, pressing a button using their left index finger when they were ready to move to the next picture. During analysis, we identified the time of movement initiation by measuring EMG onset for each subject and each button press. We then calculated the time at which the motor command required to initiate each button press was released from M1, defined as each movement's EMG onset minus that subject's CML. Mu oscillatory phases over contralateral sensorimotor regions were identified at this time point for each trial, and we determined the proportion of movements during which this time point occurred during different mu phases. Preliminary analysis showed that movements were similarly initiated across mu phases and mu phase-power combinations. Additional analysis under way include measurement mu phases at different time intervals preceding voluntary movement onset and evaluation of other sensorimotor rhythms. Our preliminary results so far

suggest that self-paced movements are consistently initiated across sensorimotor mu rhythm phases.

Title: Motor practice elicits sustained neural replay during wakeful rest

Authors: *L. CLAUDINO[1], E. R. BUCH[2], M. BÖNSTRUP[3], R. QUENTIN[4], L. G. COHEN[4]; [1]Human Cortical Physiol. and Neurorehabilitation Section, NINDS/NIH, Bethesda, MD; [2]Human Cortical Physiol. and Neurorehabilitation Section, NINDS, Bethesda, MD; [3]Natl. Inst. of Neurolog. Disorders and S, Bethesda, MD; [4]NIH, Bethesda, MD

Abstract: Background: Neural replay, spatiotemporal brain activity patterns associated with task performance during rest, has been reported during sleep and linked to overnight memory consolidation. Wakeful replay contributes to memory formation in rodents (Genzel and Robertson, 2015) but its role or even presence in the context of human motor practice is not known. Methods: To address this question, we studied data previously acquired (Bonstrup et al., 2019) in 28 subjects who practiced a novel task that involved repetitively typing a 5-item numeric sequence as fast and as accurately as possible with their non-dominant left hand. Task training consisted of 36 alternating practice and rest periods (10s each) lasting a total of 12 minutes. Simultaneous 275-channel magnetoencephalography (MEG) recordings were obtained to assess resting-state and task-induced brain activity dynamics. Support vector machine (SVM) classifiers were constructed for individual key-press events during practice and then used to identify neural replays of the trained sequence during wakeful rest periods (Kurth-Nelson et al., 2016). Events were assessed over sixteen different timescales (25-2500ms) pertaining to biologically relevant replay durations previously established in the literature (Olafsdottir et al., 2018). Results: Neural replay events were not detected prior to training. They were observed as early as the first rest period (following only 10s of practice). Replay events remained present at an average rate of 0.732±0.097 events/s (mean±SEM; 28/28 subjects) over the 36 rest periods and at 0.142±0.032 events/sec (24/28 subjects) for at least 5-minutes after the end of practice. The range of optimal replay duration was 50-250ms, with a majority of subjects (17/28) showing peak replay rates at either 75ms (11 subjects) or 100ms (6 subjects) durations. Source analysis identified a distributed bilateral parietofrontal network underlying wakeful neural replay. Conclusions: We conclude that motor practice elicits sustained neural replay during wakeful rest.

Title: Distinct causal roles of DLPFC and M1 in long-term skill learning: A combined TMS-fMRI study

Authors: *T. G. LEE, T. J. ADKINS;
Univ. of Michigan, Ann Arbor, MI

Abstract: Our day-to-day life depends on the expression of high level motor skills (e.g. typing, driving, etc). Prior work has shown that local activity and the network connections of cognitive control regions in the dorsolateral prefrontal cortex (DLPFC) show marked reductions as expertise develops. In contrast, motor cortex (M1) activity and connectivity seems to steadily increase over the course of training. The few studies that have examined skill learning at longer time scales (weeks and months) have employed the use of functional magnetic resonance imaging (fMRI). However, neuroimaging data can only provide correlational evidence for the role of particular brain regions in a given task. Here, we sought evidence for the causal role of both the DLPFC and M1 at different stages of motor skill learning by using a combination of fMRI and continuous theta-burst (cTBS) transcranial magnetic stimulation (TMS).
Human participants trained on six separate motor sequences in a sequence learning task over the course of 8 weeks. In order to examine depth-of-training effects, two sequences were practiced extensively (1200 trials), two were practiced a moderate amount (300 trials), and two were minimally trained (25 trials). After training was complete, participants returned for three separate sessions during which we administered cTBS over right DLPFC, right motor cortex, or the vertex of the scalp (control condition) just prior to performance of the six motor sequences in an MRI scanner. Preliminary results revealed that sequence information could be decoded from brain activity across a large swath of frontal cortex including DLPFC, premotor cortex, and the

supplementary motor area. The effects of stimulation on behavior was highly dependent on depth of training. M1 stimulation led to deficits in the more extensively trained skills, with relatively minor deficits in novice skills. In contrast, DLPFC stimulation led to impairments in performance across all skill levels with larger deficits for novice skills relative to expert skills. These results provide evidence that cognitive control regions play a causal role in skilled performance at all stages of learning, but that their contribution diminishes as expertise develops.

Title: Incentives modulate fronto-striatal BOLD representations of skilled action

Authors: *T. J. ADKINS, T. G. LEE;
Univ. of Michigan, Ann Arbor, MI

Abstract: People proactively modify how they perform skilled actions when they are offered rewards**,** often moving more forcefully, quickly, and accurately as the size of a monetary incentive increases. While these behavioral effects are well documented, the neural mechanisms underlying incentive-motivated skill performance are not well understood. We aimed to shed light on these mechanisms by measuring people's brain activity with functional magnetic resonance imaging (fMRI) while they performed skilled actions with opportunities for reward. Thirty human participants trained to perform two motor sequences in a discrete sequence production (DSP) task. These participants returned 48 hours later to perform the newly learned skills with opportunities to earn rewards ($5, $10, or $30) for fast and accurate performance. Each trial began with cues representing the size of the reward and the identity of the action to be performed. We used a combination of univariate and multivariate techniques (MVPA) to localize brain regions that were modulated by reward and coded for the upcoming action. We found evidence of reward-modulated action codes in the dorsolateral prefrontal cortex (dlPFC), ventromedial prefrontal cortex (vmPFC), dorsomedial striatum (DMS), and anterior cingulate cortex (ACC). Importantly, the quantity of information about action in these regions was associated with greater effects of reward on performance. These results suggest that motivational signals alter the performance of skilled actions by modulating action codes in regions important for goal-directed control.

Title: Statistical learning shapes neural sequence representations

Authors: *S. HENIN[1], N. B. TURK-BROWNE[2], D. FRIEDMAN[1], A. A. LIU[1], P. DUGAN[1], A. FLINKER[1], W. DOYLE[1], O. DEVINSKY[1], L. MELLONI[3];
[1]New York Univ. Sch. of Med., New York, NY; [2]Psychology, Yale Univ., New Haven, CT; [3]Neurosci., Max Planck For Empirical Aesthetics, Frankfurt Am Main, Germany

Abstract: Although sensory input arrives continuously, humans organize that experience into digestible and punctuated events, such as words, objects, scenes and events that are used to speak, think and remember. How is experience parsed into meaningful units? Statistical learning is thought to underlay the ability to discover structure and segment the continuous input. An ability that, for instance, babies use to discover word boundaries in the continuous speech by tracking the statistical co-occurrences of syllables. To identify the cortical circuits responsible for statistical learning (SL), we exposed subjects to auditory and visual SL while collecting direct, intracranial recordings (23 patients, 3689 electrodes). We used neural frequency tagging (NFT) to first map the cortical circuits for SL and then representational similarity analysis (RSA) to determine which aspect(s) of the temporal regularities are learned. Acquisition of higher-order units clustered in two distinct anatomically and hierarchically segregated responses: one representing the input and the higher-order units localizing to earlier processing stages (e.g., STG) associated with shorter temporal receptive fields, and another representing the higher-order units only localizing onto later processing stages (IFG) with longer temporal receptive fields. Moreover, we found that learning of sequences concurrently shapes sequence representations at multiple levels, with a division of labor across lower- and higher-order brain areas in terms of encoding of simple and generic aspects of the sequences i.e., transitional probability vs. complex and specific regularities i.e., information about the ordinal position and their specific identity. The anatomical and representational segregation of information in those circuits was observed both for SL in the visual and the auditory modality, yet the cortical areas, with the exception of IFG and anterior temporal pole, showed anatomical specificity to the modality. These findings indicate the existence of multiple computational systems for sequence processing supporting learning across hierarchically segregated cortical circuits.

Title: Dissociation of fMRI activities in the caudate nucleus supports reinforcement learning of motor skills

Authors: *Y. CHOI[1,2], E. Y. SHIN[1,2], S. KIM[1,2];
[1]Ctr. for Neurosci. Imaging Res., Inst. of Basic Sciences, Sungkyunkwan Univ., Suwon, Korea, Republic of; [2]Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: Motor skill learning involves a complex process of adopting novel movement patterns guided by evaluative feedbacks such as reward. For the study of reward-based motor skill learning, the basal ganglia (BG) is of particular interest, with the crucial role it plays in motor control and reinforcement learning. Recent primate studies have suggested that two separate circuits in the BG, rostral and caudal, are implicated in different stages of learning—early (voluntary) and late (automatic) learning, respectively. However, there remains much to be known about the respective involvement of the regions consisting of the BG throughout the course of reward-based motor skill learning in human. To investigate this issue, we conducted a novel human fMRI experiment, in which the subjects learned to control a computer cursor over a 5-by-5 grid by manipulating their right fingers, wearing an MR-compatible data-glove. By performing this task, the subjects learned the mappings between a high-dimensional motor space and a low-dimensional task space. The experiment consisted of 2 fMRI sessions ("Early" and "Late") separated by 5 behavioral training sessions, as we aimed to investigate the behavioral and neural changes over the course of extensive training. In line with existing primate studies, we identified distinct, rostrocaudally separated neural substrates in the caudate nucleus for the early and late stages of motor skill learning, using a parametric reward-modulating regressor. In addition, in the BG, significant changes in reward modulation occurred with the extensively trained mapping, but not with the untrained mapping. To our best knowledge, we first demonstrated the motor-learning-induced transition of reward-modulating regions in the human caudate nucleus.

Title: Using a massive behavioral dataset to investigate the synaptic maintenance of implicit learning

Authors: *M. R. KRAMER, P. H. COX, S. R. MITROFF, D. J. KRAVITZ;
George Washington Univ., Washington, DC

Abstract: Humans have a remarkable ability to leverage prior experience to anticipate and respond to subsequent events. When this adaptation occurs without conscious awareness, it is known as implicit learning, a complex process whose neural mechanisms remain unclear. While evidence suggests an important role for the striatum (e.g., Fernandez-Ruiz et al., 2001), the relative sparing of consolidated implicit memories with striatal damage suggests that they are ultimately stored in cortex, likely via changes in synaptic strength (see Reber, 2013). This local cortical plasticity model makes several direct behavioral predictions that we test here using a massive behavioral dataset from the mobile application Airport Scanner. If implicit learning is subserved by changes in local synaptic strength it should be: 1) systematic, taking place at every event and capturing the strength and amount of statistical evidence in favor of one behavior over another, 2) domain-general, with the same function defining the relationship between evidence and behavior across tasks, and 3) persistent across delays consistent with known mechanisms of synaptic plasticity. Specifically, synaptic change can involve *short-term* changes in membrane conductance (lasting minutes; Zucker & Regehr, 2002) and *long-term* changes in gene and protein expression (taking hours to arise; Kelleher, Govindarajan & Tonegawa, 2004). However, there is an intermediate period in which neither mechanism is active, which strongly predicts that implicit learning will be stable over short and long, but not intermediate, delays. Experiment 1 quantified the effect of prior evidence on behavior in a simple two-choice object-sorting task; implicit learning reflected both the strength and amount of prior evidence in a manner almost perfectly consistent with the binomial z-test (n=50,891; R^2=0.95, p=1.02*10^{-23}). Experiment 2 demonstrated domain-generality, showing that that the binomial z-test also strongly predicted implicit learning in an orthogonal visual search task (n=1,000,000; R^2=0.81, p=1.38*10^{-13}). Experiment 3 showed that when a delay is short (0-60 minutes) or long (12 to 48 hours), prior evidence influences behavior (n=11,028; R^2=0.97, p=6.25*10^{-5} and n=2,880; R^2=0.84, p=0.028, respectively), but with intermediate delays (1 to 12 hours), when neither short- nor long-term mechanisms of synaptic change are active, there was no effect of prior evidence on behavior

(n=2,031; R^2=0.10, p>0.60). These human behavioral results verify precise predictions stemming from known mechanisms of synaptic plasticity, suggesting that implicit learning is supported by local cortical synaptic changes.

Title: Visual shift and hand compatibility enhance spatial realignment during visuomotor adaptation

Authors: *C. L. STRIEMER[1], A. MORRILL[1], B. ANGUS-COOK[1], R. WHITWELL[2]; [1]Psychology, Macewan Univ., Edmonton, AB, Canada; [2]Psychology, The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: When a participant reaches to a target while wearing optically displacing prisms, they will initially miss in the direction of the prism shift. However, within a few trials the participant will "recalibrate" their reach in the opposite direction to compensate for the visual perturbation. If the participant continues to reach to targets while wearing the prisms over many more trials their visuomotor system will gradually realign the reference frames for the eye and the hand to adjust for the altered visual input. This "spatial realignment" is typically demonstrated through the presence of adaptation after-effects such that, when the prisms are removed, the participant will reach in the direction opposite the prism shift. Previous lesion studies have consistently demonstrated that damage to the cerebellum impairs visuomotor adaptation. In addition, it is well-known that the cerebellum exerts ipsilateral control over the limbs. However, a previous patient single-case study demonstrated that the cerebellum may also process ipsidirectional visual errors that are induced during prism adaptation such that the right cerebellum processes rightward visual errors and vice-versa. If this hypothesis is correct, then one might expect so see differences in the magnitude of the after-effects observed when the hand used during adaptation and the direction of visual shift employed are processed by the same cerebellar hemisphere (i.e., congruent) compared to opposite cerebellar hemispheres (i.e., incongruent).
Using a within-subjects design, we had participants (n=17) complete reaches with or without visual feedback prior to and following adaptation to 17° leftward or rightward optically displacing prisms using either their left or right hand (tested in separate sessions, counterbalanced). Our results revealed a "congruency effect" such that adaptation after-effects

were significantly larger for reaches performed without visual feedback (i.e., straight-ahead pointing) when the direction of prism shift and the hand used were congruent compared to incongruent. In contrast, no significant congruency effects were observed for pointing error reduction during adaptation. These results suggest that the cerebellum may play an important role in the processing of ipsidirectional visual and/or proprioceptive reach errors during visuomotor adaptation.

Title: Increased task difficulty accelerates implicit perceptual-motor sequence learning

Authors: *P. SHU, Y. C. HAN, P. J. REBER;
Northwestern Univ., Evanston, IL

Abstract: The idea of "desirable difficulty" has been advanced to explain memory phenomena where increasing task difficulty leads to better explicit learning (Bjork, 1994). This effect has not been explored from a memory systems perspective and it is unknown whether it applies to implicit learning, where errorless (easier) learning may be more effective. Here, we report the effect of increasing task difficulty in an implicit perceptual-motor sequence learning task by modifying the spatial-response compatibility between perceptual cues and motor responses.
In the Serial Interception Sequence Learning (SISL) task, participants observe circular cues that move vertically towards one of 4 target zones and attempt a precisely timed motor (keyboard) response the moment the cue intercepts the target via the D, F, J or K keyboard keys. The speed of the moving cue is individually adaptively adjusted to keep overall task performance near 80% accurate (correct key pressed at the correct time). Sequence knowledge of a covertly embedded 12-item repeating sequence is expressed through a sequence-specific performance advantage (SSPA), higher response accuracy on the trained sequences compared to unfamiliar. For half the participants, task difficulty was increased by using an incongruent spatial cue-response mapping, with cues moving left to right towards target zones arranged vertically (but same response keys). All participants completed 4 training blocks (2880 trials) prior to a sequence-knowledge test (540 trials) containing repetitions of the trained sequence and two novel repeating foils.
Since the speed was adjusted to maintain 80% accurate responding in all conditions, the increased difficulty for the spatially incongruent test was reflected in a slower average task speed for these participants (M=1.0s, SE=.04s) compared to typical (M=.7s, SE=.02s), t(45)=5.3,

p<.001. However, SSPA in the incongruent condition test (M=18.5%, SE=2.0%) was significantly higher than the typical training condition (M=7.7%, SE=2.2%), t(45)=3.6, p<.001. Increasing training condition difficulty appears to have increased the rate at which participants learned covert sequential information. It is also possible that increased difficulty led to better sequence expression even with similar learning. Simple statistical or reinforcement learning mechanisms thought to support implicit learning do not easily account for this result but is added to a growing set of findings (e.g., Chon et al., 2018) suggesting a role for attentional or strategic effects on implicit learning.

Title: Neural evidence that reward alters visual statistical learning

Authors: *S. PARK, L. L. ROGERS, T. J. VICKERY;
Dept. of Psychological and Brain Sci., Univ. of Delaware, Newark, DE

Abstract: Humans are adept at detecting, extracting, and exploiting regularities in the visual environment—a type of learning termed visual statistical learning (VSL). Many aspects of learning from reward also resemble statistical learning in some respects, yet whether and how these two forms of learning may be related is largely unknown. In two studies, we examined how monetary reward modulates VSL and the neural basis of this interaction. Thirty subjects completed a gambling task, in which they learned the values (high or low) of fractal images through a trial-and-error binary-choice gambling task. Choices to gamble were associated with a 50% chance of no reward and a 50% chance obtaining either 2 or 10 points (low and high images, respectively). If they chose “No” to gamble, there was a 100% chance of getting 1 point. Unbeknownst to subjects, we paired images so that some images always predicted other images on the following trial. This led to four types of pairings (High-High, High-Low, Low-High, and Low-Low). In the following recognition task and reward memory task, we asked them to choose the more familiar of two pairs (a target and a foil) and to recall the value of images (high or low). We found better recognition when the first item of pair was a “High” item, with High-High pairs showing the highest recognition rate. To investigate the neural basis of this finding, we measured brain responses to visual images that were associated with both varying levels of reward and

sequential contingencies with event-related fMRI. Twenty subjects completed the same gambling task. Then, subjects passively viewed a stream of the images with pairwise relationships intact. Brain responses to images during the gambling task were affected by both value and statistical contingencies. When we compared the first image of a pair with high-value to the first image of a pair with low-value, we found the orbitofrontal cortex and right nucleus accumbens showed higher activation, suggesting that the high value of the first image led more expectation of reward processing, thus potentially enabling better memory for associated items. In addition, the lingual gyrus showed greater activation for the second image of a pair with high value than the second image of a pair with low value. Our results suggest that reward contingencies affect VSL, with relatively higher value associated with stronger behavioral and neural signals of such learning. Thus, reward may play a role similar to selective attention in VSL, or affect VSL via such a mechanism.

Abstract: Visual statistical learning (VSL) describes the ability to unintentionally learn temporal and spatial statistical regularities from visual information. Little is known about how VSL is modulated by different task conditions during familiarization, or how natural and artificial groupings influence VSL. To examine this question, we had subjects view sequences of face and scene images, in which were embedded image pairs that always co-occurred (i.e., image A was always followed by image B). Participants' task was to learn, through trial and error, an arbitrarily assigned response-mapping to each image (one of two buttons). Therefore, each image possessed a natural category (face or scene) and an arbitrary response mapping (A or B). In a surprise test task at the end of the experiment, participants were informed of this structure and performed a two-alternative forced choice task to decide whether they had seen a target pair or a foil pair comprised of two temporally unassociated images. Pairs of the same arbitrary response

mapping ($p < .001$) and same natural category ($p < .001$) were much better recognized compared to mixed arbitrary response mapping and mixed natural categories, respectively. In an fMRI study, we examined how such task and category differences might shape neural signatures of VSL. Before scanning, participants were exposed to a stream of face and scene images but were now required to perform one of tasks that alternated on a block-by-block basis. Both tasks used distinct sets of images with paired images that always co-occurred. The first task was the arbitrary response mapping task described above, while the second task was a 1-back task. Inside the scanner, participants passively viewed a stream of the same images in a rapid event-related design, still presented in their original paired contexts. BOLD responses were modulated by item order and training context. First items of pairs learned under response-mapping elicited higher activity in premotor compared to the first image of a pair learned during 1-back, suggesting that response prediction may play a role in the modulation of learning during categorization. Second items did not show the same modulation by task context. However, higher activity in the lateral occipital cortex was observed for the second image of a pair learned during arbitrary response mapping compared to 1-back, potentially reflecting enhanced learning during response mapping. Our findings suggest that tasks, response-mapping, and natural categories shape multiple signatures of VSL, and that understanding the consequences of training context variation is important to understand how VSL may operate in realistic environments.

Title: Examining motor abilities and skill transfer within a virtual environment

Authors: *J. A. ARMENDARIZ[1], M. F. AWAD[2], I. J. LACHIA[4], A. X. KRAUSE[4], B. GABAY[4], R. MORALES[5], J. HINKEL-LIPSKER[4], S. A. DREW[3];

Abstract: Virtual reality (VR) systems have become increasingly popular and offer an immersive experience to the general public. It is being used more often in a variety of fields including therapeutic rehabilitation, occupational training, and commercial gaming. Currently there is little research examining the latest generations of VR technologies and the physiological

impact that could accompany use of these new devices. This study aims to determine if there are differences in movement patterns of a newly learned skill either within or outside of a virtual environment using a three-dimensional motion capture system and an HTC Vive headset. In addition, we investigated whether learned motor skills within a virtual environment can be transferred over to the real world. Participants completed an immersive VR or real-world (RW) dart throwing task for 30 minutes. Movement and accuracy of dart throwing outside of the virtual environment were measured. Preliminary results show no significant differences between participants' joint kinematics and accuracy while throwing darts during or outside of the VR task. These results suggest that training in a virtual environment is comparable to training in the real world, thereby support the viability of VR training for motor tasks, which can lead to more cost effective, accessible, and efficient training in the future.

Title: Age-related changes in sleep-dependent procedural learning consolidation

Authors: *K. A. KAINEC[1], A. B. FITZROY[2], R. M. SPENCER[3];
[2]Psychological and Brain Sci., [1]The Univ. of Massachusetts Amherst, Amherst, MA; [3]Dept Psychology, Univ. Massachusetts, Amherst, Amherst, MA

Abstract: The benefit of sleep across taxonomic classes of memory has become increasingly apparent in recent years. Over the course of normal aging, the benefit of sleep for memory declines and has been reliably shown to decrease substantially for procedural memory in particular. Previous studies have investigated either underlying functional and structural neural correlates of procedural learning, but results remain unclear. Advances in neuroimaging analysis techniques allow for combined examination of both the structural and functional neural correlates of procedural learning consolidation. Here, we use a multimodal imaging approach in which we integrate high resolution structural and functional MRI scans, diffusion tensor imaging, and high-density polysomnography, in order to investigate age-related changes in the consolidation of motor memory traces following sleep. Older (58-75 years; N = 18) and younger (18-30 Years; N = 18) adults underwent a multi-day multi-session protocol in which a nap and wake day condition were separated by one week (order counter-balanced). On each day,

participants performed an explicit variant of the serial reaction time task (SRTT) both before and after a 2-hour nap or wake interval. During the task, participants were instructed to respond quickly and accurately by pressing buttons corresponding to boxes in spatial locations. Spatial locations changed either randomly or according to a repeating pattern, which participants were instructed to learn while reaction times and imaging data were recorded. High-density polysomnography was also recorded during both nap and wake intervals. Skill learning was operationalized as the relative decrease in reaction time for patterned stimulus presentation compared to random. Brain activation patterns in young and older adults comprised similar core sensorimotor regions, namely the cerebellum, striatum, and primary motor and sensorimotor cortices before and after a nap or wake interval. Interestingly, age-related differences in anterior cingulate and dorsal prefrontal cortex emerged where young adults indicated greater activation in these regions during task performance following a nap than older adults. Additionally, following a nap interval, an evident shift from a subcortically dominant to a cortically dominant activation pattern in both young and older adults emerged.

Title: Development of simultaneity detection ability following late sight onset in congenital cataract blinds

Authors: *T. K. GANDHI[1], S. GUPTA[2], P. GUPTA[3], P. SINHA[4];
[1]Electrical Engin., IIT Delhi, New Delhi, India; [2]Electrical Engin., Indian Inst. of Technol. Delhi, New Delhi, India; [3]Project Prakash Charitable Trust, New Delhi, India; [4]Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: The elemental judgment of whether two events happened together in time forms the basis for inferring relationships between them. Past work has shown that windows of simultaneity progressively narrow over the developmental timeline. But, since the youngest infants enrolled in these studies have typically been a few months old, it is unclear what the status of simultaneity judgment is at the very onset of vision. Also, it is unknown whether the narrowing of the simultaneity window is related to physiological maturation (due to factors like myelination). To address these issues, we assess simultaneity judgments in a set of longitudinal studies with congenitally blind children who were provided sight surgeries as part of Project

Prakash (www.ProjectPrakash.org), beginning immediately after sight onset. Our paradigm involves presenting two equal-duration transient stimuli; Visual (discs) and Auditory (beeps) that transpire either precisely synchronously or have a lag (with values: ±1000, ±500, ±300, ±200, ±100, ±50 ms). Conditions were blocked and subjects indicated which stimulus in a pair came first. Data from seven Prakash children were collected before and after their sight restoring surgery. The preoperative data suggests that the subjects are partially impaired in accurate judgment of simultaneity but learn this ability in short span of time. The results have two important implications. First, they indicate whether that coarse simultaneity judgments are feasible immediately upon sight onset, and hence can subserve intra- and inter-modal integration at the outset of visual experience. Second, they present a timeline for how experience refines the width of the simultaneity windows. Third, the longitudinal data reveal when the asymmetries in simultaneity judgments (e.g. differential lag sensitivities for when A leads V, versus the other way around) become evident. By following the Prakash children over extended durations (a few years), we hope to be able to determine whether they are ever able to match the simultaneity windows of their normally sighted counterparts, or if there are potentially permanent differences, pointing to sensitive periods in development for this skill.

Title: Learning artificial sensation through long-term home use of a sensory-enabled prosthesis

Authors: I. CUBEROVIC[1,2], A. GILL[3], L. J. RESNIK[3], D. J. TYLER[1,2], ***E. L. GRACZYK**[1,2]; [1]Case Western Reserve Univ., Cleveland, OH; [2]Louis Stokes Cleveland VA Med. Ctr., Cleveland, OH; [3]Providence VA Med. Ctr., Providence, RI

Abstract: Skilled tool use in humans is acquired over time and involves neural and cognitive changes. A hand prosthesis is a specialized tool that can replace the functional capabilities of a lost hand and modify the user's perception of their body. Prior studies have shown that electrical stimulation of the residual nerves can provide sensory feedback to amputees. Extended usage of a sensory feedback prosthesis may lead to progressive changes in sensory and bodily perception, as the user learns to integrate the artificial sensory information into their sensorimotor processes and body perceptions. In this case study, a participant with unilateral upper limb loss utilized a

sensory-enabled prosthetic hand for 115 days at home. Sensory feedback was provided via electrical stimulation through implanted neural interfaces, and the sensations were controlled by three pressure sensors and one joint angle sensor embedded in a myoelectric prosthetic hand. We examined how learning over this period of home use influenced sensory perception, prosthesis function, and psychosocial outcomes. We tracked perceived sensation location, intensity, and quality at system donning and doffing each day, and found that percepts became more congruent with transduced sensor information over time. Within a day, sensation locations were more likely to shift to become aligned with the prosthesis sensor positions than misaligned for two channels ($p<0.001$). Across the 115 day study, these sensation locations also more frequently overlapped with the prosthesis sensor position at system donning ($p<0.01$), suggesting plastic changes in the cortex. Likert ratings of sensation descriptors indicate that intensity increased over the course of the study for two channels, and perceived naturalness and perceived touch increased for three channels ($p<0.01$ for all). Sensation qualities that did not correspond to transduced sensor information were either not perceived (Ex. “sharp”) or decreased over time (Ex. “vibrating,” $p<0.01$). Prosthesis function during in-lab testing was significantly better with sensation compared to without ($p<0.001$), but did not change over time. Survey scores of the perceived ability to perform daily tasks significantly improved with time (PSFS, MDC-95=1.3). Psychosocial survey scores of self-efficacy, prosthesis embodiment, and social touch with the prosthesis improved significantly within the first month of home use ($p<0.02$ for all), then plateaued. Our findings demonstrate that learning modulates the perceptual and psychological experience of a sensory-enabled prosthesis over time.

Title: Efficiency of declarative and procedural presentation to the hierarchical motor-sequence-learning

Authors: Y. SUGIHARA[1], *S. N. KUDOH[2];
[1]Dep. Human Syst. Interaction, Sch. of Sci. and Technol., [2]Dep. Human Syst. Interaction, Sch. of Sci. and Technology,, Kwansei Gakuin Univ., Sanda, Hyougo, Japan

Abstract: Motor-Sequence-Learning(MSL) is essential for acquisition of sports skill. Especially, it is often required for the learning of hierarchical motor sequence. Declarative or procedural presentations are able to be candidate for the instruction method of MSL. Declarative

presentations is verbal and episodic, and procedural presentation is non-verbal and symbolic, visually indicating the real movement. Thus declarative and procedural presentation induces declarative and procedural memory, respectively.In this study, we elucidated the efficiency of declarative and procedural presentation to the hierarchical MSL. The sequential patterns of the button-press-task includes 3 independent blocks of 3-buttons-sequence.In case of declarative presentation, both of inter-block-time and intra-block-time of button press slightly decreased during trials. Inter-block-time immediately after changing the order of the blocks increased, especially in the case of declarative presentation, though the order of the button press in each block was not changed. The θ-power of EEG at the forehead (F3, Fz, F4) tended to increase during the MSL. In addition, α-power of EEG at the parietal region (C3, Cz, C4) increased after changing the block order, especially in case of procedural presentation.These results suggest that re-learning of the block-sequence was performed after the changing order of the blocks in case of procedural presentation. On the contrary, if the sequence of button press was procedurally indicated, experimental participants can adapt the changing the block order more than in the case of declarative presentation.

Title: Effect of individual modality dominance of working memory on fNIRS-based neuromodulation for the prefrontal cortex

Authors: *M. MATSUMOTO[1], T. SAKURADA[2,3], S.-I. YAMAMOTO[1];
[1]Col. of Engin. and Sci., Shibaura Inst. of Technol., Saitama, Japan; [2]Dept. of Robotics, Col. of Sci. and Engin., Ritsumeikan Univ., Shiga-ken, Japan; [3]Dept of Neurosurg., Jichi Med. Univ., Tochigi, Japan

Abstract: Neurofeedback (NF) is a useful neuromodulation approach to improve cognitive and motor functions. Although the effect of NF training widely varies among individuals, an influential factor on the NF effect is not clear. We hypothesized that individual differences in cognitive ability affect the NF training. Regarding this point, we previously revealed that bilateral dorsolateral prefrontal cortex (DLPFC) is one of the neural bases of the individual

modality dominance of working memory. Based on our previous findings, we aimed to investigate whether the individual working memory ability determines the effect of NF training for DLPFC activities. First, 40 healthy young adults performed a searching task with the right hand. The participants had to find and memorize randomly located 6-targets on a drawing tablet as quickly as possible (pre-sequential task). We prepared 2 conditions which differ in how to memorize the target locations. When the participant's hand came close to a target location, either vibration stimuli on their hand (tactile condition) or visual stimuli on a monitor which was set over the tablet (visual condition) were presented. To evaluate the individual dominance of working memory, we compared the searching costs under the visual and tactile conditions. Next, the same participants performed NF training to increase the bilateral DLPFC activities. We randomly assigned the participants into the real group (20 participants) and the sham group (20 participants). The real group was received visual feedback based on their own DLPFC activities, whereas the sham group was received visual feedback based on the pre-recorded other's DLPFC activities. Lastly, the participants performed the searching task after NF training (Post-sequential task). In the pre-sequential task, 28 participants showed lower searching cost under the visual condition (visual-dominant), and the others showed the opposite trend (tactile-dominant). After the NF training, only tactile-dominant in the real group showed a significant increase in the connectivity between right and left DLPFCs. In the post-sequential task, we found that the individual's capacity of working memory in the non-dominant modality improved. This cognitive improvement was stronger in the real group compared to the sham group. These results suggest that the individual modality dominance of working memory characterized by the bilateral DLPFC activities is one of the influence factors to determine the NF training effect. The relationship between neural modulation in the bilateral DLPFC and the improvement of motor performance can contribute to developing a new tailor-made neurorehabilitation program.

Title: Causal interactions of medial temporal lobe and associative cortex during implicit learning

Authors: *S. LONG[1], F. CHEUNG[1], A. GUNDUZ[1,2];
[1]J. Crayton Pruitt Family Dept. of Biomed. Engin., [2]Dept. of Electrical Engin., Univ. of Florida, Gainesville, FL

Abstract: Humans have an innate ability to unconsciously recognize patterns, predict subsequent events, and adapt behaviors to interact with the surrounding environment. This ability is known

as implicit learning, and until recently was thought to rely primarily on associative cortical regions outside the medial temporal lobe (MTL). However, more recent work in animals and in human fMRI and lesion studies have pointed to the importance of the connections between MTL structures and many associative cortical regions. In this study we focus on examining functional connectivity by establishing causal relationships between intracranial stereoEEG (SEEG) local field potential (LFP) recording sites during an implicit learning task. The SEEG data was collected from subjects cleared to undergo a two-stage neurosurgery for treatment of refractory epilepsy at the Neuromedicine Hospital at the University of Florida with IRB approval. At stage one, subjects are implanted with multiple intracranial stereoEEG (sEEG) electrodes to localize the epileptic focus and at second stage the focus is resected. Subjects consented to participate in the study and performed two cognitive tasks that depend on statistical regularities and are known to induce implicit learning. The first cognitive task is an alternating serial reaction time (ASRT) task that involves an embedded probabilistic sequence of alternating sequence and random stimuli. The second task is a two-alternative forced choice (2AFC) task that involves the extraction of temporal regularities within a continuous stream of stimuli. Each run of a task lasted 8-10 minutes with periods of rest throughout the duration of the task. During each run of the cognitive tasks, multi-electrode SEEG data was collected and synchronized with the behavioral aspects of the task using a bioamplifier, custom-made hardware, and BCI2000 software. This is the first SEEG study that allows us to study the causal interactions of LFPs from MTL structures and associative cortical regions during implicit learning with high signal fidelity and temporal resolution lacking in surface EEG and fMRI studies.

Title: Rapid motor skill learning: Behavioral and neurophysiological evidence

Authors: *J. HERSZAGE[1], H. SHARON[2,3], N. CENSOR[1];
[1]Sch. of Psychological Sciences, Sagol Sch. of Neurosci., Tel-Aviv Univ., Tel Aviv, Israel; [2]Ctr. for Brain Functions and Inst. of Pain Med., Tel Aviv Sourasky Med. Ctr., Tel Aviv, Israel; [3]Sackler Fac. of Med., Tel Aviv Univ., Tel Aviv, Israel

Abstract: Learning motor skills is assumed to be a time consuming process, requiring repeated executions to enhance the performance of the skill. However, in a different learning domain, brief reactivations of a visual perceptual task were recently reported to induce efficient learning, suggesting a novel rapid learning mechanism (Amar-Halpert et al., 2017). Here, we tested the hypothesis that motor skill learning can be achieved with rapid learning through brief reactivations, requiring significantly reduced amount of practice. Participants learned a motor skill, in which they were required to tap a sequence with their non-dominant hand as fast and accurate as possible (Karni et al., 1995), and returned to the lab for a retest following one week. Participants in the *Reactivations* and *Extensive Practice* groups performed 2 additional sessions between test and retest: Participants in the *Reactivation* group briefly reactivated the skill memory for only 30 seconds, while *Extensive Practice* participants performed standard full-length sessions in which they practiced the task for 12 minutes. Non-invasive neurophysiological measurements of changes in corticospinal excitability (CSE) were evaluated, quantifying muscle EMG activity evoked by single-pulse transcranial magnetic stimulation (TMS) over primary motor cortex (M1), prior-to and post learning. Results show that these brief reactivations were sufficient to induce learning gains, with additional practice of the task further improving learning. Furthermore, these results were supported by neurophysiological measurements, with changes in CSE between pre and post learning significantly different between groups, and correlated with the behavioral retest performance. This set of results indicates that motor skill learning can be achieved by brief reactivations, significantly shortening the required practice, pointing to plastic changes in the motor system induced by rapid learning. The results demonstrate a novel form of rapid motor skill learning, having far-reaching implications, for example in accelerated motor rehabilitation following neurological injuries.

Title: Exploring exploration in reward-based motor learning

Authors: *N. M. VAN MASTRIGT, J. B. J. SMEETS, K. VAN DER KOOIJ;
Human Movement Sci., Vrije Univ. Amsterdam, Amsterdam, Netherlands

Abstract: Exploration is thought to be a key element in reward-based motor learning. This has been studied predominantly in reaching tasks, but not in balance tasks that are relevant for

rehabilitation practice. We hypothesize that exploration is explicit. Therefore, we examined whether performing a secondary cognitive task in a novel repetitive weight shifting task reduces exploration. Since both (sensori)motor noise and exploration result in motor variability, exploration is difficult to measure. We therefore tested whether our measure of exploration is sensitive enough to detect that exploration is higher after non-rewarded than after rewarded trials. In upright stance, subjects (N=12) repetitively shifted their weight to one leg, aiming for a fixed target with their center of pressure within 1.5 s. After a practice block with online visual feedback of their center of pressure, and a pretest block without feedback, subjects received only binary feedback in the feedback blocks. Sensorimotor noise was estimated as the endpoint variability in the pretest block; exploration in feedback blocks was defined as the endpoint variability minus this sensorimotor noise. Subjects performed two feedback blocks, in which they performed a visual 2-back task (cognitive task) or passively looked at a similar stimulus (control task) directly after each movement repetition. Each block consisted of 50 trials. To estimate exploration after (non-)rewarded trials, half of the motor trials were rewarded randomly. We found that subjects tended to explore less when performing a secondary cognitive task compared to performing the control task, but not significantly. Exploration after non-rewarded trials was significantly higher than after rewarded trials, and this effect tended to be more pronounced in the control task condition. However, also this interaction effect was not significant. We have established that we can detect the known effect of success on exploration in our new paradigm. These results allow us to estimate the sample size for a follow-up experiment to test our hypothesis that exploration is explicit.

Title: The influence of practice conditions on the emergence of habitual action selection

Authors: *Y. DU, S. LEE, A. M. HAITH;
Johns Hopkins Univ., Baltimore, MD

Abstract: We all sometimes perform particular actions without thinking. This automatic action could become habitual, which persists even sometimes being no longer appropriate, such as typing the wrong symbols on a foreign keyboard. Though this phenomenon is commonly seen in our daily life, it has proven difficult to demonstrate in human participants. We recently showed, in an arbitrary visuomotor association task, that participant's action selection becomes habitual within 4,000-trials of practice (Hardwick, Forrence, Krakauer, & Haith, 2018). In that task,

participants responded to arbitrary symbols by pressing specific keys as quickly and accurately as possible (free reaction time conditions). Two elements of the association were then switched in order to assess whether their action selection was habitual. Participants had no difficulty performing the revised mapping with little practice. When forced to respond at low preparation times, however, they reverted to the original association, revealing the habitual nature of their action selection. This effect did not occur in a control condition in which the original association was practiced only briefly (<100 trials). We are asking here if the habitual actions will emerge after moderate practice (e.g., 1000 trials). In addition, the emergence of habitual action selection may have been attributable simply to repetitions of the task. However, extensive training does not merely promote repetition. Reaction times improved substantially during practice. The emergence of habitual response following 4,000 trials of practice might also be attributable to more experience performing the association at low reaction times. The formation of habitual action selection might, therefore depend not just on the volume of practice, but on the nature of that practice. To test this hypothesis, we had three groups of participants practice an arbitrary visuomotor association for 1000 trials, either under free-reaction-time conditions or under forced-reaction-time conditions imposing either a relatively long (800ms) or very short (400ms) preparation time. Like our previous study, habitual action selection was examined in a timed-response task after they learned a revised association. We found that 1000 trials of practice were sufficient to create a habit in both the free-reaction-time and short forced-reaction-time groups.

Title: Investigating the brain regions and circuitry that mediate visual statistical learning

Authors: *S. KUMAR[1], E. KOELE[1], L. G. UNGERLEIDER[2];
[1]Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Though humans and animals are known to extract statistical regularities from their environment, the neural mechanisms and the brain circuitry underlying this statistical learning are still poorly understood. In this study, we used functional magnetic resonance imaging (fMRI) and behavioral measures to look at the brain regions involved in visual statistical learning. Human participants (Experiment 1, N=17; Experiment 2, N=7) performed a categorization task, in which they were asked to view and classify stimuli as belonging to one of two predefined categories. In Experiment 1, participants classified images as either animate or inanimate and, in Experiment 2, they classified shapes as either red or blue in color. The stimuli were grouped into

different sets of either ‘patterned’ or ‘random’ images. In the ‘patterned’ set, unbeknownst to the subjects, the presentation of the images for categorization followed a pattern; that is, the images were presented in a fixed order (e.g. AABBAABB, where ‘A’s represent animate and ‘B’s inanimate images in Experiment 1). In the ‘random’ set, the images followed a random order. fMRI and behavioral (reaction times and trial accuracy) data were collected while subjects performed the categorization task while viewing the ‘patterned’ and ‘random’ sets of images in separate runs. We hypothesized that the subjects would implicitly learn the embedded pattern in the ‘patterned’ runs while performing the categorization task, resulting in faster reaction times as compared to the random runs. In Experiment 1, we found 10 out of 17 subjects learned the pattern and in Experiment 2, 6 out of 7 subjects learned. In both Experiment 1 and 2, fixed effects analysis contrasting fMRI activation during ‘random’ compared to ‘patterned’ runs of images, revealed voxels with greater activation for random runs throughout visual cortex, extending from early visual areas to the ventral temporal lobe. These results suggest that visual statistical learning of patterns follows predictive coding models in which there is an attenuation of the responses for predicted patterns in the visual cortex.

Title: Perceptual-motor sequence learning using auditory cues

Authors: *Y. C. HAN, P. J. REBER;
Psychology, Northwestern Univ., Evanston, IL

Abstract: The ability to automatically extract and use statistical regularities from complex, acoustic, sequential patterns found in language and music is hypothesized to be an important component of learning such skills. Prior laboratory research in implicit perceptual-motor sequence learning, such as the Serial Interception Sequence Learning (SISL) task, has primarily utilized visually-cued, motor response sequences to characterize the neural basis and operating characteristics of this process (Gobel et al., 2011). In the SISL task, moving visual cues signal participants to make a precisely timed motor keypress response in a rapidly-paced, game-like task. While participants are not informed of an embedded repeating sequence, knowledge of the sequence is still exhibited through greater accuracy of the repeating sequence compared to performance on unfamiliar sequences (Sanchez et al., 2010). While this particular approach has established that perceptual-motor sequence learning occurs outside of awareness, it is unknown if the same mechanisms support this kind of learning in the auditory domain.

In the auditory SISL variant, auditory cues are used to signal one of four motor (keypress) responses based on the pitch of the tone at onset, with keys D, F, J, and K mapped to starting frequencies 440 Hz, 587 Hz, 698 Hz, or 880 Hz. To mimic cue movement analogous to the visual task, cues include a simulated glissando effect, in which pitch rises from the starting frequency to one 20% higher. Participants were instructed to time their response to the offset of the glissando. As in the visual SISL task, the sequence of cues (and responses) followed a covertly embedded repeating sequence on 80% of trials. The overall task speed was adaptively adjusted based on individual performance to maintain ~80% accuracy through training. Sequence-specific learning was measured as the difference in accuracy on the repeating sequence compared to unfamiliar sequences presented at test. Participants completed training with two 540-trial blocks (72 sequence repetitions) followed by a test block that contained the practiced sequence (180 trials) and two novel sequences (180 trials each). Participants who completed the task exhibited sequence learning that was reliably greater than chance (M=13.7%, SE=5.8%), $t(11)=2.3$, $p<0.05$. These preliminary results suggest that perceptual-motor sequence learning exhibited with auditory cues is similar to learning with visual cues. Moreover, these results suggest that the neural mechanism underlying implicit perceptual-motor sequence learning operates similarly for both visual and auditory perceptually-cued sequences.

Title: Computational model of complex combinatorial binding: Neurobiological simulations and hypotheses

Authors: *R. M. CALMUS[1], B. WILSON[1], Y. KIKUCHI[1], Z. KOCSIS[2,1], H. KAWASAKI[2], T. D. GRIFFITHS[1], M. A. HOWARD, III[2], C. I. PETKOV[1];

Abstract: Understanding how the brain binds complex information distributed over time is a challenging problem facing the neuroscientific community, requiring computationally and

neurobiologically informed approaches to solve. The combinatorial binding problem is particularly salient in language, whereby human syntactic knowledge supports the encoding and detection of complex regularities at multiple scales and temporal granularities. Yet nonhuman animals are also capable, to varying degrees, of detecting regularities between sensory events over time. Thus the problem is not confined to language, and addressing it is of importance for advancing both machine and animal models of human cognition. There is evidence that structured-sequence-learning tasks engage human and monkey fronto-temporal regions, including inferior frontal areas 44/45 and the frontal operculum. However, the neural mechanisms segmenting continuous sensory input and binding segregable dependencies remain unknown, as do the transformations occurring between these regions. Moreover, the role of the hippocampus, now implicated in aspects of structured sequence learning, is poorly understood within this context. We propose a vector symbolic computational model of structured-sequence-learning, integrating formally defined additive and conjunctive binding operators with a modern Spiking Neural Network implementation of neurobiologically plausible dynamics. Using defined combinatorial operators allows us to plausibly transform between internal representations, rendering these into both mathematically idealized and neurally simulated site-specific activity. The model allows binding temporally segregated dependencies in structured sequences, readily operates on multiple timescales and encodes or decodes sequences with respect to chunked items wherever dependencies occur. We show that the model can predict previous findings under structured-sequence-learning tasks that engage fronto-temporal regions, specifying mechanistic roles for areas 44/45 and the frontal operculum during interactions with temporal cortex. Moreover, the model yields principled, mechanistic predictions of oscillatory dynamic patterns of activity during the chunking of structured serial input. Finally, its predictions underscore the importance of serial position information, which requires input from “time cells” that are known to be present in the hippocampus and dorsolateral prefrontal cortex. Simulations are being tested with neurobiological data from human intracranial recordings during structured-sequence-learning tasks.

Title: Improved motor control of upper limb movement in healthy subjects after optimized sensory stimulation

Authors: *R. PANICHI[1], S. CONTEMORI[2], A. BISCARINI[1];
[1]Exptl. Medicine, Section of Physiol. and Biochem., Univ. of Perugia, Perugia, Italy; [2]Sch. of Human Movement and Nutr. Sci., Univ. of Queensland, Brisbane, Australia

Abstract: Mounting evidence suggests that improving sensory-motor behaviors may be achieved by repetitive sensory stimulations in the absence of explicit task training as well as by intense and specific practice. It has been argued that optimized sensory stimulations might cause high activation in the targeted sensory-motor systems, leading to reorganization changes that may underlie behavioral modifications. However, how effective sensory stimulation might be in impacting the motor domain remains an open question. The modulation of proprioceptive inflow by focal muscle vibration (f-MV) is well suited to investigate the effectiveness of a mere sensory stimulation in influencing motor outcomes. Thus, the aim of this study was to verify whether optimized f-MV stimulation patterns may affect motor control of upper limb movement. To answer this question, we vibrated the slightly tonically contracted anterior deltoid (AD), posterior deltoid (PD) and pectoralis major muscles in different combinations in healthy subjects at a frequency of 100 Hz for 10 minutes in single or repetitive administrations. We evaluated the vibration effect immediately after f-MV application on upper limb targeted movements tasks and 1 week later. We assessed target accuracy, movement mean and peak speed and normalized Jerk using a 3D optoelectronic motion capture system and we evaluated AD and PD activity during the tasks using wireless electromyography. We found that f-MV may induce increases in movement accuracy, mean speed and smoothness and changes in electromyographic activity. The main effects of f-MV were detected over time after repetitive vibration of AD and PD muscles. These effects were comparable to those that occur over the course of motor practice. Thus, in healthy subjects optimized f-MV stimulation patterns might over time affect the motor control of upper limb movement. Our finding implies that f-MV may improve the individual's ability to produce expected motor outcomes and may promote learning-like phenomena in the absence of explicit task training. We believe that processes underlying our observations operate through mechanisms that rely on cellular plasticity and reorganization of the circuitry controlling motor behavior. Finally, our results offer interesting insights into the possibility of developing novel strategies to enhance the efficacy of acquisition of motor skills and/or to support functional recovery in sensory-motor disorders.

Title: Does chronic low back pain affect locomotor learning or retention and is cognition a factor?

Authors: *J. E. GALGIANI[1,2], G. E. HICKS[1,2], S. M. MORTON[1,2];
[1]Physical Therapy, [2]Biomechanics and Movement Sci., Univ. of Delaware, Newark, DE

Abstract: Recent work in our lab has demonstrated that acute pain experienced during motor learning of a new walking symmetry pattern can reduce retention of learning. Therefore, individuals with chronic pain might also have impairments in motor learning or retention, however this hypothesis has not been systematically tested. Critically, chronic painful conditions, such as chronic low back pain, are associated with structural and functional changes throughout the brain, including somatosensory and multisensory association areas, affective, cognitive, and even motor areas, including the primary motor cortex, which could provide a mechanism for deficits in motor learning or retention. Likewise, cognitive changes associated with some chronic pain conditions also could negatively impact motor learning or retention. This might compromise rehabilitation for individuals with chronic pain because motor learning-based interventions are commonly used in this population. Therefore, we examined the learning and 24-hour retention of a new locomotor pattern in men and women with chronic low back pain (n=16) compared to matched controls. On Day 1, participants learned an asymmetric gait pattern while walking on a treadmill using real-time visual feedback of their step lengths. This was presented as a dynamic bar graph with two bars, one for each leg, the vertical height of which represented each leg's step length. A target line for each leg was also displayed. To teach asymmetric walking, participants were instructed to make the height of the bars match the height of the target line, however, we distorted the feedback to make it appear that one leg was taking a shorter step than it really was, and that the other leg was taking a longer step. Thus, to make the bars match the target lines, participants had to learn to change their baseline step length and adopt a novel asymmetric gait pattern. On Day 2, participants were tested for retention. They also completed a short neurocognitive battery, in order to determine whether cognitive performance was related to motor learning or retention. We measured learning and retention in terms of the accuracy of each step relative to the target step length. Learning the new stepping pattern appears to be similar between control and chronic low back pain groups, but 24-hour retention appears to be reduced in people with chronic low back pain. Further, specific cognitive measures may be correlated with measures of locomotor learning and retention. This indicates that chronic pain conditions may interfere with the consolidation of new motor memories, and that changes in cognition associated with chronic pain may be predictive of these motor learning deficits.

Title: Cerebellar transcranial alternating current stimulation in the gamma range applied during the acquisition of a novel motor skill

Authors: *M. J. WESSEL[1], L. R. DRAAISMA[1], T. MORISHITA[1], P. J. KOCH[1], P. MACEIRA-ELVIRA[2], M. DURAND-RUEL[1], A. DE BOER[1], C.-H. PARK[1], F. C. HUMMEL[1]; [1]Defitech Chair of Clin. Neuroengineering, Ctr. for Neuroprosthetics and Brain Mind Inst., EPFL, Geneva, Switzerland; [2]Defitech Chair of Clin. Neuroengineering, Ctr. for Neuroprosthetics and Brain Mind Inst., EPFL Valais, Sion, Switzerland

Abstract: Introduction: The large burden imposed by neuropsychiatric disorders emphasizes the development of novel, neurotechnology-based interventions. A promising approach is the combination of non-invasive brain stimulation with targeted behavioral training. A current limitation of this approach is the high inter-individual variability of the conventional protocols. Novel stimulation modalities and stratified protocols may optimize effect sizes in future. Here, we aimed to test the effect of (i) a novel non-invasive oscillatory cerebellar stimulation protocol on motor skill learning and (ii) evaluated the predictive potential of system-neuroscience-based biomarkers for behavioral success.
Methods: Fifteen heathy, young subjects were recruited for the study. 50 Hz transcranial alternating current stimulation (tACS) was applied to the left cerebellum in a double-blind, sham-controlled, cross-over design, while the subjects performed a motor training of a sequential grip force modulation task (SGFMT). Retention was assessed at a ~24 h and ~10 days follow-up. The training was embedded in a multi-modal systems neuroscience assessment including behavioral testing, double-pulse transcranial magnetic stimulation (dpTMS), and MRI-based neuroimaging (diffusion-weighted imaging, resting-state fMRI, task-related fMRI). The dpTMS protocol included an assessment of short intracortical GABA-ergic inhibition (SICI) during rest and in the premovement phase.
Results: The participants improved their performance in the SGFMT significantly during the training phase with an average improvement of ~16%. There was no significant effect of STIMULATION nor a significant STIMULATION x BLOCK interaction. With multiple linear regression modeling, we were able to explain ~34% of the variance in training gain. The modulation of the premovement SICI slope during training was the most influential regressor

followed by SICI rest at baseline, baseline task performance, and a composite motor performance score.
Conclusions: Gamma-range tACS applied to the cerebellum did not enhance learning of a sequential motor skill. GABA-ergic inhibition-based biomarkers were capable of predicting learning gains and may serve as a stratifier for future behavioral interventions.

Title: Tonic pupil diameter is modulated by predictability of rapid sound sequences

Authors: *A. E. MILNE, C. TAMPAKAKI, S. ZHAO, M. CHAIT;
UCL, London, United Kingdom

Abstract: The brain is highly sensitive to auditory regularities. Listeners exploit the predictable order of sounds in many scenarios, from parsing complex auditory scenes to the acquisition of language. However, objective measures of auditory sequence learning are lacking. Pupillometry can be used across populations (e.g. infants and adults) and species (e.g. human and non-human primates); therefore, offering a potential technique to implicitly study sequence processing across different subject groups. However, it remains unclear exactly how sequence processing will be reflected in the pupil response.
Previous work using slow stimulus presentation, and where participants were required to make decisions about sequence predictability, has demonstrated a correlation between tonic increases in pupil size and predictability. The response is hypothesized to reflect release of acetylcholine linked to learning processes. Here we assess if the predictability of a rapid stream of auditory tone pips modulates tonic pupil diameter.
We manipulated predictability in two ways: 1) by presenting either regular (deterministic; 'REG') or random ('RAND') sequences of tones and 2) by systematically varying the number of different tone frequencies in the sequence alphabet (5,10 or 15), e.g. random sequences created from a tone pool of 5 ('RAND5') are more predictable than those from a tone pool of 15 ('RAND15'). This created six conditions: RAND5, REG5, RAND10, REG10, RAND15, REG15. Tone frequencies were matched across the REG and RAND sequences to isolate the

effect of predictability from other acoustic factors.
We tracked pupil diameter over nine second trials while subjects completed an auditory task unrelated to the sequence structure. We found that predictability modulated tonic pupil diameter. For all alphabet sizes random sequences produced a significantly larger response than their corresponding regular sequence. Our findings demonstrate that predictability of an auditory sequence modulates tonic changes in pupil diameter and establish the potential of this technique for implicitly studying auditory regularities across cognition. It paves the way for future work to probe the underlying neurochemical drivers and cognitive processes implicated in sequence processing.

Title: Motor plasticity revealed by changes in sequence-specific fMRI activity patterns across weeks of training

Authors: *E. BERLOT, N. J. POPP, J. DIEDRICHSEN;
Brain and Mind Inst., Western Univ., London, ON, Canada

Abstract: An important aspect of many motor skills is the ability to produce complex sequences of movement. While behavioural improvements in sequence learning tasks are easily observable, the underlying neural processes remain elusive. Numerous fMRI studies have set out to illuminate these brain-related changes, but there is very little agreement about the neural changes that occur during sequence learning. The overall aim of this study was a) to reinvestigate a number of reported fMRI findings in a longitudinal motor learning study, and b) to test a set of new hypotheses regarding multivariate pattern changes. The design and predictions were pre-registered on the Open Science Framework (https://osf.io/ueswg/). We trained 26 participants over a period of 5 weeks to perform six 9-digit sequences on a piano-like device. To examine changes in brain representation with learning, participants underwent MRI scanning four times - in weeks 1, 2, and two sessions in week 5. Per session, participants performed both the 6 trained and 6 control sequences. To control for motor output, participants performed all sequences at a fixed speed in sessions 1-3. Because the paced speed was substantially slower than speed of

performance during training, we reasoned that pacing may obscure part of the skill representation. Therefore, participants produced the sequences as fast as possible in session 4. We observed an overall decrease in activation for the same speed of execution in premotor and parietal areas, while primary motor and somatosensory areas showed constant activation across scans. Additional to these decreases in mean activation, the mean activity pattern for trained and untrained sequences became more dissimilar with learning. Next we examined whether sequence-specific activation patterns change with learning. We predicted that the specific patterns of activity for each of the trained sequences change substantially early in learning, but stabilize later on. This effect was indeed observed in premotor and parietal areas and was specific to trained sequences. Patterns were significantly correlated also between scans 3 and 4 (during performance at a paced or maximal speed), indicating that even a slower execution is able to activate the neural representations of that skill. However, the faster speed revealed more clearly that the sequence-specific patterns for trained sequences became more distinct from each other than for the control sequences. In summary, our results reveal a novel fMRI indicator of motor plasticity. The session-by-session change of movement-specific activity patterns turned out to be a sensitive measure of the underlying learning related changes.

Title: The use of sensory feedback during the production of fast motor sequences

Authors: *N. J. POPP, P. L. GRIBBLE, J. DIEDRICHSEN;
Brain and Mind Inst., Western Univ., London, ON, Canada

Abstract: Current models of motor sequence production emphasize the importance of an internal sequence representation, but conceptualize the skill as being performed in a feedforward manner. While the role of feedback in speech production has been clearly demonstrated, it has been less studied in motor sequences. Here, we investigate the role of sensory feedback on the execution of sequences of fast finger presses. Specifically, we ask to what degree are humans sensitive to a

delay in feedback from an individual finger press and how this sensitivity changes with learning. While delays have been shown to negatively impact performance early in learning, it is possible that accurate feedback might be less important for highly trained individuals, for which performance may be driven by feedforward processes. We investigated this question by introducing small feedback delays during motor sequence production and examined whether they affected subsequent key presses. Participants were trained on sequences of 11 finger presses on a keyboard-like device and were asked to execute them as fast as possible while keeping the error rate low. We trained participants either with visual, auditory, or haptic feedback. On each training day on about a third of the trials we delayed the feedback of one of the finger presses by 100ms. We then measured the effect of this delay by comparing the time interval between the delayed press and the following press to a trial of the same sequence without delay. The delay in feedback resulted in a ~40ms lag of the following press, without a substantial change of this sensitivity between training days. Our findings suggest that sensory feedback remains important for adequate performance even with extensive sequence training.

Title: Associate learning results in acquiring skill: An fMRI study

Authors: *C. G. N. NAVANEEDHAN, T. KAMALANABHAN;
Mgmt. Studies, Indian Inst. of Technol., Chennai, India

Abstract: Associate learning results when an individual exposed to a given information process it by comparing it with the existing information stored in the long term memory which results in a specific changes neuronal network bringing the desirable learning outcome reflected in certain regions of the brain. The question is whether associate learning helps in acquiring skill, in this particular context it means achieving outcome of learning through a series of internal learning mechanism. In order to understand the internal learning mechanism, the experiment is carried out using fMRI technique. The sample constitutes teachers N= 20 in the age group 30 to 50 years. The subjects are visually exposed to associative learning information from a particular concept in the subject Chemistry at 9^{th} grade level in the scanner to determine the effectiveness with which every teacher associates the visual clips based on individual's thinking ability is recorded as the BOLD signals. The BOLD signals are measured for each individual teacher is analyzed using

SPM12 supported by MATLAB version 16 B. The connectivity analysis reveals the regions of the brain supporting associative learning eventually playing an important role in acquiring desirable skill.

