Title: Investigating the role of MAPK and AKT pathways downstream of Shp2 signaling in oligodendrocyte progenitor cell generation in the telencephalon

Authors: *R. R. WACLAW[1], V. KOHLI[1], D. NARDINI[1], B. DASGUPTA[2], L. EHRMAN[1]; [1]Cancer Biol. and Neural Tumors Program, Exp. Hematology and Cancer Biol., [2]Div. of Oncology, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Shp2 (PTPN11) is a non-receptor protein tyrosine phosphatase that has been implicated in several signaling pathways including the MAPK and AKT pathways. Multiple lines of evidence suggest that Shp2 plays a key role in oligodendrocyte development. However, the downstream mechanisms of Shp2 signaling that drive these crucial functions in oligodendrocytes remain largely unknown. We are using mouse genetics to understand the role of Shp2 signaling during oligodendrocyte progenitor cell (OPC) development in the ventral telencephalon. Loss of Shp2 protein in the *Olig2* lineage (*Shp2* cKO generated with $Olig2^{cre/+}$) results in severe reductions of OPC markers (Pdgfra, Olig1, and Olig2) in the parenchyma of the ventral telencephalon. Interestingly, the expression of progenitor cell markers in the medial ganglionic eminence (MGE) and preoptic area (POA) (Nkx2.1, Olig2, Zfp536, and Prox1) are unchanged in *Shp2* cKOs, suggesting a specific role for Shp2 in the generation of parenchyma OPCs. To understand the role of MAPK signaling downstream of Shp2, we generated Shp2 cKOs that also express a cre inducible constitutively active MEK1 from the *Rosa26* gene. Increasing MAPK signaling after loss of Shp2 improves OPC marker expression in the ventral telencephalon but the distribution of OPCs remained abnormal with accumulation of OPC marker positive cells near the MGE/POA. To understand the role of AKT signaling downstream of Shp2, we deleted the AKT negative regulator, PTEN in *Shp2* cKOs (*Shp2;PTEN* double cKO) . The loss of PTEN results in a hyperactivation of the AKT pathway in both control and *Shp2* ckO embryos but did not improve OPC marker expression in the Shp2 cKO ventral telencephalon. Our results suggest that the MAPK pathway and not the AKT pathway play a major role in the OPC phenotype in Shp2 cKOs. However, since Shp2 cKO are not completely rescued after increasing MEK1 activity, Shp2 likely regulates OPC development in a MAPK-dependent and -independent manner. Future experiments are focused on determining the relationship of these two pathways downstream of abnormal Shp2 signaling via RASopathy mutations and identifying additional pathways influenced by altered Shp2 protein function.

Title: Stage-dependent functions of the wnt effector tcf7l2 mediated by interaction with distinct partners control oligodendrocyte lineage progression

Authors: ***C. ZHAO**[1], Y. DENG[1], W. LIU[3], Q. LU[2];
[1]Brian Tumor Center, Cancer & Blood Dis. Inst., [2]Cincinnati Children'S Hosp. Med. Ctr., Cincinnati, OH; [3]Dept. of Pediatrics, State Key Lab. of Biotherapy Collaborative Innovation Ctr. for Biotherapy, West China Second Hosp. Sichuan Univ., Chengdu, China

Abstract: Constitutive activation of Wnt/β-catenin signaling inhibits oligodendrocyte myelination. However, specific deletion in oligodendrocyte lineage shows that Tcf7l2/Tcf4, a DNA-binding transcriptional partner of β-catenin, is required for oligodendrocyte differentiation. How Tcf7l2 modifies β-catenin signaling over development to facilitate myelination processes remains elusive. Here we show that Tcf7l2 interacts with distinct co-regulators other than β-catenin during oligodendrocyte lineage progression. Integrative analysis of genomic occupancy and gene expression profiling reveals that Tcf7l2 interacts sequentially with a competitive inhibitor of β-catenin binding, Kaiso/Zbtb33, and a differentiation-promoting factor, Sox10, to repress wnt gene eanpression and initiate and sustain myelin gene expression, respectively. We further reveal that Tcf7l2 cooperates with Sox10 to activate the genes encoding enzymes for cholesterol biosynthesis by directly targeting their proximal promoters/enhancers. Mice lacking the Tcf7l2 DNA-binding domain exhibit defects in myelination and remyelination after demyelination. Cholesterol supplementation can partially rescue differentiation defects of Tcf7l2-mutant oligodendrocyte precursors both *in vitro* and *in vivo*. Together, our studies identify Tcf7l2-regulated transcriptional switches that promote oligodendrocyte lineage differentiation, indicating a crucial role of Tcf7l2 for metabolic control of CNS myelination.

Abstract: Rapid electrical conduction in the vertebrate central nervous system (CNS) relies upon myelination of particular subsets of axons. However, the underlying mechanisms that orchestrate this process remain poorly defined. We have investigated how myelinating oligodendrocytes establish their unique topographical arrangement within white matter during early postnatal brain development. Linear arrays of glial cell somata occur in all white matter tracts throughout the CNS. These structures are characterised by the tandem alignment of glial cell bodies along the axonal axis. We demonstrate that linear arrays of cells in the corpus callosum appear before the onset of myelination of this white matter tract. Throughout postnatal ontogeny they continue to be generated and increase in size. Oligodendroglial lineage cells represent between 60-70% of all cells within linear arrays, irrespective of postnatal age, and the proportion of mature oligodendrocytes increases with age. By using Cre-lox fate mapping in transgenic mice, we demonstrate that different oligodendrocyte populations from the medial ganglionic eminence and the anterior entopeduncular area are responsible for forming intermixed as well as homogeneous linear arrays. Additional characterisation using hemizygous female mice carrying an X-linked β-galactosidase gene revealed that clonal expansion also contributes to the formation of linear arrays. Increasing the activity of subsets of transcallosal axons that project from the developing somatosensory cortex increased the generation of linear arrays. By contrast, cuprizone challenge in adult mice abolished linear arrays in the caudal corpus callosum and arrays were only partially regenerated by 7 weeks after cuprizone withdrawal. Collectively, our data provide new insights into the cellular dynamics underlying the generation of oligodendrocyte topography during normal development and ageing. Modulating electrical activity or inducing de/remyelination alters the juxtapositioning of oligodendrocyte cell bodies within white matter and could have important implications for how myelin internodes are organised in space.

Title: Oligodendrocyte differentiation deficits induced by oxidative stress are not rescued by monomethyl fumarate (mmf), the active metabolite of an ms therapeutic

Authors: *B. K. JENSEN[1], K. L. JORDAN-SCIUTTO[2], J. B. GRINSPAN[3];
[1]Perelman Sch. of Med., [2]Sch. of Dent. Med., Univ. of Pennsylvania, Philadelphia, PA; [3]Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Precipitating events leading to autoimmune targeting of myelin in MS patients are not understood. Despite this unknown etiology, consistent pathological observations are chronic oxidative stress and inflammation, which are the main focus of therapies. The drug Tecfidera (BG-12) is widely thought to act as an antioxidant, and has been shown to reduce oxidative stress through transcription factor Nrf2-mediated activation of the endogenous antioxidant response (EAR) and upregulation of target genes in neurons and macrophages. However, the mechanism by which this drug reduces MS relapse rates has not been established. Tecfidera is composed of dimethyl fumarate, which is rapidly metabolized to monomethyl fumarate (MMF). The effects of MMF on the affected cell population of oligodendrocytes (OLs) have not been examined. Effective MS therapy will require both prevention of further myelin loss and promotion of re-myelination through differentiation and maturation of brain-resident OL precursor cells (OPCs). We have previously demonstrated that oxidative stress can halt OL differentiation. We have also shown that MMF can attenuate oxidative stress-induced neurotoxicity through Nrf2-mediated EAR upregulation. The goal of the present study was to investigate whether MMF can reduce oxidative stress, upregulate the EAR, and reverse stress-induced deficits in OL differentiation. Using our primary culture system, we have shown that oxidant tert-Butyl hydroperoxide induces

reactive oxygen species (ROS) accumulation in both OPCs and mature OLs. Oxidant treatment over a 72hr differentiation period led to significant reduction in maturation by immunofluorescent staining of stage-specific markers, and reduction in myelin proteins by immunoblotting. MMF applied to cultures prior to insult significantly reduced ROS accumulation induced by multiple oxidants. Unexpectedly, this did not coincide with upregulation of EAR target genes. MMF treatment also did not rescue maturation defects induced by oxidants, as comparable significant decreases were evident in oxidant alone and oxidant+ MMF conditions. Our findings suggest that the EAR is not activated under conditions of oxidative stress in OLs to restore redox homeostasis. Additionally, while MMF prevents ROS accumulation, it also does so without EAR pathway activation and is not effective at rescuing oxidative-stress induced differentiation deficits. Therefore, it is likely that the therapeutic effect of MMF in MS patients is due to alternate anti-inflammatory pathway actions, or through upregulation of EAR proteins in other cell types which act cell non-autonomously to provide protection to mature OLs.

Title: Phosphorylation state of ZFP191 regulates maturation of late-stage oligodendrocytes

Authors: ***B. ELBAZ**, J. D. AAKER, B. POPKO;
Dept. of Neurol., Univ. of Chicago, Chicago, IL

Abstract: Myelin is a multilayered membrane that wraps axons. It provides protection to the axons and allows for the rapid conduction of action potentials along the nerves. In the brain and spinal cord (central nervous system), myelin is formed by oligodendrocytes. Previous work from our laboratory demonstrated that ZFP191 is critical for CNS myelination: *Zfp191* null mutants are severely hypomyelinated despite the presence of normal numbers of mature oligodendrocytes (Howng et al., 2010 Genes Dev 24(3):301-311). Our current results demonstrate that the phosphorylation state of ZFP191 changes as oligodendrocytes mature from their progenitors. In oligodendrocyte progenitor cells, the majority of the protein is phosphorylated, but as the cells differentiate to mature myelinating oligodendrocytes, the non-phosphorylated form of ZFP191 accumulates. We have also identified the DNA motif to which ZFP191 binds, and strikingly, we

have detected binding sites in proximity to several genes that are crucial for maturation of oligodendrocytes. Moreover, our data shows that the changes in ZFP191 phosphorylation state results in changes in ZFP191 DNA binding capability: non-phosphorylated ZFP191 has a greater capacity to bind its target DNA sequence than does the phosphorylated form. Based on these finding we have used site direct mutagenesis to demonstrate that only a mutant that resembles the non-phosphorylated form of ZFP191 was able induce oligodendrocytes maturation. Based on our results we suggest that changes in the phosphorylation state of ZFP191 control the maturation of oligodendrocyte lineage cells and the potential of oligodendrocytes to myelinate axons. Importantly, this provides a new potential target for intervention to enhance myelination and remyelination.

Title: FGF-2 signal promotes the proliferation of cerebellar progenitor cells and their oligodendrocytic differentiation at early postnatal stage

Authors: *M. NARUSE, K. SHIBASAKI, Y. ISHIZAKI;
Dept. of Mol. and Cell. Neurobiology,, Gunma Univ. Grad. Sch. of Med., Gunma, Japan

Abstract: The origin and the developmental regulation of cerebellar oligodendrocytes are largely unknown, and several origins of cerebellar oligodendrocytes at embryonic stages were suggested. It is also known that neural stem cells exist in the white matter of postnatal cerebellum, though it is unclear whether these neural stem cells generate oligodendrocytes at postnatal stages. We showed previously that CD44 is expressed by cerebellar cells including neural stem cells at around postnatal day 3. CD44-positive cells prepared from postnatal day 3 cerebellum gave rise to neurospheres, while CD44-negative cells prepared from the same cerebellum did not. These neurospheres differentiated mainly into oligodendrocytes and astrocytes, suggesting that CD44-positive cells might generate oligodendrocytes in postnatal cerebellum. We cultured CD44-positive cells from postnatal day 3 cerebellum in the presence of several signaling molecules known as mitogens or inductive differentiation factors for oligodendrocyte progenitor cells. Of these, only FGF-2 promoted survival and proliferation of CD44-positive cells, and these cells differentiated into O4+ oligodendrocytes. Furthermore, we

examined the effect of FGF-2 on cerebellar oligodendrocyte development *ex vivo*. FGF-2 enhanced proliferation of oligodendrocyte progenitor cells and increased the number of O4+ and CC1+ oligodendrocytes in slice culture. These results suggest that CD44-positive cells might be a source of cerebellar oligodendrocytes and that FGF-2 plays important roles in their development at early postnatal stage.

Title: *In vivo* role of p38alpha mitogen activated protein kinase in oligodendrocyte development and myelination

Authors: *S. CHUNG[1], S. BISWAS[2], J. SOHN[3], P. JIANG[2], C. CHEN[2], F. CHMILEWSKY[1], W. AYAZ[1], H. MARZBAN[4], W. DENG[2];

Abstract: The mitogen-activated protein kinases (MAPK) belong to the family of serine/threonine protein kinases that allow cells to respond to stimuli received from their extracellular environment including mitogens as well as to intracellular stress. Previous *in vitro* studies using p38 inhibitors suggested that p38α MAPK is required for myelination and oligodendrocyte (OL) differentiation. The proper development of OL and myelination is essential for maintaining the efficiency and speed of electrical nerve impulse. In an effort to identify the specific roles of p38α in myelination during early postnatal development, we have bred p38α-floxed mice with NG2 or PLP-cre mice to generate homozygous conditional NG2/Plp-specific p38α conditional knockout (CKO) mice for the first time. Our main finding was that, although a myelination phenotype was not evident at a gross level, there were several myelination defects at the ultra-structural level. Specifically, myelin bundles in the corpus callosum failed to develop normally, and there was a delayed onset of myelination in the corpus callosum. These defects could be partly due to a delay in OL differentiation during postnatal development since OL progenitor cell (OPC) proliferation remained normal in these knockout mice. This was supported by our observation that gene expression levels of several critical transcription factors of OPC maturation such as Olig1, Zfp488, and the OPC marker NG2 were significantly downregulated during early neonatal development in these knockout mice. Additionally, similar to previous reports, an inherent myelination defect was apparent in the

primary OPCs isolated from p38α CKO mouse brains. These OPCs failed to synthesize MBP when differentiated *in vitro*. These data indicate that p38α MAPK is as an important regulator of positive effectors of OL differentiation and myelination progression. Taken together, present study suggests p38α MAPK as a key regulator in OL development and myelination process in the CNS.

Title: The role of histone methyltransferase Ezh2 in oligodendrocyte progenitor cell proliferation and differentiation

Authors: *K. PATEL[1], J. LIU[2], S. MOYON[2], P. CASACCIA[2], A. NISHIYAMA[1]; [1]Dept. of Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT; [2]Dept. of Neurosci. and Dept. of Genet., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Oligodendrocyte progenitor cells (OPCs, NG2 cells, polydendrocytes) continue to proliferate and differentiate into adulthood. The mechanisms underlying the decision to proliferate and self-renew or differentiate into mature oligodendrocytes are not completely understood. Histone methylation is a posttranslational modification that has been shown to control cell fate by regulating transcription in various stem and progenitor cell types. We examined the role of trimethylation of lysine 27 on histone H3 (H3K27me3) in regulating OPC proliferation and differentiation. Comparison of the intensity of immunofluorescence labeling for H3K27me3 in oligodendrocyte lineage cells revealed that H3K27me3 in premyelinating oligodendrocytes is 5.4-fold higher than that in OPCs and 4.6-fold higher than that in mature oligodendrocytes, suggesting a role for H3K27me3 in cell cycle exit or the maturation of oligodendrocytes. This was further examined in Ezh2 conditional knockout mice (cko) provided by Dr. Yukiko Gotoh (Tokyo, Japan). The H3K27me3 modification is catalyzed by Ezh2, a component of the polycomb repressive complex 2 that induces chromatin compaction, thereby repressing transcription of target genes. When Ezh2 was deleted in OPCs perinatally, the proportion of Ezh2-deleted OPCs in the corpus callosum that incorporated the thymidine analog EDU (5-ethynyl-2'-deoxyuridine) was 10-fold lower than the proportion of Ezh2+ OPCs in control mice. Additionally 5 days after Cre induction, 1% of the Ezh2-deleted cells in the corpus

callosum of cko mice had differentiated into CC1+ oligodendrocytes, while 51% of induced cells were CC1+ in control mice. At 11 days after Cre induction, 52.1% of Ezh2-deleted cells had become CC1+, which was significantly lower than in the control mice where 72.2% of the induced cells had become CC1+. These data suggest that Ezh2 regulates both OPC proliferation and the timing of oligodendrocyte differentiation. We are currently quantifying the effects of Ezh2 deletion on the repair of acutely demyelinated lesions and analyzing the Ezh2 target genes affected by Ezh2 deletion.

Title: Signaling pathways underlying Neurobasal-A medium-promoted oligodendrocyte differentiation from human neural stem cells

Authors: *P. WU[1], L. WANG[1,2], J. GAO[1], Y. HAO[1,3], T. DUNN[1], E. MCGRATH[1], J. ALLENDE LABASTIDA[1], S.-Q. FENG[3], S.-Y. LIU[2];
[1]Dept Neurosci/Cell Biol, UTMB, Galveston, TX; [2]Sun Yat-sen Univ., Guangzhou, China; [3]Tianjin Med. Univ. Gen. Hosp., Tianjin, China

Abstract: Remyelination, important for neurotrauma and demyelination diseases, may restore myelin to denuded axons through the generation of oligodendrocytes (OL) from oligodendrocyte progenitor cells (OPCs). To obtain more OL lineage cells, different strategies for induction of OL lineage differentiation from neural stem cells (NSCs) have been reported previously. However, molecular mechanisms underlying NSC differentiation into OPCs are complex and still remain largely unknown. Recently we found that the Neurobasal medium (NB), but not the regular NSC cultivating medium [Dulbecco's Modified Eagle Medium with F12 (DF)], induced human fetal forebrain-derived NSCs toward the $O4^+$ OPC differentiation, To investigate the underlying mechanisms, we used several methods such as real time RT-PCR (RT^2-PCR), Western Blotting, and immunofluorescence staining. RT^2-PCR confirmed that the levels of the

OPC-related transcription factors Olig2 and Nkx2.2 were significantly different between NB and DF groups. An initial protein phosphorylation array screening revealed NB-mediated activation of several signaling molecules, including Akt, extracellular signal-regulated kinases (ERK1/2), and c-Src. Western blot analyses further confirmed that phosphorylation levels of ERK1/2 and Akt were increased during NB cultivation and sustained throughout the subsequent FGF priming procedure to promote OPC differentiation. On the other hand, c-Src phosphorylation was increased only temporarily during NB culturing. Inhibitors of PI3K/Akt (LY294002), ERK1/2 (U0126), and c-Src (Saracatinib) were confirmed for their activities to reduce protein phosphorylation. Interestingly, c-Src inhibition within a specific time window during priming increased the O4-positive OPCs, whereas inhibition of Akt and ERK1/2 decreased OPCs. This study suggested that sustained activation of ERK and PI3K/Akt pathways were required for NB-mediated oligodendrocyte differentiation, whereas c-Src activation was restricted in a narrow time window for induction of hNSC differentiation into the oligodendrocyte lineage.

Title: Mir-212 regulates glial differentiation and maturation

Authors: *S.-F. TZENG;
Natl. Cheng Kung Univ., Tainan City, Taiwan

Abstract: Spinal cord injury (SCI) causes the death of spinal neural cells, the degeneration of spinal fibers degeneration and gliosis as well as demyelination. Change of gene expression by deregulated microRNAs (mir) is an emerging mechanism involved in neurodegeneration and neuroinflammation. Mir-212 has been reported to be highly expressed in neurons and involved in regulation of neuronal survival and BDNF expression. The role of mir-212 role in CNS glia is poorly understood. Our recent study showed that differential change in mir-212 level was detected during brain development. Moreover, mir-212 was reduced at the lesion site at 1 week and 1 month after moderate and severe SCI. In addition, *in situ* miRNA hybridization combined with immunohistochemistry indicated that mir-212 was not only highly expressed in spinal neurons, but also detected in oligodendrocytes and astrocytes in the white matter of the spinal cord. The downregulation of mir-212 level induced by interferon-γ (IFN-γ) were observed in

cultured astrocytes and oligodendrocytes derived from glial progenitor cells (GPCs). Furthermore, we found that the lentivirus-mediated overexpression of mir-212 suppressed the differentiation and maturation of oligodendrocytes derived from GPCs by examining the reduction in the complexity of cell processes and myelin sheath formation. The process number of astrocytes derived from GPCs was also decreased by mir-212 overexpression. The expression of inhibitor of DNA binding protein 2 (ID2), a potential mir-212 targets, was inhibited in GPCs and derived cells by mir-212 overexpression. Myelin basic protein that has been known to be regulated by ID2 through olig1/2 action was also downregulated in GPC-derived oligodendrocytes with mir-212 overexpression. Based on our findings, we suggest that mir-212 expression can be regulated by inflammatory cytokines, such as IFN-γ; moreover, mir-212 is required for the differentiation and maturation of oligodendrocytes from GPCs through the inhibition of the expression of their target molecules, such as ID2.

Title: Ampa receptor inhibition promotes myelination in preterm rabbits with intraventricular hemorrhage

Authors: *P. BALLABH, P. DOHARE, G. VINUKONDA;
Pediatrics, Cell Bio & Anat., New York Med. Coll, Valhalla, NY

Abstract: Intraventricular hemorrhage (IVH) is the most common neurological disorder of premature infants and is an important cause of white matter injury in this population. Glutamate excito-toxicity, mediated by AMPA type glutamate receptor, damages oligodendrocytes in animal models of neonatal hypoxia-ischemia and multiple sclerosis. Accordingly, inhibition of AMPA receptors enhances remyelination in adult models of brain injury. JAK-STAT signaling are important mediators of inflammation and STAT3 inhibition represses inflammation as well as offers neuroprotection. Therefore, we hypothesized that IVH would result in distinct changes in the expression of AMPA receptors and that AMPA receptor inhibition might promote myelination and clinical recovery in preterm rabbit pups with IVH. We also postulated that AMPA receptor inhibition would reduce inflammation and oligodendrocyte cell death, and that the effect would be mediated by Stat-3 signaling. To test our hypotheses, we employed preterm rabbit (E29, Term=32d) model of glycerol-induced IVH and autopsy samples from preterm

infants (23-26 gestational weeks). To inhibit AMPA receptors, rabbit pups with IVH were treated with intramuscular NBQX (15 mg/kg twice a day, i.p.) for 5 days; and intramuscular AG490 was used to inhibit JAK-STAT signaling. We found that GluR1-4 expression was comparable between human infants and rabbits with and without IVH on immunohistochemistry and Western blot analyses. NBQX treatment significantly increased myelin basic protein (MBP) expression in pups with IVH compared to vehicle controls on both Western blot analyses and stereological quantification of immunostained sections at P14. Moreover, NBQX treatment significantly increased myelin associated glycoprotein (MAG) and CNPase levels, but did not affect the GFAP levels in pups with IVH. The mRNA levels of TNFα, IL1β, IL-6, Leukemia inhibiting factor, Ciliary neurotrophic factor, density of TUNEL+Olig2+ oligodendrocytes, Iba1+ microglia cells, and phophoStat3 levels were significantly elevated in rabbits with IVH compared to controls without IVH and substantially reduced in NBQX-treated pups with IVH compared to vehicle controls at P 3 ($P < 0.05$, n=5 each). STAT3 inhibition inhibition reduced the density of Iba1+ and TUNEL+ cells at P3. Our data suggested that NBQX treatment suppressed oligodendrocyte death and inflammation in pups with IVH, which was mediated by STAT-3 signaling. More importantly, NBQX therapy enhanced myelination and clinical recovery in rabbit pups with IVH. We speculate that AMPA receptor inhibition might improve the outcome of survivors with IVH.

Title: Sox17-mediated oligodendrocyte regeneration and protection involves coordinated stage-specific alterations in Hedgehog and Wnt signaling

Authors: *L.-J. CHEW[1], X. MING[1], J. DUPREE[2], V. GALLO[1];
[1]Ctr. Neurosci Res., Children's Res. Inst., Washington, DC; [2]Virginia Commonwealth Univ., Richmond, VA

Abstract: We have shown that Sox17 overexpression in CNP-Sox17 transgenic mice promotes postnatal oligodendrocyte (OL) development and prevents OL loss after focal lysolecithin (Lyso)

demyelination. Our present studies indicate that oligodendrocyte regeneration and attenuated cell death by Sox17 overexpression in the adult white matter (WM) are mediated by alterations in canonical Wnt and Hedgehog signaling. In addition to increased nascent generation of OLs, Sox17 reduced microglial and astrocyte activation compared with WT, and attenuated the loss of O4+ cells following cuprizone demyelination. Despite a larger NG2+ OPC population in the intact CNPSox17 mouse, demyelination did not induce an increase in NG2+ OPCs greater than that in WT; instead it increased O4 and CC1 cells, indicating enhanced differentiation. Sox17 also inhibited b-catenin activation by LYSO, evidenced by unchanged levels of activated b-catenin (ABC). Stereotaxic injections of the b-cat antagonist CCT036477 (CCT) into the adult corpus callosum showed that while ABC+ cells were reduced in both strains, CCT specifically increased O4+ cells only in WT, while it decreased NG2+ and CC1+ cells without affecting O4+ cells in the CNPSox17 WM. This indicates that b-catenin functions as an inhibitor of the O4+ cells in the WT, and that Sox17 abolished its inhibitory effect on the lineage. We analyzed whether CCT inhibition of ABC in WT WM would restore CC1 cells in LYSO lesions. Although CCT improved regeneration of CC1 OLs and reduced apoptosis in WT lesions, unlike lesions in CNPSox17, the numbers of CC1 cells remained significantly below levels in intact WT controls. This suggests additional signaling by Sox17. Since GLI2 was found to be selectively elevated by Sox17 in O4+ cells, we tested the possibility that Sox17 increased Hedgehog (HH) signaling to protect OLs and promote the generation of O4+ cells. Stereotaxic injection of the GLI antagonist GANT61 into corpus callosum indeed caused loss of MBP, and abolished Sox17-mediated protection in LYSO lesions. Increased density of Olig2+Sonic HH+ cells was detected in the intact CNPSox17 WM at P60, indicating autocrine signaling. Stereotaxic injection of the Smoothened antagonist cyclopamine-KAAD showed a reduction of NG2+ OPCs in the WT and O4+ cells in the CNPSox17, suggesting Sox17-mediated differentiation through Smoothened. Finally, stereotaxic injection of the Smoothened agonist SAG in WT WM restored to control levels O4 and CC1 cells in LYSO lesions and reduced ABC levels. Taken together, these studies support the notion that Sox17 promotes oligodendrocyte protection and regeneration by modulating HH and Wnt signaling in OPC development.

Title: Distinctions between fetal and adult human OPCs in miRNA-regulated gene expression

Authors: *N. J. KUYPERS[1], M. OSIPOVITCH[1,2], A. CORNWELL[1], D. CHANDLER-MILITELLO[1], S. SCHANZ[1], S. WANG[1], S. A. GOLDMAN[1,2];
[1]Ctr. for Translational Neuromedicine, Univ. of Rochester Med. Ctr., Rochester, NY; [2]Ctr. for Basic and Translational Neurosci., Univ. of Copenhagen, Copenhagen, Denmark

Abstract: Human fetal and adult oligodendrocyte progenitor cells (OPCs) differ in their cell cyclicity, migration and maturation rates and myelinogenic competence. To identify causal pathways underlying these differences, second trimester fetal human cortices (18-21 weeks g.a.) and adult temporal lobe samples (8-54 years old) were dissociated and respectively sorted on the basis of CD140a or A2B5 immunoreactivity. Total RNA was extracted, and the mRNA (RNAseq) and miRNA (microarray) profiles of each population were compared to one another. Differential expression was confirmed by Taqman low-density arrays and conventional qPCR. Of the 8 mature miRNAs enriched in adult OPCs, 5 displayed fold-change (FC) values greater than 4, which included the oligodendroglial miRNAs miR-219-2-3p (FC=48.8) and miR-338-5p (FC=13.6). Target prediction analysis suggested that these 5 miRNAs regulate the transition of fetal to adult OPCs by repressing the translation of key WNT signaling genes. In particular, a core set of WNT pathway components were down-regulated during the transition to adult OPC phenotype; these included FZD3 (FC=-7.4), FZD7 (FC=-7.7), FZD8 (FC=-3.6), BCL9 (FC=-2.3) and TCF7L2 (FC=-2.8). Their down-regulation as a group suggests that ß-catenin-dependent transcriptional activity might be suppressed accordingly. Additionally, expression of a number of protein tyrosine phosphatase receptors (PTPRB, PTPRD, PTPRH, PTPRM, PTPRR; FC range: 1.9-116.2), which can serve as negative regulators of ß-catenin-dependent signaling, increased sharply as OPCs transitioned to the adult state. In this regard, the oligodendroglial-specific cadherin 19 (CDH19; FC=333.1), which may sequester ß-catenin and further suppress the transcription of its dependent targets, was strongly upregulated with transition to adult OPC phenotype. Similarly, mRNA encoding the GSK3ß activator protocadherin 9 (PCDH9) increased concomitant with the transition to adult OPC phenotype (FC=8.6), thereby providing an additional mechanism by which ß-catenin-dependent transcription might be further reduced. Together, these results suggest the importance of miRNA-dependent suppression of ß-catenin signal competence during maturation of the oligodendroglial lineage, and with consolidation of the adult OPC phenotype.

Title: Dnmt3a regulates expression of myelin related genes during the differentiation of OPCs

Authors: X. CHEN, Y. WANG, *L. XIAO;
Dept. of Histology and Embryology, Third Military Med. Univ., Chongqing, China

Abstract: DNA methylation has been reported to impact brain development or neurodevelopment disorders by regulating genesis of neurons or astrocytes. It is however remains unclear the role of DNA methylation playing in oligodendroglial genesis? In this study, expression of Dnmt3a, one of the DNA methyltranferases (Dnmts) was observed during the differentiation of OPCs and myelination in OPC cultures and neonatal developing rat brains. The inhibitor (5'- AZA), agonist (methionine, Met), and Dnmt3a RNAi plasmid were used to observe the effect of Dnmt3a on the differentiation of OPCs, and methylated changes of myelin related genes by MeDIP-ChIP and BSP. Our results showed that Dnmt3a highly expressed in PDGFRa+ OPCs, and gradually decreased following the differentiation of OPCs. Methylated ratio of myelin genes such as Sox10, MBP and Olig1 genes increased in and the differentiation of OPCs delayed after Met treatment, which could be rescued by 5'- AZA or Dnmt3a RNAi. These results suggest that Dnmt3a mediates dynamic methylation of myelin related genes during the differentiation of OPCs.

Title: $S1P_1$ deficiency in oligodendroglial lineage cells: effect on differentiation and myelination

Authors: D. DUKALA, S. QUAN, *B. SOLIVEN;
Dept. of Neurol., Univ. of Chicago, Chicago, IL

Abstract: Sphingosine1-phosphate (S1P) receptors are G protein-coupled receptors expressed by many cell types, including cells of oligodendrocyte (OLG) lineage. We had previously shown that targeted deletion of *S1P1* in OLG lineage cells did not result in obvious clinical phenotype or altered number of OLGs at 3 months, but there were subtle abnormalities in myelin. In this study, we examined the role of $S1P_1$ in developmental myelination and cell survival, focusing on age 3 weeks. We found that $S1P_1$ deficiency led to delayed differentiation of OLG progenitors (OPCs) into OLGs that was independent of p38 phosphorylation. This was accompanied by decreased levels of myelin basic protein (MBP) but not of myelin-OLG glycoprotein (MOG), and slight decrease in myelin thickness in the corpus callosum of *S1P1* conditional knockout (CKO) mice. $S1P_1$-deficient OLGs exhibited slower process extension, which was associated with attenuated phosphorylation of extracellular signal regulated kinases (ERKs) and p21-activated kinases (PAKs), and with upregulation of tropomodulin1. Basal levels of pAkt were not affected, though expectedly, no response to a $S1P_1$ agonist SEW2871 was observed. $S1P_1$-deficient OLGs did not exhibit increased cell death in response to cuprizone, tumor necrosis factor-α, or deprivation of nutrients and growth factors. We conclude that $S1P_1$ signaling regulates OLG development, morphological maturation and early myelination.

Title: Endocannabinoid signaling in oligodendrocyte maturation and myelination

Authors: ***S. M. O'NEILL**, J. R. PIRO, K. MOU, T. A. SAMAD;
Neurosci. Res. Unit, Pfizer Neurosci. & Pain Res. Unit, Cambridge, MA

Abstract: Monoacylglycerol lipase (MAGL) is a serine hydrolase that breaks down the endocannabinoid 2-arachidonoylglycerol (2-AG). MAGL is expressed in neurons, oligodendrocytes, astrocytes, microglia, and endothelial cells in the brain. Inhibition of MAGL has been shown to be a promising therapeutic entry point for reducing pain, neuroinflammation, and neurodegenerative diseases. More recently, emerging data has suggested that MAGL inhibition reduces pathology in mouse models of multiple sclerosis such as experimental autoimmune encephalomyelitis and acute cuprizone treatment. However, the precise molecular mechanism(s) of 2-AG regulation of oligodendrocyte maturation and function has not yet been fully elucidated. In the present study, we examine whether 2-AG may exert its effects directly on immature and mature oligodendrocytes, or indirectly by acting on different cell types which then influence oligodendrocyte lineage cells. To assess the direct effects of 2-AG on oligodendrocyte

maturation and function we use a selective inhibitor of MAGL on primary oligodendrocyte precursor cells *in vitro*. We use a MAGL-deficient mouse as gain of function model of 2-AG signaling in the cuprizone model of demyelination, to assess oligodendrocyte markers and myelin levels *in vivo*. To assess indirect modulation of oligodendrocytes, we examined the effect of 2-AG signaling on activated astrocytes and microglia and the resulting modulation of oligodendrocyte maturation and survival in culture. Taken together, our data suggest a modulatory role for endocannabinoid signaling in oligodendrocyte physiology.

Title: White matter degeneration and aberrant oligodendrocyte differentiation during the progress of Alzheimer's disease

Authors: ***K. TSE**, A. CHENG, H.-M. CHOW, K. HERRUP;
The Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong

Abstract: White matter degeneration and demyelination are recognized, but little studied features of the Alzheimer's disease (AD) brain. Yet increasing evidence suggests that there is a significant association between the progress of AD pathology and the appearance of aberrant differentiation of the oligodendrocyte lineages that are the cellular antecedents of myelin formation. To explore this relationship, MRI data from healthy control, mild cognitive impairment (MCI) and AD subjects were obtained from the National Alzheimer's Coordinating Center (n = 507, mean age = 76.8 yr, female = 58.4%). The calculated MRI data of white matter and gray matter volume were analyzed using Spearman's correlation test. We augmented this human data with observations in R1.40 transgenic mice in which the entire human APP gene with the Swedish mutation is carried on a YAC insert that includes long stretches of both 3' and 5' regulatory sequences. Gene expression changes were investigated using real-time PCR, immunohistochemistry and western blotting. In the human MRI data, we find that the gray matter volume of the subjects is strongly reduced with the progress of dementia and correlates

with lower MMSE scores (R = 0.26). The reduction of the gray matter is correlated in turn with a reduction of the cerebral white matter volume (R = 0.58), especially in the temporal lobe. Moreover, the level of white matter hyperintensity, indicative of myelin lesions, increased with age in all groups, with the strongest correlation found in MCI (R = 0.48). In the R1.40 mice, we examined neocortex at 3 - 18 months of age and found high hAPP mRNA expression throughout the lifespan. As reported earlier, however, amyloid protein aggregates were only observed after 13.5 months. In the transgenic brains, levels of NG2 and PDGRFα mRNA (oligodendrocytes progenitors) as well as MBP and PLP1 (mature oligodendrocytes) were consistently higher than wild type littermates for the first 12 months. By 18 months, however, all of these oligodendrocyte markers declined to values lower than wild type. Consistently, a significant reduction of MBP protein was detected in the cortex of R1.40 at 12 months, despite the presence of abundant oligodendrocyte progenitors. White matter degeneration is a common feature of the aging population and it is highly associated with neurodegeneration in human AD. Such white matter lesions may be caused by the chronic toxicity of amyloid aggregates or inflammatory processes on the differentiation of the oligodendrocyte lineage and subsequent myelin deposition.

Title: Histone deacetylase 3 activates olig2 and suppresses jak-stat signaling to establish and maintain oligodendrocyte lineage progression

Authors: ***Z. LIGUO**, X. HE, L. LIU, M. JIANG, R. LU;
Brain tumor center, Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Abstract Establishment and maintenance of oligodendrocyte identity are a prerequisite for ensuring proper myelination and myelin repair after injury in the CNS, however, the molecular underpinnings of oligodendrocyte lineage commitment remain to be fully elucidated. Here, we show that the chromatin modifying enzyme Hdac3 activates the oligodendrocyte specification factor Olig2 to establish oligodendrocyte identity and functions as a molecular switch for oligodendrocyte and astrocyte lineage development. Hdac3 ablation in the progenitors of the oligodendrocyte lineage leads to severe myelination defects and striking ectopic generation of astroglia. Genome-wide targeting analysis reveals that Hdac3 coordinates with p300 acetyltransferase to control glial subtype-specific transcriptional programs. Furthermore, Hdac3 blocks the activity of Jak-Stat signaling by modulating Stat3 acetylation and

phosphorylation states to suppress astrogliogenesis. Thus, Hdac3 is a key priming factor of oligodendrocyte development by modulating both transcriptionally-linked chromatin remodeling events and Jak-Stat signaling activity to establish and maintain the oligodendrocyte lineage. These findings suggest that modulation of Hdac3 activity may represent a potential approach to suppress astrogliosis and promote remyelination after injury.