Title: Hippocampal oscillations distinguish recollected from recognized memory items in associative recognition memory

Authors: *S. KOTA[1], M. D. RUGG[2], L. ROBINSON[1], B. C. LEGA[1];
[1]Neurosurg., UT Southwestern Med. Ctr., Dallas, TX; [2]Ctr. for Vital Longevity, Univ. of Texas at Dallas Ctr. for Vital Longevity, Dallas, TX

Abstract: Dual process theory holds that distinct physiological mechanisms underlie the mnemonic functions of recognition and recollection, with the latter constituting a hippocampal-dependent process incorporating associations between items, spatial context, temporal context, or some other memory feature. But it remains an unanswered question as to which specific oscillatory patterns in the hippocampus or within wider episodic memory networks support this recognition/recollection distinction. In the fMRI literature, the associative recognition (AR) paradigm has been used to operationalize this distinction, and it reliably elicits significant hippocampal BOLD signal increases during item retrieval for recollected items. This observation supports the idea of an anatomical division in activity underlying the dual process model, with hippocampus specifically supporting recollection. The goal of investigating hippocampal oscillatory patterns to test predictions of dual process theory motivated us to apply the AR paradigm to intracranial EEG patients with depth electrodes inserted into both cerebral hemispheres, including both the anterior and posterior hippocampus simultaneously. Twenty-nine subjects performed AR paradigm. We compared oscillatory activity in the hippocampus between item pairs correctly assessed as intact (successful associative memory, recollection) versus those incorrectly called rearranged but recognized as old (failed associative memory but successful recognition). We observed a power increase in the slow-theta frequency (2-5 Hz) and gamma frequency (70-110 Hz) range that was strongest in the hippocampus during memory retrieval, consistent with previous observations in episodic memory using the free recall paradigm ($p < 0.05$ for one continuous cycle of oscillation, FDR corrected). As expected based

upon fMRI investigations, theta and gamma power increases were greatest during successful recollection. Our results describe the first application of the AR paradigm to intracranial EEG recordings from both the anterior and posterior hippocampus (in both hemispheres). Our findings provide direct electrophysiological evidence that hippocampal theta and gamma specifically may support recollection but not recognition processes in human memory circuits.

Title: Gamma oscillations during episodic memory encoding and retrieval reveal reversal of information flow between the hippocampus and prefrontal cortex

Authors: *S. E. SEGER[1], B. C. LEGA[2];
[1]UT Southwestern, Dallas, TX; [2]Neurosurg., UT Southwestern Med. Ctr., Dallas, TX

Abstract: A critical and emerging question in human episodic memory is how the hippocampus interacts with the prefrontal cortex during encoding and retrieval of items and their context. The biased competition model, synthesized using rodent models, postulates that during memory encoding, the hippocampus transmits contextual information to the prefrontal cortex, but during retrieval, this information is transmitted back to the hippocampus to govern selection of an appropriate memory trace. This “reversal of information flow” concept has been tested directly in rodents by examining theta oscillations. However, commensurate human data have not been uncovered. With the goal of specifically testing predictions of the biased competition model, we analyzed a data set of 76 individuals who performed an episodic memory paradigm with intracranial electrodes simultaneously inserted into the hippocampus and multiple prefrontal locations. Simultaneous recording allowed us to quantify the precise onset times of gamma band activation for the cortex relative to the hippocampus. Across all subjects (without any filtering of electrodes based upon their functional properties), we observed the left anterior VLPFC exhibited the following set of properties: the mean lag activation value during encoding was 13.4 msec (FDR corrected $p = 2.401 \times 10^{-5}$, t-test of activation times compared to hippocampus), while during retrieval it was -10.4 msec (FDR corrected $p = 0.0033$). For this region, the encoding versus retrieval lag distributions were significantly different (FDR corrected $p = 2.146 \times 10^{-7}$). Finally, we compared the lag distributions during successful versus unsuccessful encoding, looking for evidence of a subsequent memory effect in this measurement. For the left

aVLPFC, this was also significant (FDR corrected p = 0.0034). Taken together, these findings indicate that the lag values in the gamma activation peak in the left aVLPFC provide a signal that is sensitive to memory encoding success (exhibiting an SME), with a pattern that fits a putative model of the transfer of contextual information to the frontal cortex during encoding (significant positive lag relative to the hippocampal activation) with evidence of reversal during retrieval (significant negative lag relative to the hippocampus). Our results provide direct human evidence to support the biased competition model. We discuss how our observations fit with a wider picture of brain activity during memory encoding.

Title: Decoding memory: Patient specific models for decoding memory categories from hippocampal spiking activities in epilepsy patients

Authors: *X. SHE[1], D. SONG[1], B. MOORE[1], B. M. ROEDER[3], B. LEE[2], S. J. SHAW[4], A. NGUYEN[4], C. N. HECK[2], C. Y. LIU[2], S. A. DEADWYLER[3], R. E. HAMPSON[3], T. W. BERGER[1];
[1]Biomed. Engin., USC, Los Angeles, CA; [2]USC, San Marino, CA; [3]Neurosci., Wake Forest Sch. of Med., Winston Salem, NC; [4]Rancho Los Amigos Natl. Rehabil. Ctr., Downey, CA

Abstract: A Multi-Resolution, Multi-Trial (MRMT) sparse classification model is developed to understand how visual memories are encoded in hippocampal spiking activities in human. This model can successfully decode hippocampal spatio-temporal patterns of spikes into memory labels and thus termed Memory Decoding (MD) model. We recorded hippocampal CA1 and CA3 neural spikes from epilepsy patients when she/he was performing a Delayed Match-to-Sample (DMS) memory task. Hippocampal spikes (model inputs) are projected to a set of B-Spline basis functions to form features vector for classification. Model outputs are five mutually exclusive memory labels (i.e., Animal, Building, Plant, Tool, and Vehicle) describing categories of sample images presented in the 'Sample' phases of the DMS task. A sparse logistic regression classifier is used to map spike patterns to memory labels. Bagging method is applied to mitigate overfitting. Model performances are measured with Matthews Correlation Coefficients (MCCs). Classification are performed under three conditions with the last two conditions serve as negative controls. In the first condition, spike patterns around the 'Sample Response' events, when visual

memories are formed, are used as model inputs. In the second condition, memory labels are randomly shuffled to disrupt any possible correlation between spike patterns and memory labels. In the third condition, time windows of spike patterns are shifted to be before the 'Sample Presentation' events so that the spike patterns contain no memory information about the sample images. Results show that multiple memory labels can be predicted by memory decoding models with significantly above-zero MCCs in all 31 patients. Memory decoding *control* models show zero prediction with randomly shuffled memory labels and near-zero prediction with spike trains recorded before 'Sample Presentation'. These results indicate that (1) sparse classification models effectively avoid overfitting despite the high-dimensional feature space and the small sample size, and (2) visual memories are encoded in hippocampal spiking activities in human. This finding is consistent with previous results in nonhuman primates and further suggests that the hippocampus encodes sensory information with respect to specific categories and features.

Abstract: Development of a neural prosthetic for human memory requires an understanding of how mnemonic information is categorized and encoded for storage. Our recent report (Hampson et al. J. Neural Eng, 2018, 15:036014) showed that human memory could be successfully facilitated by delivery of patterned electrical stimulation to CA1 electrode sites in human hippocampus. Recently we have developed a Memory Decoding Model (MDM) of human hippocampal ensemble activity during performance of a memory task. Patterns were derived for

five image content categories, and patterns of neural activity positively and negatively correlated with the category were used to develop patterns for facilitatory stimulation. Patterned category stimulation was tested within a Delayed-Match-to-Sample+Delayed Recognition (DMS+DR) task, to determine whether MDM-based stimulation facilitated memory for category content of DMS+DR visual stimuli.
In human patients undergoing Phase II invasive monitoring for intractable epilepsy, recordings from an initial DMS (training) session were employed to determine neuron firing patterns for five categories of images; animal, building, plant, tool, and vehicle. Calculation of category specific stimulation patterns prior to the stimulation session allowed for identification of both CA1 and CA3 neurons as stimulation targets. During a second (stim test) session, subjects received micro-electrical stimulation on approximately 50% of trials during the sample phase of the DMS portion of the DMS+DR task. Stimulation trials were a combination of positive stim (stim pattern positively correlated with category) and negative stimulation (stim pattern negatively correlated with category) and were intermixed with non-stimulated control trials. Positive stimulation based on a patient's own hippocampal neural ensemble encoding resulted in facilitated performance and reduction of errors in all five categories. Memory for the image category was facilitated for up to 75 minutes in the Delayed Recognition phase. Facilitation was 10% over all categories, with single categories exhibiting up to 20% improvement. An additional test using a model derived across patients yielded mixed results with respect to positive vs. negative stimulation yielding facilitation in some categories. These results thus provide an important foundation for further design considerations for the current neural prosthetic to restore human memory damaged by injury or disease.

Title: Decoding memory - "Write-in" of category information on ambiguous trials via human hippocampal memory decoding model

Authors: ***S. A. DEADWYLER**[1], B. M. ROEDER[2], A. S. DAKOS[3], X. SHE[4], B. MOORE[5], D. SONG[4], T. W. BERGER[4], R. E. HAMPSON[3];

Abstract: To determine the effectiveness of a model neural prosthetic for human memory (see Hampson et al., this session) we have tested facilitation of memory retention in a combination Delayed-Match-to-Sample+Delayed Recognition (DMS+DR) task. Within this task, subjects are presented with clip-art and photographic images which are later tested for memory retention and recognition. Memory Decoding Model-based stimulation during the encoding (Sample) phase of the DMS portion of the task results in up to 34% improvement in later recognition during the DR portion. However, it is unknown whether this facilitation results from strengthening an already existing mnemonic code, or the effects of "writing-in" a code other than that produced by the patient's own memory function. The ability to write-in new codes was tested using MDM stimulation accompanying ambiguous "Sample" images in the DMS task.

MDM models and DMS-DR sessions were configured the same as in previous studies detailed in Hampson et al. (adjacent poster, this session, and J. Neural Eng. 2018). Approximately 10-15% of Sample images were replaced by a solid gray square (instead of clip-art or photographic image). Subjects were instructed to choose any image during the subsequent Match phase to measure personal preferences. Subjects were not informed that stimulation would occur during these trials; however, each "Ambiguous Sample" trial was stimulated with an MDM-based pattern derived either from the patient's individual model, or a shared model computed from other patients.

For at least three of five possible image-content categories derived by the Memory Decoding Model, stimulation with that MDM-derived pattern resulted in greater-then-chance selection of a Match-phase image appropriate to the category. Interestingly, shared model stimulation appeared more effective than individualized model stimulation. This suggests that codes derived from a patient's own model serve to reinforce existing content. When no content is present, an individual patient's "reinforcing" codes are less effective, but shared codes may contain sufficient information to serve as a cue on their own. These results thus provide an important information to the composition of memory codes necessary for a truly adaptable neural prosthetic for human memory.

Title: Decoding memory - towards building patient common memory decoding model using a transfer learning approach

Authors: *D. SONG[1], X. SHE[1], B. MOORE[1], B. M. ROEDER[2], G. NUNE[1], B. LEE[1], C. N. HECK[1], C. Y. LIU[1], S. A. DEADWYLER[2], R. E. HAMPSON[2], T. W. BERGER[1];

Abstract: We previously built memory decoding models using hippocampal spiking activities recorded from epilepsy patients. These models are patient specific in the sense that each model is estimated using input-output data recorded from one patient and thus can be predictive only in each specific patient. In this study, we seek to build a patient common memory decoding model that can be generalized to decode memory categories for multiple patients. This is a particularly difficult task, since on top of all the challenges already existing in building patient specific models, there is an additional need for defining a common coordinate system that allows combining heterogeneous dataset recorded from different patients into a single dataset. We explore two transfer learning approaches for creating the coordinate system and further building patient common models. In the first approach, neurons are grouped based on anatomical locations, i.e., anterior/posterior, CA3/CA1, and left/right regions of the hippocampus. Spike patterns of neurons from the same anatomic location are summed to form ensemble patterns. Ensemble patterns and memory labels from different patients then are concatenated to form the input-output data for the ensemble classification, which is performed using a sparse B-spline logistic regression classifier. In the second approach, neurons are grouped with respect to their firing patterns during Sample Response (SR) events, when memories are formed, in the delayed match-to-sample (DMS) task. First, principal component analysis is performed to SR patterns of spikes of all neurons from all patients to extract the principal components of spike patterns during SR. Second, each neuron's SR spike pattern is projected to the principal component space to position the neuron in an "activity space". Third, neurons are grouped within the activity space and summed to form ensemble patterns. Fourth, ensemble patterns and memory labels from different patients are concatenated to form the ensemble data. Finally, ensemble classification is performed as in the first approach. Spikes of 1594 neurons recorded during 3333 DMS trials from 28 patients are included to build two patient common models. Results show insignificant classification performance in all 5 memory categories with the first approach, and significant classifications in 3 out of 5 memory labels with the second approach. These results suggest that (1) it is possible to build patient common models for decoding memory categories from hippocampal spiking activities, and (2) there exist common features in the hippocampal spiking patterns across different patients in encoding memory information.

Title: Decoding memory - 24 hour memory facilitation of category information via a memory decoding model of hippocampus

Authors: *B. M. ROEDER[1], A. S. DAKOS[2], X. SHE[3], B. MOORE[4], D. SONG[3], T. W. BERGER[3], S. A. DEADWYLER[2], R. E. HAMPSON[2];

Abstract: In prior demonstrations of a model neural prosthetic for human memory (see Hampson et al., this session) we tested memory retention in a combination Delayed-Match-to-Sample+Delayed Recognition (DMS+DR) task. As in prior reports using a model constructed from the patients' own hippocampal neural ensemble encoding (Hampson et al. J. Neural Eng, 2018, 15:036014), we determined that model-based stimulation was highly effective in facilitating memory up to 75 minutes after stimulation (simultaneous with image presentation). In the current study, we tested retention of the same image and category information via an additional Delayed Recognition (DR24) assessment between 20 and 24 hours after the original presentation and stimulation.
Human patients undergoing Phase II invasive monitoring for intractable epilepsy were studied as detailed in Hampson et al. (adjacent poster, this session, and J. Neural Eng. 2018). MDM models were computed for each patient and used to determine CA3 and CA1 stimulation patterns during the encoding (DMS) phase of the task. Trials that were correctly recognized in the DR phase up to 75 min after presentation (including Stim and NoStim trials) were utilized to construct a set of DR trials to be tested the next day. All procedures for DMS-DR testing were identical on the day of stimulation (see Hampson et al.), with only the additional DR24 assessment conducted 20-24 hours after the original DMS trials.
All trials tested in the DR24 assessment were correctly recalled (i.e. 100% correct) in the DR phase on the day of stimulation. Both stimulated and nonstimulated trials showed a decrease in recall up to 24 hours later (mean 60-70% correct recognition); however, MDM-stimulated trials exhibited in less decline in recognition overall (10% improvement) as well as 20-40% improvement in at least three of five categories (compared to NoStim trials) indicating that

MDM stimulation resulted in improved mnemonic retention over the same time period compared to unstimulated trials. Effectiveness of individualized MDM model vs. a model computed across patients is also underway. These results indicate this implementation of a neural prosthetic has the potential for long-lasting efficacy with respect to restoring human memory function in individuals with memory deficits due to disease or injury.

Title: Human intracranial EEG reveals neural correlates of verbal memory processing across the large-scale of brain dynamics

Authors: *V. S. MARKS[1], K. SABOO[2], Ç. TOPÇU[3,4], G. A. WORRELL[4,5], M. T. KUCEWICZ[3,4,5];

Abstract: Brain processes underlying encoding, storage, and recall of verbal memory can be probed in intracranial EEG (iEEG) recordings during the presentation of words in a free recall task. The purpose of this study was to investigate the broad spectral, spatial, and temporal properties of brain activity underlying human verbal memory encoding. Recordings were obtained during the encoding of words from 139 patients implanted with intracranial electrodes for surgical evaluation of drug-resistant epilepsy. Participants were asked to study lists of words presented on a computer screen for a delayed test of free recall. Lists were composed of 12 nouns from a pool of common English nouns. After a distractor task, participants were asked to recall as many of the words as possible. For each electrode, we determined the average spectral power

density at each time point across all word presentation epochs and found the overall induced power during word presentation. Electrodes were then classified into active and inactive clusters. Analysis of recordings from active electrodes revealed consistent and robust differences in the low theta (2-4 Hz), high theta (5-9 Hz), alpha (10-15 Hz), beta (16-25 Hz), low gamma (25-55 Hz), and high gamma (65-115 Hz) frequency bands. Brodmann areas within the occipital lobe had the highest percentage of active electrodes in all bands (Fig. 1). Analysis of the induced power change showed that verbal memory processes are present in all frequency bands. The induced power of an electrode was found to have statistically significant dependence (ANOVA, $p<0.001$) on the frequency band analyzed, Brodmann area, and hemisphere. Post-hoc group analysis (Tukey-Kramer, $p<0.05$) showed that the total induced power gradually decreased from low to high frequency bands and was higher in right hemisphere. We also observed distinct temporal patterns of the induced power change in the frequency bands studied. The spectral, spatial, and temporal patterns identified in human iEEG recordings suggest large-scale distributed dynamics of verbal memory encoding.

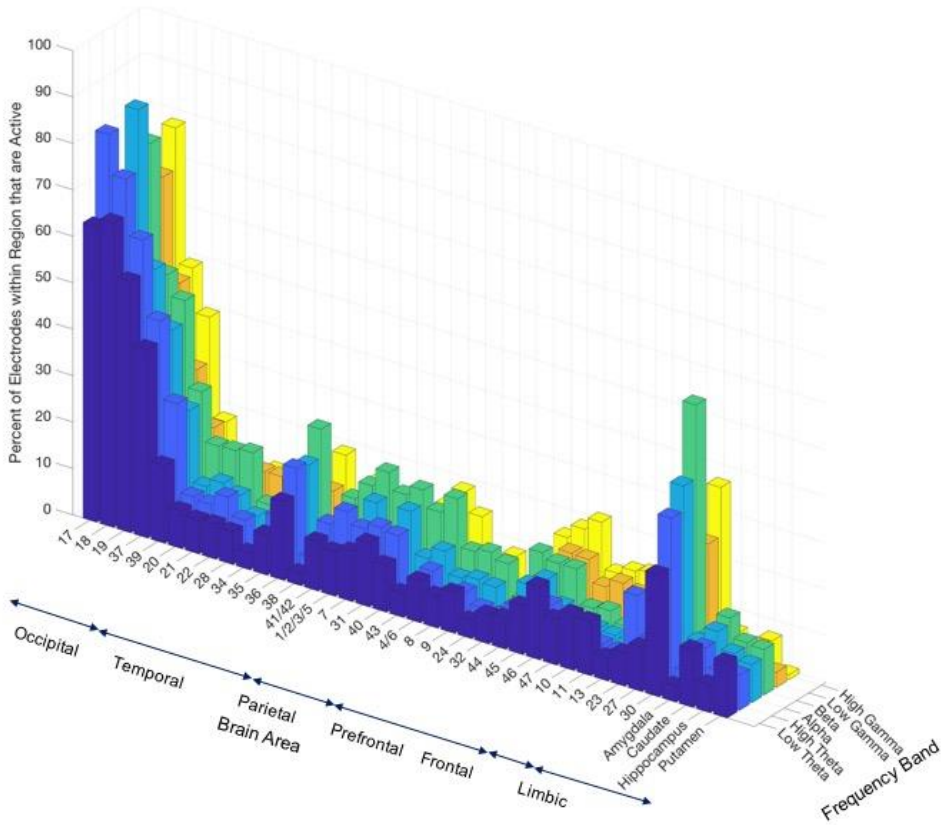

Figure 1. **Distribution of active electrodes across brain regions and frequency bands.** Proportions of active electrodes in each Brodmann area was normalized by the total number of electrodes implanted in that area. Brain areas with the highest percentage of electrodes were identified within the occipital lobe, and the frequency band with the highest percentages of electrodes was the beta band (16-25 Hz).

Title: Human verbal memory encoding is distributed across a broad range of electrophysiological activities and brain regions

Authors: *Ç. TOPÇU[1,2], K. SABOO[3], V. S. MARKS[4], G. A. WORRELL[2,5], M. T. KUCEWICZ[1,2,5];
[1]Multimedia Systems Department, Fac. of Electronics, Telecommunication and Informatics, Gdansk Univ. of Technol., Gdansk, Poland; [2]Mayo Clinic, Dept. of Neurol., Rochester, MN; [3]Univ. of Illinois, Dept. of Electrical and Computer Engin., Urbana-Champaign, IL; [4]Mayo Clinic, Grad. Sch. of Biomed. Sciences, Dept. of Physiol. and Biomed. Engin., Rochester, MN; [5]Mayo Clinic, Dept. of Physiol. and Biomed. Engin., Rochester, MN

Abstract: Understanding where and how verbal memory is processed in the human brain remains a challenging question that can be addressed using intracranial electroencephalography (iEEG) signals sampled from electrodes implanted across the cortical brain regions. In this work we investigated engagement of specific regions and oscillatory activities in encoding words. iEEG signals were recorded from 84 drug-resistant epilepsy patients performing a verbal short-term memory task, in which lists of 12 common nouns were presented for subsequent free recall. Memory processing was quantified by averaging the element-wise difference between the iEEG spectral power estimates during encoding of words that were subsequently recalled and that were forgotten, independently in six frequency bands: low theta (3-8 Hz), high theta (6-10 Hz), alpha (8-15 Hz), beta (15-25 Hz), low gamma (25-55 Hz), and high gamma (65-115 Hz). We used this power difference, the subsequent memory effect (SME), as a biomarker of the magnitude of memory encoding in a wide range of different Brodmann areas. We assessed the effect of the Brodmann area and the hemisphere localization on the population SME values using analysis of variance separately in all six frequency bands studied. Brodmann area had a significant effect

(ANOVA, $p<0.001$) in all six frequency bands. Hemisphere had a significant effect on the SME values (ANOVA, $p<0.01$) in both theta, alpha, and high gamma, but not in the beta and low gamma frequency bands. Post-hoc group comparisons (Tukey-Kramer, $p<0.05$) showed that the mean SME values gradually decreased from low to high frequency bands and they were significantly higher in left hemisphere. The highest mean SME values across all frequency bands were found in Brodmann area 31 (parietal lobe), in Brodmann area 8 (frontal lobe), and in the amygdala (mesial temporal lobe). The SME values were also found to have significant dependence (ANOVA, $p<0.05$) on the cortical lobe in all but the low gamma frequency band. Our results suggest that memory encoding is widely distributed across multiple brain regions and engages a broad spectrum of oscillatory activities in the low and high frequency bands. Human verbal memory is proposed to be supported by large-scale distributed processing of the remembered words.

Title: Event boundaries shape memory formation: Evidence from single unit recordings in humans

Authors: *J. ZHENG[1], A. GÓMEZ PALACIO SCHJETNAN[2], V. A. TAUFIK[2], A. N. MAMELAK[3], J. M. CHUNG[3], U. RUTISHAUSER[3], G. KREIMAN[4];
[1]Boston Children's Hosp., Boston, MA; [2]Krembil Res. Inst., Toronto, ON, Canada; [3]Cedars-Sinai Med. Ctr., Los Angeles, CA; [4]Harvard Med. Sch., Boston, MA

Abstract: Although our daily life unfolds as continuous experiences, the memories of these past experiences are carved and organized as discrete events (“episodes”). The ability to segment continuous experiences is highly adaptive: it can help update brain states for salient environmental changes and support the flexible recombination of these memory segments for future use. However, the neural mechanisms underlying event segmentation and how they influence later memory recall remain unclear. To investigate segmentation during memory formation, we tested subjects’ memory of clips with and without event boundaries (i.e. transition between clips from different movies) while recording single neuron activity from 13 drug-resistant epilepsy patients (6 female, age 41.1 ± 14.3) at two sites (Cedars-Sinai and Toronto).

Subjects' memory was evaluated in two subsequent sessions: a scene recognition task where they were asked to identify frames from watched clips as 'old' and novel frames as 'new'; and a temporal discrimination task where they need to identify which of two frames happened first in the presented clip. The presence of event boundaries did not affect performance in the scene recognition task ($F(2, 36) = 0.05$, $P = 0.948$). However, during the temporal discrimination task, subjects showed impaired performance ($F(2, 36) = 18.71$, $P = 2.7 \times 10^{-6}$), longer reaction times ($F(2, 36) = 22.93$, $P = 3.8 \times 10^{-7}$) and a lower confidence level ($F(2, 36) = 15.88$, $P = 1.1 \times 10^{-5}$) when retrieving the temporal order of frames across an event boundary. Such behavior outcomes confirmed the influence of event segmentation on memory formation, highlighting the loose temporal associations between experiences across event boundaries. Evidence of event segmentation was also observed at the neuronal level. Specifically, during encoding, we found neurons (33/468, mostly from the hippocampus: 42.4%) that showed increased firing rates closely following the presence of event boundaries. Moreover, during memory retrieval, these neurons increased their firing rates only when subjects successfully identified the temporal relationship of frames across event boundaries, with no change of firing rates when temporal discriminating frames from the same event, or when performing the scene recognition task. These findings provide initial steps towards elucidating the neural circuit mechanisms for boundary detection at the single cell level and suggest a putative role of these boundary responsive neurons in subsequent memory retrieval, potentially bridging separate memory segments together when needed.

Title: Persistent single-neuron activity during working memory predicts strength of long-term memory in humans

Authors: *J. KAMINSKI[1], N. CHANDRAVADIA[1], A. G. P. SCHJETNAN[3], Y. SALIMPOUR[4], I. M. REUCROFT[5], C. REED[2], J. M. CHUNG[2], S. KALIA[3], W. ANDERSON[4], T. A. VALIANTE[3], A. N. MAMELAK[1], U. RUTISHAUSER[1];

Abstract: Close interactions between Working memory (WM) and Long-Term Memory (LTM) have been known for a long time. For instance, holding an item in WM strengthens LTM for that item. Despite strong behavioral evidence of this relationship, the neuronal basis of this interaction between WM and declarative memories remains poorly understood. We performed single-neuron recordings in the Medial Temporal Lobe and the Medial Frontal Lobe in neurosurgical patients undergoing depth electrode implantation for localization of epileptic seizures. We formed a consortium between three institutions (Cedars-Sinai Medical Center, Toronto Western Hospital, and John's Hopkins Hospital) as part of the NIH BRAIN initiative to enable large-scale data collection at the single-neuron level with standardized surgical and experimental procedures. Patients performed a WM task followed by a new/old LTM recognition memory task. In the WM task we asked subjects to maintain novel images in memory for a few seconds, followed by a probe. Recognition of these images was then subsequently tested in the LTM task. We analyze 41 sessions; behavioral accuracy was 89% and 69% for the WM and LTM task, respectively. In the Medial Temporal Lobe, we identified category selective neurons during the WM task (16% of MTL neurons were category neurons). A subset of these neurons exhibited selective persistent activity during the maintenance period of WM task when a stimulus of their preferred category was held in mind. Critically, we found that the strength of this persistent activity in a given WM trial, in load 1, predicted whether an item was subsequently remembered or forgotten in the LTM recognition task. Z-scored persistent activity was 0.74 and 0.32 for remembered and forgotten trials respectively (permuted t-test t[27]=25.03, p=0.02). These results not only show a direct link between the activity of neurons in MTL and the subsequent strength of declarative memories but also demonstrates that persistent neuronal activity acts as a common neural substrate for both WM maintenance and LTM formation.

Title: March madness: An fMRI study of continuously updated surprise and suspense during basketball-watching

Authors: *J. W. ANTONY[1], S. D. MCDOUGLE[2], U. HASSON[1], K. A. NORMAN[1];
[1]Princeton Univ., Princeton, NJ; [2]Univ. of California, Berkeley, Berkeley, CA

Abstract: In domains where humans observe events unfold in time, such as listening to narratives or watching sports games, probabilistic beliefs in particular outcomes are continuously updated. In these domains, one important variable, surprise, increases when there is a large discrepancy between previous and current beliefs. Another key variable, suspense, increases when upcoming events have the potential to dramatically alter the current belief (i.e., when the perceived variance in upcoming beliefs is high). Both variables are important for understanding how events are structured and remembered. Here, we set out to characterize dissociable neural correlates of surprise and suspense in event cognition. We used fMRI to measure the neural activity of human subjects as they viewed and recalled the final five minutes of high-stakes NCAA basketball games. We operationalized momentary beliefs (i.e., which team would win) using a "win probability" metric derived from an expert basketball analyst (https://kenpom.com/). These belief values were updated every time the possession of the ball changed. We approximated surprise using the derivative of the belief time course, which often changed after a score or change in possession. We hypothesized that highly surprising events would enhance memory for those events, drive responses in the ventral striatum, and delineate neural event boundaries in multimodal association cortices, as measured by representational similarity analysis. Moreover, we also predicted that cumulative surprise would correlate with game enjoyment. We operationalized suspense by 1) finding instances in a large set of games with a particular game state (amount of time remaining and difference in win probability between the teams) and 2) calculating, for each state, the variability in the change in belief produced by the following state. We predicted that increased suspense would be associated with increased inter-subject correlations in visual and auditory cortices and multimodal association areas. Results pertaining to these predictions will be discussed. More broadly, we hope to demonstrate that sports games (which are both engaging and rich in quantifiable outcomes) are a promising way to explore the neural mechanisms underlying event segmentation and memory.

Title: Hippocampal white matter microstructure predicts rapid category learning

Authors: *M. GUMUS, T. ZHU, M. L. SCHLICHTING, M. L. MACK;
Univ. of Toronto, Toronto, ON, Canada

Abstract: People rapidly acquire new knowledge in light of their previous experiences. Emerging empirical evidence suggests such learning relies on complementary functions of the hippocampus (HPC). These findings are consistent with neurobiological memory theories positing that during learning, HPC comparator processes evaluate the overlap between new information and current knowledge. The result of this process is thought to trigger either pattern separation, wherein new information is represented distinctly from existing knowledge, or pattern integration, wherein new information is incorporated into existing memories. The extent that these HPC functions impact learning depends on the engagement of anatomically and functionally distinct HPC subfields that are interconnected through two main pathways: the trisynaptic pathway (TSP), which loops from the entorhinal cortex (EC) through dentate gyrus (DG) and cornu ammonis 3 (CA3) en route to CA1; and the monosynaptic pathway (MSP), which projects directly from EC to CA1. Whereas the slower learning rates of MSP projections are thought to be important for forming unitized representations of features over many repetitions, TSP is thought to support rapid flexible encoding via DG- and CA3-mediated functions of pattern completion and relational binding. Despite the theorized significance of intra-HPC circuitry for behaviour, providing an empirical characterization of how information flows within HPC to support learning remains a challenge in humans. Here, we combine anatomically defined hippocampal subfields with high-resolution diffusion-weighted imaging (DTI) to quantify white matter connections underlying the TSP and MSP and link their integrity to category learning behaviour. Participants learned to categorize complex visual objects composed of multiple features based on a multidimensional rule linking features to categories. Rapid learning performance was quantified by participants' ability to successfully categorize rarely-seen category members. Participant-specific structural connectomes of HPC subfields were constructed according to the relative number of interconnecting streamlines as defined by probabilistic anatomically-constrained tractography. A mixed-effects regression relating learning performance to the relative strength of TSP (CA3-CA1 connections) and MSP (ERC-CA1 connections) showed that better learning was uniquely associated with greater TSP tract integrity. By linking sophisticated DTI measures with individual differences in learning ability, these findings shed light on how information flow within HPC supports rapid category learning.

Title: Shaping visual memories with real-time fMRI neurofeedback

Authors: *E. S. LORENC, E. F. OBLAK, J. S. SULZER, J. A. LEWIS-PEACOCK;
Univ. of Texas at Austin, Austin, TX

Abstract: Mounting evidence suggests that item representations that linger in a moderately active state in working memory (WM) are susceptible to degradation from competitive processes, subsequently impairing long-term retention. Here, we examined whether real-time fMRI neurofeedback can be used to endogenously manipulate levels of competition in WM, thereby shaping the likelihood of long-term forgetting.

On an initial fMRI scan day, 3 participants completed a perceptual category localizer task, used to train multivoxel pattern classifiers in ventral temporal cortex (VTC) to distinguish between faces, scenes, objects, and periods of rest. This was followed by five runs of a WM task, in which a face and a scene image were presented on each trial, and a retrospective cue indicated which image would be probed after a delay. Pattern classifiers tracked the representational states of the two items, and confirmed that on average, the cued item showed higher delay-period activation than the un-cued item.

In a subsequent fMRI scan day, participants completed another eight runs of the WM task. Participants were instructed to complete the WM task as before, and also to maximize a visual feedback signal related to their delay-period brain activity, presented at the end of each trial. Unbeknownst to them, the feedback was based on the activation level of the un-cued item, decoded from VTC. This allowed us to manipulate the competition between WM items in two ways: in the 'isolate' condition, feedback was designed to *reduce* competition by rewarding low levels of activation for un-cued items. In contrast, in the 'compete' condition, feedback was intended to *increase* competition by rewarding higher levels of activation for un-cued items. Across participants, we found that this neurofeedback procedure successfully modulated WM activations, with more similar activation (greater competition) for items in the 'compete' condition compared to the 'isolate' condition ($p = .047$).

A final fMRI session included two reminder neurofeedback runs, and then three 'transfer' runs per condition without feedback. Participants struggled to maintain the condition-specific modulations in the absence of feedback, with no significant difference in WM competition between conditions. However, we found preliminary evidence that the neurofeedback-induced WM competition had the predicted impact on long-term memory: participants showed more forgetting of un-cued items from 'compete' runs (where they were trained to activate these items *more*) than from 'isolate' runs ($p = .026$). These data provide promising evidence that fMRI neurofeedback can be used to covertly manipulate the fate of visual memories.

Title: Transcutaneous vagus nerve stimulation strengthens semantic encoding during novel tone word learning: Evidence from event-related potentials

Authors: *I. PHILLIPS, V. P. KARUZIS, N. B. PANDŽA, P. O'ROURKE, S. E. KUCHINSKY;
Applied Res. Lab. for Intelligence and Security, Univ. of Maryland, College Park, MD

Abstract: Learning a tone language, in which pitch changes word meaning, is difficult for adult speakers of non-tone languages. Learners must rapidly discern pitch contour and height differences and link these cues to word meaning. Research shows that both speech perception training and musical experience improve tone language learning, yet interventions that more directly target neurocognitive processes are understudied. Clinical studies of vagus nerve stimulation (VNS) via implanted electrodes show improvements in associative memory, but it is unclear if non-invasive transcutaneous VNS (tVNS) has a similar effect. To test whether receiving tVNS during tone word training improves learning outcomes, we conducted a double-blind study with native English speakers learning Mandarin pseudowords, using similar methods as a recent study that found faster tone word learning for professional musicians (Dittinger, et al., 2016). We analyzed accuracy and response time (RT) to establish tVNS efficacy and the N400 event-related potential (ERP) component to determine whether learning improvements coincided with enhanced lexico-semantic word representations, as Dittinger et al. found. 43 healthy native English speakers (11 male, ages 18-34) received active or sham tVNS via electrodes placed on the left outer ear canal (21 active, 22 sham, groups balanced on self-rated musicianship, pitch aptitude, working memory) while they learned 9 tone words, made by pairing 3 syllables (/ba/, /bi/, /pi/) with 3 Mandarin tones (flat, rising, falling) over 2 days. Both days involved a passive word learning task in which subjects saw an English word on screen and then heard the tonal translation, and a matching task in which subjects saw an English word, heard a tonal word, and then pressed a button to indicate if the words were correct translations or not. Before each task, the active group received 10 minutes of continuous tVNS priming below perceptual threshold. No differences in accuracy were found for the matching task, but the active group had faster RTs for correct answers than sham. These RT improvements aligned with differences in N400 distribution and amplitude in both tasks, similar to Dittinger et al.'s findings. N400s were observed for both groups, but had a larger amplitude and a more posterior distribution for the

active group in both word learning and matching tasks, suggesting tVNS recipients developed stronger lexico-semantic representations for the trained tone words faster than the sham group. These findings largely parallel those reported for professional musicians, and suggest short periods of tVNS may confer similar benefits as musical training to tone language learners.

Title: Early learning hippocampal engagement supports flexible category learning

Authors: *Z. CHENG, T. LIU, M. L. MACK;
Univ. of Toronto, Toronto, ON, Canada

Abstract: Emerging evidence points to the hippocampus (HPC) as a key brain structure in learning flexible knowledge that extends beyond memories for individual episodes. These findings lend support to neurobiological memory theories that formalize how HPC functions of pattern completion, separation, and integration contribute to building memory structures that highlight goal-relevant information. Although recent human and animal work has identified goal-specific coding in HPC at the end of learning, it remains unknown how the interplay of neural mechanisms early in learning support the formation of such flexible knowledge. Here, we combine human neuroimaging with SUSTAIN, a computational model that formalizes how newly-encountered information is encoded in light of prior learning, to characterize how early learning processes are reflected in neural function. During fMRI scanning, participants learned to categorize visual objects composed of multiple features based on a multidimensional rule linking object features to category labels. Category prototypes were shown more frequently than non-prototype stimuli resulting in high learning performance for prototypes across all participants at the end of the task, but large individual differences in learning non-prototypes. Whereas some participants fully learned non-prototypes, others perseverated on simple rules that miscategorized non-prototypes; as such, non-prototype performance served as a behavioural index of flexible learning. We interrogated neural function during initial learning finding that univariate activation in anterior HPC not only discriminated prototypes from non-prototypes, but the degree of this effect predicted individual differences in flexible learning. Similar effects were seen in bilateral frontal pole and superior parietal cortex. SUSTAIN was fit to participants' behaviour to derive

trial-by-trial predictions of information gain, a measure reflecting the degree of knowledge updating resulting from any one trial. Across all trial types during initial learning, information gain was reflected in the engagement of the caudate, consistent with its role in prediction error and reward processing. Posterior HPC activation also correlated with information gain but did so differently for prototype and non-prototypes. Importantly, this relationship between HPC engagement and model-based information gain predicted individual differences in non-prototype learning. These findings suggest that HPC engagement to informative experiences during initial learning supports the formation of flexible knowledge that generalizes to similar experiences.

Title: Theta entrainment after learning enhances episodic memory

Authors: *N. WHITMORE, K. A. PALLER;
Northwestern Univ., Evanston, IL

Abstract: Converging evidence from computational, animal, and human approaches suggests that theta-band EEG oscillations (3-7 Hz) play a role in memory functions, but their precise role remains mysterious. Sensory entrainment paradigms allow researchers to induce theta waves and potentially link theta to specific memory mechanisms. Although this method has been used to probe the role of theta during encoding, theta's role in consolidation is less well understood. To address this issue, we investigated theta entrainment during a post-learning period when active rehearsal was discouraged. In an exploratory study, participants (N=22, 13 female, age 18-31 yrs, mean age=21.5 yrs) first viewed pictures of 30 common objects and were instructed to remember the objects. Immediately afterwards, they took free recall and recognition tests. Then they performed a continuous performance test (CPT) for 25 minutes (responding whenever "X" appeared), followed by the same two memory tests. During the CPT, we produced entrainment by flickering the brightness of the screen. Each participant performed this procedure two times using different sets of pictures and different delay-period stimulation, at either an individualized theta frequency or at a control frequency. Order of theta and control entrainment was counterbalanced. Theta rhythms were entrained, in general, but not to the same extent in all individuals. Regression revealed that the memory effects of theta stimulation depended on the strength of EEG entrainment, quantified by the degree to which EEG theta power increased with

stimulation versus stimulation-off baseline periods. Stronger EEG entrainment was associated with increased benefit from theta stimulation in recognition and recall ($p < 0.001$ for both). Participants with the strongest EEG entrainment (n=10) recognized 3% more objects and recalled 6% more objects after theta stimulation than after control stimulation. These results suggest that theta oscillations facilitate offline consolidation. Theta may improve memory by modulating plasticity and network connectivity, or alternatively by enhancing binding when memories are spontaneously reactivated. These results link theta with memory improvement, but the extent to which theta was associated with memory reactivation is unclear, given that the theta entrainment occurred during the CPT. Therefore, we conducted a follow-up study in which theta entrainment occurs during memory retrieval. Comparing results between the two studies may shed additional light on the neurocognitive mechanisms through which post-learning theta is associated with memory improvement.

Title: Levels-of-processing during memory encoding: An explanation for the other-race effect in face memory

Authors: *G. HERZMANN[1], T. CURRAN[2];
[1]The Col. of Wooster, Wooster, OH; [2]Univ. of Colorado Boulder, Boulder, CO

Abstract: People are better at memorizing own-race than other-race faces. Previous research suggests that own-race faces are automatically memorized at a deep level (e.g., holistic), whereas other-race faces are memorized on a shallow level (e.g., less holistic or part-based). In the present study, we tested if instructions to encode own-race and other-race faces either deep or shallow modulated the other-race effect in face memory performance and ERPs related to memory encoding. In Experiment 1, Caucasian participants performed deep (Would you recognize this face in a crowded airport?) and shallow (Does this face have a small nose?) encoding tasks while studying Caucasian and African-American faces for later recognition. Experiment 2 included two groups of Caucasians: One group replicated Experiment 1, and the other group studied Caucasian and African-American faces without encoding instructions to

obtain measures of natural memory encoding. Shallow encoding reduced the other-race effect in face memory by making performance for own-race faces more similar to that of other-race faces, which did not differ from natural encoding. ERPs during memory encoding for shallowly encoded own-race faces matched that of natural as well as shallowly encoded other-race faces. This suggests that an encoding task that focuses on facial features mimics memory encoding naturally seen for other-race faces. Our hypothesis of naturally occurring deep encoding for own-race faces was not confirmed. Deeply encoded own-race faces showed better performance than naturally encoded own-race faces. ERPs during memory encoding showed a stronger involvement of frontal brain regions in the deep encoding of own-race faces, which was significantly different from natural encoding conditions. The current results suggest that the main contribution to the other-race effects is the naturally occurring shallow memory encoding of other-race faces. It also shows that memory for own-race faces can be increased with encoding instructions that emphasize holistic processing.

Title: Neural oscillations in olfactory and memory regions predict episodic odor memory richness: Unraveling the Proust phenomenon

Authors: *A.-L. SAIVE[1], T. THIERY[2], E. COMBRISSON[3], J.-P. ROYET[4], S. GARCIA[4], S. RHEIMS[5], J. ISNARD[5], J. PLAILLY[4], N. RAVEL[4], K. JERBI[2];

Abstract: Odors benefit from a unique access to memory, leading to particularly specific and detailed - *i.e.*, rich - memories. However, whether our ability to remember rich episodic odor memory depends on specific patterns of neural oscillations induced during the encoding and/or the retrieval has so far remained unknown. Here, using the unmatched spatiotemporal resolution of iEEG recordings and an objective graded memory richness score, we found that the richness of odor memory is primarily based on encoding rather than retrieval processing. At encoding,

single-trial increases in broad-band gamma [30-120 Hz] activity in frontal regions alongside decreases of theta [3-7 Hz] and alpha [8-13 Hz] activity in the olfactory regions and the hippocampus (HC) predicted subsequent odor memory performance. Moreover, theta and alpha decreases linearly predicted odor memory richness and significantly correlated with retrieval speed. In addition, temporal pattern similarity analyses revealed that the reinstatement of encoding neural patterns in the hippocampus at retrieval benefited the richness of episodic odor retrieval. In sum, our results provide critical evidence for an oscillatory neural code of episodic odor memory in which HC and olfactory regions can form rich multisensory associations at encoding that would be later reinstated via the HC.

Title: The intrinsic neonatal hippocampal network: rsfMRI findings

Authors: ***A. L. HOWELL**[1], D. E. OSHER[2], J. LI[2], Z. M. SAYGIN[3];
[1]Neurosci., [2]Psychology, [3]The Ohio State Univ., Columbus, OH

Abstract: The development of the hippocampal network likely plays a significant part in the emergence of the ability to form long-lasting memories. Many adults cannot voluntarily recall memories before the ages of 3-5, a phenomenon referred to as “infantile amnesia”, possibly due to an immature hippocampus/hippocampal network. An understanding of the hippocampal network at birth and its development may elucidate the brain mechanisms behind infantile amnesia. We studied resting-state hippocampal connectivity to 7 networks across the brain in neonates scanned within one week of birth (Developmental Human Connectome Project) and adults (Human Connectome Project). In adults, our results show the greatest hippocampal connectivity to the limbic and then default networks followed by the somatosensory, visual and dorsal attention networks and an anti-correlated (i.e. negative connectivity) pattern in both the ventral attention and frontoparietal areas; these findings are similar to that previously reported. The neonates, however, lacked a clear hierarchal pattern of connectivity to the seven networks. Moreover, there were no anti-correlated networks within the neonatal hippocampus. Next, we split the hippocampus into anterior and posterior portions to assess the long axis gradient of the

hippocampus. We found greater anterior (vs posterior) connectivity to the limbic, default and somatomotor networks and greater posterior connectivity to the dorsal attention, frontoparietal and ventral attention regions, again consistent with previous work. Neonates, however, showed no significant differences in the connectivity of the anterior vs. posterior hippocampus to the networks. Together, these results indicate that the neonatal hippocampal network and the long-axis specialization of the hippocampus are not mature at birth and the development of this connectivity may have implications for memory formation and infantile amnesia.

Title: Effects of the presence of a familiar peer on eye movements and attention

Authors: ***L. TRICOCHE**, J. FERRAND-VERDEJO, D. PÉLISSON, M. MEUNIER; CRNL Inserm CNRS UCBL, Lyon, France

Abstract: "Social facilitation or impairment" (SFI) refers to the enhancement or impairment of performance engendered by the mere presence of others. It has been shown for a diversity of behaviors. This study assessed whether SFI also affects attention and eye movements, and if so, which decision-making mechanisms are involved. Adult volunteers (19-35 years, n=79, 47 females) were tested using 3 tasks assessing eye movements (saccades), spatial attention (visual search), and sustained attention (continuous performance). Subjects were tested alone (n=39) or in the presence of a familiar peer (n=40). In the saccades task, subjects performed two separate blocks of pro- and anti-saccades (simple condition) or a single block of randomly-mixed pro- and anti-saccades (complex condition). In the visual search task, subjects pressed one of two keyboard keys to signal the presence or absence of a target among distractors presented simultaneously. In the continuous performance task, stimuli appeared one at a time mixing rare targets requiring a Go response with frequent distractors requiring a NoGo response. We measured either reaction times (RTs), percent errors (%Err), accuracy, duration, and peak velocity of saccades, or RTs and %Err of manual responses. The LATER model was used to

assess two decision making mechanisms in the saccadic and continuous performance tasks: threshold and rate of rise. The saccades task showed that SFI: 1) exists for eye movements (affecting mainly RTs); 2) is modulated by task difficulty (a majority of socially tested subjects were facilitated in the simple saccade condition and inhibited in the complex one). The two attentional tasks failed to show a significant group effect. However, the individual-level analysis suggests a social effect in most subjects but with an equal proportion of facilitated and inhibited subjects. The LATER model showed a change of both the threshold and the rate of rise in subjects affected by social presence. These findings demonstrate that SFI affects eye movements, and possibly attention, in a task complexity-dependent manner, by affecting two decision making mechanisms. They also stress the need for a better understanding of SFI individual variability to better predict the impact of social presence at school or work.

Title: Examining visual selection in children across levels of attentional ability

Authors: *J. KLEIN[1], A. COOK[1], H. ALLEN[2], J. CLIBBENS[1], E. MAVRITSAKI[1]; [1]Birmingham City Univ., Birmingham, United Kingdom; [2]Univ. of Nottingham, Nottingham, United Kingdom

Abstract: Successful goal-directed behaviour is contingent upon selectively processing relevant information at the expense of the irrelevant - a process commonly referred to as attention. Within the spectrum of human behaviour, there exists a wide range of attentional ability. This range includes impairment, such as typically seen in disorders like attention-deficit hyperactivity disorder (ADHD). The classic profile of ADHD is associated with alterations in the prefrontal cortex (PFC) as well as suboptimal functioning of the powerful neuromodulators dopamine (DA) and norepinephrine (NE). These alterations have previously been linked to problems in visual selection and orienting (Brennan & Arnsten, 2008). Previous work has shown that children with ADHD have difficulty allocating attention not only to specific locations in space (Mullane & Klein, 2008), but also to moments in time (Mason, Humphreys, & Kent, 2003). The present study compared three age and IQ-matched groups based on ADHD probability on performance in four visual search tasks. In single-feature search, targets differed from distractors by one feature (shape), while in conjunction search, targets were defined by a combination of two features (colour and shape) relative to distractors. In standard preview search, one set of

distractors appears 750 ms before the onset of a second set. Finally, in preview gap search, a 250 ms temporal gap is introduced between the two distractor sets after the initial 750 ms interval. Participants were grouped based on informant responses obtained from the Conners' 3 Parent Questionnaire (Conners, 2008) which determined whether they had a low (11-39%), borderline (40-60%) or high (61-99%) probability of ADHD. This allowed for an in-depth analysis of performance, where search efficiency is measured by reaction times and accuracy, as it relates to severity of symptoms. We discuss the implications for understanding differing profiles of impairment, calling attention to the need for more comprehensive measures in identification and aid for individuals with attention difficulties. Title: A transcranial stimulation intervention to support flow state induction

Authors: *J. M. GOLD, J. CIORCIARI;
Swinburne Univ. of Technol., Melbourne, Australia

Abstract: Background: Flow states are considered a positive, subjective experience during an optimal balance between skills and task demands. Previously, experimentally induced flow experiences have relied solely on adaptive tasks. Objective: To investigate whether cathodal transcranial direct current stimulation (tDCS) over the left dorsolateral prefrontal cortex (DLPFC) area and anodal tDCS over the right parietal cortex area during video game play will promote an increased experience of flow states. Methods: Two studies had participants play Tetris or first-person shooter (FPS) video games while receiving either real tDCS or sham stimulation. Tetris recruited twenty-one untrained players who infrequently played video games while the ten FPS participants played FPS frequently. Flow experience was assessed before and after stimulation. Results: Compared to sham stimulation, real stimulation increased flow experience for both untrained Tetris and trained FPS players. No ceiling effects were noticed

between trained and untrained groups. Conclusion: Cathodal and anodal tDCS over the left DLPFC and right parietal areas respectively may encourage flow experiences in complex real-life motor tasks that occur during sports, games and everyday life.

Title: Changes in resting state functional connectivity induced by one session mindfulness meditation

Authors: *Y. HOSHINO[1], N. YAMAYA[2], S. IKEDA[2], Y. HAMAMOTO[2], A. KOBAYASHI[2], R. KAWASHIMA[2];
[1]Fac. of Medicine, Tohoku University, Sendai, Japan, Sendai, Japan; [2]Inst. of Development, Aging and Cancer, Tohoku University, Sendai, Japan, Sendai, Japan

Abstract: One-session mindfulness meditation decreases mind wandering, which often occurs at rest and is associated with negative feelings. The effect of one-session meditation has been seen even in meditation novices. However, it remains unclear how functional brain activity during rest changes immediately after meditation in novices. We assumed that one-session meditation changes resting-state functional connectivity (RSFC) among brain regions. To test the hypothesis, we recruited 28 meditation novices. All subjects were randomly divided into a meditation group (n = 13) and a sham meditation group (n = 15). In the meditation group, subjects were instructed to focus on and count their breaths (i.e., Su-soku meditation) for 10 minutes. In the sham meditation group, subjects were instructed to relax and lie still in the scanner for 10 minutes (i.e., mind wandering). The subjects underwent resting-state fMRI immediately before and after the Su-soku/sham. In addition, we collected behavioral measures of mood, sleepiness (three time points: immediately before 1st fMRI scan, and immediately before and after meditation), and effort to meditation. The fMRI images were preprocessed using the CONN toolbox. RSFC between each pair of regions of interest was
assessed using the pre- and post-meditation fMRI data. RSFC changes were calculated by subtracting the pre- from the post-meditation RSFC. The RSFC changes were then statistically compared between the So-soku and sham groups using false discovery rate (q = 0.05). As a result, the Su-soku group showed increased functional connectivity within the cerebellar regions, between the cerebellum and the fusiform gyrus, between the supramarginal gyrus and fronto-parietal network and so on. Our findings may be supported by some previous studies. The cerebellum has been known to be associated with sustained attention, which represents the ability to maintain focus on a task and is enhanced by meditation. In addition, meditation induces structural changes in the fusiform gyrus. Therefore, the increased RSFC of the cerebellum and the fusiform gyrus may be supported by the previous findings. On the other hand, the supramarginal gyrus (a part of salience network) and fronto-parietal network play a key role in mediating internally and externally directed cognition. The increased RSFC between the

supramarginal gyrus and fronto-parietal network suggests that Su-soku facilitates a function of dynamically switching between internal and external attention according to task demands.

Title: Temporal changes in the state effect of meditation on executive function

Authors: *N. YAMAYA[1], S. IKEDA[1], Y. HOSHINO[2], H. TAKEUCHI[1], R. KAWASHIMA[1]; [1]Inst. of Development, Aging and Cancer (IDAC),Tohoku Univ., Sendai, Japan; [2]Sch. of Medicine, Tohoku Univ., Sendai, Japan

Abstract: One-session mindfulness meditation has been reported to temporarily enhance executive function, which is referred to as state effect. However, it remains unclear how the state effect changes over time immediately after a meditation session. Based on previous findings, we hypothesized that the state effect lasts for at least 20 minutes and decreases with time. To test the hypothesis, we focused on the state effects of two meditations: Su-soku and sham meditations (i.e., mind-wandering). The Su-soku meditation was performed by focusing on and silently counting one's breaths. The sham meditation was performed by relaxing and keeping still. We recruited 39 healthy right-handed participants; 11 participants were excluded from the analysis for failing to complete the entire experiment. The participants were instructed to perform each meditation for ten minutes in the meditation session. To evaluate the temporal changes in the state effect on executive function, the participants performed the Stroop task at the following five time points: immediately before and after each mediation, 20, 40, and 60 minutes after each meditation. The Stroop interference (i.e., the response time of incongruent minus neutral) was used to evaluate executive function. In addition, the participants were asked to answer subjective assessments: mood scale (all the time points), effort to each meditation, and sleepiness (immediately before and after each meditation). The Stroop interference and the mood scale were analyzed across two within-subjects factors (1st factor: Su-soku/sham, 2nd factor: all the time points), using two-way repeated-measures analysis of variance. The effort and sleepiness were compared between Su-soku and sham using the Wilcoxon signed-rank test. In the Stroop interference, we observed a statitstically significant interaction effect as expected [$F(4, 108) = 2.921$, $p = 0.02$]. As a post-hoc test, we examined differences between Su-soku and sham at each timepoint using the Wilcoxon signed-rank test. Contrary to our expectations, Su-soku showed better Stroop interference than sham only at 60 minutes after the meditation ($Z = -2.437$,

p = 0.015, medium effect size r = -0.46). On the other hand, we observed no significant interaction effect in the mood and no significant differences in the effort and the sleepiness. Therefore, the significant differences of task performance between Su-soku and sham cannot be explained by effects of the mood, effort, and sleepiness. Although the obtained results were inconsistent with our hypothesis, the results suggest that Su-soku showed stable task performance even 60 minutes after the meditation compared to sham.

Title: Resting state functional connectivity of the amygdala and bed nucleus stria terminalis (BNST) in response to threat bias

Authors: *S. K. JENKS[1], C.-S. R. LI[2], S. HU[1];
[1]Dept. of Psychology, SUNY Oswego, Oswego, NY; [2]Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT

Abstract: This study investigated the resting state functional connectivity (rsFC) of the amygdala and bed nucleus stria terminalis (BNST) in healthy controls (HC) and patients with anxiety-related disorders (PAD, ICD-9) performing a Dot-Probe task. Resting state functional magnetic resonance imaging (fMRI) data and behavioral data were obtained from the Nathan Kline Institute (NKI) - Rockland Sample. Eighty-three HC and 30 PAD performed a Dot-Probe task in which two faces appeared (neutral, threatening, or happy) on each side of the screen. A subsequent dot appeared on either side replacing the face, instructing a button press to the corresponding location. Threat bias was computed as the difference in reaction time (RT) of the response to the dot replacing neutral faces and that replacing threatening faces (i.e., RT in neutral - RT in threat). A positive threat bias indicates faster response to the dot replacing threatening faces, a frequent observation in patients with anxiety disorders. We first compared whole brain rsFC of amygdala and BNST between the two groups. Compared to PAD, HC showed greater positive amygdala rsFC to the posterior cingulate cortex (PCC) and cerebellum, and greater positive BNST rsFC to the PCC; PAD did not show greater connectivity than HC at the same threshold. We then performed regressions between threat bias and rsFC of amygdala and BNST, respectively, in each group, with age as a covariate. HC showed amygdala-thalamus rsFC in positive correlation with threat bias, and PAD showed BNST-caudate rsFC in positive correlation with threat bias. On the other hand, HC did not show significant BNST rsFC and

PAD did not show significant amygdala rsFC in correlation with threat bias. Region of interest (ROI) analysis confirmed that the correlations between threat bias and amygdala-thalamus rsFC and between threat bias and BNST-caudate rsFC were significantly different between the two groups. These results suggest that the amygdala and BNST connectivities may represent important neural markers of anxiety disorders.

Title: Alpha and theta oscillations as a measure for cognitive workload - Why do they fail in certain settings and what do they really mean?

Authors: *D. MIKLODY, L. VAUTH, B. BLANKERTZ;
Technische Univ. Berlin, Berlin, Germany

Abstract: Using electroencephalography (EEG), higher cognitive workload is commonly linked to decreasing parieto-occipital alpha and increasing frontal theta oscillations also relevant in visual attention and working memory. In a series of studies, we investigated this connection in realistic scenarios. One study with a complex maneuvering task in a tug-boat simulator did not show a systematic alpha/theta effect. The alpha effect was also absent in an auditory n-back task during easy ship navigation, indicating that it is not a general measure of cognitive workload.
In the present study, we used the workload-inducing n-back task in a laboratory setting (N=10, ages 23 to 37, 6 female) in different modalities (auditory/visual/bimodal) while evaluating the effect on alpha and theta in EEG (32 channels) comparing the power spectral densities. We expected a modality-dependent effect on alpha.
We found a higher level of frontal theta for high rather than low workload for all conditions. Between the conditions, the only difference was in low workload a higher theta in bimodal than in auditory.
The alpha decreased with increasing workload for all conditions in parieto-occipital electrodes. Alpha was highest for auditory, followed by bimodal and lowest for visual-only conditions. Close to auditory processing areas, we observed a change in alpha with certain characteristics limited to auditory and bimodal. The effect was stronger in bimodal with lateralization at the peak (9Hz) more to the right while to the left for auditory. Differences are significant ($p<=0.05$).
In summary, the parieto-occipital alpha level commonly used for workload shows a weaker effect in the tasks involving auditory attention. Auditory attention has additional effects including decreased characteristic frequency.

This leads us to the conclusion that alpha and theta levels do not measure cognitive workload, but the processes of attention/suppression and working memory which are modulated by cognitive workload. With high workload, the differences between conditions decrease as attention/suppression is generally high.

Title: Population motor attention fields in human parietal cortex: Variation in pAFs predicts individual variation in behavior

Authors: *W. E. HUDDLESTON[1], A. S. GREENBERG[2], E. A. DEYOE[3];
[1]Kinesiology: Integrative Hlth. Care & Performance, Univ. of Wisconsin - Milwaukee, Milwaukee, WI; [2]Dept. of Psychology, Univ. of Wisconsin-Milwaukee, Milwaukee, WI; [3]Dept. of Radiology, Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Attention shapes perception and action by modulating a network of hierarchical brain maps in specific topographic patterns (cortical “population attention fields”; pAF) that can provide predictive models of behavior if quantified at the individual level. Yet, we lack a comprehensive, quantitative account of attention-related brain mechanisms responsible for variable behaviors across individuals and modalities. We **hypothesize** that variations in motor pAF size would account for *individual differences* in the crowding limit across saccadic motor tasks in healthy individuals. We predicted that individuals with relatively narrow pAFs would

demonstrate more precise saccades than individuals with broad pAFs. Nine participants completed a delayed saccade task during fMRI at 7 Tesla (GE, Inc) while in-scanner eye movements were quantified. Our Attentional Drift Design (ADD) required participants to selectively attend to a centrally presented RSVP stream surrounded by a thin circular outline (radius 10°) representing clock positions on a circle. Every 4 seconds, a digit appearing in the RSVP stream cued the participant to prepare an accurate saccade to the indicated 'clock' location (e.g., 3 = 3:00). However, participants delayed saccade execution until a rarely presented 'X' appeared in the RSVP stream (approx. 5 times per run). The cued locations were incremented sequentially through 24 locations around the circle, creating a focus of motor attention (i.e., saccade intention) drifting through a saccade target map modulating the successive locations representing the intended saccade trajectories. Absolute errors in both the horizontal and vertical directions of initial saccade endpoints relative to the cued target location were correlated with motor pAF sizes in saccade-related maps. fMRI data from the ADD task were used to constrain a model of the size and shape of the focus of attention, the voxel's motor pAF. Preliminary data demonstrate a trajectory-specific relationship between parietal motor pAF diameter and saccade accuracy across participants, suggesting that parietal cortex is critical for the observed behavioral limitations. Establishing a firm, predictive link between brain mechanisms and behavior will ultimately lead to a more "evidence-based" framework for diagnosing, managing, and even ameliorating attention-related deficits such as hemispatial neglect or Alzheimer's Disease.

Title: Deep learning applied to spectral ERP data for ADHD discrimination

Authors: *L. DUBREUIL-VALL[1,2], G. RUFFINI[2], J. A. CAMPRODON[1];
[1]Massachusetts Gen. Hospital, Harvard Med. Sch., Boston, MA; [2]Neuroelectrics, Cambridge, MA

Abstract: Background: Attention deficit hyperactivity disorder (ADHD) is a heterogeneous neurodevelopmental disorder that affects 5% of the pediatric and adult population worldwide.

The diagnosis remains essentially clinical, based on history and exam, with no available biomarkers. On the other hand, machine and deep learning systems have been increasingly used in clinical applications with promising results in prognosis and diagnosis applications. **Methods:** In this paper, we describe a deep convolutional neural network (DCNN) for ADHD classification derived from the time-frequency decomposition of electroencephalography data (EEG), particularly of event-related potentials (ERP) collected from 20 ADHD adult patients and 20 healthy controls (HC) while they performed the Eriksen-Flanker task. For comparison purposes, we trained another DCNN with a dataset of spontaneous EEG data recorded while the same subjects and ADHD patients were at resting state with eyes closed. **Results:** The DCNN model reaches a classification accuracy of 88%, superior to other deep learning approaches and superior to resting state EEG spectrograms, with the key advantage of avoiding the need for manual selection of EEG spectral or channel features. Through the use of feature visualization techniques, we show that the main features exciting the DCNN nodes are a decreased power in the alpha band and an increased power in the delta band around 100ms for ADHD patients compared to HC, suggestive of attentional and inhibition deficits, which has been previously suggested as a neurophyisiological signature of ADHD. **Discussion:** In this study we present a viable deep learning model for effective discrimination of patients with ADHD, providing a new tool for the analysis of EEG dynamics in ADHD and supporting the potential of deep learning strategies for biomarker development in neuropsychiatry. While confirmation with larger clinical samples is necessary, these results highlight the potential of this methodology to develop CNS biomarkers of practical clinical utility.

Title: Neural processing of unattended spatial locations predicts the detection of attended visual targets

Authors: *C. LUO, N. DING;
Zhejiang Univ., Hangzhou, China

Abstract: Individuals vary in their ability to detect visual targets in a complex visual scene. Here, we use EEG to investigate potential neural correlates of individual performance during a visual target detection task. In the experiment, colored circles are presented in a circular

grayscale background. The background is either simple, i.e., a gray screen, or complex, i.e., a grayscale cartoon movie and is divided into a central region and a peripheral region, which fluctuate with distinct time signatures. The circles are either purple or yellow, presented at random times in the random position of the central region and peripheral region. The participants are requested to press a button as soon as possible when a target circle (yellow circle) appears in the central region of the background. We analyze the event-related potentials (ERP) evoked by the colored circles and by the fluctuations of the central/peripheral regions of the visual background. It is found that when the background is complex, the detection accuracy is lower, the reaction time is longer, and the P300 response evoked by the visual target is weaker. In the complex background condition, both the P300 amplitude and the ERP evoked by peripheral fluctuations in the visual background can predict individual detection performance (both the detection accuracy and the reaction time). Importantly, the P300 and the peripheral ERP response capture different neurophysiological processes in the detection task so that jointly considering these two factors can better predict individual performance. These results suggest that the individual ability to detect visual targets in a complex visual scene is modulated by visual processing in both the attended visual region and the unattended visual region.

Title: Qigong movement meditation impacts neural correlates of attention and sensorimotor function in a population with cancer-related fatigue: A pilot clinical trial

Authors: *S. TEMEREANCA[1], C. S. ZIMMERMAN[2], D. DANIELS[1], B. CULLEN[2], H. HUGHES[3], T. CANNONIER[1], C. E. KERR[2], S. R. JONES[1];
[1]Dept. of Neurosci., Brown Univ., Providence, RI; [2]Warren Alpert Med. Sch. of Brown Univ., Providence, RI; [3]Fordham Univ., Bronx, NY

Abstract: Movement meditation training has been associated with health benefits, yet little is understood about the underlying brain-body mechanisms. Qigong, a form of movement meditation, combines low-impact body movements with meditation, training the mind to focus and engage those movements. In this pilot randomized controlled clinical trial, we test whether ten-weeks of Qigong training is not inferior to an exercise-nutrition control program in reducing fatigue (via the FACIT-Fatigue Questionnaire) in 48 female cancer survivors with cancer-related

fatigue (CRF). The study employs multi-modal physiological measures of brain, cardiorespiratory, muscle dynamics, as well as inflammatory immune markers as secondary outcomes. Here we focus on treatment effects on sensorimotor function assessed using simultaneous electroencephalography (EEG) and electromyography (EMG) during a tactile discrimination task and a precision grip task. We found that Qigong is not inferior to the exercise-nutrition program in improving fatigue in cancer survivors, with both interventions significantly reducing fatigue. Consistent with previous research, in both groups, cued-attention modulated beta (15-29 Hz) power measured from EEG electrodes over the sensorimotor cortex, showing decreased power 400-1000 ms after attention was cued to the contralateral hand and increased power after attention was cued to the ipsilateral hand. Further, while both therapies impacted attentional modulation of beta power, these changes occurred in opposite directions, with larger post-treatment attentional modulation of beta in one group and smaller in the other. No consistent attentional modulation of alpha (7-14 Hz) power occurred at the population level before or after treatments, albeit changes in alpha activity were measured in several individual subjects. Ongoing analysis examines the impact of treatment on the EMG activity as well as EEG-EMG beta corticomuscular coherence. This study helps identify potential EEG biomarkers of physiological effects of movement therapy on sensorimotor function and attention. Effect size estimates derived here will be used for sample size determination in subsequent clinical trials.

Title: The effect of mindfulness-based cognitive therapy on event-related potential markers of attentional bias in anxiety

Authors: *R. S. GUPTA[1], D. M. FRESCO[2], A. BERNSTEIN[3], H. KANG[4], E. M. MOHR[4], P. L. A. SCHOENBERG[4], D. R. VAGO[5];
[1]Vanderbilt Univ., Nashville, TN; [2]Kent State Univ., Kent, OH; [3]Univ. of Haifa, Haifa, Israel; [5]Physical Med. & Rehabilitation; Psychiatry & Behavioral Sci., [4]Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract: Anxiety disorders are associated with attentional bias to threat, which refers to differential attentional allocation towards threatening stimuli relative to neutral stimuli. Anxious

individuals direct their attention toward threat during early, automatic stages of processing, whereas during later, more strategic stages of processing, they tend to direct their attention away from threat. Attentional bias may prolong anxiety states by placing inordinate priority on potential threats in the environment, thus intensifying anxious mood states. Using a dot-probe (DP) paradigm, Mueller and colleagues (2009) observed that individuals with social anxiety disorder display enhanced P1 event-related potential (ERP) component amplitudes to angry–neutral versus happy–neutral face pairs, suggesting early hypervigilance to angry faces, and decreased P1 amplitudes to probes replacing emotional (angry and happy) versus neutral faces, suggesting reduced visual processing of emotionally salient locations at later stages of information processing—potentially a manifestation of attentional avoidance. In their mindfulness model, Vago and Silbersweig (2012) propose that meditation improves the control of attention by improving efficiency of engagement and disengagement processes, thereby reducing bias of attention. This study investigates the effects of Mindfulness-Based Cognitive Therapy (MBCT) on P1 ERPs time-locked to angry-neutral and happy-neutral face pair cues and probes in a DP task with anxious populations. Individuals with moderate to high levels of trait anxiety (n=42) will be recruited. Before and after MBCT, P1 amplitudes and latencies to cues and probes will be monitored. In our preliminary pre-MBCT data, we observed (1) longer P1-cue latencies to angry-neutral and happy-neutral face pairs, (2) larger P1-cue amplitudes for angry-neutral versus happy-neutral face pairs, (3) larger P1 amplitudes to probes replacing angry versus neutral faces, and (4) larger P1 amplitudes to probes replacing happy versus neutral faces. However, in our preliminary post-MBCT data, we observed (1) shorter P1-cue latencies to angry-neutral and happy-neutral face pairs, (2) larger P1 amplitudes for happy-neutral versus angry-neutral face pairs, (3) larger P1 amplitudes to probes replacing neutral versus angry faces, and (4) larger P1 amplitudes to probes replacing happy versus neutral faces. These preliminary results suggest that mindfulness targets and decreases threat-related attentional bias, leading to faster processing of emotional faces and more attentional allocation to non-threatening faces.

Title: Leftward bias in visuospatial attention during a non-conscious working memory task

Authors: *T. PEDALE[1], A. FONTAN[1], F. GRILL[1], F. BERGSTRÖM[2], J. ERIKSSON[1]; [1]Dept. of Integrative Med. Biol., Umeå Univ., Umeå, Sweden; [2]Coimbra Univ., Coimbra, Portugal

Abstract: A critical feature of working memory is the ability to retain task-relevant information while discarding task-irrelevant information. Previous research has demonstrated that also non-conscious information can be maintained and affect subsequent behavior. However, little is known about the possibility to prioritize and maintain non-conscious task-relevant stimuli and the neural correlates supporting this process. Here, during fMRI, we used continuous flash suppression to present stimuli non-consciously while participants performed a delayed match-to-sample task in which the task relevance of the stimuli was manipulated. An unexpected finding was that the behavioral performance was significantly better than chance when the non-conscious task-relevant targets were presented in the left visual field. This asymmetry was also supported at the neural level; multivariate pattern analyses of the BOLD signal in the occipital cortex were better at classifying the presence versus absence of the non-conscious stimuli when the targets were presented in the left than in the right visual field. Such behavioral and neural asymmetries are in agreement with the pseudo-neglect phenomenon in healthy subjects, consisting of a leftward bias in visuospatial attention. The asymmetry could be explained by different contributions of right and left parietal regions during attentional tasks. We hypothesize that the leftward bias could be evident specifically for non-consciously presented information, due to a reduction in crosstalk between hemispheres during non-conscious processing. Further fMRI analyses may help us to clarify the neural mechanisms supporting such attentional asymmetry during non-conscious working-memory tasks and possibly confirm the different contributions of the right and left parietal attentional regions during the prioritization of non-consciously perceived information.

Title: Are you concentrating or mind-wandering? Electroencephalogram signals reveal differences in attentional states

Authors: *H.-H. LEE[1], C.-Y. SHIH[2], Z.-L. CHEN[3], A.-Y. WU[2], S.-L. YEH[1];
[1]Dept. of Psychology, [2]Grad. Inst. of Electronics Engin., [3]Grad. Inst. of Brain and Mind Sci., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: When performing tasks, sustained attention is necessary for us to focus on the ongoing task and ignore irrelevant thoughts during information processing. However, technological advancement nowadays leads to the current era of distraction that people spend nearly half of the time mind-wandering. This might cause devastating effects while operating machines or jeopardize the efficiency of learning. Attentional training to regain sustained attention for longer time is thus imperative. The first step, then, is to detect the current attentional state. Participants were recruited to conduct the sustained attention to response task (SART) while their brain waves were recorded by 32-channels electroencephalogram (EEG). They were instructed to press the button as quickly as possible when they saw a letter (randomly selected from A to Z) except for the letter "C" that required them to withhold the response (stop trials). A probe question was presented at the end of each run, asking participants to rate how concentrated they were just now with a 7-point Likert scale. By analyzing the 10-second time window of FP1, FP2, and Fz channels in alpha, beta, theta, and gamma band powers prior to the target C and the probe question, we found different frequency powers in self-rated focused and non-focused state: higher powers in alpha, beta, and theta band for the self-rated focused state compared to the non-focused state. However, no such difference was found in the powers between the successful stop and fail-to-stop trials. This study suggested that EEG signals could be served as a predictor for states of sustained attention and could be further utilized in educational occasions such as distance learning to monitor students' attentional state instantly. The different patterns of brain responses found for subjective and objective measures of sustained attention indicate different underlying mechanisms of sustained attention with or without awareness.

Title: Dynamics of posterior hemispheric activity related to variable vs static cue-target interval

Authors: *A. DREW[1], K. GRAY[1], A. T. KARST[2];
[1]Miami Univ., Oxford, OH; [2]Psychology, Univ. of Wisconsin, Oshkosh, Oshkosh, WI

Abstract: The N2pc ERP component has been labeled as a marker of visual attentional selectivity because it is elicited when a participant attends to a stimulus in a lateral portion of the

visual field (Eimer, 1996). However, researchers debate what specific aspect of visual selectivity is driving the hemispheric differences in neural activity underlying the N2pc. One perspective holds that the localization of relevant information triggers these hemispheric differences (Drew & Karst, 2019; Tan & Wyble, 2015). The current work investigates static and variable intervals between a spatial cue and a target, with regard to subsequent N2pc observations. Two experiments asked participants to identify numbers amid letters presented in a dual rapid serial visual presentation paradigm. In Experiment 1, a spatial cue occurred immediately prior to the number target, and indicated the location of an upcoming target. In Experiment 2, a spatial cue occurred either immediately prior to the number target, or 700ms prior to the target. Experiment 1 showed that N2pc activity was present for cues presented in isolation, and cues that preceded targets, whereas targets presented after a cue did not elicit N2pc activity. This result supports the notion that spatial processing is driving activity giving rise to the N2pc. Experiment 2 demonstrated that when cue-target intervals are uncertain, the N2pc elicited by cue stimuli is altered. Specifically, when cues immediately precede targets, the N2pc is extended in latency such that mean amplitudes for both target and cue epochs represent an observed N2pc component. When cues are presented in isolation, or preceding targets by 700ms, an N2pc is observed with a more standard latency. These results comply with episodic models of visual attention which posit flexibly-gated selection mechanisms that operate on a time-course consistent with observations from the present studies (Wyble, Bowman, & Nieuwenstein, 2009).

Title: The effect of perceptual load on neural oscillations in multi-target visual search with free eye-movements

Authors: *A. M. HARRIS[1], J. O. EAYRS[1], O. JENSEN[2], N. LAVIE[1];
[1]Inst. of Cognitive Neurosci., Univ. Col. London, London, United Kingdom; [2]Sch. of Psychology, Univ. of Birmingham, Birmingham, United Kingdom

Abstract: Visual attention has been linked to neural oscillations in multiple frequency bands, in particular, modulations of ~10 Hz alpha amplitude and the phase of ~5 Hz theta oscillations. Alpha amplitude reflects the degree of cortical inhibition, with attention-related changes linked to neural gain modulation (e.g., Iemi et al., 2017) and gating of neural information flow (Jensen

& Mazaheri, 2010). Theta phase has also been strongly linked to attention, with recent work proposing theta oscillations reflect cyclic changes in neural signal enhancement (Fiebelkorn & Kastner, 2018). The relationship between these signals and attention has typically been ascertained as a comparison between attended and unattended conditions, however, attentional allocation is not all or none. Prior work has demonstrated that the degree of attentional engagement varies with the perceptual load of a task (Lavie & Cox, 1997). When perceptual load is low (e.g., during simple feature search) attention is engaged to some extent, however, when perceptual load is high (e.g., during conjunction search) attention is engaged more strongly. Here we asked how the amplitude and phase of neural oscillations were modulated by the degree of attentional engagement required to perform a multi-target visual search with free eye-movements. Participants searched for targets defined by either a shape feature (low load) or conjunctions of shape and colour (high load). Level of attentional engagement was confirmed by comparing performance on an auditory detection task performed during the visual search. Tone detection was significantly impaired under high (vs. low) load, confirming the manipulation of attentional engagement. EEG responses co-registered to the onset of nontarget fixations revealed that high load search was associated with significantly lower tonic alpha power and significantly higher fixation-locked theta phase alignment than low load search. These results demonstrate that different attentional requirements recruit alpha-amplitude- and theta-phase-mediated attentional processes to different extents, consistent with their role in an attentional system that is engaged to differing degrees depending on task requirements.

Title: Augmenting phasic norepinephrine activity with an irrelevant loud noise produces correlated increases in the amplitude of the P3 event-related potential, and the pattern of sparing and deficit observed in the attentional blink paradigm

Authors: *C. M. WARREN[1], A. S. HANCOCK[2], A. W. SNOWDEN[2], K.-D. TONA[3];
[2]Neurosci., [1]Utah State Univ., Logan, UT; [3]Psychology, Leiden Univ., Leiden, Netherlands

Abstract: Phasic norepinephrine (NE) release from the locus coeruleus (LC) transiently improves the signal-to-noise ratio of neural processing. NE has been linked to the accessory stimulus effect, whereby including an irrelevant tone simultaneously with a target stimulus typically improves performance through augmented phasic NE release (Tona, Murphy, Brown, & Nieuwenhuis, 2016). After a phasic release of NE, the LC undergoes a refractory-like period due to auto inhibition. This refractory-like period is a potential cause of a transient deficit in attention known as the attentional blink. The attentional blink refers to the phenomenon that when participants try to identify two targets embedded within a rapid serial presentation of distracter characters they exhibit a deficit for reporting the second target (T2) only within a very specific time-window relative to the first target (T1). If T2 falls less than 200 ms after T1, accuracy is high (termed "sparing"). If T2 falls >600 ms after T1, accuracy is normal. Only between 200 ms and 600 ms after T1, does T2 processing summer. This temporal profile shows a striking similarity to the temporal profile of phasic NE release, whereby processing benefits from a flood of NE within 200 ms, and then may suffer for a half second during the period of LC auto inhibition. We introduced an accessory stimulus consisting of an irrelevant loud tone to the attentional blink paradigm, to test if augmenting phasic NE release would affect the AB in a manner consistent with NE effects. The theory that the attentional blink is due to auto inhibition of the LC predicts that including an accessory stimulus simultaneously with T1 will (1) improve performance of T1, (2) improve performance of T2 when T2 is presented very close in time to T1, and (3) decrease accuracy for T2 if T2 is presented during LC auto inhibition. In addition, we recorded the electroencephalograph to examine a component of the event-related brain potential called the P3, which may be an electrophysiological manifestation of phasic NE. Analysis of data from 34 participants indicates that including a loud tone with T1 improved T1 performance, and improved T2 performance within 160 ms of tone onset, and this benefit to T2 switched to a deficit by 480 ms after tone onset. In addition, including the accessory stimulus increased the amplitude of the P3 component. Most importantly, the effect of the accessory stimulus on the attentional blink was correlated with the effect of the accessory stimulus on P3 amplitude. This experiment provides strong convergent evidence that phasic NE activity underlies the P3, the attentional blink, and the accessory stimulus effect.

Title: Moving vs stationary: Do we attend to a 'pop-out' stimulus equally in both cases?

Authors: *P. GHOSH, D. ROY, A. BANERJEE;
Natl. Brain Res. Centre, Manesar, GURGAON, India

Abstract: The ability to detect and orient attention toward salient, significant changes around us is critical for survival. While we need focussed attention for any goal-directed behavior, the temporal component of attention becomes very important in conditions that demand rapid shift of attention like applying brakes during driving upon seeing a pedestrian suddenly crossing the road. This brings forth two concepts: top-down attention that is critical for any goal driven activity and bottom-up attention that involves a reorientation of attention toward an unexpected (salient) stimulus. In the latter, it is the 'pop-out' feature of the stimulus that demands a shift in attention from the ongoing task. But do the underlying neural signatures involved in this attentional shift remain same when we look at a static versus a dynamic stimulus?
Using a custom-designed behavioral paradigm and simultaneous high-density EEG, we investigated the effect of saliency during two different kinds of visual search: 1) where both the task and salient stimulus were static/stationary and 2) where both the task and salient stimulus were dynamic/moving. Data were collected from 22 right-handed healthy human volunteers (21-29 years, 11 females) who signed informed consent forms, approved by the Institutional Human Ethics Committee of NBRC, India.
We observed that along with a slower reaction time in trials with saliency, the spectral power in the alpha frequency band was also significantly higher as compared to the trials without saliency for both static and dynamic tasks. The increase in alpha power was very similar in both the task conditions. Although the deployment of attention for a static task is very different from that of a dynamic task, their spectral energy enhancement was similar upon the occurrence of saliency. The underlying sources of these enhanced alpha power were also similar. We observed that the anterior insula (part of salience network) and the ventral frontal cortex (part of ventral attention network) showed an increased activation in both dynamic and static tasks. Additionally, for the dynamic task there was activation in the right temporo-parietal junction (part of ventral attention network), which is activated in response to a behaviorally relevant stimulus. The salient stimulus used in the dynamic task, was behaviorally relevant to the task whereas in the static task it was not, suggesting that the sources contributing to the enhanced alpha power change with the type of salient stimuli associated but not with the task condition *per se*. Further studies on other sensory modalities can bring forth a more general role of alpha power in the brain beyond simple visual processing tasks.

Title: Pre-stimulus alpha oscillations reflect eye dominance and bias object perception

Authors: *E. EL RASSI[1], D. ENGEMANN[2], N. WEISZ[3], V. VAN WASSENHOVE[4]; [1]Universirty of Salzburg, Salzburg, Austria; [2]INRIA, Paris, France; [3]Ctr. for Cognitive Neurosci., Univ. of Salzburg, Salzburg, Austria; [4]CEA.DSV.I2BM.Neurospin, Gif Sur Yvette, France

Abstract: Ongoing fluctuations in neural activity interact with perceptual processes. For example, the phase of pre-stimulus alpha oscillations influence whether a near-threshold target will be detected or not, and in perceptually ambiguous settings, changes in the power of alpha oscillations have been shown to counter-act individual priors or biases. Recent findings have suggested that serial order is one such individual bias such that people might be naturally biased towards perceiving an auditory or visual stimulus first. Consistent with this, it has been suggested that alpha power may regulate the timing of sensory inputs such that higher alpha power inhibits the structural prior/bias. In the present study we asked whether alpha dynamics could inform on a basic structural bias (eye dominance) and thereby predict subsequent perceptual outcomes. Specifically, at the onset of binocular rivalry, people are biased towards perceiving (first) the content shown to the dominant eye and then the content of the non-dominant eye. In this magnetoencephalography study, we presented human participants with an ambiguous image, briefly, and repeatedly. The image consisted of 2 gabor patches: each was either red or blue, and either right- or left-oriented. Participants wore red/blue glasses, looked at the image, and indicated its perceived orientation each time. Before the experiment, we determined each participant's dominant eye. We then could label MEG trials as a function of whether they were perceived with the dominant or non-dominant eye. We found evidence that higher pre-stimulus visual alpha power was needed to suppress the dominant eye compared to the non-dominant one.

Title: Mobile brain/body imaging (MoBI) during systematic changes in cognitive load

Authors: *D. P. RICHARDSON[1], K. A. MAZUREK[2], N. ABRAHAM[2], S. HOFFMAN[2], S. MIZOBUCHI[2], J. J. FOXE[2], E. G. FREEDMAN[2];

Abstract: Background Cognitive motor interference is thought to emerge as cognitive load exceeds an individual's ability to divide attention between coincident cognitive and motor tasks. This competition for limited neural resources erodes performance of either or both tasks, and is prominently demonstrated in individuals with executive function deficits. Task switching paradigms are sensitive interrogators of executive function. Task-set reconfiguration has been proposed as a mechanism for switching between the relevant tasks, though this transition exacts a toll in the form of a behavioral switch-cost. These costs manifest as increases in response times evident even in healthy young adults. Our group has previously described differential electrophysiological responses related to whether a trial was a task repetition, preceded a switch, or was a task switch. Utilizing electroencephalography (EEG) based Mobile Brain/Body Imaging, we studied cue-based task switching in healthy young adults while sitting and walking. We examined the effect of increasing cognitive load through the addition of a physical task upon the electrophysiological response to task switching. **Methods** 19 healthy young adults (18-22 years old) participated in a cue-based task switching experiment with pseudorandom task sequences while sitting or walking on a treadmill. Trials were composed of cues followed by a stimulus of gabor pairs differing in spatial frequency and rotation projected on a screen in front of the participant. Magnitudes of differences in spatial frequency and rotation between gabor pairs varied. Cues instructed subjects to identify either the gabor with higher spatial frequency, or the gabor rotated further clockwise. 64-Channel EEG, whole body motion capture, and behavioral performance were synchronously recorded. **Results** Electrophysiological alterations related to trial type (task repetitions, trials preceding a switch, or task switch trials) or physical state (sitting or walking) were identified in the cue-target interval. Moreover, alterations related to both trial type and physical state were identified in the cue-target interval. When task repetition trials containing correct responses were stratified by trial difficulty based upon group

performance, EEG alterations related to both trial difficulty and physical state were identified. These findings suggest altered cognitive processing of sensory information and decision making dependent upon the degree and modal quality of cognitive load. We will next explore the expression of cognitive motor interactions in task switching in healthy older adults, and older adults with cognitive impairments.

Title: The effect of musical engagement on auditory selective attention

Authors: *R. H. DYE, Jr, S. E. DARNELL, M. A. IZQUIERDO, D. VELASQUEZ, M. O. BONDI, A. M. SHELDON;
Psychology, Loyola Univ. Chicago, Chicago, IL

Abstract: Musicianship has been found to enhance many cognitive abilities, including executive function, auditory memory, language processing, and selective attention. Most studies have compared groups of musicians and non-musicians, but musical engagement is a multidimensional construct consisting of at least music listening, musical instrument playing, and musical training. The goal of the current study was to identify which aspect of musical engagement was most associated with enhanced auditory selective attention. Participants (N=93) completed the Musical Use (MUSE) Survey (Chin and Rickard, 2012) to assess music listening, musical instrument playing, and musical training along with various styles of musical engagement. Auditory selective attention was assessed with a task in which listeners judged the direction of a level change of one of three concurrent components that were separated by 2 octaves (253, 1012, and 4048 Hz). Each component served as the target in different 200-trial blocks. The to-be-judged target component was presented alone in interval one, followed by all three components in intervals two and three. All three intervals were 300-ms in duration. Mean levels of each component in the second interval were set to 57 dB SPL, but each level was varied independently on each trial by adding a DL chosen from a Gaussian distribution with a mean of 0 and a standard deviation of 4 dB. The signs of the DLs were reversed in the third interval. Listeners reported whether the target component went up or down in level across intervals two and three, ignoring the levels of the other (distractor) components. A correlational analysis (Lutfi, 1995) was used to assess the relative weights given to each of the three components, the proportion of responses predicted from the weights, and proportion correct. The average target

weight (across the three target frequencies) was used as the metric of auditory selective attention. It was found that only index of musical instrument playing was significantly correlated with mean target weight (R=0.297). Passive listening and even musical training were not significantly correlated with mean target weight. Only actively playing a musical instrument enhances auditory selective attention.

Title: Unveiling the mathematical brain: A meta-analysis of brain regions supporting complex arithmetic operations

Authors: *E. WEST[1], U. OFOEZIE[2], A. SPAGNA[2];
[1]Dept. of Psychology, Barnard College, Columbia Univ., New York, NY; [2]Dept. of Psychology, Columbia Univ., New York, NY

Abstract: Performing arithmetic operations is a fundamental aspect of human cognition, and math ability is a predictor of academic as well as professional success. Although the quest for the "mathematical brain" has persisted since the advent of non-invasive neuroimaging techniques, it has not yet revealed a clear map of the brain regions and networks underlying this basic cognitive function. To fill gaps in prior literature and determine the cognitive processes involved in varied mathematic operations, we conducted a large-scale meta-analysis of peer-reviewed publications which investigated the neural substrate of arithmetic using an activation likelihood estimation method (Ginger-ALE v2.3.6). This method calculates the overlap of activation across prior studies by modeling the activation foci as 3D Gaussian distributions centered at the reported coordinates. It estimates the variability of the spatial location of activation foci across different studies by accounting for the number of participants included in each study. Five-thousand permutations were conducted to generate the null distribution of the ALE scores as the random spatial overlap across studies, and the ALE map computed from the real activation coordinates was then tested against this null distribution, resulting in a statistical map representing the *p*-values of the ALE scores. The *p*-value threshold was defined as cluster-level corrected $p < 0.001$, with FDR corrected $p < 0.001$. Results showed a domain-general network of brain regions was activated when performing a variety of mathematical operations (addition, subtraction, multiplication, division, and comparison) and included regions commonly associated with cognitive control. Specifically, significant activation was found in six clusters, including the

superior parietal lobe bilaterally, the anterior insular cortex bilaterally, and the inferior frontal gyrus bilaterally. Results suggest that complex mathematical operations might rely on the activation of the cognitive control network, supporting a cognitive control model of human intelligence.

Title: Distraction hangover: Cognitive effects of distraction during simulated driving

Authors: *J. SNIDER[1], L. CHUKOSKIE[2], A.-M. ENGLER[4], S. HACKER[4], L. HILL[4], J. TOWNSEND[3];
[1]UCSD, La Jolla, CA; [2]UCSD, LA Jolla, CA; [3]Dept Of Neurosci, UCSD, La Jolla, CA; [4]UC San Diego, La Jolla, CA

Abstract: That texting and driving is a dangerous combination comes as no surprise. Distracting a driver's attention from the road for even a few seconds is an accident waiting to happen, with more than 3000 deaths directly attributed to distracted driving in the US in 2017 (National Highway Traffic Safety Administration, 2018). Audio, hands-free communication may be a safer way to communicate with our devices than active texting, but it is unclear how distracting hands-free devices are.

The Center for Human Urban Mobility at UC San Diego augmented a driving simulator to test behavior with controlled levels of distraction. The simulator consists of an intuitive combination of a steering wheel, pedals, and screen-based simulation. In addition, we mounted a smart phone next to the simulator's steering wheel and programmed it to periodically ring or popup a text at preset locations in the simulated drive. For a hands-free call, participants accepted the call by touching the smartphone and responding vocally to a recorded question. During a text, an audio text sound alerted participants to read a short text message and respond to yes/no questions. We probed driving performance with a peripheral response task followed by a tailgating task, where participants maintained a constant distance to a lead car with a variable speed. Both tasks started with a baseline drive, without any phone distraction.

The primary behavioral outcome measures are percent correct in responding to the peripheral cue and speed coherence with the lead car during tailgating. In an initial cohort of 38 participants, we observed a significant drop in accuracy during distraction from 98.4(6)% to 88.3(6)% (mean(se), $F(1,37)=220$, $p<1e-10$) and a coherence drop from a respectable 0.50(3) to an abysmal 0.061(8) where some drivers even collided with the lead car ($F(1,37)=102$, $p<1e-10$). These are the expected distraction effects on driving, but interestingly hands-free and texting distraction modalities showed no significant difference in either main effect ($F(1,37)<0.2$, $p>0.65$) or interaction ($F(1,37)<0.5$, $p>0.48$). This is evidence that the distraction from a hands-free device is just as strong as reading a text.

Title: Volitional attention selectively enhances recognition memory

Authors: *K. ZIMAN, M. R. LEE, A. R. MARTINEZ, J. R. MANNING;
Dept. of Brain and Psychological Sci., Dartmouth Col., Hanover, NH

Abstract: Our attentional systems selectively filter aspects of ongoing experiences to optimize our behaviors. This filtering can also affect how we remember those experiences later: we may remember different aspects of the same perceptual experience depending on what we attended to. Here we used two novel variants of a Posner cueing task to study the effects of volitional attention on memory. In each trial, participants viewed two images (on the left and right of the screen, respectively) while fixating a central cross (verified using eyetracking data). Each image comprised a grayscale composite of a photograph of a face and an outdoor scene. In different blocks (Experiment 1) or individual trails (Experiment 2), participants were instructed to shift the focus of their attention, without moving their eyes, to either the face or scene component of either the left or right image. In this way, the participants' perceptual experiences were held (largely) constant throughout the experiment, but their volitional attention varied. We then asked all participants to perform a recognition memory task, where they rated a set of images according to how "familiar" they were (a proxy for how much the participants "remembered" each image). Half of the rated images were novel, and the remaining half of the images were drawn equally from the images we showed participants. Across both experiments, we found that attended images received a memory "boost" (i.e. higher familiarity). The opposite-category image from the attended-side image received a (smaller) memory boost. The category-matched image from the unattended side also received a (still smaller) memory boost. The unattended image on the unattended side was slightly suppressed relative to novel images (Experiment 1) or was indistinguishable from novel images (Experiment 2). Taken together, our results indicate that aspects of our experience that we attend to (or that share features or locations of attended aspects) are better remembered than unattended aspects of our experiences. In ongoing work, we are collecting neuroimaging data to study the neural basis of these phenomena. In particular, we are studying how the changing focus of volitional attention modulates the flow of information from primary sensory to memory areas.

Title: Pattern similarity in middle frontal gyrus reflects the target template during visual search

Authors: *X. YU, J. J. GENG;
Univ. of California Davis, Davis, CA

Abstract: Theories of attention commonly refer to the collection of target features in working or long-term memory as the "target template" (or "attentional template"). It is often assumed that the contents of the attentional template are veridical, but recent studies have found that it is adjusted to increase the target-to-distractor distinctiveness when distractors are similar to the target. However, it remains unclear where the biased target template is encoded in the brain (Scolari, Byers, and Serences, 2012). We investigated this problem using representational similarity analysis (RSA) of 20 healthy young adults' fMRI data. Subjects were asked to engage in a visual search "training" task, in which they searched for a target defined by color (e.g., blue-greenish), among three distractors with colors selected from one side of the target (e.g., greener). The target representation was measured on separate template "probe" trials, in which subjects reported if a single colored circle (e.g., ranging from blue to green) was target color or not. The behavioral results replicate previous findings that the target representation was shifted away from distractor color values, and sharpened to better exclude distractors (Yu and Geng, 2019). Subjects were also more accurate in the visual search when their templates were more distinct from distractors. A whole brain RSA searchlight was conducted using the pattern of probe trial responses as the behavioral representational dissimilarity matrix. The results identified bilateral middle frontal gyrus (MFG) and motor cortex as encoding an activation pattern correlated with the behavioral matrix. The same regions were activated during visual search, suggesting that MFG encodes the target template, which is shaped by the visual search context and reciprocally defines the relevant features for target selection.

Title: Slowing-down of resting state dynamic functional connectivity as a marker of cognitive dysfunction induced by sleep deprivation

Authors: D. LOMBARDO, C. CASSE-PERROT, O. BLIN, *D. BATTAGLIA, M. DIDIC; INS, Univ. Aix-Marseille, Marseille, France

Abstract: A substantial evidence suggests that dynamic Functional Connectivity (dFC) during both rest and task conditions is an indicator of performing cognitive processing.The shift to a dynamic chronnectome perspective is however hampered by the lack of a consensus on which are the best approaches to estimate not-artefactual dFC. We have recently introduced the notion of dFC speed, quantifying in a time-resolved manner the rate at which brain-wide FC networks are changing from one time-window to the next. We thus describe dFC as a smooth flow across continually morphing connectivity configurations, rather than as a non-stationary sequence of sharp inter-state transitions. Here we probe the hypothesis that differences in resting state dFC speed correlate with differences in cognitive performance, at the whole-brain level but also selectively within specific functional subnetworks.

In particular, we concentrate on Sleep Deprivation (SD) as a reversible model of cognitive dysfunction, which has also been proposed as a cognitive challenge model of cognitive impairments arising in amnesic Mild Cognitive Impairment and Alzheimer's disease. We then study how 24 hs of sleep deprivation affect our novel dFC speed markers, in relation to cognitive performance.

We observe that the speed of reconfiguration of resting state whole-brain FC networks (global dFC speed) is significantly slowed-down by SD. However, the reduction in this global dFC speed only poorly correlate with cognitive performance variations. On the contrary, we show strong correlations between performance variations in various tasks, including a Rapid Visual Processing (RVP, which probe the capacity for sustained visual attention and its executive control) and dFC speed defined now at the level of specific functional sub-networks. Unlike global dFC speed analyses -in which information about where network changes are happening is lost, because the rate of change is averaged over the whole brain-, modular dFC speed allows quantifying a different speed of dFC reconfiguration independently for each different sub-network of interest. In particular, we find that performance in the RVP attentional task correlates with the modular dFC speed of a characteristic fronto-parietal functional module but not with global dFC speed.

Therefore our findings suggest that analyses of dFC speed variations are well able to detect the temporal reorganization of resting state FC fluctuations after SD. Furthermore, beyond mere changes in reaction time or vigilance, our quantifications of dFC variations robustly track the magnitude of the cognitive performance impairments induced by SD within each specific subject.

Title: Neuropsychological profiles of a sample of Mexican pregnant women with and without LES

Authors: *D. CHINCHILLA[1], O. GALICIA-CASTILLO[1], C. CHAO[3], M. BUENROSTRO-JAUREGUI[2];
[1]Univ. Iberoamericana, Ciudad de México, Mexico; [2]Univ. Iberoamericana, Mexico, Mexico; [3]Universiad Iberoamericana, Ciudad de México, Mexico

Abstract: Introduction: Alterations in cognitive function are neuropsychiatric manifestations of systemic lupus erythematosus (SLE); they have been reported more frequently in women than in men. 81% of the healthy women that have been pregnant reported cognitive changes. **Objective:** Describe differences in cognitive function between healthy pregnant women and pregnant women with SLE. **Method:** A case-control study was carried out, including 50 participants, 29 women diagnosed with SLE and 21 healthy pregnant women. Neuropsychological and neurophysiological assessments were carried out between week 28-35 of gestation. **Results:** Pregnant patients with SLE presented mild to severe alterations in a 17.84% on the NEUROPSI scale; in MoCA test 40.47% presented scores below the cut-off point (≤ 26) with an average score of 23.57 ± 5.76. The P300 evoked potential reported averages of 297.3 ± 63.3ms and 3.89 ± 2.89mv in latency and amplitude respectively. Healthy pregnant women presented moderate to severe alterations in 20% of the NEUROPSI scale. 41.67% presented scores below the cut-off point with an average score of 23.28 ± 10.05 in the MoCA. In P300 evoked potential, the means in latency and amplitude were 294.4 ± 57.14ms and 5 ± 2.57mv. When we compared groups, we found statistically significant differences in the language sub-scale in the MoCA evaluation (t = 0.026). **Conclusion:** Both healthy pregnant women and with SLE presented alterations in cognitive function. The alterations found in pregnant women with SLE are similar to women with non-pregnant SLE previously reported. The language was the only cognitive function with alterations that showed statistically significant differences between the groups.

Title: Attentional engagement of frontoparietal cortex in infant fMRI

Authors: *C. T. ELLIS, L. J. SKALABAN, T. S. YATES, N. B. TURK-BROWNE;
Yale Univ., New Haven, CT

Abstract: Goal-directed and stimulus-driven modes of attention remain difficult to disentangle because they interact contingently in natural settings. For instance, a typical task for investigating stimulus-driven attention requires responding as quickly as possible to event onsets; yet, in order to do this, a participant must maintain and execute task instructions. Often overlooked is the opportunity to use early development as a model system for distinguishing cognitive processes with different trajectories. In this case, infants are thought to lack adult-like goal-directed attention but have robust stimulus-driven attention, allowing us to isolate the neural underpinnings of stimulus-driven attention. In particular, reorienting spatial attention to new or unexpected stimuli engages the frontoparietal network in adults, but this same network is also involved in goal pursuit. Here we investigate whether the frontoparietal attention network is involved in stimulus-driven attention in infants even with diminished goal-directed attention. We used event-related fMRI with awake, behaving infants while they performed a child-friendly Posner cuing task. Peripheral cues were presented briefly to infants before a peripheral target appeared in the same (valid) or opposite location (invalid), as well as trials where cues appeared bilaterally (neutral). Eye-tracking was used to measure reaction time (RT), namely the time taken to saccade to the target. We found evidence of behavioral facilitation in two small samples of younger (4-7 months) and older infants (18-24 months), with faster RTs to valid vs. invalid targets. Initial fMRI analyses suggest that when attention is directed to the wrong location (invalid trials) there is greater activation throughout frontoparietal cortex, compared to valid and neutral trials. This suggests that the frontoparietal network can be engaged in stimulus-driven reorienting of attention even in infants. This also tentatively suggests that even young infants can rely on frontal brain regions to allocate attention. More generally, the field of infant cognition relies heavily on looking time measures, and this work starts to provide a mechanistic account of the behavior to help inform ongoing debates in that field.

Title: Neural features associated with mind wandering: A simultaneous fMRI, EEG, and pupillometry study

Authors: *J. M. GROOT[1,2], N. M. BOAYUE[1], G. CSIFCSÁK[1], W. BOEKEL[3], R. HUSTER[4], B. U. FORSTMANN[2], M. MITTNER[1];
[1]UiT - The Arctic Univ. of Norway, Tromsø, Norway; [2]Univ. of Amsterdam, Amsterdam, Netherlands; [3]Erasmus Univ., Rotterdam, Netherlands; [4]Univ. of Oslo, Oslo, Norway

Abstract: Humans pervasively engage in shifting attentional focus from external demands toward internal processing of self-generated thoughts and feelings, irrespective of risking a loss of reward or causing crucial performance errors (Smallwood & Schooler, 2015). The brain network most strongly associated with mind wandering is the default mode network (DMN), showing increased activity during episodes of task-unrelated thoughts (TUT's; Fox et al., 2015). Additionally, the locus coeruleus/norepinephrine (LC/NE) system has been studied in relation to mind wandering, as it is thought to adaptively modulate neural gain of cortical neurons through tonic and phasic modes of operation (Aston-Jones & Cohen, 2005). However, the exact neural systems underlying task-related and task-unrelated attentional states and the mechanisms driving transitions between these states, as well as their temporal dynamics, remain largely unknown. Therefore, the purpose of this study was to resolve the spatio-temporal dynamics of TUT's in an attempt to explain how the interplay of neural systems gives rise to the subjective experience of mind wandering. Self-reported, probe-caught mind wandering was collected for 28 healthy adults during performance of the sustained attention to response task (SART) and simultaneous fMRI-EEG. Pupil diameter was recorded as a derivative for LC/NE tonic and phasic activity (Gilzenrat et al., 2010). Features of interest were extracted for each modality based on previous literature, including: activation in and connectivity between regions of the DMN and anti-correlated network (ACN); prestimulus alpha, beta, theta, and delta oscillations; event-related N1, P1, and P300 components; and baseline and evoked pupil dilation. This yielded a total of 87 features that were collectively fed into a support vector machine (SVM). Thought probe responses were used as target labels to train the SVM to help classify individual trials as either on- or off-task cognitive states, allowing subsequent analyses of neural signatures at the single-trial level. Preliminary results of classification performance show above chance level accuracy in

predicting episodes of TUT's. Unique contributions of each modality furthermore suggest that combining measures superior in conveying either temporal or spatial information improves predictive power. This indicates that multimodal classification enabling single-trial analyses may provide new and powerful means to gain mechanistic insights into the neural basis of attentional fluctuations.

Title: Steady-state visual evoked potentials reveal parietal contributions to abstract numerosity

Authors: ***P. J. KOHLER**[1,2], B. D. MCCANDLISS[3], E. BARZEGARAN[2], A. M. NORCIA[2]; [1]Dept. of Psychology and Ctr. for Vision Res., York Univ., Toronto, ON, Canada; [2]Dept. of Psychology, [3]Grad. Sch. of Educ., Stanford Univ., Stanford, CA

Abstract: Steady-state visual evoked potentials (SSVEPs) are an EEG measure that can provide portable, high-signal-to-noise assays of cortical tuning to specific representations, and thus have high potential value for educational neuroscience. Fast periodic oddball stimulation is useful for isolating SSVEPs related to processing of complex stimuli such as faces, words, and objects (Norcia et al., 2015). When applied towards measuring cortical responses to abstract numerosity, the oddball technique has until now identified responses originating in early visual cortex (Park, 2018; Guillaume et al., 2018) rather than in parietal areas as indicated by functional MRI studies. Here, we address this discrepancy by exploring novel conditions, such as using equiluminent discs as stimuli, slower stimulation rates, and smaller quantities. In Experiment 1, arrays of 5 discs were presented, updating at a "carrier" frequency of 3, 3.75, or 6 Hz, with size, area, or density changing on each update. On half the trials, changes in numerosity (arrays of 8 dots) were introduced at a slower "oddball" frequency, ~1/6 of the carrier frequency (1 Hz, 0.75 Hz, or 0.5 Hz). After each trial (5 stimulus cycles), participants were asked if a number change had occurred. SSVEPs generated by the carrier frequency were centered over occipital cortex, consistent with visual responses to the array updates. By contrast, the oddball frequency produced parietal SSVEPs associated with changes in numerosity, evident as early as 200 ms after oddball onset. Slower frequencies produced the most reliable oddball responses, so we used the 3 Hz (carrier) and 0.5 Hz (oddball) frequency in additional experiments. In Experiment 2, we

compared number change events that were above the behavioral threshold for detecting a number change (i.e. carrier = 8 dots, oddball = 5 dots) or below threshold (carrier = 8 dots, oddball = 9 dots). Only the supra-threshold conditions produced parietal oddball responses, reflecting a "distance effect". Experiment 3 replicated the parietal oddball SSVEP effect across four distinct supra-threshold carrier-oddball pairings. Finally, we passed our stimuli through a two-stage model of early visual cortex responses (Kay et al., 2013), and found that although our disc arrays were well-matched on non-number dimensions, the model produced some evidence of dissociable responses to number-oddball arrays. These findings support the use of oddball SSVEPs for measuring parietal computations of number, but highlight that care must be taken to rule out the contribution of generic visual processing. A model-based approach to stimulus generation would be a helpful step in this direction.

Title: Prism adaptation changes resting state functional connectivity in the dorsal stream of visual attention networks in healthy adults

Authors: *K. TSUJIMOTO;
Univ. of Tokyo Hosp., Tokyo, Japan

Abstract: Unilateral spatial neglect (USN) can be defined as a failure to orient to contra-lesional stimuli in the absence of either sensory or motor defects. Although the behavioral and clinical effects of prism adaptation (PA) are widely accepted, its underlying mechanisms are still controversial. However, recent neuroimaging and neurophysiological studies support the idea that PA affects the visual attention and sensorimotor networks including in the parietal cortex and cerebellum. We investigate the effect of PA on functional connectivity (FC) in attention and sensorimotor networks, evaluating changes of resting-state FC before and after PA in healthy individuals using functional magnetic resonance imaging (fMRI). A total of 19 healthy participants (mean age 28.5 ± 5.5; 8 men and 11 women) took part in the study. The pointing tasks were performed four times throughout the entire session (baseline phase, prism adaptation phase, post prism adaptation phase (Post1), and 1 h after the post prism adaptation phase (Post2). The visual stimuli were displayed on a 25-inch monitor with a touch panel display. An optical

prism inducing a rightward shift with a 20-diopter was used for both eyes. The baseline phase was six pointing movements, without the prism. The prism adaptation phase consisted of 90 pointing movements with the prism. The Post1 and Post2 phases were both six pointing movements, without the prism. MR sessions were conducted before PA, after PA (Post1), and 1 h after PA (Post2). Functional images were acquired on a 1.5-T MR scanner. A seed-based correlation analysis was performed to investigate the FC in the attention network. We investigated the difference of FC in a Dorsal Attention Network (DAN) and Ventral Attention Network in the three phases. In addition, FEF and ACC are commonly coactivated for cognitive saccade tasks. During prism exposure, there was a significant pointing error in the first trial (3.03 ± 0.19 cm) to the right (that is in the direction for the displacement). In the Post1 phase, there was a significant pointing error (-2.08 ± 0.16 cm) to the left, which decreased in the Post2 phase (-1.08 ± 0.11 cm). The FC between the right frontal eye (FEF) field and the right intraparietal sulcus was significantly decreased at Post1 and that between the right FEF and the right anterior cingulate cortex was significantly increased after PA and recovered within 1 h. This is the first study to demonstrate transient changes of resting-state FC in the right DAN by PA in healthy adults using fMRI. These results will contribute to the elucidation of the underling mechanism of PA therapy and to devising new therapies for USN and/or other higher cortical dysfunctions.

Title: Decoding visual spatial attention control

Authors: *S. MEYYAPPAN[1], A. RAJAN[1], J. J. BENGSON[2], G. R. MANGUN[3], M. DING[1]; [1]J Crayton Pruitt Family Dept. of Biomed. Engin., Univ. of Florida, Gainesville, FL; [2]Sonoma State Univ., Rohnert Park, CA; [3]Ctr. for Mind and Brain, Univ. of California Davis, Davis, CA

Abstract: Deploying anticipatory visual spatial attention in advance of stimulus onset enhances the processing of task-relevant stimuli and suppresses distraction. In this study, we investigated the neural representations of attention control signals in visual cortex by analyzing two fMRI datasets, one recorded at University of Florida (n=13) and the other at University of California, Davis (n=18), using machine learning techniques. In both datasets, the participants performed a cued visual spatial attention task, in which each trial began with a visual cue at fixation that

instructed the subject to either attend the left or the right visual hemifield. After a random delay, a grating (Gabor patch) was presented in one of the two hemifields, and the subject was asked to discriminate the spatial frequency of the grating in the attended hemifield and ignore the grating if appearing in the un-attended hemifield. We estimated cue-evoked fMRI responses and applied multi-voxel pattern analysis (MVPA) to multiple ROIs within the visual cortex. We found that: (1) Accuracy of decoding attend-left versus attend-right was significantly above chance in all the ROIs within the visual cortex (average accuracy=65%), (2) The decoding accuracy was highly correlated across different visual ROIs, with 80% of the variance explained by the first principal component, and (3) Subjects with higher decoding accuracy performed better on the task as indexed by lower inverse efficiency measures (response time/response accuracy). These results, consistent across the two datasets, suggest that (1) attention control signals are present in both high order (e.g., intra-parietal sulcus) as well as low order visual areas (e.g., primary visual cortex) and (2) the distinctness of the neural representations of attention control in visual cortex is a trait that explains individual differences in task performance.

Title: Application of granger causality in decoding covert selective attention with human EEG

Authors: *W. NIU[1], Y. JIANG[1], Y. ZHANG[1], X. ZHANG[1], T. JIANG[2], S. YU[2];
[1]Brainnetome Ctr., Inst. of Automation,Chinese Acad. of Sci., Beijing, China; [2]Brainnetome Ctr., Inst. of Automation, Chinese Acad. of Sci., Beijing, China

Abstract: Electroencephalography (EEG)-based Brain-Computer Interfaces (BCI)s have experienced significant growth in recent years, especially the passive BCIs with a wide application in the detection of cognitive and emotional states. But it is still unclear whether more subtle states, e.g., covert selective attention can be decoded with EEG signals. To examine this issue, we used a behavioral paradigm to introduce the shift of selective attention between the

visual and auditory domain, while keeping the sensory inputs to the brain exactly the same. With scalp EEG signals recorded from eight healthy human subjects, we extracted activity features based on the Grange Causality (GC) and successfully decoded the attentional shift through a support vector machine (SVM) based classifier. The decoding accuracy was significantly above the chance level for all subjects tested. The features extracted with the GC were further analyzed with tree-based feature importance analysis and recursive feature elimination (RFE) method to search for the optimal features for classification. Visualizing these highly informative features revealed the common pattern in EEG that can reflect different information flows across the brain network during visual and auditory attention. Our results demonstrate that patterns of EEG activities extracted by the GC can be used to decode subtle state changes of the brain related to cross-modal selective attention, which opens a new possibility of using passive BCIs in sophisticated perceptual and cognitive tasks.

Title: The relationship between socioeconomic status and reading abilities in children with dyslexia and typical readers

Authors: *P. B. GREENWOOD[1], E. SCOTT[2], J. DUDLEY[2], J. S. HUTTON[2], J. VANNEST[3], T. HOROWITZ-KRAUS[4];
[1]Col. of Med., Univ. of Cincinnati, Cincinnati, OH; [2]Reading and Literacy Discovery Ctr., [3]Dept. of Neurol., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [4]Educational Neuroimaging Ctr., Technion-Israel Inst. of Technol., Haifa, Israel

Abstract: 5 to 12% of school age children have reading difficulties, defined by deficits in phonological processing, fluency, and executive dysfunction. Although dyslexia is referred to as a genetic disorder, reading ability may also be affected by inadequate exposure to linguistic stimulation due to a lack of a stimulating home reading environment. Socioeconomic status (SES) is defined by parental occupation, educational attainment and household income. Research has shown that SES is positively correlated to reading ability with higher SES children having higher exposure to print in their home during early school learning. Neuroimaging research has shown that socioeconomic inequality can have negative impacts on cognition and brain

development with low SES preschool children showing no activation within lateral prefrontal regions during cognitive tasks compared to their high SES peers. Forty-Six 8-12 year old typical readers and children with dyslexia matched for SES completed neuropsychological testing to examine language, executive functions, and reading ability. Maternal education and household income were collected for all mothers as constructs of SES. In addition, all participants completed two resting state fMRI scans to assess functional connectivity. The results showed differences in the relationship between higher maternal education and functional connectivity of cognitive control networks in dyslexics compared to typical readers. The results suggest higher maternal education may have contrasting roles on the involvement of cognitive control during the reading process for atypical readers compared to children that are typically developing readers. We conclude that higher maternal education may mediate the synchronization of cognitive control networks important for reading acquisition.

Title: Attentional hypervigilance to and attentional disengagement from test-specific threatening words in students with test anxiety is supported by alterations in alpha and theta frequency power bands in the frontoparietal attentional network

Authors: *E. A. BOURASSA, K. T. STOLL;
Biol. Sci., Mississippi Col., Clinton, MS

Abstract: Test anxiety (TA) affects up to 30% of students and is associated with a 12% decrease in academic performance. Consistent with other forms of anxiety, current research in our lab shows that students with TA have an attentional bias towards test-specific threatening (TST) words, but not generally threatening words. A general question concerning these attentional biases is whether the bias is due to hypervigilance towards threat or failure to disengage attention from threat. To differentiate between these two possibilities, twenty one students (10 low-TA and 11 high-TA) performed a modified rapid serial visual presentation (RSVP) task while connected to a 9-lead electroencephalogram (EEG) to determine whether the high-TA group failed to disengage attention from threat and measure power changes in the theta, alpha, and beta frequency bands in the frontoparietal attentional network (FPAN). Students were classified into low-TA and high-TA groups based on their blue box stress test score. The RSVP consisted of 17 number strings presented for 125 ms each; at position 8, 9, 10, 11, or 12, a word (neutral, N,

generally threatening, or TST) was shown instead of a number string. Three positions following the word, either the target word or a non-target word was shown. Each number string or word was shown in a different color; participants were asked to identify the color of the target word, if present. Continuous EEG data was epoched into 1250 ms segments with 500 ms prior to word presentation used as baseline (target presentation was 375 ms following word presentation). Event-related spectral perturbations (ERSPs) were constructed from trials in which participants responded correctly. The high-TA group had similar accuracy as the low-TA group on target trials containing both N and TST, suggesting a normal ability to disengage attention from threat. However, ERSP analysis showed significant alpha- and theta-band frequency alterations within the FPAN following the presentation of both the word and target. Low-TA participants had increased parietal alpha power following TST compared to N with decreased theta power following target presentation, whereas high-TA participants had decreased parietal alpha power following TST. In the frontal lobes, low-TA participants had decreased alpha/beta power following target presentation not seen in the high-TA group. These results suggest that the attentional bias to threat in TA is due to hypervigilance with attentional recovery following target presentation, these functions are supported by power alterations in the alpha and theta frequency bands in the FPAN, and TA may be distinct from other forms of anxiety requiring further study.

Title: Top-down and bottom-up attentional processing in students with test anxiety as measured by electroencephalography

Authors: *G. M. TALKINGTON, E. A. BOURASSA;
Biol. Sci., Mississippi Col., Clinton, MS

Abstract: The attentional control theory of anxiety states that top-down attentional control (centered in the frontal lobes) will be decreased in anxious individuals, while bottom-up attentional capture (centered in the parietal lobes) will be increased. It is hypothesized that test anxiety (TA), a very common entity that is associated with decreased academic performance, would follow the predictions of the attentional control theory. Identifying the alterations in these attentional networks in TA will provide a better understanding of the cognitive deficits associated with TA and inform the development of effective strategies to reduce its impact on students. Electroencephalography (EEG) was measured from students with and without TA during a task requiring the differential activation of these attentional networks to determine if

cortical power was different between these two groups. The task required participants to identify a target triangle based on color and orientation in an array of four triangles; the search condition (which isolates top-down attentional control) contained the target triangle and three triangles of the same color but different orientations whereas the salient condition (which isolates bottom-up attentional capture) contained the target triangle and three triangles of different color and orientations. Twenty participants completed the task; twelve that were classified as highly test anxious and eight that were classified as non-test anxious as determined by the blue box stress test. The continuous 9-lead EEG was epoched into segments that were 1200 ms long with the first 200 ms (pre-target) used as baseline. Event-related spectral perturbations (ERSPs) were constructed from the epoched data. Task accuracy was lower in both conditions in participants with high-TA compared to low-TA. Cortical activity as measured by EEG was significantly lower in the top-down task, specifically in the beta frequency range (12-20 Hz). As predicted, this difference was centered in the frontal lobes. Cortical activity in the parietal lobes was also lower in the bottom-up task, in contrast to our hypothesis. These results may indicate that students with test anxiety have reduced ability to purposefully suppress distracting or task-irrelevant stimuli, decreasing task performance under both conditions. This implies that, in contrast to generalized anxiety disorder, the system of attentional control most influenced by TA is the top-down network.