Title: The RNA binding protein QKI stabilizes SIRT2 transcripts and promotes SIRT2 expression during oligodendrogenesis

Authors: ***M. P. THANGARAJ**[1], J. R. DOUCETTE[2,3], S. JI[1,4], A. J. NAZARALI[1,3];
[1]Col. of Pharm. and Nutr., Univ. of Saskatchewan, Saskatoon, SK, Canada; [2]Anat. and Cell Biology., Univ. of Saskatchewan, Saskatoon, SK, Canada; [3]Cameco Multiple Sclerosis Neurosci. Res. Ctr., Saskatoon, SK, Canada; [4]Biochemistry, Univ. of Henan, Henan, China

Abstract: Oligodendrocytes (OLs) are the myelin forming glial cells, involved in the repair of the central nervous system (CNS) lesions in multiple sclerosis (MS). The cellular and molecular mechanisms that control remyelinating ability of OLs are still unclear. Sirtuin2 (SIRT2) is a class III NAD^+ dependent deacetylase that is predominantly expressed in OLs promoting process outgrowth and differentiation. However, the mechanism involved in regulating SIRT2 expression during oligodendrogial development is largely unknown. The RNA binding protein quaking (QKI) is known to regulate the expression of several myelin transcripts for normal OL development and myelination. Deletion of QKI in OLs results in severe hypomyelination in *quaking viable* (qk^v) mutant mice. Interestingly, SIRT2 protein is not expressed in qk^v mutant mice. However, whether QKI interacts directly with *Sirt2* mRNA during OL development and myelination is unknown. We have investigated the molecular mechanism by which QKI regulates SIRT2 expression during OL development. Prediction of QKI binding sites in the 3UTR of *Sirt2* mRNA revealed the presence of two quaking response elements (QREs). RNA co-immunoprecipitation experiments confirmed that QKI binds to all the three variants of *Sirt2* mRNA, implying that RNA binding of QKI plays role in stabilization of *Sirt2* transcripts. Consistent with this, mRNA stability assay showed that QKI binding stabilizes and protects *Sirt2* transcripts from degradation. QKI significantly increased the luciferase reporter activity of the

Sirt2 3UTR, which was dependent on the binding of QKI to the QRE at 1853bp in the 3UTR of *Sirt2* mRNA. In addition, overexpression of QKI promotes the expression of *Sirt2* mRNA and protein in the OLs both in growth and differentiation condition. In conclusion, our findings indicate that QKI directly binds to the *Sirt2* mRNA at 3UTR to promote the expression of SIRT2 during OL development. (Funded by CIHR)

Title: Identifying genes implicated in oligodendrocyte progenitor cell differentiation after white matter stroke using complementary *in vitro* screening systems

Authors: *D. J. DITULLIO[1,2,3], S. T. CARMICHAEL[2,3];
[1]UCLA, Los Angeles, CA; [2]Interdepartmental Program for Neurosci., [3]Dept. of Neurol., David Geffen Sch. of Medicine, Univ. of California, Los Angeles, Los Angeles, CA

Abstract: White matter stroke comprises 25% of all ischemic stroke, leading to significant cognitive and motor deficits. Death of oligodendrocytes leads to demyelination, but oligodendrocyte progenitor cells (OPCs) are limited in their ability to replenish dead cells and remyelinate axons. It is of central importance to the treatment of this widespread disease to identify genes that promote OPC differentiation and enhance recovery after white matter stroke. An OPC transcriptome has been generated at key time points after white matter stroke in a mouse model of disease. To examine the most differentially expressed genes in this set, two complementary *in vitro* culture systems are used. The CG-4 cell line was derived from rat OPCs in 1992 and has served as a tool to screen for gene effects prior to studies in other systems. On the other hand, primary OPC cultures from neonatal rats demonstrate the most genetic and functional similarity to OPCs *in vivo*. The OPC transcriptome was analyzed using relative and absolute intensity measures to identify putative regulators of OPC differentiation. Genes of interest are examined in CG-4 cells and primary OPCs. Because CG-4 cells can be generated in large numbers at low cost, these are used as a screen for genes that affect OPC differentiation,

while primary OPCs are used to confirm results in a system more genetically similar to OPCs *in vivo*. Morphology analysis and qPCR are used to assess cell maturation. Results from CG-4 cells and primary OPCs are compared to assess the viability of each system to identify genes that play a role in initiating the OPC differentiation pathway. Both qPCR and Sholl analysis of morphology suggest that CG-4 cells exhibit limited capacity for differentiation. In primary OPC cultures grown in the presence of thyroid hormone, expression of OPC markers (Pdgfra and Cspg4) decrease significantly as the cells are exposed to differentiating conditions, while oligodendrocyte markers (Cnp and Mbp) increase significantly. Sholl analysis reveals extensive elaboration of branching networks. In comparison, CG-4 cells do not demonstrate significant increases in branching complexity. Pdgfra expression does not change after induction to differentiate, and oligodendrocyte markers such as Cnp and Mbp demonstrate no change in expression and even unexpected decreases with differentiation. These results indicate that CG-4 cells, based on their limited capacity for differentiation *in vitro*, are not a reliable system in which to analyze regulators of OPC differentiation and myelination, while primary OPCs represent a valuable tool to identify genes that play a role in the physiological response to white matter stroke.

Title: Endosulfatase regulation of fate and differentiation of human oligodendrocyte progenitors

Authors: *S. U. POL, H. SHAYYA, R. WELLIVER, J. POLANCO-GARCIA, D. BRATTON, A. MILLIRON, M. O'BARA, F. SIM;
Dept. of Pharm and Tox, Univ. At Buffalo, Buffalo, NY

Abstract: In demyelinating diseases such as multiple sclerosis, remyelination is limited by impaired human oligodendrocyte progenitor cell (hOPC) differentiation. Identification of extracellular signals that regulate human OPC differentiation may provide novel means to induce remyelination. Weighted Gene Co-expression Network Analysis (WGCNA) was applied to define hOPC differentiation specific gene networks. Using lentiviral over-expression in hOPCs, we tested the functional importance of individual genes within cross-species conserved networks. Over-expression of SULF2, a hOPC-expressed extracellular sulfatase, significantly reduced the fraction of differentiating O4+ oligodendrocytes from 17 ± 5% in controls to 11 ± 3% (p-value < 0.5, n=4). hOPCs over-expressing SULF2 or control mCherry were transplanted into neonatal hypomyelinating shiverer/rag2 mice. At 8 weeks post-implantation, SULF2 over-expression

reduced the proportion of differentiating CC1+ oligodendrocytes (9.8 ± 0.6% vs control 15.9 ± 2%, t-test $p < 0.05$, n=4) and increased the proportion of GFAP+ astrocytes (13.6 ± 2.2% vs control 7.5 ± 0.2%, t-test $p < 0.05$, n=3). To determine whether sulfatase expression was regulated during remyelination, we analyzed murine spinal cord following lysolecithin-induced demyelination. SULF2 mRNA and protein were found in demyelinating lesions. Preliminary data from OPC-specific SULF1/2 conditional knockout mice suggest that sulfatase expression regulates OPC fate following demyelination. In cultured OPCs, we found that sulfatases may act to facilitate both BMP and WNT signaling in OPCs suggesting a mechanism by which they regulate OPC fate *in situ*. As such, sulfatase inhibitors may be ideally positioned to interfere with inhibitory factors blocking OPC differentiation in chronically demylinated lesions and thereby promote remyelination.

Hosp., Stockholm, Sweden

Abstract: Oligodendrocytes wrap layers of specialized cell membrane around nerve fibers forming myelin, which facilitate fast propagation of nerve impulses and trophic support of axons. Myelination can in theory be modified by mature oligodendrocytes generating new myelin and/or by exchanging oligodendrocytes and their myelin sheaths. In a previous study we assessed the dynamics of oligodendrocyte generation and myelination in the human brain. By analyzing the concentration of ^{14}C, derived from nuclear bomb testing during the Cold War, in genomic DNA of oligodendrocytes, we found that human white matter oligodendrocytes are remarkably stable with limited turnover, whereas myelin is exchanged at a high rate. This indicates that

myelin modulation in humans may be carried out by mature oligodendrocytes. There are different kinetics of oligodendrocyte generation and turnover in gray and white matter, with a longer period of oligodendrocyte generation and higher turnover rate throughout life in gray matter, suggesting the possibility of de novo myelination in the sparsely myelinated cortex. However, how these generation kinetics of the oligodendrocyte population may change under pathological conditions such as in the demyelination disease multiple sclerosis (MS) has been unknown. A hallmark of MS is the loss of oligodendrocytes and myelin, as well as axons, leading to conduction deficits and a variety of neurological symptoms. In early stages of MS, regeneration of myelin (remyelination) has been observed to occur. Studies in experimental animal models of MS support that new oligodendrocyte generation contributes to the remyelination process. However, it is not fully known if existing mature oligodendrocytes may contribute to remyelination. The question is to what degree oligodendrocyte generation is affected in MS, and whether remyelination occurs by generation of new oligodendrocytes or by generation of new myelin by pre-existing oligodendrocytes. To address this we are using the strategy of analyzing the content of ^{14}C in genomic DNA of oligodendrocytes from MS brain tissue. We hope to reveal how the generation pattern of the oligodendrocyte population may change during MS and further our understanding of the disease process and potentially point to targets for new therapeutic interventions aiming at affecting the remyelination process.

Abstract: Fragile X Syndrome (FXS) is a leading, genetic cause of autism and mental retardation. FXS occurs in 1 in 4000 males and 1 in 8000 males. Symptoms include language impairments, social deficits, as well as auditory processing deficits, including hyperacusis. The Fmr1 knockout (KO) mouse displays similar auditory impairments, including impaired critical

period plasticity, hypersensitivity to tones, increased response variability, reduced habituation of auditory ERPs and broader receptive fields. Determining whether these phenotypes arise during development and the mechanisms through which they occur will provide the basis for creating lasting treatments for FXS. In this study, we characterized the development of inhibitory and excitatory processes, which may underlie auditory hypersensitivity observed in the KO mouse model. We analyzed dendritic spines in excitatory neurons and perineuronal net (PNN) formation around parvalbumin (PV)-positive cells in KO mouse auditory cortex. Our previous studies suggest an important role for Matrix metalloproteinase-9 (Mmp-9), a protein that regulates the extracellular matrix and influences spine plasticity necessary for learning and memory in FXS-associated structural, functional and behavioral deficits. Mmp-9 is a target of Fmrp transcriptional regulation and has been shown to play a role in regulating spine morphology and enzymatic cleavage of the extracellular matrix, in particular PNNs formed around PV-positive interneurons. We found that Mmp-9 levels are elevated in FXS and Fmr1 ko mice, whereas genetic deletion of Mmm-9 demonstrated a reversal of some FXS phenotypes in Fmr1/Mmp-9 double KO mice. In the normal auditory cortex Mmp-9 levels peak during the first postnatal week followed by a down-regulation during second and third postnatal weeks. This mirrors an increase in PNN structures correlated with the closer of the critical period, and maturation of dendritic spines. Our data show that Mmp-9 levels remain high in the auditory cortex of Fmr1 ko mice during third postnatal week, suggesting that elevated MMP-9 levels may be responsible for the abnormal development of PV/PNN, spine maturation in the auditory cortex of Fmr1 KO mice leading to the development of auditory processing deficits. Targeting drug treatments during developmental ages may therefore be crucial for FXS treatment.

Title: Auditory fear extinction learning in fmr1 and mmp-9 knockout mice

Authors: *S. AFROZ[1], S. REINHARD[2], I. ETHELL[1], K. RAZAK[2];
[1]Biomed. Sci., [2]Psychology, Univ. of California Riverside, Riverside, CA

Abstract: Fragile X Syndrome (FXS) is the leading heritable cause of intellectual disability and the only known genetic cause of autism. Symptoms include cognitive, behavioral and social

deficits, problems with sensory processing and speech production, as well as abnormal dendritic spine morphology. The Fragile X mental retardation-1 knockout mouse (*Fmr1* KO) is a well-established model for FXS which exhibits multiple characteristic phenotypes found in FXS, including altered dendritic spine morphology, hyper-responsiveness to sensory stimuli and reduced habituation, altered vocalizations, hyperactivity and abnormal socialization. Though cognitive impairments are a hallmark of FXS in human subjects, behavioral tests in *Fmr1* KO mice have shown mixed results perhaps due to limitations in relevant tests. Emerging evidence in FXS shows an important role for Matrix metalloproteinase -9 (MMP-9), a protein that regulates the extracellular matrix and influences spine plasticity necessary for learning and memory, which is upregulated in FXS and can exacerbate multiple phenotypes in *Fmr1* KO mice. We tested the performance of *Fmr1* KO mice on a fear conditioning and extinction paradigm and compared their performance to three models in which MMP-9 levels are manipulated: homozygous MMP-9 KOs, heterozygous MMP-9 KOs crossed with *Fmr1* KO mice for a reduction but not total deletion of MMP-9, and MMP-9/*Fmr1* double KO mice. Potential deficits in fear learning and extinction were then tested in *Fmr1* KO mice treated with Minocycline, a broad spectrum tetracycline antibiotic which reduces MMP-9 levels and which has been used in trial treatment of FXS subjects. *Fmr1* KO mice appear to take more trials to reach the same level of freezing in response to foot shock paired with a tone as WT mice and show altered trajectories during extinction learning. Similar to *Fmr1* KO mice, MMP-9 and MMP-9/*Fmr1* double KO mice show consistently lower levels of freezing across training and extinction trials, possibly due to hyperactivity of these mice. These findings may suggest the use of this fear conditioning/extinction paradigm as a potential behavioral assay for the detection of behavioral abnormalities in Fragile X Syndrome studies. *This work is supported by funding from the NIH Grant 1U54HD082008-01*

Title: Linking sensory experience to abnormal synaptic development in the Fmr1 knockout mouse model of Fragile X Syndrome

Authors: *E. ARROYO, D. FIOLE, C. HUANG, C. PORTERA-CAILLIAU;
UCLA, Los Angeles, CA

Abstract: Fragile X Syndrome (FXS) is the leading cause of inherited intellectual disability and autism affecting roughly 1 in ~2,500 males. It is caused by a CGG triplet repeat expansion of the 5' UTR of the *Fmr1* gene on the X chromosome. The gene product, FMRP, is a translational repressor that has been shown to interact with mRNAs of genes involved in synaptic function at post-synaptic dendritic spines. Previous research suggests that dendritic spines in individuals with FXS exhibit an abnormally immature morphology resembling filopodia. Furthermore, several independent *in vivo* imaging studies, including our own, have shown that spines of cortical pyramidal neurons are abnormally unstable in the best-studied animal model of the disease, *Fmr1* knockout (KO) mice. Given that changes in sensory experience modulate spine dynamics in sensory cortices, it is conceivable that *Fmr1* KO mice might experience impaired experience-dependent synaptic plasticity. Interestingly, a hallmark of FXS is sensory hypersensitivity and hyper-reactivity across sensory modalities, and *Fmr1*KO mutant mice exhibit similar defects. Thus, we tested the hypothesis that hypersensitivity to external stimuli in FXS is due to impaired modulation of spine dynamics and synaptic connectivity in somatosensory cortex during a critical period of postnatal development. We performed *in vivo* time-lapse two-photon imaging of apical dendritic spines of L2/3 neurons in barrel cortex in 2 week-old wild type and Fmr1 KO mice. Here, we will report on the effects of environmental enrichment on spine density, turnover, and head volume, as well as the effects of single whisker stimulation on spine dynamics and calcium signals in both WT and *Fmr1* KO mice.

Abstract: Autism spectrum disorders (ASDs) comprise a highly heritable, diverse group of neurodevelopmental disorders, which are characterized by repetitive behaviors and impairments in social interactions. A variety of point mutations have been identified in X-linked Neuroligin-3

and 4X genes in patients with ASDs. The neuroligin (NLGN) gene family consists of five members (Nlgn1, 2, 3, 4X, and 4Y) within the human genome that encode transsynaptic cell adhesion molecules that are critical for synapse assembly, maintenance, and plasticity. Interestingly, all of the autism-associated mutations reported thus far reside in the NLGN extracellular domains except for a single point mutation in the cytoplasmic domain of NLGN4X in which an arginine is mutated to a cysteine (R704C). Here we show that NLGN4X is robustly phosphorylated by protein kinase C (PKC) at T707. The autism mutation, R704C, completely eliminates T707 phosphorylation. We observe a dramatic increase in endogenous T707 phosphorylation in NLGN4X upon PKC stimulation in human neurons. Furthermore, a phospho-mimetic mutation at T707 has a profound effect on NLGN4X-mediated synaptogenesis and excitatory potentiation. Our results now establish an important interplay between a genetic mutation, a key posttranslational modification, and robust synaptic changes, which can provide insights into the synaptic dysfunction of ASDs.

Title: Transcriptional regulation of the rim1 promoter by neurod1

Authors: T. LEE[1,2], I. CHO[1], S. LEE[1,2], J. CHOI[1], Y. LEE[1,2], S. KIM[1,2], *H. K. SUH-KIM[1,2]; [1]Dept. of Anat., Ajou Univ, Sch. Med., Suwon, Korea, Republic of; [2]Dept. of Biomed. Sci., Suwon, Korea, Republic of

Abstract: NeuroD1 is a transcription factor with a basic-helix-loop motif, which is known to regulate differentiation and survival of neuronal cells, enteroendocrine cells, and pancreatic beta cells. Previous reports showed that targeted depletion of NeuroD1 caused decreases in Rab3 interactive molecule-1 (RIM1), RIM2, and Munc18-1. Since these proteins are known to play critical roles in exocytosis of secretory vesicles in neuronal and endocrine cells, NeuroD1 may be a master transcription factor that regulates expression of members of secretory machinery. Here, we report a potential role of NeuroD1 in the regulation of RIM1 transcription in neuronal cells. Since NeuroD1 is known to be highly phosphorylated by diverse protein kinases, we also investigated the effects diverse phosphorylation sites of NeuroD1. We will also discuss the diverse phosphorylation mutations with respect to the functions of NeuroD1.

Title: Taurine increases neurite outgrowth and promotes synapse development in the central nervous system

Authors: ***F. XU**[1,2], K. MA[1], M. QAZZAZ[1], N. I. SYED[1];
[1]Univ. of Calgary, Calgary, AB, Canada; [2]St. Louis Univ., St. Louis, MO

Abstract: Taurine (2-aminoethanesulfonic acid), is an abundant sulfur-containing amino acid that is widely present in the human brain, heart, retina, and muscle tissues. Humans obtain it from either diet or from biochemical synthesis. Taurine deficiency is associated with cardiomyopathy, renal dysfunction, abnormalities of the developing nervous system, and epilepsy. However, both its role during brain development and cellular mechanisms of action are largely unknown. Here, we investigate whether taurine affects neurite outgrowth, synapse formation, and synaptic transmission using rat cortical cell cultures and invertebrate snail (Lymnaea stagnalis) soma-soma synapses. Our study demonstrates that taurine applied at physiological concentrations enhances neurite branching and up-regulates expression of cytoskeleton proteins. Taurine also significantly increases both the density and size of synaptic puncta revealed by immunostaining of pre-synaptic synaptophysin and post-synaptic PSD-95, indicating the role of taurine in synapse development. To further deduce the functional consequence of taurine-induced anatomical changes in synaptic structures, we next examined the role of taurine in synapse formation and synaptic transmission using Lymnaea brains. Lymnaea neurons in culture reconstitute synapses between defined single pre- and post-synaptic neurons, providing an opportunity to study synapses at a resolution that cannot be achieved using mammalian cell cultures due to their intrinsic complexity. We found that taurine significantly increases both the synaptic efficacy (reflected by the percent of cells that form synapses) and synaptic strength (reflected by the amplitude of post-synaptic potentials). This study provides the first direct anatomical and functional evidence that taurine plays an important role in neurite outgrowth and synapse development in the early stage of brain development.

Title: The adaptor protein complex AP-1 modulates synaptogenesis in hippocampal neurons through sorting of neuroligin 1

Authors: *L. E. CUITINO, S. JAIN, G. FARIAS, J. S. BONIFACINO;
NICHD, NIH, Bethesda, MD

Abstract: Neurons are highly polarized cells displaying specialized somatodendritic and axonal domains. The distribution of transmembrane proteins between these two domains and synapse formation are tightly regulated processes that ensure proper neuronal connections. Abnormalities in these processes are considered to be responsible for neurodegenerative and psychiatric disorders. Several proteins, including the clathrin adaptor protein complex AP-1 and members of the neuroligin (NL) family have been proposed to be important for these processes. AP-1 is a heterotetrameric complex composed of γ, β1, μ1, and σ1 subunits, some of which occur as two or three isoforms. Four NL (NL 1-4) proteins have been identified, with NL1 and NL2 predominantly found at excitatory and inhibitory synapses, respectively. We studied the effects of overexpressing a dominant negative mutant of the obiquitous specific AP-1 μ1A subunit (μ1A-W408S), which cannot recognize specific transmembrane cargos, on synaptogenesis and NL1 sorting in rat hippocampal neurons. Upon overexpression of μ1A-W408S we detected morphological changes in dendritic spines and a decreased number of excitatory synapses in neurons at day *in vitro* 18 (DIV18). Confocal microscopy also showed a decreased number of PSD95-positive protrusions and changes in the synaptic location of NMDA glutamate receptors. In contrast, we did not observe changes in the number, morphology or composition of the inhibitory synapsis when analyzing the expression and localization of either the γ2 GABAA-receptor subunit, gephyrin or the vesicular GABA transporter (vGAT). Importantly, NL1 was restricted to the somatodendritic domain in neurons expressing wild-type μ1A, it exhibited a non-polarized distribution in neurons expressing μ1A-W408S. Further analyses showed that residues in the cytosolic tail of NL1 are important for the polarized sorting and the synaptic localization of this protein, as well as for its interaction with AP-1. These results are consistent with an important role of AP-1 in synaptogenesis, through the regulation of NL1 sorting. This work was funded by the Intramural Program of NICHD, NIH (ZIA HD001607)

Title: S-nitrosylation-dependent proteasomal degradation restricts Cdk5 activity to regulate hippocampal synaptic strength

Authors: *A.-Y. FU[1,2,3], P. ZHANG[1,2,3], W.-Y. FU[1,2,3], N. Y. IP[1,2,3];

Abstract: The precise regulation of hippocampal synaptic strength requires coordinated activity and functions of synaptic proteins, which are controlled by specific post-translational modifications. While cyclin-dependent kinase 5 (Cdk5) has been suggested to regulate synaptic strength and functions through phosphorylation of its substrates at synapses, the molecular control of its activity remains unclear. Here, we show that S-nitrosylation of p35, the activator of Cdk5, by nitric oxide (NO) is important for the regulation of excitatory synaptic strength. Blockade of NO signaling reduced mature dendritic spine density and surface expression of glutamate receptor subunits, indicating structural and functional synaptic deficits. Meanwhile, reduced NO production aberrantly upregulated the phosphorylation of numerous synaptic substrates of Cdk5 and its activity. Furthermore, the NO stimulation caused the reduction of Cdk5 activity through p35 S-nitrosylation, resulting in the ubiquitination and degradation of p35. Silencing p35 protein in hippocampal neurons partially rescued the NO blockade-induced synaptic deficits. These findings collectively demonstrate that p35 S-nitrosylation by NO signaling is critical for regulating hippocampal synaptic strength.

Title: Identification of the genetic factors underlying cell-type specific synaptic organization of developing visual cortex

Authors: *J. TOMORSKY, C. DOE, C. NIELL;
Univ. of Oregon, Eugene, OR

Abstract: In visual cortex, precise synaptic connections are known to form circuits with a wide variety of functions, including the detection of orientation, contrast, and spatial frequency. However, the mechanisms that enable neurons to identify different targets during synaptogenesis, resulting in functional visual circuits, remain unknown. To identify genes important in synapse formation within the visual cortex, we utilized the transcriptional profiling technique, TU-tagging, to identify cortical layer-specific differences in gene expression that appear at eye-opening, when many cortical synapses are forming. TU-tagging enables the detection of differential gene expression between distinct cell-types within complex tissues without cell dissociation, which is important to preserve pre- and post-synaptic RNAs [1]. This technique uses the cre-lox system to express the enzyme UPRT in specific cell-types. UPRT converts injected 4-thiouracil to 4-thiouridine, which is then incorporated into newly transcribed RNA, which can be purified and analyzed by RNAseq. In this study, NR5a-cre and NP39-cre lines were used, with targeted expression in layers 4 and 2/3 of cortex, respectively. In addition, visual cortex samples were collected at two different time-points: P12 (just before eye-opening) and P16 (just after eye-opening). Layer-specific thio-tagged RNA was purified and subjected to high-throughput Illumina sequencing. Differential gene expression between time-points and cell-types was analyzed using the DESeq package. Enrichment of a particular gene in a particular layer was confirmed by examining Allen Brain Atlas *in situ*s performed at P14. Differential gene expression analysis yielded multiple genes that were enriched in layer 2/3 of visual cortex that also showed distinct temporal patterns of expression around eye-opening. A gene ontology search revealed that many of the layer 2/3 enriched genes have known functions in cell-adhesion and neuron-projection development. While the TU-tagging technique has been previously demonstrated in endothelial cells [1], this is the first time it has been shown to be effective in mouse neurons. This study has identified several genes that may be important in developing the circuits responsible for aspects of visual function such as orientation and spatial frequency selectivity. Future functional studies will determine the role of these genes in the development

and/or function of layer 2/3 visual cortical neurons. **REFERENCES: [1]** Gay, L. et al., Genes & Development, 2013. 27: 98-115.

Title: Regulation of Neuroligin-2 Phosphorylation

Authors: *N. F. SHANKS[1], M. A. BEMBEN[1,2], Y. LI[1], K. W. ROCHE[1];
[1]NINDS, NIH, Bethesda, MD; [2]Dept. of Biol., Johns Hopkins Univ., Baltimore, MD

Abstract: Neuroligins (NLs) are postsynaptic cell adhesion molecules involved in synapse development and function. They have a strong genetic link to autism spectrum disorders, and have been implicated in the regulation of the balance between neuronal excitation and inhibition. The NL isoform, NL-2 is located and specifically functions at inhibitory synapses, whereas other NL isoforms function only at excitatory synapses or can act at both types. Because the NL sequences are highly conserved, it is unclear how and why this synapse-specificity occurs. We are interested in investigating potential mechanisms. Here, using *in vitro* kinase methods, we demonstrate that c-AMP dependent kinase (PKA) robustly phosphorylates the cytosolic tail of NL-2. Using mass spectrometry analysis and scanning phospho-null mutants we have identified a PKA site. We have generated a phospho-specific antibody against this site, and characterized it's specificity. We observe that overexpressed NL-2 is phosphorylated in heterologous cells, and endogenous NL-2 is phosphorylated in cultured cortical rat neurons and in rodent brain. Using this antibody we are characterizing the regulation of NL-2 phosphorylation over developmental time points, in different brain regions, and in different brain fractions. We have also determined that NL-2 phosphorylation is regulated by synaptic activity, and are investigating the mechanisms by which this occurs.

Title: Activity-dependent regulation of liprinα1 phosphorylation during synapse development

Authors: *H. HUANG[1,2], K.-O. LAI[1,2], A. FU[1,2], N. IP[1,2];
[1]Div. of Life Science,HKUST, Hong Kong, China; [2]Mol. Neurosci. Center, State Key Lab. of Mol. Neuroscience, HKUST, Hong Kong, China

Abstract: Neuronal activity plays an essential role in guiding synapse development, which underlies experience-dependent shaping of brain circuitry. Synapse development requires concerted regulation of different types of synaptic components to drive specific functions, but the manner in which neuronal activity coordinates the process is not clear. Liprinα1, a scaffold protein that mediates protein assembly of synaptic components, has been suggested to play indispensable roles in dendrite development and excitatory synapse maintenance. Here we report that liprinα1 was highly expressed at the postsynaptic regions, while knockdown of endogenous liprinα1 severely impaired dendrite and dendritic spine development. Interestingly, liprinα1 is identified as a novel substrate of the serine/threonine kinase 5 (Cdk5). The Cdk5-dependent phosphorylation of liprinα1 was reduced in the mouse visual cortex during eye opening, while dark-rearing reversed the effect, suggesting that neuronal activity regulates liprinα1 phosphorylation during development. Importantly, phosphorylation of liprinα1 inhibited spine maturation and reduced spine density as well as surface expression level of AMPA receptors, indicating the inhibitory roles of liprinα1 phosphorylation in synaptic functioning. Collectively, these findings provide molecular basis for the instructive roles of neuronal activity during synapse development.

Title: Cdk5-dependent phosphorylation of p70 ribosomal S6 Kinase (S6K) is required for dendritic spine morphogenesis

Authors: *Z. LIANG, K.-O. LAI, E. FEI, H. HUANG, N. Y. IP;
Hong Kong Univ. of Sci. and Technol., Hong Kong, China

Abstract: The maturation and maintenance of dendritic spines depend on neuronal activity and protein synthesis. One potential mechanism involves mammalian target of rapamycin (mTOR), which promotes protein synthesis via the phosphorylation of 4E-BP and p70S6 kinase 1 (S6K). Nonetheless, the regulatory control of S6K and its cellular roles during the process remains unexplored. The present study demonstrated that S6K in neurons is phosphorylated at Ser-411 within the auto-inhibitory domain by cyclin-dependent kinase 5 (Cdk5). Ser-411 phosphorylation was regulated by neuronal activity and brain-derived neurotrophic factor (BDNF). RNAi-induced S6K knockdown in hippocampal neurons led to a loss of dendritic spines, which mimics neuronal activity blockade by tetrodotoxin. Notably, co-expression of wild-type S6K but not the phospho-deficient S411A mutant rescued the spine defects. These findings demonstrate the importance of Cdk5-mediated phosphorylation of S6K at Ser-411 in spine morphogenesis driven by BDNF and neuronal activity.

Title: Generation and analysis of cnr1 and cnr2 zebrafish mutants

Authors: *A. ACEVEDO-CANABAL[1], L. COLON[1], M. BEHRA[1], G. YUDOWSKI[2]; [1]Univ. of Puerto Rico - RCM, San Juan, PR; [2]Univ. of Puerto Rico - Inst. of Neurobio., San Juan, PR

Abstract: Marijuana is the most commonly used drug among teenagers. The main psychoactive ingredient, Δ9-tetrahydrocannabinol (Δ9-THC), activates two cannabinoid receptors, CB1 and CB2. These receptors are encoded by the cnr1 and cnr2 genes, respectively. Both genes are expressed early on during vertebrate development and the manipulation of the cannabinoid system in chick and zebrafish embryos results in axonal fasciculation errors . It remains unclear if these neurodevelopmental changes are mediated by CB1 or CB2 receptors. Furthermore, the long-term effects of the absence of one or both of the receptors of the endocannabinoid system on the behavior of larvae and mature zebrafish have not been explored. We used CRISPR-Cas9 genome-editing tool to generate cnr1 and cnr2 mutant zebrafish lines. Those mutant lines will allow us to identify the roles of CB1 and CB2 receptors during the early stages of brain development. We have designed two targets per gene and co-injected them with Cas9 mRNA. We have identified 4 alleles for cnr1 and 2 alleles for cnr2 which have been generated in different transgenic background, namely brn3c:GFP, expressed in a subsets of neurons and mechanosensory hair cells (HC) and atoh:TOM, expressing tomato red in nascent neurons in the midbrain-hindbrain boundary in the early embryo and in maturing HC. The confirmed founders have been outcrossed to establish stable mutant transgenic lines. This will allow us to follow brain development in mutants as compared to wild type animals through a comprehensive structural/anatomical analysis. To monitor neuronal wiring and axonal fasciculation formation we did immunohistochemistry with a numbers of axonal markers. We will also use the mutants to test specific roles of the cannabinoid system during swimming behavioral tasks. To assess swimming patterns, we analyzed wild type animals for freezing, cruising, and bursting patterns after treating with different cannabinoid agonists: Δ9-THC and CP55,940 . Our studies will be crucial in identifying the roles of CB1 and CB2 during brain development and the effect of early exposure to cannabinoids.

Title: GluN2B-containing NMDA receptor antagonist ifenprodil produces long-lasting increases in dendritic spine density: Within-subject longitudinal multiphoton imaging

Authors: *J. D. RAYBUCK[1], S. A. THAYER[2];
[1]Dept. of Pharmacol., UMN, Minneapolis, MN; [2]Pharmacol., Univ. of Minnesota, Minneapolis, MN

Abstract: Serious brain disorders such as depression, cognitive dysfunction, and addiction are strongly linked to regulation of dendritic spine density in cortical and sub-cortical regions. Much work has characterized the mechanisms underlying spine regulation in *in vitro* neuronal cultures, and many of these mechanisms have been demonstrated with *ex vivo* techniques, such as Golgi staining. However, to date, little work has examined the mechanisms of dendritic spine regulation *in vivo*. Because neuronal cultures lack the complex milieu of the living brain, characterization of these mechanisms with *in vivo* models will be critical to understanding normal brain function and the treatment of brain disorders. The regulation of dendritic spines critically depends on NDMA receptor signaling. Notably, many studies have characterized a unique role for GluN2b-containing NMDA receptors in the suppression of dendritic spine formation. To begin to understand how GluN2b signaling regulates spine formation in live animals, we used *in vivo* cranial window multiphoton microscopy to image spines on apical dendrites of layer 5 pyramidal neurons. Specifically, we administered the GluN2b selective antagonist ifenprodil to Thy1-eGFP(h) transgenic mice. Repeated ifenprodil administration (4, daily doses, ip, post imaging) produced a dose-dependent increase in spine density within 24 hours of the first dose. Further, longitudinal imaging (up to 8 weeks after ifenprodil treatment) revealed that increases in spine density remained for several weeks following drug wash out, and that the duration of enhancement was dose dependent, with higher doses producing longer lasting effects. This novel finding suggests that NMDA receptors may act as a short-term regulator of spine density *in vivo*. These results may shed light on the differences between SSRIs and NMDA antagonists in the treatment of depression, as well as how spine regulation relates to this disorder. Additionally, this work has implications for synaptic changes that accompany neurodegenerative diseases, such as HIV-associated neurocognitive disorder (HAND). Further examination of the role of GluN2b receptors in spine regulation may lead to the development of more effective treatments for depression, dementia, cognitive dysfunction, and substance abuse.

Title: Matrix metalloproteinase 9 inhibition may counteract neurodevelopmental abnormalities in a Xenopus tadpole model for VPA-induced neurodevelopmental disorders

Authors: *E. J. JAMES, C. AIZENMAN;
Brown Univ., Providence, RI

Abstract: Autism is a prevalent neurodevelopmental disorder that affects the brain's normal development and impairs social and communication skills. Prenatal exposure to valproic acid (VPA), a commonly prescribed antiepileptic medication, is known to greatly increase risk for autism and other neurodevelopmental disorders (NDDs). Previous research using tadpole and rodent models, as well as human studies, suggests that neurodevelopmental disorders are marked by significant increases in neural network connectivity and excitability. These abnormal networks are postulated to arise from misexpression of synaptic proteins that function to stabilize, maintain, and refine synapses. Matrix metalloproteinase 9 (MMP9), an endopeptidase involved with synaptic refinement, has been associated with various NDDs, and microarray and qPCR data from our lab revealed that chronic exposure to VPA caused significantly altered expression MMP9 mRNA. Thus, we hypothesize that inhibiting the function of MMP9, in our Xenopus laevis tadpole model for VPA-induced NDDs, would rescue the increased neural network connectivity and excitability that result from early life exposure to VPA. To test this hypothesis, we exposed developing VPA-treated tadpoles to 3uM SB-3CT, a MMP9 inhibitor, during a critical period of synaptic stabilization and refinement in the optic tectum. We then used whole cell patch clamp recording to assay for changes in intrinsic excitability and synaptic transmission. Results from these experiments revealed that chronic exposure to SB-3CT may counteract the effects of chronic exposure to VPA and produced a statistically significant increase in intrinsic cell excitability. These results suggest that manipulation of MMP9 has the potential to rescue the effects of early life exposure to valproic acid.

Title: Opposing roles of actin signaling during the developmental stage of spine formation and maturation

Authors: *E. SPENCE, S. SODERLING;
Cell Biol., Duke Univ., Durham, NC

Abstract: Excitatory spinogenesis (dendritic spine formation) is a key neurodevelopmental process that begins with filopodia formation, leads to axonal contact, spine maturation, recruitment of AMPA type glutamate receptors, and functional synapse formation. Later, in adulthood, actin-rich spine synapses undergo both rapid changes in morphology as well as slower alterations in spine turnover that are associated with experience and are thought to encode long-term modifications in neural network connectivity. However, the underlying mechanisms and regulation of these stages of spine development are poorly understood. Results from a range of genetic and state-of the art *in vivo* proteomics will be shown that suggest a critical actin regulatory pathway that controls fundamental features of spinogenesis.

Title: Pointed-end capping of actin filaments by tropomodulin regulates dendritic spine development

Authors: *O. OMOTADE[1], V. FOWLER[2], J. Q. ZHENG[1];
[1]Dept. of Cell Biol., Emory Univ. Sch. of Med., Atlanta, GA; [2]Dept. of Cell and Mol. Biol., The Scripps Res. Inst., La Jolla, CA

Abstract: Dendritic spines are tiny, actin-rich protrusions on the surface of dendrites that serve as the platform for postsynaptic specializations of most excitatory synapses in the vertebrate central nervous system. Dynamic remodeling of the actin cytoskeleton drives the structural changes associated with the formation and modification of dendritic spines during development and synaptic plasticity, but the detailed mechanisms remain poorly understood. Actin filaments are polarized with a barbed and a pointed end: the former favors assembly whereas the latter favors disassembly. Tropomodulins (Tmods) are a conserved family of proteins that cap the pointed end of actin filaments, thereby blocking monomer exchange and inhibiting filament depolymerization. Tmod-mediated capping of pointed ends is known to regulate the stability, length, and architecture of actin networks in non-neuronal cell types. Knockout of Tmod2 in mice leads to defects in learning and memory, but the underlying cellular mechanisms are unclear. In this study, we investigated the role of Tmods in dendritic spine development and synapse formation. We find that Tmods 1 and 2, but not Tmod 3, are highly enriched in dendritic spines in cultured hippocampal neurons. Interestingly, both Tmod1 and 2 are found to concentrate in the spine neck and a small region in the center of the spine head, suggesting that Tmods may be localized to specific sub-spine regions to regulate the local actin structures. Knockdown of Tmods in cultured hippocampal neurons caused a marked loss in the number of mushroom-shaped dendritic spines with an increase in filopodia-like protrusions. These results provide the first evidence that pointed end capping of actin filaments by Tmod plays a role in the development of dendritic spines. Capping of the pointed end of actin filaments is likely important for the construction and maintenance of the actin architecture underlying postsynaptic function. Title: nArgBP2 regulates dendritic spine formation and spine-synapse formation at glutamatergic synapses

Authors: *S.-E. LEE[1,1], Y. KIM[1], J. HAN[1], G. CESTRA[2], S. CHANG[1];
[1]Dept. of Physiol. and Biomed. Sci., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of;
[2]Dept. of Biol. and Biotech. Charles Darwin, IBPM, Consiglio Nazionale delle Ricerche c/o Univ. of Rome La Sapienza, Rome, Italy

Abstract: nArgBP2 was originally identified as a protein that directly interacts SAPAP3, a postsynaptic scaffolding protein critical for the assembly of glutamatergic synapses. Although recent genetic deletion of nArgBP2 in mice leads to mania/bipolar-like behaviors, resembling many aspects of symptoms in bipolar disorder patients but the function of nArgBP2 at the synapse is completely unknown. Here we found that knockdown (KD) of endogenous nArgBP2 by specific shRNAs in cultured rat hippocampal neurons resulted in a dramatic reduction in dendritic spine formation. Reintroducing shRNA-resistant nArgBP2 reversed these defects. In addition, nArgBP2 KD significantly increased the levels of phosphorylated WAVE1 and Rac1, which results in the marked increase of dynamics of actin cytoskeletons in spines. We showed that nArgBP2 KD selectively impairs spine-synapse formation at glutamatergic synapse where excitatory synapses terminate mostly at dendritic shafts instead of spine heads while inhibitory synapse formation was not affected by KD. Thus, our results suggest that nArgBP2 functions to regulate spine formation and subsequent spine-synapse formation at glutamatergic synapse. Our data also raise the possibility that the reduction in expression of nArgBP2 may be related to the synaptic dysfunction observed in bipolar disorder.

Title: HIP1r required for the formation of functional excitatory synapses in cultured hippocampal neurons of rats

Authors: *L. PENG, X. XU, Y. DU, L. ZHU, J. LUO;
Sch. of Med., Zhejiang Univ., Zhejiang, China

Abstract: Huntingtin-interacting protein 1-related (HIP1r), a homologue of HIP1 and Sla2p, is an actin-binding protein, which binds to clathrin and inositol lipids via its putative central coiled-coil domain and epsin N-terminal homology (ENTH) domain, respectively. Similar to Sla2p, HIP1r also binds to F-actin with its COOH-terminal talin-like domain. It is known that HIP1r may play important roles in actin organization and endocytosis. Previous studies identified CCDC62/HIP1R as a candidate gene region for PD. However, it is little known that how HIP1r functions in the nervous system even though it is highly expressed in the brains. Here, we found that knockdown of HIP1r with shRNA in cultured hippocampal neurons induced alternation of dendritic development and synaptogenesis. Dendritic branches and complexity were reduced. PSD95 density and amplitude of mEPSC also decreased, suggesting that the number of excitatory synapses is decreased. Consistent with these resultd the total and surface expression

levels of excitatory receptors were decreased. Interestingly, inhibitory receptors remain unchanged. Take together, these data indicates that HIP1r is required for dendritic development and excitatory synaptogenesis in cultured neurons.