Title: Visuo-spatial attention task and handedness: A cerebral electrical activity study

Authors: *S. P. CAÑARTE VARELA, I. Y. DEL RÍO PORTILLO, I. G. GALÁN LÓPEZ; Sleep Lab., Univ. Nacional Autónoma De México, CDMX, Mexico

Abstract: Differences in brain organization and brain processing between right- and left-handers have been described, nevertheless is continue to be an issue of fact. There is also known that visuo-spatial attention processing is different for both hemispheres in relation to handedness. The aim of this study was to analyze brain response and behavioral response between right- and left-handers during visuo-spatial attention task. Fifty stimuli (red and blue circles, 1.6s each) were presented. Stimuli presented in a classical random block design for each group (left- and right-handers). After each run, subjects (n=20 male, n=20 female) responded on a PC keyboard

according to the place they saw the stimuli (right or left side) with their dominant hand and simultaneously gaze on the direction they saw the stimuli (right side if the stimulus were blue or left side if the stimulus were red). For eye movements recording were placed electrodes according to the electrooculogram (EOG).Results showed significant differences on brain activity between left and right handers based on visuo-spatial attention task. Behavioral data analysis in relation to PC keyboard answers, got a greater number of correct answers ($p=0.03$) and a longer reaction time for left-handers. For brain activity, intrahemispheric (INTRAr) correlation was analyzed with electroencephalographic activity ($p<0.05$). Left handers showed differences in theta2 band for INTRAr between F4-C4, F8-T6, C4-T6, T4-T6 including alpha1 between F4-C4 in right hemisphere during the task. Right handers showed differences in delta band for INTRAr between F4-T4, beta1 between F1-T5, F3-O1 and beta2 between F1-O1 for both hemispheres previous the task. These results support the hypothesis that exist different brain functional organization between right- and left-handers on visuo-spatial attention processing.

Title: Interaction between exogenous attention and conscious visual perception: An MEG study

Authors: *A. SPAGNA[1], D. J. BAYLE[2], A. CHICA[3], C. TALLON-BAUDRY[4], P. BARTOLOMEO[5];
[1]Dept. of Psychology, Columbia University, NYC, USA, PICNIC Lab, ICM, Paris, France, NYC & Paris, NY; [2]Ctr. De Recherche Sur Le Sport Et Le Mouvement, Nanterre, France; [3]Dept. of Exptl. Psychology,, Univ. of Granada, Spain, Granada, Spain; [4]Cognitive Neurosci. Lab., Paris, France; [5]Inserm UMRS 1127, Brain and Spine Inst., Paris, France

Abstract: Do we need attention to become aware of an external object? The relationships between attention and visual perception has fostered an intense debate in cognitive neuroscience. Extensive neuroimaging evidence from the past 25 years does not seem to have been able to unequivocally support the separability or interdependence of these processes. Here we used

magnetoencephalography (MEG) to assess the effect of peripheral non-predictive supra-threshold visual cues on the conscious perception of near-threshold Gabor patches. Eighteen participants underwent MEG recordings while performing an exogenous orienting task, in which peripheral visual cues (small dots presented for 50 ms) oriented attention toward one of two boxes located in the lower left and right quadrants of the display. Three-hundred milliseconds after the visual cue, the Gabor target (duration: 16 ms) was presented with equal probability in the same (valid) or in the opposite (invalid) box indicated by the cue. Participants were then required to perform two tasks: (1) a discrimination task, which required pressing a button to indicate the orientation of the target gratings; (2) a detection task, which required pressing a button to indicate the location of seen targets or whether the target was unseen. At the behavioral level, results showed that exogenous attention increased the percentage of detected targets and biased the observers to report signal occurrence by adopting a more liberal decision criterion, but there was no evidence for an increase in sensitivity due to the presentation of the visual cue. Source reconstruction of MEG recordings in the cue-target period showed that activity in the right temporoparietal junction, an area important for the exogenous orienting of attention, increased for seen *vs*unseen targets. No evidence for the involvement of other brain areas was found in the cue-target period. Source reconstruction in the post-target period showed a widespread increase in activity of areas within the fronto-parietal and the cingulo-opercular networks bilaterally for seen valid trials compared to unseen valid trials, and for seen invalid trials compared to unseen invalid trials. No difference was found between MEG activity in seen valid *vs*seen invalid cue trials. The absence of validity effects at the behavioral level as well as in the MEG recordings was surprising, and possibly due to the cue stimulus used. Despite this negative finding, results of the contrasts between seen and unseen trials separately for the valid and invalid cue confirm that neuronal activity related to exogenous orienting of attention can enhance visual conscious perception.

Title: Intermodal attention differentially adjusts frequency and phase of entrained oscillations in sensory and non-sensory regions

Authors: *N. SUESS, T. HARTMANN, N. WEISZ;
Ctr. for Cognitive Neurosci., Univ. of Salzburg, Salzburg, Austria

Abstract: Continuously extracting behaviourally relevant information from the environment for optimal stimulus processing is one of the crucial functions of attention. Low-frequency phase alignment (~"entrainment") in primary sensory areas with respect to attended / ignored features has been suggested to support this selection function. While activation of frontoparietal areas has been shown to be relevant for top-down selection, entrainment of nonsensory regions has been far less studied in the context of attention. In this MEG study we were interested in how different sensory and non-sensory regions show temporally coordinated activity to rhythmic stimulation dependent on attention. Participants performed an established intermodal selective attention task where low-frequency auditory (1.6 Hz) and visual (1.8 Hz) stimulation were presented simultaneously. We instructed them to either attend to the auditory or the visual stimulation and detect targets while ignoring the other stimulus stream. As expected, highest entrainment was observed in primary sensory areas for the respective stimulation independent from attentional focus. We found higher differences in entrainment between attended and ignored stimulation for the visual modality and that auditory regions can to some extended reflect attention dependent entrainment for visual stimulation. Furthermore, we show phase differences in primary sensory areas for the respective stimulation dependent on attentional focus both present in the auditory and visual modality, suggesting similar processes in both modalities for guiding attention. Importantly, we also found a frontoparietal network which entrains flexibly to the to-be-attended frequencies, suggesting that these higher-order nonsensory regions exploit the temporal structure of stimulation to adjust excitability optimally. Overall, our results suggest that while intermodal attentional focusing acts in particular via phase adjustment at the modality-specific stimulation frequency in primary sensory areas, nonsensory frontoparietal areas adjust their frequency to be in line with the attended modality.

Abstract: Hearing impaired (HI) listeners report listening as demanding and effortful in challenging environments with multiple speakers to be ignored, while attending to a target speaker. Therefore, hearing-aid signal processing often includes noise-reduction (NR) schemes to support the user in such environments. However, objective outcome measures to quantify the user benefits in such a listening situation are still warranted. To explore the benefit of a NR scheme in HI, electroencephalography (EEG) and pupillometry were used to study the impact of a typical hearing aid NR scheme in different listening conditions on selective auditory attention and listening effort (LE). Selective attention was investigated by the correlation coefficient between stimulus (speech) reconstructed from EEG and actual stimulus, while LE was quantified in terms of pupil dilation and alpha oscillations obtained from EEG. Twenty-two participants were instructed to attend to a target speaker while ignoring competing talkers in a spatial arrangement of loudspeakers. Speech stimuli consisted of 33 seconds of news clips to mimic a realistic listening scenario followed by a control question to obtain sustained attention. Both EEG and pupillometry were recorded in different listening scenarios with changing signal-to-noise (SNR) (3 and 8 dB) and signal-processing of the hearing aid (NR active vs inactive). Results indicate enhanced decoding of attended speech (Figure 1) and reduced LE for high vs. low SNR and active vs inactive NR. In summary, the combination of EEG and pupillometry analysis may in the future lead to better understanding of neural mechanisms involved in aided listening.

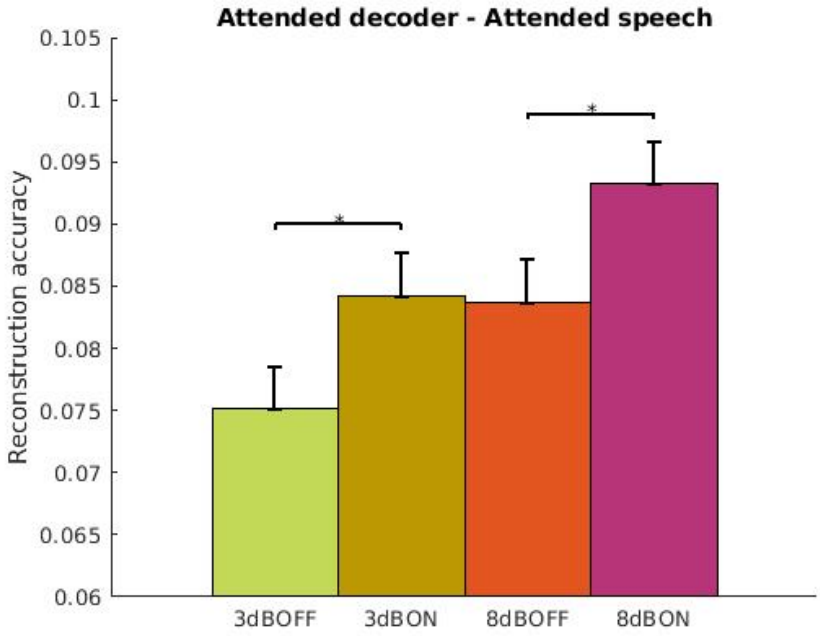

Figure 1: Reconstruction accuracy between reconstructed and actual speech for the four conditions. Active noise-reduction (ON) increased selective auditory attention for both 3 and 8 dB conditions.

Title: The role of cortical alpha-band oscillations during anticipatory gating of spatial attention: An ECoG study

Authors: *X. YANG[1], I. FIEBELKORN[2], O. JENSEN[3], J. PARVIZI[4], R. T. KNIGHT[5,6], S. KASTNER[1,2];

Sci., Stanford Univ., Stanford, CA; [5]Dept. of Psychology, [6]Helen Wills Neurosci. Inst., Univ. of California Berkeley, Berkeley, CA

Abstract: Across the visual attention network, classical effects of selective attention on low frequency suppression have been characterized in human EEG and MEG studies. However, direct cortical measurements of the spatial selectivity and temporal dynamics of alpha-band oscillations in the human brain, and how they are modulated by attention, have not been reported. We recorded electrocorticographic (ECoG) signals in eight epilepsy patients implanted with intracranial electrodes while they were performing a variant of the Eriksen flanker task. Following a spatial cue and a variable delay interval, subjects differentiated between two shapes at the cued location in an array of distracters. Using our probabilistic atlas of the human visual system, we localized electrodes to visual topographic areas and identified those with spatially-selective power profile in the alpha frequency range. We found that low frequency suppression modulated by attention was spatially tuned and showed differential topographic dynamics during

the delay period. Specifically, extrastriate cortex and posterior intraparietal sulcus (pIPS) displayed the classical contralateral alpha suppression and ipsilateral enhancement with respect to the upcoming target location. Surprisingly, anterior intraparietal sulcus (aIPS) showed consistently decreased alpha activity regardless of the cued location. Moreover, we found an anti-correlation between the low frequency activity and the high-frequency broadband (HFB) signals with respect to spatial tuning, especially at pIPS regions. The tuning widths of delay-evoked alpha activity also correlated with HFB signals, further suggesting that these two frequency components were systematically related across the visual hierarchy. We, therefore, investigated the cross-frequency coupling between alpha phase and HFB amplitude within each topographic area and revealed a significant attention effect on coupling (greater ipsilateral than contralateral) observed only in pIPS. We then examined cross-region coupling and discovered that alpha phase of aIPS was significantly coupled with HFB amplitude of pIPS (also greater ipsilateral than contralateral), and this interregional modulation was only found significant in the top-down manner (aIPS to pIPS) but not bottom-up (pIPS to aIPS). In conclusion, these results suggest a parallel yet distinctive representation of spatial information in low and high frequency bands and provide direct neural evidence to support the gating-by-inhibition theory of spatial attention by facilitating a coordinated processing of visual space that may integrate feedback modulation across the visual system.

Title: Resting-state connectivity fingerprint model predicts individual intra-areal intraparietal sulcus retinotopic organization

Authors: *J. A. BRISSENDEN, D. C. SOMERS;
Psychological and Brain Sci., Boston Univ., Boston, MA

Abstract: Human intraparietal sulcus (IPS) contains multiple, retinotopically organized (Swisher et al., 2007) cortical maps. However, the reliable identification of IPS visual field maps in individual subjects requires the collection of a substantial amount of fMRI data and places strong eye-fixation demands on subjects. Connectivity fingerprint models have proven to be a

successful method for predicting area-level organization from diffusion imaging and resting-state connectivity measures (Saygin et al. 2011; Osher et al., 2015, 2019; Tavor et al., 2016; Tobyne et al., 2018). However, these methods have not yet been successfully applied to predict finer scale functional organization, such as that revealed by retinotopic mapping. Here, we applied a connectivity fingerprint model to the Human Connectome Project 7T dataset (N = 181) to characterize individual intra-areal IPS visual responsivity and retinotopic organization. Hierarchical Bayesian regression models were trained to predict vertex-wise IPS population receptive field (pRF) model variance explained (R^2) and polar angle preference estimates from patterns of resting-state functional connectivity. Model performance was evaluated using a split-half cross-validation scheme. Model predictions were found to accurately reflect IPS visual responsivity and polar angle organization in individual subjects. Predicted polar angle maps further allowed for the delineation of boundaries between adjacent intraparietal retinotopic regions, IPS0-3. Recent work indicates that averaging fMRI time series across subjects and then fitting a pRF model produces results that align with previous parcellations of visual areas (Benson et al., 2018). Our connectivity fingerprint model significantly outperforms this group-average model (LH: 0.52 vs. 0.30; RH: 0.50 vs. 0.39). This work presents a method for examining the retinotopic organization in individuals for which the collection of sufficient retinotopic mapping data is difficult. These findings also extend connectivity fingerprinting methods to predict fine-scale gradients in functional organization within a cortical area.

Title: 'Connectivity fingerprint' modeling reveals task-specific, individualized patterns of overlapping visual attention and working memory activation in human posterior parietal cortex

Authors: *V. TRIPATHI, S. M. TOBYNE, J. A. BRISSENDEN, A. L. NOYCE, D. C. SOMERS;
Boston Univ., Boston, MA

Abstract: Introduction: Connectivity Fingerprinting (CF) can predict specific task activation patterns in individual subjects using anatomical connectivity (Saygin et. al. 2012) or resting state functional connectivity (Tavor et. al. 2016; Tobyne et. al. 2018). However, it remains unclear

whether the CF approach reveals an individual's broad-scale network supporting several cognitive functions(e.g. the dorsal attention network) or if it can capture fine-scale task-specific activation within a common network. Methods: We examined fMRI data from 3 tasks known to strongly activate posterior parietal cortex: Multiple Object Tracking (MOT, n=9), Visual Short-Term Memory - Change Detection (VSTM-CD, n=9) and Visual 2-back vs. Auditory 2-back working memory (VAWM, n=14) along with resting-state data. For each task, we constructed CF models using ridge regression to relate functional connectivity to task activation and a nested leave-one-subject-out cross-validation procedure for model parameter tuning. CF models predicted task activation for every cortical surface vertex within a search space, which spanned posterior parietal cortex, by applying an individual subject's connectivity matrix to the model. Task-specific CF models consisted of the set of weights corresponding to each parcels relative importance to predicting the search space. We performed permutation testing to get distributions for the weights which were compared across tasks. Results: CF modelling was highly effective in predicting individual-subject activation patterns in each of the three tasks (MOT: R=0.67; VSTM: R=0.71; VAWM: R=0.61). While the CF models exhibited some parcel connections common to all 3 tasks, significant task-level differences were observed in the model structure. Weights for parietal and temporoparietal regions were particularly informative in the MOT model, visual area weights in the VSTM model, and temporal regions weights in the VAWM task. Conclusions: CF models make task-specific activity predictions within posterior parietal cortex for individual subjects and these differences are observable in the estimated model coefficients. This demonstrates that CF modelling goes beyond large-scale resting-state networks to make task-specific predictions. More broadly, this work demonstrates the utility of CF modelling in revealing fine scale networks even for tasks that involve similar cognitive processes and colocalized brain activation such as working memory and attention.

Title: Beta band activity reflects anticipatory sensorimotor planning during covert visual attention oculomotor dual task

Authors: *J. TORRES-ELGUETA[1], P. MALDONADO[2];
[1]Dept. of Neurosci. - Dept. of Kinesiology, [2]Dept. of Neurosci., BNI - Univ. de Chile, Santiago, Chile

Abstract: It has been proposed that orientation of visual attention is coupled to oculomotor planning, giving that saccade planning leads to facilitation of the visual processing of targets at the same visual locus. However, there is evidence of complete mechanistic independence between both processes. If visual attention depends on oculomotor planning, we expect to find interference between both processes when each one is directed to a different locus. This interference would manifest itself through a drop of saccadic behavior or a different time course of electrophysiological markers. Nine subjects (4 male) performed the dual task in order to track the location of an attentional focus by discriminating the identity of a peripheral target (OD), while they have to perform a saccade to a target that is in the same location of the primary task (congruent trial), or to a neighboring site (incongruent, INC1 and INC3). Each trial begins with the gaze on a central fixation which is replaced by an arrow whose direction and color indicate the side of the OD and the position of the saccade, respectively. The saccade was withheld during a variable time until a Go signal. We found that target discrimination was significantly higher for incongruent trials compared to but there was no difference between congruent and INC1. During post CUE period, oscillatory activity (Beta band) showed a spectral power decrease at posterior electrodes, contralateral to the cued target, compared to ipsilateral, both in congruent and INC1. Such lateralization of beta had an earlier time course in INC1 than congruent trials. During the Go period, beta band showed clear lateralization of spectral power in congruent trials and was not present in incongruent trials. Our results suggest that there is no interference, without a time cost for the direction of saccade and visual attention to different sites. However, the different time course of beta band activity during post CUE period may reflect an anticipatory process for sensory-motor integration, which avoids a time cost in the post GO period. The experiment showed no evidence of interdependence between visual attention orienting and oculomotor planning. The results suggest a dissociation between the two processes and no interference between them.

Title: Individual attention-emotion differences in spontaneous neural connectivity during rest

Authors: *K. CHEEMA[1], A. SHAFER[2], R. BAHKTIARI[1], M. MOORE[3], F. DOLCOS[3], A. SINGHAL[1];
[1]Univ. of Alberta, Edmonton, AB, Canada; [2]Wayne State Univ., Detroit, MI; [3]Univ. of Illinois, Urbana, IL

Abstract: Background. Recent work from our group using simultaneous EEG-fMRI recordings has shown multi-modal evidence in support of the two major neural circuits involved in emotion-cognition interactions. These circuits include hubs in dorsolateral prefrontal cortex (dlPFC) and ventrolateral prefrontal cortex (vlPFC). While several task-based studies have outlined the neural circuitry associated with these two key regions, their intrinsic connectivity is not fully clear. Moreover, it remains open as to how the connectivity of these networks relates to the individual differences in attention and emotional processing. In this study, we employed a simultaneous EEG-fMRI protocol to further characterize the intrinsic connectivity of dlPFC and vlPFC in healthy controls, and examine how the spontaneous resting-state connectivity of the two circuits relate to individual differences in attention and emotion processing. **Methods**. 20 healthy adults (18-31 years old, 13 females) completed the Emotion Regulation Questionnaire (ERQ; Gross & John, 2003) and the Test of Variables of Attention (TOVA; Greenberg, 2011). During scanning, participants were asked to close their eyes for 5 minutes and remain still. The resting-state analysis was performed using the CONN toolbox to examine the resting state connectivity for right dlPFC and vlPFC. Finally, the ERQ and TOVA scores were correlated with connectivity patterns of right dlPFC and vlPFC. Both positive and negative connections from the two hubs were analyzed. **Results**. As expected, dlPFC was intrinsically connected to areas related to executive functioning, while vlPFC displayed spontaneous connections with areas associated with emotional processing. These two hubs were also both connected with amygdala and cingulate cortex. Only right dlPFC was found to be negatively correlated with medial prefrontal cortex (part of the default mode network), indicating the functional significance of dlPFC network for attention processing. Finally, better performance on sustained attention (TOVA) and emotion regulation (ERQ) was associated with stronger intrinsic connectivity from right vlPFC. **Conclusion**. This study provides emerging evidence for the presence of distinct but separate spontaneous networks for the two prefrontal cortices associated with emotion-cognition interactions. It is critical to understand the brain circuitry responsible for emotion-attention interaction to better understand how this circuitry is impaired in mood and anxiety disorders.

Title: Anticorrelated inter-network electrophysiological activity varies dynamically with attentional performance and behavioral states

Authors: *A. KUCYI[1], A. L. DAITCH[2], O. RACCAH[3], B. ZHAO[4], C. ZHANG[4], M. ESTERMAN[5], M. ZEINEH[1], C. HALPERN[1], K. ZHANG[4], J. ZHANG[4], J. PARVIZI[1]; [2]Lab. of Behavioral and Cognitive Neurosci. (LBCN), [1]Stanford Univ., Stanford, CA; [3]Neurol. & Neurolog. Sci., Stanford Univ., Palo Alto, CA; [4]Capital Med. Univ., Beijing, China; [5]Boston Univ. Med. Sch., Boston, MA

Abstract: The default mode network (DMN) is thought to exhibit infraslow, negatively correlated (or “anticorrelated”) activity with dorsal attention (DAN) and salience (SN) networks across various behavioral states. To investigate the fine-grained dynamics of activity across these networks, we used human intracranial electroencephalography (iEEG) in a unique cohort of 7 neurosurgical patients with simultaneous recordings within core nodes of the three networks (posteromedial cortex within DMN, dorsal posterior parietal cortex within DAN, and dorsal anterior insula within SN). Pre-operative resting state fMRI confirmed that these implanted electrode sites were functional connected with their constituent networks within individuals. During iEEG recordings, participants performed multiple runs of a visual continuous performance task requiring sustained attention, and spontaneous activity was also recorded during wakeful rest and sleep. During attentionally-demanding stimulus processing, the three network-specific sites showed dissociable profiles of high-frequency broadband (HFB) activity: DAN and SN sites showed task-evoked HFB power increases (with an error monitoring signal in the SN but not DAN), while DMN sites showed HFB power decreases. Inter-network, continuous anticorrelation of infraslow HFB activity was found consistently during task performance but during wakeful rest or sleep, anticorrelation only emerged intermittently and in tandem with expression of task-like brain states. Critically, on a finer timescale, task-evoked DAN and SN activations preceded DMN deactivations by hundreds of milliseconds. Moreover, greater lagged, but not zero-lag, DMN-DAN anticorrelation was associated with better attentional performance. These findings have implications for interpreting antagonistic network relationships and confirm the behavioral importance of time-lagged inter-network interactions.

Title: Personalized neuromodulation for attention networks

Authors: *B. L. DECK[1], B. YEAGER[1], J. ZIMMERMAN[2], A. KELKAR[1], B. ERICKSON[1], J. D. MEDAGLIA[1];
[1]Psychology, Drexel Univ., Philadelphia, PA; [2]Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Attention to simple stimuli has been shown to dissociate into three separate but interacting networks using task-evoked fMRI. However, our understanding of how these networks comport with networks estimated from modern precision fMRI mapping approaches is unclear. Here, we test whether applying transcranial magnetic stimulation (TMS) to three distinct networks estimated within subjects, evaluated using modern approaches yield dissociable effects on behavior. We hypothesize that inhibitory TMS to the cingulo-opercular network (CO), dorsal attention network (DAN), and a fronto-parietal executive control network (FP) individually will reduce performance on alerting, orienting, and executive control behavioral efficiency, respectively. In this study individualized intrinsic connectivity systems were identified in subjects based on previously collected resting-state fMRI data. An iterative mapping procedure was used in a normative template of 18 distributed systems are registered to each subject's fMRI data and system labels are iteratively updated based on the correlation of voxel time-series to the time-series of the 18 distributed systems. The attention network task (ANT) was administered to participants before and after continuous theta-burst (cTBS) TMS delivered to both the left CO network and the FP network (as a control) both in the middle frontal gyrus. Efficiency scores were calculated for the ANT based on previous literature. Based on each ANT efficiency score, we observed that alerting and executive control became slower while orienting became faster after performing cTBS on the left CO network. Our results show that inhibitory stimulation applied to the CO network not only inhibits the network stimulated but also inhibits normal function of the FP network. We provide evidence that the inhibition of both of these networks may allow the DAN network to perform better at orienting an individual's attention. These results point to the need for additional neuromodulation studies that clarify the relationship between modern precisely mapped networks and attention performance. Our results further

suggest that subject-specific attention interventions could be supported by precision fMRI network mapping.

Title: Differential functional patterns of the human posterior cingulate cortex during activation and deactivation: A meta-analytic connectivity model

Authors: *J. BUSLER, J. YANES, R. BIRD, M. REID, J. ROBINSON;
Auburn Univ., Auburn, AL

Abstract: The posterior cingulate cortex (PCC), a cortical hub, facilitates and modulates a diverse set of neural network operations. The PCC activates when emotional stimuli are encountered, displays functional connectivity to frontoparietal networks indicating its role in attention and cognitive control, and is a pivotal component of the default mode network. Moreover, the PCC has been shown to be involved in a range of psychiatric and neurological disorders. However, very little is known about the specific activated/deactivated functional profiles of the PCC. We employed a dual-analytic approach using robust quantitative meta-analytical connectivity modeling (MACM) and ultra-high field, high resolution resting state functional magnetic resonance imaging (rs-fMRI) to identify state-specific functional activity patterns of the human PCC. We defined the PCC region of interest (ROI) using the Harvard-Oxford Structural Probability Atlas (thresholded at 50% probability, distributed with FSL neuroimaging analysis software. Whole-brain meta-analytic co-activation and co-deactivation profiles were generated for the PCC ROI using the BrainMap database. In addition, using tools within Mango imaging analysis software, we conducted behavioral and paradigm analyses on resultant functional profile differences between the activation and deactivation meta-analyses. The MACM results provided evidence for regions of convergence for PCC co-activation and co-deactivation (i.e., left medial frontal gyrus, left amygdala, and left anterior cingulate) as well as regions of divergence specific to either PCC activation (i.e., bilateral inferior frontal gyri) or PCC deactivation (i.e., left parahippocampal gyrus). Resting state connectivity analyses showed widespread connectivity similar to that of the PCC co-activation-based MACM, but also demonstrated additional regions of activity, including bilateral superior parietal regions and right superior temporal regions. Behavioral and paradigm analyses showed significant behavioral domain and paradigm classes associated with PCC co-activation but not for PCC co-

deactivation. These analyses provide additional insight into the dynamic functional activity patterns of the human PCC as it switches between activated, deactivated, and resting states and associatively improves our understanding of PCC function via a multi-state, multi-method assessment that may elucidate models of disease.

Title: Resting - state functional connectivity of the right temporoparietal junction relates to belief updating and attentional reorienting

Authors: *A.-S. KÄSBAUER[1], P. MENGOTTI[1], G. FINK[1,2], S. VOSSEL[1,3];
[1]Cognitive Neurosci., Inst. of Neurosci. and Med. (INM-3), Res. Ctr. Juelich, Juelich, Germany; [2]Dept. of Neurol., Fac. of Med. and Univ. Hosp. Cologne, Univ. of Cologne, Cologne, Germany; [3]Dept. of Psychology, Fac. of Human Sciences, Univ. of Cologne, Cologne, Germany

Abstract: Whereas the resting-state functional connectivity (rsFC) pattern of the right temporoparietal junction (rTPJ) has been characterized by multiple studies [1], little is known about the link between rTPJ-rsFC and cognitive functions. The first evidence for a significant relationship between rsFC networks and deficits in the domain of attention has been provided by studies in stroke patients [2]. Given a putative involvement of rTPJ in both reorienting of attention and the updating of probabilistic beliefs [3], the present study aimed at characterizing the relationship between rsFC of rTPJ with dorsal and ventral attention systems and these two cognitive processes.
Twenty-three healthy participants (14 females, mean age 27 years, all right-handed) performed a modified location-cueing paradigm allowing for the assessment of belief updating and attentional reorienting. Resting-state fMRI was recorded before and after the task. To study the rsFC of rTPJ, seed-based correlation analysis with a coordinate derived from a previous fMRI and TMS study was used. The rsFC pattern of this rTPJ region was characterized at the whole-brain level. Using a ROI-based approach with key nodes of the dorsal and ventral attention systems, correlations of each behavioral parameter with rsFC before the task, as well as with changes in rsFC after the task were analyzed.

The whole-brain rsFC pattern of the present rTPJ region resembled the pattern described by previous studies. Regarding the link between connectivity and behavior, weaker rsFC of rTPJ and the right intraparietal sulcus before the task was associated with faster updating of beliefs about the validity of the spatial cue. Moreover, an increase of the interhemispheric rsFC of rTPJ and left TPJ after the task was related to faster belief updating as well as faster reorienting. These results are in line with task-based connectivity studies. Moreover, they extend existing patient studies on the role of interhemispheric interactions for optimal behavioral performance [2]. In conclusion, the present findings argue for mutual interactions between cognitive processing and resting-state connectivity architectures.

Abstract: Despite growing advances in the field of neuromodulation, not all participants and patients respond to non-invasive brain stimulation. The emergence of the study of large scale brain networks has allowed investigation of communication between brain regions independent of tasks or symptomology.
In a first experiment, we used voxelwise whole-brain analysis to identify a cerebellar-prefrontal cortex network linked to the negative symptoms of schizophrenia with resting state functional connectivity (n=44). We then tested in n=11 participants if network modulation (twice-daily, 5

days) with cerebellar-targeted transcranial magnetic stimulation (TMS) would be linked to symptom improvement. In a second experiment, we repeated the stimulation in healthy participants (n=26) within single sessions. We obtained large-scale network connectivity measures before and immediately after stimulation. Concurrent with network collection, participants performed a continuous performance task. The dose intensity of cerebellar TMS was varied across three separate sessions in each participant.
In schizophrenia patients, we identified a cerebellar-prefrontal cortex network deficiency was linked to negative symptoms. In the TMS cohort, the magnitude of increased connectivity following stimulation directly corresponded to negative symptom improvement ($r=-0.809$). In healthy participants, the absolute machine intensity of stimulation was not related to improved attentional improvement (d'), but modulation of the default network and dorsal attention network with stimulation intensity is predictive of subsequent improvement ($p=0.015$).
In conclusion we show that a comprehensive approach to mental illness can be taken where functional connectivity imaging is used to identify networks which correspond to symptoms. This same approach can be translated into healthy participants for briefer duration experiments to parameterize network modulation using cognitive performance as a surrogate for symptom measures.

Title: Anosognosia for alexia without agraphia: Implications for understanding anosognosia, right brain reading and right brain logic

Authors: *E. L. ALTSCHULER;
Metropolitan Hosp., New York, NY

Abstract: In1965 Geschwind called alexia without agraphia (AwoA), originally described by Dejerine in 1892, the first disconnection syndrome. Indeed, a lesion to the left visual cortex combined with a lesion of the splenium of the corpus callosum disconnects intact vision in the right cortical hemisphere from the language centers in the left brain (in a right handed individual) rendering the patient unable to read. Writing is intact as the left-brain language centers—Wernicke, Broca's areas—are intact as are the white matter tracts connecting them. Study of patients with AwoA has the potential to yield insights on a number of conditions. For example, I saw a patient who after a large stroke affecting the left visual cortex and splenium of the corpus

callosum could not read any text correctly but was able to write normal sentences spontaneously and to dictation. When asked to read, her response bore no connection to the text before him. When pressed on this she said there may have been some mistakes due to a vision problem secondary to something in her eye. When told that examination showed there was nothing in her eye, she said it was still a problem as there was a feeling of something in the eye. The patient's visual acuity was normal and the she could instantly find even a small mark on a piece of paper. Thus the patient had anosognosia for her AwoA. This is the third such example we have seen of this (Multari, Ramachandran & Altschuler, 2011; Williams, Patira & Altschuler, 2016). Conversely to (incorrect) attempts to read English, when shown a page of Chinese text, the patient immediately said, "I cannot read this because it is written in a foreign language." In our previously two reported cases the patient responded similarly. This suggests that the anosognosia for AwoA is due to a vacuum of afferent information. The patient could sometimes identify individual letters, but could not read even a two-letter word. It will be interesting to study the length of words that other patients with AwoA can read to assess the reading ability of the right brain. Finally, studying patients with AwoA may give an unprecedented opportunity to assess the capacity of the right brain for reasoning and logic: Recently we have described a method, using question stimuli presented either as pictures or words, e.g., does a bone go with a dog, cat (or do not know the answer), to assess whether or not Wernicke's aphasia patients understand or not that they do not understand language (Hartman et al., & EL Altschuler, 2017). This method can be used with the picture stimuli—processed by the brain—as the test stimuli and the same questions asked verbally which should be able to be answered normally by the left brain as (positive) control stimuli.

Abstract: Phonemic paraphasias in language-impaired patients are thought to reflect deficits in phonological (post-semantic) stages in the process of language production. Here we present evidence that phonemic paraphasias in non-semantic primary progressive aphasia (PPA) may also be driven by an underlying deficit in the semantic representation of words. Agrammatic and logopenic PPA patients and control participants performed a word-to-picture visual search task where they were asked to match a stimulus noun to one of 16 object pictures, one of which was the correct target. Participants were subsequently asked to name the same items. We measured the taxonomic interference (ratio of time spent viewing related versus unrelated foils) during the search task for each item. Target items that elicited a phonemic paraphasia during object naming elicited increased taxonomic interference (semantic blurring) during the search task in agrammatic PPA patients but not in logopenic PPA patients. These results suggest a semantic (pre-phonological) basis for phonemic paraphasias in at least one variant of PPA. The findings are also consistent with cascade models of phonological production, presumably reflecting impaired inhibition of competing phonological representation in instances where semantic access has lost its robustness.

Title: Factors modulating the organization of languages in the bilingual brain: A systematic review

Authors: *M. M. POLCZYNSKA[1], S. Y. BOOKHEIMER[2];
[1]Univ. of California Los Angeles, Los Angeles, CA; [2]Psychiatry and Biobehavioral Sci., UCLA, Los Angeles, CA

Abstract: There have been numerous studies on linguistic factors that predict the representation of bilingualism in the brain, many of which have been based on patient data. The factors include age of acquisition of the second language (L2), proficiency level of L2, the amount of exposure to each language, manner of L2 acquisition (implicit vs. explicit), the linguistic distance between the first language (L1) and L2, multilingualism, the modality of acquisition (oral vs. sign language) and the frequency of language switching. However, there is a need for general organizing principles that incorporate all these linguistic factors explaining how the factors modify the degree of functional overlap between L1 and L2 in the brain. Here, we review bilingual studies on clinical language mapping. Methods available for study in patient mapping, with invasive techniques in particular, are much more vast than those available in healthy volunteers. We performed a literature search of articles published in English through January 2019 using four databases (e.g., PubMed). We included 29 studies with 208 participants. The reviewed data show several significant generalized principles of the neural organization of languages. Here we present two of the findings: (1) All the studies focusing on shared vs. separate language organization in bilinguals reported a tremendous degree of functional separation between L1 and L2 that is far more extensive than what is widely assumed, (2) Early L2 acquisition is associated with a more significant functional overlap between L1 and L2, in contrast to late L2 acquisition. This paper introduces a general model of bilingualism that integrates and organizes principles of bilingual representation in the brain (see the Figure). The reviewed studies validate the model. The main conclusion stemming from this review is that there is a high amount of separation between L1 and L2, therefore, it is crucial to pre-surgically map *all* languages that the patient needs to communicate in post-surgically. The results of the review will inform both basic research and clinical language mapping.

Title: Electrocorticographic recordings enable intraoperative language network mapping

Authors: ***B. LIPKIN**[1], J. PLASS[1], S. KAKAIZADA[3], C. VALDIVIA[3], O. SAGHER[2], S. HERVEY-JUMPER[3], D. BRANG[1];
[1]Psychology, [2]Neurosurg., Univ. of Michigan, Ann Arbor, MI; [3]Neurosurg., Univ. of California, San Francisco, CA

Abstract: Brain tumors and epilepsy can be life-threatening pathologies requiring neurosurgical treatment. To offer patients a high post-operative quality of life, neurosurgical procedures must strike a fine balance between removing pathological tissue, while preserving vital cognitive networks. The most common approach to identifying healthy cognitive functions relies on

extensive cortical stimulation mapping (CSM) during awake neurosurgery, in which electrical stimulation temporarily disrupts cortical functions, thus identifying critical areas. However, only ~1/3 of brain tumor patients meet the clinical requirements for this procedure, limiting its utility. Furthermore, CSM is time consuming and can be non-specific about cognitive functions localized to a region. To improve the efficacy and precision of intraoperative mapping, we assessed the use of intracranial recordings (electrocorticography; ECoG) as a supplement to CSM. Data were acquired from electrodes implanted along the left peri-sylvian language cortex in neurosurgical tumor patients (n=7) during a series of speech production tasks: text reading, word repetition, audio naming, picture naming, and syntax production. ECoG recordings were time-locked to speech onset for each task and filtered to track changes in mean population spiking rates (high gamma power: 70-150 Hz) at each electrode. Preliminary results suggest that the timing of ECoG responses can be used to distinguish between nearby pre-motor (motor planning) and primary motor (motor execution) activity during speech production. Using these event-locked recordings, we confirmed a temporally specific activation cascade during speech onset from superior temporal gyrus (STG) through Broca's area to primary motor cortex, as was previously observed in epilepsy patients, extending this model to a new patient population and lending validity to intraoperative ECoG. Ongoing analyses are examining the specificity and selectivity of ECoG results relative to both CSM and functional deficits following tumor removal.

Title: Overextension of the concrete semantic processing network in autism

Authors: *H. LEVINSON, L. COULANGES, M. J. ROSENBERG-LEE, W. W. GRAVES; Psychology, Rutgers Univ., Newark, NJ

Abstract: Autism spectrum disorder affects roughly 1 in 59 US children, almost half of whom have average to above average intellectual functioning. While basic verbal skills are intact in this group, issues with social pragmatics and abstract language persist. It remains unknown whether the basis of these issues is social or linguistic in nature. In neurotypicals (NT), cortical networks supporting semantics and social cognition largely overlap, notably in the inferior parietal lobe

and medial prefrontal cortex. A separate line of research has identified the anterior temporal lobe (ATL) as a primary hub for semantic and social knowledge representation, with graded specialization of function. For example, the ventral ATL (vATL) has been associated with concrete concepts, and the superior ATL (sATL) for abstract and social concepts. We examined differences in resting state functional connectivity between ASD and NT groups using abstract social (sATL) and concrete semantic (vATL) seed regions. A sample of 120 right-handed males was selected from the Autism Brain Imaging Data Exchange-II (ABIDE-II) database (see table). One striking pattern that emerged was the relative paucity of significant differences in functional connectivity between the groups. The significant differences that did emerge were specific to right vATL connectivity. There was heightened connectivity in the ASD group between the vATL and (1) right anterior superior temporal sulcus, a region involved in abstract-social concept processing, and (2) right posterior cingulate, a core default mode region involved in concrete semantics. Thus, seeding a region associated with concrete semantics revealed an over recruitment of the concrete network into regions usually associated with more abstract processing in NTs. Although exploratory, these results suggest heightened connectivity between brain regions that process concrete semantics and those for more abstract social processing as a potential neural basis for the challenges with abstract social processing often encountered by people on the autism spectrum. These challenges typically manifest as a tendency to interpret statements literally, the neural basis of which we are currently investigating in a separate task-based study.

Phenotype Summary from the ABIDE-II sample

	ASD	**NT**	***p***
N	59	61	
Avg Age (SD)	15.3 (3.1)	16.1 (3.3)	0.18
Full-Scale IQ (SD)	110.4 (12.2)	113.6 (11.9)	0.16
Verbal IQ (SD)	111.5 (13.3)	115.6 (11.7)	0.08
Mean Framewise Displacement (mean FD)	0.11	0.10	0.52
Age range was 12-24 for both groups. Groups did not significantly differ in age, FIQ, VIQ or mean FD

Title: Severity not fluency is the clinical hallmark of aphasia

Authors: *K. WAKAIZUMI[1,2], R. JABAKHANJI[1,2], R. HURWITZ[1], S. ASHALE[1], E. BAVVITT[1], L. CHRNERY[1], M. N. BALIKI[1,2];
[1]Shirley Ryan AbilityLab, Chicago, IL; [2]Physical Med. and Rehabil., Northwestern Univ., Chicago, IL

Abstract: The cortical language system is thought to be a paradigmatic example of a modular functional system that is necessary for explaining the variability, and neuro-psychological dissociations of language impairments in aphasia, such as comprehension (Wernicke's aphasia) and fluency (Broca's aphasia). We challenge these ideas using data-driven approaches to identify the principal aspects of chronic aphasic performance, and their neural bases.
We applied principal component analysis (PCA), and network-based statistics to identify unique components of language impairments assessed using the Western Aphasia Battery-Revised (WAB-R) in 187 patients with chronic stroke aphasia. All language properties exhibited high inter-correlations and dependency. PCA identified one component with a high eigenvalue (7.47) and a high percentage of explained variance (62.2%). In addition, aphasic performances showed little clustering and topological properties similar to that of random networks.
We also used a data-driven approach to identify different classes of patients with unique behavioral properties, and contrasted them to classical diagnostic classifications of aphasia type. We used k-means and hierarchical clustering paradigms in half of our sample (discovery group, n=94) and validated our result in the other half of the data (validation group, n=93). We observed that patients robustly segregated into two major groups identified by the total propensity of their symptoms (i.e. mild and severe). The classes (mild and severe) showed significant segregation based on the aphasia quotient (AQ) score (Accuracy > 90%, $p<0.01$), but not the fluency score (Accuracy = 55%, $p>0.8$). Clinical diagnosis, such as Broca's and Wernicke's, did not follow the same classification ($p>0.5$, chi-square test), except for Anomic aphasia which mostly classified as mild. Finally, we used validated functional and anatomical neuroimaging methods to identify the neural properties of each class. We observed that total lesion size was not associated with severity of aphasia. Furthermore, resting-state fMRI analysis showed that patients in the severe group exhibited decrease connectivity within the left side of the default mode network. Overall, we show that data-driven approaches can improve our understanding of brain-behavior relationships in stroke aphasia. Our results challenge the classical modular functional systems view for aphasic impairments and indicate the need for an improved data driven framework for understanding, studying, and managing aphasia.

Title: A new method for comparing the predictive validity of brain lesion-behavior mappings

Authors: *J. S. PATTERSON, J. F. MAGNOTTI, T. T. SCHNUR;
Baylor Col. of Med., Houston, TX

Abstract: Lesion-behavior mapping (LBM) is used to identify causal relationships between brain regions and behavior. LBM techniques provide a voxel-wise mapping between brain damage and individual differences in behavior that enable accurate prediction of behavior from lesion patterns. A common use of LBMs is to find the brain regions uniquely associated with different behaviors. Problematically, there is currently no accepted method for determining if two LBMs are significantly different. Most often, researchers compare the LBM output values (e.g., beta weights) either by subtraction or by correlation. However, a more principled statistical criterion remains elusive. Here, we propose a statistical method for comparing two LBMs based on the notion of predictive validity. Two LBMs are different if and only if they provide unique predictive power for the two behaviors assessed. The method produces as output a single statistical test that allows researchers to determine if the LBMs trained on separate behaviors provide equivalent predictive accuracy as a single LBM trained on the average of the two behaviors.

To validate our method, we assessed its ability to correctly identify brain-behavior relationships in two simulations for which the ground truth was known: the two behaviors resulted from damage to different brain regions *vs.* the same brain region. The lesion data came from a dataset of 131 persons with aphasia due to left MCA chronic stroke (source: Moss Rehabilitation Research Institute's Neuro-Cognitive Rehabilitation Research Patient Registry). We created LBMs from the simulated behavior and the lesion data using a sparse multivariate LBM technique (SCCAN; Pustina et al., *Neuropsychologia*, 2018). For each simulation, our new method compared the predictive validity of the LBMs trained on each behavior independently *vs.* a single LBM trained on the averaged behavior. The method correctly identified when the LBMs were similar (paired Wilcoxon $p = 0.46$) and when they were different ($p = 0.003$). In summary, our approach provides a statistical method to objectively determine whether two behavioral deficits are driven by similar patterns of brain damage. The technique works regardless of how the LBMs were generated and can be generalized to situations of more than two behaviors.

Title: Auditory perception and theta activity in specific language impairment

Authors: *I. G. GALÁN[1], N. LAGARDA[1], M. GALICIA[2];
[1]UNAM, Mexico City, Mexico City, Mexico; [2]Natl. Rehabil. Inst., Mexico City, Mexico

Abstract: Phonemes are the smallest contrasting unit of language that distinguishes the meaning of words (Pulvermüller & Fadiga, 2010), that allow perceptual equivalence within a given language (Binder, 2016) and established during the development through the input of the environmental language. The Specific Language Impairment (SLI) proposes an auditory deficit that could hypothesize a posible immaturity in the auditory cortex as a dificulty in the perception of language sounds wich would impact on the development of defined phonological representations. The theta band frequency (4-8 Hz) has been use in the study of linguistic cortical networks and the processing of words and syllables, associated to temporal regions (Carmona et al., 2014; Turken & Dronkers, 2011). ERD/ERS (event-related de-synchronization /synchronization) can be an indirect measurement of functional specificity of neuronal groups mediated by maturational processes to understand the characteristics of language processsing. The objective of this work was to compare phonemic perception skills in children with SLI and children with typical development (TD) through neuropsychological evaluation and quantitative EEG measurement (ERD/ERS) in theta band. We studied 22 children aged 5-6 years divided in two groups: SLI = 12, TD = 10. The phonemic perception performance was assessed using "ENI" Battery (Matute et al., 2007) and EEG recording was made during phonemic stimulation to obtain the ERD/ERS. We used non parametric methods to analize the data. This results indicated lower scores in phonemic perception of children with SLI compared with children with TD, the difference was significant ($Z = 17{,}500$, $p < .05$) with an average range of 7.96 for SLI children and 15.75 for TD. We also made a correlation analysis between the phonemic perception performance and ERD/ERS, the results showed that TD group presented negative association in T3 derivation, $r = -0.72$, $p = 0.04$; meanwhile, SLI presented in F7, $r = -0.87$, $p = 0.05$. This results showed that phonemic perception is influenced by perceptual expectations and phonemic aference (Arnal et al., 2016). In relation to phonemic perception, a greater involvement of left frontal regions in children with SLI could indicate a differential functioning of the linguistic network that explains the lower phonemic perception abilities in these children, which could be interpreted as a compensatory mechanism in the face of poor sensory processing.

Title: Impaired neural pitch encoding associated with autism spectrum disorders in Cantonese-speaking children

Authors: J. LAU[1], X. KANG[1], C. TO[2], M. LOSH[3], *P. C. WONG[1];
[1]The Chinese Univ. of Hong Kong, Shatin, Hong Kong; [2]Univ. of Hong Kong, Pok Fu Lam, Hong Kong; [3]Northwestern Univ., Evanston, IL

Abstract: One feature observed in individuals with Autism spectrum disorders (ASD) is atypical pitch processing. Pitch, in tone languages including Cantonese, conveys word meaning. Impairment of pitch processing thus not only affects their social and emotional communication, but also structural language. This research investigates linguistic pitch processing deficits in Cantonese-speaking children with ASD. We test a version of the Weak Central Coherence (WCC) hypothesis, which posits that impairment to pitch processing associated with ASD is associated with increased sensitivity to local cues at fundamental levels of auditory processing. Despite such hyper-sensitivity to local cues, pitch processing is ultimately impaired due to impairment in the processing of global cues at higher-level processing. We investigated lexical tone processing at behavioral and neural levels of children diagnosed with ASD (N=30) versus those who are typically developing (TD, N=32). Behavioural lexical tone processing was investigated with a tone categorical perception task. Neural encoding of three lexical tones was tested by examining the Frequency-following Response (FFR), a phase-locking electrophysiological component known to provide a faithful `snapshot' of neural auditory encoding with high fidelity. We found that linguistic pitch processing is impaired at both behavioral [marked by less sharp categorical perception (β =-0.13679, Z=-2.889, p=0.0039)] and neural levels [marked by less robust FFR peak autocorrelation [$F(1,60) = 4.222$, p=0.0443], indexing lower pitch encoding fidelity] compared to TD controls. Contrary to the WCC hypothesis which predicts hyper-sensitivity at fundamental levels of processing, results point to a general linguistic pitch processing impairment associated with ASD across the hierarchy of the auditory pathway. This research has identified behavioral and neurophysiological correlates to linguistic pitch processing deficits in Cantonese-speaking children with ASD. An understanding of the behavioral and neural characteristics of their language abilities could lead to better

treatment for language and communication deficits in ASD in the long run, especially those children who are learning a tone language.

Title: Left perisylvian cortex damage selectively impairs pseudoword spelling

Authors: ***J. J. PURCELL**[1], J. SHEA[2], G. PETROZZINO[2], R. WILEY[2], B. RAPP[2];
[1]Univ. of Maryland, College Park, MD; [2]Johns Hopkins Univ., Baltimore, MD

Abstract: Spelling involves retrieving orthographic knowledge from orthographic long-term memory (OLTM) or computing phoneme-to-grapheme correspondences (PGC), and then processing the letter information via orthographic working memory (OWM) prior to producing a written or oral spelling response. Although recent work has used lesion symptom mapping to identify regions associated with OLTM in the inferior frontal gyrus and ventral occipitotemporal cortex and with OWM in the left parietal cortex (Rapp et al., 2015), this work did not test for regions uniquely associated with PGC. In this study, we address this knowledge gap by using a recently refined multivariate lesion-symptom mapping technique (DeMarco & Turkeltaub 2018) to examine the brain basis of PGC, while simultaneously accounting for impairments in either OLTM, OWM or auditory comprehension deficits. We studied 33 participants with post-stroke, chronic dysgraphia (age range 36-80; 15 female). The JHU Dysgraphia battery was used to measure of pseudoword spelling, length effects (i.e. worse spelling for long vs short words) and frequency effects (i.e. worse spelling for low vs high frequency words). Linear mixed effects models were used to obtain beta estimates for the severity of impairment in pseudoword spelling, frequency effects, and length effects in each participant; these served as estimates of damage to the PGC, OWM, and OLTM systems respectively. To account for impairments phonological input processing, we also included a pseudoword auditory discrimination (PALPA1; Kay et al., 1992). Each participant had a T1-weighted MRI scan. Enantiomorphic normalization was used to standard lesions (Nachev et al. 2008). To identify brain regions selectively associated with PGC, we used support vector regression lesion-symptom mapping (SVR-LSM; DeMarco and Turkeltaub, 2018). This analysis accounted for other variables such as frequency effect, length effect, lesion volume, age, digit span, and PALPA1. We found that impairment in PGC was associated with damage to the anterior supramarginal gyrus, pre/post-central gyri, and dorsal

IFG. Second, severity of auditory comprehension impairment (PALPA1) was exclusively associated with damage to the superior temporal gyrus. These findings fit with previous literature reporting that impairments in PGC in spelling - along with phonological input deficits - were associated with damage to left Perisylvian cortex (Henry et al. 2007). We extend this work by demonstrating that impaired PGC in spelling were restricted to damage dorsal to the Sylvian fissure.

Abstract: Cochlear implants (CIs) are neuroprosthetic devices that can restore hearing to patients with profound hearing loss, but with a loss of acoustic detail compared to healthy biological hearing. The brain networks required to extract meaning from this degraded signal are poorly understood. Here we use high-density diffuse optical tomography to quantify source-localized cerebral blood flow in adult patients with cochlear implants during spoken word perception. Patients all had unilateral right-side cochlear implants, and ranged in age from 31-72 years. We compared brain activity in CI patients to a group of young adults, and to a separate group of age- and sex-matched controls. Participants listened to lists of single, unrelated words in a block design, with 15 seconds of spoken words alternating with 15 seconds of silence. Each participant listened to 12 blocks of words (about 6 minutes of data). We recorded regional changes in blood flow using near infrared spectroscopy and a large field-of-view cap with 96 sources and 92 detectors, covering large portions of the occipital, temporal, and frontal lobes.Source localized results were analyzed using a voxelwise general linear model framework in standard space. We found that while listeners with normal hearing showed speech-related

activity in temporal cortex, CI listeners additionally showed activity in left dorsolateral prefrontal cortex. This frontal activation is consistent with a need to rely on executive resources to compensate for a degraded acoustic signal.

Title: Ablation and resection for mesial temporal lobe epilepsy: Analysis of neuropsychological performance in language and memory

Authors: *K. TOMBRIDGE[1], C. DONOS[1], L. MOSS[2], J. JOHNSON[1], J. BREIER[2], P. ROLLO[1], N. TANDON[1,3];
[1]Vivian L. Smith Dept. of Neurosurg., [2]Children's Learning Inst., Univ. of Texas Hlth. Sci. Ctr.

at Houston, Houston, TX; [3]Mischer Neurosci. Inst., Mem. Hermann Hosp. Texas Med. Ctr., Houston, TX

Abstract: INTRODUCTION: Brain activation studies using fMRI and electrocorticography have frequently been used to map language and memory in stroke and epilepsy patients. Voxel-wise lesion-based symptom mapping (VLSM) techniques, typically conducted in stroke patient populations, are vital in delineating the anatomical organization of language. This technique does not consider both important pre-morbid individual differences and reorganization that occurs after damage. Accounting for these factors will maximize the predictive power that connectivity has on behavioral outcome. By applying this technique in a controlled-lesioned epileptic patient population, we can disambiguate the components of the temporal lobe.
METHODS: To elucidate the cognitive impact, lesioned tissue was related to neuropsychological assessments in a sample of 63 patients who underwent surgery to treat mTLE. These patients underwent one of the surgical techniques: Anterior Temporal Lobectomy (ATL; n=42) or Laser Interstitial Thermal Therapy (LITT; n=21), in the left, language-dominant hemisphere. Pre- and post-operative behavioral and neuroimaging measures were conducted to measure pre-surgical differences and post-surgical functioning. The neuropsychological test battery included measures of verbal fluency, naming, and memory (semantic, verbal, and spatial). Lesion volumes were outlined using a post-operative T1 contrasted MRI in MRIcron software. Seizure outcomes were measured using Engel classification. VLSM and percent damage of brain region were analyzed with neuropsychological subtests.
RESULTS: In both ATL and LITT, post-surgical declines in verbal memory were found. Region-based analyses provided a distinct relationship between percent damage to anterior temporal lobe sub-regions and neuropsychological task performance. Comparison of neuropsychological outcomes between surgery types showed significant differences in verbal learning, auditory memory, and visual memory. No significant impact on naming was detected within the ablation surgical group.
CONCLUSIONS: This study leverages a unique patient population for the comparison of the effects of lesions on individuals' cognition. Consequently, we can better quantify the functional organization of language-dominant temporal lobe and the impact ATL and LITT surgeries have on cognitive outcomes. This will inform future refinement of psycholinguistic models of language as well as provide insights to design surgical interventions for mTLE that minimize cognitive deficit.

Title: The neural correlates of emotional influence on semantic processing in alexithymia

Authors: *S.-H. LEE[1], C.-L. YU[1], T. CHEN[2], C.-C. LIAO[2];
[1]Natl. Tsing Hua Univ., Hsinchu, Taiwan; [2]Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Alexithymia has been found as a major risk factor for a variety of psychiatric disorders, including somatoform disorders, panic disorders, drug addiction, and alcoholism (Waller & Scheidt, 2004). Individuals with alexithymia demonstrate disabilities in both affective and cognitive dimensions characterized by identifying, analyzing, and verbalizing the emotions of the self (Vorst & Bermond, 2001). Specifically, alexithymia has been thought as a linguistic deficit in processing emotions of self and also in understanding the emotions of others (Moseley et al., 2015). Thus, individuals with alexithymia may show both affective and semantic deficits, demonstrating disruptions in both emotion-related regions and semantic-related regions in the brain. However, the neural correlates of this interaction is not clear. In the current study, we aimed to use event-related fMRI to examine the neural correlates of emotional influence on semantic processing in alexithymia. In order to have a better understanding of the emotional influence on semantic processing, we aimed to adopt an emotional semantic judgment task. In the semantic judgment task, association strength (strong, weak) and emotional valence (negative, neutral) are independently varied. This systematic manipulation allowed for a more precise determination of the role of emotion in processing meaning. In the current study, we conducted analyses for the individuals with high alexithymia in the contrast of [(Negative strong association > Neutral strong association) - (Negative weak association > Neutral weak association)]. The results revealed significant activation in the left inferior parietal lobule (IPL), supporting the semantic integration for the incoming semantic information into a larger unit of concept for stronger association pairs. In addition, the results also demonstrated significant activation in right temporal parietal junction (TPJ), medial prefrontal cortex (mPFC) and precuneus, suggesting the engagement of self-recognition over negative emotion. Our current analyses gave an overview of the networks of the impact of emotion over semantic processing in individuals with high alexithymia. Thus, we may evaluate the dysregulation of brain regions associated with emotional processing and semantic processing and the inter-connection between these brain regions for both high and low alexithymia groups in our future research.

Title: LiP-MS: A novel approach to probe protein (mis)folding and drug-protein interactions

Authors: *Y. FENG[1], L. MALINOWSKA[2], L. VERBEKE[1], N. BEATON[1], R. BRUDERER[1], L. REITER[1], P. PICOTTI[2];
[1]Biognosys AG, Schlieren-Zurich, Switzerland; [2]Inst. for Mol. Systems Biol., ETH Zurich, Zurich, Switzerland

Abstract: Background Protein misfolding and aggregation are commonly observed phenomena in a wide range of neurodegenerative diseases. For example, aggregates of the amyloid-beta (Aβ) peptide and of the protein alpha-Synuclein (αSyn) are formed in brains of Alzheimer's disease (AD) and Parkinson's disease (PD) patients, respectively. (Mis)folding and aggregation events of these disease-related proteins have been extensively investigated in vitro. However, little is known about their structure-function/toxicity relationship in vivo, largely due to the lack of experimental tools that can assess protein structural features in complex biological matrices. To address this challenge, we developed a strategy combining limited proteolysis (LiP) and quantitative mass spectrometry (MS) that enable the proteome-wide probing of protein structural alterations directly in cell and tissue lysates. We showcase the power of this approach in two major applications that are highly relevant to drug development and discovery in the neuroscience space.
Results In the first application of LiP-MS, we deployed this method to compare in vitro and in situ structures of αSyn. We generated a library of structure-specific proteolytic signatures using well-characterized structures of αSyn prepared from the recombinant protein. We then measured the proteolytic signatures of αSyn in cells overexpressing αSyn and used in vitro reference structures in a mathematical framework for predicting the αSyn structural composition in cells. As a second application, we developed dose-response (DR) LiP-MS for drug target deconvolution. Detection and quantification of LiP-peptides allowed us to probe small molecule drug-binding sites and to estimate binding affinities (IC50) in cellular lysate. To demonstrate the performance of this workflow, we profiled the target space for a specific kinase inhibitor, selumetinib (SE), as well as a broad-band inhibitor, staurosporine (ST). Our approach successfully identified the known target MEK1 for SE while for the unspecific ST, we found a significant enrichment of kinase targets in our drug-binding candidate list.
Conclusions We present a method that enables two key applications to address unmet needs in neurodegeneration research. On the one hand, LiP-MS can be employed to assess the structural landscape of disease-related proteins in clinically relevant cells and tissues. On the other hand, LiP-MS has demonstrated its capabilities as a powerful target deconvolution and identification strategy, regardless of the specificity of the compound.