Title: Structural and functional insights into the latrophilin3 - FLRT3 complex that mediates glutamatergic synapse development

Authors: *F. RANAIVOSON, F. MARTINI, F. BERGAMI, S. VON DAAKE, D. COMOLETTI;
Child Hlth. Inst. of New Jersey, Rwjms/Rutger, New Brunswick, NJ

Abstract: Fibronectin leucine-rich repeat transmembrane 3 (FLRT3) was recently identified as a high affinity ligand of latrophilin-3 (LPHN3) and it was described that these proteins play an important role in glutamatergic synapse development *in vitro* and *in vivo*. LPHNs are a small family of neuronal adhesion-GPCRs originally discovered as receptors for the black widow spider toxin -latrotoxin. Mutations in LPHN3 have recently been identified as risk factors for attention deficit hyperactivity disorder (ADHD) in humans, but little is known about the physiological function of LPHNs. FLRT3 is a leucine rich repeat protein member of the FLRT protein family which contains three isoforms encoded by three distinct genes, Flrt1-3. They are predominantly expressed in central nervous system and have been implicated in specifying neuronal connectivity, functioning in axon guidance, synaptic target selection and synapse formation. Here, using a series of biochemical and biophysical techniques, including single particle electron microscopy, mass spectrometry, isothermal titration calorimetry, and protein crystallography we 1) mapped the domains of LPHN3 involved in binding to FLRT3, 2) we determined the crystal structure of the olfactomedin domain of LPHN3 in two crystal forms, and 3) we solved the crystal structure of the complex between the associating domains of LPHN3 and FLRT3. These results helped delineate the mode of association of the high affinity complex between these two synaptic adhesion proteins.

Abstract: Adhesion GPCRs have large extracellular regions decorated by numerous adhesion domains and a conserved GPCR Autoproteolysis Inducing (GAIN) domain that mediates self-cleavage of the receptor. Discovery of the novel GAIN domain and determination of its high-resolution crystal structures revealed the mechanism of self-cleavage and provided the great hints as to why these receptors are regulated by tethered agonists hindered within the GAIN domain. The presentation will focus on our recent unpublished data on further structural/functional understanding of the extracellular domains of select adhesion GPCRs that are essential for different functions in the brain such as cortex development and synapse maturation. Our studies revealed unpredicted domains in the extracellular regions, identified the conserved surfaces of these domains, and shed light on the atomic details of how these domains interact with their extracellular ligands to regulate receptor function. In addition, we engineered and determined the structures of synthetic proteins that specifically and tightly bind to the extracellular domains of adhesion GPCRs to be used as potential lead compounds for future drug discovery. These structural studies serve as a starting point to understand and dissect the distinct roles of these domains in the functions of adhesion GPCRs.

Title: Small G- protein regulation of Neurexin localization in *C. elegans* neurons

Authors: *S. K. VALAPPIL[1], K. SENAGBE[1], D. HYNDS[1], T. L. GUMIENNY[2];
[2]Biol., [1]Texas Woman's Univ., Denton, TX

Abstract: Synapse formation and stabilization are key processes involved in learning and memory formation. Synaptic proteins play crucial roles in synaptogenesis, signaling across synapse and specifying synaptic function. Neurexin is a presynaptic trans-membrane protein that interacts with postsynaptic neuroligin to form a trans-synaptic cell adhesion complex. Variants of neurexins and neuroligins recruit specific proteins to the synaptic membrane to determine the type of synapse that is formed (excitatory or inhibitory). An imbalance of excitatory and inhibitory synapses results in neuropsychiatric disorders like autism spectrum and intellectual disability. Although the functional roles of neurexin are being widely explored, how neurexins are localized to the presynaptic membrane is not well elucidated. We propose that specific Rabs direct the localization of neurexin, to presynaptic terminal, and Rho GTPases regulate neurexin membrane loading. Rab and Rho proteins are molecular switches that cycle between guanosine triphosphate (GTP)-bound, active forms and guanosine diphosphate (GDP)-bound, inactive forms to transduce intracellular signals and regulate cytoskeletal dynamics. Transport of membranous proteins is regulated by the Rab family whereas Rho GTPases are best known for regulation of actin dynamics. Studies in the nematode model organism Caenorhabditis elegans have demonstrated fundamental mechanisms that direct cargo sorting, vesicle budding, and membrane localization. We employed RNA interference of specific Rab and Rho genes in *C. elegans* expressing fluorescently tagged neurexin to determine their involvement in neurexin localization in nerve cord cells. Using confocal microscopy, we demonstrate differential distribution of neurexin along the nerve cord as a result of Rab or Rho gene knock down. Results regarding small GTPase involvement in transport and localization of neurexin in primary cell cultures from *C. elegans* using RNAi and live-cell imaging will be presented. This work will contribute to a better understanding of the mechanism involved in formation of different types of synapses, potentially leading to novel strategies to treat autism and other cognitive disorders.

Title: Tyrosine phosphorylation of neuroligin-1 regulates synaptic specification

Authors: C. SAPHY[1], M. LETELLIER[1], K. CZONDOR[1], I. PAPASIDERI[1], I. CHAMMA[1], B. TESSIER[1], M. SAINLOS[1], *O. THOUMINE[2];

Abstract: The differentiation of neuronal connections into excitatory or inhibitory synapses during nervous system development is a key question in neurobiology. However, the mechanisms which govern the apposition of the proper post-synaptic neurotransmitter receptors in front of their respective glutamatergic or GABAergic pre-synaptic terminals are unclear. Neuroligins are key adhesion molecules implicated in synaptic specification which could play a role in this process. We examined here the functional impact of neuroligin-1 (Nlg1) tyrosine phosphorylation on synaptic differentiation using two previously described Nlg1 point mutants which differentially recruit the scaffolding molecules PSD-95 (Y782A) and gephyrin (Y782F) (Giannone et al., Cell Reports 2013). Expression of the Nlg1Y782A mutant in dissociated hippocampal neurons increased the density of pre-synaptic VGlut1 and post-synaptic AMPA receptor clusters, and the frequency of excitatory miniature currents, with respect to control GFP-expressing cells. In contrast, the Nlg1Y782F mutant increased the number of pre-synaptic VGAT puncta and post-synaptic GABAA receptor clusters, as well as the frequency of miniature inhibitory currents. When expressed in CA1 pyramidal cells of organotypic hippocampal slices from Nlg1 knock-out mice, Nlg1Y782A, but not Nlg1Y782F, increased the amplitude of evoked AMPA-receptor mediated currents upon stimulation of Shaffer collaterals. This effect was associated with a doubling of dendritic spine number induced by Nlg1Y782A, not observed for Nlg1Y782F. Thus, a unique tyrosine residue located in the Nlg1 intracellular domain responsible for a differential binding to scaffolding molecules, acts as a switch that determines the assembly of excitatory versus inhibitory post-synapses.

Title: Imaging Rab GTPase activities in single dendritic spines during structural plasticity

Authors: ***J. WANG**[1,2], J. NISHIYAMA[1], R. YASUDA[1];
[1]Max Planck Florida Inst., Jupiter, FL; [2]Duke Univ., Neurobiology, NC

Abstract: Endosomal trafficking is important for synaptic delivery of AMPARs during long term potentiation (LTP). However, endosomes are heterogeneous and dynamic structures, with different distribution of Rab GTPases. For the better understanding of the molecular identity and each Rab's involvement in synaptic plasticity, we developed highly sensitive FRET sensors for four Rab GTPases, Rab4, Rab5, Rab8 and Rab10. Combining two-photon glutamate uncaging with two-photon fluorescence lifetime imaging microscopy (2pFLIM), we measured the spatiotemporal dynamics of individual Rab GTPase activity in single dendritic spines during structural plasticity. Our data show that, upon glutamate uncaging, Rab4 is transiently activated

in the stimulated spines, which decays within 15min. Rab8 is rapidly activated in the stimulated spines, which sustains for more than 30min. Surprisingly, Rab5 and Rab10 are inversely inactivated in the stimulated spines, which last for more than 30min. All these activities are highly compartmentalized in the stimulated spines. Furthermore, suppression of Rab4 only inhibits transient phase of structural plasticity while suppression of Rab8 inhibits both transient and sustained phase of structural plasticity. In contrast, suppression of Rab5 and Rab10 enhance both transient and sustained phase of structural plasticity. Our results suggest that highly compartmentalized activation of Rab4 and Rab8, as well as inactivation of Rab5 and Rab10, are important for structural plasticity in single dendritic spines.

Title: A novel tool for active zone protein orientation: Dually tagged full length mRFP-Bassoon-mGFP protein

Authors: T. GHELANI[1], F. GÖTTFERT[2], R. EBRECHT[3], F. WOUTERS[3], N. WITTENMAYER[1], *T. DRESBACH[1];
[1]Univ. of Goettingen Med. Sch., Goettingen, Germany; [2]Dept. of NanoBiophotonics, Max Planck Inst. for Biophysical Chem., Göttingen, Germany; [3]Dept. of Neuropathology, Univ. Med. Göttingen, Göttingen, Germany

Abstract: Bassoon is one of the largest scaffolding proteins found in the cytomatrix of the active zone (CAZ) of a neuron's presynaptic terminal. The CAZ is a specialized sub-compartment assembled in close proximity to the neurotransmitter release site, or active zone, and is comprised of interconnected active zone proteins. The CAZ and its proteins have been shown to promote short-term plasticity and long-term plasticity by enabling priming and docking of synaptic vesicles and binding to Ca2+ channels. Bassoon, one of the two large CAZ proteins, binds to other AZ proteins and provides structural stability to the protein complex. This large protein is therefore a good tool to study AZ formation. First-generation recombinant Bassoon constructs have become well-established tools for studying trafficking of active zone precursor organelles, as well as active zone assembly and maintenance. Here we introduce a dually tagged second-generation Bassoon construct. This construct carries an intramolecular mRFP tag close to its N-terminus, thus leaving the N-myristoylation consensus site of Bassoon intact. In addition, it

carries a C-terminal mEGFP tag with an optimized spacer that increases the stability of the recombinant construct. The construct possesses all of the expected properties of endogenous Bassoon and known constructs, including correct targeting and CAZ incorporation. Using specific nanobodies against the fluorescent tags and stimulated emission depletion (STED) nanoscopy, we are able to resolve and characterize the localization of the N- and C-termini of the protein at different developmental stages of maturing cultured neurons. Bassoon is one of the first proteins to be incorporated into young synapses, and tracking the changes in conformation of the protein would enhance our knowledge of AZ assembly and synapse maturation as well as serve as a ruler to compare orientation of other AZ and synaptic proteins at the synapse.

Abstract: Whereas dendritic spine morphogenesis is critical for the development of glutamatergic synapses and excitatory neurotransmission, scaffold proteins are critical for orchestrating protein complexes to regulate dendritic spine development. The multi-domain scaffold protein Axin (“axis inhibitor”) regulates various developmental processes including the proliferation/differentiation of neural progenitor cells and axon formation. Our recent findings

revealed that Axin is concentrated in postsynaptic fractions and colocalizes with the postsynaptic marker PSD-95. Knockdown of Axin significantly reduced dendritic spine density in cultured neurons and in the mouse hippocampus. The stabilization of Axin by small molecule XAV939 reduced the elimination rate of dendritic spines, resulting in increased dendritic spine density and synaptic transmission. We found that Axin interacts with Ca2+/calmodulin-dependent protein kinase II (CaMKII) in synaptosomal fractions. Moreover, the dendritic spine deficits in Axin-knockdown neurons could be rescued by the small Rho-GTPase Cdc42, whose activity is regulated by CaMKII. These findings collectively suggest that Axin regulates dendritic spine morphogenesis via Cdc42-dependent signaling.

Title: Foxp2 regulates dendritic spine formation in medium-sized spiny neurons during postnatal maturation of the mouse striatum

Authors: Y.-C. CHEN[1], H.-Y. KUO[1], K.-M. LU[1], S.-Y. CHEN[1], W. ENARD[2], S. PÄÄBO[3], *F.-C. LIU[1];
[1]Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Ludwig Maximilians Univ. Munich, Munich, Germany; [3]Max Planck Inst. for Evolutionary Anthrop., Leipzig, Germany

Abstract: Human-specific two amino acids substitutions in mouse Foxp2 gene results in increases of dendrite length of medium-sized spiny neurons (MSNs) and enhancement of long-term depression in humanized Foxp2H/H striatum (Enard et al., 2009). It implicates that humanized version of Foxp2H/H protein functions more efficiently than mouse Foxp2 protein in regulating neuronal morphology and function of MSNs. The dendritic spines of MSNs are the main loci in which corticostriatal and thalamostriatal synapses are localized. We examined dendritic spines of MSNs in postnatal day (P) 14 brains of Foxp2H/H mice. We analyzed dendritic spines of MSNs in the dorsolateral (DL) sensorimotor and dorsomedial (DM) associative striatum. We found that the dendritic spine density was increased in MSNs of both

DL and DM striatum of Foxp2H/H mice. To further analyze the morphology of dendritic spines in details, we classified the morphology of dendrites according to Harris et al. (1992) with slight modification. The dendrites were categorized into six types: stubby, thin/filopodia, mushroom, branched, multiple-branched and atypical. In DL striatum, the densities of thin/filopodia, mushroom, branched and multiple-branched spines were significantly increased. It was of particular interest that multiple-branched dendritic spines were found in a few Foxp2H/H MSNs. Such multiple-branched spines were barley found in wild type MSN. In DM striatum, only thin/filopodia spines were increased in Foxp2H/H MSNs. Therefore, in general, the spine morphology of Foxp2H/H MSNs was more complex than wild type MSNs. Note that the spine density was higher in DL than DM striatum either in wild type or Foxp2H/H mice at P14. Most interestingly, the multiple-branched spines mainly appeared in MSNs of DL striatum of Foxp2H/H brains, suggesting that the humanized Foxp2 has a stronger effect than mouse Foxp2 in promoting spine formation in DL MSNs. Taken together with the decrease of dendritic spines in MSNs of Foxp2-/- knockout striatum (Chen et al., 2014), our study suggests a positive regulation of corticostriatal excitatory synapses by Foxp2 in MSNs during postnatal maturation of the mouse striatum.

Title: Nitric oxide in the retina and its role in synaptogenesis processes

Authors: ***L. T. WALTER**[1], C. SCHMELTZER[2], G. S. V. HIGA[1,3], E. R. KINJO[1], G. CERCHIARO[1], A. H. KIHARA[1];

Abstract: In the nervous system (NS), nitric oxide (NO) is associated with various physiological and pathological processes. The endogenous NO production depends on nitric oxide synthases

(NOS), nNOS, eNOS and iNOS; whose names are related to the majority production in neurons, endothelium and inflammatory processes, respectively. Although structurally similar, these enzymes have different expression and regulation properties. The aim of this project was to evaluate gene expression (by real-time PCR) and protein distribution (by immunofluorescence) of the three NOS isoforms using rat retina as a model. We also measured NO production levels (by the EPR technique) during retinal development (P0, P5, P10 and P60) and under effect of pharmacological intervention (blocker L-NAME and 7-NI). Moreover, the effects caused by the blockade of genes involved in synaptogenesis were evaluated (by real-time PCR). The results showed that mRNA levels of the three isoforms are present at all studied ages. Moreover, eNOS and nNOS seems to be distributed only in vascular plexus and specific layers of retina, respectively. nNOS presence was observed in amacrine cells, double-labeling experiments and morphological observations revealed two distinct populations of nNOS positive amacrine cells, named as round and balloon cells. The data obtained from the nonspecific NOS blockers (L-NAME) and specific nNOS blocker (with 7-NI) showed a reduction of synapsin, synaptophysin and connexin 45 transcripts. Taking together, our data suggests that NOS are present in initial stages of postnatal development and nNOS pla ys an important role in electrical and chemical synapses during development of NS.

Abstract: Palmitoylation is a reversible post-translational modification involving the attachment of palmitate to cysteine residues on substrate proteins. This process is catalyzed by a family of palmitoyl acyltransferase (PAT) enzymes that contain a conserved DHHC motif. Palmitoylation enhances the recruitment of proteins to the membrane and the palmitoylation of a number of synaptic proteins is believed to regulate synapse organization, function and plasticity. Although this is a relatively new field of research, disruption of DHHC function has been implicated in a number of neurodegenerative and neurodevelopmental disorders, underscoring their importance

for proper brain development and function. DHHC9 loss of function mutations have been identified in patients with intellectual disability, however its role in the development and function of neural circuits is still unknown. Here we demonstrate that DHHC9 is localized to both excitatory and inhibitory neurons where it plays an important role in promoting dendritic outgrowth and arborisation and constraining exuberant synapse formation. Preliminary data suggest that this is mediated through the palmitoylation of the DHHC9 substrate, Ras. Taken together, this work suggests that palmitoylation-dependent regulation of Ras by DHHC9 modifies neural complexity by regulating neuronal growth and synaptic density.

Title: Effect of parasitism on the distribution of serotonin-like immunoreactivity in the central nervous system of Biomphalaria alexandrina

Authors: *S. ROLÓN-MARTÍNEZ[1,2], M. R. HABIB[3], L. O. VAASJO[1], R. P. CROLL[4], M. W. MILLER[1,2];
[1]Inst. of Neurobio., San Juan, PR; [2]Anat. and Neurobio., Univ. of Puerto Rico- Med. Sci. Campus, San Juan, PR; [3]Theodor Bilharz Res. Inst., Cairo, Egypt; [4]Dalhousie Univ., Halifax, NS, Canada

Abstract: Schistosomiasis, or bilharzia, is estimated to affect about 200 million people worldwide. The digenetic trematode worm, *Schistosoma mansoni* that causes intestinal schistosomiasis, employs the freshwater snail genus *Biomphalaria* as its primary intermediate hosts. It has been proposed that the transition from the free-living *S. mansoni* miracidium to parasitic mother sporocyst depends upon uptake of biogenic amines, e.g. serotonin (5HT), from the snail host. However, little is known about potential sources of serotonin in *Biomphalaria alexandrina* tissues and its potential changes during the course of infection. The purpose of this investigation was to localize serotonin-like immunoreactivity (5HTli) in the central nervous

system (CNS) of *B. alexandrina* and examine 5HTli at critical points of the host-parasite interaction. 5HTli fibers were observed innervating the cephalopedal integument, the major site of *S. mansoni* miracidium penetration and transformation. However, no peripheral 5HTli neurons were detected. Clusters of 5HTli neurons were observed in the cerebral, pedal, left parietal, left pleural and visceral ganglia, suggesting that the peripheral serotonergic fibers originate from the CNS (see also Delgado et al. 2012). Specimens infected with *S. mansoni* were examined at 10 days post infection (10 dpi) and during their shedding stage. The total number of central 5HTli neurons decreased from 162.2 ± 40.0 (n = 5) under control conditions to 118.8 ± 11.9 10 dpi and 130.4 ± 6.7 at the shedding stage (one-way ANOVA, $p < 0.05$). Reductions of 5HTli were most evident in the pedal ganglion (control: 33.6 ± 8.8; 18.0 ± 3.7, 10 dpi; 25.6 ± 5, shedding; $p < 0.05$) and the left pleural ganglion (3.2 ± 2.8, control; 0 ± 0, 10 dpi; 0 ± 0, shedding; $p < 0.05$). The changes in 5HTli observed following infection by *S. mansoni* indicate that reductions in serotonin levels can occur in specific central neurons in parasitized snails and that these changes might contribute to the modifications in several behaviors that are observed during the course of infection.

Title: Direct measurement of histamine release evoked by light in the eye of the fly Calliphora

Authors: *J. BORYCZ[1], J. A. BORYCZ[1], S. R. SHAW[1], I. A. MEINERTZHAGEN[1,2]; [1]Dept. Psychology & Neurosci., [2]Biol., Dalhousie Univ., Halifax, NS, Canada

Abstract: Histamine (HA) is a neurotransmitter released at arthropod photoreceptor (PR) terminals. After release, most HA is recycled via conjugation to β-alanine by the action of Ebony, to form carcinine; carcinine is then transported back to PRs where Tan hydrolyzes it back to HA and β-alanine. So far the only means to assay light-evoked transmitter release has been indirect, from ERG recordings. Here we apply a direct method for HA measurement using *in vivo* microdialysis of the eye of the blowfly *Calliphora erythrocephala*, both wild-type and the white-eye mutant *chalky*. In *Drosophila* the total head HA is unchanged by light, does not change in wild-type flies kept in constant light, but does decrease after 3 days in constant light in the mutant *white*. White-eyed fly mutants show potentiated ERG responses to light, supposedly

due to enhanced photon capture in eyes lacking screening pigment. To measure HA release we inserted a 300 µm microdialysis probe into the left compound eye's retina in wild-type *Calliphora*, perfusing it with Ringer solution at 1 µl/min, and sampling at 30-min intervals for HA determination. If deep, the probe tip penetrated the lamina to measure HA release from PR terminals, but otherwise lay within the retina and detected recycled HA liberated by Tan. The eye was illuminated by 2 blue-white LEDs (Luxeon Star/O, LXHK- WE8). Illumination increased HA release by 82%, which plateaued after 2 h. After light-off it also took 2 h for HA release to subside to the constant dark phase level. In the white-eye mutant *chalky* HA release increased by 251% relative to wild-type after light-on and again took 2 h to plateau after light-on or -off. Our results are the first to show direct release of HA in the fly's retina, this possibly representing the Tan hydrolysis product. They also accord with our earlier studies showing reduced head HA after prolonged illumination in *Drosophila white*. We showed earlier that *Drosophila white* has abnormal head levels of other biogenic amines (Borycz et al. 2008), indicating that the effect of White might be related not only to the failure to screen out stray light, but may result also from the lack from the *white* eye of this important transporter of multiple substrates.

Title: Effect of a phytochemical on failure by oxidative damage of GABAergic neurotransmission visualized through motor behavior in the nematode Caenorhabditis elegans

Authors: *G. CAMARGO HERNÁNDEZ[1], M. A. RAMIREZ HERRERA[2], M. L. MENDOZA MAGAÑA[2], G. DIAZ VEGA[2], L. HERNANDEZ[2];
[1]CUCBA UNIVERSIDAD DE GUADALAJARA, Guadalajara, Mexico; [2]DEPT. DE FISIOLOGIA, CUCS - UNIVERSIDAD DE GUADALAJARA, GUADALAJARA, Mexico

Abstract: Background: Oxidative stress (OS) is an imbalance between reactive oxygen species (ROS) and antioxidant defense system in favor of ROS. Indeed, high concentrations, ROS cause injuries in cell components (lipids, proteins and DNA). Therefore, OS has been associated with Ageing and Chronic-Degenerative diseases, including neurodegenerative and psychological diseases. From the latter, mental disorders as depression and anxiety, linked to GABA levels, could be associated with OS. Several studies in relation to oxidative stress have been executed in

animal models, including the nematode Caenorhabditis elegans (*C. elegans*). *C. elegans* is one of the simplest organisms with a nervous system, which is constituted by 302 neurons, 26 of these neurons establish GABAergic system. In this work, using *C. elegans*, we evaluated the effect of oxidative damage induced by hydrogen peroxide on GABAergic system through the "nose touch response" or Not assay, and we investigated if this noxious effect could be counteracted by antioxidative properties of the phytochemical diferuloylmethane. Methods: Age-synchronized Wild type N2 worms, grown on NGM-agar plates at 20°C seeded with E. coli OP50 were used in this study. 20 worms/well were placed in 12-well plates and exposed to H2O2 (0.1, 0.35 μM and 0.5mm in M9) at different times (15, 30, 45 and 60 min). Subsequently, worms were relocated to NGM-agar plates lacking food. Mechanosensory reflex (nose-touch avoidance response mediated by GABA neurotransmission) was evaluated. This protocol was repeated in a group of worms treated with GABA as a receptor GABAA agonist, and in a group of worms treated with Diferuloylmethane (DFM) as antioxidant agent by adding. Results and Conclusions: Worms after exposure to H2O2 (H2O2 concentrations from 0.35 μM and up) demonstrate a decreased nose touch avoidance response (around 39%) in relation to control. It follows that the oxidation induces a deterioration of the GABAergic system. The co-exposition of H2O2 plus GABA Partially reversed this effect. On the other hand, the deterioration of nose touch response was improved by co-exposition DFM with H202, although this effect was not statically significant.

Nacional de Córdoba, CIBICI-CONICET, Córdoba, Argentina

Abstract: Triatoma infestans, a blood feeding triatomine insect, is the main vector of Chagas'disease in Argentina and neighboring countries. Morphological, biochemical and molecular biology approaches have been employed to study the central nervous system (CNS) of this insect species. Neuropeptides have been mapped and characterized in the brain and CNS ganglia. However, within the recognized neurotransmitters only the distribution of serotonin has been reported. Cathecholamines play important roles in the brain of animal species. In insects, these neurotransmitters are involved in locomotion, learning and cuticle sclerotization among other functions. Tyrosine hydroxylase (TH) catalyzes the rate limiting step of cathecolamine biosynthesis but at present, there are few studies focused on insect TH. Two isoforms have been reported in insects; the shorter one which lacks a highly acidic region is present in neural cells. The distribution of TH in adult specimens of T. infestans was studied with our current immunocytochemistry protocol employing an antiserum developed by O' Gorman and co-workers (2007) in Manduca sexta. Our experiments have revealed the presence of numerous TH-immunoreactive (IR) cell bodies and a profuse network of neurites in all the CNS compartments. Thus, in the protocerebrum, TH-IR somata were observed in the anterior, lateral and posterior soma rinds forming clusters with variable numbers of cell bodies. Most of the immunopositive cell bodies displayed a uniform size of about 10 μm. A group of 12 somata was detected above the mushroom body calices and another one was seen at the anterolateral edge. The pars intercerebralis housed a cluster of 3 somata, their neurites were observed along the median bundle. Other protocerebral regions with TH-IR were the posteromedial soma layer and the proximal optic lobe. The antennal lobe contained TH-IR somata in both the lateral and medial soma layers; neurites from those of the lateral layer projected to the glomeruli. A small cluster of immunolabeled cell body was found in the dorsal lobe. In the prothoracic ganglion bilateral TH-IR somata were seen at the level of the exit prothoracic nerve II. Regarding the meso-metathoracic ganglionic mass, bilateral somata were found in the meso- and metathoracic neuromeres while a cell body cluster was observed in the abdominal neuromeres. A profuse network of TH-IR processes formed commissures and connectives. In homogenates of the brain and CNS ganglia, the anti-TH antibody recognized an immunoreactive band of ~ 60kDa, compatible with the values of beetles and moths. These studies revealed a widespread presence of TH in the brain and CNS ganglia of these triatomine insects.

Title: Fulicin neuropeptides in the central nervous system of Biomphalaria glabrata, the intermediate host for intestinal schistosomiasis

Authors: M. B. RODRIGUEZ, S. ROLÓN-MARTÍNEZ, L. O. VAASJO, *M. W. MILLER; Inst. Neurobio., San Juan, PR

Abstract: Approximately 200 million people worldwide live at risk of contracting the parasitic disease schistosomiasis. The digenetic trematode worm species *Schistosoma mansoni* that causes the most widespread form of intestinal schistosomiasis employs the freshwater snail *Biomphalaria glabrata* as its primary intermediate host. As infection of *B. glabrata* by *S. mansoni* is known to cause profound behavioral changes in the snail host, including parasitic castration and parasitic gigantism, a neural transcriptomics approach was undertaken to identify precursor prohormones that could encode neuropeptides involved in *Biomphalaria* reproductive and feeding behaviors. A transcript (1616 nucleotides) was found to encode a putative precursor polypeptide (316 amino acids) that could give rise to the neuropeptide fulicin (Phe–D-Asn-Glu-Phe-Val-NH_2; Ohta et al. 1991; Yasuma-Kamatani et al. 1995) and five additional related peptides. For this investigation, affinity purified polyclonal antibodies (rabbit) were generated against the predicted fulicin neuropeptide. Fulicin-like immunoreactivity was observed throughout the central nervous system (CNS) with distinct neurons and clusters on the ventral and dorsal surfaces, as well as in peripheral tissues. Large and small diameter fulicin-li cells were present on the dorsal and ventral surfaces of the buccal ganglion. In the cerebral and pedal ganglia, dispersed clusters of small diameter cells were observed. While no fulicin-li neurons were present in the right pleural ganglion, it was rich in immunoreactive fibers. Within the left parietal and visceral ganglia, clusters of large prominent cells appeared to give rise to axons projecting to the anal and intestinal nerves. These results suggest that fulicin and other peptides derived from the fulicin precursor could regulate behaviors related to food intake, reproduction, and growth that are altered during the course of infection in this host-parasite system.

Title: Histamine immunoreactivity in nervous system of crayfish Cambarellus montezumae of F0 and F1 generations

Authors: M. RODRÍGUEZ-MUÑOZ, E. OÑA-CÓRDOVA, *E. G. ESCAMILLA-CHIMAL; Univ. Nacional Autonoma De Mexico, Mexico City, Mexico

Abstract: Cambarellus montezumae (de Saussure, 1857) is endemic crayfish inhabiting at Mexico. Today is threatened by anthropocentric alteration of their habitat, for the loss of volume of water in their environmental, by chronic pollution, overfishing and the introduction of aggressive exotic species such as carp and tilapia. Although crayfish C. montezumae has a commercial, economic, historical, biological and scientific importance, this species have not been explored potential neurotransmitters that may be playing a key role in the response to stress. The increase of histamine (HA) is an indicator that there is stress in the organism, affecting locomotor activity and HA is very important for the adaptation of animals to environmental changes. The aim of this study was to determine if there immunopositivity to HA and in what areas of eyestalk and brain of C. montezumae it is presented in adults crayfish F0 generation (collected in Michoacán, place with high levels of contaminants that are considered stressful for crayfish), and if this positivity decreased in the F1 generation (adults crayfish cultured under optimal conditions of laboratory). For that, immediately after to be collected 12 animals of F0 generation were maintained in a light dark (LD) 12:12 for 15 days, 3 animals of each were sacrificed at 07:00, 11:00, 19:00 and 23:00 hours to obtain the eyestalk and brain. 12 crayfish of F1 generation are processed in the same way as F0. Tissues were fixed and subsequently cut in 10 μm slices, several preparations were randomly chosen to perform immunohistochemistry using polyclonal antibody anti-histamine, Warp Red Chromegen Kit (Biocare Medical) and subsequently the preparations were analyzed in a microscope. The crayfish F0 generation showed immunopositivity to HA mainly in the lamina ganglionaris of eyestalk, in brain was not positivity. In organisms F1 generation not immunopositivity observed in brain, although immunoreactivity was itself presented at the lamina ganglionaris but this was lower than the F0 generation, so we can conclude that water pollution, where organisms live, it might be being a stressor in the animals, these crayfish answering with an increase in HA, primarily in the eyestalk that is the tissue that is more exposed to water pollutants, because they are located in a front position outside the body, unlike the F1 animals found with good nutrition and unpolluted water where he found little positivity to HA.

Title: Cephalopod neural transcriptomes reveal unique strategies for memory centers

Authors: *G. C. WINTERS[1], A. B. KOHN[2], N. STERN[3], B. HOCHNER[3], E. T. WALTERS[4], R. J. CROOK[4], L. L. MOROZ[1];
[1]Neurosci., Univ. of Florida- Whitney Lab. for Marine Biosci., Saint Augustine, FL; [2]Whitney Lab. for Marine Biosci., Univ. of Florida, Saint Augustine, FL; [3]Hebrew Univ. of Jerusalem, Jerusalem, Israel; [4]Integrative Biol. and Pharmacol., Univ. of Texas Hlth. Sci. Ctr. at Houston, Houston, TX

Abstract: Cephalopod molluscs (*Octopus, Sepia, Loligo,* and *Nautilus*) exhibit flexible behavior and are capable of advanced learning and memory. One of the most distinct cephalopod innovations is the Vertical Lobe (VL), an analog to the mammalian hippocampus containing circuitry essential for memory formation. Little is known about the molecular organization of the VL and related memory centers. We constructed, sequenced and analyzed neural transcriptomes from *Octopus* VL, CNS, SFL (Superior Frontal lobe) and arm cords, and compared these transcriptomes to neural transcriptomes of gastropod molluscs including *Aplysia californica*. We

identified 17,841 transcripts in the VL and found12,379 (69.4%) appear to be cephalopod-specific (no known annotation). Only 15 of the 50 highest expressed transcripts in the VL had homologs in other bilaterians, many of which are involved in cellular energetics and homeostasis. Only 12.4% of the transcripts detected in the *Octopus* VL share identity with transcripts from *Aplysia*. Remarkably, indicators for many memory related signal molecules and transmitters like NO (NOS), GABA (GAD), and acetylcholine (ChAT) were not identified in the VL transcriptome, suggesting a distinct cephalopod-specific complement of molecules independently recruited in the organization of learning and memory-forming circuits. Second, we characterized the complement of neuropeptide precursors expressed in the *Octopus* VL and SFL (containing presynaptic cells to the VL circuit). Two of the most abundant transcripts in the VL encode novel neuropeptides unique to *Octopus*. We used the well characterized neuropeptide precursor complement of *Aplysia* and found 22 homologs in *Octopus* VL and 23 in the SFL. Overall, we identified 50 neuropeptide precursors in cephalopods and compared them to 88 known prohormones encoded in the *Aplysia* genome. Only 31 prohormones detected in *Nautilus, Loligo, Sepia* and *Octopus* were homologous to *Aplysia* neuropeptides with 19 being cephalopod-specific. One of the unique cephalopod neuropeptides, PMEFLamide is highly expressed in *Octopus* brain, but absent in the ancestrally branching *Nautilus* CNS (which lacks a VL). This expansion of novel signaling molecules in the VL circuit is likely a key feature of the unique memory systems of cephalopods. Finally, using *in situ* hybridization we characterized expression of 17 neuropeptide mRNAs in *Octopus*, and 13 in *Loligo pealei*, and each exhibits distinct and reproducible localization patterns. Only FLRIamide, Bradykinin, Conopressin, and Buccalin have been localized to the VL, further implying extensive parallel evolution of cephalopod brains and memory circuits in particular.

Title: Single cell genome-wide analysis of ion channel expression in simpler neural circuits

Authors: *A. B. KOHN[1], E. C. DABE[1,2], C. BOSTWICK[1,2], L. L. MOROZ[1,2];
[1]Universtiy of Florida Whitney Lab., Saint Augustine, FL; [2]Univ. of Florida, Dept of Neurosci., Gainesville, FL

Abstract: Ion channels are intimately involved in virtually every physiological process in any neural circuit but little is known about their cell-specific expression at the genomic scale. Here, we combined single-cell RNA-seq and epigenomic profiling to characterize the entire ion channel complements from identified neurons of the feeding and defensive networks of *Aplysia* californica. The developed protocols also allowed both quantification of expression respective mRNAs and analysis of their methylation status in cells of interests. The *Aplysia* genome encodes for 221 ion channels compared to the genomes of Homo, *C. elegans* and *Drosophila* with 235, 227 and 132 genes coding for ion channels, respectively. However even though the numbers of ion channels are similar for humans and *Aplysia*, their composition is vastly different. *Aplysia* as well as other molluscs, Lottia and Crassostrea have a large expansion of the ligand-gated ion channels (LGICs) however, less voltage gated ion channels compared to all other metazoans. First, we quantify the expression of ion channels in known identified sensory, motor and interneurons within a functionally characterized circuit controlling stereotyped and learned behaviors. For example, we identified and quantified on average 56 ion channels in a single presynaptic mechanosensory neuron (VC) compared to 94 in a single postsynaptic motoneuron, L7 and a single serotonergic MCC neuron expresses an average of 67 ion channels. Interestingly, the mechanosensory VC neurons and MCC express a similar number of ionotropic glutamate receptors (iGluRs) at 7 whereas L7 expresses on average 11 iGluRs. The most abundant transcript expressed in mechanosensory neuron is a voltage-gated sodium channel yet in L7 a voltage-sensitive calcium-activated chloride channel, anoctamin is most highly expressed. Second,we developed a direct and efficient method to perform unbiased capture and sequencing of newly synthesized RNA (nRNA-seq) following long-term plasticity on the scale of the entire genome and tested differential expression of ion channels following application of 5HT (2hrs) in sensory neurons. Overall, the expression levels of all the ion channel mRNAs increased 25% in the 5HT treated compared to control but the number of iGluR transcripts increased 50% under the same conditions. The obtained data about the dynamic nature of ion channel complement together with comparative genomic analysis across metazoans allows us to begin to reconstruct the molecular basis of neuronal identity and plasticity.

Title: Capture of nascent RNAs during classical conditioning in *Aplysia californica*

Authors: *C. BOSTWICK[1,2], Q. YANG[3], A. B. KOHN[1], R. D. HAWKINS[3,4], L. L. MOROZ[1,2];
[1]Neurosci., Univ. of Florida, Whitney Marine Lab., Saint Augustine, FL; [2]Neurosci., Univ. of Florida, Gainesville, FL; [3]Neurosci., Columbia Univ., New York, NY; [4]New York State Psychiatric Inst., New York, NY

Abstract: A requirement for the formation of long term memories is the synthesis of new RNA and proteins as well as epigenetic changes in the genome underlying orchestrated gene regulation, including a requirement for DNA methylation (c.f. Hawkins et al, 2015). We developed a direct and efficient method to unbiasedly capture and sequence newly synthesized RNA (nRNA-Seq) (Kohn et al., 2015), and have now applied it to behavioral learning. We used a reduced preparation of the *Aplysia* siphon withdrawal reflex (Antonov et al., 2007) in which it is possible to record the activity and synaptic connections of identified neurons during several simple forms of learning including classical conditioning, and to examine the dynamics of newly synthesized RNAs at any selected time during the learning. The reflex is mediated by neurons in the abdominal ganglion, which was removed after the end of either paired training (conditioning) or unpaired training (control) and prepared for nRNA-Seq. We sequenced three biological replicates, each comparing ganglia from paired-trained and unpaired-trained preparations. We found 55 transcripts at >2 fold change and $p< 0.05$ to be differentially expressed between preparations that had received paired compared to unpaired training. There were 23 transcripts upregulated in paired-trained ganglia. Some of these transcripts include: a DNA transposase, a multidrug resistance-associated transporter protein and apolipoprotein D (a neuronal lipoprotein thought to function in lipoprotein metabolism). We also found 32 transcripts to be downregulated, including two neuropeptides, a T-box type transcription factor, and sidekick-2, a cell adhesion protein that functions to guide synaptic growth in neurons. Also of interest are the set of differentially expressed "uncharacterized" transcripts, including non-protein-coding RNAs. These transcripts may serve a variety of roles, including regulating gene expression or post-transcriptional modifications. They may also be neuronal-specific noncoding RNAs that mediate other unknown regulatory roles within the nervous system. This study is the first to unbiasedly characterize the set of nascent RNA molecules transcribed as a result of associative learning, and

has the potential to provide insights into the transcriptional changes and cellular signaling pathways activated by classical conditioning.

Title: High-level mRNA expression of orthologous secreted proteins is a feature of the sea slug brain

Authors: A. SENATORE[1,2], *J. W. BOYKIN[1], P. GANUPURU[1], P. S. KATZ[1];
[1]Georgia State Univ., Atlanta, GA; [2]Univ. of Toronto, Toronto, ON, Canada

Abstract: Secreted proteins play key roles in animal nervous systems, where they can function as peptide neurotransmitters, hormones, growth factors, and in maintaining extracellular matrix structure. We sequenced and *de novo* assembled the CNS transcriptomes of six sea slug species, *Tritonia diomedea*, *Melibe leonina*, *Dendronotus iris*, *Hermissenda crassicornis*, *Flabellina iodinea*, and *Pleurobranchaea californica* (Gastropoda, Nudipleura), and used a novel ortholog-guided approach to predict between 718 and 841 secreted proteins for each species. Comparative gene expression profiling revealed that orthologous secretory genes are consistently enriched in the sea slug brain relative to all other genes, and that a small subset of these exhibit dramatically high expression levels. Among these are homologs for molluscan cerebral peptide 1, small cardioactive peptide, and neuroactive polyprotein R15, as well as several uncharacterized proteins. While the majority of orthologous secretome genes exhibit similar expression levels across the six species, some show species-specific enrichment, perhaps reflecting unique adaptations. The predicted secreted proteins and their corresponding gene expression profiles provide a means for probing the physiology of secretion in the sea slug brain, and for evaluating evolutionary changes in peptidergic signaling.