Title: Integrative proteomics and pathway analyses reveal perturbed mitochondrial signaling in ApoA2-kocout mice brain

Authors: M. KHALIFA[1], *S. AZZAM[2], J.-E. DAZARD[2], K. STROHL[2];
[1]St. George's Univ. Sch. of Med., St. George's, Grenada; [2]Case Western Reserve Univ., Cleveland, OH

Abstract: Apolipoprotein A2 (ApoA2) is a brain apolipoprotein. ApoA2 gene and its downstream interactions have broad effects on breathing and fictive brainstem phrenic rhythm stability (Gillombardo et al, 2017). The lack of fundamental information relevant to its unexpected CNS presence and potential effects at cellular level leads one to further investigate the topic. To address this and understand system-level perturbations mediated by ApoA2 presence (ApoA2-WT mouse) or absence (ApoA2 knockout (KO) mouse), we performed integrative omics profiling and pathway analyses. Our previous proteomics data showed no ApoA2 protein in the KO mouse; and a lesser abundance of the protein in WT brainstem, and hypothalamus in comparison to either WT liver or plasma (P=0.0001). In this study, label-free expression proteomics and phosphoproteomics profiles of brain tissue from WT (n = 8) and ApoA2-KO (n = 8) were acquired by LC-MS/MS (LTQ Orbitrap). LC-MS/MS raw files were imported into Rosetta Elucidator^{TM} software for peptides identification and quantification. To reduce the dimensionality of the data, and reduce the error rates, pre-filtered proteins with at least two quantified peptides were analyzed for differential expression using a Bayesian ANOVA model. To examine how APOA2 KO-induced differential proteomic expressions predict the downstream changes in APOA2 KO-induced phosphorylation signaling pathway(s), we integrated both omics-datasets using Partial Least Square (PLS) and Kinase-Substrate Enrichment Analysis (KSEA) approaches. While Bayesian ANOVA yielded a total of 387 unique annotated proteins (209 up- and 178 down-regulated) and 162 unique annotated proteins (127 up- and 35 down-regulated) from label-free and phosphoproteomics data, respectively, PLS revealed a subset of differentially expressed proteins correlated with 22 activated kinases/phosphatases proteins upon ApoA2-KO. Analyzing this integrated data by two novel pathways tools, Ingenuity Pathway Analysis (IPA) and Crosstalker, identified mitochondrial function (oxidative phosphorylation, citric acid cycle and respiratory electron transport) as the top dysregulated canonical pathway. This finding is consistent with our previous quantitative

proteomic and pathway analyses of liver tissue that have indicated an effect of ApoA2 on mitochondrial electron transport chain. In conclusion, integrative omics profiling and pathway analyses identify protein, and kinase, activity perturbations in mitochondrial signaling as a consequence of ApoA2 loss with implication for energy homeostasis and cellular bioenergetics systems in the brain.

Title: Transcriptomic changes in the arcuate nucleus of the hypothalamus in response to prolonged high fat diet: Insights from single-nucleus RNA-sequencing

Authors: *G. DENG, L. L. MORSELLI, S. A. SAPOUCKEY, V. A. WAGNER, A. E. KWITEK, J. L. GROBE, H. CUI;
Univ. of Iowa, Iowa City, IA

Abstract: Selective leptin resistance (SLR) is a pathological state caused by prolonged high fat diet (HFD) feeding in which cardiovascular responses to leptin are preserved, but metabolic effects are attenuated. Thus, SLR is hypothesized to contribute to obesity-associated hypertension, but the mechanisms causing SLR are unclear. Neurons expressing agouti-related peptide (*Agrp*) within the arcuate nucleus (ARC) represent a major target for leptin signaling and may play a role in SLR. Previous studies in various rodent models indicate that while shorter-term (4-14 weeks) HFD feeding suppresses ARC *Agrp* expression, this suppression is lost with longer-term (10-20 weeks) exposure. Further, 10 weeks of 45% HFD (D12451) feeding is sufficient to cause SLR in wildtype C57BL/6J mice. To examine the transcriptomic changes induced by prolonged HFD exposure specifically in *Agrp* neurons, we performed single-nucleus RNA-sequencing on nuclei isolated from ARC of *ad libitum* fed male C57BL/6J mice fed chow diet (7013; CD, n=5) or 45% HFD (n=6) from 8 to 18 weeks of age. At 18 weeks, fat mass (+10.1±1.4 vs +3.2±0.4g, $p<0.01$) was increased in mice fed HFD vs CD, energy expenditure was decreased (feed efficiency: 17±2 vs 12±1 mg/kcal, $p<0.05$), and caloric intake was normal (10±1 vs 9±1 kcal/d after correction for body mass, $p=0.3$). After pooling replicates and filtering

out nuclei with low quality reads, a total of 6,621 (CD) & 14,396 (HFD) nuclei remained. Unbiased clustering (Seurat) identified 22 cell-type clusters, including one cluster with high expression of *Agrp* (n=136 CD & 453 HFD cells). HFD caused differential expression of 73 genes in this cluster, including genes previously implicated in energy balance such as *Grm5* (69% of CD, FDR q<0.01). Interestingly, although 10 weeks of HFD feeding increased circulating leptin (119±43 vs 486±148 pg/mL, p<0.05), *Agrp* expression was increased (126%, FDR q<0.01) and Ingenuity Pathway Analysis revealed gene expression perturbations in canonical pathways implicated in the pathogenesis of obesity, including "Leptin Signaling in Obesity" and "Protein Kinase A (PKA) Signaling." These results correlate dysregulated *Agrp* expression within ARC *Agrp* neurons with the development of SLR, and may implicate altered PKA signaling in this process.

Abstract: The Human Protein Atlas (HPA, http://www.proteinatlas.org) is a public online database that provides an integrated overview of protein expression and location in all major human organ and tissue types. Within this portal, we have now created a brain-centric sub atlas, where a similar approach is used to provide a comprehensive overview of protein expression in the main anatomical structures of the human, mouse and pig brain. RNA expression levels in the major anatomically defined regions of the mammalian brain are compared and used for classification of all human protein-coding genes (one-to-one orthologous genes) in human, pig and mouse. Antibody-based protein profiling in human and mouse enable spatial resolution

down to almost single cell level. Thus, we provide additional information on the detailed localization of proteins in cells compared to ISH, with proteins located at synaptic compartments being a clear example of targets that benefit of this antibody-based investigation. Thanks to such multi-omics approach, we have found several genes with an expression profile unique to the human brain when compared to mouse and pig. Notably, among all investigated brain regions, the cerebellum had the highest level of variation when compared to other brain regions or when compared with other species.

Abstract: Identifying the molecular organization of the brain, at the regional, cellular and sub cellular levels is important to provide detailed molecular information to advance our understanding of the brain physiology and disease. In the Human Protein Atlas (HPA) we use an integrated omics approach based on transcriptomics analysis and antibody-based mapping to better understand protein expression and localization. We now created a brain-centric sub atlas, where a similar approach is used to provide a comprehensive overview of protein expression in the main anatomical structures of the human, mouse and pig brain. The transcriptomics analysis of the basic brain structures (olfactory bulb, cerebral cortex, hippocampal formation, amygdala,

basal ganglia, hypothalamus, thalamus, midbrain, pons, medulla oblongata and cerebellum) reveals the fundamental molecular organization of the mammalian brain, but also unique features not shared by all 3 species. Antibody-based protein profiling in human and mouse enable spatial resolution down to single cell details. Serial sections of the mouse brain provide a full brain overview for a selection of over 250 targets, available as online virtual microscope of high-resolution images. And more than 800 genes were selected for protein mapping in human, in collaboration with the Tissue Atlas. By combining the brain-centric perspective with the whole-body view, established in an updated version in the HPA Tissue Atlas, we are able to classify protein-coding genes based on the expression level and group genes into different categories. Genes with higher expression in brain compared to other tissue types are highlighted as "brain elevated" (in total 2587 genes) and when comparing the expression levels within brain, 1059 genes are classified as regionally elevated. This unique strategy enables comparison of expression within brain to the whole-body perspective. And for the first time we facilitate a gene based comparison of RNA expression in three different mammalian brains, side by side, grouped into the major regions of the brain.

Title: Chemoproteomics identifies key KDM1A interactors and unravels mechanisms of action of vafidemstat on aggressive behavior and cognition

Authors: M. M. P. LUFINO, C. MASCARÓ, D. ROTLLANT, C. BUESA, *T. MAES; Oryzon Genomics S.A., Cornella de Llobregat, Spain

Abstract: Epigenetic dysregulation plays an important role in neurodegenerative and psychiatric disorders. Vafidemstat (ORY-2001) is an orally available, brain-penetrant KDM1A/MAO-B inhibitor. Vafidemstat is currently in PhIIa clinical trials in Alzheimer's disease (AD), Multiple sclerosis and in aggression. We previously reported that vafidemstat restores the cognitive deficit and behavior alterations including aggression in SAMP8 mice; and the responsiveness of

immediate-early genes (IEG) in their prefrontal cortex following exposure to stress. Recent data from the PhIIa basket trial in aggression indicate that vafidemstat also reduces aggression in patients with BPD and ADHD. KDM1A is a FAD-dependent amine oxidase recruited to active chromatin by transcription factors (TFs) and demethylates primarily H3K4me2/1 marks, thus repressing gene expression. We analyzed the KDM1A interactome in human neuroblastoma cells using a biotinylated KDM1A chemoprobe that binds specifically to the active enzyme. KDM1A-containing complexes were pulled down and analysed by mass spectrometry. This chemoproteomics approach permitted identification of components of the core KDM1A complex including RCOR and HDAC proteins, in addition to KDM1A-recruiting TFs ZMYM2, ZNF516 and ZNF217. KDM1A-interactor ELISAs on neuroblastoma cells and on human hippocampal tissue confirmed the interactions detected by MS and identified several other KDM1A-recruiting TFs, including REST, ZNF878, OVOL2, SRF and GTF2I. The last two TFs are particularly interesting as they control the transcription of the IEG *Fos* and have been involved in cognition and behavior. *GTF2I* duplication is involved in autism spectrum disorders in the 7q11.23 duplication syndrome. SRF is important for activity-dependent gene expression and its loss in the forebrain of rodents impairs acute stress-associated immediate and long-term coping mechanisms, learning and memory. KDM1A transcription regulation circuits are complex, and the role of many TFs that recruit KDM1A in the brain is still largely unknown and requires further studies. Nevertheless, the identification of SRF and GTF2I as key elements in the mechanism of action of vafidemstat provides solid support for the observed therapeutic activity of this compound in cognition and behavior.

Title: Determining cell-type specific striatal synaptic proteomes in mice

Authors: *H. WANG[1], Y.-Z. WANG[2], J. N. SAVAS[1];
[2]Neurol., [1]Northwestern Univ., Chicago, IL

Abstract: Mammalian synapses display a high degree of structural and functional diversity. The large number of neuron and neurotransmitter types make it extremely challenging to isolate the proteome of a single type of synapse with biochemistry, micro dissection, or cell sorting. Until recently, our understanding of the synaptic proteome has been limited by composite measures of heterogeneous synaptosome biochemical fractions. We set out to develop a modular tool kit in order to systematically measure many different discrete synapse types in the mouse brain. We merged several previously described tools to leverage a new set of probes based on BioID (a biotin ligase, BirA*). We fused BirA* to the pre- and post- synaptic membrane localization domains from pre-mGRASP (BirA*-pre) or post-mGRASP (BirA*-post). We characterized our probes in cultured hippocampal neurons and found that about 90% BirA*-pre puncta co-localized with the excitatory synapse marker VGluT1 but only 20% with the inhibitory synapse marker VGAT. Similarly, 80% of the BirA*-post puncta colocalized with PSD95 but 40% with Gephyrin. In this way we aim to achieve promiscuous biotinylation of synaptic proteins interacting with the probe or in close proximity. The biotinylated proteins are pull-down by streptavidin or anti-biotin antibodies and analyzed by tandem mass spectrometry-based proteomic analysis. To test the tools, we stereotactically delivered them as viruses to several basal ganglia circuits: 1) targeting synapses at direct or indirect pathway spiny projection neurons (e.g. dSPNs or iSPNs) in striatum that are affected in autism spectrum disorder (ASD); 2) targeting synapses at striatopallidal projection that is affected in Huntington's disease (HD). With IHC we found that both BirA*-pre and BirA*-post successfully facilitated biotinylation within striatum without recruiting astrocytes or microglia. In our proteomic analysis on wild-type striatum samples, we quantified 1,740 proteins at similar levels in both cell types, 842 proteins specific for dSPNs, and 77 for iSPNs. Additional bioinformatic analysis showed that the BirA*-post datasets were enriched for proteins known to localize to postsynaptic membranes and presynaptic proteins in BirA*-pre datasets. These data documented our progress towards obtaining a near complete draft of specific synaptic proteome. In the future we will apply our probes to a panel of synapses in mouse models of HD and ASD. It is our hope that by determining how discrete synaptic proteomes are remodeled we will gain new insight on how synapse are hampered during diseases.

Title: A universal evolution-based nomenclature for the oxytocin and vasotocin ligand and receptor families

Authors: *C. THEOFANOPOULOU[1], G. GEDMAN[2], J. A. CAHILL[4], C. BOECKX[5], E. D. JARVIS[3];
[1]Univ. of Barcelona/Rockefeller Univ., Barcelona, Spain; [2]The Lab. of Neurogenetics and Language, [3]The Rockefeller Univ., New York, NY; [4]Rockefeller Univ., New York, NY; [5]Univ. de Barcelona, Barcelona, Spain

Abstract: Oxytocin (*OT*) and vasopressin/vasotocin (*VT*) are neurotransmitter ligands that function through specific receptors to control a diverse set of brain functions. Here we performed genome analyses in 34 species spanning all major vertebrate lineages and 4 outgroup invertebrate lineages to resolve orthology and the evolution of oxytocin and vasotocin ligands and receptors (*OT*, *VT* and *OTR-VTRs*). We included genomes of newly re-sequenced species with long-read technology that filled in gaps and corrected errors in previous shorter-read assemblies, some of the former being assemblies contributed by the G10K Vertebrate Genomes Project (VGP; https://vertebrategenomesproject.org). We performed pair-wise BLAST/BLAT analyses, analyzed gene synteny from microchromosomal to macrochromosal scales, across and within species, and performed phylogenetic tree inference of genes families. Our findings support the claim that *OT* and *VT* are adjacent paralogous genes resulting from a local duplication, which we infer was through DNA transposable elements near the origin of vertebrates, with *VT* the parental gene. We identified six *OTR-VTR*s among vertebrates, and propose they arose from a single invertebrate-like *VTR* through a combination of whole genome and large segmental duplications at the origin of vertebrates, followed by lineage-specific losses and gains. Based on these findings we propose a universal evolution-based nomenclature for the oxytocin and vasotocin ligand and receptor gene families, where they be given the same

orthologous names across vertebrates and paralogous names relative to each other, according to their relationships and evolutionary history. This terminology and vertebrate-wide perspective should prevent further confusion and errors of orthology and paralogy due in part to differential naming in the pre-genomic era, allow easier translation of findings across vertebrates, foster more informative design of functional experiments across species, and further understanding of their evolution.

Title: A mouse model for chronic intermittent electronic cigarette exposure exhibits nicotine pharmacokinetics resembling human vapers

Authors: *X. M. SHAO[1,2], B. LOPEZ[2], D. NATHAN[2], J. WILSON[2], E. BANKOLE[2], H. TUMOYAN[2], A. MUNOZ[2], J. ESPINOZA-DEROUT[2], K. M. HASAN[2], S. CHANG[2], C. DU[3], A. P. SINHA-HIKIM[2], K. LUTFY[4], T. C. FRIEDMAN[2];

Abstract: The use of electronic cigarettes has increased in recent years, particularly among youths. Animal models for e-cigarette exposure with pharmacokinetics resembling human e-cigarette users are lacking. We developed an e-cigarette aerosol exposure system for rodents and a chronic intermittent delivery method that simulates e-cigarette users who vape episodically during wakefulness and abstain during sleep. Mice were exposed to e-cigarette in a programmed schedule at very low, low, medium, and high doses defined by duration of each puff, number of puffs per delivery episode and frequency of episodes in the dark phase of a 12/12-h circadian cycle for 9 consecutive days. The plasma nicotine/cotinine levels and their time courses were

determined using LC/MS-MS. We assessed the body weight, food intake and locomotor activity of Apolipoprotein E null mice exposed to chronic intermittent e-cigarette aerosol. Plasma nicotine and cotinine levels were positively correlated with exposure doses. Nicotine/cotinine levels showed a circadian variation as they increased with time up to the maximum nicotine level of 21.8 ± 7.1 ng/mL during the daily intermittent e-cigarette exposure in the 12-h dark phase and then declined during the light phase when there was no e-cigarette delivery. Chronic e-cigarette exposure to ApoE-/- mice decreased body weight, food intake and increased locomotion. Our rodent e-cigarette exposure system and chronic intermittent exposure method yield clinically relevant nicotine pharmacokinetics associated with behavioral and metabolic changes. The methodologies are essential tools for *in vivo* studies of the health impacts of e-cigarette exposure on CNS, cardiovascular, pulmonary, hepatic systems, metabolism and carcinogenesis.

Title: Strain-dependent sexual dimorphism in the cns: Proteomic analysis of the mouse retina

Authors: ***J. C. HARMAN**[1], J. J. GUIDRY[2], J. M. GIDDAY[1];
[1]Ophthalmology, Physiology, Neurosci. Ctr. of Excellence, Biochem., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA; [2]Biochemistry-Proteomics Core Facility, LSUHSC, New Orleans, LA

Abstract: The neuroscience research enterprise depends on preclinical models to gain insight into human physiology and pathophysiology. While studies in rodents have historically represented a large fraction of this endeavor, studies of strain-dependent differences are rare. Only recently have calls been made to systematically include females. In our efforts to understand disease, we often consider the resting, baseline condition as only a control, and not as the very foundational basis for such disease. To document the significance of these shortcomings at the phenotypic level, we undertook a quantitative proteomics approach to analyze the retina of adult mice, with strain and sex as independent variables. Retinae were harvested from 5 male and

5 female mice of both the inbred C57Bl/6J (B6) strain (Jackson Labs, Bar Harbor ME), and the outbred Swiss Webster-ND4 (SW) strain (Envigo, Indianapolis IN), during daylight hours under resting conditions. Retinae were processed for MS3 analysis on a Fusion Orbitrap mass spectrometer using Tandem-Mass-Tags for quantification. Approximately 4000 unique proteins were identified in the both the inbred and outbred retinae. 77 proteins were differentially expressed (at levels >1.5 fold) between male and female mice in B6. In SW mice, 76 proteins showed sex-dependent expression differences. Downstream bioinformatic analysis implicates many of these proteins as enriched in metabolic pathways. Of note, only about 25% of the differentially expressed proteins were identical between strains. These data indicate that, in the resting state, significant differences exist in the adult retinal proteome of inbred and outbred mice, and that the adult retinal proteome exhibits a number of distinct, sex-dependent differences unanticipated for a tissue unrelated to reproductive fitness. On the one hand, these differences provide a phenotypic foundation for the epidemiological findings that the incidence of many neurological diseases varies by sex. On the other hand, these differences also raise serious caution about assuming the physiologic and anatomic ubiquity, as well as the translational relevance, of preclinical neuroscience research results derived from studies based on a single inbred or outbred strain, or a single sex.

Title: Dissecting individual differences in alcohol sensitivity using *C. elegans*

Authors: *B. L. CLITES[1], K. EVANS[2], E. ANDERSEN[2], J. T. PIERCE[1];
[1]Inst. for Cell. and Mol. Biol., Univ. of Texas at Austin, Austin, TX; [2]Dept. of Mol. Biosci., Northwestern Univ., Evanston, IL

Abstract: Despite its high heritability, the genetic basis of alcohol use disorder (AUD) remain poorly understood. Attempts at genome-wide association studies (GWAS) for AUD in human populations have largely failed, due to a lack of controls for life history and an inability to precisely measure AUD phenotypes. To overcome these limitations, we are conducting a GWAS for alcohol sensitivity, the best predictor of later life alcoholism, using 250 whole-genome sequenced *C. elegans* wild-isolates. We have already identified four significant loci associated with resistance to acute alcohol intoxication: one near the known alcohol target BK-channel, and

three at novel sites never before implicated in alcohol response. We are now using CRISPR gene-editing to identify and functionally characterize causal variants at these loci. A more complete knowledge of the genetic underpinnings of AUD will contribute to a better understanding of the neuronal and behavioral dynamics that lead to alcohol abuse.

Title: Best practices for mosaic variant discovery in the human brain using whole-genome sequencing data

Authors: *T. B. BAE[1], .. BRAIN SOMATIC MOSAICISM NETWORK[2];
[1]Dept. of Hlth. Sci. Research, Ctr. for Individualized Med., Mayo Clin., Rochester, MN; [2]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Mosaic mutations, which arise post-zygotically and exist in only a subset of the cells of a single individual, are common in brain development of healthy individuals and may contribute to brain-related disorders. Despite the advent of high-throughput sequencing technologies, the accurate detection of mosaic variants is still challenging due to their presence in a very low proportion of cells. The Brain Somatic Mosaicism Network (BSMN), which is a multi-institutional initiative for the comprehensive understanding of somatic mosaicism in the human brain, generated a whole-genome sequencing data resource from the human brain to develop, optimize, and evaluate the performance of methods for mosaic variant discovery. First, we simulated mosaic variants at various allele frequencies by mixing and sequencing the DNA of four unrelated individuals. Using this data, we evaluated the performance of commonly used tools for the purpose of mosaic variant discovery. This exercise revealed that the naive application of germline variant calling from a single sample or somatic variant calling from paired samples (as typically done in cancer studies) is neither precise nor sensitive. Next,

different labs produced several replicates of whole-genome sequencing data of bulk cortical tissue and dural fibroblasts from a reference healthy human brain including standard Illumina 250X deep sequencing, linked read sequencing by 10X, and sequencing of 12 single cell neurons amplified by multiple displacement amplification. We then developed and applied several analytical approaches for calling and filtering mosaic variants from these data. Through validation experiments and the consideration of multiple orthogonal supporting evidence for 400 candidate mosaic calls, we identified a set of 44 true mosaic variants. Guided by the validation results, we derived consensus best practices for mosaic variant discovery that achieves 80%-95% precision with 70%-95% sensitivity towards the validated set. This data resource and best practices implementation will be made available to the scientific community.

Title: Cell type specific analysis of selenium-related genes in brain

Authors: A. R. SASUCLARK[1], V. KHADKA[1], ***M. W. PITTS**[2];
[1]Univ. of Hawaii, Honolulu, HI; [2]Univ. of Hawaii Syst., Honolulu, HI

Abstract: Selenoproteins are a unique class of proteins that play key roles in redox signaling in the brain. This unique organ is comprised of a wide variety of cell types that includes excitatory neurons, inhibitory neurons, astrocytes, microglia, and oligodendrocytes. Whereas selenoproteins are known to be required for neural development and function, the cell-type specific expression of selenoproteins and selenium-related machinery has yet to be systematically investigated. Due to advances in sequencing technology and investment from the NIH-sponsored BRAIN initiative, RNAseq data from thousands of cortical neurons can now be freely accessed and searched using the online RNAseq data navigator at the Allen Brain Atlas. Hence, we utilized this newly developed tool to perform a comprehensive analysis of the cell-type specific expression of selenium-related genes in brain. Select proteins of interest were further verified by means of multi-label immunofluorescent labeling of mouse brain sections. Of potential significance to neural selenium homeostasis, we report co-expression of selenoprotein P (SELENOP) and

selenium binding protein 1 (SELENBP1) within astrocytes. These findings raise the intriguing possibility that SELENBP1 may negatively regulate astrocytic SELENOP synthesis and thereby limit downstream Se supply to neurons.

Title: Unravelling mGluR5 dynamic interactions, signaling, and mGluR-LTD mediated protein synthesis using multilayered mass spectrometry-based proteomics approaches

Authors: *C. A. G. H. VAN GELDER, R. PENNING, C. C. HOOGENRAAD, H. D. MAC GILLAVRY, M. ALTELAAR;
Utrecht Univ., Utrecht, Netherlands

Abstract: Long term depression (LTD), or activity regulated reduced synaptic strength, is a form of plasticity that is key in many brain processes (e.g. learning, memory) and in disorders such as autism. This desensitization is the result of chemical stimulation of the metabotropic glutamate receptor 5 in the dendritic spines of hippocampal neurons results in LTD, which leads to internalization of AMPA-type glutamate receptors. We use a variety of mass spectrometry-based proteomics approaches to study the molecular mechanisms of mGluR5-LTD in primary hippocampal and cortical neurons. Low sample amounts and local, dendritic protein synthesis in very short time points are challenging characteristics of these neuroproteomics experiments. Utilizing specialized proteomics approaches, including highly sensitive Fe(III)-IMAC cartridges in an automated platform to enrich for phosphorylated peptides and azide labeled methionine replacement azido homo alanine (AHA) for the labeling and enrichment of newly synthesized proteins. This allowed for the creation of a proteome wide and unbiased map of LTD signaling routes, as well as the identification of key kinases in these pathways. Moreover, we use APEX2, a chemical biology approach utilizing biotin labeling of proximal proteins, to map the mGluR5 interactome. Stimulation of the mGluR5-APEX2 fusion construct with H_2O_2 allows for rapid, 60 second, biotinylation of proximal proteins, creating a snapshot of the mGluR5 interactome in space and time in living cells. This led to the identification of novel, and location dependent mGluR5 interactors, further confirming a differential role of intracellular mGluR5.

Title: Bench-marking behavioral effects of methamphetamine in casper zebrafish for the development of photoaffinity probes

Authors: *A. WISNER, A. HORTON, F. S. HALL, F. WILLIAMS, I. SCHIEFER;
Univ. of Toledo, Toledo, OH

Abstract: Background*:* Novel synthetic psychostimulants (i.e., 'bath salts') have begun to replace common drugs of abuse like methamphetamine (MA) and 3,4-methylenedioxymethamphetamine (MDMA) in recreational drug markets. The rate at which novel synthetic psychostimulants are produced has rapidly outpaced their pharmacological evaluation in mammalian animal models. The zebrafish has become a widely used model in neurobehavioral research due to its high-throughput capabilities and diverse behavioral repertoire. This work aims to utilize the Casper zebrafish line ($roy^{-/-}$; $nacre^{-/-}$) with photoaffinity labeling techniques to assess the behavioral effects of psychostimulants and identify the associated drug targets. Methods: Adult Casper zebrafish are transferred from the home tank into an exposure chamber for a 20 min waterborne exposure of varying equimolar concentrations of either MA (5-65 mg/L) or an equimolar amount of a novel methamphetamine related photoreactive probe (named MAP). Fish were then transferred to a novel tank and their behavior tracked and analyzed via a collection of freeware programming functions (available at http://iEthology.com/ and https://www.r-project.org/). Behavioral data was assessed for MA and MAP's ability to elicit a change in zebrafish locomotor and anxiety-related behavior in the novel tank test paradigm. Results/Conclusion: We successfully bench-marked a dose-response curve for MA and MAP in the Casper zebrafish line. MAP elicited similar behavioral changes as MA in the novel tank test, albeit MAP appears to be slightly more potent than MA at lower doses.

Title: Methamphetamine probe synthesis and *in vivo* psychostimulant target identification

Authors: *A. HORTON[1], A. WISNER[2], E. TACKIE-YARBOI[1], K. HAGOOD[1], T. CHAU[3], F. S. HALL[4], F. WILLIAMS[2], I. T. SCHIEFER[1];
[1]Medicinal and Biol. Chem., [2]Pharmacol. / Toxicology, [3]Chem. Engin., Univ. of Toledo, Toledo, OH; [4]Pharmacol., Univ. of Toledo Col. of Pharm. and Pharmaceut. Sci., Toledo, OH

Abstract: Background: Psychostimulant drugs have long been abused by every culture throughout history. Advances in synthetic chemistry techniques have introduced an ever growing variety non-naturally occurring psychostimulatory molecules ripe for abuse. Many of these drugs of abuse come from a class of molecules known as phenethylamines. Examples of commonly abused phenethylamines include methamphetamine (MA), a Schedule II psychostimulant, MDMA (commonly referred to as 'Ecstasy'), and a variety of synthetic cathinones (i.e., 'bath salts') which are new to the marketplace and have yet to be fully regulated or rigorously evaluated scientifically. Gaining a more complete understanding of the drug targets, mechanism of action (MOA), and toxicity associated with novel synthetic psychoactive agents is an important step to effectively treat substance abuse disorders, long term toxicity, and episodic lethality. This work seeks to utilize a novel experimental platform employing transparent pigment-free zebrafish (known as "casper" fish), photoaffinity labeling, and click chemistry to define target receptors of these agents. Methods/Results: We synthesized a novel MA-like photoreactive probe (named MAP), employing a Grignard dependent synthetic strategy, and demonstrated that upon irradiation with UV light (i.e., black light), MAP readily converts (half-life = 3.2 min) to a highly reactive intermediate which will react with proteins in close proximity, presumably its target proteins. Efficacy of the probe relative to MA was confirmed using the zebrafish novel tank test. After recording effects on behavior, the fish were irradiated with UV light to covalently modify target proteins/receptors. The brain tissue was homogenized and we performed click chemistry to visualize the protein targets by SDS PAGE and fluoroimaging. Conclusion: MAP displays similar activity to MA in its ability to elicit behavioral changes as assessed in the zebrafish novel tank test. Protein targets were visualized through click chemistry and proteomic validation of targets is ongoing. *In vivo* photoaffinitly labeling using casper

zebrafish represents a novel tool which allows for target ID in a live system capable of providing distinct phenotypic behavioral readouts upon exposure to CNS agents.

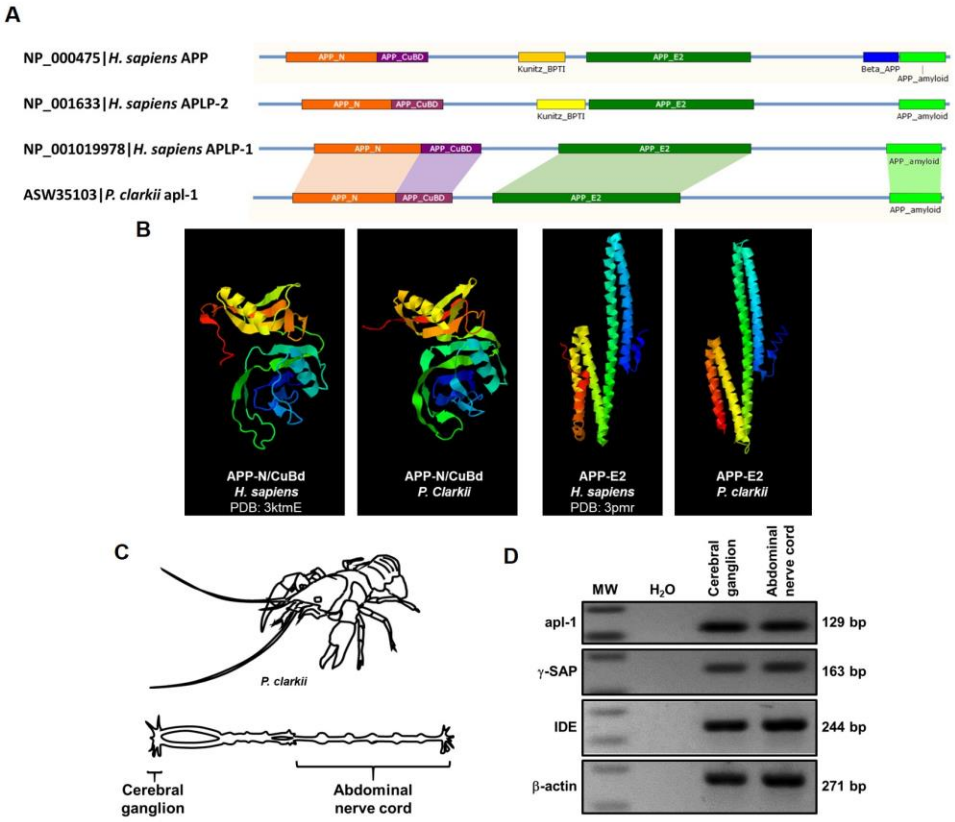
Nacional Autónoma de México, Ciudad de México, Mexico; [4]Dept. de Ciencias Biológicas, Univ. Popular Autónoma del Estado de Puebla, Puebla, Mexico

Abstract: The amyloid precursor protein (APP) and the amyloid precursor-like proteins 1 and 2 (APLP-1/2) are growth factors related to neuronal differentiation, migration of NPC, neurite outgrowth and proper synaptic function. The red swamp crayfish (*Procambarus clarkii*) is an animal model used in physiology and environmental biotechnology studies; however, gene information of this crayfish are scarce. We sequenced the transcriptome of the abdominal nerve cord of *P. clarkii* by NGS. So far, we have assembled 309 sequences *de novo*; from these, we identified a gene related to human APP gene family named amyloid precursor-like 1 (apl-1) and three genes related to the APP processing: the γ-secretase activating protein (γ-SAP), the insulin-degrading enzyme (IDE) and the integral membrane protein 2B (ITM2B). In this work, we made *in silico* analysis of the apl-1 gene (KY974303) and protein (ASW35103.1). Structural analysis of apl-1 reveals four domains: APP-N from 41 to 143 aa; APP-CuBD from 146 to 201 aa; APP-E2 from 243 to 431 aa; and APP-amyloid from 644 to 695 aa (Table; Figure A and B).

Additionally, we evaluated the transcription of apl-1, γ-SAP, and IDE by RT-PCR. Interestingly, there is a high transcription activity for γ-SAP and IDE genes in the cerebral ganglion and the abdominal nerve cord (Figure C and D). In conclusion, *in silico* analysis of P. clarkii apl-1 shows structural homology to human APLP-1. Interestingly, the APP-amyloid region of apl-1 preserves the peptide sequence "GYENPTY" that is strongly conserved among species from tapeworm to human. These data describe the crayfish as a possible study model to compare the molecular and physiological roles of the APP family.



Identity matrix of P. clarkii apl-1.

	APP_N	**APP_CuBD**	**APP_E2**	**APP_amyloid**
APP	44%	46%	35%	51%
APLP-1	35%	44%	32%	38%
APLP-2	39%	46%	35%	49%

The percentages indicate the identity of the domains of the crayfish apl-1 with respect to human APP family

Title: Imaging axonal sodium influx at high spatial and temporal resolution

Authors: *L. FILIPIS, M. CANEPARI;
Liphy-Cnrs UMR5588, Saint Martin D'Heres, France

Abstract: Recording the activity of voltage-gated Na^+ channels in the axon initial segment (AIS) is of extreme importance at understanding the origin of neuronal excitability and to explore the channelopathies associated with this fundamental phenomenon. Using the Na^+ indicator Asante natrium green-2 excited by a 520 nm laser and the ultrafast CMOS camera DaVinci2K, we have been able to monitor Na^+ influx in the AIS associated with a single action potential, at 10 kHz with a spatial resolution of ~1 µm in layer-5 neocortical pyramidal neurons in brain slices of the mouse. We could combine at the same resolution Na^+ imaging either with membrane potential imaging, using the voltage sensitive dye JPW1114, or with Ca^{2+} imaging using the low-affinity indicator FuraFF using a 405 nm laser. From these data, we could precisely monitor the spatial profile of Na^+ influx in the AIS, estimating Na^+ lateral diffusion, or spatially correlate Na^+ entry either with the generation of the action potential of with the concomitant Ca^{2+} influx. We could confirm that the critical all-or-none activation of voltage-gated Na^+ channels starting the action potential occurs at 20-30 µm from the cell body and more proximal voltage-gated Na^+ channels are activated as the action potential back-propagates towards the soma. Finally, we pharmacologically blocked voltage-gated Na^+ channels to further assess the technique. Our methodological achievement opens the gate to the full understanding of the complex ion channel activity underlying the action potential generation.

Title: Ultra compact miniature fluorescence microscope for simultaneously imaging neuronal activities from two brain areas in freely moving mice

Authors: *F. XUE, K. ZHANG, P. LAU, Q. ZHU, G.-Q. BI;
Univ. of Sci. and Technol. of China, Hefei, China

Abstract: Miniature fluorescence microscopes have been successfully used in the study of behaviorally relevant neuronal population activity in freely moving animals. However, currently available devices are still not sufficient for simultaneously studying activity in two or more areas in the mouse brain, a task that requires an even smaller and more lightweight solution. Here, by optimizing opto-mechanical design, together with high density interconnect (HDI) PCB and 3D printing, we develop an ultra-compact microscope that is much smaller and lightweight than currently available systems, and allows for a mouse to carry two of them in the same time. Using this system, we successfully recorded behavior-triggered neuronal activities in different brain areas in freely moving mice expressing calcium sensitive fluorescent protein GCaMP6.

Abstract: This research aims to realize a CMOS-based battery-less, implantable optogenetic stimulator. We developed a CMOS-integrated optical power receiver chip that can drive an InGaN blue LED, and then integrated the chip with an external capacitor and the blue LED. For reducing size and weight of the device, we integrated the photovoltaic (PV) cells onto the CMOS chip. The volume and weight of the device are approximately 1 mm^2 and 2.3 mg. The operation of the device starts with the device is illuminated with IR light, the capacitor is charged with the current generated by the integrated PV cells. When the voltage of the capacitor is high enough to operate the LED, a control circuit supply power to operate the blue LED. After that, the voltage of the capacitor drops, the control circuit stops to supply power to the LED. Then, the capacitor voltage starts to increase toward next operation. With this functionality, the device can be used to perform on-brain optical stimulations in freely moving animals. We can illuminate the head of the animal with this device to perform the optical stimulation.

Title: Simultaneous, multi-site imaging of deep brain regions related to feeding behavior in freely-moving GCaMP6 transgenic mice using an implantable micro-imaging device

Authors: *M. S. GUINTO, Y. OHTA, M. KAWAHARA, M. HARUTA, K. SASAGAWA, J. OHTA;
Nara Inst. of Sci. and Technol., Ikoma, Japan

Abstract: Feeding behavior is regulated by neural circuits that are primarily implicated in the processing of satiety, reward and pleasure, of which many critical regions are located in the deep brain. Currently, imaging methods available for studying these regions are still difficult to implement without interfering with the normal behavior of an awake, freely-moving mouse. To this end, here we report a scheme for investigating the neural mechanisms of feeding behavior in

mice using an implantable micro-imaging device developed in our laboratory. The micro-imaging device consists of a CMOS-based image sensor chip and a μ-LED excitation light source embedded on a flexible printed substrate and is designed to minimize invasiveness with its streamlined structure. Fluorescence emission from putative somas expressing GCaMP6 was used to indicate neuronal activity. Following deep-brain implantation, neuronal activities in the lateral and arcuate nucleus of the hypothalamus, portions of the striatum, and the amygdala were recorded in GCaMP6 transgenic mice. We also report recent improvements in the implantation protocol and environmental lighting for observing the behavior of the mouse, in addition to the emission filter applied to the sensor area, which have reduced the occurrence of artifacts in the fluorescence recordings. Moreover, the miniature size (0.5-mm device width) and relatively light weight (~20 mg) of the device has enabled simultaneous imaging of multiple sites across the mesocorticolimbic circuit to yield new insights on how distant regions interact with one another during specific behavioral sequences that characterize feeding. Our previous study shows that distinct patterns of fluorescence have been observed in different brain regions over a range of behavioral states (e.g., grooming, eating, sleeping) exhibited by the animal. Taken together, this work presents a new platform designed to access deep brain regions and monitor neuronal activity from calcium dynamics in freely-moving mice, opening avenues to establish links between robust patterns of neural activity with complex behaviors such as feeding.

Title: A comparison of remote focusing strategies for two-photon functional imaging

Authors: ***J. C. DONOVAN**[1], F. HUHN[2], T. O. HELMBRECHT[1], J. KAPPEL[1], M. DAL MASCHIO[3], G. RAPP[2], H. BAIER[1];

Abstract: Many common forms of functional imaging record from a single plane, but brains consist of interconnected circuits that extend in three dimensions. Volumetric imaging is crucial for capturing network activity associated with rare behaviors, or in combination with 3D

holographic photostimulation. There are many techniques that enable fast volumetric functional imaging; however, two-photon approaches are preferred for deep imaging and for use in light-sensitive visual experiments. Experiments investigating multiple interconnected regions would often be best served by recording in multiple distinct subvolumes, to avoid the high power and other challenges associated with recording from large volumes. Common two-photon microscopes rapidly scan a laser focus in XY, and with the addition of an element for rapid focusing in Z can flexibly scan different subvolumes without optical reconfiguration. Here we compare several fast Z scanning configurations, two based on remote focusing (where a second objective is refocusing by a moving mirror) and one based on an Optotune electrically tunable lens. We characterize and compare performance in terms of speed, power efficiency, range, and point spread function (PSF). The remote focusing approaches outperform the electrically tunable lens in speed, but are more complex to setup and increase pulse dispersion. For fast point-scanned volumes, the limited dwell time per voxel can reach challenging signal to noise levels, thus we examine strategies for improving signal and determining the optimal volume rate. We demonstrate large volume and multi-subvolume scanning *in vivo* with larval and juvenile (~3 weeks) zebrafish, and show the usefulness of these approaches for simultaneous recording of visual responses across multiple brain areas.

Title: Imaging the axonal action potentialwith genetically-encoded voltage sensors

Authors: *V. GONZALEZ SABATER, M. RIGBY, J. BURRONE;
Developmental Neurobio., King's Col. London, London, United Kingdom

Abstract: The axonal action potential (AP) has traditionally been considered an all-or-none event that encodes information in its firing frequency. A handful of recent studies now suggest multiple factors can influence the AP waveform. However, due to the relative inaccessibility of

the mammalian axon to electrophysiological methods, such studies are either limited to a few large synapses, or rely on indirect measures of axonal voltage. Recent advancements in the development of genetically-encoded voltage sensors (GEVIs) open the possibility of visualizing the presynaptic AP in small en-passant varicosities with enhanced temporal and spatial resolution.
We performed a comparative analysis of two state-of-the-art GEVIs: Ace2N-mNeon-4AA (Gong et al. 2015) and Archon2 (Piatkevich et al. 2018), and assessed whether their kinetics and sensitivity are sufficient to monitor the AP waveform in dissociated hippocampal neurons. Simultaneous whole-cell patch-clamp recordings and somatic voltage imaging performed at a frame rate of ~ 3KHz allowed a detailed characterization of the kinetics of each probe during an AP in control conditions and following drug-induced alterations of the AP waveform. Using local extracellular somatic stimulation with a bipolar electrode, we also measured the AP waveform along the axon and in presynaptic boutons, identified by genetic markers. Repeated imaging of these probes provided measures of the signal-to-noise ratio, as well as bleaching rates and overall probe stability. We find that both GEVIs can reliably report the AP waveform, but with different kinetics and sensitivities.
We then went on to measure the AP waveform along the axon with GEVIs in order to investigate factors that govern its shape and plasticity. We used specific pharmacology to assess the role of different types of potassium channels in shaping the axonal AP waveform. We found that the axonal AP width and amplitude increase upon pharmacological blockade of voltage-gated and G protein-activated potassium channels, but not large conductance calcium-activated potassium channels. In contrast, we did not observe AP amplitude modulation in the soma.
Our observations underline the importance of axonal properties in shaping the AP and suggest the possibility of local analogue signal computation. We next aim to further investigate physiological factors that govern the axonal AP waveform and its plasticity, whilst simultaneously imaging genetically-encoded sensors of Ca2+ or neurotransmitter release.

Title: Label free characterization of attenuation lengths of cortical regions via three photon microscopy in awake mice

Authors: *M. YILDIRIM[1], M. HU[1], P. SO[2], M. SUR[3];
[1]Picower Inst. for Learning and Memory, [2]Dept. of Biol. Engin., [3]Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Our understanding of large population activity of cortical neurons has been greatly advanced by two-photon microscopy. However, due to light scattering and absorption, it is still a challenge to be able to imaging neurons at deep layers. Moreover, the attenuation length of the cortex may change from area to area depending on its structure. Thus, it is critical to characterize the attenuation length of the area of interest in order to precisely image/modulate cortical and subcortical regions. Current state of art for determining the attenuation length of any cortical region is to label blood vessels with high absorption cross-section dyes injected retro-orbitally in anesthetized mice. However, these injections do not last long enough to characterize multiple brain regions at once so multiple retro-orbital injections are required. Attenuation lengths of multiple cortical regions in awake mice has never been reported. Here, we developed two label-free methods to characterize attenuation lengths in multiple brain regions in awake mice via our custom-made three photon microscope. The first method is based on imaging blood vessels in the cortex and axonal tracts in the white matter via third-harmonic generation (THG) microscopy. The second method is to ablate four different depths in the cortex with varying pulse energy. THG imaging of blood vessels is advantageous since it is practical for multi-site imaging whereas it is disadvantageous since it relies on both excitation and emission wavelengths. Ablation is a more precise method since it relies on only the excitation wavelength whereas it is disadvantageous since it creates small lesions in multiple depths. We performed these imaging and ablation experiments in several brain regions including primary visual cortex (V1), and somatosensory cortex (S1) in four awake mice. Comparing the attenuation length between these regions obtained with THG imaging and ablation, we concluded that ablation experiments consistently generate 10% longer attenuation lengths compared to those obtained with THG imaging. Also, we found that there were significant differences in attenuation lengths between cortical regions. For example, V1 has an attenuation length of 254.0 ±8.1 μm whereas S1 has an attenuation length of 312.0 ±10.2 μm. Our work shows that the attenuation lengths of cortical regions in awake mice can be reliably estimated by performing label-free THG imaging of blood vessels at 1300 nm wavelength. These measurements place fundamental constraints on two-photon imaging depths and three-photon imaging power for analysis of cortical activity.

Title: Longitudinal imaging of calcium functional connectivity in the developing mouse cortex

Authors: *R. M. RAHN[1], L. M. BRIER[2], A. R. BICE[2], J. D. DOUGHERTY[3], J. P. CULVER[2]; [1]Radiology, Genet. and Psychiatry, [2]Radiology, [3]Genet. and Psychiatry, Washington Univ. In St. Louis, Saint Louis, MO

Abstract: Functional connectivity (FC) networks in human infants have been previously shown to vary in their development, with sensorimotor areas showing more connectivity than association cortex in infancy. However, the developmental trajectory of FC changes between infancy and adulthood is not well-characterized. We therefore used longitudinal mesoscopic calcium imaging to evaluate functional connectivity across development in the cortex of transgenic mice expressing the genetically-encoded calcium indicator GCaMP6f under the *Thy1* promoter. We collected calcium and hemoglobin resting-state data at five developmental timepoints (postnatal day 15 (P15), P22, P28, P35, and P60) proximal to developmental milestones such as eye-opening and critical periods such as that for vision. Fluorescence imaging of the cortex was performed transcranially (using a chronic optical window affixed to the intact skull) and by sequential LED illumination (λ=470nm (GCaMP6 fluorescence excitation), 530nm, 590nm, 625nm) and sCMOS detection. Seed-based functional connectivity for all timepoints displayed characteristically high correlation for homotopic contralateral regions and passed quality control metrics with a manageable signal-to-noise ratio typical of adult data collected on the fluorescence imaging system. Vascular and cranial bone-derived features were used to perform image registration, benefiting group-based analysis. Survival to adulthood following window placement surgery and imaging at P15 was high (92%), and mice windowed at P14 display similar quality data at later timepoints as well. Calcium data within the delta frequency band, 0.4-4.0 Hz, produce stable, consistent FC maps with 30s or more of imaging, as has been found in previous adult studies. Taken together, these results indicate that mesoscopic optical intrinsic signal imaging permits longitudinal study of cortical dynamics across development in the mouse, and preliminary analysis suggests region-specific developmental trajectories for functional connectivity. The methodology shows great potential for elucidating the functional

architecture typical of specific developmental timepoints both in healthy controls and disease or injury models.

Title: Fluoropolymer nanosheet as a candidate for an artificial dura for long-term two-photon imaging of the mouse brain *in vivo*

Authors: *T. TAKAHASHI[1,2], H. ZHANG[3], R. KAWAKAMI[4], K. YARINOME[5], Y. OKAMURA[5,3], T. NEMOTO[6,2];

Tokai Univ., Kanagawa, Japan; [4]Ehime Univ., Toon, Japan; [5]Grad. Sch. of Engineering, Tokai Univ., Kanagawa, Japan; [6]Hokkaido Univ., Sapporo, Japan

Abstract: *In vivo* two-photon microscopy has become widely used for deep tissue imaging. For *in vivo* imaging of the deep regions in mouse brains, open skull method is used to make a cranial window. In this operation, the dura mater was sometimes removed. Otherwise, thickening of the dura on the inner surface of the coverslip was frequently observed after a week post-surgery, that deteriorated the transparency of the window (Heo et al., 2016) and the optical path of the microscope (Goldey et al., 2014). However, removing the dura tended to cause inflammation and bleeding in the brain, which was not compatible with long-term imaging. In the previous meeting, we proposed newly-developed fluoropolymer nanosheet"PEO-CYTOP" as a sealing material for the chronical cranial window instead of glass coverslip (Takahashi et al., Program No. 796.05. San Diego, CA: Society for Neuroscience, 2018). At that time, we demonstrated that PEO-CYTOP nanosheets immediately stopped bleeding, though the dura was not removed. In this study, we examined the facilitation of PEO-CYTOP nanosheets after removing the dura, especially for a long-time observation over several months. First, we confirmed that sealing with PEO-CYTOP nanosheets also successfully suppressed bleeding from the brain surface even when the dura was removed. Next, for the protection of the brain from mechanical damages, we inserted and glued a round glass coverslip (2.7 mm diameter round, about 0.17 mm thickness, #1S, Matsunami Glass, Japan) in the cranial hole sealed with PEO-CYTOP nanosheet. In addition, the regrowth of the dura was suppressed inside the window and kept the transparency up to 14 weeks post-surgery. From these results, we tried to achieve two-photon imaging in

Thy1-EYFP-H transgenic mice (over 8 week-old, male) (Feng et al., 2000) to access the effect to deep imaging. As a result, we could observe same axons and neurons over at 700 μm depth corresponding to layer 6 of the cerebral cortex up to 14 weeks post-surgery. To summarize, PEO-CYTOP nanosheets could be a component for artificial dura in living mouse brain. In future, the nanosheets will be applied as an artificial dura to other animals including rats and marmosets for long-term imaging in deep regions of living brains.

Title: High-efficiency *in vivo* stimulation of neurons using two-photon holographic illumination

Authors: A. FORLI[1], M. PISONI[1], Y. PRINTZ[2], O. YIZHAR[2], *T. FELLIN[1];
[1]Optical Approaches to Brain Function Lab., Inst. Italiano di Tecnologia, Genova, Italy; [2]Dept. of Neurobio., Weizmann Inst., Rehovot, Israel

Abstract: Optical techniques to simultaneously image and manipulate neuronal activity with high spatial resolution in the intact mammalian brain promise to be fundamental tools to causally investigate how ensembles of cells drive behavior. In order to achieve cellular-resolution two-photon (2P) stimulation over large number of cells, efficient generation of action potential (AP) firing by 2P stimulation is required. Towards this goal, we combined a new high conductance soma-targeted excitatory opsin (stCoChR) with 2P holographic illumination using a low-repetition rate laser source and a non collinear optical parametric amplifier at 920 nm. stCoChR expression in principal cells and interneurons was achieved in the mouse cortex through injections of adeno-associated viruses. We measured efficiency and resolution of 2P stimulation by combining holographic illumination with juxtasomal electrophysiological recordings from stCoChR-expressing neurons of layer 2/3 *in vivo*. We found that stCoChR-positive cells reliably increased their AP firing rate in response to brief 2P holographic illumination with an extended circular shape covering their soma. AP frequency increase during stimulation was proportional to the average illumination power and significant responses to 2P holographic stimulation were observed at low average power levels *per* cell (average power under the objective: 0.25 mW - 5

mW depending on the repetition rate). Latency to first AP was in the range 4 - 21 ms and the AP jitter in the range 0.2 - 8.7 ms. These results demonstrate high-efficiency 2P activation of a blue-shifted soma-targeted opsin that can be used for effective large scale stimulation of distributed neural networks in the intact mouse cortex.

Title: Multi channel fiber photometry based mapping of axonal terminal activity in freely moving mice

Authors: *H. QIN[1,2], X. CHEN[3], J. LU[4], L. FU[2], W. JIN[3];
[1]Army Med. Univ., Chongqing, China; [2]Britton Chance Ctr. for Biomed. Photonics, Wuhan Natl. Lab. For Optoelectronics-Huazhong Univ. of Sci. and Technol., Wuhan City, China; [3]Brain Res. Ctr. and State Key Lab. of Trauma, Burns, and Combined Injury, [4]Brain Res. Ctr., Third Military Med. Univ., Chongqing, China

Abstract: Fiber photometry has been increasingly popular in neuroscience research in freely behaving animals. In combination of the use of genetically encoded Ca^{2+} indicators, it serves as an efficient approach for real time monitoring of neural activity in neuronal somata, dendrites and axonal terminals. Here, we demonstrated a new version of multi-channel fiber photometry used for functional mapping in sub-regions of axonal terminals. To reduce the recording range of each channel, we chose a wee type of fiber with a core diameter of only 50 μm. A fast and sensitive sCMOS was equipped to simultaneously detect the Ca^{2+} signals of multi-channel. Optical fibers were integrated into a bundle, with the neighboring channel close to a distance of ~250 μm, to delivery excitation light to and collect the emission light from different sub-regions of neural projections. The design of the bundle shape and channel number were flexible according to the specific recording situation. The sample rate of the system was 100 frames/s, which was restricted to the maximal frame rate of sCMOS. Through theoretical analysis and experiment testing, we got the recording depth of 200-250 μm and found that there was no interference among different channels. Using a Ca^{2+} indicator GCaMP5G, we demonstrate the feasibility of this system for recording the activities in axonal terminals from the medial entorhinal cortex layer II (MECII) to the hippocampal dentate gyrus (DG) in freely moving mice. We detected spatially separated Ca^{2+} signals at four different sites at the DG. Therefore, our multi-channel fiber photometry provides a simple but powerful method for functional mapping

of axonal terminals in a spatially confined brain area of freely moving animals.

Title: Functional imaging of long neuronal processes and network in behaving animal in any arbitrary tilted plane in 3D

Authors: *M. MAROSI[1], K. OCSAI[1], T. TOMPA[1], Z. MEDVECZKY[2], G. SZALAY[1], G. KATONA[2,1], B. ROZSA[1,2];
[1]IEM-HAS, Budapest, Hungary; [2]Pázmány Péter Catholic Univ., Budapest, Hungary

Abstract: Understanding neural computation requires the detection of processes in all three dimensions simultaneously, as dendritic integration *in vivo* in the neural tissue takes place in an intricate network of neural connections with elements, most of the time, not parallel to the surface. Conventional functional microscopy methods are limited to 2-dimensional planes parallel with the front lens of the microscope and the cortical surface. Imaging through cortical layers was only possible either non-simultaneously or with highly invasive methods (ie: microprisms).
Using two-photon acusto-optical (AO) microscopy we presented already a method the overcome the limitation of the 2-dimensional scanning, by a random-access point scanning method (Katona et al 2012), we later complemented with the 3D drift AO scanning (Szalay et al 2016). 3D drift AO scanning can extend each scanning point to small 3D lines, surface or volume elements, preserving fluorescence information for fast off-line motion correction. With this method *in vivo* motion artifacts can be effectively eliminated, allowing fast 3D measurement of over 100 dendritic spines with 3D lines; hundreds of somata with squares and cubes; multiple spiny dendritic segments with surface and volume elements.
However, this earlier solution contained some limitation regarding the scanning patterns and acquisition speed. Here we present a complex scanning solution which can exploit the full

capabilities of the 3D scanning options, providing virtually compromise-free ROI scanning options. This technique allows us to measure various scanning patterns on any arbitrary tilted frame, with 40 Hz scanning speed for a full field imaging and up to 3Khz on special scanning patterns. This feature makes it possible to record raster videos of all cortical layers simultaneously or record individual neurons with their entire apical dendrites, or obliquely running neural elements with high speed.
Here we present our results from the visual cortex (V1) of awake behaving mice involved in a visual task and show calcium events occurring along the entire length of the cortical pyramidal neuron's soma and apical dendrites and within a group of neurons. On these elements we record local dendritic spikes.

Title: Spatiotemporal features of large scale motor-evoked calcium activity patterns

Authors: ***A. SCAGLIONE**[1,2], E. CONTI[1,2], A. ALLEGRA MASCARO[1], F. S. PAVONE[1,2]; [1]LENS, European Lab. for Non-linear Spectroscopy, Univ. of Florence, Sesto Fiorentino, Italy; [2]Dept. di Fisica e Astronomia, Univ. of Florence, Firenze, Italy

Abstract: Understanding the link between brain function and behavior represents a fundamental question in modern neuroscience. Recent advancements in imaging techniques, such as widefield calcium imaging, are especially well suited to address this question by allowing to monitor neural activity of large cortical areas in awake behaving animals. In this study, we wondered if the information contained in the calcium activity patterns over a large portion of the cortex is sufficient to discriminate motor evoked output from baseline activity on a single trial basis. Intact skull widefield calcium imaging was acquired while Thy1-GCaMP6f mice performed a motor task. Briefly, mice were head-fixed under a microscope and placed on a robotic platform were at the beginning of each trial their left arm is passively extended. Animals were then delivered a milky reward when they pulled the left arm to target position when cued with a tone. Next, we use a Euclidean distance based classifier to assign trials to two different classes: either 1) baseline, a 75 ms period of activity collected at random before the task started or 2) motor-

outcome, a 75 ms period of time around the time of the successful pull. Our results show that: 1) we can successfully discriminate rewarded pulls from baseline activity on a single trial basis with high accuracy in all subjects (about 80% averaged across all subjects); 2) activity across all imaged cortical areas contributed similarly to the performances of the classification and 3) classification performances increased significantly (about 60% in average) as early as 400 msec before time of pull and were highest at the motor onset. Taken together these results suggest that large scale motor evoked calcium activity patterns are distributed over a large portion of the cortex in a small time window (800 msec) supporting the idea that different cortical areas act in concert over a short temporal scale to produce the motor output.

Title: Study of RuBi-GABA uncaging by non-linear photoactivation and patch clamp technique in cerebellar granule cells

Authors: *E. GATTA[1], M. COZZOLINO[1,2], V. BAZZURRO[1], E. ANGELI[1], P. BIANCHINI[2], A. DIASPRO[1,2], M. ROBELLO[1];
[1]Dept. of Physics, Genoa, Italy; [2]Nanophysics, Inst. Italiano di Tecnologia, Genoa, Italy

Abstract: RuBi GABA is a photoactivatable molecule whose activity can be controlled by a pulse of light. These probe compounds are prepared via covalent appendage of a light-sensitive protecting group "the cage" (RuBi) to a signaling molecule (GABA). With the cage bound, the signaling molecule is unable to activate its receptor [Diana D., J Am Chem Soc., 2014]. One photon (UV-VIS light) and two-photon (700-900nm) absorption can be used to break the "cage" binding. The uncaged molecule becomes active and can bind on $GABA_A$ receptor site [Rial Verde E.M., Front Neural Circuits., 2008]. Uncaging technology and fluorescence microscopy coupled to patch clamp technique provide approach to detect a selected biological target in a temporally and spatially confined way. We analyzed how the change of physical parameter such as uncaging distance, exposure time, laser power, linear and non-linear photoactivation influence the measurements and we determine how these parameters change the modality and efficacy of the GABA release and consequently the $GABA_A$ response. Specifically, localization precision can be improved using advanced fluorescent optical methods, in particular, we used the super-

resolved and non-linear fluorescence microscopy [Diaspro A., BioMedical Engineering OnLine, 2006]. These allow exploring the release of caged GABA topically applied *in situ* at defined concentration and in a specific region of neuronal cells for mapping the localization and the functional distribution of $GABA_A$ receptors in cerebellar granule cells *in vitro.* We aim to achieve a $GABA_A$ receptors super resolved map in cerebrellar granule cells or within brain slices integrated by electrical measurements. Specific blocking factors can be used to identify receptor type (on the basis of subunit composition) presence in different neuronal regions. Finally, we are able to explore the responses generated by specifics drugs in different regions of neuron. Localization precision can be improved by using advanced fluorescent optical methods as the ones in use in super resolved and non-linear fluorescence microscopy.

Title: *In vivo* three-photon excited fluorescence imaging of neural activity in the spinal cord of awake, locomoting mice

Authors: *Y.-T. CHENG[1], K. M. LETT[2], S. DENOTTA[3], D. RIVERA[2], S. HU[2], J. RAIKIN[2], D. G. OUZOUNOV[4], T. WANG[4], J. CRUZ HERNANDEZ[2], I. BASTILLE[2], N. NISHIMURA[5], J. R. FETCHO[1], C. XU[4], C. B. SCHAFFER[6];

Abstract: Nonlinear optical microscopy and genetically encoded calcium indicators (e.g. GCaMP) enable recording of the activity of large numbers of neurons in the central nervous system of awake, behaving rodents. Much of this work has focused on cortical activity, and anatomical regions that are more difficult to access optically have received less attention. The rhythmic limb movements that underlie locomotion are controlled by spinal cord interneurons in central pattern generator (CPG) circuits. Measuring activity in these CPG circuits in locomoting

animals could help uncover how alternating limb motion and different locomotor speeds are produced, as well as how this fails in movement disorders. We developed an implantable chamber that provides long-term optical access to the spinal cord, and have shown that mice can be trained to run on a treadmill while they are held firmly by the implanted chamber. We found only modest differences in the gait cycle between spine-fixed and free-running mice. The spine-fixed mice had a slightly longer stance phase in their gait, and while they ran with a similar speed to free-running mice they spent about half as much time running. The white matter on the dorsal surface of the spinal cord is highly optically scattering and limits the maximum depth that even scattering insensitive imaging modalities, such as two photon excited fluorescence, can reach. We imaged fluorescently-labeled blood vessels and neural processes to a depth of only 150 µm in mouse spinal cord before losing image contrast due to increased background. Due to the longer excitation wavelengths used and the higher order nonlinear excitation process, three-photon excited fluorescence microscopy (3PEF) enables deeper imaging into scattering samples. In the mouse spinal cord we imaged fluorescently labeled blood vessels to a depth of 500 µm with 3PEF, limited by the optical power we could apply before causing thermal damage. The V2a neurons are excitatory interneurons that have been implicated in shaping the left-right alternation of limbs during locomotion and which express the embryonic transcription factor chx10. We crossed chx10-cre mice with TIGER-line GCaMP6s reporter mice and now aim to use 3PEF to correlate V2a neuron activity patterns to limb movements.

Title: Multiple scale quantitative analysis of white matter connectivity on a MYRF knock-out mouse model using spatial light interference microscopy (SLIM)

Authors: *J. A. MALDONADO[1], C. BEST[2];
[1]neuroscience, Univ. of Illinois Urbana Champaign, Champaign, IL; [2]Univ. of Illinois Urbana Champaign, Urbana, IL

Abstract: The brain architecture is organized hierarchically and is extended from the nanometric scale to the centimeter scale, however most studies on neurodegeneration, due to resources and time are limited to only a few orders of magnitude. De-myelinating diseases display significant alterations in all the seven orders of magnitude depending on the disease stage. Here our goal is to do a multi-scale analysis on a mouse Myrf knock-out transgenic model of de-myelination using Spatial Light Interference Microscopy (SLIM) combined with standard immunohistochemical methods.
Our study focused on three brain regions: the corpus callosum, anterior commissure; motor cortex optic nerve and spinal cord. We quantify variations in both gray and white matter.
To analyze our data, we use fiber orientation analysis, density mapping and optical related measures to quantify fiber and myelin integrity respectively in 4um tissue slices, and across 16 um reconstructed tissue volume blocks. Our results show that MYRF knock-out mice fibers continuity, and density in corpus callosum and other areas of concentrated white mater were significantly decreased compared to the controls. Subtle changes in mature oligodendrocyte number were also observed.

Title: Complex event analysis for neurotoxic profiling of compound effects on human iPSC-derived neural spheroid 3D cultures

Authors: *O. SIRENKO[1], C. CRITTENDEN[1], F. ZANELLA[2], R. GORDON[2], C. CARROMEU[2];

Abstract: To speed up the development of more effective and safer drugs, there is an increasing need for more complex, biologically relevant, and predictive cell-based assays for drug discovery and toxicology screening. Human iPSC-derived neural 3D co-cultures (microBrain 3D platform) have been developed as a high throughput screening platform that more closely resembles the constitution of native human cortical brain tissue. Neural spheroid 3D cultures are a physiologically relevant co-cultures of iPSC-derived functionally active cortical glutamatergic and GABAergic neurons co-differentiated and matured with astrocytes from the same donor. 3D neural spheroids contain a neural network enriched in synapses, creating a highly functional neuronal circuitry and display spontaneous synchronized, readily detectable calcium oscillations. Here, we describe a method for the complex analysis of calcium oscillations that allows

detection and multi-parametric characterization of oscillation peaks that include the oscillation rate, peak width and amplitude, characterization of secondary peaks, waveform irregularities, and several other read-outs. In addition, cellular and mitochondrial toxicity were assessed by high-content imaging.
For assay characterization, we used a set of neuromodulators with known mechanisms of action affecting GABA, NMDA and dopamine targets. Then we characterized the neurotoxic profile of a set of 30 known neurotoxic or seizurogenic drugs, including anticancer compounds, antipsychotics, and antibiotic, as well as selected environmental chemicals. Our results show that neural 3D cultures when paired with complex event analysis and cytotoxicity assays form a promising, biologically-relevant system for assessing the neurotoxic potential of pharmaceutical drugs and environmental toxins.

Title: Imaging odor associated neural activity in piriform cortex and hippocampus using gradient index lenses

Authors: *C. MCCULLOUGH[1], M. MA[2], D. RAMIREZ-GORDILLO[2], G. FUTIA[1], B. OZBAY[1], N. AREVALO[2], D. RESTREPO[2], E. GIBSON[1];

Abstract: Olfaction is a crucial sense for navigating environment, assessing threats, mating, and eating. Yet, olfaction is one of the least understood sensory modalities because of the inherently complex space it samples. Brain regions known to process olfactory information include the piriform cortex (PCTX) and hippocampus (HC). Substantial progress has been made understanding the role of PCTX and HC in olfaction using electrical recordings to identify single unit and large ensemble activity in these regions. Multiphoton imaging of neural activity in these

regions would allow for spatial localization of cells and cell specific recording selectivity using viral expression or transgenic models. However, PCTX and HC are located approximately 2 mm and 5 mm below the surface of the brain respectively, beyond the imaging depth of 3-photon imaging. To overcome this depth restriction, we have used implanted gradient index (GRIN) lenses: rod shaped lenses of small diameter. Here we present our progress using GRIN lenses to record high signal-to-noise GCaMP6 activity in PCTX and HC of mice participating in odor discrimination tasks. Additionally, we present our progress developing a device to incorporate electrical recording alongside optical recording through a GRIN lens.

Title: Live cell imaging of 3D primary cortical microtissue via AAV-induced fluorescence

Authors: *S. BROWN[1], E. ATHERTON[2], A. ALLAWALA[1], D. BORTON[1,3,4];
[1]Brown Univ. Sch. of Engin., Providence, RI; [2]Mol. Pharmacology, Physiology, and Biotech., Brown Univ., Providence, RI; [3]Carney Inst. for Brain Sci., Providence, RI; [4]Dept. of Veterans Affairs, Providence Medial Center, Ctr. for Neurorestoration and Neurotechnology, Providence, RI

Abstract: Reliable performance of devices implanted in the brain for the purpose of recording neural activity relies heavily on the stability of the tissue environment surrounding the device. One of the greatest challenges in optimizing device performance is the onset of acute inflammation and a chronic foreign body response that often occurs at the device-tissue interface upon implantation. In developing effective neural implants and devices, detailed and thorough characterization of the device-tissue interface is paramount. We have previously demonstrated an *in vitro* model of the neuroinflammatory response using cultured three-dimensional primary cortical microtissues for evaluating interface passivation solutions. A major limitation in our understanding of the device-tissue interface the lack of dynamic visualization and quantification of the foreign-body response, including adaptation of neural infrastructure and composition around implanted devices. Here, we present a live cell imaging platform for real time capture of the dynamic neuroinflammatory response to an electrode in a three-dimensional neural microtissue via virally mediated expression of fluorescent reporter proteins in three key cell types: neurons, astrocytes, and microglia. This model of induced fluorescence allows for the capability of a longitudinal analysis of the neural microenvironment in a single microtissue

without the implementation of traditional cross-sectional studies using fixed sample immunohistochemical staining. We provide continuous visualization and quantification of the cellular response by tracking the morphological and migrational dynamics of the three cell types during the foreign-body induced inflammatory response to chronically implanted electrodes. The application of fluorescent tagging via viral transduction to monitor cell-specific dynamics offers a new perspective on the device tissue interface with real time longitudinal visualization of the device-tissue microenvironment.

Title: Identifying active neural circuits in freely moving, adult fruit flies with the optogenetic tool CaMPARI

Authors: *K. A. EDWARDS[1], M. B. HOPPA[2], G. BOSCO[1];
[1]Mol. and Systems Biol., [2]Biol. Sci., Dartmouth Col., Hanover, NH

Abstract: Linking neural circuitry to behavior by mapping active neurons *in vivo* is a challenge. Currently, genetically encoded calcium (Ca^{2+}) indicators (GECIs) allow quantitative identification of active neurons during behavior, but can only be viewed in a restricted area of the brain and limit the movement of the behaving organism. Alternatively, staining of immediate early genes, such as Arc and cFos, can label highly active neurons within the entire brain but the temporal resolution is poor. To overcome these spatial-temporal challenges, CaMPARI (calcium-modulated photoactivatible ratiometric integrator) was engineered from the circular permutation of the photoconvertible protein, EosFP, and attachment to the Ca^{2+} binding protein, Calmodulin, and its associated peptide, M13. This combination of components allows photoconversion to occur specifically in the presence of high intracellular Ca^{2+} in an active neuron. The photoconversion can then be quantified by taking the ratio of the red channel signal to the green channel signal. CaMPARI promises the ability to trace active neurons during specific stimulus; however, CaMPARI's uses in adult fruit flies have been limited to photoconversion with a laser during fly immobilization and, in some cases, with the head cuticle removed. Here, we demonstrate our setup allows photoconversion of multiple freely-moving intact adult flies during a stimulus. Fruit flies were placed in a Petri dish with filter paper wet with acetic acid (pH=2) or neutralized acetic acid (pH=7) and exposed to photoconvertible light (60 mW 405 nm) from an

LED for 30 min (500 ms on, 200 ms off). Immediately following photoconversion, whole flies were fixed and imaged by confocal microscopy. The red:green ratio was quantified for the DC4 glomerulus, a convergence of neurons expressing *Ir64a*, an ionotropic receptor that senses acids in the fruit fly antennal lobe. Flies exposed to acetic acid showed 1.6-fold greater photoconversion than flies exposed to neutralized acetic acid. These results were recapitulated using apple cider vinegar (4-fold greater photoconversion). These results indicate that CaMPARI can be used to label neurons in intact, freely-moving adult flies and will be useful for identifying the circuitry underlying complex behaviors.

Title: 1p2c: A miniscope for multiplexed single-photon imaging of two spectrally distinct fluorescent reporters in freely-behaving animals

Authors: W. W.-S. YEN[1], *D. P. LEMAN[1], J. R. CLEVENGER[2], N. PERKINS[2], H. FAWCETT[2], W. A. LIBERTI, III[3], T. NGUYEN[2], I. G. DAVISON[1], A. CRUZ-MARTIN[1], T. J. GARDNER[1], T. M. OTCHY[1];
[1]Dept. of Biol., [2]Dept. of Biomed. Engin., Boston Univ., Boston, MA; [3]Univ. of California Berkeley, Berkeley, CA

Abstract: The combination of genetically encoded fluorescent indicators and miniaturized, head-mounted fluorescence microscopes (“miniscopes”) offers the ability to record the activity of large populations of neurons in freely-behaving small animals. The freedom of movement afforded by miniscopes enables imaging during a wide range of naturalistic behaviors that have been challenging (if not impossible) to study in traditional head-fixed preparations. The availability of reporters that fluoresce at spectrally separable wavelengths has made it possible to target functionally distinct cell populations for simultaneous imaging, providing insight into how the activity of two neuronal populations are correlated to specific behaviors. However, currently available miniscope systems are limited to capturing fluorescent signals within a single spectral band. Here, we present an expanded-capability miniscope based on our open-source FinchScope project that overcomes this limitation.
We have developed a two-color system based on multiplexing of excitation wavelengths that can

be used to simultaneously image spectrally distinct fluorescent reporters. Frame sync signals from the CMOS sensor are used to toggle the excitation LEDs on alternative frames at rates up to 60 Hz, providing two imaging streams at 30 Hz resolution. The intensity of each illumination channel can be independently controlled by our software package. Our current GRIN-lens based optical path is designed for GCaMP and jRCaMP, avoiding the photo-switching effects associated with other red-shifted calcium sensors such as jRGECO. This system will also allow identification of genetically identified cell types within networks broadly labeled with single-wavelength activity sensors, such as anatomically defined populations that project to different target areas, identified by retrograde labeling. We demonstrate these capabilities in bench-top characterization, ex-vivo histological slices, and in-vivo recordings from awake, freely-moving animals.
Overall, dual-color imaging - in conjunction with advances in genetically-targeted fluorescent reporters - will enable improved access to the activity of functionally distinct ensembles within heterogeneous neural circuits. Future miniscope development efforts will aim at further improving image quality and reducing the chromatic aberration that is inherent to GRIN-lens based multi-color systems.

Title: SCAPE microscopy for high-speed 3D neuronal imaging of behaving larval and adult *Drosophila*

Authors: *W. LI, V. VOLETI, R. VAADIA, N. MISHRA, E. SCHAFFER, W. B. GRUEBER, E. M. C. HILLMAN;
Mortimer B. Zuckerman Mind Brain Behavior Inst., Columbia Univ., NEW YORK, NY

Abstract: It is a major challenge to understand functional neuronal circuits across the whole brain. The current methods we use to observe neuronal activity represent a major bottleneck in addressing biological problems, even for small animal model such as *Drosophila*. Our method, Swept Confocally Aligned Planar Excitation (SCAPE) microscopy offers the ability to image a large 3D volume (e.g. 1000x800x250um) at speeds exceeding 10 volumes per second, while preserving sufficient spatial resolution to identify cellular level neuronal activity. Together with different genetically encoded fluorescent indicators, SCAPE enables us to observe neuronal activity across a much larger population of neurons of freely crawling *Drosophila* larva and head-fixed behaving adult *Drosophila*.
Here, two research projects using high-speed SCAPE imaging will be presented. Taking advantage of the high-speed and large field of view of SCAPE microscopy, we were able to image freely crawling *Drosophila* larvae and characterize the full set of proprioceptive neurons during crawling and turning in dendrites, axons and soma. With the same setup, we are also able to image the entire adult head-fixed *Drosophila* brain at cellular resolution. Using both dense pan-neuronal or sparse subset labels, we are able to record and identify brain-wide functional circuits with olfactory stimuli while the fly was walking on an air suspended ball. Latest developments of SCAPE microscopy for different applications will also be shown.

Title: Novel molecular strategies for *in vivo* dual-color imaging

Authors: *J. F. NORMAN, B. RAHSEPAR, J. NOUEIHED, J. A. WHITE;
Biomed. Engin., Boston Univ., Boston, MA

Abstract: Calcium imaging has provided neuroscientists with the ability to monitor the activity of large networks of neurons *in vivo*. Novel molecular tools allow simultaneous imaging of multiple cell types, in order to better understand their real-time interactions and how they related

to behavior. We compared two strategies to record simultaneously from distinguishable CaMKII-positive pyramidal cells and GAD2-positive inhibitory interneurons. In the first, transgenic strategy, GAD2-tdTomato transgenic mice were injected with jGCaMP7f expressed under the synapsin promoter. In second, double-virus strategy, AAV viral injections in GAD2-cre mice were used to drive expression of cre-dependent tdTomato and synapsin-promoted jGCaMP7f. In principle, both strategies should allow us to record from both neuronal subtypes, and distinguish interneurons based on the presence of the tdTomato signal. Our preliminary results indicate that transgenic expression of tdTomato appears to limit expression of the calcium indicator, whereas the double-virus strategy allows for greater co-expression. We have quantified the statistics in brain slices and showed that the double-virus strategy leaves around half of the GAD2+ neurons labeled with tdTomato fluorophore co-expressing jGCaMP7f. In contrast, in response to our transgenic strategy, fewer than 10% of interneurons co-expressed the calcium indicator and tdTomato. Consistent with these results, *in vivo* calcium recordings from double-virus animals show substantially more jGCaMP7f-based activity than obtained using the transgenic strategy. These results, currently being followed up using immunohistochemical analysis, suggest that the double-virus method is much preferred for dual-color recordings from separate, identified cell types.

Title: Use of nIRCat to image the development of dopamine release in a wild-derived mouse with protracted adolescence

Authors: *G. S. PROUNIS, L. WILBRECHT;
Dept. of Psychology and Helen Wills Neurosci. Inst., UC Berkeley, Berkeley, CA

Abstract: In order to achieve independence adolescent mammals must disperse from the natal site and be motivated to engage in high-risk exploration for distal resources. Changes in striatal dopamine (DA) systems are believed to play a role in regulating these motivational changes. The scope of this transition may be muted in strains of mice engineered in the lab, as these animals are far removed from ecological selective pressures. The steppe mouse (Mus spicilegus) is a wild-living species closely related to typical lab mice (derived from Mus musculus domesticus) distinctly characterized by its protracted adolescent development when compared to other mice.

We posit that steppe mice exhibit phenotypes shaped by ecological selection which, proximal to adolescence, reflect changes that are critical for dispersal. These changes include increased locomotion, risk taking, and novel object investigation, and may correlate with patterns of dopamine signaling in the striatum. We examined the behavior of steppe mice at various post-weaning ages (postnatal day (P) 22-120) within an open field apparatus; notably, this marked the first instance of exposure to a novel environment, an experience relevant to dispersal. At the conclusion of the open field test, we scored the behavior of mice towards a novel object placed within the apparatus. We find that, between ~P60-80, male mice exhibit peaks in total distance travelled, risk taking (i.e., time spent in the center), and time spent interacting with a novel object in the open field. We are determining how changes in striatal DA signaling relate to these observations. A synthetic nanosensor-based infrared optical catecholamine sensor (nIRCat) allows us to compare spatiotemporal properties of evoked DA release across regions of the striatum (i.e., dorsolateral, dorsomedial (DMS), and ventral (VS)) in mice prior to (P30), during (P60), and after (P120) our observed behavioral peaks. When compared to P30 males, we find that P60 males have higher amplitudes of evoked DA release in the striatum. This suggests a potential mechanism by which developmental changes in DA signaling mediates a dispersal-related behavioral transition during adolescence.

Abstract: In this study, we aim to characterize tissue pO_2 in awake mice free from confounding effects of anesthesia on the animal physiology. We measured emission decays from the pO_2 probe (Oxyphor 2P; 75 kDa, ~3 µL, 30 µM) by using two-photon phosphorescence lifetime microscopy. The probe stays in the extracellular space once delivered into the tissue by direct injection to the site via a pressured glass micropipette, through a silicone-filled port in the chronic glass cranial window (Fig. 1b). For consecutive imaging of the microvasculature by the two-photon fluorescence microscopy, we labelled the blood plasma via retro-orbital injection of a dextran-conjugated Fluorescein isothiocyanate (FITC; 2 MDa, 0.2 mL, ~8.3 mg/mL). All injections were completed during brief isoflurane anesthesia, ~1 hr before imaging. At each cortical depth, we measured pO_2 over a grid of locations around arterioles, venules, and capillaries. We mapped the tissue pO_2 distribution and calculated the cerebral metabolic rate of oxygen in the whisker barrel cortex of awake mice at rest across different cortical layers under normal physiological conditions, hypercapnia, hypoxia, and hyperoxia. Our results will support efforts towards a better understanding of the oxygen transport in cortical tissue at microvascular scales and more quantitative interpretation of the blood oxygen level dependent functional magnetic resonance imaging (BOLD fMRI) signal.

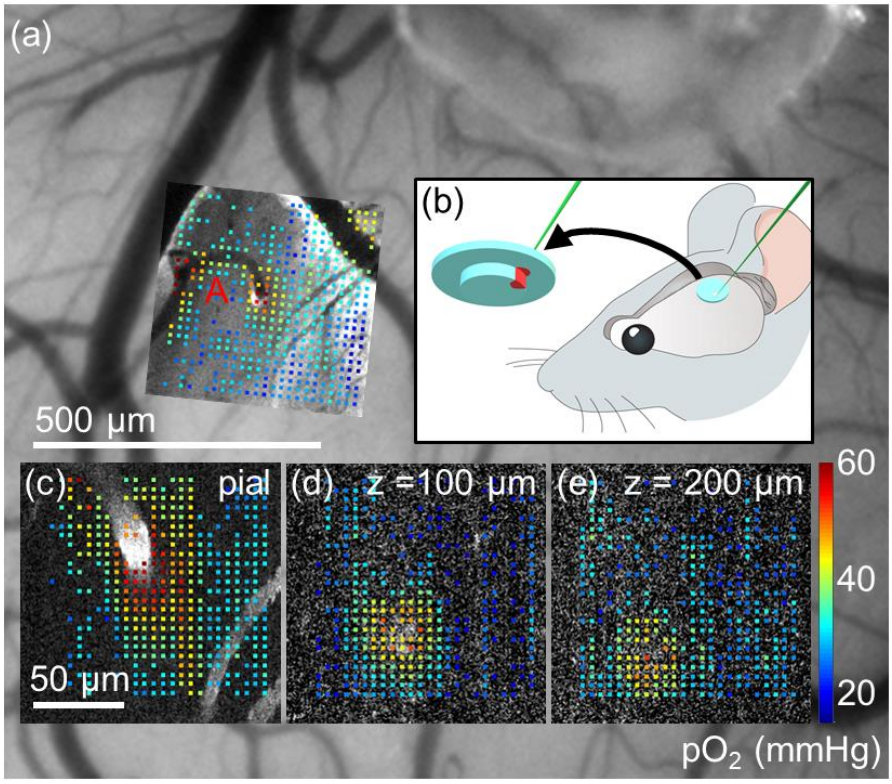

Figure 1. (a) Tissue pO_2 measurements in awake mouse. pO_2 values around a diving arteriole are

color-coded and overlaid over a bright field image of the pial surface. (b) Oxyphor 2P injected with the glass micropipette through a silicone-filled port in the chronic sealed cranial window. The inset shows the bottom of the glass window that is partially inserted through the cranial window. Silicone-filled port is highlighted red for better visibility. (c, d, and e) pO_2 measurements around the same diving arteriole marked in (a) overlaid over two-photon images of the FITC dextran-labeled plasma at the pial surface (c), and at cortical depths of 100 µm (d) and 200 µm (e).

Abstract: Current attempts to infer the timing of action potentials from calcium-associated fluorescence (e.g. as measured via in-vivo two-photon microscopy) assume action potentials to be the only source of calcium in the neuron. Moreover, typically, the increase in calcium following a single action potential is modeled as stationary.
In this work, we present juxtacellular recordings paired with simultaneous *in vivo* two photon calcium imaging in transgenic mice, which show compelling violations of the above universal assumptions.
In 6/15 recordings from the Emx1-IRES-Cre;Camk2a-tTA;Ai93 line, but only in up to 3/19 in the other recorded line, Cux2-CreERT2;Camk2a-tTA;Ai93, significantly more of the variance in the fluorescence response could be explained by the presence and duration of after-depolarizations that followed spikes, than by the number of action potentials immediately preceding the fluorescence increases.
These observations indicate that, at least for some neurons, interpreting the magnitude of changes in calcium-associated fluorescence purely in terms of an instantaneous firing rate may be confounded by intracellular processes only weakly related to the cells' output spike train. We present a quantitative analysis of these effects and discuss plausible mechanisms.

The first row of the figure shows analysis of isolated and burst-like spiking events, which are followed by after-depolarizations of various duration for a single Emx1-IRES-Cre;Camk2a-tTA;Ai93 cell; the second row shows the same analysis but for spiking events without after-depolarizations.

Title: A validated GCaMP viral method for microendoscopic imaging in rat hippocampus CA1 during active behavior

Authors: ***S. GULATI**, D. CHENG, J. J. NASSI, A. M. STAMATAKIS;
Inscopix, Palo Alto, CA

Abstract: A large part of our understanding of the neurophysiological basis of sleep, memory, motivation and addiction has been derived from rodent experiments, particularly those involving rats. Studying behavior precisely paired with in-vivo cell specific neurological recordings is essential in deciphering how certain regions of the brain are involved in these behavioral attributes. One such tool that is extensively used to gather such information utilizes genetically encoded calcium indicators in combination with cell-specific viral-mediated delivery and one-photon imaging in freely behaving animals. Here we demonstrate an end-to-end solution to obtain stable neural recordings from hundreds of pyramidal neurons in rat CA1 region of

hippocampus using the Inscopix nVista3 miniature microscope paired with an active behavior responsive commutator. We utilized pre-diluted and validated ready-to-image virus to label the CA1 pyramidal neurons and studied their firing pattern while the animals actively explored an open field arena. Together these solutions will enable researchers to link behaviors to patterns of activity in the rat brain which will in turn lead to cutting-edge discoveries in neurophysiology and systems neuroscience.

Title: Engineering 3D neural tissues for drug screening

Authors: *A. N. VO, S. KUNDU, M. J. SONG, M. FERRER, M. E. BOUTIN;
Natl. Ctr. for Advancing Translational Sci., Rockville, MD

Abstract: In 2017, the opioid crisis in the U.S. was declared a public health emergency. To help combat this crisis, the 3D Tissue Bioprinting Laboratory at NCATS is supporting the NIH Helping End Addiction Long-Term (HEAL) Initiative by developing morphologically- and physiologically-relevant human 3D neural tissue models for the discovery of new treatments for pain and opioid addiction and overdose. Predictive *in vitro* 3D neural tissue model systems must contain functional mixtures of neurons and glial cells of the brain and mimic the native brain microenvironment. Our group is developing 3D biofabricated neural tissue models using human induced pluripotent stem cell (iPSC)-derived neuronal and astrocyte cells with macromolecular crowding (MMC) agents to induce extracellular matrix (ECM) production and deposition. Initial studies were performed in 2D monocultures to identify media which supports spontaneous neuronal activity in human iPSC-derived dopaminergic neurons and determine MMC agents which induce deposition of endogenous matrix by astrocytes. Among the tested media, neurons seeded in iCell Complete Maintenance Medium and transitioned to BrainPhys complete media on 2 days *in vitro* were found to have the most consistent spontaneous firing over a 28-day period. MMC optimization studies show that addition of Ficoll 70/400 crowding with ascorbic acid in astrocyte monoculture increased secretion and deposition of ECM proteins collagen I, collagen IV, and laminin. Ongoing studies include testing the optimal medium with MMC for co-culture of neurons and astrocytes in 3D and optimizing the hydrogel components for the

support of the 3D co-cultures. Future studies aim to utilize this 3D culture models to develop *in vivo*-relevant assays for HEAL-related experiments.

Title: Discovery of novel antidepressant agents targeting protein kinases in oligodendrocytes

Authors: *S. MIYATA[1], S. SHIMIZU[1], Y. ISHINO[1], M. TOHYAMA[1,2];
[1]Kindai Univ/ Res. Ins Trad Asian Med., Osaka-Sayama, Japan; [2]Osaka Prefectural Hosp. Organization, Osaka, Japan

Abstract: Major depressive disorder (MDD) is thought to be a multifactorial disease susceptible to both environmental and genetic factors. Though the responsible genes and pathogenesis of MDD at the molecular level remain unclear. In the current study, we focused on the stress hypothesis. Hypothalamic-pituitary-adrenal axis, HPA axis, activation is one of the major stress-responsive reactions for the biological defense mechanism. In approximately 50% of patients with MDD, dysregulation of this negative feedback mechanism has been reported. However, the molecular pathway in the brain affected by the excess level of plasma glucocorticoids has not been well understood. Thus, we firstly developed an animal model of depression by exposing mice to chronic stress. These mice showed depression-like symptoms including chronically elevated plasma levels of corticosterone. We further found oligodendrocyte (OL)- specific activation of the protein kinase X cascade, increased expression of axon-myelin adhesion molecules, and elaboration of the OL arbor in the corpus callosum of chronically stressed mice. Next, we generated active protein kinase X transgenic mice to investigate the relationship between OL morphological changes and protein kinase X cascade activation in OL. These protein kinase X transgenic mice showed depression-like symptoms, but these transgenic mice

with repeated administration of inhibitor Y did not show these depression-like symptoms. Furthermore, our clinical and basic studies by diffusion tensor imaging in the anterior corpus callosum indicated that significantly lower fractional anisotropy values and axial diffusivity in patients with MDD and chronically stressed mice. This compromised white matter integrity were possibly related to axonal damage, and that specific white matter abnormalities might be closely associated with MDD onset. Thus, inhibition of protein kinase X cascade in OLs could provide us with new antidepressant therapy.

Title: Isoform analysis of blood transcriptomic biomarkers for depression in human lymphocytes and hippocampal tissue

Authors: *S. L. WERT, E. REDEI;
Psychiatry and Behavioral Sci., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Access to brain tissue for psychiatric disorders is limited by the availability and quality of postmortem brain samples. Consequently, surrogate peripheral tissues, such as blood samples, have become common to employ. However, the extent to which transcriptomic changes from peripheral tissues can be used to represent or predict those of brain tissues is unknown. Additionally, the presence of transcript variants is known to differ between brain and blood, and therefore, it is important to identify what we measure in the blood as a surrogate for the brain. In the present study, we investigated previously identified blood transcriptomic markers for depression (Redei et al., 2014) for the expression of splice variants in human lymphocyte and hippocampal tissue. Expression for unique transcripts was measured by quantitative RT-PCR. Primers were designed to amplify specific isoforms. Transcript levels of *CD59*, *CADM1*, *KIAA1539*/*FAM214B*, were higher in the hippocampus in contrast to *ADCY3*, *DGKA*, *ATP11C*, *FAM46A* and *PSME1*, which had greater expression in lymphocytes. Although there were clear variations in isoform expression in both tissues, there were no extreme tissue-specific expression differences in these transcripts. Although *ASAH1* has 69 splice variants, there were no differences in transcript levels between hippocampus and lymphocytes. In contrast, large differences were found in the expression of the 13 splice variants of Ras association (RalGDS/AF-6) and pleckstrin homology domains 1 (*RAPH1*) within blood and hippocampus,

and compared to each other. The expression pattern of these differences clearly aligned to specific splice variants, and candidate mechanisms include the presence or absence of microRNA binding sites on the splice variants. Thus, isoform expression in the blood and brain is relatively homologous, but when it is not, tissue-specificity needs to be evaluated.

Title: The pharmacological dichotomy of ketamine: *In vitro* assays to evaluate neuronal structure and EEG-like oscillations

Authors: I. BARBIERO[1], M. CUNNINGHAM[2], C. KILSTRUP-NIELSEN[1], ***M. BIANCHI**[3,2]; [1]Univ. of Insubria, Busto Arsizio, Italy; [2]Trinity Col. Dublin, Dublin, Ireland; [3]Ulysses Neurosci. Limited, Dublin, Ireland

Abstract: Ketamine (NMDA antagonist) is the only pharmacological therapy for treatment resistant depression (TRD) at sub-anaesthetic doses. However, ketamine is also used as an experimental pharmacological model for schizophrenia (SCZ) in the clinic due to its psychedelic effects. This pharmacological dichotomy is explored by pharmaceutical companies in order to develop new drugs for TRD and SCZ. Rapid *in vitro* assays are required to accelerate progression of compounds in the drug discovery phases. Here, we describe two *in vitro* assays to investigate effects of ketamine. 1) The antidepressant efficacy of ketamine is hypothesized to be linked to synaptic plasticity. We have explored effects of ketamine (0.3 and 1μM) on the structure of mouse hippocampal primary neuronal cultures at 24h and 72h post-exposure compared to vehicle (0.1% DMSO). Axonal length was analysed at DIV4 by staining with the axonal marker Tau1. Dendritic arborization was investigated at DIV10 by staining with the dendritic marker Map2. Spine maturation was analysed at DIV14 by staining PSD95 to visualize mature spines (PSD95-puncta). Quantitation was made by using ImageJ and FuJi software. The results showed no effects of ketamine on axonal length, while dendritic arborization was significantly increased at both concentrations at either 24h ($P<0.01, n\geq3$) or 72h ($P<0.05, n\geq3$) post-exposure compared to vehicle. PDS95-puncta were not changed by ketamine at both concentrations at 24h post-administration, while a significant increase ($P<0.05, n\geq3$) was observed at 72h at 1μM compared to vehicle. 2) Disruption in oscillatory EEG activity of gamma frequency is a biomarker of ketamine activity in the clinic. Rats were treated with ketamine (30 mg/kg) once a day for 5 days which is the standard pre-clinical protocol to model SCZ. The frontal section of the brain was then sliced isolate the anterior cingulate cortex (ACC). Slices

were transferred to an interface chamber and electrodes placed in the ACC in either deep or superficial layers. EEG-like activity including peak frequency, peak amplitude and area power were obtained from power spectra generated with Fourier analysis performed off-line using a 60s period every 10 minutes. The data showed that ketamine induced a significant ($P<0.05$) increase in peak frequency compared to vehicle indicating increase in speed of oscillatory activity compared to vehicle (0.9% NaCl). In contrast, ketamine did not induce changes in peak amplitudes or area powers. We have therefore developed *in vitro* assays which can be used by pharmaceutical companies for a first and rapid screening of ketamine-like compounds on synaptic plasticity and EEG-like oscillations.

Title: Safety assessment of esketamine administered via dry powder inhalation in animals and humans during preclinical toxicology and phase I clinical study

Authors: ***M. MATLOKA**[1], S. JANOWSKA[1], J. SIERZPUTOWSKA[1], K. JARUS-DZIEDZIC[2], J. PIECZYKOLAN[1], M. WIECZOREK[1];

Abstract: Despite ketamine has been used as a medicine for over 50 years, there are only single reports on the safety of ketamine in animals and humans, in particular for other than parental administration routes. Esketamine inhaled as dry powder represents a new approach that may provide additional advantages over currently used administration routes. Here we present the safety profile of esketamine inhaled as dry powder assessed during preclinical and clinical studies. Preclinical safety has been assessed during safety pharmacology and toxicology studies. The animals were administered with esketamine as dry powder via inhalation. Wistar rats received doses up to 58.8 mg/kg during a single or 14-day administration study. Beagle dogs were exposed to doses up to 40.8 mg/kg during a single, 7 or 28-day toxicology studies. Safety pharmacology study assessed respiratory, cardiovascular and behavioural, neurological and

autonomic parameters. The clinical study consisted of an open label, two-part, single-ascending dose and multiple dose, randomized, double-blind, placebo controlled, ascending dose study with four administrations twice a week over 2 week period in healthy volunteers. Subjects received up to 48 mg of esketamine delivered by dry powder inhaler. Safety assessment included adverse events (AE) reporting, clinical laboratory tests, vital signs, physical examination, electrocardiography and psychoactive side effects. Most of the side effects observed during preclinical toxicology studies included slight to extreme incoordination, slight to extreme salivation, slight decreased activity, shaking, labored and/or slight increased respiration. Most of theses signs dissipated 1 hour post-exposure and were not observed following each dose occasion and not in every animal. All observations were not deemed toxicologically adverse since all signs were transient. Safety pharmacology study revealed no influence on respiratory or cardiovascular functions. Functional Observation Battery confirmed known anesthetic activity of esketamine. Administration of inhaled esketamine as dry-powder during clinical studies was generally safe and well tolerated with no serious AEs. The most common drug related AEs (mild to moderate intensity) were dizziness, a feeling of relaxation, numbness of the mouth and tongue, and hypertension. No discontinuation due to adverse effects was recorded. No abnormalities in laboratory tests or ECG were observed. The presented studies confirm that esketamine administered via dry powder inhalation is well tolerated and safe at doses intended to be used for efficacy studies in treatment-resistant and bipolar depression.

Title: Resting-state functional MRI outperforms structural MRI in predicting transdiagnostic depression severity

Authors: *M. S. MELLEM, Y. LIU, H. GONZALEZ, M. E. KOLLADA, W. J. MARTIN, P. AHAMMAD;
Blackthorn Therapeut., San Francisco, CA

Abstract: Uncovering the biological basis of patient heterogeneity is a key to creating clinically-relevant biomarkers. Non-invasive imaging is enabling the visualization of the brain-to-symptom links underlying neurobehavioral disorders, but the technology is often too narrowly applied by only examining one aspect of biology (e.g., anatomical or functional MRI measures) or a single diagnostic group. Since symptoms such as depression span multiple neurobehavioral disorders, a more robust symptom biomarker could be better captured by examining transdiagnostic patient cohorts and utilizing multiple neuroimaging modalities. Here, we built a transdiagnostic multimodal MRI model that successfully identified biomarkers that can reliably predict clinician-rated depression severity across multiple neurobehavioral disorders. We utilized the Consortium for Neuropsychiatric Phenomics dataset, which includes resting-state functional MRI (rs-fMRI) and structural-MRI (sMRI) imaging measures from patients with schizophrenia, bipolar disorder, and attention deficit and hyperactivity disorder (n=142 total). Input features included preprocessed sMRI volume, surface, and thickness measures (270 features) and preprocessed rs-fMRI connectivity measures (34,716 features). Our outcome measure of depression was the clinician-rated 28-item total score from the Hamilton Rating Scale for Depression (HAMD). We used an importance-ranked forward selection procedure with Elastic Net regression and cross-validation for an efficient, data-driven feature selection approach to identify the most predictive features from these high-dimensional data. This data-driven approach yielded a highly predictive transdiagnostic model that explained 61% of variance of the HAMD total score. Moreover, the feature selection step of this machine learning procedure returned a subset of features that were predictive and highly interpretable. Of the rs-fMRI connectivity features, the Default Mode Network was the primary source, while other predictive features were widely distributed across various resting-state networks including the Fronto-parietal Task Control, Salience, Somatosensory/motor, Subcortical, Attention, and Sensory networks. Structural features did not contribute much to the predictive strength of this model, representing only about 1% of features found to be predictive. Thus, we created an algorithm to predict depression across multiple neurobehavioral disorders. The features important to this algorithm suggest that functional connectivity, rather than anatomy, provides a “depressive brain signature” which could be targeted for intervention.

Title: Biomarker of neurofeedback response

Authors: M. RANCE[1], J. EILBOTT[3], S. A. KICHUK[2], W. N. KOLLER[1], D. SCHEINOST[1], P. GRUNER[2], C. J. PITTENGER[2], ***M. HAMPSON**[1];
[1]Radiology and Biomed. Imaging, [2]Psychiatry, Yale Univ., New Haven, CT; [3]Surveybott, Guilford, CT

Abstract: To facilitate personalized medicine, we are interested in identifying biomarkers that predict response to our fMRI neurofeedback interventions. We have developed an intervention for obsessive-compulsive disorder (OCD) in which we train patients to control activity in a region of the ventral frontal cortex (Hampson et al, 2012). This intervention involves four scanning sessions per subject: two feedback scans, a pre-assessment scan and a post-assessment scan. In the assessment scans, we collect resting state data and measures of ability to control the target brain area in the absence of feedback. A yoked sham control group is used. In previous work, we tested the intervention in subjects with subclinical contamination anxiety. Results were promising in that neurofeedback subjects showed greater improvement in control over their contamination anxiety than sham subjects (10 neurofeedback and 10 sham subjects; Scheinost et al., 2013). Furthermore, we identified a region of the frontal pole in which global resting connectivity prior to neurofeedback training predicted response to the intervention in this subclinical study (Scheinost et al., 2014). We are now running a double-blind, randomized clinical trial of the same intervention in patients with OCD. The Y-BOCS (Yale-Brown Obsessive-Compulsive Symptom Scale) is our primary measure of symptom severity in the clinical population. About a year into this clinical trial, the 1.5T scanner we were using was decommissioned and we moved the protocol to a 3T system. Taking the data collected prior to

the scanner change (6 neurofeedback and 6 matched sham subjects), we examined whether the biomarker previously identified in the subclinical population also predicted neurofeedback response in this interim data from the clinical trial. Indeed, there was a significant correlation between pre-intervention global resting connectivity in the frontal pole (using an a-priori defined region based on the predictor we identified in the subclinical study) and symptom improvement in the neurofeedback group ($r=0.95$, $p<0.05$). There was no significant correlation between global connectivity in the frontal pole and symptom change in the yoked sham control group, consistent with the hypothesis that this biomarker of response is related to the mechanism of action of the active intervention and not a marker, for example, of an individual's susceptibility to placebo effects. We conclude that we have identified a biomarker of response to our neurofeedback intervention that is shared across subclinical and clinical populations.

Title: Safety and pharmacokinetic study of phosphodiesterase 10A inhibitor (CPL500036) after a single dose in healthy volunteers

Authors: *S. JANOWSKA[1], K. JARUS-DZIEDZIC[2], J. SIERZPUTOWSKA[1], M. MATLOKA[1], M. WIECZOREK[1];
[1]Celon Pharma S.A., Lomianki, Poland; [2]BioResearch Group Sp. Z O.O., Kajetany, Poland

Abstract: Background: Phosphodiesterase 10A (PDE10A) hydrolyses cyclic nucleotides and is highly expressed in striatal medium spiny neurons (MSNs). PDE10A inhibition may modulate the MSNs action in an efficient way. Therefore, PDE10A inhibitors may be used in the treatment of various types of psychosis. In the course of preclinical development CPL500036 proved to be effective in several animal models of psychotic and neuromotor disorders. The present study was intended to determine the safety and pharmacokinetic properties of CPL500036 after single oral administration in healthy volunteers. **Methods:** This was an open label, dose-escalation study with single oral administration of CPL500036 in healthy volunteers being in a fasted state. The study was performed in conventional '3+3 design', where MTD (maximum tolerated dose) is to be determined. 21 Caucasian male and female subjects were enrolled in 7 cohorts (n=3 per cohort). Volunteers received CPL500036 in doses ranging from 1 to 100 mg. Safety assessment

included adverse events (AE) reporting, clinical laboratory tests, vital signs, physical examination, electrocardiography. Blood samples for pharmacokinetic (PK) analysis were collected up to 72 hours after administration. Concentration analysis was evaluated by HPLC/MS/MS method. PK parameters were computed using a non-compartmental modelling approach. **Results:** Administration of CPL500036 was generally safe and well tolerated with no serious AE. The drug related AEs, of mild to moderate intensity, were drowsiness, sensation of heat, anxiety and difficulty speaking. Despite administration up to 100 mg of CPL500036, no dose limiting toxicities (DLT) was observed, therefore no MTD was determined. The CPL500036 exposure increased in a dose-dependent manner. The CPL500036 mean maximum plasma concentration (Cmax) values were in range of 13.76 - 284.96 ng/mL for cohort 1-7, respectively, and were recorded from 45-50 minutes (for the first two doses) to 3h (for the highest dose) after administration. The area under the curve of plasma concentration vs time (AUC0-72) for the first and the last cohort was 105.85 ng/mL*h and 9493.89 ng/mL*h, respectively. **Conclusion:** CPL500036 administration in all doses was safe and well tolerated by volunteers and resulted in few AE with mild to moderate severity. Pharmacokinetics of CPL500036 supports once daily dosing regimen. The obtain results justify further clinical development.

Title: Analysis of methylation and -141C Ins/Del polymorphisms of the dopamine receptor D2 gene in patients with schizophrenia

Authors: *Y. FUNAHASHI[1], Y. YOSHINO[3], K. YAMAZAKI[4], S. OCHI[2], J. IGA[5], S.-I. UENO[6];
[1]Ehime Univ. Grad. Sch. of Med., Toon, Japan; [2]Ehime Univ. Grad. Sch. of Med., Toon / Ehime, Japan; [3]Neuropsychiatry, Toon, Japan; [4]Ehime Univ. Hosp., Ehime, Japan; [5]Neuropsychiatry, [6]Ehime Univ., Toon, Japan

Abstract: The gene for dopamine receptor D2 (DRD2) is associated with schizophrenia (SCZ). Epigenetic changes may be related to SCZ pathology. The -141C Ins/Del polymorphism in DRD2 (rs1799732) is functional and associated with SCZ. Fifty SCZ patients and 50 control subjects were newly recruited and analyzed in addition to 50 previously reported SCZ samples and 50 previously reported control samples. Genomic DNA from peripheral leukocytes was analyzed. We replicated analysis of DNA methylation rates at seven CpG sites (CpG 1-1 to 1-7) and also analyzed five additional sites (CpG 2-1 to 2-5) in the upstream region of DRD2. We also performed genotyping of -141C Ins/Del and analyzed the effects of -141C Ins/Del on methylation of DRD2. Methylation rates were significantly lower in SCZ patients compared to control subjects, respectively. In control subjects, the methylation rates were significantly lower in individuals with the Ins/Ins genotype than in Del allele carriers. We replicated hypomethylation of the DRD2 promoter region in SCZ patients compared to age-matched control subjects. The -141C Ins/Del polymorphism affected the methylation rates in regions of DRD2. Hypomethylation and the -141C Ins/Del polymorphism of DRD2 may be biomarkers for SCZ.

Title: EEG signal complexity as a computational bio-marker for schizophrenia

Authors: *E. J. WOLFSON[1], Y. LOEWENSTEIN[2], O. SHRIKI[3];
[1]Dept. of Brain and Cognitive Sci., BGU, Beer-Sheva, Israel; [2]Hebrew Univ., Jerusalem, Israel; [3]Ben-Gurion Univ., Beer-Sheva, Israel

Abstract: Schizophrenia (SCZ) is a severe disruption in cognition and emotion, affecting the most fundamental human functions: language, thought, perception, affect, and sense of self. It is

thought to be associated with alterations in the balance of excitation and inhibition, which lead to changes in the underlying network dynamics.
To identify potential biomarkers that could provide new insights and indicate altered neural dynamics, we applied multi-scale entropy (MSE) analysis, which quantifies signal complexity, along with conventional power spectrum analysis to resting-state MEG data from 54 SCZ patients and 98 healthy control subjects. To assess the feasibility of this analysis as a biomarker, we applied various machine learning classifiers, trained to differentiate between SCZ patients and control subjects.
The MSE method uses the concept of sample entropy to assess the level of temporal complexity of the measured signal across different time scales. Our analysis showed that sample entropy across specific time scales of SCZ patients is significantly higher than the sample entropy ascribed to controls. Specifically, a higher sample entropy is observed on 216 out of 273 channels and reaches a significance level of $p < 0.05$ on 114 channels, most of which are located at the center of the central, parietal and occipital lobes. The difference peaks between the frequencies 15 and 24 Hz.
To dissect the contributions of the amplitude and phase components to the entropy, we generated, for each subject, a phase-shuffled surrogate signal and applied to it the same MSE analysis. We found that in those channels in which a significant difference between the SCZ patients and controls was observed, this difference was dominated by the signal amplitude. Those channels also showed good agreement with the spectral analysis, in terms of both localization and quality of classification. Surprisingly, the phase shuffling exposed differences between the SCZ patients and control subjects in the areas in which the amplitude component (and also spectral analysis) did not show a significant difference between the two groups, mainly the frontal and temporal lobes.
These findings pave the way for new insights into the differences in the underlying neural dynamics of schizophrenia patients and may be useful as a diagnostic tool which goes beyond spectral features.

Title: Thalamic neuroinflammation is associated with thalamo-cortical gating dysfunction in schizophrenia

Authors: *F. M. HOWELLS[1,2], H. S. TEMMINGH[1], J. H. HSIEH[1,2], D. J. STEIN[1,2,3]; [1]Psychiatry and Mental Hlth., Univ. of Cape Town, Cape Town, South Africa; [2]Neurosci. Institute, Univ. of Cape Town, Cape Town, South Africa; [3]Dept. of Psychiatry and Mental Health, Univ. of Cape Town, SU/UCT MRC Unit on Risk and Resilience in Mental Disorders, Cape Town, South Africa

Abstract: *Introduction:* Thalamo-cortical circuitry, as measured by delta/alpha electroencephalography (EEG) frequency activity has been suggested to delineate the following psychotic disorders: schizophrenia (SCZ), bipolar I disorder with a history of psychosis (BPD), and methamphetamine-induced psychotic disorder (MPD) (Howells et al., 2018). Recent literature suggests neuroinflammatory mechanisms may underlie in part the presentation of psychotic disorders. Proton magnetic resonance spectroscopy (^{1}H-MRS) is able to provide an *in vivo* measure of active neuroinflammation, i.e. increased *myo*-inositol (mI) with decreased n-acetyl-aspartate metabolite (NAA and NAA with NAAG) concentrations. The aim of the current study was to investigate whether ^{1}H-MRS markers of neuroinflammation (mI/NAA+NAAG) in the thalamus are associated with the pronounced delta/alpha cortical activity in SCZ, BPD and MPD. *Method:* This study included individuals with diagnosis of SCZ (n=17), BPD (n=22), MPD (n=23), and demographic-matched controls (CON, n=25). On the same day, between 09h00-11h00 participants underwent (1) EEG frequency record (electrodes: F_3,F_4,C_3,C_4,P_3,P_4) during resting conditions, eye open and eyes closed, and during a simple attention task and (2) proton magnetic resonance spectroscopy (^{1}H-MRS) of their left thalamus. Correlation analyses were performed as appropriate to determine relationships between delta/alpha frequency activity and mI/NAA+NAAG concentration, *a priori* setting Rho>±0.6 and p<0.01. *Results:* Only SCZ were found to hold significant positive relationships between delta/alpha frequency activity and left thalamic mI/NAA+NAAG concentrations. These relationships were apparent only during resting eyes closed condition, and apparent for bilateral frontal (F_3 and F_4), left central (C_3) and right parietal (P_4) electrodes. The remaining two electrodes (C_4 and P_3) showed positive relationships (Rho>±0.4 and p<0.5) but did not meet the *a priori* thresholds set. *Conclusions:* These findings are consistent with the hypothesis that neuroinflammatory processes play a role in dysfunctional thalamo-cortical connectivity in SCZ, but not in BPD and MPD. Further work is, however, needed to replicate and consolidate these findings.

Title: SEP-363856, a novel psychotropic agent with a unique, non-D2 mechanism of action

Authors: *N. DEDIC[1], P. G. JONES[1], S. C. HOPKINS[1], R. LEW[1], T. HANANIA[2], U. C. CAMPBELL[1], K. S. KOBLAN[1];
[1]Sunovion Pharmaceuticals Inc., Marlborough, MA; [2]Psychogenics Inc., Paramus, NJ

Abstract: For the past 50 years, the clinical efficacy of antipsychotic medications has relied on blockade of dopamine D_2 receptors. Drug development of non-D_2 compounds, seeking to avoid the limiting side effects of dopamine blockade, has failed to date to yield new medicines for patients. Here we report the discovery of SEP-363856 (SEP-856), a novel psychotropic agent with a unique mechanism of action. SEP-856 was discovered in a medicinal chemistry effort utilizing a high throughput, high content, mouse-behavior phenotyping platform known as SmartCube®, in combination with *in vitro* screening, aimed at developing non-D_2 (anti-target) compounds that could nevertheless retain efficacy across a variety of D_2-based animal models of schizophrenia. SEP-856 demonstrated broad efficacy in rodent models relating to positive- and negative symptoms of schizophrenia, including Phencyclidine (PCP)-induced hyperactivity, prepulse inhibition and PCP-induced deficits in social interaction. Autoradiography and positron emission tomography studies in rats and non-human primates demonstrated lack of D_2 receptor occupancy by SEP-856 at concentrations up to 200-fold greater than those observed to be behaviorally efficacious. In addition to its favorable pharmacokinetic properties and the absence of catalepsy, SEP-856's broad profile was further highlighted by its antidepressant activity in the mouse forced swim test and robust suppression of rapid eye movement sleep in the rat. Although, the mechanism of action has not been fully elucidated, *in vitro* and *in vivo* pharmacology data suggest that agonism at both 5-HT_{1A} receptors and trace amine-associated receptor 1 (TAAR1) are integral to its efficacy. This was further corroborated with electrophysiological slice recordings, demonstrating inhibition of dorsal raphe nucleus and ventral tegmental area neuronal firing via 5-HT_{1A} and TAAR1 receptors, respectively. Based on its unique mechanism of action and broad efficacy in preclinical animals models, SEP-856 was advanced into clinical development and represents a promising candidate for the treatment of schizophrenia and potentially other neuropsychiatric disorders.

Ctr. of Neurol. and Psychiatry, Tokyo, Japan; [6]Dept. of Neuropsychiatry, Fac. of Life Sci., Kumamoto Univ., Kumamoto, Japan

Abstract: [Background]
Lysophosphatidic acid (LPA) is a phospholipid involved in various physiological processes such as inflammation in the central nervous system. LPA is synthesized from lysophosphatidylcholine (LPC) by lysophospholipase D (lyso-PLD), also known as autotaxin (ATX), and degraded by lipid phosphate phosphatases (LPPs). In addition, LPC and LPA have multiple molecular species. Both serum and cerebrospinal fluid (CSF) autotaxin levels are significantly lower in major depressive disorder (MDD) patients than in healthy controls (Itagaki et al., 2019). However, levels of multiple molecular species of LPA and LPC, and lyso-PLD activity in the CSF have not been measured in patients with major psychiatric disorders. Therefore, CSF levels of LPAs and related substances in patients with MDD and schizophrenia were examined in the current study.
[Method]
CSF was obtained from Japanese patients with MDD (n=26) and schizophrenia (n=27) and from

age- and gender-matched healthy controls (n=27). All participants underwent the Mini-International Neuropsychiatric Interview (M.I.N.I), Japanese version. For participants with MDD and schizophrenia, a diagnosis was made according to DSM-IV criteria on the basis of the M.I.N.I. Each level of LPAs and LPCs and lyso-PLD activity were measured by using liquid chromatography-tandem mass spectrometry (LC-MS/MS). LPP1 levels were quantified with ELISA. The ethics committee of the National Center of Neurology and Psychiatry and National Hospital Organization Kure Medical Center approved this study. All participants provided written informed consent.
[Results]
Between the three groups, there were no differences in levels of LPAs and LPCs, lyso-PLD activity, and LPP1 levels. However, the LPA/LPC ratio showed a significant reduction of 22:6 (docosahexaenoic acid; DHA) - LPA/LPC ratio in patients with MDD and schizophrenia. Additionally, a significant correlation between DHA-LPA levels and lyso-PLD activity was found in healthy controls, which was not observed in patients with either MDD or schizophrenia.
[Conclusion]
Turnover of DHA-LPC to DHA-LPA was specifically reduced in patients with either MDD or schizophrenia. The abnormal metabolism of DHA-LPA in CSF could explain reduction of DHA, known to have anti-inflammatory effects, in previous studies of postmortem brain with major psychiatric disorders, and might serve as a part of pathophysiology of the disorders.

Title: Orphan GPCR ligands from ethnobotanical sources as novel drugs for mental disorders

Authors: *C. GALLO, G. POLETTI, R. ROJAS, A. VAISBERG;
Univ. Peruana Cayetano Heredia, Lima, Peru

Abstract: Traditional medicine knowledge is an important tool to direct the discovery of novel therapeutics that will eventually help to unravel biological processes behind the occurrence of mental disorders. We have compiled information on the traditional use of plants for the treatment of mental disorders in several Peruvian localities and geographical regions and currently have repository of ethanol extracts from 477 plant collections corresponding to 265 species from 87 different plant families. These plants have been used for centuries in traditional medicine for one or more of the following actions: antipsychotic, antidepressant, anxiolytic and/or sedative.
Working in collaboration with the NIMH Psychoactive Drug Screening Program, we have been able to identify plant extracts with potential antagonist activity for the orphan G-protein-coupled receptors (GPCRs) GPR4, GPR65 and GPR68; potential agonist and inverse agonist activity for GPR52, GPR68 and GPR88 and potential agonist activity for the orphan GPCRs MRGPRX1, MRGPRX2 and MRGPRX4.
These receptors belong to the rhodopsin (class A) family, which is the largest and extensively studied family of GPCRs; however, they are considered orphans because their endogenous ligands are yet putative or unknown. An additional challenge is that there is a lack of pharmacologically active compounds identified or developed for these targets.
Interestingly, all the studied orphan GPCRs have been shown to be expressed in the mammalian brain. Moreover, several of our extracts show activity for more than one of these receptors, which could mean the presence of shared binding domains or potential biological interactions between them in the biology of these disorders.
We are currently working on the isolation and characterization of the active molecules through bioassay-guided fractionation of the raw extracts.
GPCRs participate in diverse physiological functions and are promising targets for drug discovery. For this reason, elucidating the biological function of orphan receptors is compelling.

Title: Resting-state EEG delta predicts neurofeedback treatment long-term response in nicotine addiction

Authors: J. BU, *X. ZHANG;
Univ. of Sci. & Technol. of China, Hefei, China

Abstract: Neurofeedback, as a novel cognitive neurostimulation technology, has been clinically employed in drug addiction over six decades. However, about 30% of participants fail to learn to self-regulate their brain activity during neurofeedback. Recently we developed a novel EEG neurofeedback protocol and found that it can impressively reduce cigarette consumption even at 4-month follow-up for smokers. However, obvious individual differences in long-term effects were observed. Therefore, it is critical to identify who will benefit at pre-neurofeedback. In current study, we examine whether resting-state EEG characteristics at pre-neurofeedback predict long-term effects and further explore the mechanism of the resting-state EEG predictor. With a randomized clinical trial (RCT), sixty nicotine-dependent participants were randomly assigned to the real-feedback group and the yoked-feedback group. They underwent two novel neurofeedback training sessions. At pre-neurofeedback and post-neurofeedback, participants underwent a 6 min resting EEG recording. At 4-month follow-up after neurofeedback training, the number of cigarettes smoked per day was assessed. First, the power of resting-state delta (1-3 Hz) at pre-neurofeedback strongly correlated with long-term effects in the real-feedback group ($r=0.70$, $p<0.001$). After control for all clinical variables and other EEG band power, the delta could also predict the long-term effects ($r=0.62$, $p<0.001$). The significant prediction was only observed in the realfeedback group, which suggested the delta represented a specific predictor of neurofeedback training. In addition, the strong correlation between pre-neurofeedback and post-neurofedback indicated the stability of the delta power ($r=0.69$, $p<0.001$). Moreover, the leave-one-out cross-validation procedure using machine learning methods revealed the relationship between the observed long-term effects and predicted effects by the delta power was strongly significant ($r=0.61$, $p<0.001$). Furthermore, previous studies have showed that late positive potential (LPP) was an indicator of addiction incubation effect. We found significant LPP appeared at 4-month follow-up. In addition, the delta predictor was significantly correlated with the LPP ($r=0.59$, $p<0.001$). Further, the EEG source analysis revealed that the delta was related with orbital frontal cortex which was also involved with incubation effect of addiction. With the RCT, we found resting-state delta power may represent a strong, stable and specific prognostic marker of neurofeedback effects, and the predictor may be linked to the addiction incubation effect.