Title: Spider, Cupiennius salei, mechanosensory neurons have multiple biogenic amine receptor types, including constitutively active receptors

Authors: *P. H. TORKKELI[1], V. SUKUMAR[1], S. MEISNER[1], I. PANEK[2], A. S. FRENCH[1]; [1]Dept Physiol & Biophysics, [2]Dept. of Med. Neurosci., Dalhousie Univ., Halifax, NS, Canada

Abstract: Peripheral mechanosensory neurons of spider, Cupiennius salei, are innervated by efferent neurons that contain γ-aminobutyric acid (GABA), glutamate, acetylcholine and octopamine (OA). Strain detecting VS-3 neurons in the spider leg patella respond to these transmitters with changes in sensitivity to mechanical or electrical stimuli. OA has an excitatory effect on VS-3 neurons. A search of the spider leg peripheral tissue transcriptome revealed eight complete and three partial putative G-protein coupled receptor sequences that are homologous to invertebrate α- and β-adrenergic-like OA and tyramine (TA) receptors. However, it is not known which cells contain these receptors, so we asked if TA also modulates VS-3 neurons, and whether it acts via the same or different receptors than OA. Immunohistochemistry with an antibody against tyramine found no labeling in the efferent fibers surrounding the VS-3 neurons. However, some of the VS-3 neurons were immunoreactive to this antibody and there was strong labeling in small cells adjacent to the main leg nerve and the VS-3 neurons, suggesting that there is a local source of TA in the periphery. VS-3 neurons were stimulated electrically with pseudorandom noise before and during TA application. TA depolarized the neurons by about 5 mV and caused a dose-dependent rise in action potential firing rate with an EC50 of 15.1 μM that saturated at about 50 μM. TA concentrations above 200 μM caused a smaller change in firing rate. Frequency response analysis showed that TA increased the VS-3 neuron sensitivity significantly at all frequencies, but more in the high frequency range. These effects were similar to OA effects on VS-3 neurons, but OA effects saturated at 20 μM. Mianserin (10 μM), an antagonist of β-adrenergic-like OA receptors, blocked both OA and TA effects on VS-3 neurons. The same concentration of yohimbine, an antagonist of α-adrenergic-like TA and OA receptors, did not significantly change the TA or OA effects on firing rate, but reduced the firing under control conditions. Removal of yohimbine from superfusion caused a rebound effect with a significant increase in VS 3 neuron sensitivity. These results indicate that there are at least two different types of adrenergic-like receptors in the VS-3 neurons. Both OA and TA activate

mianserin sensitive β-adrenergic-like receptors. The yohimbine effect suggests that VS 3 neurons also have constitutively active α-adrenergic-like biogenic amine receptors. These types of receptors could provide precise control of neuronal sensitivity by using different ligands to modulate basal activity of the neuron.

Title: A key role for GluN2D NMDA receptor subunits in ketamine's stimulation of brain activity; implications for schizophrenia and depression

Authors: *K. SAPKOTA[1], Z. MAO[1], V. GAUTAM[2], D. MONAGHAN[1];
[1]Pharmacol. and Exptl. Neurosci., Univ. of Nebraska Med. Ctr., Omaha, NE; [2]Mass Gen. Inst. of Neurogenerative Dis., Harvard Med. Sch., Charelstown, MA 02129, MA

Abstract: The hypothesis that N-methyl-D-aspartate receptor (NMDAR)-hypofunction underlies the symptoms of schizophrenia (SZ) is supported by many observations, including the finding that acute ketamine administration mimics many of the positive, negative, and cognitive symptoms of schizophrenia (SZ). Under *in vivo* conditions, ketamine has highest affinity for NMDARs containing GluN2C and GluN2D subunits, thus these subunits may have a dominant role in ketamine's psychotomimetic actions. Given that GluN2D subunits are expressed in the parvalbumin-containing GABAergic interneurons that are critical to SZ-related behavior and the generation of gamma neuronal oscillations, we examined the potential role of GluN2D subunits in ketamine's actions. We determined the ability of ketamine to alter regional brain activity as measured by [14C]-2-deoxy-glucose (2-DG) uptake in wildtype (WT) C57BL/6 mice and GluN2D-knockout (GluN2D-KO) mice. In the WT mouse, ketamine (30 mg/kg, i.p.) significantly increased relative regional brain activity 15 minutes post-injection in the medial prefrontal cortex (mPFC), retrosplenial cortex (RSPL), entorhinal cortex, caudate putamen, hippocampus, and presubiculum and decreased 2DG uptake in sensory cortex and inferior colliculus. In the GluN2D-KO mouse, however, there was no significant ketamine-induced increase in 2DG in any brain region. Ketamine-induced reductions in 2-DG uptake were, however, still observed in the sensory cortex and inferior colliculus of GluN2D-KO mice. Likewise, ketamine-induced increases in open field locomotor activity were present in WT mice

and absent in GluN2D-KO mice. These findings suggest a potential role of GluN2D in SZ symptoms. Further evidence for a GluN2D role is suggested by the observation that GluN2D KO mice were found to have a reduced number of PV-immunopositive cells in the mPFC, a finding that parallels that seen in SZ. Thus, GluN2D subunit hypofunction may underlie important components of SZ. Since acute ketamine administration can also reduce symptoms of depression after ketamine is eliminated, the present results also suggest a potential role for GluN2D subunits in the treatment of depression. Acknowledgement: The authors thank Dr. Masayoshi Mishina for generously providing the GluN2D-KO mouse.

Title: The tyrosine kinase Abl2/Arg regulates GluN2B-containing NMDA receptors

Authors: *A. D. LEVY[1], X. XIAO[2], M. JEDRYCHOWSKI[4], S. GYGI[4], A. J. KOLESKE[2,3,1]; [1]Interdepartmental Neurosci. Program, [2]Mol. Biophysics and Biochem., [3]Neurobio., Yale Univ., New Haven, CT; [4]Cell Biol., Harvard Med. Sch., Boston, MA

Abstract: NMDA receptors (NMDARs) are important for learning, memory, and plasticity and regulate dendritic spine structure. Accordingly, tight orchestration of their activity, surface expression and synaptic localization by regulatory proteins is critical for proper neuronal signaling. Loss of NMDAR regulators leads to misregulation of NMDAR currents, which can cause dendritic spine loss or even cellular excitotoxicity. We have shown previously that the integrin-regulated Abl2/Arg (Arg) tyrosine kinase is required for dendritic spine stability, as *arg–/–* mice have normal spine density at postnatal day (P) 21 but lose spines and synapses by P31. In primary hippocampal neurons, late *arg* knockdown also causes spine loss and can be rescued by inhibiting NMDARs with APV or the GluN2B-specific antagonist ifenprodil. These

results suggest that Arg normally inhibits GluN2B-containing NMDAR currents to stabilize spines. In agreement with this hypothesis, we have recently shown that *arg–/–* mice have increased synaptic NMDAR currents through channels containing the GluN2B subunit as early as P21, suggesting that increased GluN2B-mediated currents may precipitate spine loss in *arg–/–* mice. However, the molecular link between Arg and GluN2B that regulates NMDAR currents and spine stability is unknown. Arg can interact with another tyrosine kinase, Src, and Src family kinases phosphorylate Y1472 on the GluN2B intracellular tail. This phosphorylation event prevents synaptic GluN2B internalization, increasing surface receptor content and NMDAR currents, suggesting a possible mechanism by which Arg can regulate GluN2B. However, we found that Y1472 phosphorylation at the synapse was not increased in *arg–/–* mice, demonstrating that Arg does not regulate GluN2B Y1472 phosphorylation to control NMDAR currents. To further pursue this mechanism, we performed a mass spectrometry screen for proteins with altered relative phosphotyrosine levels in *arg–/–* post-synaptic densities compared to wild type to identify in an unbiased manner new synaptic substrates or signaling partners of Arg that might regulate NMDAR currents. This screen identified several regulators of plasma membrane protein trafficking with significantly reduced tyrosine phosphorylation at P21 and P31 in *arg–/–*, including a known Arg substrate. These preliminary experiments suggest that Arg acts on one of these targets to regulate GluN2B trafficking.

Title: Differential splicing of GluN1 C-terminus controls NMDA receptor unitary conductance and pore architecture

Authors: *A. NIGAM[1], G. IACOBUCCI[1], B. GEORGE[2], G. POPESCU[1];
[1]Dept. of Biochem., [2]Dept. of Biol., Univ. of Buffalo, Buffalo, NY

Abstract: NMDA receptors (NMDARs) are glutamate-gated excitatory channels with fundamental roles in synaptic transmission and plasticity. Despite their involvement with multiple neurological disorders, a complete understanding of their functional regulation is lacking. NMDARs assemble as obligatory heterotetramers from three gene products, GluN1 through GluN3, of which the GluN1 subunit is common to all receptor isoforms. The GluN1

transcript is alternatively spliced to form four functional variants that differ in their intracellular C-termini. To investigate how this regulation affects channel properties we examined single-channel and whole cell currents from four types of recombinant GluN1-a/GluN2A receptors expressed in HEK 293 cells. We found that the GluN1 C-terminus controlled channel unitary conductance (, pS): GluN1-1, 66 ± 2 (n, 5), GluN1-2, 67 ± 2 (n, 6; $p>0.05$); GluN1-3, 74 ± 2 (n, 5; $p<0.05$), GluN1-4, 54 ± 2 (n, 5; $p<0.05$). Further, we found that these conductance changes correlated with changes in permeability to organic cations of known size. Specifically, the permeability to di-methyl ammonium, as estimated by measuring the reversal potential (mV), decreased from -40 ± 1 (n, 5) to -20 ± 1 (n, 4; $p<0.05$) for receptors containing GluN1-1 or GluN1-3 subunits, respectively. Based on these result, we propose that regulated splicing of the GluN1 C-terminus controls the unitary current amplitude of NMDARs by controlling pore size. This novel finding has important implications for understanding the structural and mechanistic bases of ionic flux through NMDARs and therefore, how the synaptic signal is controlled at central synapses.

Title: Characterization of the Grin2adeltaPKC Mouse

Authors: ***D. BALU**[1], J. R. LARSON[2], J. V. SCHMIDT[3], J. P. LEONARD[3];
[1]Dept. of Biol. Sciences, Lab. of Integrative Neurosci., [2]Dept. of Psychiatry, Univ. of Illinois at Chicago, Chicago, IL; [3]Biol. Sci., Univ. of Illinois - Chicago, Chicago, IL

Abstract: The NMDA receptor subunit GluN2A, has a number of sites directly phosphorylated by kinases such as CaMKII, PKA, and PKC. Previous studies from our lab have identified Ser 1291 and Ser 1312 as two important sites for direct PKC phosphorylation; while Tyr 1292 and Tyr 1312 are two of the sites indirectly phosphorylated by PKC via Src kinase. In the oocyte expression system, mutation of those Serine sites to Alanine (that cannot be phosphorylated) in the GluN2A subunit, resulted in a decreased PKC stimulated current enhancement through the receptors compared to control (WT) NMDA receptors. To investigate the behavioral and physiological significance of those sites *in vivo*, the *Grin2adeltaPKC* mouse expressing GluN2A with those four mutated amino acids (S1291A, S1312A, Y1292F and Y1387F) was generated using homologous recombination. The mutant mice were like their WT-littermate controls in

their body weight, appearance, and general activity. Mutant and WT mice also have similar expression levels of *Grin2a* mRNA, and GluN2A protein. In this study, we provide evidence suggesting that at least one of those sites that is phosphorylated in the C-terminal domain of the GluN2A subunit contributes to anxiety-related behavior. The mice expressing the mutant GluN2A subunit show anxiolytic-like behavior in open field test, light dark emergence test, and elevated plus maze. The mutants also show mild spatial working memory deficits such as reduced spontaneous alternation in a Y maze and a decreased alternation in a T maze. Interestingly, immunostaining for c-fos (a neuronal activation marker) in the hippocampus after exposure of the animals to novel environments shows region specific differences between the mutants and WT mice. There was no increase in c-fos levels in mutants after exposure to novel environments in CA1 and CA3 compared to home-cage (basal) c-fos levels, while the c-fos increased in the WT mice in CA1, CA3 and dentate gyrus (DG). However, both groups had similar basal c-fos levels in the CA1, CA3, and DG. To determine if the mutants had impaired synaptic plasticity in the hippocampus, the Schaffer collateral-CA1 synapses were stimulated using a theta-burst protocol. In hippocampal slices obtained from mutant mice, there was no impairment in LTP. Also, the mutant mice showed no significant differences in input-output curves and paired-pulse facilitation. Taken together, these results suggest that PKC-mediated phosphorylation of at least one of those four sites regulates NMDAR-mediated signaling that modulates anxiety, and spatial working memory. *Grin2adeltaPKC* mice generation was supported by a National Institute of Health grant (R03-NS056321).

Abstract: Over-activation of neuronal N-methyl-D-aspartate receptors (NMDAR)s causes excitotoxicity and is critical for neuronal death. In the classical view, these ligand-gated Ca2+ permeable ionotropic receptors require co-agonists and membrane depolarization for activation. We report that NMDARs signal during ligand binding that can occur independent of activation of their ion conduction pore. Pharmacological pore block with MK-801 or physiological pore block with Mg2+ prevented NMDAR currents, but failed to block secondary excitotoxic membrane currents and dendritic blebbing induced by NMDA-overstimulation. Recruitment of pannexin-1 (Panx1) channels was critical in this latent excitotoxic response. Indeed, Panx1 opening mediated the bulk of excitotoxic Ca2+ influx during NMDA receptor excitotoxicity. In contrast to MK-801, competitive antagonists that prevent ligand binding to the NMDAR prevented downstream Panx1 opening, membrane currents and blebbing. NMDARs, Src family kinases and Panx1 were found in a signaling complex and activation of Panx1 involved phosphorylation at Y308. Block of this NMDAR-Src-Panx1 signalsome was neuroprotective *in vitro* and *in situ* - dramatically reducing Panx1 currents, Ca2+-dysregulation, membrane blebbing, and cell lysis. Further, NMDAR/Src-dependent Ca2+-influx through Panx1 was critical in activating the mitochondrial permeability transition pore (mPTP) and subsequent dysfunction. Lastly, disrupting NMDAR-Src-Panx1 *in vivo* was tested by administration of TAT-Panx308 either before or 2 hours after transient middle cerebral artery occlusion (tMCAO) reduced stroke lesion volume and preserved neurological output in a skilled reaching task. Our observations provide key insights into a novel signaling modality of NMDARs that has broad reaching implications for brain physiology and pathology.

Title: Impact of human anti-GluN1 antibodies on synaptic and extrasynaptic NMDA receptors

Authors: *J. A. PANZER[1], A. RATTELLE[2], D. LYNCH[2];
[1]Neurol., [2]Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Neuronal N-Methyl-d-aspartate receptors (NMDARs) are located at both synaptic and extrasynaptic locations; signaling from receptors at synaptic sites can promote synaptic plasticity and cell survival whereas extrasynaptic signaling has been linked to neurodegeneration. In the autoimmune disease anti-NMDAR encephalitis, antibodies bind the GluN1 subunit of the NMDAR, resulting in psychosis, altered consciousness, seizures, dyskinesias, and autonomic dysfunction. Antibodies bind to the GluN1 extracellular amino-terminal domain (ATD), resulting in transient stabilization of the receptor's open conformation, which is then followed by displacement of synaptic NMDARs and NMDAR hypofunction due to receptor cross-linking and internalization. To explore the role of receptor conformational state on antibody recognition, we have identified a GluN1 mutant that enhances antibody binding and studied its functional properties. Furthermore, we have investigated determinants of NMDAR internalization, demonstrating that enhancement of receptor crosslinking results in increased internalization, and explored approaches to block and evaluate this internalization at synaptic and extrasynaptic sites. Finally, we have investigated antibody impact on NMDAR-mediated downstream signaling at synaptic and extrasynaptic sites, demonstrating specific effects on molecular mediators of synaptic NMDAR signaling. These results may explain the unique clinical symptoms of the disease, which do not precisely replicate global NMDAR knockdown, and may point towards potential therapeutic targets in anti-NMDAR encephalitis. The unique properties of these antibodies also raise the possibility of their use as tools to explore NMDAR function.

Title: Evidence for a GluN2D NMDA receptor subunit contribution to ketamine and MK-801 stimulation of gamma oscillations; a potential role for GluN2D in schizophrenia

Authors: *Z. MAO[1], P. SYNOWICKI[2], D. LIEBER[1], K. SAPKOTA[1], V. GAUTAM[3], D. MONAGHAN[1];
[1]Univ. of Nebraska Med. Ctr., Omaha, NE; [2]Univ. of Nebraska at Omaha, Omaha, NE; [3]Harvard Med. Sch., Charlestown, MA

Abstract: The hypothesis that N-methyl-D-aspartate receptor (NMDAR)-hypofunction underlies the symptoms of schizophrenia (SZ) is supported by many observations, including the finding that acute ketamine and MK-801 administration mimics many of the positive, negative, and cognitive symptoms of schizophrenia (SZ). Studies have now demonstrated an impairment of gamma oscillatory activity during cognitive tasks in schizophrenic patients. Since NMDAR blockade augments basal neuronal oscillations in the gamma and other frequency bands, the acute cognitive disruptions of NMDAR blockade could be due to their ability to alter neuronal oscillations. We hypothesized that GluN2D subunits may have a preferential role in regulating gamma oscillations for two reasons: 1) Ketamine has highest affinity for NMDARs containing GluN2C and GluN2D subunits *in vivo* and 2) GluN2D subunits are expressed in the parvalbumin-containing GABAergic interneurons that are critical to the generation of gamma oscillations. Thus, we examined the potential role of GluN2D subunits in ketamine stimulation of neuronal oscillations in wildtype (WT) and GluN2D-knockout (GluN2D-KO) mice. Neuronal oscillations were measured by electrocorticography (ECoG) before and after ketamine (30 mg/kg, i.p.) in WT and GluN2D-KO mice. Frequency spectrum analysis indicated that ketamine induced a 120% increase in the upper gamma band's (45-80 Hz) oscillatory power in retrosplenial (RSPL) cortex of WT mice, but only a 20% increase in GluN2D-KO mice. Ketamine-enhanced power was also significantly reduced in the 110-140 Hz frequency band in GluN2D-KO compared to WT mice. Blockade of NMDA receptors by MK-801 caused a similar enhancement in neuronal oscillations in WT mice that were reduced in GluN2D-KO mice. These findings suggest a potential role of GluN2D in neuronal oscillations and SZ pathology. Thus, GluN2D subunit hypofunction may underlie important components of SZ by altering neuronal oscillations in specific brain regions. Acknowledgement: The authors thank Dr. Masayoshi Mishina for generously providing the GluN2D-KO mouse.

Title: Interactions of ketamine administration and mtor signaling on parvalbumin positive neurons

Authors: *M. M. BOLTON, C. F. HEANEY, A. S. MURTISHAW, M. A. LANGHARDT, J. W. KINNEY;
Psychology, Univ. of Nevada, Las Vegas, Las Vegas, NV

Abstract: Ketamine is a high affinity non-competitive antagonist of the ionotropic N-methyl-D-aspartate (NMDA) glutamate receptor. Several previous investigations in our laboratory using chronic (15 days) subanaesthetic administration of ketamine have demonstrated learning and memory deficits in rodents. We have also repeatedly observed an increase in the number and altered position of parvalbumin positive (PV+) neurons in the CA3 field of the hippocampus in ketamine treated animals. Numerous recent clinical studies have demonstrated a rapid-acting antidepressant effect of subanaesthetic ketamine, however the mechanisms responsible are not fully understood. To understand the mechanism through which ketamine induces a change in PV+ neurons, we performed an experiment to inhibit the mTOR signaling pathway using rapamycin. The same chronic, subanaesthetic dose and administration of ketamine was performed for 15 days along with bilateral hippocampal infusion of rapamycin (inhibitor of mTOR signaling). In this investigation, we demonstrated that rapamycin reduced the ketamine-induced increase in struggle in the forced swim test. In the present study, we evaluated PV+ neuronal number and position in hippocampus and cortex to determine if rapamycin ameliorated the ketamine induced changes. Our data indicate that rapamycin attenuated ketamine induced changes in number of PV+ cells in the CA1 region of the hippocampus and cortex. These data indicate mTOR signaling may be a mechanism involved in the altered PV+ neuronal number and may be associated with ketamine induced increase struggle time in the forced swim task. Further, PV+ number and position were not changed in the dentate gyrus and CA3 field by the ketamine administration consistent with our previous learning and memory investigations. These data may indicate the change in PV+ neurons in discrete regions may depend on training and activity. This study suggests that a mechanism linking ketamine administration and parvalbumin alteration may be mediated via mTOR signaling. The reduction in ketamine induced struggle time by rapamycin indicates the mechanism underlying ketamine may also involve mTOR signaling.

Title: Critical role for NMDA receptor subunit in layer 5 prefrontal cortex dopamine modulation

Authors: *J. IAFRATI[1], S. ROBINSON[1], K. SAKIMURA[2], V. SOHAL[1];
[1]Dept. of Psychiatry - Ctr. for Integrative Neurosci., Univ. of California San Francisco - UCSF, San Francisco, CA; [2]Brain Res. Institute, Basic Neurosci. Branch, Dept. of Cell. Neurobio., Niigata Univ., Niigata, Japan

Abstract: Prefrontal cortex (PFC) plays a key role in cognitive and emotional behaviors which are affected in many neuropsychiatric disorders. Dopamine is a major modulator of PFC activity and recent studies show that layer 5 (L5) pyramidal neurons, a major source of prefrontal output, can be divided in two main subpopulations. These L5 pyramidal subtypes project to different brain areas and exhibit specific modulation of intrinsic excitability after D1R or D2R activation (Gee et al, 2012; Seong and Carter, 2012). Indeed, we previously show than the D2-expressing subtype exhibits a prominent afterdepolarization following D2 receptor (D2R) activation and coincident NMDAR stimulation. The role of specific NMDAR subunits in this phenomenon remains unclear. Moreover the afterdepolarization specifically appears in adult mice. NMDAR subunit composition is known to switch during development, typically from prominent expression of GluN2B to increased expression of the GluN2A subunit. To test whether the D2R-induced afterdepolarization depends on specific NMDAR subunits, we used conditional transgenic mice to delete NMDAR subunits in prefrontal cortex. We used a combination of optogenetic techniques, pharmacology, and patch-clamp recordings from D1R and D2R expressing neurons. Our preliminary data suggest that the D2R-induced afterdepolarization is markedly enhanced by GluN2B deletion. This effect is cell type specific and can be suppressed by D2R antagonists. Further experiments will investigate the detailed mechanism and potential consequences of this effect. Funded by NIMH/NIH.

Title: Modulation of hippocampal extrasynaptic NMDA receptor function by stress

Authors: Y. C. TSE[1], J. LOPEZ[2], A. S. WONG[2], *T. WONG[2];
[1]Douglas Inst., Montreal, QC, Canada; [2]Neurosci., Douglas Inst., Verdun, QC, Canada

Abstract: N-methyl-D-aspartate receptor (NMDAR) are located in both the synaptic and extrasynaptic regions. Findings from previous studies suggested distinct roles of NMDARs in these two regions in neuronal survival and synaptic plasticity. NMDAR functions are also highly sensitive to stress and stress hormone corticosterone (CORT). We have shown that synaptic NMDARs function can be enhanced by stress-level CORT in CA1 pyramidal neurons of adult rats. Impact of stress on extrasynaptic NMDAR function remains unknown. Here, we report that a brief treatment of stress-level CORT (100 nM) also reduced hippocampal extrasynaptic NMDAR function, which was induced by either TBOA or a brief tetanus (10 pulses at 100 Hz) after the blockade of synaptic NMDARs by MK801. To determine whether synaptic and extrasynaptic functions can also be modulated by chronic stress, we measured hippocampal synaptic and extrasynaptic NMDAR functions in mice that were stressed by chronic social defeat. Notably, we found that while extrasynaptic NMDAR function was reduced in mice that were susceptible to chronic social defeat by exhibiting social avoidance in a social interaction test after stress, decrease in extrasynaptic NMDAR function was not observed in mice that were resilient to chronic social defeat (i.e. mice displayed no social avoidance after stress). Hippocampal synaptic NMDAR function in both susceptible and resilient mice was not altered by chronic social defeat. Our findings suggest that stress-induced reduction of extrasynaptic NMDAR function is important for the development of social avoidance, a depression-related behavior in socially defeated mice.

Title: Memantine and ketamine differentially alter desensitization kinetics of NMDA receptors

Authors: *N. G. GLASGOW[1], A. AZOFEIFA[2], J. W. JOHNSON[1];
[1]Dept. of Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [2]Dept. of Neurosci., Univ. of Pttsburgh, Pittsburgh, PA

Abstract: Memantine and ketamine act similarly as open channel blockers of NMDA receptors (NMDARs), yet the two drugs have remarkably divergent effects in humans. Memantine is a very well-tolerated drug that is approved for treatment of moderate to severe Alzheimer's disease, whereas ketamine causes psychotomimetic side effects, but also exhibits rapid

antidepressant effects in depressed patients. The basic mechanisms underlying the divergent clinical effects of memantine and ketamine are not well understood and are under debate. One proposed explanation for the differential effects of memantine and ketamine focuses on the hypothesis that the drugs inhibit distinct subpopulations of NMDARs. Subpopulations that might be differentially inhibited by memantine versus ketamine include receptors distinguished by the typical duration of their exposure to glutamate (e.g., synaptic versus extrasynaptic receptors), or distinguished by their subunit composition (that is, NMDAR subtype). We focus on GluN1/2A and GluN1/2B receptor subtypes because of their predominant expression in cortical and hippocampal pyramidal cells, neuron subtypes thought to be broadly involved in neurodegenerative and depressive disorders. We found that inhibition of heterologously expressed NMDARs by memantine and by ketamine depends on duration of glutamate application and on receptor subtype. We used kinetic modeling to investigate the mechanism by which inhibition of GluN1/2A receptors by memantine depends on duration of glutamate application. Our results suggest that memantine stabilizes a desensitized state of GluN1/2A receptors. Therefore, we measured the time course of recovery from desensitization of GluN1/2A and GluN1/2B receptors in the absence or presence of memantine and of ketamine. We found that memantine slows recovery from desensitization of GluN1/2A receptors, but not of GluN1/2B receptors. In contrast, ketamine does not affect the time course of recovery from desensitization of GluN1/2A receptors, but speeds recovery from desensitization of GluN1/2B receptors. Further, we found that memantine slows recovery from desensitization of GluN1/2A receptors in a Ca2+-dependent manner. Our results suggest that memantine and ketamine differentially alter NMDAR desensitization kinetics in a subtype-dependent manner.

Title: The mechanism underlying NMDA receptor blockage-induced fast-acting antidepressant effect

Authors: K. ZHANG[1], T. XU[1,2], V. NAGAI YAMAKI[1], M. HUANG[2], *X. CAI[1];
[1]Physiol., Southern Illinois Univ., Carbondale, IL; [2]The Second Affiliated Hosp. of Guangzhou Med. University, Inst. of Neurosci., Guangzhou Med. Univ., Guangzhou, China

Abstract: Major depressive disorder (MDD) is a serious public health problem with a lifetime prevalence of 17% in the United States. Despite the high incidence of MDD and its socioeconomic impact, the etiology of MDD remains largely unknown. Recent evidence from clinical trials shows that a single subanesthesia dose (0.5-20 mg/kg) of ketamine, a noncompetitive ionotropic glutamatergic NMDA receptor antagonist, produces rapid antidepressant responses in patients suffering from MDD. However, recent studies on the mechanism underlying ketamine's fast-acting antidepressant effect are controversial. Moreover, the psychotomimetic properties and abuse potential of ketamine necessitate caution in promoting this compound as a general treatment for depression. Understanding the underlying mechanism of action of ketamine linked to behavioral improvement is of significant importance for developing novel, safe and fast-acting antidepressants. In the current study, we provide evidence to support a new hypothesis on how NMDA receptor blockage induces fast antidepressant effect, which is quite different from the prevalent theories about fast antidepressant action of ketamine.

Title: Assessment of memantine on long-term potentiation in the Ts65Dn, a mouse model of Down syndrome

Authors: *J. J. SCOTT-MCKEAN, A. L. ROQUE, A. C. S. COSTA;
Dept. of Pediatrics, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS), or trisomy 21, is the most common genetically defined cause of intellectual disability, and the Ts65Dn is the most studied mouse model of DS. Recently, our research group has shown that the Ts65Dn mouse displays pharmacological responses consistent with a dysfunction in molecular pathways coupled to the gating of N-methyl-D-aspartate (NMDA) receptors. We and other groups also found that the uncompetitive NMDA receptor antagonist memantine rescues learning and memory deficits in these mice. In addition, we found that Ts65Dn mice showed a greater NMDA mediated long-term depression (LTD) when

compared to euploid controls, and that memantine-treated hippocampal slices from Ts65Dn mice displayed control levels of LTD. In the present study, we used electrophysiological techniques to probe the effects of memantine on long-term potentiation. To study these effects, hippocampal slices of Ts65Dn or euploid control mice were dissected out and moved to a holding chamber containing artificial cerebral spinal fluid (aCSF) and allowed to recover for at least 1 h at room temperature. Half of the slices were then moved to another holding chamber with aCSF containing 1 μM memantine, allowed to recover for an additional 4 h before being placed in the recording chamber. First, we studied the effects of memantine on either continuous high-frequency stimulation (HFS; 100 Hz for 1 s) induced LTP or theta burst stimulation (TBS; 4 trains of 5 pulses at 100 Hz, 200 ms inter-train interval) induced LTP in the CA1 region of the hippocampus in Ts65Dn and euploid control mice. Previous studies by our group have shown that Ts65Dn mice display deficits in TBS-induced LTP but not HFS-induced LTP. Second, we studied the effects of memantine on late-phase LTP (L-LTP) in the CA1 region of the hippocampus in Ts65Dn and euploid control mice. L-LTP was induced in the CA1 region of the hippocampus by 4 stimulus trains (HFS; with a 5 min inter-train intervals). In agreement with our previous studies, our results show no significant difference in HFS-induced LTP between Ts65Dn and euploid control mice, but we found a reduction in TBS-induced LTP. Interestingly, Ts65Dn hippocampal slices also showed a deficit in L-LTP when compared to euploid control mice. Memantine pretreatment at the concentration of 1 μM used in this study did not inhibit the induction or maintenance of any form of LTP tested in Ts65Dn or euploid control hippocampal slices. Given the role of NMDA receptors in synaptic plasticity and learning and memory, this research may bring us one step closer to understanding the mechanistic basis for previous electrophysiological and behavioral studies in this important mouse model of DS.

Abstract: N-methyl-D-aspartate receptor (NMDAR) is a subtype of ionotropic glutamate receptor, which play a central role in learning, memory, synaptic development and is linked to excitotoxic neuronal death. NMDARs are assembled from four transmembrane subunits that bind to glycine or D-serine (GluN1 and GluN3A/B) or which are activated by glutamate (GluN2A-D). The GluN2A and GluN2B subunits are highly expressed in cortex and hippocampus and are the primary determinants of the functional properties of the NMDA receptors, including features such as the agonist affinity, kinetics of deactivation, the single channel conductance and the permeability to Ca2+. Nowadays, many natural and synthetic molecules have been identified as NMDAR modulators, they bind to the receptor and cause an increase or decrease in the maximum response or in the agonist affinity. Since the discovery of antagonists for binding sites of the NMDA receptor, the pharmaceutical industry has developed them as tools to study their properties and develop therapeutically useful molecules for glutamate excitotoxicity, however, despite his need no drug has proven be effective and reliable even when annual incidence of brain diseases such as traumatic brain injury and/or stroke are about 10 million people worldwide and are projected to become the third leading cause of global disease in 2020, surpassing complex diseases like breast cancer, HIV, heart disease and chronic degenerative diseases. In adition to, recent reports have proposed to dapsone (DDS, 4.40-diaminodiphenylsulfone), an antimicrobial, as a neuroprotective agent for its effects to reduce the glutamate excitotoxicity (through NMDARs), the myeloperoxidase activity, oxidative damage, the inflammatory response, and apoptotic death. Also, decrease morphological damage in models of vascular occlusion and induced injury by kainic acid and quinolinic acid. Although it is known that dapsone acts on the NMDA receptor the effect that it produces and its mechanism of action are not clear yet. In this study we analyzed NMDA activated currents from pyramidal neurons of the primary motor cortex of Wistar strain male rats (30 days), obtained with voltage-clamp technique, we made a dose response of dapsone on NMDA receptor and finally we examine the binding subunit of DDS using specific antagonists for GluN2A (TCN-201) and GluN2B (Ifenprodil).

Title: Regulation of AMPA receptor acetylation by SIRT2: implications in synaptic plasticity and learning

Authors: *G. WANG[1], S. LI[3], J. GILBERT[1], H. GRITTON[2], X. HAN[2], D. SELKOE[3], H.-Y. MAN[1];
[1]Biol., [2]Dept. of Biomed. Engin., Boston Univ., Boston, MA; [3]Ctr. for Neurologic Dis., Brigham and Women's Hosp. and Harvard Med. Sch., Boston, MA

Abstract: Sirtuins, the NAD+-dependent protein deacetylases, are well-known for their involvement in longevity and metabolism. Recently, sirtuins have been shown to play an important role in cognitive functions like learning and memory. The α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR) is an important glutamatergic receptor that mediates the majority of fast excitatory synaptic transmission and synaptic plasticity in the brain, serving as the substrate for learning and memory. AMPARs are subject to several post-translational modifications, such as phosphorylation and ubiquitination, to maintain normal receptor function and expression in the brain. We therefore investigated the role of sirtuins on AMPAR regulation. We found that AMPARs are subject to protein acetylation, which is regulated by SIRT2, but not other members of the sirtuin family. Inhibition/deletion of SIRT2 up-regulates GluA1 acetylation, leading to an accumulation of AMPARs and an alteration in AMPAR trafficking. Consistently, in SIRT2 knock-out mice (Sirt2-/-), AMPAR acetylation and protein levels are increased. Acute hippocampal slice electrophysiology revealed impaired synaptic plasticity (LTP/LTD) in Sirt2-/- mice. Also, Sirt2-/- mice showed a significant impairment in contextual and spatial memory. Taken together, these data indicate a novel regulatory mechanism in synaptic plasticity and memory formation via SIRT2-mediated AMPAR deacetylation.

Abstract: The delta family consisting of glutamate receptor GluD1 and GluD2 has been classified as an ionotropic receptor subunit, but recent studies have revealed that GluD2 contributes to synapse formation occurring between parallel fibers and Purkinje cells in cerebellum. GluD2 is abundantly expressed in cerebellum, but moderately expressed in other brain regions, while GluD1 is widely observed in mouse brain. Although the functional significance of GluD1 is inferred from human genetic studies reporting that the *GRID1* is a strong candidate gene for schizophrenia, bipolar disorder, major depressive disorder, and autism spectrum disorder, the relationship between molecular function of GluD1 and the onset mechanism of these diseases has been still unknown. To approach the issue we generated GluD1 conditional knockout mice from C57BL/6N strain RENKA ES cells with pure genetic background for behavioral analysis, because conventionally used GluD1KO mice were produced by backcrossing 129-derived ES cells to C57BL/6 mice, thus affecting its genetic background. We first generated a GluD1 floxed mouse in which 34-bp *loxP* sequence and neo cassette flanked by two *frt* sites were inserted into the upstream of exon4. Another *loxP* sequence was inserted into the downstream of exon4. After removing a neo cassette, the floxed mice were crossed with telencephalin Cre driver mice to generate GluD1 null KO mice, and 8-12-week-old male mice were used for behavioral analyses. GluD1 deficient mice showed hyperactivity and low anxiety in the open field test, but no difference in the elevated plus maze. They were less mobile in the forced swim test and demonstrated less social behavior in the three-chamber test. Although some of our findings are similar to those of previous reports, some contradict with other results, which is supposedly caused by the different genetic background. To find responsible regions for the abnormal behavior, we are crossing the GluD1 floxed mice with driver mice that express Cre in different brain regions.

Title: Molecular pathophysiology of human anti-glutamate receptor 2 autoantibodies on AMPA-receptor mediated synaptic transmission

Authors: *C. GEIS, H. HASELMANN, B. GRÜNEWALD, C. WERNER;
Dept. of Neurol., Jena Univ. Hosp., Jena, Germany

Abstract: Background: Autoantibodies (AB) to α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPAR) were recently described in patients with autoimmune encephalitis. In this study we purified AB from plasma exchange material of a patient with autoimmune encephalitis to determine the molecular effects of the patient IgG fraction on the synaptic glutamatergic transmission. Methods and findings: Patient IgG was highly specific to the critical glutamate receptor 2 (GluR2) subunit of AMPAR as shown by using transfected HEK293 cells, brain slices of GluR1 or GluR2 deficient mice, and mass spectrometry. Primary hippocampal neurons preincubated with anti-GluR2-specific IgG showed a time-dependent reduction of GluR2-specific fluorescent puncta. We iontophoretically applied glutamate to individual synapses of cultured hippocampal neurons that were identified by intravital FM1-43-labelling and measured single-synapse evoked EPSCs by whole-cell patch-clamp recording. We found increased AMPAR-mediated EPSC amplitudes and disturbed receptor kinetics after preincubation with anti-GluR2-specific patient IgG. Furthermore, short-term plasticity was affected by reduced recovery after desensitization. Interpretation: These neurophysiological properties are consistent with previous findings of GluR2 deficient neurons. We suggest that anti-GluR2-specific patient IgG leads to a decrease of GluR2-containing receptors in active synapses (e.g. by internalization). Synaptic scaling mechanisms may generate a compensatory overexpression of other than GluR2 subunits resulting in synaptic AMPA-receptor insertion with higher conductivity and increased calcium-permeability. The present data show a possible mechanism of how anti-GluR2 specific IgG can directly affect synaptic transmission in the hippocampus possibly resulting in cognitive deficits and behavioral abnormalities in anti-AMPAR mediated autoimmune encephalitis.

Title: Dissecting the role of AMPARs in development and function of hippocampal CGE-derived interneurons

Authors: *G. AKGUL[1], L. BARKSDALE[2], K. A. PELKEY[1], C. J. MCBAIN[1];
[1]Natl. Inst. of Hlth., Bethesda, MD; [2]Federtion of American Societies for Exptl. Biol., Bethesda, MD

Abstract: Disrupting the excitatory synaptic recruitment of GABAergic inhibitory interneurons can promote excitation-inhibition imbalance within cortical circuits that can precipitate neurological diseases such as schizophrenia and epilepsy. In the hippocampus, two major lineages of inhibitory interneurons, derived from caudal ganglionic eminence (CGE) and medial ganglionic eminence (MGE), contribute distinct subgroups, which give rise to microcircuit complexity. The specific biophysical properties of excitatory input onto distinct interneurons strongly correlate with cellular lineage and dictate the circuit recruitment of discrete forms of feedforward and feedback inhibition. CGE-derived interneurons primarily express calcium impermeable AMPARs. In contrast MGE-derived interneurons typically express GluA2-lacking calcium permeable AMPARs. To investigate the role of AMPAR-mediated glutamatergic input in the development of CGE-derived interneurons and its significance for brain activity, we created two knockout (KO) mouse lines that eliminate either the GluA2 subunit (A2-KO) or GluA1&A2&A3 subunits (A1/2/3-KO) selectively in CGE-derived interneurons. KO mice have been tested for AMPAR activity in CGE-derived interneurons and compared with the activity in wild type (WT) CGE-derived interneurons. A2-KO CGE-derived interneurons display inwardly rectifying AMPAR-mediated EPSCs with fast kinetics confirming successful targeted loss of GluA2 within this interneuron cohort. In A2-KO and A1/2/3-KO CGE-derived interneurons, spontaneous excitatory input was reduced more than 50% and 95% respectively, revealing a deficit in the circuit integration CGE-derived interneurons in both mutant lines. In addition, Scholl analysis on the dendritic tree of the recorded interneurons showed that the loss of all three AMPAR subunits in CGE-derived interneurons (A1/2/3-KO) leads to decreased dendritic branching. Early in cortical and hippocampal development, dendrite targeting CGE interneurons play a role in creating a patterned activity in nascent local circuits called giant depolarizing potentials (GDPs). GDPs are an essential step in the maturation of newly formed synaptic connections and circuits. In A1/2/3-KO's, we observed a significant increase in hippocampal GDP frequency inside the CA3 subfield at age P7-8 compared to WT, while the average peak amplitudes of GDP's did not change. In contrast GDPs monitored in A2-KO's showed comparable properties to WT's across all age ranges tested (P5-10). The data highlight a role for AMPARs on CGE interneurons for maturation and correct assembly of the newly formed circuits.