Title: Stem cell-derived grinch neurons for high throughput screening and profiling

Authors: *R. HEILKER[1], S. TRAUB[2], D. BISCHOFF[3];
[1]Boehringer Ingelheim Pharma Gmbh & Co. KG, Biberach, Germany; [2]Trenzyme GmbH, Konstanz, Germany; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany

Abstract: Human induced pluripotent stem (hiPS) cell-derived neurons promise to provide better model cells for drug discovery in the context of the central nervous system. Using GRowth factor-driven expansion and INhibition of NotCH (GRINCH) during maturation, sufficient numbers of hiPS cell-derived GRINCH neurons were generated to accommodate for the immense material needs of high-throughput screening (HTS). GRINCH cells displayed neuronal markers, and their functional activity could be demonstrated by electrophysiological recordings. The GRINCH neurons were employed as model cells to search for positive modulators of synaptic plasticity. Pharmacological characterization in GRINCH neurons paves the way for a new generation of predictive cell-based drug discovery and development.

Title: Development of a PC12 cell-based assay for *in vitro* screening of catechol-O-methyltransferase inhibitors

Authors: *G. V. CARR[1,2], G. ZHANG[1], I. BUCHLER[1], M. DEPASQUALE[1], M. WORMALD[1,2], H. WEI[1,2], J. C. BARROW[1,2];
[1]Lieber Inst. for Brain Develop., Baltimore, MD; [2]Pharmacol. and Mol. Sci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: The male rat adrenal pheochromocytoma PC12 cell line can synthesize and release catecholamines (dopamine, epinephrine, and norepinephrine), and has been widely used as an *in vitro* model system in studies of neurotransmitter regulation. Catechol-*O*-methyltransferase (COMT) is involved in the inactivation of the catecholamine neurotransmitters and serves a critical role in regions of the brain with low expression of the dopamine transporter, such as the prefrontal cortex. In this study, we explored the feasibility of utilizing PC12 cells as a medium-

throughput drug screening platform. Our characterization data confirmed the presence of measurable tyrosine hydroxylase (TH), monoamine oxidase A (MAO-A), MAO-B, and COMT protein levels. Additionally, PC12 cells express the D1, D2, and D5 dopamine receptors. In agreement with previous studies of PC12 cells, no dopamine transporter protein was detected. Incubation of PC12 cells with tolcapone, a highly potent and selective COMT inhibitor, reduced the concentrations of dopamine metabolites 3-MT and HVA and increased concentrations of dopamine and DOPAC, another metabolite, in the cell culture medium. The effects of tolcapone in the PC12 assay were in agreement with *in vivo* measurements taken from the brain across species. Our novel COMT inhibitor, LIBD-3 produced qualitatively similar effects when compared to tolcapone. The relative changes in dopamine metabolites produced by LIBD-3 were slightly smaller than those produced by tolcapone, in line with the difference in potency measured in cell-free enzyme assays. Moreover, tolcapone and LIBD-3 incubation significantly potentiated the amount of dopamine released in response to high K^+-mediated depolarization, similar to the published results of *in vivo* microdialysis studies in rats. Together, our data support the view that PC12 cells represent a robust system that can serve as a bridge between cell-free enzyme assays and costly *in vivo* efficacy models in determining which COMT inhibitors should be advanced in a drug discovery setting.

Title: Topographical patterns of brain function at the individual level: Informative and interpretable

Authors: *B. C. TABER-THOMAS;
SUNY Geneseo, Geneseo, NY

Abstract: Technological advances have allowed for the collection of large amounts of neuroimaging data, but relatively less progress has been made in developing analysis techniques that provide easily understandable and clinically useful information. This is partly due to the difficulty of reducing neuroimaging data to a format that is at the same time (i) human readable and (ii) information rich. A breakthrough is possible by leveraging the topography brain

organization to capture robust network phenomena in a simple, intuitive profile representing an individual's functional brain organization. The present analyses build on a recently developed topographical data reduction approach (Taber-Thomas et al., 2016; Deen et al., 2015) in order to extract individual patterns of brain organization. This analysis technique has revealed group differences in the topography of brain function; for example, children at risk for anxiety show a flattened pattern of salience network connectivity across the anterior cingulate cortex (Taber-Thomas et al., 2016). Here, topographical patterns of salience network connectivity are extracted at the individual level, providing a simple curve that represents an individual's topographical pattern of brain function or connectivity. Data previously analyzed at the group level and data culled from publicly available neuroimaging datasets are re-analyzed to reveal topographical patterns of brain function at the individual level. Insula connectivity is extracted for a series of regions of interest spanning the limbic system to provide a topographical pattern of salience network connectivity. Group analyses reveal the expected topographical pattern of insula connectivity: greater connectivity with dorsal and less connectivity with ventral anterior cingulate cortex. However, at the individual level significant variability in topography is observed. The reliability and utility of topographical patterns of brain function at the individual level will be discussed. In sum, a topographical data reduction approach has the potential to advance the discovery of neuroimaging biomarkers that are meaningful and interpretable at the individual level.

Title: Parameter optimization in personalized Virtual Brain models using stochastic gradient descent

Authors: Z. WANG[1], K. SHEN[1], J. D. GRIFFITHS[1,2], *A. R. MCINTOSH[1];
[1]Baycrest Ctr., Toronto, ON, Canada; [2]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: In large-scale dynamic network modeling, a brute force search on model parameters is often used to optimize the fit between empirical and simulated functional connectivity (FC). Finding the optimal fit in such a search is dependent on the choice of search step and space. Fitting many parameters at once, such as considering connection parameters individually, can also become computationally expensive. Using tools implemented in machine learning may be a powerful way to estimate large sets of model parameters. Here we describe the integration of

stochastic gradient descent using TensorFlow, a machine learning library, with the generative model in TheVirtualBrain (TVB; thevirtualbrain.org). The advantage of using a framework like TensorFlow is the automatic computation of Jacobians which substantially improves the speed and tractability of optimization problems. Using data from the Human Connectome Project, we created personalized connectome-based models of 200 individuals. In each model, each node was represented by a neural mass model, coupled together according to the subject's structural connectome. The resultant model can be considered a type of recurrent neural network whose state weights can be trained. Noise served as the input to state weights. State-to-state weights were parameters of interest. Simulated resting-state BOLD-fMRI FC was computed in windowed increments of 15 time points and fit to corresponding windows of empirical FC using the stochastic gradient descent algorithm in TensorFlow (Adam). Fits were assessed using the Pearson correlation (r) between the simulated and empirical FC, and parameters were iteratively updated for each window. For each iteration, initial conditions for state variables were randomly selected. This was repeated 40-100x until the parameter estimates reached an asymptote and the average of parameters from the last 10 steps were kept. Fitting only three parameters - global coupling, noise and local gain - resulted in an average fit of r=0.45. By also fitting the interareal couplings (up to 83x83 additional parameters), the fits increased to an average of r=0.75. Our findings suggest that integrating machine learning methods into the generative model in TVB can be a powerful tool for large-scale network modeling efforts.

Title: Using personalized virtual brain models to reveal mechanisms of cognitive impairment in Parkinson's disease

Authors: *K. SHEN[1], Z. WANG[1], T. BROWN[1], D. SODUMS[2], A. R. MCINTOSH[1,3]; [1]Rotman Res. Institute, Baycrest, Toronto, ON, Canada; [2]Kunin-Lunenfeld Ctr. for Applied Res. & Evaluation, Baycrest, Toronto, ON, Canada; [3]Psychology, Univ. of Toronto, Toronto, ON, Canada

Abstract: Although Parkinson's disease (PD) is initially characterized by motor symptoms, >80% of patients develop dementia over the course of the disease. Using static neuroimaging profiles alone to develop biomarkers for PD-dementia is challenging because affected brain networks are also implicated in other dementias. Moreover, disease mechanisms occur at cellular/molecular scales and are undetectable with current noninvasive neuroimaging tools. We begin to address these challenges by integrating neuroimaging data with underlying cellular mechanisms via large-scale dynamic network models using TheVirtualBrain (TVB; thevirtualbrain.org) simulation platform. Personalized models of PD (N=70), prodromal forms of PD (N=13) and healthy controls (N=19) were created in TVB using each individual's structural connectome. The local dynamics of each brain region was modeled using a mean field model of coupled excitatory and inhibitory populations. Model parameters (global coupling, noise, & local coupling) were varied to optimize the fit between empirical and simulated resting-state functional connectivity. Good fits were obtained for all subject groups (mean: 0.38; range: 0.26-0.49). A multivariate analysis showed that increased global coupling and lower noise were related to better cognitive scores ($p < 0.01$). These findings suggest that disruptions to long-distance integration underlies cognitive impairment in PD. Our models are a solid first step towards the deliberate integration of neuroimaging data with computational modeling to elucidate the biophysical substrates of disease mechanisms in dementia.

Title: Large scale modeling of the mouse brain dynamics

Authors: *L. KUSCH[1], S. PETKOSKI[2], V. K. JIRSA[3];
[1]Inst. de Neurosciences des Systèmes, Aix-Marseille Univ., Marseilles, France; [2]Inst. de Neurosciences des Systèmes, Aix-Marseille Univ., Marseille, France; [3]Inst. De Neurosciences Des Systemes UMR1106, Marseille, France

Abstract: Modeling the mouse whole-brain dynamics is viable using the paradigm of brain network models based on the structural connectivity of the mouse brain. This approach is implemented in the neuroinformatic platform The Virtual Brain (TVB) [1], where the tracing data from Allen Institute [2] can be combined with a range of neural mass models [3]. Another

common strategy is based on spiking neural networks and uses experimental data at the cellular level for the parameters, leading to bottom-up models such as the Blue Brain project. The former are better suited for study from dynamical systems viewpoint, while the complexity of the latter makes them more physiological plausible.
In this work we bridge the two approaches, by building a connectome based large-scale brain network model, where each region contains a population or a surface of spiking neurons, thus allowing a direct link to neuroimaging data, while increasing the biological realism. As a first step we use our modeling paradigm to analyze the impact of heterogeneous connectivity on the network synchronisation. For this, we reproduce earlier analysis of FitzHugh-Nagumo neurons on a torus[4], using adaptive exponential integrate and fire neurons. This is a more complex and realistic neuron model [5] and it is implemented with the Nest simulator [6] After this, we analyze the dynamics of the whole-brain model, and we compare the simulated activity with experimental results, with a focus on different metrics of functional connectivity. This allows us to link the results at the brain activity levels to the spiking neural networks, and to validate the model by using functional data. Hence, the new modelling approach allows bridging from neural mass model to spiking neural networks and using the advantages of the macro- and meso-scopic scales.

Title: The Virtual Brain decodes molecular pathways by large-scale computational modeling in Alzheimer's disease

Authors: *L. STEFANOVSKI[1], P. TRIEBKORN[1], A. SPIEGLER[1], M.-A. DIAZ-CORTES[1,2], D. PERDIKIS[1], A. SOLODKIN[3], V. K. JIRSA[4], R. MCINTOSH[5], P. RITTER[1];

Sci., Toronto, ON, Canada

Abstract: In this work, we demonstrate how computational multi-scale brain modeling links phenomena of different scales in Alzheimer's Disease (AD) and therefore identifies potential disease mechanisms leading the way to improved diagnostics and treatment. The Virtual Brain (TVB; thevirtualbrain.org) neuroinformatics platform allows standardized large-scale structural connectivity-based simulations of whole brain dynamics. As a novelty, we connect chemical compounds measured with positron emission tomography (PET) with neural function in TVB addressing the phenomenon of hyperexcitability in AD related to the protein amyloid beta (Abeta). We construct personalized virtual brains based on individual PET derived distributions of Abeta in patients with mild cognitive impairment and Alzheimer's Disease and in age-matched healthy controls using data from ADNI-3 data base (http://adni.lni.usc.edu). In the personalized virtual brains, individual Abeta burden modulates regional inhibition, leading to disinhibition and hyperexcitation with high Abeta loads. We analyze simulated regional neural activity, electroencephalograms (EEG) and compute functional connectivity. Known empirical alterations of EEG in patients with AD compared to HCs were reproduced by simulations. The virtual AD group showed slower frequencies in simulated local field potentials and EEG compared to MCI and HC groups. The heterogeneity of the Abeta load is crucial for the virtual EEG slowing which is absent for control models with homogeneous Abeta distributions. Slowing phenomena primarily affect the network hubs, independent of the spatial distribution of Abeta. Modeling the N-methyl-D-aspartate (NMDA) receptor antagonism of memantine in local population models, reveals potential functional reversibility of the observed large-scale alterations (reflected by EEG slowing) in virtual AD brains. Finally, we use modern machine learning techniques to demonstrates the ability of TVB to decode the empirical data and improve the diagnostic process in a clinically relevant way. When using the simulated data in addition to state-of-the art empirical multimodal datasets for machine learning classification, TVB leads to a significant improvement of accuracy. Title: Music-induced emotions decoded by large-scale brain network modeling using the virtual brain

Authors: *J. COURTIOL[1,2], A. R. MCINTOSH[3,4], P. RITTER[1,2,5];
[1]Brain Simulation Section, Dept. of Neurol., Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Bernstein Ctr. for Computat. Neurosci., Berlin, Germany; [3]Baycrest Ctr., North York, ON, Canada; [4]Dept. of Psychology, Univ. of Toronto, Toronto, ON, Canada; [5]Berlin Inst. of Hlth., Berlin, Germany

Abstract: Emotions are increasingly considered as complex nonlinear large-scale cortical-subcortical brain networks rather than one circumscribed regions. A valuable tool for the investigation of emotions and their neural correlates is through the lens of music, which has the potential to induce and convey strong emotions over time. Although recent neuroimaging studies on music-induced emotions have revealed important insights into how emotions change brain functions, the neural mechanisms underlying the emotional brain are still largely unknown. To shed light from a dynamical system's perspective, we propose a large-scale brain network model of emotions invoked by music-listening using subject-specific connectomes derived from diffusion tensor imaging (DTI), subject-specific EEG data, together with time-varying subject-specific ratings of arousal and valence over the course of music to simulate the fMRI activity. Using the neuroinformatics platform The Virtual Brain, we systematically carry out parameter

space explorations, fit and validate the brain model against the subject's empirical fMRI images.This new framework may guide future research on emotional processing and the development of music-based therapies for the treatment of neurological and psychiatric disorders, including neurodegenerative disease such as Alzheimer's disease, associated with dysfunctions in emotion brain networks.

Title: Mechanisms of functional disconnection in AD: Explorations with TheVirtualBrain

Authors: *A. SOLODKIN[1], C. M. ANDREYKA[2], M. MAPSTONE[3], S. CHEN[2], A. R. MCINTOSH[4], P. RITTER[5], M. J. BREAKSPEAR[6], V. K. JIRSA[7];

Med. Berlin, Berlin, Germany; [6]Queensland Inst. of Med. Res., Herston, Australia; [7]Inst. De Neurosciences Des Systemes UMR1106, Marseille, France

Abstract: Objective:
TheVirtualBrain (TVB), is a multi-scale approach that uses empirical neuroimaging data to create brain's dynamic models cataloguing biophysical parameters producing empirical brain states. These biophysical parameters are invisible to brain imaging devices, thus TVB acts as a "computational microscope" that allows the inference of internal states and processes of the system. Using this unifying computational framework, this work focuses on the identification of basic mechanisms associated with changes in functional connectivity in aging and AD.
Methods:
We built dynamic network models of 77 subjects (16 AD, 35 aMCI and 16 cognitively normal (NC) and 10 cognitively supernormal (SNC)) using neuroimaging data from the Sydney Memory and Aging Study database (MAS). Each model was constrained by the individual's own large-scale 'connectome' derived from diffusion-weighted images. Models using the Stefanescu-Jirsa approach, focused on the systematic manipulation of the parameter "Global coupling (G)" to determine the value(s) associated with the simulation of regional oscillations in a 16-node limbic network. In addition, we determined the lowest value of G associated with oscillations (G

critical), the quality of oscillations and its association with the empirical rsfMRI.
Results:
Our results showed that: 1) G critical (Gc) differed among groups (from super normal to AD); 2) Compared to SNC, frequency of oscillations was higher in NC and aMCI and lower in AD; 3) brain dynamics in SNC and NC tended to operate at Gc but not in aMCI and AD; 4) G optimal (G value producing optimal simulations of rsfMRI) tended to be higher in aMCI and AD compared to healthy controls; 5) the larger G values showing oscillations correlated with stronger functional connectivity.
Interpretation:
The parameter Global coupling is a numerical correction that modifies globally, the gain of structural connections and can be thought as representing systemic effects of modulatory systems. In this context our results suggest a progressive decline on the efficiency of the system across groups (from SNC to AD) where NC and aMCI show an apparent compensatory behavior before the system shuts down in overt AD cases. These changes could be associated with deficiencies in adrenergic or cholinergic systems.
Our long-term goal with this work is by generating testable hypotheses, to develop multi-scale precision biomarkers with strong biophysical grounding that can serve as basis for personalized prognosis and/or therapeutic selection.

Title: Validation workflow of the region-specific models: Frequentist vs Bayesian methods

Authors: *H. E. WANG, M. HASHEMI, V. K. JIRSA;
Aix Marseille Univ, INSERM, INS, Inst. Neurosci Syst, Marseille, France

Abstract: Brain regions differ between each other with respect to cell types and distributions, receptors, neuromodulators, transcriptomes, synaptic densities, multiscale and nested connectomes as well as morphological gradients across the cortex. This variability translates into a dynamic repertoire of cell populations, microcircuits and networks, accessible via invasive and non- invasive brain imaging and physiological methods, for instance as expressed in the region-specific physiological patterns in iEEG. Now the scientists start to map the regional data features

upon the multiscale regions models to simulate the functional rhythms. In our study, we are interested in the functional validation of multiscale brain models against empirical data. We design the model validation workflow which outputs quantitatively the veracity of models (model evidence) and infer mechanisms underlying the emergence of the large repertoire of brain states (model inversion). To do so, we first design examples to benchmark the capability of two branches of parameter inference methods: frequentist and Bayesian approaches. Both frequentist and Bayesian methods are used for identification of the optimal parameters on the region-specific models. We use for frequentist approaches local search gradient-based methods (such as LBFGS algorithm) and global search gradient free (evolutionary algorithm from artificial intelligence); and for Bayesian methods, we use Markov Chain Monte Carlo both on gradient-free (such as Metropolis-Hasting algorithm) and gradient-based (such as Hamiltonian Monte-Carlo algorithm), as well as variational inference methods (such as Stein variational gradient scent and automatic variational inference). For systematic comparison of these approaches, we operationalize variation of priors in application to an instructive toy model composed of network nodes and low-dimensional dynamic systems. The priors are differently specified over the nodes based on the experimental anatomical and/or functional data. Using model evidence measured by different information criteria and the standard error metrices, we evaluate these methods on both synthetic datasets with defined ground truth and experimental datasets with their own data features. In this work, we demonstrate the trade-off between different used methods. We also show the conditions when the variational inference methods and MCMC converge to the similar results.

Title: Revealing the evolution of brain dynamics in response to emotional music using topological data analysis

Authors: M. SAGGAR[1], ***S. E. FABER**[2], S. SHAKIL[3], A. R. MCINTOSH[4];
[1]Psychiatry & Behavioral Sci., Stanford Univ., Palo Alto, CA; [2]Baycrest Hlth. Sci. Ctr., Toronto, ON, Canada; [3]Baycrest Hlth. Sci., Toronto, ON, Canada; [4]Baycrest Ctr., North York, ON, Canada

Abstract: Emotional responses to music are personal. Here, we estimated personal reactivity to music. Participants rated their response to music while we collected EEG. The goal was to map subjective experience with the manifolds of the EEG to uncover neurophysiological signatures of the evolving dynamics of emotional reactivity in response to music. Data were collected from 14 adults (5 males). Subjects completed a questionnaire of music listening habits and training, and the Barcelona Musical Reward Questionnaire (BMRQ). EEG data were acquired using a 76 channel BioSemi system and processed with BrainStorm. Forty excerpts (each approximately 40s) from Western art music from various eras were selected. As subjects listened to a piece, they moved a cursor across a rating map to indicate their level of arousal and valence.
To extract the shape or manifold of the evolution of neuronal dynamics in response to music, we applied the Topological Data Analysis (TDA) based Mapper algorithm (Saggar et al. 2018) on concatenated source-localized EEG data across all pieces for each individual. Each node in the Mapper-generated graph represents whole-brain cortical activity at one or more time points during the experiment. Nodes connected in the graph represent a high-degree of similarity between cortical activity at those time points. Mapper-derived shape graphs for each participant were annotated using the piece that the individual was listening to at each time point and the modularity of each graph was computed. High modularity indicates well-separated neurodynamical representation across compositions (Figure 1A-B). Graph modularity was positively related to BMRQ measures and musical habits/training. Our results suggest that participants who give higher importance to music show more segregated brain dynamics during music perception.

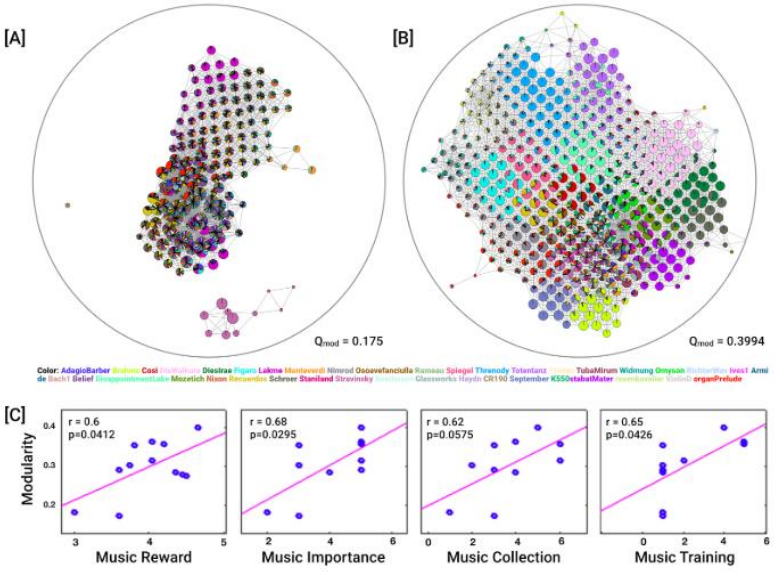

Figure 1: [A-B] Manifolds (or shape graphs) extracted from source-localized EEG data using TDA-based Mapper approach. The graphs are colored (annotated) by music-piece. Graphs from two participants are shown here - [A] participant with the lowest modularity and [B] with the highest modularity. [C]

Abstract: Central to this article is The Virtual Brain (TVB; thevirtualbrain.org) neuroinformatics platform. TVB allows standardized large-scale structural connectivity (SC)-based models for simulating whole brain dynamics. In a former study, we demonstrated how the systematic implementation of pathogenetic candidate mechanisms in TVB reveals their systems effects in human virtual brains (1). Here, we will demonstrate how individual models can explain mechanistically inter-subject variability of functional activity and cognitive performance and therefore can serve as mechanistic biomarkers. Using machine learning, we demonstrate the superiority of mechanistic model derived biomarkers compared to imaging derived markers for the classification of individual patients. For the Alzheimers Disease (AD) group simulations of brain models that were personalized using individual beta-amyloid PET data, yielded slower frequencies in neural activity and EEG, global graph theoretic disconnection and less efficient functional network structure compared to healthy controls (HC) and individuals with mild cognitive impairment (MCI). The combination of model-derived 'virtual' biomarkers with an empirical state-of-the-art multi-modal dataset (Abeta and Tau-PET, MRI volumetry) significantly outperformed the usage of empirical data alone. This effect was stable across a wide range of tested classification methods and corrections in feature space. Our results hold the potential to lead in future to clinically relevant benefits not only in the diagnosis of AD patients

but also for the identification of mechanistic targets for therapeutic interventions.

Title: Simulating large-scale cortical function and resulting behavior

Authors: *H. CHO[1], G. SCHALK[1,2,3];
[1]Natl. Ctr. for Adaptive Neurotechnologies, Wadsworth Ctr., New York State Dept. of Hlth., Albany, NY; [2]Dept. of Neurol., Albany Med. Col., Albany, NY; [3]Dept. of Biomed. Sci., State Univ. of New York, Albany, NY

Abstract: Neuroscience is often referred to as “data-rich, but theory-poor.” While there are useful biophysical models of individual or small groups of neurons, these models cannot readily explain the large-scale function of the brain or its resultant behavior. Some functional-anatomical models (such as the thalamo-cortical system producing movements) are useful for making general predictions about specific behaviors, but do not make specific predictions about the underlying neural signal dynamics. In our ongoing work, we seek to define general principles of brain function, to implement them in a simulator, and to use simulations of brain signal dynamics to infer behavior.
Our cortical simulator is based on five principles that govern signal dynamics and their translation into behavior: they are 1) excitatory and rhythmic inhibitory input to the cortex; 2)

phase selectivity of cortical output; 3) task-relevant pre-stimulus alpha suppression; 4) event-related de-/synchronization; and 5) propagation delay between cortices. We validated our cortical simulator by comparing its output to behavioral results presented in the literature. Specifically, we implement simple auditory and visual reaction-time tasks within our cortical simulator. To do this, we modeled task-related cortical networks using a series of cortical patches, each of which implemented the same five principles described above. Using this simulation, we replicated the well-described effects of alpha power, phase, and frequency on cortical excitability and behavior; and the effects of stimulus intensity, duration, contrast, modality and congruency on behavior. We varied these parameters and used the cortical simulator to infer the neural signal dynamics at each cortical node as well as the resultant behavioral output.
The results show that, despite its current simplicity, the output of our cortical simulator is in substantial congruence to physiological and behavioral results of studies that investigated similar stimulus-response tasks. Specifically, alpha power and phase reduced cortical excitability and behavioral response rate, whereas higher intensity/contrast, congruent and multi-modal stimuli decreased reaction time and increased response rate. In summary, the results of our ongoing study show that five simple and general principles of cortical function can accurately model a variety of brain signal dynamics and different behaviors.

Title: Short latency (~100 ms) markerless video tracking of body parts in mice using deep neural networks

Authors: *B. J. FORYS, D. XIAO, P. GUPTA, J. D. BOYD, T. H. MURPHY;
Dept. of Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Real-time, markerless tracking of animal movement would open up the possibility of manipulating motor feedback, allowing detailed explorations of the neural basis for behavioral control. However, there is currently no robust real-time tracking system that allows for tracking of specific body part movement (as opposed to whole-body movement) based on one's own datasets. To address this need, we present a method that leverages DeepLabCut (Mathis et al.,

2018) - a robust yet flexible movement-tracking framework - for real-time tracking of body part movements in mice. To demonstrate our method's real-world efficacy, we present DeepCutRealTime. We stream footage of a head-fixed mouse to a computer running DeepLabCut, which estimates the pose and location of the mouse's paws in each frame. To test the response latency of the system, we then use GPIO to trigger an LED when the mouse's running movements exceed a pre-defined threshold. Across all of our trials (n = 37) with n = 3 male mice (who were between 2-4 months of age), we found that our system can track movement at a frame rate of M = 30.30 Hz, SD = 0.53 Hz, with a mean time delay between movement initiation and the LED flash of M = 93.44 ms, SD = 8.79 ms. These results represent critical progress towards building a real-time tracking framework for individual body parts that can provide feedback to the subject based on analysis of this movement. Our exploratory study suggests a robust yet easy-to-implement method for real-time movement tracking that can be easily integrated with other methods such as optogenetic stimulation and wide-field brain imaging, allowing us to better understand the links between cognition and action at a more granular level than before. This real-time movement tracking framework could also be used to provide closed-loop feedback directly to the brain based on specific behaviours.

Title: Why does ICA-decomposed EEG sometimes show deep dipoles?

Authors: *M. M. MIYAKOSHI[1], S. MAKEIG[2];
[1]Swartz Ctr. For Computat. Neuroscience, INC, UCSD, La Jolla, CA; [2]Inst. of Neural Computation, UCSD/INC/SCCN, La Jolla, CA

Abstract: Independent component (IC) analysis (ICA) has been used for scalp-recorded EEG preprocessings. For IC source localization, a common practice is to fit a single equivalent current dipole to IC scalp maps. A problem of deep dipoles has been known; dipoles are localized deeper than cortices, which is physiologically implausible. Interestingly, the deep dipoles usually show well-defined event-related potential (ERP). We hypothesized that these deep dipoles have a systematic cause that has not been investigated yet. The alternative hypothesis is that the deep dipoles are noise due to localization errors. To investigate this issue, we performed a study. The 32-ch EEG data recorded from 24 healthy young adults during visual discrimination task (faces and objects) with 600-700 trials were used (all conditions merged). Offline, the EEG data were

preprocessed using EEGLAB to filter the data, artifact rejection using artifact subspace reconstruction, ICA, and dipole fitting using Fieldtrip functions. In doing so, 1) the default EEGLAB's unit system was changed from A to nA (x10^9) and from mm to m (x10^-3) to calculate dipole moment, for which peak amplitudes of the absolute ERP (0 to 1 sec window) of each IC was calculated to be multiplied with the IC scalp maps, then 2) EEGLAB plugin ICLabel was used to identify brain components (criterion > 0.70); 3) probabilistic anatomical labels were assigned using Talailach daemon (confusion sphere 20 mm) to classify ICs into three classes; basal/limbic, cortical, and outside the brain (criterion > 0.50). The outside-the-brain ICs were excluded; 4) The brain ICs were compared between cortical vs. basal/limbic groups for dipole moments and equivalent patch size that was computed by using estimate of 100 nAm per 4 cm^2. The results showed that 249 ICs were identified to be cortical and 21 ICs basal/limbic, the latter were contributed by 17/24 participants. The mean dipole moments were 196 (312) vs. 26 (31) nAm, and the mean equivalent patch sizes 7.8 (12.5) vs. 1.1 (1.3) cm^2 for basal/limbic and cortical ICs, respectively. As typical dipole moment for averaged sensory evoked response being about 100 nAm, and the estimated minimum active patch size to produce scalp-measureable single-trial EEG being 6.5 cm^2, the obtained values are confirmed to be in a valid range. We concluded that there is clear tendency of the deep dipoles toward larger dipole moment/patch size, indicating systematic influence rather than random process. Moreover, this tendency was also found in the cortical ICs. We speculate that ICA may identify a temporally independent synchronous patches that are much larger than we have conventionally thought.

Title: State space oscillator models with priors on frequency

Authors: *A. M. BECK[1], H. SOULAT[2], E. P. STEPHEN[2], P. L. PURDON[3];
[1]Electrical Engin. and Computer Sci., [2]MIT, Cambridge, MA; [3]Anesthesia, Critical Care, and Pain Mgmt., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Oscillatory neuronal activity reflects the functional coupling of brain networks and can be measured with local field potentials, or in the aggregate at the scalp with electroencephalogram (EEG). Many well-established oscillatory patterns have been characterized in response to tasks or states of arousal. These patterns are often composed of multiple oscillations, such as slow waves and spindles during sleep, slow oscillations and alpha waves during anesthesia, or harmonic series representing nonlinear oscillations such as mu-rhythms. In some scenarios, the data analysis problem focuses on determining whether or not an oscillation is present; in others, the problem focuses on separating component oscillations so that their distinct features or interactions may be studied, revealing new information (Cole & Voytek Cell 2017).

State space models have been developed to identify oscillations with varying frequencies and estimate their instantaneous phase (Matsuda & Komaki Neural Comp. Feb 2017). These models significantly improve the estimation of the oscillatory signals, and may provide a means to distinguish oscillations from broadband "1/f" noise (Beck et al. IEEE EMBC 2018). A major advantage of this approach is that inferences about underlying oscillations or waveforms can be made based on model parameters estimated from the data with the expectation maximization algorithm. However, this parameter estimation is also one of the most challenging aspects of this approach. Models with multiple oscillations may not always converge, particularly in low signal-to-noise scenarios, and are highly dependent upon parameter initialization. We will describe novel methods for parameter estimation in state space oscillatory models and apply model selection procedures to help identify the presence or absence of oscillations, including the contribution of nonlinear terms. We follow an empirical Bayes approach and define prior probability distributions on the state space model parameters, and evaluate methods of model selection to account for the large number of estimated states. These improvements increase the accuracy of the model and signal estimates, while maintaining a simple initialization procedure to enable practical application in neuroscience data analysis.

Title: Feasibility study on super resolution using deep convolutional neural networks; auditory ERP data

Authors: *M. KWON, S. C. JUN;
Sch. of Electrical Engin. and Computer Sci., Gwangju Inst. of Sci. and Technol., Gwangju, Korea, Republic of

Abstract: Super-resolution (SR) is a technique that enhances data quality from low-resolution (LR) to high-resolution (HR) with data-driven approach in image processing, which requires to solve underdetermined inverse problems. Recently, deep convolutional neural network (CNN) has been applied to develop SR-techniques. Also, audio processing has applied SR-techniques to increase sampling rate of audio signals. In a conceptual manner, we may adopt them to improve EEG spatial resolution. EEG has relatively high temporal resolutions that is easy to do real-time monitoring, however, it has poor spatial resolution of a few fractions of centimeter. Poor spatial resolution may yield incorrect source localization, thus high-density EEG system is required at a quite tremendous expense. For comfortability and efficiency of EEG system, it is necessary to measure brain activity with as small number of sensors, keeping high quality signals. Therefore, we proposed CNN model to enhance the spatial resolutions from LR to HR using auditory evoked potential (AEP) EEG data.
EEG data was collected from 64 channels for brain activity. Beep sound was given to subject for each trial. A total of 1,000 trials were done and inter-stimulus-interval was randomly between 1,000 and 1,500 ms. The data was band-pass filtered with 1 - 50 Hz; noise components and bad trials were rejected. After preprocessing, we generated low resolution data as choosing 32 (2x), 16 (4x), 8 (8x), 4 (16x) channels. Remaining channels were interpolated with neighboring sensors. Our proposed CNN model are similar to autoencoder; He initializer, Adam optimizer and linear activation function was used. We used 80 % of trials for training and 20 % of trials for testing.
SR data estimated by CNN showed the clear ERP patterns for all kinds of up-sampling rates (2x, 4x, 8x, 16x) and almost channels; N1, P2 amplitudes resembled HR patterns more than LR patterns on cento-parietal channels, which are representative channels of ERP signal. However, latencies of N1, P2 were not that significantly different for SR, HR, and LR. Frontal lobe with

many noisy components and temporal lobe containing high frequency signal yielded higher errors in SR than those in LR. In source imaging, even original data (HR) showed two sources on right/left temporal regions, LR data yielded the incorrectly located source on left hemisphere, while SR data likely yielded sources correctly located.
Our proposed deep neural networks come up with a possibility for improving EEG spatial resolutions from even far small number of sensors.

Title: Forward and inverse modeling between local field potential and intracranial macroelectrodes for neuroprosthetic applications

Authors: *Y.-J. CHANG[1], J. M. CARMENA[3,4], S. R. SANTACRUZ[1,2];
[1]Biomed. Engin., [2]Inst. for Neurosci., Univ. of Texas at Austin, Austin, TX; [3]Electrical Engin. & Computer Sci., [4]Helen Wills Neurosci. Inst., Univ. of California at Berkeley, Berkeley, CA

Abstract: Local field potential (LFP) is pre-synaptic activity of hundreds of neurons typically recorded using microelectrodes, and is a signal type commonly used for both neuroscientific studies and therapeutic applications. Although this signal is rich and has high signal-to-noise ratio (SNR), it requires the most invasive method of acquiring neural activity. In this work, we consider how LFP data can be estimated using signals recorded from intracranial macroelectrodes (ICME). Both LFP and ICME signals are recorded simultaneously in awake behaving rhesus macaques. LFP data is recorded from one hemisphere, whereas ICME signals are acquired across both hemispheres. We develop an ICME / LFP inverse model to investigate the signal translation between these two measurements. NonLinear Principal Component Analysis (NLPCA) is employed to reduce the complexity of computation. The forward model is then derived from an electro-physiological perspective to capture the dynamics of the neural signals. To represent nonlinear approximations, a NeuroBondGraph (NBG) approach is introduced to model both the system dynamics and nonlinearities in a more efficient way. The inverse solution is then established by integrating with the de-mapping part of NLPCA. Here we demonstrate the applicability of this technique to the experimental data, and address both accuracy and stability of the inverse models used to estimate LFP from ICME recorded data. The

inverse solution produced with this methodology could significantly improve the performance of LFP-based closed-loop neuroprosthetic applications without increasing the LFP channel count.

Abstract: The Neurodata Without Borders: Neurophysiology (NWB:N) data standard provides neuroscientists with a common standard to share, archive, use, and analyze neurophysiology data. NWB:N supports a large range of neurophysiology data, including from intracellular and extracellular electrophysiology and optical physiology experiments, as well as tracking and stimulus data. The NWB:N data standard is defined via a formal specification language and organizes data in a modular collection of neurodata types that can be reused via inheritance and composition. This approach allows users to create extensions to NWB:N in a formal and backward compatible way. Extension are central to enabling the neurophysiology community to adopt and curate NWB:N, support the integration of new data types and use cases, and definition of canonical data organizations for data analysis and management.
We present the Neuro Data Extensions Catalog (NDXC), a novel online resource for sharing, deploying, and validating NWB:N extensions. NDXC provides a web-archive and associated tools to enable users to easily create, search, review, access, and install extensions. NDXC enables the neurophysiology community to share and maintain extensions, curate NWB:N, and collaborate to create new standards for emerging use cases. As part of the NDXC, we are also developing a formal review process for inclusion of extensions into the core NWB:N format so that NWB:N can adapt to the evolving neuroscience needs.
We demonstrate the application of extensions in practice for integrating new data types and interfacing with data analysis and management tools. We present the simulation output extension

to support storage of continuous data from compartments of simulated cells and compartment metadata. Another key application of extensions is to define a rigid organization of neurodata types and refinement of required fields for standardized experiments, analysis pipelines, and tools. We demonstrate the application of extensions to standardize the organization of experiments and for integration of NWB:N with analysis tools (e.g, Brainstorm).

Title: Implementing evolutionary optimization to model resting state functional connectivity

Authors: K. MAILE[1], R. MIIKKULAINEN[1], ***M. SAGGAR**[2];
[1]Computer Sci., Univ. of Texas at Austin, Austin, TX; [2]Psychiatry & Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: Computational models are crucial in understanding brain function. One particularly interested class of models is designed to replicate known brain structures using structural connectivity (SC) measured with diffusion spectrum imaging, and the behavior that emerges is then compared to empirical functional connectivity (FC), measured using functional magnetic resonance imaging. As the models become more accurate and more complex with more parameters, they can explain more of the observed phenomena, and may eventually be used for diagnosis and design of treatments of brain disorders. However, those parameters need to be carefully optimized for the models to work best, which becomes intractable to do manually or with traditional computational techniques like gradient descent as the models grow. Evolutionary computation techniques use adaptation over generations in nature as inspiration to optimize functions that are otherwise difficult and have succeeded in solving optimizations in similarly difficult search spaces (Miikkulainen, 2019). In this work, the Covariance Matrix Adaptation Evolutionary Strategy (CMA-ES) was configured to optimize continuous parameters of a large-scale biophysical network model that stimulates neural activity from structural connectivity of 66 cortical parcellations and computes FC (Deco et al., 2013). Empirical SC and FC data were collected and aggregated from 24 right-handed healthy young volunteers (Deco et al., 2013). The

application of CMA-ES on this data resulted in a significantly better fit to empirical FC data than manually selected parameters in all four trials run of the CMA-ES algorithm so far. The best parameter set from the best trial run generates a functional connectivity matrix with a correlation of 0.5205 +- 0.0102 with empirical FC, compared to the previous best set of manually selected parameters that yield a correlation of 0.4647 +- 0.0114. This work provides a basis for utilizing evolutionary computation to optimize neural activity models. Statistically significant improvement has already been achieved with a relatively simple approach. To further increase the optimization potential, this approach will be combined with other evolutionary computation techniques to optimize other parameters, and these techniques will be scaled up to more detailed and patient-specific SC and FC data and more complex computational models. Optimizing neural activity models will further our understanding of the human brain and bring the field of neurology closer to personalized medicine.

Title: The neuroscience gateway: Enabling large scale modeling and data processing in neuroscience on supercomputers

Authors: *A. M. MAJUMDAR[1], S. SIVAGNANAM[2], K. YOSHIMOTO[1], N. T. CARNEVALE[3];
[1]Univ. of California San Diego, La Jolla, CA; [2]San Diego Supercomputer Ctr., UCSD, La Jolla, CA; [3]Neurosci., Yale Univ. Sch. Med., New Haven, CT

Abstract: We review the origin and evolution of the Neuroscience Gateway (NSG; http://www.nsgportal.org) providing access to high performance computing (HPC) resources for neuroscientists. When it first becameavailable to users in 2013, NSG's design goal was to provide neuroscientists free and easy access to simulation software installed on HPC hardware for their increasingly complex models of biological neurons, neural circuits, and systems. More recently we have expanded it to also serve cognitive and experimental neuroscientists facing

large scale data analysis problems (e.g. fMRI processing, connectome pipelines). It is also being used for educational purposes in neuroscience courses and workshops. The diverse and growing set of modeling and data analysis tools currently available via NSG includes BluePyOpt (from the European Human Brain Project), Brian,CARLsim, DynaSim, EEGLAB, Freesurfer, Human Neocortical Neurosolver (HNN), Large Scale Neural Modeling Simulator, MATLAB, MOOSE, NEST, NetPyNE, NEURON, Octave, PGENESIS, PyNN, Python, R, TensorFlow, and The Virtual Brain Personalized Multimodal Connectome Pipeline.These can be accessed either through a web portal or programmatically through a RESTful API. NSG allows a wide range of use cases: individual users with NSG accounts can work directly with individual tools, or with packaged pipelines, or configure their own pipelines; users of communityprojects that take advantage of NSG's RESTful API (e.g. OpenSourceBrain) can employ HPC resources via NSG without having to leave their familiar working environment or even obtain their own NSG accounts; software developers can use NSG for dissemination of their projects, e.g. BluePyOpt, CARLSim, DynaSim, EEGLAB, HNN. NSG is being used by neuroscienceresearchers, educators, and students at institutions and laboratories around the world, and its user base is currently is about 900 and still growing. Based on increasing demand and usage, we have successfully obtained progressively larger allocations of HPC resources through the competitivepeer review process of the Extreme Science and Engineering Discovery Environment (XSEDE) program. Developing and operating the NSG has given us a unique opportunity to understand the diverse HPC needs of neuroscientists and explore associated issues and needs forcollaboration, data sharing/management and various forms of computing. Supported by NSF 1458840 (SS, KY, AM), NIH #1R01EB023297-01A1 (SS, KY, AM) and NSF 1458495 (NTC).

Abstract: The simulation of biological neural networks (BNN) is essential to neuroscience. The complexity of the brain's structure and activity combined with the practical limits of in-vivo measurements have led to the development of computational models which allow us to decompose, analyze and understand its elements and their interactions.
Impressive progress has recently been made in non-spiking but brain-like learning capabilities in ANNs [1, 3]. A substantial part of this progress arises from computing-intense learning-to-learn (L2L) [2, 4, 5] or meta-learning methods. L2L is a specific algorithm for acquiring constraints to improve learning performance. L2L can be decomposed into an optimizee program (such as a Kalman filter) which learns specific tasks and an optimizer algorithm which searches for generalized hyperparameters for the optimizee. The optimizer learns to improve the optimizee's performance over distinct tasks as measured by a fitness function (Fig 1).
We have developed an implementation of L2L on High Performance Computing (HPC) [6] for hyperparameter optimization of spiking BNNs as well as hyperparameter search for general neuroscientific analytics. This tool takes advantage of large-scale parallelization by deploying an ensemble of optimizees to understand and analyze mathematical models of BNNs. Improved performance for structural plasticity has been found in NEST simulations comparing several techniques including gradient descent, cross entropy, and evolutionary strategies.

Abstract: Advances in neuro-engineering have opened up new avenues for ‘electroceuticals’ devices that affect organ function through neuromodulation. The NIH SPARC initiative was established to “transform the understanding of nerve-organ interactions” and “advance the neuromodulation field towards precise disease treatment”. A key component of SPARC is a freely accessible online platform (o^2S^2PARC) to support modeling-related activities. o^2S^2PARC is designed to allow studying the interaction of physical stimuli with the human body and its physiology via multi-physics/-scale simulations. It is an open-source framework to create, host, connect, and execute computational models, as well as solvers for anatomical model-centred multi-physics simulations. At the core of o^2S^2PARC are detailed, human and animal models, which are functionalized with dynamic nerve models and serve as integration centres for

computational (tissue/organs/⋯) models and measurement data and as context for physical modeling. Multiple o^2S^2PARC prototypes (front/back-end, communication, and compute services) were realized to compare technologies and identify pitfalls. A full-stack system production-version of the platform has been implemented and deployed in the cloud. It involves a (i) front-end built on the qooxdoo framework, (ii) Python-based web-server, (iii) scalable network of computational services deployed inside Dockers, (iv) director to orchestrate the services/interact with the web server. Critical solvers (e.g., for coupled electromagnetic-neuronal dynamics modeling) were developed, validated, and successfully applied to study a range of therapeutic applications. Anatomical phantoms were extensively functionalized with peripheral nerves based on high-resolution cryosection images these nerve trajectories are associated with dynamic electrophysiology models (sensory/motor MRG models). Selected models from SPARC teams (cardiac physiology & regulation, compound action potential prediction, enteric nervous system) can now be executed within containerized services. The evaluated technologies demonstrate that the ambitious vision of o^2S^2PARC is feasible. It is an important contribution towards open and extendable simulation platforms for electroceuticals/ neuroprosthetics research.

Title: Scientific validation of data-driven neuroscience models despite complexity and sparse data

Authors: P. E. GARCIA-RODRIGUEZ, L. SHARMA, S. APPUKUTTAN, *A. P. DAVISON;
ICN, Paris-Saclay Inst. of Neurosci., Ctr. Nationale De La Recherche Scientifique (CNRS), Gif sur Yvette, France

Abstract: Computational simulations are a valuable tool to gain insight into brain function, from the sub-cellular to the network scale. However, before a model can be used in research or medical applications, an assessment of its performance is required, including a validation with respect to experimental data. Validating a model concerns its generalization/predictive power, i.e. its ability to replicate observations obtained in experimental scenarios other than those used in constructing the model. To that end, a prediction error can be calculated to quantify the model's performance by the match between model prediction and experimental observation. Model validation implies scientific challenges such as intensive data searching or meta-analysis, reconciling conflicting findings, and deciding the weighting of different validations. The application of traditional statistical hypothesis testing, to judge the relevance of the discrepancy between experiment and model, requires the specification of a probability distribution for the reference data. However, many studies report too few observations to accurately determine the statistical description needed. Such sparse experimental data also presents a serious handicap to accurately estimate prediction errors using bootstrap or cross-validation methods.
An alternative to hypothesis testing in model assessment is model selection, where different alternatives are compared to choose the most appropriate model. Models often differ in terms of complexity, and prediction errors are known to follow a non-monotonic curve, showing a minimum at intermediate complexity (Hastie et al. 2001). This behavior is related to the bias-variance trade off and the well known under- and over-fitting compromise. It is caused by the opposite trends of these two quantities that determine the prediction error. Finally, each model can be assigned a score defined as the relative prediction error with respect to the uncertainty level present in the data and in the model.
We are attempting to address the above challenges by developing test suites that automate comparison between different models, and allow tracking the performance of a model over time as it is refined. In these test suites, model and test definitions use the SciUnit interface (Gerkin & Omar, 2014), which supports model-agnostic validation suites by decoupling test and models. MorphoUnit is for validating morphologically-detailed cell models according to neurite features. eFELUnit is designed to validate the biophysical behavior of single cell models. BasalUnit and CerebUnit provide validation tests specific to the basal ganglia and cerebellum respectively.

Abstract: In general, since both mechanisms of the generating observation signals and neural activities are complex, and computational modeling is essential to understand brain activities. To overcome these difficulties, recently, we developed an analytical scheme of electrophysiology data of the voltage sensitive dye imaging (VSDI) and calcium imaging (CaI) adopting the dynamic causal modeling (DCM) method. In the present study, we present a novel analytical scheme for the multimodal electrorheology data analysis, named multimodal electrophysiology data. We connected VSDI-DCM and CaI-DCM scheme by sharing the neural activity, and named it multimodal electrophysiological data-DCM (med-DCM). Since the CaI signals are usually recorded with high-spatial and low-temporal resolutions, and the VSDI with shows low-spatial and high-temporal resolutions, in the med-DCM modeling, we utilized these signals to extract neural state parameters properly.
To describe both of CaI and VSDI signals, we construct a hierarchical neural state model. Specifically, in the CaI data analysis, neural state model directly converted to the CaI signals. However, the VSDI signals from one region were estimated from multiple neural populations. Thus, spatially a region of the VSDI model can contain multiple regions of the CaI model. We optimized the DCM parameters in three steps. Firstly, DCM parameters were estimated for the CaI signals which give us high spatial information. Secondly, the parameters were fitted for the VSDI signals which contain better temporal information. Then, finally, we optimized all DCM parameters simultaneously for both signals.
In the present study, to validate the novel system, we simulated multimodal data of the CaI and VSDI based on the DCM results of the hippocampus VSDI signals. Our results suggested that the multimodal data can increase the accuracy of the model inference, and provide an entire analytic scheme for the multimodal mesoscale electrophysiological data with DCM. The present multimodal data analytic scheme could be extended and applied to the various mesoscale electrophysiological data. We also developed graphic user interfaces for these simulations and model inference calculations.

Abstract: The current practice of spectral analysis of spike data involves direct application of the Fourier transform to the data, which is problematic for two reasons: 1) The binary nature of the data makes the spectral content diffuse across all frequencies, and 2) the spectral estimates overfit the data and often are not interpretable. We introduce a model-based framework for spectral analysis of binary data, where a latent harmonic process is assumed to be driving the spikes. We cast the latent process estimation problem within an Empirical Bayes framework, in which the posterior distribution of the states given the spikes is maximized. Specifically, we use a group sparsity prior which emphasizes the dominant oscillatory components and simultaneously tracks the temporal dynamics within these components. To this end, we develop a statistical and computational approach rooted in Minorization-Maximization (MM) algorithm and Kalman filter/smoother, that is more efficient than existing model-based approaches [1]. We apply the framework to data collected from electrocorticography (ECoG) of human patients under propofol general anesthesia, and for which the slow oscillation (0.1~0.5Hz) is believed to strongly modulate the ensemble of spikes [2]. The algorithm successfully identifies the slow frequency bands as the dominant process modulating the spikes when the patient is unconscious. Furthermore, it is able to detect the change point of the underlying brain states when the patient loses consciousness, in an unsupervised manner. Overall, this framework offers a principled approach for analyzing the dominant oscillatory content of the binary data, capable of tracking the dynamics over the duration of the entire recording.

Title: Evaluating spectral estimation methods for time-resolved measurement of aperiodic activity

Authors: *T. FARNAN, T. DONOGHUE, B. VOYTEK;
Cognitive Sci., UC San Diego, La Jolla, CA

Abstract: Electrophysiological neural time series, when considered as frequency representations, exhibit both periodic (oscillatory) components, as well as an aperiodic, 1/f-like, component wherein power exponentially decreases as frequency increases. This aperiodic component can be measured as $1/f^{\chi}$, whereby the χ value is equivalent to the slope of the power spectrum in log-log space.Prior work measuring aperiodic activity in neural time series has shown that it is a dynamic property. Aperiodic activity “flattens” with age, is a robust marker of sleep-wake or anesthetization status, and can vary in a trial-by-trial manner with cognitive and perceptual demands. Past measurements of aperiodic activity have relied on relatively long time windows, with coarse temporal resolution. However, short-time, sliding-window Fourier analyses—and other similar approaches—should permit a time-resolved aperiodic analysis. In this project, we extend a previously described method for parameterizing neural power spectra, which estimates both periodic and aperiodic components from frequency representations of neural data (Haller et al, 2018). Using this method, we examine short-time, sliding window analyses and develop a procedure for accurate, time-resolved aperiodic estimates. Our experiments use simulated neural time series that are either statistically representative or real electrophysiology. This allows us to simulate a range of dynamic variations in both aperiodic and periodic components. Given these ground truth neural time series, we implement existing spectral estimation methods to generate a suite of power spectra that represent frequency content across time. Specifically, we explore short-time Fourier transforms, wavelet transforms, and multi-taper approaches and assess their performance across a range of settings. We then evaluate the accuracy of our method’s aperiodic property reconstruction by stepping across the suite of generated spectra, internal method settings, and additional processing steps such as spectral smoothing. We report a comprehensive analysis on these time-resolved power spectra estimation procedures and provide benchmarks for ideal approaches given different constraints of the data, such as sampling rate, recording modality, and fitting range. Finally, we demonstrate these

approaches on a series of real datasets of local field potential (LFP) and electrocorticography (ECoG) data, and show how aperiodic properties change over time in real data.

Title: Statistical accuracy of fMRI retinotopic mapping in patients with altered neurovascular function: Sequential vs random stimulus presentation

Authors: *G. PATIL[1], C. L. SCHNEIDER[2,4,5], B. SAHIN[6], B. Z. MAHON[4,6,3,7];
[2]Brain and Cognitive Sci., [3]Ctr. for Visual Sci., [1]Univ. of Rochester, Rochester, NY;

Abstract: Functional Magnetic Resonance Imaging (fMRI) measures neural activity indirectly by monitoring local changes in blood oxygenation and blood flow. Researchers have used fMRI to understand the role of neuroplasticity in functional recovery after brain injury; however, the altered patterns of cerebral blood flow that occur, for instance, in stroke patients, may affect the analysis and interpretation of fMRI data. We hypothesized that a random presentation sequence will lead to less systematic bias in the fMRI analysis than a sequential (or stereotyped) presentation sequence when the hemodynamic response is delayed. We used computational modeling to determine how the accuracy and precision of retinotopic mapping is affected by altered hemodynamic responses for both general linear modeling (GLM) and population receptive field mapping (pRF). Hemodynamic response functions (HRFs) for both analyses were modeled using a 2-gamma function with a time-to- peak (TTP) varying between -3 and 9 repetition times (TRs) from stimulus onset. We found that the GLM analysis was more robust to an altered hemodynamic response when the stimuli were presented in a random sequence rather than an ordered sequence. Sequential stimulus presentation sequences led to systematic errors that were not present with a random presentation sequence. There were, however, limitations to the random presentation sequence: if the TTP was delayed by greater than +/- 1 TR the sensitivity and specificity of the analysis greatly deteriorated (window of resilience = +/- 1 TR). Prolonging the stimulus duration to 10 TRs led to no difference in accuracy between the ordered and random presentation sequence and the window of resilience increased to -3/+5 TRs for both presentation paradigms. The pRF results showed that the window of resilience was no different between sequential and randomized data: +/- 1 TR for polar angle and 0 TRs for both eccentricity and receptive field size. These results highlight the importance of tailoring

experimental designs to altered hemodynamic responses, and point to the need for subject- and voxel-specific hemodynamic response functions when analyzing fMRI data in patient populations with neurovascular abnormalities.

Title: Cyclicity vs. similarity measures for fMRI resting state time series analysis

Authors: I. T. ABRAHAM[1], S. SHAHSAVARANI[3], B. ZIMMERMAN[4], Y. M. BARYSHNIKOV[1], *F. T. HUSAIN[2];
[1]ECE, [2]Neuroscience, Speech and Hearing Sci., Univ. of Illinois at Urbana-Champaign, Champaign, IL; [4]Neurosci. Program, [3]Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: The present study is a comparison of novel type of analysis based on cyclicity with traditional fMRI resting state functional connectivity measures. Cyclicity analysis captures pairwise relations between multiple time series by generating translation and reparametrization invariant features amenable to matrix analysis methods. The resting state fMRI time series demonstrate cyclic patterns that may not be periodic, indicating an underlying self-sustained cycling among processes in different regions of the brain. Such cyclic interactions remain indiscernible to correlation-based methods, which formulate functional interactivity by measuring the similarity among time series. Contrary to correlation-based features, those generated by cyclicity analysis can provide information germane to the cyclic ordering among time series, as a measure of functional interactivity. In this study, we compared the stability and robustness of cyclicity analysis with (1) zero-lag correlation, (2) lagged cross-correlation, and (3) dynamic time warping analyses. To do so, we obtained and analyzed fMRI data from patients with tinnitus (N=49) and healthy controls (N=29) in two visits held one week apart, using a 3T Siemens Prisma magnet. The dataset consisted of four 10-minute resting state EPI scans per subject. Both cyclicity and correlation-based analyses resulted in more stable feature matrices across two scan visits compared with dynamic time warping analysis in patients and controls.

However, the degree of this stability depends on preprocessing choices including global signal regression and filtering specifications. In general, global signal regression was in favor of cyclicity and correlation-based analyses. Whereas filtering was detrimental to cyclicity analysis, it increased the stability of correlation-based analyses. Dynamic time warping analysis, while more robust to the choice of preprocessing steps, was found it to be less stable over the week. No single analysis method was found to have distinct advantage in classifying patient and control populations when used in traditional techniques such as discriminant analyses and support vector machines. Due to the fact that cyclicity and correlation methods capture different aspects of functional interactivity, current efforts are targeted towards on developing methods accounting for both cyclic ordering and similarity between time series. Future work will investigate dynamic functional interactivity focusing on these features as they evolve through the duration of the scan.

Title: A new method for large-scale neuronal simulation

Authors: N. WANG[1], *D. B. FORGER[2];
[1]Univ. of Michigan, Ann Arbor, MI; [2]Mathematics, Bioinformatics and Data Sci., Univ. of Michigan, Ann Arbor, MI

Abstract: With many large-scale datasets being collected, much recent effort has focused on developing computational tools which can simulate large regions of the brain. In addition to a large number of neurons, other complications in developing these tools include accurately representing the synaptic, paracrine or other signaling that occurs between neurons, and accounting for the fact that neurons are intrinsically noisy. A common approach to these problems is to use neural mass models, which treat neurons probabilistically. However, these models are based on a mean-field approximation of population density and a one-or-two-dimension simplification of neuron dynamics such as the Theta model. Consequently, these methods do not allow detailed dynamics for neurons at the level of individual ionic conductance. An alternative approach is simulating a network of individual noisy neurons. But such a

simulation for a large brain region is computationally intensive. Here, we present a numerical scheme, based on a novel asymmetric particle method, for simulating coupled noisy neuronal populations with a detailed (Hodgkin-Huxley type) description of ionic channel conductances. We find very accurate agreement with a direct simulation of neuronal networks over a range of noise and coupling levels, which is achieved at a fraction of the computational cost. Our method is versatile in that it can be easily applied to other Hodgkin-Huxley type models with minimal modification. This technique could lead to new computational approaches that can be integrated with the new large-scale neuronal datasets currently being collected.