Title: Structure-function analysis of stargazin-dependent ampa receptor autoinactivation

Authors: *K. P. KEINANEN, T. MÖYKKYNEN, S. K. COLEMAN;
Dept Biosciences, Univ. of Helsinki, Helsinki, Finland

Abstract: Stargazin, a transmembrane AMPA receptor regulatory protein, increases glutamate responses of AMPA receptor channels by slowing down desensitization. This allosteric regulatory effect is short-lived due to functional uncoupling (autoinactivation) in the stargazin-receptor complex. The extent of autoinactivation is strongly dependent on receptor subunit but underlying mechanisms are poorly understood. Here, we have examined the role of C-terminal tail, Q/R editing and alternatively spliced flip/flop segment in stargazin-dependent autoinactivation in homomeric AMPA receptors. Wild-type and mutated receptors were expressed in 293 cells in the presence of stargazin and their agonist responses were studied by using patch clamp electrophysiology. Our results indicate that neither Q/R site editing in the channel pore, native in GluA2 or artificially introduced in GluA4, nor the length of the carboxyl terminal tail (in GluA2 and GluA4) have any significant effect on the strength of autoinactivation. In GluA2 receptors , residues within the flip/flop segment have a strong influence of the extent of autoinactivation. These data help delineate the critical structures responsible for the stability of stargazin-AMPA receptor modulatory interaction.

Title: Subtype-specific effects of auxiliary subunit GSG1L on AMPA receptor function

Authors: *T. P. MCGEE, C. BATS, M. FARRANT, S. G. CULL-CANDY;
UCL, London, United Kingdom

Abstract: AMPA-type glutamate receptors (AMPARs) mediate fast excitatory neurotransmission in the mammalian brain and are integral to a variety of processes, including

postsynaptic plasticity and synapse development. They also play a key role in triggering neuron damage in a number of neurological conditions. The AMPAR pore-forming subunits, GluA1-4, are expressed differentially with respect to brain region and ontogenetic period, providing considerable functional diversity. This diversity is increased by a variety of auxiliary transmembrane proteins. These coassemble with AMPAR subunits to form macromolecular complexes, the composition of which can influence receptor trafficking, gating and pharmacology. Proteomic studies recently identified a number of new AMPAR-interacting proteins, among which is the tetraspanin GSG1L. Structurally similar to transmembrane AMPA receptor regulatory proteins (TARPs), GSG1L has been validated as a bona fide AMPAR auxiliary protein capable of modulating receptor gating and cell surface expression. To investigate the potential influence of GSG1L at different synapses we have explored its functional effects in different AMPAR assemblies. Specifically, we recorded currents activated by fast application of glutamate to outside-out membrane patches from cells expressing various combinations of AMPAR pore-forming subunits and auxiliary proteins. To constrain receptor stoichiometry in these assemblies we generated AMPAR-GSG1L tandem constructs, in which the N-terminus of GSG1L was directly linked to the C-terminal tail of the GluA subunit. Using these methods we found GSG1L to have novel and subtype-specific effects on AMPARs.

Title: Desensitized ligluk2 receptors are immobilized at glutamatergic synapses

Authors: *A. I. POLENGHI[1], E. M. PETRINI[1], P. GOROSTIZA[2], A. BARBERIS[1]; [1]Fondazione Inst. Italiano Di Tecnologia, Genova, Italy; [2]Inst. of Bioengeneering of Catalonia, Barcelona, Spain

Abstract: The lateral mobility of neurotransmitter receptors is a crucial determinant for the fine tuning of the number of the receptors at the post-synaptic site and, consequently, for the short- and long-term modulation of synaptic responses. Although a considerable effort has been made to characterize the role of lateral diffusion in the control of neuronal network activity, the relation between the conformational state and the mobility of the receptors is poorly investigated. To address this issue, we exploited light-sensitive glutamate receptors (LiGluK2) in combination with the single particle tracking technique. LiGluK2 are engineered glutamate receptors in which a molecular photoswitch operates the glutamate binding and unbinding upon azobenzene *cis/trans* photoisomerization obtained by illumination with 380 nm and >460 nm light,

respectively. By manipulating the different conformational states of LiGluK2 with light, we investigated the lateral mobility of LiGluK2 in cultured hippocampal neurons. We report that desensitized LiGluK2 receptors are strongly and reversibly immobilized at excitatory synapses. In contrast the desensitization state did not alter the lateral mobility of extrasynaptic LiGluK2, suggesting a selective mechanism for synaptic receptors. First, we aimed at assessing whether the light-induced immobilization of LiGluK2 lateral diffusion might be due to changes in intracellular Ca^{2+} induced by LiGluK2 activation. Interestingly, the suppression of the Ca^{2+} permeability of LiGluK2 and the block of the principal sources of intracellular calcium increase did not affect the immobilization of desensitized LiGluK2 at synapses. Next, we hypothesized that the mechanism underlying this phenomenon could be due to altered interactions between scaffold proteins and synaptic receptors in the desensitized state. To this end, we generated a mutant form of LiGluK2 lacking of the PDZ binding motif. Interestingly, we found that the deletion of the PDZ binding domain completely abolished the desensitization-induced trapping of LiGluK2 at synapses. We propose here that the conformational changes occurring during desensitization may strengthen the interaction between receptors and scaffold proteins, thus promoting the trapping of LiGluK2 at synapses.

Title: Extending the influence of the cerebellar climbing fiber through non-synaptic signaling

Authors: *A. K. NIETZ[1], L. CODDINGTON[2], L. OVERSTREET-WADICHE[2], J. I. WADICHE[2];
[2]Neurobio., [1]Univ. of Alabama, Birmingham (UAB), Birmingham, AL

Abstract: Sensory information arrives at the cerebellar cortex through mossy fibers (MFs) originating from many areas of the cortex, brainstem, and spinal cord. In the granule cell layer, MFs synapse onto excitatory granule cells (GCs) and inhibitory Golgi cells (GoCs). GoCs provide feed-forward and feedback inhibition to GCs to regulate the initial stage of cerebellar processing of sensory input. Excitatory climbing fibers (CFs) that originate in the inferior olive make synaptic contacts with Purkinje cells (PCs). Recently, it has been shown that CFs also signal to molecular layer interneurons through a form of glutamatergic transmission mediated

entirely by neurotransmitter spillover in the absence of anatomically defined synaptic connections [1-3]. Here, we show that CF-mediated spillover transmission also influences GoC activity supporting functional connectivity despite the lack of reported anatomical connections between CFs and GoCs [4,5]. We recorded electrically-stimulated or channelrhodopsin-driven climbing fiber (CF)-mediated currents in GoCs from acute mouse slices. CF-GoC EPSCs showed marked depression to paired-pulse stimulation ($EPSC_2/EPSC_1$ 0.28 ± 0.03, n = 18) in contrast with facilitation of MF/PF evoked synaptic responses (1.27 ± 0.10, n = 20). CF-EPSCs were slower to rise (1.31 ± 0.15 ms; n = 20) than MF/PF-EPSCs (0.61 ± 0.06 ms; n = 21) and sensitive to glutamate transporter inhibition (241.4 ± 36.3%, n = 18). CF stimulation increased the probability of spiking (2.0 ± 0.2 action potentials, n = 12) and generated a pause of spontaneous spiking that increased the next inter-spike interval (67.1 ± 22.9%, n = 7). Our ongoing experiments are aimed at understanding the mechanisms underlying these observations that reveal an extended influence of CFs over the cerebellar cortex beyond signaling to Purkinje cells and molecular layer interneurons. Title: TARPs affect the gating of AMPARs by sub-saturating glutamate concentrations

Authors: *I. D. COOMBS[1], D. M. MACLEAN[2], V. JAYARAMAN[2], M. FARRANT[1], S. G. CULL-CANDY[1];

Abstract: AMPARs are tetrameric glutamate-gated ion channels that mediate fast excitatory synaptic transmission. Functional and proteomic studies have revealed native AMPARs can interact with numerous classes of ancillary proteins, including the transmembrane AMPAR regulatory proteins (TARPs). TARPs are crucial for the correct trafficking of AMPARs, and also affect their functional properties. Notably, TARPs increase glutamate potency and slow receptor deactivation and desensitization, thereby directly shaping phasic synaptic transmission (1). Both synaptic and extrasynaptic AMPARs can also be exposed to low glutamate concentrations following synaptic spillover (2,3). We set out to investigate how TARPs affect AMPAR channel activation and desensitization at low agonist concentrations by recording glutamate-evoked currents from outside-out patches taken from HEK293 cells transfected with GluA1 or GluA1 + TARP γ-2. As expected, γ-2 increased the potency of glutamate (measured from either peak- or steady-state currents) by ~3-fold. This TARP-induced increase in glutamate potency was due, at least in part, to increased efficacy at low occupancy, as directly revealed by both macroscopic and single-channel analysis. The γ-2-induced increase in efficacy was also apparent with heteromeric GluA1/2 receptors. In contrast with the enhancement of channel activation, we found that TARPs reduced by ~8-fold the potency of glutamate to desensitize GluA1. This was also apparent from decreased rates of entry into desensitized states at a range of sub-saturating glutamate concentrations. Taken together, our data suggest that under conditions of low receptor occupancy the presence of TARPs greatly alters the balance between activation and desensitization. These findings suggest that TARPs may profoundly influence the response of AMPARs to glutamate spillover. 1)Tomita et al. Nature 435, 1052-8 (2005). 2)DiGregorio et al. Title: Lk6 regulates synaptic levels of the glutamate receptor subunit, GluRIIA, at the *Drosophila* neuromuscular junction

Authors: *F. L. WYGLE-LIEBL, T. DELANEY, N. HUSSEIN;
Southern IL Univ. Edwardsville, Edwardsville, IL

Abstract: Synaptic communication depends on the spatially correct formation of presynaptic terminals and the localization of postsynaptic receptors. The development and assembly of glutamatergic synapses is of particular importance because the majority of excitatory transmission in the mammalian central nervous system occurs via ionotropic glutamate receptors. We found, through a forward genetic screen, that the translational regulator, Lk6, is important for the levels of GluRIIA-containing receptors at the *Drosophila* neuromuscular junction. Lk6 is the *Drosophila* homolog of MNK1/2, which is downstream of the mitogen activated protein kinase (MAPK) pathway. Our data suggests that Lk6 specifically regulates GluRIIA as mutations in lk6 do not affect the synaptic levels of other proteins including Brp and DLG and the glutamate receptor subunits GluRIIB and GluRIIC. Lk6 is known to regulate translation by influencing eIF4E activity. Knockdown of eIF4E in postsynaptic cells results in a reduction in the synaptic levels of GluRIIA similar to that of the lk6 mutant. Further, overexpression of eIF4ES251A, a nonphosphorylatable eIF4E, results in a reduction in synaptic GluRIIA. Our results indicate that Lk6 and Target of rapamycin (TOR) signaling regulate eIF4E activity in parallel thereby influencing synaptic levels of GluRIIA.

Abstract: Trafficking and function of AMPA receptors (AMPARs) are regulated by a number of auxiliary subunits, including TARPs and CNIH2/3, which are important for AMPAR forward trafficking to synapses. Recently, a number of new membrane proteins have been found in neuronal AMPAR complexes. However, their function in the regulation of synaptic transmission remains largely unclear. We have investigated the role of the membrane protein GSG1L and found that it is important for AMPAR targeting to the neuronal surface and synapses. In addition, we have determined the GSG1L domains important for its function. Interestingly, GSG1L also uniquely modulates AMPAR deactivation and desensitization kinetics in hippocampal neurons. Finally, we also examined the role of GSG1L in the regulation of AMPAR synaptic transmission

in GSG1L knockouts. These data suggest that GSG1L represents a new class of auxiliary subunit with distinct modulatory properties for AMPARs.

Title: Molecular determinants underlying heterogeneity in AMPAR content across CA1 Schaffer collateral synapses

Authors: ***M. YAMASAKI**[1], M. FUKAYA[2], M. YAMAZAKI[3], M. ABE[3], K. SAKIMURA[3], M. WATANABE[1];

Abstract: Retaining AMPA-type glutamate receptors (AMPARs) at synapses requires specific interaction with postsynaptic density (PSD)-95 via transmembrane AMPAR regulatory proteins (TARPs). AMPAR content varies depending on synapse-type; however, the underlying molecular mechanisms remain unclear. By quantitative immunogold analysis, we compared three Schaffer collateral synapses in hippocampal CA1: non-perforated and perforated synapses on pyramidal cell spines, and synapses on parvalbumin-positive dendrites (PV-synapses). Although PSD-95 labeling was similar across three types of synapses, AMPAR labeling was increased in PV- and perforated synapses. While TARP γ8 labeling was homogeneous across three types of synapses, γ2 labeling was limited to PV- and perforated synapses. In γ2 knockout mice, AMPAR labeling in PV- and perforated synapses was markedly decreased, effectively eliminating the heterogeneity in AMPAR content. This raises the possibility that γ2 is more potent in accommodating synaptic AMPARs than γ8. Taken together, our results indicate that differential composition of TARPs may underlie synapse-type specific regulation of AMPAR content among CA1 Schaffer collateral synapses.

Title: Modulation of AMPA receptor tetramerization by auxiliary subunits

Authors: *Q. GAN, L. P. WOLLMUTH;
Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Ionotropic glutamate receptors (iGluRs) are ligand-gated ion channels that play critical roles in excitatory neurotransmission. Functional iGluRs are tetramers composed of four identical or similar core subunits and are usually associated with transmembrane proteins known as auxiliary subunits. Transmembrane AMPA receptor regulatory proteins (TARPs) and cornichons (CNIHs) are the major auxiliary subunits for AMPA-type iGluRs. They regulate the trafficking, localization as well as the functional properties of AMPA receptors, thereby modulating the strength and kinetics of AMPAR-mediated synaptic transmission. However, the roles played by auxiliary subunits in the earlier stages of the AMPAR biosynthetic pathway are yet unclear. The present study focuses on the effects of CNIH-2/3 and TARP γ-2 on the tetrameric assembly of GluA1 and GluA2 homo-tetramers. We used blue-native PAGE (BN-PAGE) to assess the oligomeric state of AMPARs either expressed alone or co-expressed with auxiliary subunits. Previously we identified a face in the third transmembrane segment (M4) of AMPARs that is critical to the tetramerization process. Here we find that co-expression with CNIH-2 completely rescues the deficit in tetramerization caused by moderate mutations within this face of M4. Co-expression with CNIH-3 has a similar albeit slightly weaker effect. However, cornichons are unable to counteract the abolishment of tetramerization caused by more radical mutations. Compared to cornichons, TARP γ-2 does not significantly enhance the mutants' tetramerization, regardless of the types of mutations introduced. Furthermore, we found that deletion of the intracellular carboxy-terminal domain (CTD) disrupts tetramerization, an effect that is also rescued by cornichons. Our results suggest that cornichons, but not TARP γ-2, act as chaperones that enhance the ability of AMPARs to form tetramers. This is consistent with previous findings that cornichons associate with AMPARs in ER/cis-Golgi, where tetrameric assembly takes place. Understanding how cornichons modulate AMPAR tetramerization may help us gain better insight into the biogenesis of AMPARs and its regulation by other neuronal proteins.

Abstract: AMPA (α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) receptors are a primary protein involved in epileptogenic phenomenon and the AMPA receptor antagonist, perampanel (®Fycompa), was recently approved in Europe and the United States for the treatment of partial seizures. Transmembrane receptor regulatory protein (TARP) γ-8 is an auxiliary protein associated with some AMPA receptors and has high brain localization in the hippocampus. We hypothesized that we could maintain the antiepileptic functionality while eliminating the motoric side effects inherent in globally-acting (non-TARP-dependent) AMPA receptor antagonists (i.e., perampanel) with a small molecule selectively targeting forebrain AMPA receptors. Specifically, AMPA receptors associated with TARP γ-8 (high localization in hippocampus associated with seizures) while simultaneously avoiding pharmacological interaction with TARP γ-2 (high localization in cerebellum associated with dizziness and motor coordination). We discovered LY3130481 (6-[(1S)-1-[1-[5-(2-hydroxyethoxy)-2-pyridyl]pyrazol-3-yl]ethyl]-3H-1,3-benzothiazol-2-one)), an orally-bioavailable compound and the first molecule rationally designed to target selective regions of the central nervous system while providing a relative sparing of interactions with non-desired brain regions. LY3130481 produced broad-ranging anticonvulsant efficacy in rodents including in models utilizing both acute and subchronic convulsant stimulation and either chemical or electrical stimuli. As AMPA receptors are involved in sensitization within the central nervous system, the blockade of seizure sensitization (kindling) was also demonstrated, thereby revealing a potential for disease modification of epilepsy. Moreover, the relative sparing of cerebellar Perkinje neurons from blockade of AMPA currents translated to a marked reduction in deleterious effects on motor function. Given these findings, the door has opened to the utilization of the TARP scaffolding proteins as a means of designing brain region-specific interactions along with the large therapeutic potential it offers.

Title: An assay system for the detection of transmembrane AMPA receptor regulatory protein (TARP) γ-8-selective antagonists: *In vitro* characterization of LY3130481

Authors: C. DING, B. HEINZ, A. S. KATO, H. YU, K. M. GARDINIER, D. L. GERNERT, D. S. BREDT, J. M. WITKIN, *K. D. BURRIS;
Lilly Res. Labs., Indianapolis, IN

Abstract: Alpha-amino-3-hydroxy-5-methyl-4-isoxazole-propionate (AMPA) receptors, a subtype of ionotropic glutamate receptors, mediate fast excitatory amino acid transmission in the mammalian central nervous system. AMPA receptors are hetero- or homomeric tetramers constructed from iGluA1-4 subunits, each of which can be alternatively spliced to yield two isoforms (flip and flop). Transmembrane AMPA receptor regulatory proteins (TARPs) are auxiliary subunits that associate with AMPA receptors and modulate both trafficking and channel activity. TARPs consist of six isoforms (stargazin/ γ-2, γ-3, γ-4, γ-5, γ-7 and γ-8) which show distinct expression patterns in the brain. These properties make specific AMPA-TARP receptors promising targets for treating CNS diseases. The goal of these studies was to develop high-throughput assays to selectively screen and profile TARP subtype-selective AMPA receptor antagonists. The ability of compounds to block glutamate-stimulated increases in intracellular Ca^{++} was examined in CHO-S cells expressing iGluA1flip alone (TARP-dependence) or iGluA1flop plus different TARP subtypes (TARP selectivity) using fluorescence imaging plate reader (FLIPR)-based assays. GYKI-53784, a nonselective AMPA receptor antagonist, blocked glutamate-stimulated responses in cells expressing iGluA1flip or iGluA1flop co-expressed with either TARPγ-2 or TARPγ-8. In contrast, LY3130481 blocked responses to glutamate in cells co-expressing iGluA1flop and TARPγ-8, but had no effect in cells expressing iGluA1flop with TARPγ-2 or in cells expressing iGluA1flip alone. LY3130481 represents the first molecule targeting specific populations of AMPA receptors in the brain. The development of assay systems to screen for TARP subtype-selective AMPA receptor modulators and the identification of LY3130481 as a TARPγ-8-selective AMPA receptor antagonist provide a new opportunity for selectively regulating AMPA receptor activity for therapeutic benefit. Given the relative densities of TARPγ-8 hippocampus vs. cerebellum (γ-2 dominant), it was predicted that

LY3130481 would have efficacy in hippocampal neural circuits (e.g., antiepileptic) without major effect in cerebellum (e.g., dizziness, ataxia).

Title: Discovery of a selective TARP-g8 dependent AMPA receptor antagonist (TDAA)

Authors: *D. GERNERT, K. M. GARDINIER, J. WITKIN, W. PORTER, J. REEL, K. BURRIS, C. DING, V. BARTH, F. STEVENS, P. HAHN, P. SPINAZZE, S. HOLLINSHEAD, D. MAYHUGH, J. SCHKERYANTZ, A. KHILEVICH, D. BREDT, H. YU, P. ORNSTEIN; Discovery Chem., Eli Lilly, Indianapolis, IN

Abstract: Modulation of AMPA receptors has long been proposed as a method to treat various neurological disease states, however antagonists of AMPA receptors has, to date, suffered from motor impairment at efficacious doses. The discovery that Transmembrane AMPA Receptor Regulatory Proteins (TARPs), which are auxiliary subunits of AMPA receptors that modulate pharmacology and trafficking of AMPA receptors, show differential expression levels in the central compartment led us to hypothesize that by targeting specific AMPA-TARP complexes that we could selectively target forebrain and not hindbrain excitatory synaptic transmission. We present here our discovery of the first known antagonist molecules which are both selective for, and dependent on the AMPA-TARP-γ8 complex.

Abstract: AMPA receptors are pivotal glutamate-operated cation channels for fast excitatory synaptic transmission in mammalian brain. AMPA receptors function *in vivo* in concert with various types of auxiliary subunits, including TARPs and cornichons (CNIH-2/3). TARPs associate with most of native AMPA receptors if not all, and modulate their functions dramatically in various aspects, e.g. trafficking, gating and pharmacology. TARPs are a multi-gene family protein group with differential expression in brain areas. TARP gamma-8 is expressed in forebrain with especially high enrichment in hippocampus, but not in cerebellum. The regional specificity of TARP expression and the marked changes of AMPA receptor pharmacology by TARPs inspired us to screen compounds that specifically block gamma-8-containing AMPA receptors with the hypothesis of retaining AMPA receptor blocking efficacy while minimizing cerebellar-driven ataxia. Indeed, we successfully identified a gamma-8 specific AMPA receptor antagonist, LY3130481, which selectively antagonizes gamma-8 containing AMPA receptors but not the other TARP, using FLIPR (a high-throughput intracellular-calcium detection system) and electrophysiological methods for recombinants. This compound has no selectivity in AMPA receptor principal subunits, i.e. it blocks GluA1, GluA2, GluA3 or GluA4,

if gamma-8 is co-expressed. The compound potently blocks glutamate-evoked currents through native gamma-8-containing AMPA receptors in forebrain, but not gamam-8-lacking cerebellar Purkinje neurons. Field EPSP recordings revealed that LY3130481 potently but partially blocks hippocampal synaptic transmissions. The inhibitory effects of LY3130481 for native AMPA receptors are abolished in TARP gamma-8 -null mice. LY3130481 is the first brain-region specific AMPA receptor antagonist.

Title: Tarp gamma-8 dependent ampa receptor antagonists as a novel therapeutic approach for chronic pain

Authors: K. L. KNOPP, R. M. A. SIMMONS, W. GUO, B. L. ADAMS, J. M. WITKIN, K. M. GARDINIER, D. L. GERNERT, W. PORTER, P. ORNSTEIN, J. REEL, C. DING, H. WANG, Y. QIAN, K. BURRIS, A. NEED, V. BARTH, F. PASQUI, R. ZWART, E. SHER, K.-C. CHOONG, A. S. KATO, T. M. WALL, *E. S. NISENBAUM;
Neurosci. Discovery Res., Eli Lilly & Co., Indianapolis, IN

Abstract: Non-selective ionotropic glutamate receptor antagonists are efficacious in chronic pain conditions, but are accompanied by significant tolerability issues, likely arising in part from the ubiquitous expression of AMPA receptors in the CNS. Recently, a glutamate receptor antagonist, LY3130481, has been identified which selectively blocks TARP γ8-containing AMPA receptors. Expression studies show that γ8 is heterogeneously distributed in the CNS with highest expression in hippocampus, but significant expression also in spinal cord, anterior cingulate (ACC) and somatosensory (SS) corticies. In addition to having potential therapeutic utility in epilepsy (see Witkin et al., SfN., 2015), these data have suggested that LY3130481 may provide a novel approach to chronic pain conditions, providing the focus of the current studies. Potent and selective blockade of recombinant γ8-containing AMPA receptors (IC50=62 nM) by LY3130481 was also evident in rodent ACC (IC50=73 nM) and SS (IC50=142 nM) pyramidal neuron and human spinal neuron (IC50=480 nM) AMPA receptors, but not rodent Purkinje or human cerebellar neuron AMPA receptors (IC50>10 uM) which do not express γ8. LY3130481 (0.3-3 uM) partially suppressed, whereas the non-selective AMPA antagonist GYKI53784 (50 uM) completely blocked glutamatergic EPSPs in ACC neurons. LY3130481 (1-10 mg/kg i.v.) similarly attenuated discharge of wide-dynamic range spinal sensory neurons *in vivo* in response to trains of stimulation of peripheral nerve afferents. Consistent with an effect on neurotransmission in ascending pain pathways, LY3130481 significantly reduced nocifensive behavior in the formalin assay (ED50=3.7 mg/kg, p.o.) that was correlated with occupancy of CNS γ8-containing AMPA receptors, but was not effective in γ8-/- mice. LY3130481 also dose-dependently (1-30 mg/kg, p.o) attenuated gait disturbances in a model of established joint pain in

the absence of motor side effects. Collectively, these data demonstrate that LY3130481 can selectively reduce excitatory transmission in pain pathways expressing γ8-containing AMPA receptors and significantly reduce nocifensive behaviors in multiple preclinical models of pain in the absence of motor impairment. These results suggests that selective blockade of TARP γ8-containing AMPA receptors may provide an effective and safer approach for the treatment of chronic pain conditions.

Title: Sap97 and cask block the rxr er retention signal of grik5

Authors: *S. H. STANDLEY, X. HONG, M. RONILO, M. AVETISYAN;
Grad. Col. of Biomed. Sci., Western Univ. of Hlth. Sci., Pomona, CA

Abstract: In several prior publications, it has been demonstrated that Grik5 has an arginine-based RXR endoplasmic reticulum (ER) retention signal in its cytoplasmic C-terminus. The classical function of these trafficking signals is to impose a requirement for assembly with other cognate subunits, in this case Grik2, before exiting the ER. However, assembly has been reported to have little effect on ER exit or surface expression. Here, we show that SAP97 and CASK block the RXR endoplasmic reticulum (ER) retention signal in Grik5. Heterologous cells co-transfected with Grik2/Grik5 were largely ER-retained as has been previously described. Co-transfection of SAP97 alone had little effect on ER exit or cell surface expression of Grik2/Grik5, however when co-transfected with CASK, ER exit was dramatically enhanced.

Further experiments using truncations and fragments of SAP97 indicated that the SH3 and GuK domains of SAP97 were critical for blocking the ER retention signal of Grik5. SAP97 and CASK have previously been shown to be necessary for sorting of the NMDA receptor, GluN1-1, into a local non-conventional secretory pathway. GluN1-1 also has an RXR ER retention signal in its C-terminus that does not appear to function classically. We propose that these ER retention signals are imposing a requirement for binding SAP97/CASK and thereby sorting into a local, non-conventional secretory pathway.

Title: N-linked glycans modulate AMPA and kainate receptor functional properties

Authors: ***C. VERNON**, J.-Z. YAN, B. A. COPITS, Y. F. GUZMÁN, G. T. SWANSON; Dept. of Pharmacol., Northwestern Univ., Chicago, IL

Abstract: Diverse types of post-translational modification are known to affect the function of ionotropic glutamate receptors (iGluRs), for example by altering receptor affinity for interacting proteins or by controlling receptor localization and stability at the cell membrane. *N*-linked glycosylation is one such modification and iGluRs, including the AMPA and kainate receptor (KAR) subfamilies, are glycosylated at multiple sites. Glycosylation is known to be important for proper iGluR folding and exit from the secretory pathway and is more generally important for proper nervous system development and function, but its impact on the functional properties of signaling proteins like ligand- and voltage-gated ion channels is not well defined. We hypothesize that *N*-linked glycans on iGluRs contribute not only to receptor folding but also to biophysical functions of these receptors. To test this, we pharmacologically restricted glycan maturation on recombinant AMPARs and KARs by inhibiting α-mannosidases. We find that α-mannosidase inhibition alters receptor biophysical properties such as the rate of desensitization, recovery from desensitization, and apparent glutamate affinity. Effects on receptor function vary dependent upon both the processing enzyme targeted and the receptor subunit composition. When α-mannosidase-I is inhibited, GluA1/2-containing AMPAR desensitization slows from 10.4±0.6 ms (n=27) to 21.6±3.4 ms (n=22) but by contrast, GluK2-containing KAR desensitization speeds from 4.0±0.2 ms (n=27) to 2.9±0.1 ms (n=26). We also tested whether enriching for complex glycans impacted receptor biophysical properties. The charged glyco-

epitope HNK-1 altered receptor biophysical properties for a subset of receptors including GluK2-containing KARs, which we find to be a substrate for HNK-1 conjugation in the mouse CNS. We are investigating how glycan content impacts native receptor properties, as our findings suggest that regional variation in oligosaccharide processing could result in differential synaptic function of iGluRs. The work presented here supports the idea that the molecular composition of *N*-glycans contributes to diversity in AMPAR and KAR functional properties, increasing receptor complexity beyond that provided by different subunit combinations. Glycan processing is dynamically regulated throughout development and diseases altering glycosylation enzymes are known to severely impact CNS development and function. Greater understanding of iGluR modulation by *N*-glycans is essential to fully appreciate receptor function during normal development as well as in disease states. Supported by NIH R01NS080598 to G.T.S.

Title: Kainate receptors mediate endocannabinoid mobilization in the striatum

Authors: *J. MARSHALL, A. CONTRACTOR;
Physiol., Northwestern Univ. - Dept. Of Physiol., Chicago, IL

Abstract: The striatum is the main input structure of the basal ganglia, integrating information from the thalamus and cortex to control planning and modulation of movement. The principal neurons of the striatum, spiny projection neurons (SPNs), express high levels of kainate receptors, members of the ionotropic glutamate receptor family, whose functional roles within SPNs have not been well-characterized. Kainate receptors play diverse modulatory roles at synapses in many different brain regions where they are expressed. In addition to contributing to excitatory post-synaptic currents (EPSCs) they have been shown to presynaptically regulate neurotransmitter release and in some cases are metabotropically coupled to intracellular signaling pathways—activating downstream signaling independent of ionotropic currents. Here we demonstrate that kainate receptors are present at postsynaptic sites at corticostriatal synapses onto SPNs where they are activated by endogenously released glutamate. Direct activation of kainate receptors with low concentrations of exogenously applied agonist, that produces little or

no inward current, reduces glutamate release at corticostriatal excitatory synapses onto SNPs. In a subset of recordings, the suppression was blocked by a cannabinoid type 1 (CB1R) antagonist, indicating that activating kainate receptors leads to endocannabinoid (eCB) mobilization. Furthermore, this effect of low-agonist activation of kainate receptors is sensitive to a number of postsynaptic pharmacological manipulations that suggest kainate receptors mobilize eCBs through a metabotropic signaling pathway that is independent of ion flux through the channel pore. Cannabinoid signaling itself has a well-established role in the striatum playing a crucial role in different forms of striatal plasticity. Therefore these results suggest a novel and significant role for kainate receptors in tuning striatal synapses and regulating striatal activity.

Title: Identification of novel Neto2-interacting proteins in the central nervous system

Authors: *Y. F. GUZMAN[1], J. N. SAVAS[2], G. T. SWANSON[1];
[1]Northwestern Univ. Dept. of Pharmacol., Chicago, IL; [2]Dept. of Neurol., Northwestern Univ., Chicago, IL

Abstract: Kainate receptors, like other ionotropic glutamate receptors in the central nervous system, exist as part of macromolecular signaling complexes. These complexes are composed of scaffolds, enzymes, and auxiliary proteins that directly impact receptor function and localization. Neuropilin and tolloid-like protein 2 (Neto2) is thought to be an important member of the signaling complex for kainate receptors. Interaction of kainate receptors with Neto2 increases the open probability of the receptor and slows the decay kinetics of glutamate-gated currents from these receptors. In addition, Neto2 distributes the GluK1 subunit of kainate receptors to neuronal synapses. The precise mechanism by which Neto2 contributes to kainate receptor trafficking is unknown. Identification of Neto2-interacting proteins might provide some insights on how Neto2 modulates native kainate receptor function or localization of these receptors in the central nervous system. The aim of the current study is to identify Neto2-interacting proteins by use of high-scale proteomic analyses. We performed immunoaffinity purification of native Neto2 followed by liquid chromatography-tandem mass spectrometry. As expected, successful purification of Neto2 with a specific antibody showed an enrichment of the Neto2 protein.

Preliminary results validated the known interaction of Neto2 with GluK2 and GluK3 kainate receptor subunits suggesting successful co-purification of Neto2 protein and its interacting proteins. This pilot screen did not find evidence of association with KCC2 or NMDA receptors subunits, both putative Neto2-interacting proteins. The majority of proteins identified in this preliminary screen have known trafficking functions, including members of the ASAP and Arf families. Interestingly, several proteins involved in metabotropic signaling pathways were also identified, such as G(o) alpha and G(I)/G(S)/G(T) beta-1 and beta-2. Thus far, we have established a possible interaction of Neto2 with proteins involved in cellular trafficking and metabotropic signaling. Future work will focus on validating some of these interactions and identifying a functional role for these proteins in Neto2 and kainate receptor physiology. These future studies are compelling because they might address unresolved questions in the kainate receptor field. Firstly, this work might help elucidate the mechanisms by which Neto proteins aid kainate receptor trafficking. Secondly, these studies might provide insight on how these ionotropic receptors can mediate metabotropic signaling. Title: Retromer-dependent trafficking of the kainate receptor auxiliary proteins Neto1 and Neto2

Authors: ***K. WILKINSON**, D. L. ROCCA, J. M. HENLEY;
Sch. of Biochem., Univ. of Bristol, Bristol, United Kingdom

Abstract: Retromer is an endosomal sorting complex that has recently been shown to mediate the recycling of endocytosed surface proteins back to the plasma membrane. In neurons, retromer regulates the recycling of AMPA and NMDA-type glutamate receptors via binding of the C-termini of the receptor subunits GluA1 and NR1, respectively, to SNX27, a PDZ domain-containing cargo adaptor for retromer. However, a role for SNX27-retromer in the trafficking kainate-type glutamate receptors (KARs) has not been investigated. Here, we show that GluK2-containing KARs associate with SNX27/retromer. SNX27 immunoprecipitates with GluK2 from cultured neurons and brain, however, binding of SNX27/retromer to GluK2 is not direct, but instead mediated by the recently identified KAR auxiliary subunits Neto1 and Neto2, which have been primarily implicated in regulating the channel properties of KARs. Neto1 binds SNX27 via

its C-terminal PDZ ligand, while Neto2 associates with retromer in a manner independent of SNX27. Notably, GluK2 can only be immunoprecipitated with SNX27 in the presence of Neto1, indicating that the Neto proteins couple GluK2-containing KARs to retromer. Knockdown of SNX27 or the core retromer component Vps35 in cultured cortical neurons dramatically reduces the steady-state levels of both Neto1 and Neto2, suggesting SNX27/retromer may function in rescuing Neto-containing KAR complexes from lysosomal degradation. Moreover, in heterologous systems, binding to retromer regulates the surface expression and stability of the Neto proteins. We are now examining the effects of knockdown of SNX27 or retromer on synaptic KAR responses. Together, these data highlight a role for retromer in the regulation of KARs, and identify trafficking of the Neto proteins as a potential mechanism to control KAR function.

Title: Kainate and AMPA receptors are required for error correction during taxis behaviors

Authors: *P. J. BROCKIE, P. MALDONADO, J. E. MELLEM, D. M. MADSEN, A. V. MARICQ;
Dept. of Biol., Univ. of Utah, Salt Lake Cty, UT

Abstract: In order to survive animals must locate necessary resources and environs. This can be achieved by navigating along gradients of sensory cues, moving towards those that are favorable and away from those that are harmful. A relatively simple neural circuit required for navigation along temperature and chemical gradients has been described in the nematode *C. elegans*. Central to this circuit is the pair of RIA interneurons that receive glutamatergic synaptic inputs from several different sensory neurons. We have shown that the GLR-3 and GLR-6 kainate receptor subunits are exclusively expressed in the RIA neurons, which also express the GLR-1 AMPA receptor. Heterologous expression of GLR-3 and GLR-6 demonstrated that they constitute the components of a heterologous ionotropic glutamate receptor that can be gated by both glutamate and kainate. To determine the role of GLR-3/GLR-6 kainate receptors in taxis behaviors, we generated null mutations in both the genes. *In vivo* electrophysiological analysis of these mutants showed that GLR-3 and GLR-6 mediate a component of the excitatory glutamate-gated current in RIA that is kinetically distinct from that mediated by GLR-1 AMPA receptors.

Using behavioral assays that test a worm's ability to chemotax towards an attractive odor, we have shown that both *glr-3* and *glr-1* mutants are less proficient at this behavior than wild-type animals. We propose that GLR-3/GLR-6 kainate receptors are required for subtle changes in navigation necessary to steer the worm towards an attractant, whereas GLR-1 AMPA receptors are recruited when a worm moves dramatically off course. Together, our results indicate that kainate and AMPA receptors in RIA mediate distinct components of taxis behavior that together allow animals to successfully navigate along sensory gradients thus increasing their chances of locating important resources.

Title: The role of the embryonic form of the GluK2 kainate receptor subunit in regulating neuronal excitability

Authors: *T. NOMURA, J. CATCHES, H. FERNANDES, A. CONTRACTOR;
Physiol., Northwestern Univ., Chicago, IL

Abstract: Kainate receptors (KARs) are glutamate-gated ion channel receptors that have multiple roles in modulating synapses and circuits. While the cellular and synaptic roles of KARs have been well described, we currently have an incomplete picture of how they impact circuit and network activity during development. As with subunits of the AMPA receptors (AMPARs), GluK2, one of the principal subunits of KARs is subject to RNA editing. RNA editing of KARs is strictly developmentally regulated, where the GluK2 subunit is unedited in the embryo and neonate, but >85% of GluK2 mRNA transcripts are edited by two weeks after birth. RNA editing at a site within the channel pore (Q/R site) is known to impact on KAR function by altering the Ca2+ permeability and single channel conductance of the receptor; however it still remains elusive what the role of this modification is during early embryonic and postnatal development. Here we found that the unedited embryonic / neonatal form of GluK2 plays a critical role in the regulation of intrinsic neuronal excitability in the developing hippocampus. We performed *in vitro* patch clamp recordings from hippocampal slices from mutant mice in which the editing complementary sequence of GluK2 was deleted (GluK2ΔECS). The GluK2 transcript cannot be edited and therefore all GluK2 receptors expressed in this mouse

are in the embryonic form unedited form (Vissel et al. Neuron 2001). We found that CA3 neurons in the hippocampus of neonatal GluK2ΔECS mice displayed higher spontaneous action potential firing rates than WT mice. The slow afterhyperpolarization (sAHP) recorded in these same cells was reduced compared to that in littermate controls. There were no detectable changes in basic membrane properties of CA3 neurons in these mice, including resting membrane potentials and action potential thresholds. Long term treatment of slices with the AMPARs / KARs antagonist NBQX resulted in an elevated sAHP in GluK2ΔECS mice to an amplitude equivalent to that in WT mice. However the AMPAR specific antagonist GYKI had no effect, suggesting that specific activation of unedited KARs chronically suppresses sAHP. Treatment with an inhibitor of Gi/o G proteins, pertussis toxin, also resulted in an elevated sAHP, suggesting that G protein mediated signaling was required for the effect. We conclude that the embryonic / neonatal form of the GluK2 subunit of KARs plays an important role in regulating neuronal excitability by a chronic metabotropic mediated suppression of the sAHP. Title: Glutamate receptor-like channels in plants: putative agonist profile and intersubunit interactions

Authors: ***T. LU**[1,2,3], D. TAPKEN[1], M. HOLLMANN[1];
[1]Biochem. I – Receptor Biochem., Ruhr-University Bochum, Bochum, Germany; [2]Grad. Sch. of Chem. and Biochem., [3]RUB Res. Sch., Ruhr Univ. Bochum, Bochum, Germany

Abstract: Glutamate receptor-like proteins in the model plant Arabidopsis thaliana (AtGLRs) are homologous to mammalian ionotropic glutamate receptors (iGluRs) in sequence and predicted membrane topology. Since their discovery in the late 1990s, their functional characterization has progressed slowly. Only in the last years, two of the 20 receptor subunits have been found to be gated by a broad spectrum of amino acids: AtGLR1.4 is activated by seven amino acids: methionine, tryptophan, phenylalanine, leucine, tyrosine, asparagine and threonine [1]; AtGLR3.4 is activated by asparagine, serine and glycine [2]. We used two-electrode voltage clamp (TEVC) in Xenopus oocytes to test the putative agonists of additional AtGLR subunits with a focus on the 20 naturally occurring amino acids. In addition, we employed a bimolecular fluorescence complementation assay (BiFC) to study potential

interactions between different AtGLR subunits that might be required to assemble functional ion channels. Initial BiFC data indicate that a long linker sequence is required when attaching half fluorophores to the C termini of AtGLR subunits of interest, in order to allow assembly and successful fluorophore reconstitution. With this method we have identified several heteromeric combinations and analyzed them electrophysiologically. So far, however, we have not found any influence of such heteromerization on the properties of functional AtGLR subunits. 1.Tapken D, Anschütz U, Liu L, Huelsken T, Seebohm G, Becker D, Hollmann M: A plant homolog of animal glutamate receptors is an ion channel gated by multiple hydrophobic amino acids. Abstract: Dynamic AMPA receptor (AMPA-R) trafficking at the postsynaptic membrane is a major mechanism underlying the cellular basis of normal learning and memory as well as psychiatric and neurological disorders marked by cognitive dysfunction. We identified like-acetylglucosaminyltransferase (LARGE) as a novel component of the AMPA-R complex. Patients with LARGE mutations have intellectual disabilities as well as muscular dystrophy.

Here, our functional studies demonstrated that LARGE downregulates the surface and synaptic targeting of AMPA-Rs by modulating AMPA-R trafficking from the Golgi apparatus to the plasma membrane. Knockdown of LARGE in the hippocampus resulted in occlusion of hippocampal long-term potentiation (LTP) and deficits in associative fear memory, which were attributable to an increase in the number of AMPA-Rs at the synapse. These results thus identify LARGE as a central component in the machinery that regulates synaptic targeting of AMPA-Rs, synaptic plasticity and, ultimately, memory.

Title: The WNK signaling pathway as a link to altered intracellular chloride and trafficking of voltage-gated ion channels following stimulation of GABA receptors in cerebellar neurons

Authors: *E. M. CILENTO[1], B. BALLIF[2], J. FUCHS[3], J. GREEN[3], M. WILLIAMS[5], A. MORIELLI[4];
[1]Neurosci. Grad. Program, [2]Biol., [3]Psychological Sci., [4]Pharmacol., Univ. of Vermont, Burlington, VT; [5]Dept. of Physiol. and Neurobio., Dartmouth Col., Lebanon, NH

Abstract: Kv1.2 is a voltage-sensitive ion channel that influences neuronal excitability. GABA, the principle inhibitory neurotransmitter of the brain, minimizes Purkinje cell (PC) excitability in the cerebellum in part by influencing the expression of Kv1.2 at the cell surface. Activation of GABAA receptors is known to alter chloride passage inside neurons, however it is unknown if intracellular chloride ([Cl-]i) influences Kv1.2 trafficking, leaving the mechanism by which GABA influences Kv1.2 trafficking unclear. Recently, the family of chloride-sensing WNK kinases have been hypothesized to respond to GABA-induced [Cl-]i changes by signaling events to restore both chloride homeostasis and neuronal excitability (Alessi et al., 2014). In this study, we investigated WNK signaling as a potential mechanism to link GABAergic inhibition of Kv1.2

and the alterations of [Cl-]i that follow. We used mass spectrometry to develop an interactome of Kv1.2 in the rat cerebellum and provide, to our knowledge, the first report of WNK family kinases associating with a voltage-gated ion channel in the brain. Using immmunoflourescence, we further demonstrate that both WNK1 and SPAK strongly localize to PCs. With overexpression systems, we show that WNK1 and SPAK operate through duel, opposing mechanisms to balance the trafficking of Kv1.2, however disrupting the presence of WNK1, the ability for WNK kinases to bind SPAK, or even extracellular tonicity can dramatically alter this balance. As a result, we propose a model where GABAergic inhibition of PC excitability alters PC [Cl-]i. The resulting level of [Cl-]i then determines the manner and degree of WNK signaling driven trafficking of Kv1.2. Finally, we highlight our model with a demonstration that, following cerebellar learning, WNK1 has decreased detected interaction with Kv1.2.

Title: Hyperglycemia reduces astrocytic potassium channels and function

Authors: *D. E. RIVERA-APONTE[1], M. P. D. MENDEZ-GONZALEZ[1], A. RIVERA-PAGAN[1], Y. KUCHERYAVYHK[1], L. KUCHERYAVYHK[1], S. N. SKATCHKOV[2], M. J. EATON[1];
[1]Biochem., [2]Biochemistry/Physiology, Univ. Central Del Caribe, Bayamon, PR

Abstract: Diabetics are at risk for a number of serious health complications including an increased incidence of stroke and poorer recovery after ischemic stroke. Astrocytes play a critical role in protecting neurons by maintaining extracellular homeostasis and preventing neurotoxicity through glutamate uptake and potassium buffering. These functions are aided by the presence of potassium channels, such as Kir4.1 inwardly rectifying potassium channels, in the membranes of astrocytic glial cells. The purpose of the present study was to determine if hyperglycemia alters Kir4.1 potassium channel expression and homeostatic functions of astrocytes. We used q-PCR,

Western blot, patch-clamp electrophysiology and a colorimetric glutamate clearance assay to assess Kir4.1 channel levels and homeostatic functions of astrocytes grown in normal and high glucose conditions. We found that astrocytes grown in high glucose (25mM) had an approximately 50% reduction in Kir4.1 mRNA and protein expression as compared with those grown in normal glucose (5mM). These reductions occurred within 24 hours of exposure to hyperglycemia, whereas reversal occurred within 7 days after return to normal glucose. The decrease in functional Kir channels in the astrocytic membrane was confirmed using barium to block Kir channels. In the presence of 100μm barium, the currents recorded from astrocytes in response to voltage steps were reduced by 45%. Furthermore, inward currents induced by stepping extracellular $[K^+]_o$ from 3 to 10 mM (reflecting potassium uptake) were 50% reduced in astrocytes grown in high glucose. In addition, glutamate clearance by astrocytes grown in high glucose was significantly impaired. Taken together, our results suggest that down-regulation of astrocytic Kir4.1 channels by elevated glucose may contribute to the underlying pathophysiology of diabetes-induced CNS disorders and contribute to the poor prognosis after stroke.

Title: Dephosphorylation of N-terminal serines promotes biogenesis of the sodium-activated potassium channel Slack-B

Authors: *G. E. KIM[1], M. R. FLEMING[1], J. KRONENGOLD[1], L. K. KACZMAREK[2]; [1]Pharmacol. Dept., [2]Pharmacol. Dept. and Cell. and Mol. Physiol. Dept., Yale Univ., New Haven, CT

Abstract: The Slack sodium-activated potassium (KNa) channel is the largest known potassium channel. Encoded by KCNT1, Slack is expressed throughout the brain. Human KCNT1 mutations lead to severe learning disability that is linked to intractable seizures with early-to-mid-life onset. Slack exists as multiple isoforms, of which Slack-B is the largest, and is expressed predominantly in brainstem regions and the olfactory bulb. Using liquid-chromatography tandem mass spectrometry, we determined that two serine residues (S34 and S44) close to the N-terminus of Slack-B are phosphorylated under basal conditions. To test the

biological role of these sites we performed site-directed mutagenesis and generated 8 different combinations of S34 and S44 mutations that mimic either phosphorylation or dephosphorylation at each site. We found that levels of the "dephosphorylated" mutant channel (AA Slack) are greatly increased in cRNA-injected Xenopus oocytes and transiently transfected HEK293 cells compared to wild type Slack. This is correlated with an increase in currents measured in two-electrode voltage clamp experiments using oocytes and immunofluorescent localization of the protein in HEK cells. The increase in current was not associated with alterations in channel kinetics or single channel properties. Similarly, changes in Slack protein expression could not be explained by our choice of codons in generating the AA or EE mutant channels. Next, to determine whether the increase in Slack protein accumulation resulted from an increase in Slack translation or a decrease in its degradation, we measured the time constant for Slack protein accumulation, Slack protein half-life and the effect of preventing proteasomal degradation. Protein accumulation was biphasic with a rapid increase that tailored off into a plateau for AA Slack in both cell systems, whereas there was a much slower, linear accumulation for wild-type Slack and EE Slack ("phosphorylated" mutant). The rate of accumulation of AA Slack was significantly greater, and inhibiting proteasomal degradation with MG-132 in HEK cells for six hours could not enhance the level of wild-type expression to that of AA Slack. Finally, measurements of protein half-life in the presence of the protein synthesis inhibitor cycloheximide revealed no difference among the three groups. Taken together, the results indicate that dephosphorylation of these two N-terminal residues is a key step during biogenesis of Slack. Our findings also suggest that regulation of the phosphorylation state of S34 and S44 during biogenesis may allow neurons to alter channel abundance rapidly in response to stimulation.

Title: Slick (Kcnt2) sodium-activated potassium channels expressed in peptidergic CGRP neurons regulate nociception and peptide release

Authors: *D. L. TOMASELLO[1], A. BHATTACHARJEE[2];
[1]Program in Neurosci., [2]Pharmacol. & Toxicology, SUNY at Buffalo, Buffalo, NY

Abstract: Previous work has identified the Slack (Kcnt1) K_{Na} channel as a key contributor to excitability in dorsal root ganglion (DRG) neurons and pain signaling, however little is known about the functional role of the closely related Slick (Kcnt2) K_{Na} channel. We studied the phenotypic consequences of *Slick* deletion using a novel Slick-lacZ reporter knockout (KO) mouse line. Utilizing the sciatic nerve cuff model for neuropathic pain we tested thermal hyperalgesia on KO and wild type (WT) littermates. Prior to nerve injury Slick KO mice exhibited sensitized basal nociception, and following injury KO mice had exacerbated hyperalgesia compared to WT mice in both male and female groups. Staining of Slick in the DRG indicated prominent staining localized to the cytoplasm of calcitonin-gene related peptide (CGRP) small and medium sized neurons only. CGRP is a neuroinflammatory peptide. Slick staining was also identified in the spinal cord and within the paw indicating Slick is localized to cell bodies and to nerve endings. Strikingly, a pool of Slick channels localized to large dense core vesicles (LDCV) containing CGRP as determined by immunohistochemistry. Fractionation of DRGs confirmed that Slick channels migrate with LDCV positive fractions. CGRP immunolabeling within Slick KO mouse DRG neurons displayed lower intensity and dispersed localization within the cytoplasm, however no change in Substance P staining was observed. Next we tested the electrophysiological properties of peptidergic DRG neurons from KO and WT mice. We found a decrease in the total outward potassium current, a decrease in action potential rheobase, and an increase in the height of action potential from DRG neurons isolated from Slick KO mice compared to WT neurons indicating that Slick deletion produces hyperexcitability. Our data indicate that Slick channels limit the excitability of CGRP peptidergic neurons and reduce pain behavior after nerve injury. Moreover, Slick channels are likely recruited to the membrane during CGRP release functioning to constrain excessive CGRP release. Given the specificity of Slick expression to CGRP positive neurons only, Slick channels are desirable pharmacologic targets for the treatment of pain and inflammation.

Title: Non-invasive control of cellular excitability using focused ultrasound: Effects on ion channels

Authors: *J. KUBANEK[1], J. SHI[2], J. CUI[2];
[1]Washington University, Sch. of Med., Saint Louis, MO; [2]Biomed. Engin., Washington Univ., St. Louis, MO

Abstract: Ultrasound (US) has recently been found to modulate cellular excitability in the brain. US propagates through the skull and can be well focused. These properties make US an attractive new method to stimulate particular brain regions with the goal to treat diseases of the nervous system non-invasively. However, to arrive to such clinical applications, it is necessary to first determine the mechanism/s by which US mediates membrane excitability. Using the Xenopus oocyte expression system, we found that focused US (10 MHz frequency, 100--500 kPa amplitude) is capable of activating ion channels of the K2P family (TREK-1, TREK-2, TRAAK) natively present in neuronal, retinal, and cardiac cells. The transmembrane current due to the US exhibits an early rapid response (within about 20 ms), and then steadily increases with the time of the sonification. The average peak effect represents about 20% modulation of the transmembrane current. The effect is not present when the channels are blocked using BaCl2. An effect of US on ion channels presents a safe mechanism of US action on cellular excitability, and thus paves the way to future non-invasive treatments of neurological or cardiac diseases.

Title: Pituitary adenylate cyclase-activating peptide modulates neuronal Kv4.2 channel via convergent phosphorylation by PKA and ERK1/2

Authors: *R. GUPTE[1,2], R. MERRILL[2], A. J. SHEPHERD[3], S. STRACK[2], D. P. MOHAPATRA[3,2];
[1]Dept. of Anesthesiol., Washington Univ. In St. Louis Sch. of Medic, Saint Louis, MO; [2]Pharmacol., The Univ. of Iowa, Iowa City, IA; [3]Dept. of Anesthesiol., Washington Univ. Sch. of Med. in St. Louis, Saint Louis, MO

Abstract: The endogenous neuropeptide pituitary adenylate cyclase-activating polypeptide (PACAP) exerts various neuromodulatory functions, including enhancement of synaptic activity, and chronic inflammatory and neuropathic pain conditions. However, it remains unclear whether PACAP signaling could directly influence the function of intrinsically excitable ion channels, thereby altering the excitability of neurons. Kv4.2, the major dendritic voltage-gated K^+ channel in mammalian neurons, is a key regulator of neuronal excitability and modulation of synaptic inputs, and plays a critical role in central sensitization of inflammatory pain. We determined whether PACAP signaling could dynamically influence neuronal Kv4.2 channel activity. We found that isoforms of the PACAP receptor, PAC1, are expressed in rodent brain neurons, and their activation led to the downstream activation of protein kinase A (PKA) and extracellular signal-regulated protein kinase-1/2 (ERK1/2). Using cultured rat hippocampal neurons and HEK293T-based heterologous expression system, we show that PACAP induces phosphorylation of Kv4.2 protein, and consequently decreases channel current density. Such modulation of Kv4.2 was dependent on the activity of both PKA and ERK1/2. PACAP effects on Kv4.2 channel density was abolished in phospho-disruptive mutations at three ERK1/2-phosphorylation sites, T602, T607 and S616, in Kv4.2; however, it was unaffected in phospho-disruptive mutation at PKA-phosphorylation site, S552. PACAP38 did not induce any significant change in the voltage-dependence and time course of activation of Kv4.2 channel. Although PACAP38 did not alter the voltage-dependence of channel's steady-state inactivation, it led to a decrease in the time course of fast-inactivation, which was attenuated with the inhibition of ERK1/2. Conversely, PACAP38 exposure led to an increase in the extent of non-inactivating current component of the channel, which was attenuated with the inhibition of PKA, but not ERK1/2, and was abolished in the Kv4.2-S552A channel. These results indicate a convergence of PACAP-mediated PKA and ERK1/2 activation, in order to influence the current density and kinetic properties of Kv4.2 channel. Our findings suggest that PACAP/PAC1 signaling modulates Kv4.2 channel function in a manner that could lead to increased intrinsic excitability of neurons. Since PACAP levels are elevated in multiple pathological conditions, such as stroke-reperfusion injury, chronic inflammatory and neuropathic pain, modulation of Kv4.2 channel function could lead to hyperexcitability in these pathologies.

Title: Functional consequences of amino acid variation in pain-pathway kv1 channels in a wild rodent (Onychomys) exhibiting reduced pain sensitivity

Authors: *K. SHERER[1], R. BARAJAS[2], A. ROWE[2];
[1]Neurosci., [2]Zoology, Michigan State Univ., East Lansing, MI

Abstract: In 1931 French physician Dr. Albert Schweitzer declared, "Pain is a more terrible lord of mankind than even death itself." A variety of pain conditions affect more people in the United States than diabetes, cancer and heart disease combined. Unfortunately, current drugs are inadequate for managing pain, mainly due to our incomplete understanding of how pain states develop. Small- and medium-diameter sensory neurons transmit pain signals to the central nervous system via action potentials (APs). While sodium (Na^+) ion channels initiate AP firing in sensory neurons, potassium (K^+) ion channels are responsible for inhibiting APs and returning the neuron to its resting potential, thus terminating pain signals. Currently, we understand that pathologic pain states are associated with excessive firing, or hyperexcitability, of nerves, creating the sensation of pain. Rodent pain models indicate that altered K^+ channel expression and function are associated with hyperexcitability of sensory neurons and pain-related behaviors. Grasshopper mice (*Onychomys*) provide a unique model for studying the K^+ ion channels that regulate pain signals. Grasshopper mice prey on scorpions (*Centruroides*) whose venom induces burning pain and hypersensitivity to touch in humans. However, the mice exhibit minimal pain-related behaviors in response to the scorpions' defensive stings. Grasshopper mice sensory neurons exhibit decreased excitability compared to house mice. Thus, this model provides the opportunity to study the role of K^+ channels in a hypoexcitable system. RNA-seq data (confirmed by Sanger sequencing) revealed multiple amino acid variants in both the coding and regulatory regions of $K_v1.1$, $K_v1.2$, and $K_v1.4$ *Shaker* channel α-subunits and the leak channel TWIK1 compared to the house mouse (*Mus musculus*). K_v1 channels produce A- and D-type currents that accelerate repolarization of neurons after AP firing. TWIK1 is a weak inward rectifier that contributes to the resting membrane potential of neurons. Thus, K_v1 and TWIK1 are critical for controlling the excitability of sensory neurons. I hypothesize that amino acid variants in grasshopper mice K^+ channels produce functional changes that inhibit sensory neuron excitability and decrease pain signaling. Current experiments are aimed at understanding the functional consequences of amino acid variants in K_v1 and TWIK1 channels. Elucidating how structural and functional changes in K^+ channels lead to alterations in AP firing in sensory neurons will contribute to our understanding of how pain states develop.

Title: Cell-type specific channel phenotypes in the prefrontal cortex of the fmr1-/y mouse model of Fragile X syndrome

Authors: B. E. KALMBACH, D. JOHNSTON, *D. H. BRAGER;
Ctr. for Learning and Memory, Univ. Texas at Austin, Austin, TX

Abstract: Fragile X syndrome (FXS) is caused by a single gene mutation resulting in the loss of expression of fragile X mental retardation protein (FMRP). FXS patients display several behavioral phenotypes associated with prefrontal cortex (PFC) dysfunction. Voltage-gated ion channels, some of which are targets of FMRP-regulation, heavily influence neuron function. In the *fmr1-/y* mouse model of FXS we tested for alterations to ion channels in L5 pyramidal neurons of medial prefrontal cortex (PFC). Using somatic and dendritic patch clamp recordings we show that the functional expression of h-channels (I_h) is downregulated, whereas a rapidly inactivating A-type K^+ current is upregulated in pyramidal tract-projecting (PT) PFC neurons. These channel phenotypes are opposite to our published findings from hippocampus. Additionally, we found that a slowly inactivating K^+ current is downregulated at the soma of PT neurons, resulting in increased excitability. Importantly, these K^+ channel phenotypes are not found in neighboring L5 intratelencephalic-projecting (IT) PFC neurons. Thus, the absence of FMRP has divergent effects on the function of individual types of ion channels not only between brain regions, but also across cell types within the same brain region.

Title: Kir2 leak conductance dampens the excitability of lamina I projection neurons in the neonatal rat

Authors: *N. C. FORD, M. L. BACCEI;
Anesthesiol., Univ. of Cincinnati, Cincinnati, OH

Abstract: Background leak conductances are implicated in determining the excitability and modulating the firing properties of CNS neurons. Previous studies demonstrated that classic inward-rectifying potassium (Kir2) conductance contributes to membrane excitability and shapes burst-firing in interneurons of the neonatal rat superficial dorsal horn (SDH). However, little is known about which types of leak conductance are responsible for regulating the intrinsic excitability of lamina I projection neurons (PNs), which correspond to a major output of the spinal nociceptive network. The present study investigated the contribution of Kir2-mediated leak conductance to the intrinsic membrane excitability in identified lamina I PNs during the neonatal period. Lamina I PNs were back-labeled via injection of DiI into the rat parabrachial nucleus (PB) or periaqueductal gray (PAG) at postnatal day 1 (P1), and whole-cell patch clamp recordings were obtained from these cells using an *in vitro* intact spinal cord preparation at P3-5. $BaCl_2$ (200 μM) was bath applied to block Kir2 conductance. Ba^{2+} block of Kir2 channels in spino-PB neurons significantly depolarized the resting membrane potential, decreased rheobase, and increased the membrane resistance, rate of spontaneous activity, AP duration and repetitive firing rate. AP threshold was not affected by blocking Kir2 channels in spino-PB neurons. Perfusion with the Kir2-selective antagonist ML133 (10μM) also enhanced the excitability of spino-PB neurons. Similarly, Ba^{2+} block of Kir2 channels in spino-PAG neurons significantly depolarized the resting membrane potential, increased AP duration and repetitive firing rate, while decreasing rheobase. However, AP threshold, membrane resistance and spontaneous activity were not affected by blocking Kir2 channels in spino-PAG neurons. Comparing the level of Ba^{2+} sensitive K^+ conductance between spino-PB and spino-PAG neurons revealed no significant differences. We conclude that Kir2-mediated leak conductance plays a role in dampening the excitability and shaping the firing properties of lamina I PNs in the neonatal rat. These data suggest that changes in Kir2-mediated conductance during early life could significantly alter the level of ascending nociceptive transmission to the developing brain.

Action on Hearing Loss

Title: Kv3 channels in the auditory brainstem are composed of Kv3.1 and Kv3.3 subunits

Authors: D. M. LINLEY[1], S. ROBINSON[2], J. R. STEINERT[2], C. KOPP-SCHEINPFLUG[3], *I. D. FORSYTHE[1];
[1]Univ. of Leicester, P.O. Box 138. Leicester, United Kingdom; [2]MRC Toxicology Unit, Leicester, United Kingdom; [3]Ludwig-Maximilians-University Munich, Munich, Germany

Abstract: Fast high fidelity action potential (AP) firing is vital for accurately encoding sound and for extracting sound localisation cues in the ascending auditory pathway. High frequency firing is aided by the presence of high voltage activated Kv3 channels, which have rapid kinetics and promptly repolarise APs. We investigated the contribution of different Kv3 subunits (Kv3.1-Kv3.4) to AP repolarisation in three nuclei of the superior olivary complex (SOC) in the auditory brainstem. Respective tissue samples were collected from recently sacrificed CBA/Ca mice, Kv3.1 knockout (KO) and Kv3.3-KO strains (both backcrossed onto CBA/Ca). RT PCR was used to assess the distribution of Kv3 subunit mRNA across the SOC (in animals aged P13-P33), and immunohistochemistry was conducted using antibodies targeting Kv3 subunits. Whole-cell patch recording in transverse brainstem slices was performed in both voltage and current-clamp mode (P14-P19). Immunohistochemistry and RT PCR revealed that Kv3.1b and Kv3.3 subunits are co-expressed in the medial nucleus of the trapezoid body (MNTB) and the superior paraolivary nucleus (SPN) in wild-type (WT) mice. In the lateral superior olive (LSO), Kv3.3 subunits appear to predominate over Kv3.1b. Kv3.2 and Kv3.4 subunits showed negligible expression across the whole SOC. Current-clamp recordings in the WT SPN gave AP half-widths (HW) of 0.27±0.02ms (mean ± SEM) which were prolonged in the Kv3.1-KO and slowed further in the Kv3.3-KO mice (respectively, 0.50±0.09ms and 0.59±0.10ms). Voltage gated repolarising K^+ currents in the SPN were reduced in both the Kv3.1-KO and Kv3.3-KO compared to WT (respectively, 17.5±3.9nA, 23.3±5.4nA and 42.7±2.2nA at +50mV). However, in the LSO, AP HW in the Kv3.1-KO was unchanged compared to WT (respectively 0.27±0.03ms and 0.28±0.02ms), while AP HW in the Kv3.3-KO was prolonged to an even greater extent than in the SPN (0.7±0.06ms). Voltage-clamp data from the LSO showed no significant change in the Kv3.1-KO compared to WT (respectively, 46.4±3.5nA and 39.8±7.9nA at +50mV; p=0.792) but voltage gated K^+ currents in the Kv3.3-KO were greatly reduced (7.9±1.7nA). Preliminary studies in the MNTB suggest that KO of either Kv3.1 or Kv3.3 produces only a small change in AP duration and K^+ current amplitudes. This will be further investigated. In conclusion, Kv3.3 is co-expressed with Kv3.1b in the auditory brainstem. We postulate that Kv3.3 influences AP repolarisation to a greater extent in the more lateral nuclei of the SOC.

Title: L-type voltage gated calcium channels activate IKCa channels to generate the slow afterhyperpolarization in CA1 pyramidal cells

Authors: *G. SAHU, J. MICLAT, G. W. ZAMPONI, R. W. TURNER;
Hotchkiss Brain Inst., Univ. of Calgary, Calgary, AB, Canada

Abstract: Calcium activated potassium (KCa) channels control the frequency and pattern of spike discharge in hippocampal pyramidal neurons. The role of big conductance (BK) and small conductance (SK) channels in generating the fast (~10 ms) and medium (~100 ms) afterhyperpolarization has been long established. The molecular identity of the channel responsible for the slow afterhyperpolarization (sAHP) that lasts for seconds was recently identified as intermediate conductance KCa (IKCa) channels. Previous work suggested that L-type calcium channels provide calcium influx to drive the sAHP in CA1 pyramidal cells. This study tested if the L-type channel isoforms CaV1.2 or CaV1.3 are capable of activating IKCa channels and the sAHP in CA1 pyramidal cells. Transient transfection of CaV1 cDNA in tsA-201 cells established that the initial onset and peak current for CaV1.2 channels was evoked at -30 mV and +10 mV, and for CaV1.3 channels -40 mV and 0 mV at physiological levels of [Ca]o. We found that either CaV1.2 or CaV1.3 was sufficient to activate IKCa channels when coexpressed in tsA-201 cells. Moreover, when coexpressed IKCa channels were activated in a voltage-dependent manner that closely followed the activation voltages of the CaV1 isoforms, including a decrease in IKCa amplitude as calcium conductance decreased upon approaching ECa. Importantly, a step command for 5-150 msec to +10 mV for CaV1.2 and 0 mV for CaV1.3 to maximally activate the CaV1 isoforms produced a graded tail current for IKCa that lasted 1-5 sec, effectively recreating an sAHP current (IsAHP). By comparison, neither IKCa nor CaV1 channel isoforms expressed in isolation produced a long-lasting tail current. In concurrence with the expression results, CA1 cells produced an IsAHP in the presence of blockers against all CaV channel isoforms except L-type channels, as well as SK, BK, KV1, KV7, and Na channels. Moreover, internal perfusion of 1 μM TRAM-34, a selective blocker for IKCa channels, abolished the IsAHP/IKCa currents in either CA1 cells or tsA-201 cells. Immunocytochemistry revealed an overlapping expression pattern for IKCa and both Cav1.2 and Cav1.3 immunolabels in tsA-201 cells and CA1 cells but no obvious co-localization with either L-type channel isoforms. The CaV1-mediated activation of IKCa channels was also blocked by internal perfusion of 5 mM EGTA or BAPTA, suggesting a microdomain based interaction. The results suggest that L-type calcium channel isoforms are sufficient to activate IKCa channels in a manner consistent with the sAHP in CA1 pyramidal neurons. This work was supported by Canadian Institute of Health Research (CIHR) and a University of Calgary Eyes High PDF (GS).

Title: The role of neuronal Kv2.1 potassium channels under physiological conditions

Authors: ***J. L. SMALLEY**, B. PIGOTT, I. D. FORSYTHE;
Cell Physiol. and Pharmacol., Univ. of Leicester, Leicester, United Kingdom

Abstract: Kv2.1 is a voltage-dependent potassium channel that is highly expressed in the cortex and hippocampus. It is postulated that this delayed rectifier is a key regulator of neuronal excitability and integral for co-ordinating intrinsic plasticity. The channel is tetrameric with each subunit consisting of a short N-terminal domain, 6 membrane-spanning domains, and a long intracellular C-terminal domain that is highly phosphorylated. Previous work *in vitro* has demonstrated that Kv2.1 is localized in clusters that are dispersed during hypoxia and plays a role in axonal injury and synaptic excitation. Clustered Kv2.1 is highly phosphorylated, while declustering is associated with distinct dephosphorylation, although the mechanism(s) of phosphorylation/dephosphorylation and changes in localisation that occur upon neuronal excitation have not been well characterised. Here we use an unbiased proteomic-based approach and bioinformatic analysis to identify the proteins and biochemical processes associated with Kv2.1 *in vivo*, and combine this with an *ex vivo* system of acute cortical slices to determine phosphorylation and neuronal excitability. We carried out LC-MS/MS on freshly isolated and fractionated cortical tissue and achieved a high degree of Kv2.1 sequence coverage. Our results suggest that Kv2.1 phosphorylation *in vivo* occurs at a few, but not all of the C-terminal sites formerly identified *in vitro*. Our data also suggests that under normal conditions, Kv2.1 is expressed within clusters with a unique proteome containing endoplasmic reticulum (ER), Golgi, and synaptic vesicle proteins. Transition through these cellular compartments would be expected for any large and complex protein and therefore it would not be surprising that ER/golgi remnants remain. However during hypoxia/excitation, the majority of clusters disperse, indicating that these Kv2.1 structures are not simply extensions of the ER or Golgi, but are a distinct vehicle for the storage and delivery of Kv2.1. Unbiased functional analyses of Kv2.1 binding proteins, using several large curated databases of protein interactions, suggest a prominent role for kinases/phosphatases, including several kinases not previously implicated. The analysis also highlighted microtubule-associated trafficking proteins, which may be involved in the movement and dispersion of Kv2.1 clusters. This work demonstrates how the use

of native tissue-based systems combined with shotgun proteomics and bioinformatics can be used to generate new insights into the function and regulation of an important neuronal signalling protein.

Title: Effects of cold temperatures on trigeminal neuron excitability and KCNQ channel activity

Authors: ***H. KANDA**[1], R. IKEDA[2], J. G. GU[1];
[1]Dept. of Anesthesiol. and Perioperative Med., Univ. of Alabama at Birmingham, Birmingham, AL; [2]Dept. of Orthopaedic Surgery, Jikei Univ. Sch. of Med., Tokyo, Japan

Abstract: In the present study we studied the effect of cooling temperatures on trigeminal afferent neuron excitability and KCNQ channel activity by using the whole mount trigeminal ganglion (TG) preparation and the whole-cell patch-clamp recording technique. In 49% of small-sized TG neurons recorded, cooling temperature of 15 oC increased neuronal excitability as was evidenced by the reduction of action potential rheobase and increases of action potential firing numbers in response to membrane depolarization. In the remaining 51% of TG neurons cooling temperatures decreased or had little effect on their excitability. Since KCNQ channels play an important role in controlling neuronal excitability, we studied whether cooling temperatures affected KCNQ channel activity (M-currents) and thereby causing the increases of neuronal excitability in some TG neurons. We found that M-currents in TG neurons were significantly inhibited by cold in a cooling temperature-dependent manner. Inhibition of M-currents pharmacologically by linopirdin (10 μM) could increase TG neuron excitability in a manner similar to cold-induced increases of TG neuron excitability. Furthermore, retigabine, a KCNQ channel activator, enhanced M-currents and abolished cold-induced increases of neuronal excitability. Our results suggest that cold temperatures increase trigeminal afferent neuron excitability via KCNQ channel inhibition.

Title: Inhibition of hERG Channel by Acepromazine

Authors: Y. JOO, *K.-W. SUNG;
The Catholic Univ. of Korea, Sch. of Medicine, Dept. of Pharmacol., Seoul, Korea, Republic of

Abstract: Acepromazine is a first generation of antipsychotics as phenothiazine group, like chlorpromazine. Phenothiazine derivative antipsychotic drug has been shown its sedative effects by blocking of dopamine receptors in the central nervous system. Chlorpromazine is still used in human medicine for treatment of psychosis, but acepromazine isn't because it has a little therapeutic effect. Whereas acepromazine is used in veterinary field as a seditave medicine in a case of a captive wild animals or pre-treatment of anesthesia. Chlorpromazine that is closely related analogue, acepromazine, is known as a drug that inhibited hERG channel. Human ether-a-go-go-related gene(hERG) encodes for a protein known as Kv11.1 that is the alpha subunit of the rapid delayed rectifier potassium current(*Ikr*). The channel is highly expressed in cardiomyocytes and the most critical factor in the repolarization process. It is terminated cardiac action potentials and can affect the action potential duration. Inhibition of hERG channel by genetic defect or drug side effect cause long QT syndrome which is prolonged QT interval in the electrocardiogram and sever arrhythmias. We studied whether acepromazine affect hERG channel. This study was investigated using the whole cell patch clamp technique in human embryonic kidney (HEK293) cells expressed human ether-a-go-related gene (hERG) channels. The hERG channels were inhibited by acepromazine in a concentration-dependent manner with an IC50 value 1.2μM and Hill coefficient of 0.81. Acepromazine blocked hERG currents voltage-dependent manner between -40 and +60mV. Before and after application of the 1μM acepromazine, the half activation potential(V1/2) was -37.9mV and -44.57mV, slope value was 5.70 and 4.60. There was no frequency-dependent inhibition on hERG channel by the acepromazine. Acepromazine also blocked the hERG current during the repolarization pulse in a concentration-dependent manner. The extent of the blocking by acepromazine in the repolarizing current was more than that in the depolarizing pulse, implying that acepromazine has a high affinity for the open state of the channel, with a relatively lower affinity during the inactivated state of hERG channel. Keywords: hERG Channel, Acepromazine, Patch clamp technique

Title: Coupling of distinct ion channel types in neurons mediated by AKAP79/150

Authors: *J. ZHANG, M. S. SHAPIRO;
Univ. of Texas Hlth. Sci. Ctr. At San Antonio, San Antonio, TX

Abstract: M-type K+ channels, comprised of KCNQ2-5 (Kv7.2-7.5) subunits, play key roles in the regulation of neuronal excitability in the peripheral and central nervous systems. In diverse neurons, L-type Ca2+ channels (LTCCs) drive transcriptional regulation via NFAT transcription factors, and in sensory neurons, TRPV1 cation channels excite neurons in response to heat, acidity or chemical ligands, driving nociception. The A-kinase-anchoring protein (AKAP)79/150 has been shown to orchestrate regulation of all three types of channels by PKC, PKA, calcineurin or NFAT transcription factors. Using stochastic optical reconstruction microscopy (STORM), which offers sub-diffraction (~20 nm) resolution, we have directly visualized individual signaling complexes containing endogenous and cloned AKAP79/150, these three ion channels and G protein-coupled receptors in neurons and tissue-culture cells. We also observe AKAP150-mediated clustering of KCNQ, LTCCs and TRPV1 channels at the single-complex level. Thus, AKAP79/150 links different channel types together, raising the possibility of their functional, as well as physical, coupling. In nodose ganglia sensory neurons, application of capsaicin induced the translocation of YFP-tagged PH probe from plasma membrane into the cytoplasm, suggesting membrane PIP2 depletion triggered by TRPV1 activation. In neurons isolated from AKAP150+/+ mice, application of very low concentration of capsaicin (100 nM) for a very short time, which is believed to trigger only local PIP2 depletion, induced ~40% suppression of M-current amplitude (IM), suggesting the close localization of TRPV1 and M-channels, which thus can be suppressed by capsaicin-induced local PIP2 depletion. However, in AKAP150-/- neurons, IM was shown to be not affected by this modest activation of TRPV1 channels, implying the critical role of AKAP79/150 in bringing together complexes involving these two ion channels. Furthermore, with the application of the LTCC blocker, nifedipine, but not the N-type Ca2+ channel blocker, ω-conotoxin GVIA, IM was significantly suppressed, and both acute desensitization and tachyphylaxis of TRPV1 current was greatly impaired, suggesting the functional coupling of LTCCs with KCNQ, and TRPV1 channels, consistent with our findings suggesting their physical coupling at the single-complex level with STORM. We will further investigate the role of AKAP79/150 in the functional coupling of these three ion channels in sensory neurons and their physiological roles in tuning the nociceptive response to painful stimuli.

Title: Scaling of pyramidal neuron excitability in auditory cortex by nitric oxide-mediated inhibition of K_v2 currents during postnatal development

Authors: *B. PIGOTT, J. L. SMALLEY, M. HAMMETT, I. D. FORSYTHE;
Univ. of Leicester, Leicester, United Kingdom

Abstract: The intrinsic and synaptic properties of cortical pyramidal neurons change throughout postnatal development in a manner that enables the cortex to adapt its output to fluctuating sensory input, for example, as sense organs become active. Alterations in voltage-gated K^+ (K_v) currents have been well-documented, and could underlie adjustments in neuronal excitability, but the identity of the channels involved and the mechanisms underlying their regulation are unknown. To address these questions, standard techniques were used for whole-cell patch-clamp recording in slices of mouse auditory cortex. Data are mean values ± SEM. In good agreement with past reports, outward K_v currents recorded in layer 2/3 pyramidal neurons increased significantly from hearing onset (P11-14) to maturity (> P28; respective currents were 13 ± 0.5 nA and 24 ± 2 nA at +50 mV; unpaired *t* test, $p < 0.05$; n = 11-30 cells). This increase was explained by the addition of a current that was sensitive to the K_v2 channel inhibitor gunangxitoxin-1E (100 nM), which reduced the total current at +50 mV by 34 % in neurons from mature mice (P28-32; $p < 0.05$ compared to control; n = 6-8 cells), but had no effect in slices from animals aged 11-14 days old ($p = 0.36$; n = 6-7 cells). The absence of a K_v2 current in neurons from the younger mice could not be explained by a lack of K_v2 protein, as determined immunohistochemically (n = 3 mice). Rather, K_v2 currents were suppressed in these animals by endogenous nitric oxide (NO); the NO synthase inhibitor L-nitroarginine (100 μM) increased the total outward current from 13 ± 0.5 nA to 21 ± 1 nA ($p < 0.05$; n = 12-23 cells) and the percentage block by guangxitoxin-1E (100 nM) from 13 % to 25 % at +50 mV (n = 6-7 cells) but was without effect in slices from mature mice ($p = 0.35$; n = 5-11 cells). The NO signal appeared to be generated by the endothelial isozyme of NO synthase, which was detected in blood vessels throughout layer 2/3, and transduced via activation of the guanylyl cyclase-coupled NO receptor and protein kinase G. Under current clamp, NO synthase inhibition (100 μM L-nitroarginine) reduced the peak frequency of action potential firing from 39 ± 1 Hz to 29 ± 3 Hz in slices from the young mice ($p < 0.05$; n = 12-14 cells), indicating that NO augments neuronal excitability at this age. These data show that native K_v2 currents are subject to significant regulation during postnatal development. We postulate that the inhibition of K_v2 by NO at

hearing onset allows neurons to scale their output (in terms of action potentials) to their synaptic input, such that the firing of L2/3 pyramidal neurons will be facilitated at a time when hearing thresholds are high and hence cortical input (acoustic or synaptic) is low.