Title: Discovery of dynamic functional connectivity of cortical networks by learning fast correlation sequences in large-scale neural activity data

Authors: *C. GRABER, *R. LOH, Y. VLASOV, A. SCHWING;
Univ. of Illinois, Urbana, IL

Abstract: What can we learn about the functional organization of cortical microcircuits from large-scale recordings of neural activity? Most of the current efforts are focused on decoding multidimensional manifolds by various implicit methods [1-4] of dimensionality reduction to reconstruct the behavior. A key component, however, to furthering our understanding of organization of cortical networks is the ability to extract time-dependent functional connectivity and to establish the dynamics of the cortical information flow. To obtain interpretable results for neural activity dynamics, we develop a method which explicitly models correlations across space and time between all recorded neurons in the network. This approach is based on Neural Relational Inference [5], a variational autoencoder-based model where the latent variables represent connections between output variables, i.e. dynamics of neurons spiking. This approach not only explicitly models the functional connections between neurons, but also capture the dynamics of their change over time. Furthermore, this formulation allows for the use of arbitrarily expressive models, unlike previous approaches such as [2] which are restricted to generalized linear models. We experiment on neural spiking data obtained from the primary somatosensory cortex of a mouse while performing a whisker-guided navigation task. On this data, we show that our approach not only performs well in reconstruction, but also explicitly models the connections between neurons across cortical layers in the barrel cortex and how they change during various phases of experimental trials. Correlation of dynamic network

connectivity with whisker-guided navigation behavior can shed light on specific dynamic organization of columnar microcircuits and reveal stages of tactile information flow during perceptual decision making. Title: Multilevel principal component regression for brain imaging

Authors: ***B. PETRE**[1], C.-W. WOO[2], E. LOSIN[3], H. EISENBARTH[4], T. D. WAGER[5]; [1]Univ. of Colorado Boulder, Boulder, CO; [2]Ctr. for Neurosci. Imaging Res., Sungkyunkwan Univ., Suwon-Si, Korea, Republic of; [3]Univ. of Miami, Miami, FL; [4]Victoria Univ. of Wellington, Wellington, New Zealand; [5]Psychology and Neurosci., Univ. of Colorado Boulder Dept. of Psychology and Neurosci., Boulder, CO

Abstract: Multivariate modeling of brain imaging data, or multivoxel pattern analysis (MVPA), captures useful brain representations of theoretically constructs and clinically meaningful outcomes. Here we present an MVPA technique to take into account hierarchical structure in brain imaging data (e.g. subjects or imaging sites). We extend principal component regression (PCR) by substituting mixed effect regression for ordinary least squares and multilevel component analysis for principal component analysis. Finally, we incorporate Bayesian optimization to select principal components to retain at each level of the model. Resultant models yield separate MVPA maps for predicting outcome variance within and between subjects. We compare MLPCR and PCR model performances according to variance explained in out of sample observations using nested cross validation in two datasets and three tasks. We show MLPCR has similar sensitivity and specificity in all cases (table I). In dataset 1 (n = 86, 4542 single trial images) models trained to predict subjective thermal pain intensity ratings or subjective sound intensity ratings successfully predict corresponding out of sample ratings. However, models trained to predict pain do worse than an intercept only model in predicting sound intensity ratings and vice versa, indicating specificity. Similar results were obtained in the second dataset (n = 32, 2939 single trials) comparing thermal pain rating and nonpainful thermal

rating tasks. MLPCR shows comparable performance to PCR, but has several advantages over established MVPA methods. First, MLPCR provides greater model transparency by segregating different levels of pattern representation across hierarchical levels of an experimental design. This allows greater insight into obtained representations, for instance by identifying subject or site effects. Second, MLPCR reduces experimenter degrees of freedom by creating a framework within which common analytic design decisions can be automated (e.g. mean centering subjects). Further work is needed to evaluate MLPCA performance in the case of unbalanced designs and heteroskedastic noise, scenarios where mixed effects regression models have distinct advantages over more naïve models.

Title: *In silico* modeling of temporally interfering electric fields for deep brain stimulation

Authors: *I. DALLA BETTA[1,2], A. M. CASSARA[3], E. S. BOYDEN[2], E. N. BROWN[2,4,5], F. J. FLORES[4,5];

[1]Wellesley Col., Wellesley, MA; [2]MIT, Cambridge, MA; [3]IT'IS Fndn., Zurich, Switzerland; [4]Harvard Med. Sch., Boston, MA; [5]Massachusetts Gen. Hosp., Boston, MA

Abstract: The use of electric fields to manipulate neural activity and function has been common practice in research and the clinic for several decades. Non-invasive techniques, such as transcranial direct current stimulation (tDCS) and transcranial alternate current stimulation (tACS), and invasive techniques such as deep brain stimulation (DBS) have a variety of uses in the treatment of psychiatric and neurological disorders. Recently, the discovery that temporally interfering (TI) electric fields can achieve a finer focus of neural stimulation has combined the non-invasive quality of tACS with the localized stimulation obtained with DBS. However, to position the focus of TI within the brain, it is necessary to consider several parameters such as current intensity, tissue properties, electrode position, and others. In this study, we assessed the distribution of electric fields and maximal TI in a laminar head model and a realistic mouse model and studied the effects of current intensity, electrode size, and electrode position geometry. To solve Maxwell's equations, we used the finite element method under an electro ohmic quasi-static regime with Dirichlet boundary conditions. We found that the focus and depth of maximal TI is directly proportional to the size of the return electrodes, and inversely proportional to the angle between source and return electrodes and to the distance between the source electrodes. Also, increase in current intensity increases the strength of the maximal TI but not its focus or its depth. The focus provided by TI is always better than that provided by the same tACS configuration. Our *in silico* study provides a systematic assessment of the relevant parameters to optimize TI and can guide future *in vivo* studies seeking to achieve neural stimulation of deep brain regions.

Title: Temporally-rotating and orientation-selective electric fields enable finer control of axonal activation with deep brain stimulation applications

Authors: *S. S. SANG[1,2], L. LEHTO[2], J. SLOPSEMA[1], L. WU[2], S. MAMGIA[2], S. MICHAELI[2], M. D. JOHNSON[1];
[1]Biomed. Engin., [2]Ctr. for Magnetic Resonance Res., Univ. of Minnesota, Minneapolis, MN

Abstract: Introduction: The therapeutic benefits of deep brain stimulation (DBS) strongly depend on the electrode configuration and stimulation pulse patterns. Commercial DBS probes have a limited number of electrodes that in turn limit the flexibility to which electric fields can be steered and sculpted within the brain. Here, we demonstrate in computational models that with high-density electrode arrays one can achieve (1) more efficient axonal activation with temporally rotating electric fields, and (2) unidirectionally propagating action potentials using spatial ambulation of electric fields over time. **Approach:** Computational models consisted of a finite element model of a high-density electrode array coupled with biophysical multi-compartment myelinated axon models that were distributed across a broad range of orientations relative to the electrode array. Stimulation thresholds for axonal activation were investigated in the context of sinusoidal waveforms applied with varying phase offsets across multiple electrodes. The degree to which unidirectionally propagating action potentials and action potential block could be elicited was investigated in terms of the spatial electric field gradient over time along the shank surface. **Main results:** Narrow aperture rotating electric fields using three or more electrodes were found to have lower stimulation thresholds than monopolar configurations and bipolar configurations across a broad range of axon orientations. Unidirectionally propagating action potentials from 2um diameter myelinated axons could be elicited in close proximity to the electrode array within 150 um using linearly increasing stimulation amplitudes along the surface of the high-density electrode array. This method could also be used to block the propagation of action potentials along an axon. **Significance:** These results suggest that higher density electrode arrays using novel temporally rotating electric fields and orientation-selective electric fields can enable finer scale manipulation of axonal activation over traditional approaches to electrical stimulation within the brain.

Title: Canvas: A computational neuroscience Matlab design tool for large scale synthetic nervous systems

Authors: *F. R. YOUNG[1], A. J. HUNT[2], R. D. QUINN[1];
[1]Mechanical and Aerospace Engin., Case Western Reserve Univ., Cleveland, OH; [2]Portland State Univ., Portland, OR

Abstract: Animals demonstrate the complex environmental interactions roboticists seek to emulate with machines. The coupled nature of the nervous system's form and function indicates that its composition is crucial to task-level flexibility. The enviable benchmark set by this neural tractability has lead to the development of control systems modeled after the nervous system. Development of "synthetic nervous systems (SNSs)" serves the dual purpose of a robotic control platform and a modeling tool for computational neuroscience.
By decomposing the nervous system into functional subunits, it has been shown that established neural functionality can be replicated in an accessible, hierarchical nature. Specifically, functional subunits associated with rhythmic oscillations called central pattern generators (CPGs) have been used to implement locomotor control in simulation. Once the system architecture has been established, optimization techniques are used to tune individual neuron parameters and coordinate motion.
The complex nature of SNSs makes their implementation computationally expensive. While some methods already exist for the design and optimization of relatively small neural systems, we are unaware of an existing tool for the creation of large-scale SNSs. This work presents a Matlab modeling tool capable of rapid design and deployment of SNSs to ease their creation while implementing fundamentals developed on the subject.
This tool, called Canvas, features a graphical user interface (GUI) wherein a user is able to develop their own large-scale SNSs. Users are able to define system geometry for their specific task with the capability of exporting and importing neural designs. Canvas allows users to define synaptic and neuron parameters for each node in the simulation individually. Additionally, functional subunits can be easily created with the appropriate calcuated parameters allowing users to quickly perform algebraic combinations of neural signals.
This tool currently offloads simulation results into an open source program called Animatlab.

Animatlab is a simulation environment used to simultaneously integrate neural control with physiological motor manipulation. While Animatlab is a useful tool for implementing neuromechanical control, it lacks the functionality for creating large-scale neural systems. Canvas allows users to automatically generate an Animatlab project file for rapid deployment of SNS designs for neural simulations. With this tool, it will become possible to generate large-scale SNSs for the control of complex neuromechanical simulations, aiding both the robotics and biology communities.

Abstract: There is a growing need for sharing of research data and computational models to address the reproducibility and transparency challenges that are currently manifested across all scientific disciplines. In addition, an increasing number of researchers are recognising the benefits of sharing research data to obtain greater exposure of their research and to access shared data assets for re-analysis and re-use in new combinations. Today, several general data repositories are offering opportunities for researchers to share research data and models. However, many of these repositories lack the necessary stewardship and standards for making the research data and models Findable, Accessible, Interoperable and Reusable (FAIR), in accordance with the FAIR principles (Wilkinson et al., Scientific Data 3:160018, 2016). To address these challenges, the Human Brain Project (HBP) is developing a new research infrastructure, EBRAINS FAIR data service, providing tools, workflows and curation services

tailored for integration and sharing of heterogeneous, multimodal neuroscience data and computational models. Curation includes also verification of relevant permissions and adherence to regulations and ethical standards. Data are stored at HPC centers, close to compute resources, made citable through DOIs, and tagged with a Creative Commons copyright license, chosen by the data provider. Data sharing through EBRAINS is one of several services delivered by the EBRAINS infrastructure, developed by the HBP. We demonstrate currently available services and provide examples showing the added values of sharing data through the new infrastructure.

Title: Find and explore rodent brain data using 3D atlases in the new EBRAINS infrastructure

Authors: *C. H. BLIXHAVN, K. A. ANDERSSON, H. KLEVEN, U. SCHLEGEL, M. A. PUCHADES, J. G. BJAALIE, T. B. LEERGAARD;
Inst. of Basic Med. Sci., Univ. of Oslo, Oslo, Norway

Abstract: The neuroscience community steadily produces a richness of multi-scale and multi-modal data, but so far these data are difficult to find, access and reuse. By comparison, Google Earth allows us to find and view different sites, services and information of interest, connected to specific locations in geographic maps. Following a similar logic, the new EBRAINS infrastructure makes use of three-dimensional brain atlases to provide anatomical context for different research data, allowing users to find and reuse selected data of interest to solve new questions. With the interactive EBRAINS platform, users can navigate and combine datasets in atlas viewers. The shared datasets are linked to collections of tools and workflows that can utilise the anatomical atlas information for further analyses of data. We here present workflows used to localise anatomical positions in different types of neuroscience data. We exemplify the added value of presenting, navigating and analysing spatially relevant data within an atlas framework. The Human Brain Project now invites the community to use the new research infrastructure to share, find and use open access research data.

Title: Using filter bank to estimate functional connectivity in both low and high frequencies: Application to schizophrenia

Authors: *A. FAGHIRI, E. DAMARAJU, V. CALHOUN;
Mind Res. Network, Albuquerque, NM

Abstract: Dynamic functional network connectivity (dFNC) among different parts of the brain can be estimated using sliding window Pearson correlation (SWPC). Selecting a window size is required for SWPC where using a very short window size increases standard error while faster changes in connectivity can go undetected if we use long window sizes. Here, we propose a new method inspired by SWPC that uses filter bank to estimate dFNC in all frequency bands.SWPC is essentially two systems in series. In the first system, two time series are demeaned and multiplied (Pearson correlation part). The output is then filtered using a low pass filter in the second system (the sliding window). Here, we use a filter bank covering the whole frequency space instead of the second system.We analyzed an fMRI dataset including healthy controls (HC, n = 163) and schizophrenia patients (SZ, n = 151). First, group independent component analysis is used to decompose the data into 100 spatial maps and their time series. Next, 48 components were selected and grouped into 8 functional domains. We designed 10 filters to divide 0 - 0.25 Hz (TR=2s) space into equal band passes and used them to estimate dFNC matrix. Finally, we clustered all dFNC values into 8 clusters (Figure 1 first row). The number of occurrence of each cluster for each frequency band (Figure 1 second row) and the amount of time each subject stayed in each state (dwell time) was compared between HC and SZ (Figure 1 third row). States 1 and 8 occur mainly in the lowest frequency band. HC stay more in cluster 8 while SZ stay more in cluster 1 suggesting that SZ and HC subjects have different static connectivities. In addition, we have some clusters that almost never occur in low frequency band (cluster 2 and 4).

Note that these are high frequency states which are not visible in SWPC results.To summarize, this approach enables us to estimate high frequency states not detected using SWPC and allows us to differentiate between low and high frequency states. In addition, we were able to detect some cluster pairs that have opposite patterns which we speculate subjects oscillate between them.

Abstract: Within the last years, there has been growing awareness of the negative repercussions of unstandardized planning, conduct and reporting of preclinical research. Several initiatives have set the aim of increasing validity and reliability in reporting of studies and publications. While these overlap significantly, they differ in detail, and show variance in generalizability or specific challenges for a single field. Additionally, reporting guidelines do not cover planning and conduct of studies, which face a similar situation. Consequently, it is hard for researchers to decide which guidelines to follow, especially at the stage of planning future studies.Aim of the EQIPD (European Quality in Preclinical Data) framework was to unify current suggestions, find a basis in evidence behind their rationale, and prospectively test the newly set framework for feasibility in multi-center animal experiments.
In a first step, in a systematic review of guidelines, a systematic search yielded 13,863 results, in which 62 publications fit to the inclusion criteria. From these, a list of 58 unique items were extracted, and in a two-round Delphi process with a subsequent consensus meeting, 33 of these items were included in the final framework. This framework was constructed into five major domains.
DOMAIN 1: Exploratory vs. confirmatory research: Answer the following question: Is your experiment testing a predefined scientific hypothesis which is statistically testable (confirmatory research) or is it exploring a space of interesting options to generate hypotheses (exploratory research)?
DOMAIN 2: Pre-planning and standard operating procedures (SOPs): Prespecify, document and standardize all methods and analyses before the experiment.
DOMAIN 3: Statistics: Think about which form of aggregate measures are meaningful for your data and choose appropriate statistical methods, and plan your sample size accordingly.
DOMAIN 4: Randomization and blinding: Randomize and blind your processes to avoid the introduction of confounding and systematic error.
DOMAIN 5: Documentation: Not all bias can be avoided, but most can be uncovered: use full and comprehensive documentation.
The EQIPD framework is currently prospectively tested for feasibility and blind spots in a multi-center animal study, which will further inform the final version. In parallel, a literature search is conducted to identify the provenance of diligence - the evidence for an impact of the proposed items, and the history of their application. While, for the moment, the framework is being developed around animal work, its applicability to in vitro studies will also be assessed.

Title: Automatic diagnosis of epilepsy using current source estimate with a deep neural network

Authors: *N. URA[1], T. YANAGISAWA[2], R. FUKUMA[3], T. HARADA[4], S. YAMAMOTO[3], J. AOE[5], H. KISHIMA[2];
[1]Osaka Univ., Suita, Japan; [3]Dept. of Neurosurg., [2]Osaka Univ. Grad. Sch. of Med., Suita, Japan; [4]RIKEN, Tokyo, Japan; [5]Osaka Univ. Inst. for Advanced Co-Creation Studies, Suita, Japan

Abstract: Introduction: Epilepsy is one of the most common neurological disorders in the world. Magnetoencephalography (MEG) is an important examination for the diagnosis of epilepsy, but seizures are identified by epileptologists who read extensive MEGs, which is time-consuming and requires experience. Developing a practical and reliable intelligent diagnosis algorithm would be of great significance. We explored the feasibility of using automatic interpretation of MEG signals by a deep neural network to diagnose epileptic patients. **Method :** We used MEG signals and MRI images from 80 epileptic patients and 80 healthy subjects, recorded at Osaka University Hospital. The MEG system was a 160-channel whole-head MEG equipped with a coaxial-type gradiometer housed in a magnetically shielded room (MEGvision NEO; RICHO Electric Corporation, Kanazawa, Japan). During MEG measurements, subjects were in a supine position with the head centered in the gantry. Participants were instructed to close their eyes and, not move their head. MEG signals recorded in one session (either 240s or 300s) during which the subject was awake. Sampling frequency was 2k Hz, with the high-pass filter at 0.1 Hz. We aligned the head image and estimated the current source estimation from the magnetic field signal through spatial filtering processing using MEG signals and the MRI images. The source estimation data was divided into 800-ms segments, which were used as input for a convolutional neural network (CNN), called MNet, to classify epilepsy patients and health volunteers using 10-fold cross-validation. MNet was designed to extract global features of 160 channels of segment data. To compare the MNet classification accuracy, we studied the accuracies for the same combination of subjects using a support vector machine (SVM). **Result :** The classification accuracy using MNet was 81.07%, which was higher than the study using an SVM with source estimate data. **Conclusion :** The trained MNet succeeded in differentiating subjects with neurological disease from healthy subjects using big data from MEG signals. This is the first study to classify such subjects using current source estimation data from magnetic field signals. Using deep learning with big datasets will improve the diagnosis of neurological disease.

Title: CA2 area detection from hippocampal microscope images using deep learning

Authors: *H. OJIMA[1], S. MORINAGA[1], T. ISHIKAWA[2], M. YASUI[2], S. AKIZUKI[1], M. HAMADA[1], T. KURODA[1];

Abstract: The Cornu Ammonis area in the hippocampus divides into three subregions, including the CA1, CA2, and CA3. Anatomical and functional properties of each subregion have been extensively studied; however, it has been difficult to identify the anatomical area of each subregion. Molecular markers provide a powerful tool to assess anatomical area of the subregions, on the other hand, additional time-consuming techniques, such as preparation of transgenic animals or post-hoc immunostaining, are necessary. The aim of our research is the creation of an alternative method to assess anatomical area of the CA2 subregion from hippocampal microscope images by deep learning, which is a time efficient computational machine learning approach. As an initial step towards creating such a system, we utilized a modified version of a convolutional neural network architecture for medical image segmentation called U-Net, to assess the CA2 subregion from a microscope transmitted-light images of the mice hippocampus. The output of our system is a confidence heatmap and a maximum confidence coordinate, which provides the CA2 location in the hippocampal CA2 area. This proposed system was trained by a dataset which consists of 220 transmitted-light images and manually labeled CA2 region masks created from fluorescent images. We tested the system on another dataset which consists of 12 images. All images were obtained from PFA-fixed horizontal hippocampal slices from adult (9-11 weeks) C57BL/6J mice. Based on the probability that the maximum confidence coordinate exists in the CA2 area, the proposed system achieved the detection accuracy of 100% on the test dataset. This work will provide biologists with efficient and accurate tools to assess the CA2 subregion, improving the efficiency of studies in the area.

Title: Model-based decoupling of evoked and spontaneous neural activity in calcium imaging data

Authors: *M. A. TRIPLETT, Z. PUJIC, B. SUN, L. AVITAN, G. J. GOODHILL;
Queensland Brain Inst., Univ. of Queensland, St Lucia, Australia

Abstract: The pattern of neural activity evoked by a stimulus can be substantially affected by ongoing spontaneous activity. In calcium imaging data this spontaneous activity often appears highly structured, and may reflect parallel encoding of non-sensory variables, mechanisms for circuit development, or other internal state factors that regulate sensory-guided behaviour. Accurately studying the interplay between stimulus-evoked and spontaneous activity therefore requires the ability to reliably separate these two components. However, this is challenging as the internal factors that give rise to spontaneous activity typically cannot be directly observed or measured.
To address this problem we developed a latent variable model that decouples the components of calcium imaging data due to evoked activity from those driven by structured spontaneous activity. We use Bayesian methods to fit the model to data and identify low dimensional structure underlying spontaneous activity that proceeds unimpeded during stimulus presentation. Our model also fits a simple linear receptive field, ensuring that the estimated stimulus tuning properties already account for the variability that this ongoing spontaneous activity introduces. After validating the model on surrogate data we then apply it to data from zebrafish tectum and mammalian cortex. By analysing the variance that the evoked and spontaneous components contribute to neural activity, the model allows us to characterise how neurons are differentially driven by external stimuli, latent internal factors, and their interaction.

Title: Time-varying monitoring of dynamic neural connectivity using calcium imaging

Authors: *C. RENTERIA, Y.-Z. LIU, S. A. BOPPART;
Beckman Inst. for Advanced Sci. and Technol., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Recent advances in optical imaging technologies and connectome research have rapidly increased the volume and complexity of imaging data, and the need to comprehensively understand the network properties of the brain. This complexity is furthered by the many metrics used to identify connection strength, causing uncertainty about appropriate metric selection. One limitation of these metrics is the inability to track dynamic connectivity changes. Current techniques also do not provide directionality of signal propagation, and consequently provide limited information about information transfer in neural systems. We propose a time-varying, time-frequency approach for analysis to overcome these weaknesses. For these studies, hippocampi were isolated from P2-P3 mice expressing GCaMP6 (C57BL/6J-Tg(Thy1-GCaMP6s)GP4.12Dkim/J, Jackson Lab) and cultured. Cultures were optically excited and imaged with a commercial Zeiss microscope (Axio Observer.D1) at 22.7 Hz using a Zeiss CCD camera (Axiocam 503 mono) for 10 minutes, followed by perfusion of 10, 25, and 100 μM glutamate to monitor chemically-induced changes. Cell culture media (NbActiv4) was used as a control. For analysis, somas were identified by manual selection, and the ΔF/F calculated for all cells from their fluorescence. A ten-second, windowed Pearson's correlation coefficient was used to analyze dynamic connectivity. The prominent frequency of these signals was quantified by averaging the signals from all cells over time, calculating the Welch's power spectrum, and identifying the maximum frequency. The wavelet transform was also implemented to monitor the frequency content over time. Wavelet coherence was used to monitor the coherence and phase between cellular signals at the prominent frequency. Spike-sorting was implemented by thresholding for signals larger than two standard deviations above the mean, and peak-identification of the calcium transients was used to determine the firing properties of individual cells, and the network. Our results demonstrate a strong agreement between the time-varying correlation and coherence approaches for monitoring network connectivity, and consequently support that the two give complimentary information. The phase from the wavelet analysis

provides information regarding information flow, demonstrating an ability to resolve directionality of signal propagation alongside the connectivity metrics. This combined approach for analyzing neural signals and connectivity could provide new information about the network structure of neural circuits and the brain, not just for optical imaging, but for other functional brain imaging techniques.

Title: *In-vitro* structural neurotoxicity testing using deep convolutional neural networks

Authors: *M. MADDAH[1], K. LOEWKE[1], H. TRUONG[2], H. YU[2];
[1]Dana Solutions, Palo Alto, CA; [2]Gilead, Foster City, CA

Abstract: The incidence of neurological disorders is increasing around the world. There is a need for more advanced tools that can be used to screen large sets of compounds for potential neurotoxicity. Human induced pluripotent stem cell (iPSC)-derived neurons are emerging as widely-used cell models in toxicity testing. To fully leverage their potential, the development of robust and accurate assays is of the utmost importance. We present a novel tool, PhenoTox, which uses deep convolutional neural networks to capture subtle and complex compound-induced structural changes in cell-based models, such as iPSC-derived neurons. The input to PhenoTox is a collection of microscopy images captured and grouped at multiple doses and time-points for the drug of interest and a control set for each time point where no drug is applied. PhenoTox performs a series of 2-class neural network trainings comparing the test conditions to the controls and generates a classification accuracy for each training. The final output is a heatmap of the z-factors across all test conditions, depicting the doses and timepoints at which structural changes have happened and how strongly they differ from controls. Here, we present the results of our first experiments applying PhenoTox for evaluating drug-induced structural toxicity using iPSC-derived Gaba neurons. Cells from Cellular Dynamics were cultured on a 384-well plate. A panel of 7 compounds, 5 with known neurotoxicity profiles and 2 proprietary compounds, were applied at 10 different concentrations (with highest concentration of 50uM and 1:3 serial dilution) with 3 replicates each for 48 hours. Cells were fixed and stained with Beta III Tubulin and Hoechst and fluorescence microscopy images were collected at 9 locations per well. PhenoTox detected dose-dependent structural changes for all 5 known drugs, while no changes were detected for the two proprietary compounds. Structural changes detected by PhenoTox were more pronounced for the Beta III Tubulin marker compared to Hoechst as expected. EC50

values derived from PhenoTox were compared to EC50 values calculated from a commercial neurite-length assay. The concentrations nearest to EC50 matched exactly for Vincristine, Brefeldin A, FCCP, and Tunicamycin. For Staurosporine, PhenoTox was more sensitive than the neurite-length assay, showing half-maximal response 3 concentrations sooner (6.29nM vs. 360nM). For the 2 proprietary compounds, PhenoTox and the neurite-length assay showed EC50 greater than max concentration. These results are the first demonstration of PhenoTox in successfully capturing of dose-dependent structural changes on a panel of drugs with known neurotoxicity profiles.

Title: Brainwide coactivation patterns revealed by multi-site electrophysiological recording and resting state fMRI in awake rodents

Authors: *Q. ZHANG, N. ZHANG;
Biomed. Engin., The Pennsylvania State Univ., State College, PA

Abstract: How populational neuronal firing in a local brain region relates to brain-wide network patterns is still an intriguing question. This issue has been thwarted by insufficient electrophysiological samplings from all neuronal populations and the challenge of simultaneous measurement from a large number of neurons across distributed regions during fMRI scanning. Here we analyzed the spiking rate data recorded using neuropixel probes across multiple brain regions with hundreds of neurons in each area when the animal was in darkness, and correlated the co-firing patterns derived from the electrophysiology data to resting state fMRI (rsfMRI) data acquired in separate animals. We found two cell types in the caudoputamen were coupled to other regions (thalamus, V1, motor cortex) in a distinct manner. Specifically, MSN's response was anticorrelated with the populational activity in the thalamus, whereas FSI's activity was positively correlated with the thalamus spiking. The co-firing patterns across multiple regions including caudoputamen, thalamus, V1 and motor cortex also well corresponded to the co-activation patterns in the rsfMRI data. We will confirm this result through simultaneous electrophysiological and fMRI recordings in awake rats.

Title: Spatial temporal organisation properties of neural oscillations in primate cerebral cortex

Authors: *X. LONG[1,2], S. G. SOLOMON[3,5], P. R. MARTIN[2,3,4], P. GONG[1,2];
[1]Sch. of Physics, [2]Australian Res. Council Ctr. of Excellence for Integrative Brain Function, [3]Discipline of Physiol., [4]Save Sight Inst., Univ. of Sydney, Sydney, Australia; [5]Dept. of Exptl. Psychology, Univ. Col. London, London, United Kingdom

Abstract: Neural oscillations emerging from cortical circuits exhibit oscillatory bands covering frequencies from a few tenths to hundreds Hz. These oscillations have been widely observed in the cortex, but their spatial and temporal organisation properties remain unclear. In this study, we adapt concepts and methods from turbulence physics to analyse neural oscillations in local field potential (LFP) activity recorded from the extrastriate visual cortex of marmosets. We find that rather than being sustained, regular oscillations, neural oscillations at all frequency bands exhibit intermittent, bursting properties with varying peak frequencies and that these bursts are organised as spatially localized, propagating patterns. We further demonstrate that the higher the frequency bands, the smaller the averaged size of the propagating patterns and that the averaged sizes of these patterns scale as a power function of their frequencies with an exponent of -1.2. Such a scaling behaviour of the propagating patterns is invariant across different recordings. In addition, we find that there exist rich interactions of these propagating patterns across temporal scales.

Title: Detection and characterization of gamma bursts in LFP signals

Authors: *Z. CHEN[1], F. FENG[2], D. B. HEADLEY[3], D. K. C. HO[1], D. PARE[4], S. S. NAIR[1]; [1]Electrical & Computer Engin., Univ. of Missouri Columbia, Columbia, MO; [2]Electrical & Computer Engin., Univ. of Missouri-Columbia, Columbia, MO; [3]Rutgers, The State Univ. of New Jersey, Newark, NJ; [4]Rutgers Univ. Newark, Newark, NJ

Abstract: Gamma oscillations (30-80 Hz) are expressed in many brain regions, where they are reflected in signals arising from the electroencephalogram (EEG) and local field potential (LFP). However, the accuracy of gamma burst detection and estimation is diluted by unrelated spontaneous activities and background noise. To overcome this, we developed a robust technique for the detection of gamma bursts in an LFP signal and subsequent estimation of burst frequency and duration. We tested the method on three types of artificial LFP signals: (i) those constructed by adding synthetic bursts at several frequencies to noise generated using the $1/f^{\alpha}$ characteristic; (ii) same as the previous case but with noise generated using the power density spectrum recorded *in vivo* from BL of freely behaving rodents; and (iii) LFP recorded in a large scale computational model of rodent BL.
Noise in neural signals is generally modeled with a $1/f^{\alpha}$ characteristic (pink noise) in the power spectrum where α ranges from 1.5 to 4. We considered the problem of detecting gamma bursts in the presence of such noise using the three LFP signal types presented above. The proposed detector exploits the pink noise characteristics and reduces noise using a linear predictor before bandpass filtering and energy detection. Since the gamma bursts vary in width continually, it is difficult to determine a suitable window size to determine short-term energy. Hence we adopted a Hilbert transform approach and appropriate thresholds to detect gamma bursts. The performance of this algorithm was evaluated as a function of whether linear prediction was used, characteristics of our filtering, and the threshold set for detection. Once detected, we characterized their amplitude, duration, frequency of individual detected gamma bursts, and overall burst properties such as their rate. The ROC curves of detection provided insights into performance with different burst characteristics such as amplitude and duration. For example, detection rate exceeded 50% with burst amplitudes higher than 0.4 of the noise amplitude and duration longer than 30 ms. Furthermore, an investigation of false positives in the synthetic LFP signal (case (i) above) revealed that most, ~95%, come from true bursts with high amplitude, and frequencies <10 Hz from the filter band edges, rather than from pure noise. This suggests that many false positives are actually bursts close to the filter band. However, these false positive bursts tend to have lower Hilbert transform amplitude and longer durations than the true positive bursts.

Title: Whole-brain cell count analysis: Crowd-sourcing manual cell counting

Authors: *L. H. KIM[1,4], L. MOLINA[4], Z. H. T. KISS[2,4], P. J. WHELAN[3,1,4];
[1]Neurosci., [2]Clin. Neurosciences, [3]Dept. of Comparative Biol. & Exptl. Med., Univ. of Calgary, Calgary, AB, Canada; [4]Hotchkiss Brain Inst., Calgary, AB, Canada

Abstract: Amazon's Mechanical Turk (MTurk) service is being used to crowd-source annotations at a relatively low cost and high speed across a variety of research settings, including in neuroscience. With the increasing use of data-intensive whole-brain imaging techniques, we tested the feasibility of using this crowd-sourcing platform to expedite cell counting. A C57BL/6 mouse brain was cleared using the iDISCO method with immunohistochemistry for presence of tyrosine hydroxylase expression (a marker for dopaminergic cells). The cleared brain was imaged using the LaVision BioTec Ultramicroscope II Light Sheet Microscope (2X objective with 4X optical zoom, 640 nm laser) with ethyl cinnamate-mediated refractive index matching. Images were obtained in the coronal plane of the brain with Z-step of 15 microns. The image tiles were stitched using Fiji and colour-encoded maximum intensity, 90 µm Z-projections, were produced. These images were resized to have a width of 7680 pixels while maintaining the aspect ratio and exported to JPG format with 90% quality to reduce the download time on the client side of the MTurk platform. We compared the performance of MTurk annotations under three different instructions (A, B, and C) against two expert counters using one mouse brain. These instructions varied in terms of the breadth, complexity, quality, and effort required for the task per image. Each image was annotated by at least ten unique MTurk workers. To discourage premature, incomplete submissions, they had to annotate 1-3 cell hidden sites serving as positive controls. All images and counting annotations were imported into the WholeBrain Software and registered with the Allen Brain mouse atlas. Based on the results obtained by three different instructions, we found the changes in the following variables to improve their reliability: i) simplicity of the task (less effort and time spent per image), ii) quality of instruction with troubleshooting tips and, iii) real-time validation of annotation accuracy using positive and

negative controls. Further improvements could be made by incorporating a short-training period and optimizing the images to minimize dense cellular areas and overlapping expressions.

Title: A novel deep learning framework for automated lesion segmentation of structural MRI data

Authors: *I. PAPPAS[1], H. HECTOR[2], K. HAWS[3], B. CURRAN[4], A. S. KAYSER[2], M. D'ESPOSITO[1];
[1]Helen Wills Neurosci. Inst., Univ. of California, Berkeley, Berkeley, CA; [2]Neurol., Univ. of California, San Francisco, San Francisco, CA; [3]Neurol., [4]Res., VA Northern California Hlth. Care Syst., Martinez, CA

Abstract: In MRI studies of patients with neuropathology (e.g. stroke, trauma), it is critical that the full extent of the brain lesion is identified. Typically, segmentation of the lesion from the areas without pathology is performed manually by one, sometimes two, experts who outline the area of damage slice-by-slice using different types of MRI scans (e.g. T1-weighted, T2-weighted, Flair). This process is time-consuming, prone to human error and likely not reliable. Deep learning techniques have recently emerged as state-of-the-art approaches to supervised learning in large, complex datasets (Krizhevsky, Sutskever, Hinton, 2012). Deep learning refers to the use of multi-layered neural networks that extract a hierarchy of features from raw input images. Despite their widespread prevalence in identifying features in 2D image datasets, deep-learning approaches have not been applied to automated lesion segmentation of 3D MRI scans. We implemented a deep learning network, which uses MRI T1 images as inputs and outputs a lesion segmentation prediction. Our approach implements a neural network that consists of two parts: (1) First a 3D-UNet network that consists of an analysis pathway including a series of 3D convolution and max pooling operations on the T1 image, and a synthesis pathway including a series of 3D up-convolution operations on the downsampled image (Çiçek et al., 2016). (2) In turn, the output feature maps are inserted into a second 3D convolutional pipeline. This pipeline employs a dual pathway architecture that processes input maps at multiple scales simultaneously: one pathway processes high-resolution samples with a series of 3D convolutions, while a second pathway processes low-resolution samples (Kamnitsas et al. 2017). The two parts thereby extract

multi-scale features of the input image and, eventually, output a segmentation mask representing the lesion. Using consensus human expert predictions as the current standard and training our deep learning network on 59 T1-weighted MRI scans from stroke patients, we produced the following results: training data mean accuracy (0.9544), sensitivity (0.9017), specificity (0.9011), and Dice coefficient (0.9014), demonstrating a very high level of accuracy in lesion segmentation. Moreover, we note that performance of our deep learning network will improve as it incorporates a large number of MRI scans from patients with brain lesions. We propose that this automated approach is a more reliable, more accurate method for brain lesion segmentation, as compared to widely used user-defined approaches.

Title: Calcium imaging analysis with graph filtered temporal dictionary learning

Authors: A. S. CHARLES[1], N. CERMAK[2], J. SCHILLER[3], ***G. MISHNE**[4];
[1]Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ; [2]Technion, Haifa, Israel; [3]Neurobio., Haifa, Israel; [4]UC San Diego, San Diego, CA

Abstract: Optical calcium imaging is a versatile imaging modality that permits the recording of neural activity, including deep neural populations as well as single dendrites and spines using two-photon microscopy. Calcium imaging analysis relies on extracting the temporal fluorescence fluctuations of each component (e.g., spines, cell bodies or dendrites) from the full video. Traditional segmentation methods used spatial information to extract regions of interest (ROIs), and then projected the data onto the ROIs to calculate the time-traces. Current methods rely on strong a-priori spatial and temporal regularization to isolate each component, which can bias time-trace estimation and restrict applicability across imaging scales.
We reverse the modeling and instead aim to minimize the spatial inference, while focusing on finding the set of temporal traces present in the data. We reframe the problem in a dictionary learning setting, where the dictionary contains the time-traces and the sparse coefficient are spatial maps. To learn the dictionary of time-traces, we introduce constraints to implicitly infer the number of components and suppress their redundancy, while ensuring stable convergence. To learn the spatial maps, we propose a new sparse coding solution, ReWeighted l1 Graph Filtering

(RWL1-GF), which adapts Reweighted l1 spatial filtering to a graph-based filter. The filter incorporates non-local spatial information, thus handling both components with compact spatial support such as cell-bodies, in addition to far ranging spatial components such as dendrites. We demonstrate on synthetic and real calcium imaging data at different scales (population and dendritic imaging) that our solution has advantages regarding initialization, implicitly inferring number of neurons and simultaneously detecting different neuronal types. We compare our method to a current state-of-the-art algorithm, Suite2p, on the publicly available Neurofinder dataset. The flexible spatial constraints allows our model to isolate both disconnected portions of the same neuron and small components otherwise over-shadowed by stronger components. This latter case is important as such configurations can cause scientifically-misleading false transients. For densely labeled dendritic data (GCaMP6f signals recorded at 30 Hz from tuft dendrites of M1 layer 5 pyramidal tract neurons), our method isolates dozens of individual spines and dendrites.

Title: Low-dimensional global dynamics and underlying network architectures in the *Caenorhabditis elegans* dynome

Authors: *R. S. MCGEE[1], E. SHLIZERMAN[2];
[1]Biol., [2]Applied Mathematics, Univ. of Washington, Seattle, WA

Abstract: Neurosensory networks integrate information from environmental signals to encode internal representations of prevailing conditions and direct corresponding behavior. A thorough understanding of sensory integration requires a framework that relates the physical connections that route signals with the collective neural dynamics that process and encode information. The nematode *Caenorhabditis elegans* is an attractive model system for studying the interplay of neural connectivity and dynamics, given that its stereotypic nervous system is comprised of only 302 sensory, motor, and interneurons with well-characterized electrophysical connections. We combine the known connectome structure with a physiologically appropriate neuron model to simulate the dynamics of the entire *C. elegans* network in response to stimuli. Through systematic stimulation of all neurons in the network, we find that the space of the whole-network dynamics is low-dimensional, with 6 dimensions capturing 95% of induced network activity. We show that these low-dimensional dynamics have a large number of unique attractors, which can be classified into functional groups corresponding to neural states and motor behaviors.

Furthermore, we assess the sensitivity of the observed dynamics to the particular network architecture by comparing the dimensionality and attractor characteristics of the wild-type *C. elegans* network to those of systematically perturbed networks. This work contributes to a foundational understanding of how connectivity and dynamics combine to generate complex functionality, and informs how evolved network architectures shape global network dynamics.

Title: Automated cell segmentation for *in vivo* two-photon Ca^{2+} imaging data using deformable convolutional networks

Authors: *X. LIAO[1], J. GUAN[2], X. LI[1], Z. ZHAO[2], S. LIANG[2], L. LUO[2], H. JIA[3], X. CHEN[2]; [1]Ctr. for Neurointelligence, Chongqing Univ., Chongqing, China; [2]Brain Res. Ctr., Third Military Med. Univ., Chongqing, China; [3]Brain Res. Instrument Innovation Ctr., Suzhou Inst. of Biomed. Engin. and Technology, Chinese Acad. of Sci., Suzhou, China

Abstract: Two-photon Ca^{2+} imaging has been widely used in tracking brain activity *in vivo* with cellular resolution and high-throughput properties. However, the advances in technology have also led to a deluge of imaging data, making data analysis an extremely challenging task. In the analysis pipeline for Ca^{2+} imaging data, separating individual cells from the background is the basis for the extraction of neuronal activity information, and it is also the most time-consuming work by manual annotation. To address this issue, we aim to develop computational approaches that can facilitate the automated and efficient segmentation of neurons in Ca^{2+} imaging data. In this study, we developed an efficient method based on a deep convolutional neural network with transfer learning to perform cell detection and segmentation. We integrated deformable convolution within the network and hence enhanced the segmentation power by adapting to the variability of cell morphologies. We tested this approach on *in vivo* two-photon Ca^{2+} imaging datasets obtained from mouse cortical neurons with differently sized view fields, and particularly for the imaging cells labelled by a variety of chemical and genetically encoded Ca^{2+} indicators. Through testing, we demonstrate that the algorithm can efficiently detect and segment cells labeled by different indicators and achieve excellent results with minimal training data. In

addition, we show that this approach exhibits superior performance for cell detection and segmentation compared with the existing published tools. Therefore, the proposed method in our study can be used to process Ca^{2+} imaging data automatically and efficiently, and it will be a useful tool for *in vivo* brain activity mapping.

Title: Homeostatic plasticity supports cortical activity enhancement as a novel treatment for post traumatic epilepsy

Authors: *A. C. MOORE[1,2], J. WANG[3], W. XIONG[1,2], X. JIN[2,1];
[1]Indiana Univ. Sch. of Med., Indianapolis, IN; [2]Stark Neurosci. Res. Inst., Indianapolis, IN; [3]Indiana Univ., Indianapolis, IN

Abstract: INTRODUCTION: Traumatic brain injury (TBI) can cause post-traumatic epilepsy (PTE), a condition characterized by chronic seizures caused by aberrant hyperexcitability. Homeostatic plasticity is a self-tuning phenomenon where neurons adjust their intrinsic properties and synaptic transmission in response to an imposed increase or decrease in activity. It could induce a compensatory response to TBI-induced cell death and loss of activity and lead to PTE. If true, enhancing activity could suppress this compensatory response. In a partially isolated neocortex (undercut) model of PTE, we tested the hypotheses that homeostatic plasticity contributes to PTE and that enhancing activity will control PTE by suppressing homeostatic plasticity.
METHODS: Adult Thy1-GCaMP6 transgenic mice received undercut injury and activity of cortical pyramidal neurons were imaged with *in vivo* two-photon microscopy at baseline, day 1, and weeks 1-4. Correlation analyses were used to quantify changes in functional network connectivity and network topology, modeled by path length, betweenness centrality, and clustering coefficient. To treat PTE, undercut Thy1-Channelrhodopsin-2 transgenic mice received either daily intraperitoneal injection of D-cycloserine (DCS), a partial NMDAR agonist, or optogenetic stimulation on days 30-40 after undercut. Then continuous wireless EEG and video recordings were used to monitor spontaneous seizure activity for two weeks, and seizure susceptibility was measured using a pentylenetetrazol (PTZ) test.

RESULTS: *In vivo* 2-photon imaging showed acute decrease in the proportion of active neurons in the network at day 1, followed by progressive increase from week 1 - week 4 ($F(5,38 = 9.22$, $p<0.01$). Peak area followed the same trend ($F(5,38 = 8.12$, $p<0.01$), higher at week 3 compared to baseline ($p<0.01$). The trend was observed for synchronization ($F(5,38 = 19.19$, $p<0.01$), with more synchronized neurons at week 3 and 4 compared to baseline ($p<0.01$). Centrality ($F(5,46 = 12.51$, $p<0.01$) and clustering ($F(5,68 = 207.63$, $p<0.000001$) showed the same trend, with higher centrality at week 4 ($p<0.01$) and higher clustering coefficients at week 3 ($p<0.01$) compared to baseline. EEG data showed that both DCS ($p<0.01$) and LED ($p<0.01$) groups had fewer spontaneous seizures per day compared to undercut. In the PTZ test, seizure latencies to first observed seizure in both DCS ($p<0.05$) and LED ($p=0.0189$) groups were longer compared to undercut.
CONCLUSIONS: Taken together, these data suggest that undercut brain injury induced homeostatic plasticity regulation and that chronic activity enhancement reduced spontaneous seizures and seizure susceptibility.

Title: Deep learning for seizure forecasting in canines with epilepsy

Authors: *P. NEJEDLY, V. KREMEN, V. SLADKY, M. NASSERI, H. GURAGAIN, P. KLIMES, J. CIMBALNIK, Y. VARATHARAJAH, B. BRINKMANN, G. WORRELL; Mayo Clin., Rochester, MN

Abstract: This research introduces a fully automated, subject-specific deep-learning convolutional neural network (CNN) system for forecasting seizures using ambulatory intracranial EEG (iEEG). The system was trained and tested on 75 seizures collected over 1608 days (~38500 hours) of continuous data from 4 canines with naturally occurring epilepsy. The trained CNN models were tested in pseudo-prospective mode in all canines, and were compared

to Monte Carlo simulations using a Poisson random predictor with equal time in warning to evaluate seizure forecasting performance. The results show the CNN models forecasted seizures at rates significantly above chance in all 4 dogs ($p<0.01$, with mean 0.79 sensitivity and 18% time in warning).
The deep learning method presented here surpassed the performance of previously reported methods using computationally expensive features with standard machine learning methods like logistic regression and support vector machine classifiers. In order to show that the method can be deployed in real-time and work with implantable neurostimulation (INS) integrated with hand-held devices with limited CPU execution, we deployed the trained models on the Mayo Epilepsy Patient Assistant Device (EPAD) (Kremen V. et al. 2018). The Mayo EPAD is a tablet computer with a software application that acquires iEEG data streaming from an INS and runs a custom suite of algorithms including seizure detection and seizure forecasting. The average processing time for 30-seconds of 16 channels iEEG sampled at 400 Hz was 80 msec. The running model utilized ~120 MB of RAM. This demonstrates that our CNN model using continuous iEEG as input can be deployed on a commercial tablet computer, and provide online near real-time predictions for patients.
The seizure forecasting framework presented here reliably identified preictal periods associated with increased seizure probability and with performance exceeding previously reported approaches when tested on the same datasets. Notably, the identified pre-ictal states are generally not detectable by trained epileptologists when visually reviewing the iEEG. We demonstrated the feasibility of using our approach on a tablet computer, and in future work will apply the proposed system in prospective trials clinical trials.

Title: A novel method for multi-frequency components of a single channel in brain state classification

Authors: *D. GWON[1], M. AHN[2];
[2]Neurosci., [1]Handong Global Univ., Pohang-Si, Korea, Republic of

Abstract: In general, more channels are likely to have rich information which is beneficial for classifying different brain states. However multiple channels may not be available in practical situation. In particularly, only one to two electrodes may be sufficient for deep brain stimulation in treating diseases (e.g. Parkinson'sdisease patients). Usually power spectral density (PSD) is popularly adopted as representative feature in neural signal processing. However recent studies have highlighted the importance of cross-frequency coupling in brain function. In this study, we introduce a novel method to reflect the both information in generating discriminative features of brain states from the limited number of channel. In the proposed method, covariance matrix is composed of low frequency and envelop of high frequency components from a single channel signal. Then covariance matrices of two brain states are used in generalized Eigen-value problem to obtain the spectral filter which maximizes the difference between two states. Finally the variances of the projected components by chosen spectral filters represent the discriminative feature set. The method was tested with electroencephalogram (EEG) from 52 healthy subjects; each subject conducted 100 motor imagery trials for left and right hand respectively. We calculated the classification accuracy from a single channel (e.g. C4) over 14 subjects showing themeaningful performance (70% or above) in common spatial pattern method with 64 channels. Accuracies were calculated through three different methods. First, PSDs were estimated at intervals of 8Hz from 4 to 100 Hz and used as feature vector. The second and third methods employed low frequency (4 to 40Hz / 4Hz step) and high frequency (30 to 100Hz / 5Hz step) components. In the second method (CFC_W), the covariance matrix was estimated from combined signal of low and high frequency components, and spectral filters were obtained. Meanwhile each covariance matrix was obtained per each component, and spectral filter was also estimated separately in the third method (CFC_S). We fixed the size of feature vector to 12 for fair comparison, and linear discriminant analysis was used for classification. The final mean accuracy was obtained from 30 estimates through cross validation technique. As a result, the accuracy were 63.64% (PSD), 66.70% (CFC_W) and 68.94% (CFC_S) respectively. Statistical test (Wilcoxon signed rank test) revealed that using multi-frequency information, especially CFC_S, outperforms than conventional PSD method by showing $p = 0.0203$. We conclude that our proposed method will contribute to brain state classification in a single channel data.

Title: A statistical approach to the dynamic analysis of synchronous spiking in neuronal ensembles

Authors: *S. MUKHERJEE[1], K. M. O'NEILL[2], B. L. FIRESTEIN[4], W. LOSERT[3,2], B. BABADI[1];
[1]Dept. of Electrical and Computer Engin., [2]Inst. Phys Sci. & Tech., [3]Dept. of Physics, Univ. of Maryland, College Park, MD; [4]Dept Cell Biol Neurosci, Rutgers Univ., Piscataway, NJ

Abstract: Neuronal synchrony in circuits is well-documented to occur across many areas of the brain and is closely linked to memory and learning. Characterizing synchrony has largely consisted of correlational analyses of smoothed spike trains, but more recent work has utilized likelihood models of spike train data. Existing likelihood methods use either of the two following approaches. The first approach uses spiking statistics from repeated trials to capture dynamics in synchronous spiking. The second uses spiking statistics from a single trial to fit a static multinomial Generalized Linear Model (mGLM) that characterizes the rates of all possible higher-order interactions.
While the former approach can capture dynamics in synchrony, it is developed for settings where multiple repeated trials are available and assumed to be identical. Furthermore, limiting assumptions on the relevant higher-order interactions are required to solve the problem tractably in practice. Conversely, the latter approach can characterize all higher-order interactions in a single trial but assumes that the underlying model is static and lacks an accompanying statistical framework.
To address these limitations, we propose an algorithm that dynamically identifies synchrony of any order based on spiking statistics of a single trial. Adapting recent theoretical results related to Adaptive Granger Causality (AGC) analysis, we also provide a precise statistical inference framework for dynamically quantifying the significance of synchronous activity in an ensemble of spiking neurons. In simulation studies, we demonstrate the utility of our algorithm in tracking synchronous behavior of an ensemble with statistical confidence. Applying our algorithm to microelectrode array data from general anesthesia and *in vitro* hippocampal cell cultures reveals unique information about the function of the underlying networks.

Title: Using machine learning techniques and ground-based analogs of inflight stress to assess effects of space exploration on brain function

Authors: *H. YOON[1], A. KHAN[2], L. D. SANFORD[3], L. L. WELLMAN[3], B. L. WILLIAMS[3], R. A. BRITTEN[4];
[1]Neural Engin. Lab., [2]Norfolk State Univ., Norfolk, VA; [3]Div. of Anat, Dept of Pathol & Anat, [4]Dept of Radiation Oncology, Eastern Virginia Med. Sch., Norfolk, VA

Abstract: Potential neurocognitive impairments and associated neural structural alterations are a great concern for any deep space mission, especially the planned mission to Mars where astronauts may spend several hundred days on the planet before returning to Earth. While the effects of inflight stress, radiation and microgravity on central nervous system function in prolonged missions have been examined, their mechanisms are largely unknown. The aim of this study was to use depth electrodes and multichannel data acquisition systems to assess how neural network activity is altered during exposure to ground-based models of space-flight stressors. Neurophysiological signals from various regions in the rat brain were recorded and collected signals were preprocessed to remove artifacts using Independent Component Analysis (ICA). By applying Hilbert transform to the signals, directionality and time lag of local field potentials were identified. An unsupervised machine learning algorithm will be introduced that can analyze brain function and the impact of space-related stressors without requiring or incorporating prior knowledge of underlying brain activity patterns.

Title: Determining the number of states in dynamic functional network connectivity using cluster validity indexes

Authors: *M. S. SALMAN[1], V. M. VERGARA[1], A. ABROL[2], V. CALHOUN[1];
[1]The Mind Res. Network, Albuquerque, NM; [2]Dept. of Psychology, Georgia State Univ., Atlanta, GA

Abstract: Background: The functional network connectivity (FNC) in the human brain demonstrate temporally dynamic behavior. The reoccurring patterns of temporal activity, or states, can be identified using clustering analysis. Due to the high dimensionality and noisy nature of the dynamic FNC (dFNC), it is difficult to determine the number of clusters or states in the data.
Methods: In this work we examine the use of several clustering validity indexes (CVIs) for determining the number of states. The Davies-Bouldin index (Davies & Bouldin, 1979), McClain-Rao index (McClain & Rao, 1975) and Ray-Turi index (Ray & Turi, 1999) are based on the ratio of within-cluster and between-cluster distances among the data points and the cluster centroids, whereas the SD index is based on the scattering (S) within clusters and the dispersion (D) between clusters (Halkidi et al., 2001). The number of clusters in a certain dataset for which it results in the minimum index value for any of these, indicates the optimal number of states in the dataset. The subjects for the current experiment have been previously used to study the replication of time-varying connectivity patterns (Abrol et al., 2017). 7000 subjects were divided into 28 equal age-matched folds. The dFNC was estimated for each subject using the averaging sliding window correlation (ASWC) method and for five different window lengths between 10-50 seconds (Vergara et al., 2019). Finally, the CVIs were estimated from the dFNC data of each fold.
Results: Fig. 1(A) shows the mean of the CVI values computed across 28 groups for number of clusters (K) between 3 and 8 and for different sliding window sizes. All subfigures indicate minimum CVI values for K=4. Fig. 1(B) presents a bar plot of the number of times each index estimated a K between 3 and 8 as optimal. Fig. 1(C) depicts the average dFNC in 4 different states as surface maps. The results clearly indicate the presence of 4 states in the data.
Conclusion: We demonstrate that the above indexes deliver a unique discrete response to provide robust automated selection of the number of states in dFNC analysis.

Title: Deep learning to extract single-trial trajectories from two-photon calcium imaging

Authors: *R. TANDON[1], H. GRIER[2], M. T. KAUFMAN[2], C. PANDARINATH[1,3];

Abstract: Activity can be monitored from vast numbers of neurons with two-photon (2P) calcium imaging. However, a tradeoff with this technique is that sampling larger volumes in space permits less frequent sampling of each neuron in time. This is a critical limitation: it is vital to sample different cortical layers and areas, since they perform different processing, yet activity changes on fast time scales. A potential solution comes from findings that activity in cortical circuits changes in coordinated ways across neurons. If activity of a given neuron can be inferred from activity of spatially-distant neurons, then reducing the sampling frequency for each neuron should be possible with minimal loss. Here, we tested whether modeling the low-dimensional dynamics of a neural population, using a subset of neurons, could enable recovering activity in other neurons. We used a publicly available 2P dataset from mouse Anterior Lateral Motor cortex (ALM; Li, Chen et al., Nature 2015) in which 145 neurons were simultaneously imaged. To uncover the population's dynamics, we used Latent Factor Analysis via Dynamical Systems (LFADS; Pandarinath et al., Nature Methods 2018), a deep learning approach that uses artificial recurrent neural networks to uncover nonlinear dynamics from high-dimensional data in an unsupervised manner. We divided the imaged plane into two sections and used LFADS to infer single-trial latent dynamics from one half (76 neurons). The single-trial activity of the 69 held-out neurons - half the field of view - could be reconstructed from the inferred dynamics with high fidelity. In these reconstructions it was generally apparent whether the trial involved a left vs. right lick, even though this information was never provided to LFADS. These results demonstrate that single-trial dynamics can be captured in calcium imaging of mouse motor cortex during behavior, and that high-resolution temporal sampling of each neuron is not necessary in order to precisely capture their activity. These results lay the groundwork for sampling massive numbers of neurons without sacrificing temporal resolution, and pave the way for trial-by-trial understanding of motor activity in a system where cell types and layers can be readily identified.

Title: Null-space based sampling of brain networks

Authors: *A. NANDA, M. RUBINOV;
Vanderbilt Univ., Nashville, TN

Abstract: Much of network neuroscience is devoted to applying graph theory methods to analyze structural and functional neuroimaging datasets. Statistically principled modeling of these datasets represents a cornerstone of this field. Such modeling consists of two main steps: 1) the specification of constraints based on existing neuroscientific knowledge and obtained from empirical data, and 2) the sampling of networks that satisfy these empirical constraints.
The sampling of networks with arbitrary constraints is, in general, an NP-hard problem that has no known polynomial-time solution. Current network-science approaches to such sampling fall into two general types: 1) The so-called grand-canonical methods, which include analytic approaches based on maximum-likelihood maximization. These methods are fast but can sample networks in a way which only satisfies the imposed constraints in the ensemble average and which do not satisfy nonlinear constraints (such as correlations between timeseries). 2) The so-called microcanonical methods, which include numerical randomization approaches based on simulated annealing. These methods sample individual networks with exactly satisfied linear and nonlinear constraints, but are often slow.
There thus exists the need for a fast method that can sample networks exactly with linear and nonlinear constraints. Here we describe a "null-space" based sampling method that satisfies these criteria. This method consists of two steps. In the first step, we represent empirical constraints as an underdetermined set of equations with the weights of the network as variables. In the second step, we use the null-space of the coefficient matrix to sample networks accurately and with orders of magnitude faster than simulated annealing. We apply this method to study constraints associated with dynamic functional connectivity, as measured with resting-state functional MRI. We sample time-series with constrained correlations between brain regions and module averaged time-series and the global signal, and compare module partitions of the time-varying connectivity of the sampled and empirical data. Our results show that differences in node-to-module correlations capture substantially, but not completely, properties of time-varying connectivity. The speed and accuracy of our method allows it to be applied to a wide range of datasets, to answer a range of network neuroscientific questions. The combined strengths of this method fill a gap in the current repertoire of techniques for statistical modeling of neuroscience networks and timeseries.

Title: Deep learning convolutional networks for segmenting vasculature in multiphoton microscopy images

Authors: *C. T. POON[1], P. TEIKARI[2], K. HYNYNEN[3];
[1]Sunnybrook Hlth. Sci. Ctr., Toronto, ON, Canada; [2]Visual Neurosciences Group, Singapore Eye Res. Inst., Singapore, Singapore; [3]Med. Biophysics / Physical Sci., Univ. of Toronto / Sunnybrook Res. Inst., Toronto, ON, Canada

Abstract: Background: Despite advances in deep learning networks for segmentation of 3D medical images, networks for vasculature segmentation in basic science images, particularly volumetric multiphoton microscopy image stacks, remain sparse. Current standards for segmenting vasculature in multiphoton microscopy images require semi-automated 3D vasculature reconstruction, followed by manual annotation of vasculature types. Reproducible vasculature segmentation methods would facilitate easier, faster, and more subjective quantitative analyses of image stacks. We are particularly interested in vasculature segmentation to better understand focused ultrasound and microbubble (FUS+MB) treatments to increase the permeability of the blood-brain barrier. The change in barrier permeability poses a challenge in vasculature segmentation, as the fluorescent dye used to label vasculature leaks into the extravascular space during treatment. We demonstrate the use of our network to predict the type and characteristics of blood vessels that are more sensitive to FUS+MB treatments.
Rationale: To develop a deep convolutional network for volumetric vasculature segmentation in multiphoton microscopy images. We hope that our network will be easily used by others in the multiphoton microscopy field to analyze their datasets.
Methods: All multiphoton image stacks were taken using a FV1000MPE multiphoton laser scanning microscope (Olympus Corp., Japan) with an InSight DS tunable laser (Spectra-Physics, USA), and 25x water-immersion objective lens (XLPLN25XWMP2, NA 1.05, Olympus Corp., Japan). Brain and tumor vasculature were visualized by intravenous injection of Texas Red (70 kDa) or fluorescein (70 kDa) dextran. Our deep learning network consisted of 2D and 3D convolutional filters, derived from the ZNN framework designed by Lee *et al.* for electron microscopy image segmentation (arXiv:1508.04843).
Results: Using the Average Hausdorff Distance (AVD) as a performance metric, we find that VD2D3D ("Very Deep 2D-3D") provides a reasonable segmentation of volumetric multiphoton image stacks of vasculature.
Conclusion: We demonstrate the development of a deep convolutional network based on convolutional filters that yields reasonable segmentation of multiphoton fluorescence image stacks of brain and tumor vasculature that is less time-intensive and more objective than current semi-automatic gold standards.