Title: The role of glutamate release in the nucleus accumbens core during cocaine reinstatement in rats with a history of both alcohol and cocaine self-administration

Authors: *B. STENNETT, L. KNACKSTEDT;
Univ. of Florida, Gainesville, FL

Abstract: One of the difficulties in successful treatment of cocaine addiction is reducing the high risk of relapse that exists even after long periods of abstinence. Relapse can be modeled in animals using the extinction-reinstatement paradigm. This paradigm involves training animals to lever-press for cocaine reinforcement in an operant chamber. The operant response is then extinguished and reinstated either with cues previously paired with the response made to attain cocaine delivery, or an IP injection of cocaine. Previous research has established the role of nucleus accumbens glutamate transmission in the reinstatement of cocaine-seeking and has shown that the antibiotic ceftriaxone prevents relapse to cocaine seeking in rats. However, it is estimated that 60% to 90% of cocaine addicts use alcohol with cocaine. The combination of alcohol and cocaine potentially produces unique neuroadaptations that differ from those produced by either drug alone. Therefore, we developed a model of poly-drug addiction in which rats self-administered cocaine for two hours in an operant chamber and subsequently drank alcohol (20% v/v) from bottles in the home cage for 6 hours. Following two weeks of drug consumption, animals underwent extinction training for a minimum of two weeks. Animals were treated with IP ceftriaxone (200 mg/kg) or vehicle for 6 days prior to being tested for cue- and/or cocaine-primed reinstatement. During reinstatement testing, animals were probed with a microdialysis cannula in the nucleus accumbens to measure glutamate levels during relapse to drug seeking. In agreement with previous work by our group and others, an increase in glutamate was found during the reinstatement to cocaine seeking in rats that did not consume alcohol. However, in animals that self-administered both cocaine and alcohol, cocaine+cue-primed reinstatement of the operant response that previously delivered cocaine was not accompanied by an increase in glutamate in the nucleus accumbens. In addition, we found that ceftriaxone was not effective in preventing relapse in animals that consumed both alcohol and cocaine, and in

these animals we observed a decrease in glutamate relative to baseline during the reinstatement test. In conclusion, glutamate transmission in the nucleus accumbens does not mediate relapse to cocaine-seeking in animals that consumed ethanol with cocaine. These findings indicate that medications targeting glutamate may not be effective therapies for preventing relapse in humans that drink alcohol with their cocaine.

Title: Inhibition of eEF2K enhances hippocampal synaptic transmission by presynaptic p38 MAPKα in rat

Authors: ***W. WENG**, T. BEHNISCH;
Inst. of Brain Sci., Fudan Univ., Shanghai, China

Abstract: The strength of synapses does not only depend upon their history of use but undergoes compensatory scaling together with other synapses to normalize neuronal activity. Whereas compensatory scaling that takes days is widely investigated the mechanisms of fast compensatory scaling are not well understood. Here we present data showing that a 60 min inhibition of NMDA-receptors by MK-801 is sufficient to induce a lasting potentiation of hippocampal synaptic transmission of Schaffer-collateral CA1 synapses. It was suggested that de-novo protein synthesis by altering the activity of the eukaryotic elongation factor 2 kinase (eEF2K; CaMKIII) could represent an underlying mechanism. Thus we studied if inhibition of eEF2K is sufficient to induce an enhancement of synaptic transmission. We found that inhibition of eEF2K by A484954 induces a potentiation of excitatory postsynaptic field potentials (fEPSP) within 10 minutes that lasted for up to 2 hours. In contrast to the initial hypothesis, this enhancement was not prevented by co-application of protein synthesis inhibitors and also not by inhibitors of Erk and Akt. However, inhibition of p38 mitogen-activated protein kinase α and β isoforms (p38 MAPKα/β) was very effective to prevent eEF2K-mediated fEPSP enhancement. Analysis of mEPSCs and paired-pulse stimulated fEPSPs before and after eEF2K inhibitor application points towards a presynaptic origin of the enhanced synaptic transmission. Thus, the data suggest that modulation of p38 MAPKα/β activity by eEF2K could contribute to synaptic scaling by altering presynaptic vesicle release probabilities.

Title: Proper statistical analyses of electrophysiological data

Authors: *E. C. CHURCH[1], S. ALFORD[2];
[1]Grad. Program in Neurosci., Univ. of Illinois At Chicago, Chicago, IL; [2]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Many of the most commonly used statistical techniques (e.g. t-tests, ANOVAs) require the data analyzed be normally distributed. As others have pointed out, looking for "statistically significant" deviations from normal can prove less than ideal, particularly when experimental sample sizes are small and more is known about the underlying population from whence the data came. Here, we use simulations in R to test hypotheses regarding patch clamp data analysis and statistician-recommended approaches of data manipulations for distributions common in electrophysiology. Additionally, if we consider a problem that has interested neuroscientists for more than 60 years, probability of release can give rise to a number of different skewed distributions of synaptic response amplitudes that do not meet requirements for commonly used statistical approach. Other analysis approaches must be used to investigate ratio distributions in neuroscience (eg paired pulse ratio) that are mathematically skewed. Different statistical approaches can at times produce wildly different results. Here, we use simulations in R to test hypotheses regarding patch clamp data analysis and statistician-recommended approaches of data manipulations for distributions common in electrophysiology.

Title: Functional characterization of the genomic imprinting of the Bcl-xL gene in mouse cortex

Authors: ***M. D. CAIATI**, L. NEEDLEMAN, C. DULAC, T. K. HENSCH;
Mol. and Cell. Biol., Harvard Univ., Cambridge, MA

Abstract: Genomic imprinting, the epigenetic silencing of either the paternal or maternal allele, leads to the expression of only one working copy of the imprinted gene. Although limited to a small fraction of genes, genomic imprinting plays a crucial role in brain development as its dysfunction has been linked to neurodevelopmental disorders, such as Angelman and Rett syndromes. Here we report the functional consequences of a selective neuronal deletion of either the maternal or paternal allele of the Bcl-xL gene, an anti-apoptotic gene showing a predominant paternal expression in mouse cortex. Mice in which only the maternal allele (MAT mice) had been deleted from cortical neurons were largely comparable to controls. However, several anatomical and physiological alterations were observed in mice devoid of the paternal allele (PAT mice): lower brain size, reduced cortical thickness and reduced neuronal cell number as adults. Interestingly, only glutamatergic but not GABAergic neurons were affected, as confirmed by largely normal inhibitory transmission even in young animals. Instead, excitatory postsynaptic currents recorded from layer 2/3 pyramidal cells in primary visual cortex of P16-18 mice, occurred at higher frequency in PAT mice. Accordingly epileptiform bursts, recorded in the presence of GABAA receptor antagonist bicuculline, produced more spikes/burst in PAT mice, further supporting a dys- regulation of cortical excitation following loss of the paternal allele. Evoked AMPA and NMDA currents upon layer 4 stimulation exhibited normal amplitude and kinetics in both PAT and MAT mice. However, AMPA currents displayed an inward rectification only in PAT mice, indicating the presence of calcium permeable AMPA receptors and confirmed by lower GluR2 AMPA subunit mRNA expression. Notably, GABAB receptor expression was also reduced in PAT mice, implicating their dysfunction in the altered glutamatergic transmission. Altogether, these findings provide strong evidence in support of the functional significance of genomic imprinting in neuronal synaptic transmission, cell signaling and network activity.

Title: Prolonged ketamine exposure induces increase in the expression and activity of GluN2B-containing NMDARs in the neurons of neonatal rat brain

Authors: *S. KOKANE, R. STEVENS, X. ZOU, Q. LIN;
Psychology, Univ. of Texas At Arlington, Arlington, TX

Abstract: Ketamine is a widely used pediatric anesthetic with a strong potential to cause widespread neuroapoptosis in the developing brain when administered repeatedly or for prolonged periods of time. Since ketamine is a non-competitive antagonist of N-methyl-D-aspartate receptor (NMDAR), several studies have proposed that ketamine-induced neuroapoptosis occurs via its effects on NMDAR expression and activity. At the molecular level, prolonged ketamine exposure has been associated with consequent increase in the expression of NMDARs. GluN2 (GluN2A-D) sub-units are involved in regulating the functions of the NMDARs and are differentially expressed across developmental stages - specifically, the expression pattern of GluN2A and GluN2B subunits. Being that GluN2B-containing NMDAR sub-type is predominantly expressed in the brain during the neonatal stage. We hypothesized that this NMDAR sub-type is the basis of increased neuronal vulnerability of the developing brain to ketamine-induced compensatory up-regulation of NMDARs, ultimately resulting in neuroapoptosis. Previous data from our group have shown that ketamine led to time dependent increase in NMDAR channel activity beginning 4 h after the last ketamine dose and peaked at 6 h after the last dose. In the present study, we used Ro 25-6981, a specific GluN2B antagonist, to selectively block GluN2B subunits. We then recorded the channel activity of NMDARs, using whole-cell patch clamp, from forebrain neurons of neonatal (PND 7) rats that were treated with either ketamine (20 mg/kg, six times at 2 h intervals) or saline (control). Our results demonstrated that at 6 h after the last ketamine dose, application of Ro 25-6981 significantly decreased spontaneous excitatory postsynaptic currents (EPSC) mediated by NMDARs. This indicated that NMDAR-mediated channel activity in neurons of the developing brain is majorly regulated by GluN2B sub-units. Western blot analysis revealed that there was also a time-dependent increase in expression and phosphorylation of the GluN2B sub-unit after ketamine administration. Based on these findings, we conclude that prolonged ketamine exposure induces an up-regulation of GluN2B-containing NMDARs in neurons of the developing brain. We propose that this increased expression is closely associated with the neuroapoptosis in these neurons. We thus propose a novel mechanism for ketamine-induced neuroapoptosis mediated specifically by GluN2B sub-unit of the NMDARs in the neurons of the developing brain.

Title: Glucose modulation of inputs and outputs in the ventral tegmental area dopamine neurons

Authors: *S. LIU[1], J. HUANG[2], S. BORGLAND[1];
[1]Dept. of Physiol. and Pharmacol., Univ. of Calgary, Calgary, AB, Canada; [2]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Glucose is the only energy source for the human brain under normal conditions. Historically, glucose concentrations in artificial cerebrospinal fluid (aCSF) for brain slice electrophysiology are much higher than in the living brain (10-26 mM), likely to support the health of tissues undergoing hypoxia by providing increased lactate. Brain glucose concentrations are 2.5 mM under physiological conditions, but can rise to 4.5 mM after a meal. Dopamine neurons in the ventral tegmental area (VTA) play a critical role in reward learning and can serve as primary metabolic sensors. While early studies have indicated that alterations in VTA glucose can change dopamine output, little is known if changes in glucose level influences excitatory synaptic transmission onto dopamine neurons in the VTA. Therefore, we investigated differing glucose concentrations on excitatory synaptic transmission of putative dopamine neurons in midbrain slices using whole cell path clamp. When aCSF was prepared with 11 mM glucose, frequency of spontaneous or miniature excitatory postsynaptic currents (EPSCs) was significantly less when aCSF was prepared with 4.5 mM glucose. Glucose concentration did not alter sEPSC or mEPSC amplitude suggesting that glucose concentration primarily influences presynaptic glutamate release probability, but not postsynaptic number or function of AMPA receptors. We also examined glucose effect on dopamine release in the nucleus accumbens (NAc) with *in vivo* fast scan cyclic voltammetry. We observed a decreased evoked DA release in the NAc core with intra-VTA application of 11 mM glucose. Taken together, concentrations of glucose typically used in electrophysiological recordings decrease release probability of glutamate onto VTA neurons.

Title: Alterations in dopamine system regulation of inhibition in an animal model of transcriptional dysregulation and hippocampal circuit dysfunction

Authors: *L. BRADY, A. F. BARTLEY, Q. LI, L. E. DOBRUNZ;
Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Hippocampal circuit dysfunction and transcriptional dysregulation occur in many neuropsychiatric disorders including schizophrenia. Parvalbumin-positive (PV+) GABAergic interneurons, which play an essential role in hippocampal network activity, are regulated by the transcriptional coactivator PGC-1α. Genetic deletion of PGC-1α in mice results in decreased expression of PV in interneurons, as is seen in schizophrenia. Previous data from our lab has shown that the inhibitory/excitatory (I/E) ratio is increased in PGC-1α-/- mice at the Schaffer collateral - CA1 pathway, caused by enhanced inhibition. This causes a reduction in the spread of activation in hippocampal CA1 as measured with voltage-sensitive dye imaging. PGC-1α-/- mice also have impaired nesting behavior, indicating hippocampal circuit dysfunction. Dopamine (DA) has been shown to modulate GABAergic inhibitory synaptic transmission in hippocampus. Previously we found that haloperidol, a DA receptor antagonist with selectivity for D2-like receptors, has different effects on synaptic transmission and circuit function in PGC-1α-/- mice, suggesting that there are alterations in DA system regulation of the I/E ratio. It is not yet known how alterations in the DA system in PGC-1α-/- mice affect hippocampal circuit function. Here we use PGC-1α-/- mice to investigate the interaction between dysfunction of the dopaminergic and GABAergic systems caused by interneuron transcriptional dysregulation. We find that DA has a disinhibitory effect on synaptic responses in WT and PGC-1α-/- slices, although there was no significant difference in the magnitude. There was also no difference in the effects of a D2 receptor antagonist; instead we saw differences in the effects of D4 antagonists, which increased the field potential in PGC-1α-/- mice due to disinhibition. These data suggest that there is a tonic effect of D4 activation to enhance feedforward inhibition in PGC-1α-/- slices, which may contribute to the enhanced I/E ratio in these mice. DA D4 receptors are located on PV+ GABAergic interneurons in hippocampus, and have been shown to be important for regulating gamma oscillations. Consistent with this, we find enhanced power of kainate-induced gamma oscillations in hippocampal slices from PGC-1α-/- mice. These results suggest that alterations in the DA system's modulation of inhibition, through changes in D4 receptor effects, are involved in the circuit dysfunction caused by deletion of PGC-1α. These results may lead to a greater understanding of circuit dysfunction in disorders of I/E imbalance and provide information for the development of alternate pharmacotherapeutic approaches.

Title: Differential effects of anesthetics on network activity versus monosynaptic responses in auditory cortex

Authors: *B. M. KRAUSE[1], H. HENTSCHKE[3], A. RAZ[2], M. I. BANKS[2];
[1]Neurosci. Training Program, [2]Anesthesiol., Univ. of Wisconsin-Madison, Madison, WI;
[3]Anesthesiol., Univ. Hosp. of Tübingen, Tübingen, Germany

Abstract: Introduction: Loss of consciousness under volatile anesthetics is likely mediated via direct actions on the cortico-thalamic network, but how these agents alter activity at the network level is unclear. The volatile anesthetic isoflurane (ISO) is well known to depress Up states: synchronous, propagating network discharges which share key characteristics with the aroused cortical state and occur spontaneously or are evoked by afferent input. We have previously demonstrated that ISO depresses short-latency ('early', presumably monosynaptic) corticocortical (CC) afferent responses to a higher degree than early thalamocortical (TC) responses (Raz et al., Frontiers in Systems Neuroscience 8:191-2014). Here, we hypothesized that this differential early anesthetic susceptibility translates to the susceptibility of evoked Up states. We investigated the magnitude and horizontal propagation of early responses and Up states elicited by CC or TC stimulation. Methods: Acute auditory thalamocortical brain slices were prepared from 4-13 wk mice. Local field potentials (LFPs) and multiunit activity (MUA) were recorded using silicon multielectrodes (16 shanks, 100μm spacing, 1 site/shank) oriented rostro-caudally in layer 5 of auditory cortex. TC and CC afferents were stimulated with bipolar tungsten electrodes. Early responses were quantified from MUA in a time interval of [1 10] ms post-stimulus. Up states were quantified from the same signal in an interval of [1 1000] ms. Results: Afferent stimulation of both pathways reliably evoked UP states; early responses were not discernible in all cases. Early responses to CC afferent stimulation were usually strongest close to the stimulation site, whereas those evoked by TC stimulation were more dispersed along the recording sites and were usually stronger. Up state activity propagated several mm at a rate dependent on stimulus efficacy (range 8 - 42 μm/ms). Although the lags and direction of propagation of Up states often differed for CC and TC stimuli, their amplitudes and shapes were similar. ISO (0.2 -2.4%) reversibly decreased both early responses and Up states, but the latter much more dramatically. Specifically, at 0.2% ISO, Up states evoked by CC stimuli were already depressed by about 80%, whereas those elicited by TC stimuli were depressed by about half. Early responses were depressed by about 30% (CC) and 15% (TC). Conclusions: The observation that early spiking responses were less affected by ISO than Up state activity suggests

that ISO acts preferentially on synapses within the cortical network, or that small modulatory effects of ISO accumulate across multiple synapses in a polysynaptic chain, or both.

Title: Discovery of novel compounds that restore synaptic communication in synapses intoxicated with botulinum neurotoxin

Authors: *P. H. BESKE, K. M. HOFFMAN, A. B. BRADFORD, P. M. MCNUTT;
US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD

Abstract: Botulinum neurotoxins (BoNTs) are highly lethal bacterial toxins produced by *Clostridium botulinum, C. butyricum*, and *C. barati*. Following internalization into presynaptic termini, BoNTs act with exquisite selectivity to cleave SNARE proteins associated with synaptic vesicle release, thereby preventing the exocytosis of neurotransmitters. The combination of efficient neuronal targeting and presynaptic activity renders BoNTs the most potent substances known. BoNTs are epidemiologically associated with food-borne botulism, but the ease of production, extreme potency, and prolonged intracellular persistence of BoNTs also render the toxin a Tier-1 Biothreat agent. Despite the description of the intracellular target and proteolytic mechanism of BoNTs over 20 years ago, effective therapies to reverse intoxication or restore synaptic function have yet to be identified. To address this gap, we developed a novel synaptic function-based assay termed the “Restoration of Quantal Exocytosis” (ResQuE) assay, which we employed in therapeutic screening studies. Following comprehensive synaptic impairment with BoNT/A, /D, or /E, we applied whole-cell patch-clamp electrophysiology to *in vitro* CNS neuron populations to measure the ability of repurposed drugs to rescue neurotransmission. Using this approach, we have identified a novel category of drugs that restores activity in synapses that are fully paralyzed by BoNT/A. Further testing of effective drugs was also performed in *ex vivo* phrenic nerve-hemidiaphragm preparations. The identification of clinically viable compounds that effectively restore synaptic communication following BoNT/A poisoning represents a

promising therapeutic approach by which BoNT/A-induced paralysis can be reversed.

Title: Development of a moderate thoughput assay to detect novel modulators of synaptic efficacy in neuronal cultures

Authors: *R. NEFF[1], C. LINDWALL-BLOM[2], Å. JÄGERVALL[2], B. BALANA[1], M. KARLSSON[2], P. KARILA[2], T. LOVENBERG[1];

Abstract: In their native environment ion channels involved with fast synaptic neurotransmission are embedded in an intricate protein matrix. This scaffolding, signal transduction, modulatory, and neurotransmitter release machinery plays a critical role in determining the timing and efficacy of the signals that ion channels generate. Traditional high throughput screening approaches, however, primarily rely on heterologous expression systems which lack the ability to replicate synaptic complexity. Here, in a 96 well format, we used Cellaxess Elektra® electric field stimulation to excite cultured mouse cortical neurons loaded with the calcium fluorophore Calcium 5 in an imaging-based microplate reader. By simultaneously stimulating a discrete subset of the neurons in each well we recorded transient, synaptically mediated calcium elevations in neurons privileged from the stimulating field. These responses were mediated by AMPA and NMDA receptors, as evidenced by concentration dependent block by NBQX and MK-801, respectively. Calcium responses in neurons directly stimulated by the electric field, however, persisted in the presence of these compounds. In contrast, the voltage-gated sodium channel blocker tetracaine blocked calcium responses both distant from and within the electric field. In addition we have profiled other modulators of synaptic transmission to further characterize the assay including the NMDAR anagonists Ro 25-6981 and PEAQX, the mGluR5 modulator VU29, and the AMPA modulator LY404187. Together, these data demonstrate a novel, moderate throughput platform for assaying synaptic ion channel activity in a more physiologically relevant context.

Title: Ionic current dynamics through the ultrastructure of dendritic spines

Authors: *D. PATIRNICHE[1], M. BREIT[2], T. WEINKAUF[3], M. STEMMLER[1], S. PHAN[4], E. BUSHONG[4], M. H. ELLISMAN[4], G. QUEISSER[2], A. V. M. HERZ[1];

Abstract: The electrical role of dendritic spines is still a topic of intense debate today, more than a hundred years since these structures were first described. Time-dependent variations in spine morphology are likely related to changes in synaptic efficacy. Precise and direct electrophysiological measurements of morphology modulating current initiated at the post-synaptic density are, due to the small size of the dendritic spines, so far unavailable. Optical techniques that relying on signals based on different bio-physical processes than ionic current propagation provide, at best, just a coarse estimate. Using the smallness of the spine to our advantage, we simulate electro-chemical signal transduction on 2D idealized spine-geometries within the full non-linear Poisson-Nernst-Planck framework. The inner volume of spines is densely tiled by highly branched filamentous actin, which, with its electrostatic charges, causes ions to condensate in its vicinity. Within the condensation-profile (known as the electrical double-layer) cations, the main charge carriers for depolarizing phenomena, will propagate with great ease due to the high local concentration. Thus, a significant fraction of the current within the volume of the spines is constrained to flow in nano-slits along charged structures. Consistent biophysical boundary conditions as well as accurate ion-channel kinetics are enforced to guarantee physiological input-output relationships of our model. Micro-second time-step dynamics allows us to investigate how the ultrastructual features of the geometry shape the electrical properties of the dendritic spines. We present preliminary 3D simulations of ionic

current propagation in topologically-consistent segmentations of the filamentous actin network extracted from electron microscopy tomograms of cerebellar dendritic spines.

Title: Beta-neurexin proteins at the synapse: Functional link with the endocannabinoid signaling system

Authors: *G. R. ANDERSON[1], J. AOTO[1], K. TABUCHI[2], C. FÖLDY[1], J. COVY[1], A. YEE[1], D. WU[1], S.-J. LEE[1], L. CHEN[1], R. C. MALENKA[1], T. C. SÜDHOF[1];
[1]Stanford Univ., Stanford, CA; [2]Shinshu Univ., Matsumoto, Japan

Abstract: Alpha- and beta-neurexins are presynaptic cell-adhesion molecules that have been implicated in the development of autism and schizophrenia neuropsychiatric disorders. Each of the three neurexin genes expressed in mammals contains two distinct promoters. The first promoter sits 5' upstream and initiates transcription of the full length neurexin known as alpha-neurexin. The second promoter is positioned internally within the neurexin gene and serves to initiate transcription of the short, truncated neurexin known as beta-neurexin. While the elimination of alpha-neurexins in neurons has previously been shown to have an essential role in maintaining release probability at both inhibitory and excitatory synapses, the role of beta-neurexins in neurons however is unknown. Here, we find that beta-neurexins are expressed at 10 to 100-fold lower levels than their alpha-neurexin counterparts. Yet despite being only a minor form of the neurexin molecule pool, we find that conditional knockout of beta-neurexins with continued expression of alpha-neurexins dramatically decreases the release probability at a subset of excitatory synapses in the hippocampus. Mechanistically, we find evidence for altered endocannabinoid signaling being present at these synapses upon loss of beta-neurexins. Moreover, deletion of beta-neurexins in CA1 hippocampal neurons impaired contextual fear

memory, suggesting that beta-neurexin-dependent endocannabinoid signaling is behaviorally significant. Thus, our data show that beta-neurexins control synaptic strength in a subset of excitatory synapses, revealing an unexpected role for beta-neurexins in the endocannabinoid-dependent regulation of neural circuits.

Title: Possible involvement of Dopamine D1-D2 receptor heteromers in enhancement of excitatory synaptic transmission by SKF38393 in CA1 of the hippocampus

Authors: N. RIZVI, *A. C. ARAI;
Dept of Pharmacol., Southern Illinois Univ. Sch. Med., Springfield, IL

Abstract: Formation of heteromers has been reported among G-protein coupled receptors (GPCRs) as well as between GPCRs and ionotropic receptors. In many such cases, cooperativity of agonists exerts a rather complex functional regulation of each receptor and it may also change the coupling of the underlying biochemical cascade. Heteromers of D1- and D2-like dopamine receptors have been identified in the striatum and shown to play a significant role in regulating striatal function. In the present study, we show that SKF38393 (SKF), a D1/D5 dopamine receptor agonist, induces a lasting enhancement of excitatory postsynaptic potentials (EPSPs) in area CA1 of the hippocampus, possibly through activation of dopamine D1-D2 heteromers. SKF (20 μM) increased EPSP amplitude without significantly altering paired-pulse facilitation or waveform, and the enhancement persisted after termination of the drug. The effect of SKF was blocked by administration of an antagonist of D1/D5 receptors (SCH 23390) as well as by a selective antagonist of D2 receptors (sulpiride), but with the interesting difference that the former reversed only a late phase of the enhancement while the latter produced significant inhibition at all time points. These results suggest that combined activation of both D1/D5 and D2 receptors is required for the subsequent enhancement of synaptic transmission. Moreover, the synaptic enhancement appears to involve a non-conventional biochemical cascade in that it was not dependent on activation of adenylate cyclase or protein kinase A, but was abolished by an inhibitor of phospholipase C. Most importantly, the SKF-induced synaptic enhancement was greatly attenuated by application of a peptide which mimics the putative site of interaction between D1 and D2 receptors and according to published studies disrupts dopamine receptor

heteromers. These findings suggest that dopamine receptor heteromerization has a profound influence on synaptic function in hippocampal area CA1.

Title: Role of OculoCerebroRenal Lowe syndrome protein (OCRL) in synaptic function

Authors: ***N. E. MOHAMMED**, M. FERNÁNDEZ-MONREAL;
Inst. De Investigación Hosp. Universitario, Majadahonda,Madrid., Spain

Abstract: The enzyme OCRL is one of the main Inositol-5-phosphatases that regulate the levels of cellular Phosphatidylinositol-(4,5)-biphosphate. Mutations in OCRL gene cause Lowe Syndrome, an X-linked rare disease characterised by eye alterations, renal dysfunction and mental disease.Research in cell lines and fibroblasts from Lowe syndrome patients have shown that OCRL is mainly localized in Golgi, and have evidenced its participation in protein trafficking between plasma membrane and intracellular compartments. However, its function in the Central Nervous System is mostly unknown. We aim to characterized OCRL distribution and function in brain using molecular biology, biochemistry and fluorescent microscopy. We have found that OCRL expression increases during development in the hippocampus in parallel with synaptic proteins, which suggest a role in synaptic function regulation. In addition, we have localized OCRL protein in synapses of hippocampal neurons *in vitro*. On the other hand, we have investigated the cellular defects in neurons depleted on OCRL by using lentivirus driving the expression of shRNA for OCRL. We have found that young neurons deficient in OCRL presented alterations on actin cytoskeleton. Interestingly, OCRL depletion did not affect synaptic density in cultured hippocampal neurons. Furthermore, electrophysiological recordings on organotypic slices infected with the shRNA lentivirus showed that basal transmission was not affected by OCRL depletion. Finally, we have found that OCRL was involved in several forms of synaptic plasticity. These results are in agreement with the role of phosphoinositide metabolism in synaptic function, and could explain some of the neuropathological features of Lowe syndrome.

Title: Dopamine release in the prefrontal cortex: implications for the stimulant emission tomography paradigm

Authors: *D. HERNAUS[1], M. MEHTA[2];
[1]Dept of Psychiatry and Neuropsychology, Maastricht Univ., Maastricht, Netherlands; [2]Ctr. for Neuroimaging Sciences, Inst. of Psychiatry, King's Col. London, C, London, United Kingdom

Abstract: Background: PET has been essential in revealing the functional properties of the dopamine (DA) system *in vivo* in humans. These PET paradigms typically utilize either an experimental task[1] or stimulants[2] (e.g. amphetamine challenge) to probe DA release. Although the striatum has often been the focus of attention, PET studies have recently started to investigate DA function in the PFC. However, one important observation is that stimulants make use of an indirect, primarily non-synaptic, route to increase extracellular PFC DA levels[3]. This contrasts with psychological tasks, which rely on an endogenous synaptic mechanism throughout the brain[1; 4]. A pertinent question therefore is: are task- and stimulant-induced PFC DA release captured equally well with PET? Given its more direct mechanism of action, we predicted that task-induced PFC DA release would be more uniformly captured with PET than stimulant-induced PFC DA release. Methods: We first review the mechanisms of task-induced (i.e. endogenous) and stimulant-induced PFC DA release. This is followed by a systematic review and meta-analysis of all PET studies investigating PFC DA function using tasks and stimulants. The aim was to investigate how reliably task- and stimulant-induced PFC DA release is detected with emission tomography. Results: Stimulant-induced PFC DA release was only detected with high-affinity radioligands (FLB 457; not fallypride), greater sample size (n>20) and/or PFC regions that showed the highest DA innervation (anterior cingulate). Task-induced PFC DA release was consistently detected across radioligands (FLB 457 & fallypride), sample sizes and PFC regions. The normalized BPND values were considerably higher for tasks (mean=1.23; SD=.31) than stimulants (mean=.59; SD=.36) (p=.005). Conclude: Although the magnitude of stimulant-induced PFC DA release measured with microdialysis is greater than task-induced PFC DA release (>200% vs. ≈20%), this is not reflected in the PET literature. Task-induced PFC DA release measured with PET is similar to/greater than stimulant-induced PFC

DA release. We suggest that this discrepancy may stem from the fact that stimulants increase PFC DA release outside the vicinity of the D2/3-bound ligand, leading to an underestimation of stimulant-induced PFC DA release measured with PET. In contrast, task-related DA release occurs via a direct route that is more uniformly captured with PET. These results indicate that task and stimulant-induced PFC DA release should be regarded as separate phenomena; detection of one does not guarantee the other.

Title: Quantifying the number of presynaptic voltage-gated calcium channels that are activated at different times during the action potential

Authors: M. SCARNATI, S. CLARKE, *K. G. PARADISO;
Cell Biol. and Neurosci., Rutgers Univ., Piscataway, NJ

Abstract: Small changes in calcium current in a presynaptic terminal will affect synaptic transmission. We examined the number of voltage-gated calcium channels that are opened at different times during the action potential (AP) to better understand how the recruitment of calcium channels during the AP affects calcium entry and subsequent synaptic transmission. During an AP, the number of calcium channels that are open and the driving force for calcium entry are continually changing, making it difficult to measure the number of open calcium channels at different times. To address this, we designed an approach using voltage jumps at different times during an AP waveform to determine the number of calcium channels activated at each time point. Although calcium channels begin to activate during the depolarization of the AP, the majority of calcium entry occurs during the repolarization. This reflects both the time required for the channels to reach an open state, and the changing driving force for calcium entry. During the repolarization, calcium channels continue to open, and the driving force for calcium entry steadily increases which results in the majority of calcium entering during the AP repolarization. Therefore, the duration and shape of the repolarization phase of the presynaptic AP strongly affect calcium entry and therefore synaptic transmission. To determine the amount of calcium channel activation at different times during the AP, we did patch-clamp recordings in calyx of Held nerve terminals and blocked voltage-gated sodium and potassium channels to isolate the presynaptic calcium channel response. Using an AP-like stimulation, we used voltage

jumps to negative potentials during the repolarization phase to determine the relative number of calcium channels that are open at each time point tested. For an AP-like stimulation, we find ~25% of the voltage-gated calcium channels that will open during the AP are open at the peak of the AP. The number of open calcium channels steadily increase during the repolarization phase until the AP reaches approximately 0 mV. When the AP stimulation reaches ~ -10 mV, the number of open channels steadily decreases, and when the stimulus ends at -80 mV, ~20 to 25% of the calcium channels are still open. We also find that 90% of the presynaptic voltage gated channels that are opened by an AP-like stimulus are open when the stimulus is between +20 and -28 mV. Shorter APs shift the peak activation to a later time in the repolarization, and longer APs shift it earlier in the repolarization phase. We also tested the postsynaptic target neuron of the calyx of Held to test the effects of different calcium channel kinetics calcium channel activation during APs.

Title: MHCI regulates NMDAR-mediated synaptic transmission through cell-autonomous postsynaptic signaling mechanisms

Authors: *K. K. FRIETZE[1], C. M. TYLER[2], L. M. BOULANGER[1,2];
[1]Mol. Biol., [2]Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: Proteins of the major histocompatibility complex class I (MHCI) are known for their role in the adaptive immune response. MHCI proteins are also expressed by healthy neurons, and are critical for normal brain development and plasticity. Hippocampal synaptic transmission mediated by N-methyl-D-aspartate receptors (NMDARs) is enhanced in mutant mice that express reduced levels of cell-surface MHCI. In addition, NMDAR-dependent hippocampal synaptic plasticity is altered in MHCI-deficient mice, and NMDAR- and hippocampus-dependent forms of learning and memory are impaired. MHCI is expressed in the postsynaptic density of hippocampal neurons, where NMDARs are found, but the molecular mediators of MHCI's effects on NMDARs are unknown. MHCI's effects on NMDAR-dependent synaptic transmission and plasticity have been studied using non-conditional β2m-/-TAP-/- knockout mice, which lack the obligatory MHCI light chain β2m and the MHCI peptide transporter TAP1. These double-mutant mice express reduced levels of MHCI on the surface of most cells throughout life, and have severe immune impairments, including a complete lack of CD4-8+ T cells. Thus changes in NMDAR-dependent synaptic transmission and plasticity in these mice

could be an indirect effect of compromised immune function, or reflect a non-immune role for MHCI in other cell types. Here we show that acutely disrupting MHCI function in individual WT neurons is sufficient to mimic the effects of genetic MHCI knockdown on synaptic transmission. To block MHCI function, we infused competitor peptides derived from the cytoplasmic domain of MHCI into individual WT CA1 pyramidal neurons in acute hippocampal slices via the patch pipette. Infusing MHCI competitor peptides significantly disinhibited NMDAR- but not AMPAR- mediated EPSCs, mimicking the phenotype of β2m-/-TAP-/- mice. Infused peptides likely compete with endogenous MHCI for intracellular binding partners, because they do not affect synaptic transmission in neurons that lack endogenous MHCI. These studies suggest that MHCI cell-autonomously regulates postsynaptic NMDAR function, and identify an unexpected signaling role for the cytoplasmic domain of MHCI at neuronal synapses.

Title: TLR3 activation inhibits synaptic activity in primary hippocampal cultures via multiple mechanisms

Authors: L. RITCHIE[1], *T. J. BUSHELL[2];
[1]Strathclyde Inst. of Pharm. & Biomed. Sci., [2]Univ. of Strathclyde, Glasgow, United Kingdom

Abstract: Toll like receptors (TLRs) belong to a family of pattern recognition receptors that recognise broadly shared molecules found on pathogens referred to as pathogen associated molecular patterns (PAMPs). TLRs are well known for their involvement in innate immunity however despite their presence in the CNS, our knowledge of their function in the CNS is limited. Therefore in the present study, we investigated the cellular localisation of TLR3 and the consequence of its activation on synaptic activity. Primary hippocampal cultures were prepared using P1-2 rats and used experimentally between 10-14 DIV. Standard whole cell patch clamp electrophysiology recordings in voltage and current clamp were used to monitor ion channel function and synaptic activity, respectively. In agreement with previous studies, immunocytochemical experiments revealed TLR3 expression in neurons, astrocytes and oligodendrocytes within our primary hippocampal cultures. Synaptically driven spontaneous action potential (AP) firing was significantly reduced by the acute application (5min) of the TLR3 specific activator, poly I:C (25μg/ml and 200μg/ml). Furthermore chronic poly I:C application (1 hr) resulted in a dramatic reduction in AP firing (1μg/ml and 25μg/ml) in comparison to controls. In agreement with this, poly A:U, another TLR3 activator, resulted in a

significant reduction in AP firing when applied chronically (25µg/ml) whereas the TLR4 activator, LPS, was without effect. Investigations were carried out to determine the mechanisms underlying these effects. Acute application of poly I:C (200µg/ml) significantly reduced the frequency and amplitude of miniature excitatory postsynaptic currents (mEPSCs) however no effect on sodium and potassium channel function was observed. In contrast, chronic application of poly I:C (25µg/ml) resulted in a significant reduction in mEPSC amplitude and peak sodium current. Furthermore chronic application of poly I:C (25µg/ml) resulted in a significant reduction of surface AMPAR expression in comparison to controls when investigated using immunostaining. These data imply that TLR3 activation modulates hippocampal synaptic activity. Further investigations regarding the mechanisms and signalling pathways underlying these effects are on-going and will give further insight into the role TLR3 plays in modulating synaptic activity and how this contributes to virally-mediated behavioural changes.

Title: Optogenetic stimulation reveals distinct modulatory properties of thalamostriatal vs corticostriatal glutamatergic inputs to striatal fast-spiking interneurons

Authors: *G. SCIAMANNA[1,2], G. MANDOLESI[2], G. PONTERIO[2], P. BONSI[2], A. PISANI[1]; [1]Dept. Systems Med., Univ. of Rome TorVergata, Roma, Italy; [2]Lab. Neurophysiol. and Plasticity, Fondazione Santa Lucia, Rome, Italy

Abstract: Parvalbumin-containing fast-spiking interneurons (FSIs) exert a powerful GABAergic inhibition on striatal medium spiny neurons (MSNs), playing a critical role in timing striatal output. However, how glutamatergic inputs modulate their firing activity is still unexplored. In the present study by means of combined optogenetic and electrophysiological approach, we provide evidence for a differential modulation of cortico- vs thalamo-striatal synaptic inputs to FSIs in transgenic mice carrying light-gated ion channels channelrhodopsin-2 (ChR2) in glutamatergic fibers. Corticostriatal synapses show a postsynaptic facilitation, whereas thalamostriatal synapses present a postsynaptic depression. Moreover, thalamostriatal synapses exhibit more prominent AMPA-mediated currents than corticostriatal synapses. Furthermore, during current-evoked firing activity, simultaneous corticostriatal stimulation increases bursting activity. Conversely, thalamostriatal fiber activation shifts the canonical burst-pause activity to a

more prolonged, regular firing pattern. Finally by means of viral-injected animals carrying ChR2 in GABAergic fibers we characterized the inibitory input onto FSIs. Our findings demonstrate that cortical and thalamic glutamatergic input differently modulate FSIs firing activity through specific synaptic properties and represents an important step towards dissecting basal ganglia activity in both physiological and pathological conditions.

Title: Investigating the role of the Gαs pathway in neurotransmission

Authors: *L. MANNING, A. MARTIN, O. BHETUWAL, J. RICHMOND;
Biol. Sci., Unviersity of Illinois At Chicago, Chicago, IL

Abstract: The $G\alpha_s$ pathway has been studied as an important G-protein-coupled receptor-mediated modulator of neurotransmission. Specifically, cAMP and one of its primary targets, PKA, are implicated as molecular substrates for learning and memory in a variety of organisms. Previous work in *C. elegans* suggests that the $G\alpha_s$ pathway converges on the core $G\alpha_q$ pathway that is required for UNC-13-dependent priming of synaptic vesicles. However, the molecular mechanisms that underlie $G\alpha_s$ pathway regulation of synaptic function are not well understood. In *C. elegans*, the $G\alpha_s$ pathway is completely dependent on adenylyl cyclase (ACY-1) to increase intracellular levels of cAMP that can bind to the regulatory PKA subunit, KIN-2, releasing, and consequently activating, the catalytic subunit of PKA, KIN-1. A leading hypothesis is that cAMP-dependent PKA activity modulates neurotransmitter release by enhancing the readily releasable pool (RRP) of vesicles. To test this hypothesis, we are conducting an in-depth characterization of $G\alpha_s$ pathway mutants in *C. elegans*. Loss-of-function mutations in *acy-1* are predicted to reduce synaptic transmission, resulting in severe uncoordinated locomotory phenotypes. Conversely, gain-of-function mutations in this gene, which are expected to enhance transmission and confer hyperactivity in worm locomotion. Similarly, Loss-of-function mutations in *kin-2*, which result in constitutively active PKA, mimic the enhanced locomotion seen in *acy-1(g.o.f.)* animals. We first examined mutant sensitivities to the acetylcholinesterase inhibitor, Dylox, as a readout of synaptic function. We found *kin-2* and *acy-1(g.o.f.)* mutants to be Dylox-hypersensitive, where as *acy-1* mutants showed wild-type responses to the drug. Evidence from electrophysiological recordings at the neuromuscular junction (NMJ) of mutant worms suggests that mutations hyperactivating $G\alpha_s$ mildly enhance evoked release, and opposite

phenotypes are observed in *acy-1(l.o.f)* mutants. Ongoing experiments examining synaptic depression and release under low calcium conditions will test whether ACY-1 and PKA influence the RRP as predicted. Fluorescence and electron microscopic imaging provide additional insight into synaptic vesicle regulation by these proteins. Imaging both vesicular and non-vesicular synaptic makers suggests altered vesicle localization in $G\alpha_s$ mutants. Preliminary data from ultrastructural analysis suggests that there may be a change in docking of synaptic vesicles and the number of dense core vesicles (DCV) at *acy-1(lf)* and *kin-2* synapses, suggesting that the $G\alpha_s$ pathway also regulates a neuropeptide release pathway.

Title: Alpha3 glycine receptors in glycinergic transmission to hypoglossal motoneurons

Authors: *S. HÜLSMANN[1], Y. KONO[2];
[1]Georg August Univ. Goettingen, Goettingen, Germany; [2]The Jikei Univ. Sch. of Med., Tokyo, Japan

Abstract: Glycinergic neurons provide an important mechanism to control excitation of hypoglossal motoneurons. Impairment of glycinergic inhibition can be deleterious such as in hyperekplexia or amyotrophic lateral sclerosis. Second messenger systems that change cyclic AMP and lead to phosphorylation of the alpha3 subunit (Glra3) of the glycine receptor have been shown to be potent modulators of synaptic inhibition. In this study we analyzed the role of Glra3 on glycinergic miniature synaptic inhibitory currents (mIPSCs) in the hypoglossal nucleus. We observed that glycinergic mIPSCs are normal in Glra3 -/- mice. However we found a slight increase of the glycinergic mIPSC amplitude in older Glra3 -/- mice. Modulation of synaptic transmission by cAMP-mediated pathways was diminished in Glra3 -/- mice. Forskolin (10 μM) induced an increase of mIPSC frequency in both Glra3 +/+ and Glra3 -/- mice. However, in the second postnatal week the forskolin-induced increase of mIPSC frequency was significantly larger in Glra3 +/+ as compared to Glra3 -/- mice indicating that glycine release in the hypoglossal nucleus can be modulated via presynaptic α3 containing glycine receptors.

Title: Sigma-1 receptor stimulation improves depressive-like behaviors and adult hippocampal neurogenesis in CaMKIV null mice

Authors: *S. MORIGUCHI[1], H. SAKAGAMI[2], K. FUKUNAGA[1];
[1]Tohoku Univ. Grad Sch. Pharm Scis, Sendai, Japan; [2]Kitasato Univ. Sch. Med., Sagamihara, Japan

Abstract: Sigma-1 receptor (Sig-1R) is molecular chaperone regulating calcium efflux from endoplasmic reticulum to mitochondria in neurons (Shioda et al, 2012). We previously documented that impaired cognition and depressive-like behaviors in olfactory bulbectomized mice are improved by chronic oral administration of dehydroepiandrosterone (DHEA) (Moriguchi et al., 2011; PLoS One 2013). It is reported that calcium/calmodulin-dependent protein kinase IV (CaMKIV) is involved in adult hippocampal neurogenesis, in which fluoxetine induces CaMKIV-dependent CREB phosphorylation in the hippocampal dentate gyrus (Song et al., 2013). In fact, CaMKIV null mice showed the depressive-like behaviors and reduced neurogenesis assessed by bromodeoxyuridine (BrdU)/NeuN incorporation in the dentate gyrus. In the present study, we demonstrated that chronic stimulation of Sig-1R by treatment with SA4503 or fluvoxamine for 14 days improve depressive-like behaviors observed in CaMKIV null mice. By contrast, paroxetine without affinity for Sig-1R failed to improve the depressive-like behaviors. Reduction of BrdU/NeuN-positive cells or Akt (Ser-473) phosphorylation in the hippocampal dentate gyrus in CaMKIV null mice was significantly restored by chronic administration of Sig-1R agonists. Taken together, Sig-1R stimulation ameliorates depressive-like behaviors in CaMKIV null mice by increased adult hippocampal neurogenesis through activation of Akt.

Title: Acute and chronic effects of inhibiting mTOR by rapamycin on development, behvaior, and physiology in *Drosophila*

Authors: *S. J. POTTER[1,2], R. S. POTTER[2], S. L. E. BLÜMICH[3], R. L. COOPER[2]; [2]Biol., [1]Univ. of Kentucky, Lexington, KY; [3]Vet. Sci., Univ. of Leipzig, Leipzig, Germany

Abstract: Rapamycin is a compound that can specifically block mTOR signaling and is therefore used in experimental biology. It is being utilized clinically as an immunomodulator after transplantation procedures and treatment for some forms of cancer. Due to its many possible effects on different molecular pathways, it could have any number of impacts on synaptic transmission. This issue has not, however, been addressed in a developing system. We hope to address it by feeding second and third instar *Drosophila* larvae varying concentrations of rapamycin and monitoring larval stages, pupation, and survival. Typical larval behavioral assays being examined are mouth hook movement while eating and body wall movement while crawling on apple juice agar plates. Behaviors in the adults fed rapamycin include climbing, righting response, and movement assays. The results to date suggest 2nd instar larvae are more susceptible to rapamycin as compared to 3rd instar, based on a higher death rate. Adults fed rapamycin climb less over time and tend to fall off the wall when climbing. Dose-response studies are being established. This study is significant as we are starting to address the acute and long-term action of inhibiting the mTOR pathway on neuronal function and potential mechanisms to account for altered physiological function.

Title: Functional and morphological analysis of Neuronal Ca^{2+}-binding protein 2 (NECAB2)

Authors: *A. METHNER[1], T. SCHACHT[2], K. FRAUENKNECHT[3], V. WUELLNER[2], S. RITZ[4], L. MAJEWSKI[5], L. GREMER[6], J. KUZNICKI[5];
[1]Johannes Gutenberg Univ. Mainz, Mainz, Germany; [2]Neurol., [3]Neuropathology, Univ. Med., Mainz, Germany; [4]IMB, Mainz, Germany; [5]The Intl. Inst. of Mol. and Cell Biol., Warsaw, Poland; [6]Inst. für physikalische Biologie, Heinrich Heine Univ., Duesseldorf, Germany

Abstract: NECAB2 is a **Ne**uronal **Ca**$^{2+}$-**b**inding protein characterized by the combination of EF-hand Ca^{2+}-binding domains, two coiled-coil domains (CC) and a monooxygenase (ABM) domain. It is expressed exclusively in the brain with strongest expression in the striatum where it co-localizes and interacts with metabotropic glutamate and adenosine receptors increasing their basal constitutive signaling. High concentrations of Ca^{2+} drastically reduce the ability of these proteins to interact with NECAB2. Prokaryotic homologs of NECAB2 possess monooxygenase activity and are involved in the detoxification of reactive oxygen species, suggesting a similar function in eukaryotes distinct from the interaction with membrane receptors. A structural analysis of prokaryotic NECAB2 homologs also suggests that the active enzyme is a homodimer. NECAB2 is indeed highly expressed in the striatum, the habenulae, and, with a predominant neuropil pattern, in the hippocampus. It is highly enriched in synaptic microsomes and colocalizes with presynaptic and postsynaptic marker proteins. Recombinant NECAB2 binds Ca^{2+} and dimerizes and oligomerizes similar to its prokaryotic orthologues. Ca2+ binding increases dimerization of mammalian NECAB2. We generated mutants of NECAB2 which lack distinguishable domains (CC1, CC2 or ABM) or have a non-functional EF hand (by mutating Glu residues to Ala) to further address the different functions of NECAB2. We found that the CC1 domain is responsible for the interaction with the metabotropic glutamate receptor 5 and homodimerization. A thorough analysis of the phenotype of NECAB2-deficient mice, which are viable, is currently underway and might be ready by the time of the annual meeting. Our data suggests that the increase in the cytosolic Ca^{2+} concentration causes homodimerization of NECAB2 in the cytosol, resulting in subsequent receptor desensitization in a negative feedback loop. The dimerization probably activates its monooxygenase activity, which probably serves to process reactive oxygen species and protons generated in active, stimulated neurons

Title: Connexin 36 in hippocampus of rats submitted to neonatal anoxia

Authors: *S. H. TAKADA[1], J. M. IKEBARA[1], D. S. CARDOSO[1], E. SOUSA[1], G. S. V. HIGA[2], A. H. KIHARA[1];
[1]Univ. Federal Do ABC, Sao Bernardo Do Campo, Brazil; [2]Inst. de Ciências Biomédicas, Univ. de São Paulo, São Paulo, Brazil

Abstract: Neonatal anoxia is the main cause of death in the perinatal period, especially in premature infants. When surviving the anoxic insult, most of these individuals have motor deficits, behavioral, sensory and /or cognitive impairments that persist throughout life and, for these reasons, neonatal anoxia is considered a major public health concern. Although extensively studied in different models of neonatal oxygen deprivation, the mechanisms of hippocampal neuronal death resulting from oxygen deprivation remains to be elucidated, particularly the injury that occurs secondary to the initial hippocampal cell death. Hypotheses about the involvement of connexin (Cxs) channels in the gap junctions (GJ) in the spreading of death caused by hypoxia-ischemia have been proposed, but in other models of deprivation of blood or oxygen. The aim of this study was to identify possible changes in the expression of Cx 36 caused by anoxic insult in neonatal rat. Eight litters of Wistar rats (Rattus norvegicus) were used for anoxia and sham groups. Anoxia was performed in P1/P2 neonates according to described system of neonatal anoxia composed by 25 minutes of 100% nitrogen gas exposure at 37°C (Takada et al., 2011). 24 hours after neonatal anoxia, the PCR analysis showed a decreased genic expression of Cx36 in anoxia treated animals ($p<0.05$). In the western blotting analysis, the protein levels of Cx36 was decreased too ($p=0.0096$). Interestingly, the density of immunolabelled hippocampal cells for Cx36 did not present differences in all hippocampal subfields. These results allow further investigation of Cx36 involvement in hippocampal cell death caused by anoxic insult and provide support for therapeutic approaches related to gap junctions functioning.

Title: Synchronizing cortical dynamics via gap junctions between excitatory neurons

Authors: *J. KILE[1], G. KOVACIC[2], D. CAI[3];
[2]Mathematical Sci., [1]Rensselaer Polytechnic Inst., Troy, NY; [3]Courant Inst. of Mathematical Sciences, New York Univ., New York, NY

Abstract: Brain networks are known to give rise to global oscillations that are linked to synchronized neuronal activity, which has been shown to contribute to cognitive processes such as perception, motor performance, learning and memory. Electric coupling through gap junctions may facilitate the emergence of synchronized oscillations, and influence their properties. Gap junctions between inhibitory neurons in the mammalian cerebral cortex have been well studied, but gap junctions between excitatory, pyramidal neurons have only recently been discovered experimentally. In this study, we closely follow experimental data to construct a detailed, comprehensive model with both synaptic and electric coupling for both excitatory and inhibitory neurons using a modified version of the Hodgkin-Huxley equations. We have successfully replicated data for the interaction between pairs of electrically connected excitatory neurons, and pairs of electrically connected inhibitory neurons, using our mathematical model. Our realistic, computational network model includes 25% inhibitory neurons and 75% pyramidal cells coupled both electrically and synaptically. We use a 5% coupling probability for gap junctions to occur among neighboring pyramidal cells, and a 50% coupling probability for gap junctions between interneurons less than 80μm apart, mimicking the medial prefrontal cortex, and visual cortex, of rats and ferrets. We describe a uniform, external input to this small patch of the cortex, modeling the influences of neurons from other parts of the brain, in the form of a Poisson spike train. The neurons are placed on a grid to capture the highly structured spatial properties of a network containing both synaptic and gap-junction connections, and to ensure that the probability of neurons being coupled is dependent on their location within the network. Using this network model, we examine the resulting dynamical regimes from the inclusion of both electric and synaptic connections, with a specific interest in the emergence and properties of synchrony. We find that the addition of gap junctions increases the synchrony in the model network.

Title: Sensitivity of presynaptic pH on synaptic transmission: Differences in evoked and spontaneous release

Authors: *W. P. PIEDADE[1,2], F. KOCH[3], Z. MAJEED[4], E. BRAILOIU[5], S. L. E. BLÜMICH[6], R. PUTMAN[7], R. L. COOPER[2];
[1]UNESP, Bauru, Brazil; [2]Univ. of Kentucky, Lexington, KY; [3]Univ. Leipzig, Leipzig, Germany; [4]Univ. of Salahaddin, Erbil, Iraq; [5]Temple Univ., Philadelphia, PA; [6]Univ. of Leipzig,, Leipzig, Germany; [7]Wright State Univ., Dayton, OH

Abstract: The presynaptic terminals package transmitter into vesicles based on a proton gradient. We address issues related to altering this gradient in influencing synaptic responses. We are addressing two issues: (1) the influence of pH_i on vesicular packaging of neurotransmitter; (2) response of glutamate receptors on postsynaptic targets with altering extracellular and intracellular pH. These investigations are being addressed at the model crayfish and *Drosophila* neuromuscular junctions (NMJs). These two projects are interrelated as transmission at glutamatergic synapses is retarded in the presence of CO_2 which cannot be fully accounted for by a reduced pH_i within the presynaptic nerve terminal or within the postsynaptic muscle fiber since the EPSPs increase in amplitude with rebound acidification after a pulse of NH4Cl. High (40 mM) proprionic acid acidifies both the pre- and post-synaptic cells. When used the frequency and amplitude of mini's increases despite a slight membrane depolarization. However, evoked transmission is blocked. Examining low pH on mammalian glutamatergic neurons with Fura 2 (Ca2+ indicator) in culture indicated Ca2+ release from ER as a potential mechanism to explain some of the observations for the increase in frequency of minis. The use of high [CO_2] containing saline blocks evoked and mini's as well as the sensitivity of glutamate receptors. These NMJs are glutamatergic and the evoked (non-spiking) synaptic potentials and spontaneous (quantal) events are readily measured. Addressing the mechanisms underlying these observed phenomena may help in understanding synaptic depression after high frequency stimulation and feedback process in synaptic transmission. These studies tackle fundamental principles which are likely present in glutamatergic neurons for all animals.

Abstract: It is well known that cross-talk between receptors represent an important mechanism of neuromodulation and plasticity. Although, these interactions have been mostly localized post-synaptically, receptors cross-talk which involves common intracellular pathways have been reported to occur also at the presynaptic level (for a recent review see Marchi et al 2015). Neuronal nicotinic acetylcholine receptors (nAChRs) in the CNS are located mostly presynaptically and have been implicated in facilitating release of neurotransmitter. It has been shown that dopaminergic and noradrenergic axon terminals in the nucleus accumbens and hippocampus possess nAChRs mediating enhancement of dopamine (DA) and noradrenaline (NA) release respectively. We investigated whether nAChRs and N-methyl-D-aspartic acid (NMDA) receptors interact on the same nerve endings using rat synaptosomes pre-labelled with [3H]DA or [3H]NA. The *in vitro* short-term pre-exposure of synaptosomes (10 min) to different concentrations of acetylcholine (from 0.01μM to 10 μM) caused a significant reduction (maximal effect: -54.0 % at 10 μM) of the 100 μM NMDA-evoked [3H]DA overflow in the rat nucleus accumbens . This inhibitory effect was abolished when synaptosomes were pretreated with acetylcholine plus atropine (0.1 μM) and completely counteracted when nerve endings were pretreated in the presence of the selective antagonist DHβE indicating that the changes of the NMDA-dependent [3H]DA release reported was dependent to the activation of a β2* nAChR subtype. Similarly, the pre-exposure of synaptosomes to nicotine (from 0.01μM to 30 μM) caused a significant reduction of the 100 μM NMDA-evoked [3H]NA overflow in the rat hippocampus. Nicotine pre-incubation failed to modify the 10 μM 4-aminopyridine-induced [3H]NA overflow suggesting that the changes in the exocytotic machinery of release does not account for the nicotine-induced modifications of the NMDAR function. The pre-exposure of synaptosomes to nicotine or acetylcholine also caused a marked reduction of the nicotine-induced [3H]DA or [3H]NA overflow (-85.0% and -91.2 % respectively) suggesting that these nAChRs could undergo an agonist-induced receptor desensitization. To conclude our results show that the NMDA receptor function can be dynamically and negatively regulated in neurons in response to a brief incubation with different nicotinic agonists. Title: Maternal deprivation induces hyperexcitablity and synaptic abnormalities of lateral habenula glutamatergic neurons

Authors: *M. E. AUTHEMENT, F. NUGENT;
Pharmacol., Uniformed Services Univ., Bethesda, MD

Abstract: Adverse early life experiences increase the risk of cognitive impairment and later life mental health disorders such as depression, schizophrenia and substance abuse. Maternal deprivation (MD) is one particularly potent early life stressor that impairs brain dopamine (DA) and serotonin (SER) systems, both of which are implicated in the aforementioned disorders. The lateral habenula (LHb) exerts strong inhibitory influence over the brain monoaminergic systems, namely DA and SER systems. Here we investigated whether a single 24 hour episode of MD promotes dysfunction of DA and SER systems through changes in the activity of the LHb. Using a combination of whole-cell and cell-attached electrophysiology in rat brain slices, we show that MD induces a robust hyperexcitability of glutamatergic LHb neurons. We also examine the contribution of both excitatory and inhibitory synaptic transmission onto glutamatergic LHb neurons to determine whether MD-induced hyperexcitability is due to an imbalance of excitation and inhibition. Overall, MD-induced hyperexcitablity of LHb neurons and synaptic abnormalities may be the mechanistic link between early-life stress and an increased later-life propensity for mental health disorders involving dysfunction of brain DA and SER systems.

Title: Connexin36 expression in major centers of the auditory system in mouse and rat: evidence for neurons forming purely electrical synapses and morphologically mixed synapses

Authors: *M. E. RUBIO[1], J. I. NAGY[2];
[1]Otolaryngology, Univ. of Pittsburgh Med. Sch., Pittsburgh, PA; [2]Dept. of Physiol. and Pathophysiology, Fac. of Med., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Electrical synapses formed by gap junctions composed of connexin36 (Cx36) are widely distributed in the mammalian central nervous system. Here, we used immunofluorescence methods to document the expression of Cx36 in the cochlear nucleus and along upstream nuclei of the auditory pathway of rat and mouse. Labelling of Cx36 visualized exclusively as Cx36-puncta was densely distributed primarily on the cell body and initial dendrites of neuronal populations in the ventral cochlear nucleus, and was abundant in superficial layers of the dorsal cochlear nucleus. Other auditory centers displaying Cx36-puncta included the medial nucleus of the trapezoid body (MNTB), regions surrounding the lateral superior olivary nucleus, the dorsal nucleus of the medial lemniscus, the nucleus sagulum, all subnuclei of the inferior colliculus, and the auditory cerebral cortex. In EGFP-Cx36 transgenic mice, EGFP reporter was detected in neurons located in each of auditory center that harboured Cx36-puncta. In the ventral cochlear nuclei and the MNTB, many neuronal somata were heavily innervated by nerve terminals containing vesicular glutamate transporter-1 (vglut1) and Cx36 was frequently localized at these terminals. Cochlear ablation caused a near total depletion of vglut1-positive terminals in the ventral cochlear nuclei, with a commensurate loss of labelling for Cx36 around most neuronal cell bodies, but preserved Cx36-puncta at somatic neuronal appositions. The results suggest that electrical synapses formed by Cx36-containing gap junctions occur in most of the widely distributed centers of the auditory system. Further, it appears that morphologically mixed chemical/electrical synapses formed by nerve terminals are abundant in the ventral cochlear nucleus, including those at endbulbs of Held formed by cochlear primary afferent fibers, and those at calyx of Held synapses on MNTB neurons.

Title: Interaction between Aβ and membrane cholesterol underscores presynaptic transmission

Authors: *R. M. LAZARENKO[1], A. KAMALOVA[2], Q. ZHANG[3];
[1]Dept Pharmacol, [2]IGP/VISP, [3]Pharmacol., Vanderbilt Univ., Nashville, TN

Abstract: Synaptic dysfunction is known to precede the clinic symptoms of Alzheimer's disease (AD) and if the neurodegeneration to be prevented - that is the time point of intervention. Ample evidence supports the notion that β-Amyloid peptides (Aβs) are genetically and pathologically associated with AD. Furthermore, Aβs alter the structure and function of neuronal synapses via mechanisms that remain unclear. Recent structural studies revealed that the C-terminal fragment (C99) of Amyloid Precursor Protein (APP) can directly bind to cholesterol via six key amino acid resides, which all reside in Aβ40, the most common form of Aβs. In neonatal as well as mature brain, cholesterol is essential for synaptogenesis and synaptic plasticity. In particular, cholesterol plays an important role in the origination and maintenance of synaptic vesicles. Therefore, we set up to investigate how APP and Aβ interact with synaptic membrane cholesterol and how such interaction affects synaptic transmission. By using TopFluor cholesterol (TFC) as a fluorescent surrogate for cholesterol, we monitored in real time how Aβ or APP affects the distribution of cholesterol in the membranes of cultured hippocampal neurons and consequently regulates evoked or spontaneous synaptic transmission. Our results indicate that the application of Aβ40 or the direct manipulation of synaptic membrane cholesterol causes profound changes to spontaneous release of synaptic vesicles. We find that Aβ40 sequesters and enriches cholesterol on the plasma membrane. The magnitude of the effect depends on the levels of endogenous APP or Aβ40 level and is higher in APP-overexpressing cells. These results collectively suggest that soluble Aβ40 stabilizes cholesterol in the neuronal membranes, which facilitates synaptic transmission. We thus propose that the abnormality in Aβ species or amount along with the unbalanced cholesterol homeostasis impairs presynaptic integrity and leads to synaptic dysfunction or neurodegeneration.

Title: Simulation of synchronization and reverberation of excitation in a network of neurons interconnected through a 16-state gating model of gap junction channels

Authors: *F. BUKAUSKAS[1,2], K. MACIUNAS[2], M. SNIPAS[3,2];
[1]Neurosci., Albert Einstein Col. of Med., Bronx, NY; [2]Inst. of Cardiol., Lithuanian Univ. of Hlth. Sci., Kaunas, Lithuania; [3]Dept. of Mathematical Modelling, Kaunas Univ. of Technol., Kaunas, Lithuania

Abstract: Gap junction (GJ) channels formed of connexin (Cx) proteins provide a direct pathway for electrical cell-cell interaction in neuronal networks. We combined Hodgkin-Huxley equations of membrane excitability with a gating model of GJ channels to simulate the spread of excitation in neuronal networks coupled by gap junctions. The model includes changes of junctional conductance (g_j) induced by transjunctional voltage, unitary conductances and I-V rectification of *fast* and *slow* gates, and allows analysis of synchronization of weakly coupled neuronal networks and changes in g_j at macroscopic and single channel levels. We show that inhomogeneity of I-V rectification can cause unidirectional action potential transfer resulting in reverberation of excitation in the 2-D network composed of more than 100 cells in response to a single depolarizing electrical stimulus and can be terminated by a single depolarizing or hyperpolarizing electrical stimulus if applied in a relatively narrow 'window' of the reverberation cycle. The model accounts for the influence of dynamically modulatable electrical synapses in shaping network responses and the formation of reverberation, which, as proposed earlier, may be important for the development of a short-term memory and its consolidation into a long-term memory.

Title: Effect of endogenous estradiol on the lateral amygdala synapses

Authors: *A. MANGANARO[1], I. NINAN[2];
[1]NYU Dep. Psychiatry, New York, NY; [2]Dept. of Psychiatry, New York Univ. Langone Med. Ctr., New York, NY

Abstract: Evidence suggest that changes in estradiol levels exert a profound effect on anxiety-like symptoms and affective behaviors. Endogenous estradiol has been shown to enhance fear extinction, an inhibitory learning believed to play an important role in relieving anxiety- and trauma-related symptoms which are also risk factors for affective disorders. However, the mechanism underlying these effects is largely unknown. A recent study from our group showed

that endogenous estradiol favors synaptic potentiation in the medial prefrontal cortex, a potential mechanism in fear extinction. Here, we studied whether endogenous estradiol affects excitatory synaptic transmission in the lateral nucleus of the amygdala (LA), which serves as the sensory interface of the amygdala, a key brain region involved in fear memory processing. Comparing diestrus mice (low estradiol) with proestrus mice (high estradiol), we observed an increase in the spontaneous glutamatergic transmission in the principal neurons of LA during periods of high estradiol. Our results suggest that endogenous estradiol modulates excitatory synapses in the lateral amygdala which might play a role in the regulation of fear behavior.

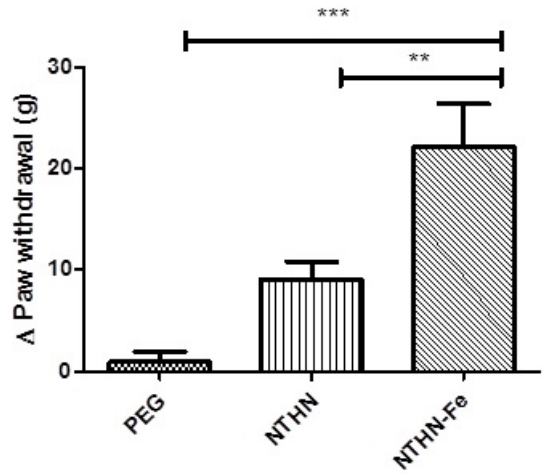
Title: Magnetic nanoparticles induce hyperalgesia in rats

Authors: *L. MANZO[1], H. CERAGIOLI[2], I. J. M. BONET[3], C. A. PARADA[1];
[1]Laboratório de Estudos da Dor - IB - UNICAMP, [2]Faculdade de Engenharia Eletrica e Computacional, [3]Dept. de Biologia Estrutural e Funcional, UNICAMP, Campinas, Brazil

Abstract:



The interaction between living organisms and nanoparticles has been growing, thus raising more concerns about its effects and consequences. This work aims at investigating the consequences of the administration of high magnetic (NTHN-Fe) and low magnetic (NTHN) nanoparticles in the subarachnoid space of rats. Rats that received 0,5 ug/uL (polyethyleneglycol as vehicle at a total volume of 20 uL) of highly magnetic nanoparticles showed a time-dependent decrease in the paw withdrawal threshold in the Electronic Von Frey test when compared to animals that received low-magnetic nanoparticles, such effect was present even when dexamethasone (1 mg/Kg) was administered (i.p) 1 hour prior to the nanoparticles. The hyperalgesia was set 20 minutes after administration and gradually decreased until the 24th hour. These data are very intriguing because the highly magnetic nanoparticles NTHN-Fe induced a strong hyperalgesia while NTHN induced it weakly (figure 1). Since dexamethasone was pre-injected and nevertheless the hyperalgesia was not reverted, the hyperalgesia was not due to an inflammation caused by the nanoparticles. According to the cytometry assay, dorsal root ganglion (DRG) cells incubated with the nanoparticles (NTHN-Fe) for 24 hours showed higher granulocity compared to non-incubated cells (53,8 and 45,4 respectively). This data may suggest that the nanoparticles are internalized by the cells. The strong hyperalgesia caused by highly magnetic nanoparticles may be due to a magnetic effect which depends on the spacial orientation of the nanoparticles in the extra-cell space and once the cells internalize the nanoparticles, the effect is gone. We, however, cannot assure how and why this effect is seen. More efforts are being made to assess this very intriguing phenomenon.

Title: Exploring the roles of electrical and chemical synapses in a *C. elegans* chemotaxis circuit

Authors: *M. DOBOSIEWICZ[1], J. LARSCH[2], C. BARGMANN[1];
[1]The Rockefeller Univ., New York, NY; [2]Max Planck Inst. of Neurobio., Munich, Germany

Abstract: Neurons communicate through chemical synapses, which propagate directed signals through neurotransmitter release, and through electrical synapses, in which current and small molecules can pass bidirectionally between two neurons. In the nervous systems of *C. elegans*, the only organism with a complete anatomical wiring diagram, there are 600 predicted electrical synapses as well as ~7000 chemical synapses, and most neurons have both types of connections. Despite the prevalence of both electrical and chemical synapses, their relative contributions in transmitting information are poorly understood. *C. elegans* senses the attractive odor diacetyl

using the AWA sensory neuron. AWA forms chemical synapses and electrical synapses onto several interconnected interneurons, which in turn connect to command and motor neurons to drive the animal's chemotaxis toward diacetyl. We are studying the AWA circuit using a high-throughput microfluidic device that allows us to deliver odor stimuli in precise patterns while simultaneously recording calcium levels in single neurons as a proxy for neural activity (Larsch et al., 2013). We find that AWA responds to odor in a complex, concentration-dependent manner, but one downstream interneuron gives a stereotyped response to odor increases, regardless of their magnitude. This interneuron may thus be responsible for signaling any change in odor concentration, while information about absolute concentration may be transmitted through other neurons in the circuit. AWA connects to this normalizing interneuron exclusively with electrical synapses. We have used synaptic mutants and transgenic animals to selectively manipulate electrical and chemical synapses and explore the consequences on circuit dynamics. Our initial results suggest that the electrical and chemical synaptic components of the circuit account for distinct temporal components of the odor response.

Title: Synaptic mechanisms underlying suppression of neuronal activity induced by Cortical spreading depression (CSD)

Authors: *P. S. SURYAVANSHI, P. M. SAWANT-POKAM, K. C. BRENNAN;
Univ. of Utah, Salt Lake City, UT

Abstract: Cortical spreading depression (CSD) is a self-propagating wave of neuronal and glial depolarization. Apart from its association with several forms of brain injury, CSD is widely considered to be the physiological correlate of migraine aura, a form of sensory hallucination preceding migraine attacks. CSD causes long lasting changes in sensory processing - sharpening of sensory maps, potentiation of response and blunted adaptation. However precise synaptic and cellular mechanisms underlying these network changes are not fully understood. In this study, we used *in vivo* whole cell current clamp techniques to test effects of CSD on evoked and spontaneous post-synaptic potentials (PSPs) from layer 2/3 neurons in mouse somatosensory cortex. Upon CSD induction, the membrane potential rapidly depolarized resulting in of action

potentials followed by complete silencing of neuronal activity. Although rheobase was increased 5 minutes after CSD induction, other measures of excitability such as slope of the frequency current curve and input resistance were not affected by CSD. The frequency and amplitude of spontaneous PSPs were suppressed from 5 minutes up to 30 minutes post-CSD. CSD induced modification of excitatory and/or inhibitory synaptic activity could be responsible for reduction in PSPs we observed. To uncover the precise synaptic mechanisms, we used *in-vitro* whole cell voltage-clamp recordings to examine changes in spontaneous and miniature excitatory and inhibitory postsynaptic currents (EPSCs and IPSCs). We observed reduction in the frequency of sEPSCs and mEPSCs at 5 and 30 minutes post-CSD, thus providing evidence for pre-synaptic changes in the release probability at glutamatergic synapses. Additionally, *in-vitro* experiments showed an increase in the amplitude of sIPSCs and mIPSCs at 5 and 30 minutes post-CSD, suggesting possible post-synaptic modification of GABA receptors which thus further affects the output of pyramidal neurons. This is the first study to perform electrophysiological characterization of CSD *in-vivo*. Together with the *in-vitro* experiments, we propose novel synaptic mechanisms underlying the effects of CSD on sensory networks.

Title: Activating transcription factor 4 (ATF4) gates gabaergic neurotransmission by regulating GABABRs levels

Authors: *C. CORONA, S. PASINI, J. LIU, L. GREENE, M. SHELANSI;
Dept. of Pathology and Cell Biol., Columbia Univ., New York, NY

Abstract: Activating Transcription Factor 4 (ATF4) is a member of the ATF/cAMP responsive element binding protein (CREB) family described to be involved in learning and memory processes. In this regard, we previously reported that specific hippocampal ATF4 downregulation induces synaptic plasticity and memory deficits accompanied by a reduction in glutamatergic functionality. Here we extend our studies to address the role of ATF4 in GABAergic neurotransmission. Our electrophysiological data, obtained after long-term knockdown of ATF4 levels in cultured rat hippocampal neurons by lentiviral infection, show that ATF4 downregulation significantly increases the frequency without affecting the amplitude of miniature inhibitory post-synaptic currents (mIPSCs). These findings, along with the observation that GABAA receptors (GABAARs) levels are not changed upon ATF4 downregulation, led us to hypothesize a role for ATF4 in controlling GABA release. The metabotropic GABAB

receptors (GABABRs) are one of many neuromodulatory receptors that can effectively influence the release of neurotransmitters. We therefore next queried whether modulating ATF4 levels would in turn influence the expression of GABABRs. Western immunoblotting analysis revealed that altering ATF4 levels significantly affects the expression of the subunit R1 of GABABRs. Specifically, we found that ATF4 downregulation strongly reduces (by about 80%) the expression of GABAB R1, whereas simultaneous co-infection with shATF4 and a rescue construct which overexpress ATF4 (ATF4add) produces a 3-fold increase in the levels of GABAB R1. Noteworthy, differently from the effect of ATF4add, transfecting with a transcriptionally inactive mutant form of ATF4 (ATF4add/mut) is unable to rescue both the electrophysiological and biochemical phenotypes observed upon ATF4 downregulation. This suggests that ATF4 needs to retain its transcriptional activity to influence GABABRs expression as well as mIPSCs frequency. However, qRT-PCR analysis revealed that ATF4 does not directly regulate GABABR transcription, indicating an indirect mechanism of regulation. Finally, we found that specific pharmacological manipulations of GABABR function mimic the effects of alteration of ATF4 levels on the frequency of mIPSCs. This further supports the idea that our observed effects of ATF4 on inhibitory neurotransmission are due to regulation of presynaptic GABABRs and consequently, to the capability to release GABA. In conclusion, our data favor a model in which ATF4 regulates GABAergic function by modulating presynaptic GABABRs.

[2]Biologic Inst., Redmond, WA

Abstract: Selenium (Se) is a trace element that is integral for life and known to have protective effects against oxidative damage. Severe dietary selenium deficiency is associated with neurological dysfunction. Se is incorporated into selenoproteins as selenocysteine (Sec), the 21st

amino acid. Selenoprotein M (SelM) is an endoplasmic reticulum (ER) localized protein abundantly expressed in the brain relative to other tissues. Reeves et al. (2010) previously demonstrated that SelM modulates calcium release from intracellular stores and has a protective effect against oxidative stress in SH-SY5Y neuronal cells. Studies in an Alzheimer's disease mouse model have shown that mutation in the presenilin-2 gene leads to suppression of SelM. Here, we investigate the role of SelM in synaptic physiology in hippocampal slices of SelM knockout (SelM KO) and wild type mice. We demonstrate that SelM KO male mice are deficient in long-term potentiation (LTP), a cellular model for learning and memory, in the CA1 region of the hippocampus. Notably, we reveal this deficit in synaptic plasticity is gender specific, as SelM female KO mice have normal LTP. We also found an overall increase in synaptic efficacy, shown by an augmented input-output relationship of the field excitatory postsynaptic potential (fEPSP) in response to increasing stimulation of the Schaffer collateral fibers. We observed no difference in paired pulse facilitation (PPF), arguing against any presynaptic changes. Our findings strongly demonstrate an important gender-specific role for selenoprotein M in maintaining normal hippocampal function and facilitating synaptic plasticity. These data provide a foundation for further studies on the role of SelM in neurological function and neurodegenerative disorders such as Alzheimer's disease.

Title: The role of cAMP in presynaptic synaptic vesicle recruitment at high and low output neuromuscular junctions

Authors: *R. S. POTTER[1], S. POTTER[1], W. WU[2], R. L. COOPER[1];
[1]Univ. of Kentucky, Lexington, KY; [2]The Univ. of Texas MD Anderson Cancer Ctr., Houston, TX

Abstract: Synaptic efficacy among neurons communicating to other neurons or to targets, such as skeletal muscle, is a dynamic process throughout development and for established synapses. The ability of synaptic function to increase or decrease in regulating the appropriate range of synaptic transmission is important in maintaining correct neural responses. Subtle changes in synaptic modulation can have pronounced acute and chronic effects. Vesicles are distributed inside a nerve terminal as a readily releasable pool (RRP) and a reserve pool (RP). The ability to mobilize the RP is known to be regulated by various second messengers (i.e. cAMP, IP3, PKA)

depending on the type of preparation. Few studies have examined the differences in mobilizing the RP by cAMP following synaptic depression induced by high frequency stimulation; the same goes for synapses which are deemed high or low in synaptic efficacy. We are examining the crayfish and larval *Drosophila* neuromuscular junctions (NMJs) and addressing these hypothesis: (1) Low output synapses will show a greater degree of synaptic enhancement due to activation of cAMP as compared to high output synapses; (2) after induction of high frequency evoked depression, little recruitment of RP vesicle will occur in either synapse type; and (3) enhancing the cAMP production will lead to enhanced synaptic depression in the low output synapses as compared to high output synapses. Activation of cAMP by application of forskolin, an activator of adenylate cyclase, was used. Low output NMJs increased by 127.8% with prior 1hr incubation and only 36.16% without incubation of forskolin (N=5, P< 0.05). A 56.29% (n = 5) increase occurred after depression without incubation. Studies are underway with high output crayfish and *Drosophila* NMJs. These studies are significant as the results will inform us which types of synapses may be modulated by pharmacological agents for therapeutic targets.

Title: Intrinsic circuitry of the lateral central amygdala

Authors: ***S. HUNT**, P. SAH;
Queensland Brain Inst., St Lucia, Australia

Abstract: The amygdala is a region of the brain that is responsible for the processing and memory of emotions. Understanding the neural circuitry of this area is essential to grasping how it achieves this function and may aid in developing treatments for a range of anxiety disorders. Two main subregions of the amygdala, the basal and lateral nuclei (BLA), and the central nucleus (CeA), play key roles in the acquisition and expression of emotions respectively. While the BLA has been extensively studied, the CeA has only recently gained interest, and as such, its intrinsic circuitry is under intense study. Cells in the CeA are mainly inhibitory GABAergic (gamma-aminobutyric acid) cells and single unit recordings of the activity of specific cell populations suggest that these cells form strong local inhibitory connections. These local connections are central to the proposed circuitry underlying the behavioural roles of the CeA. However, our understanding of these local connections at the cellular level is in its infancy; the strength and physiological role of individual connections are largely unknown. We have made dual whole-cell recordings in the lateral CeA to determine the physiological properties and

strength of local inhibitory connections. Current-clamp recordings showed three types of discharge properties: regular spiking (RS), late firing (LF) and fast spiking (FS). In paired recordings, 32 out of 94 (≈ 34%) were connected, of which 29 connected pairs were unidirectional and three were bidirectional. Connections were on average 22 ± 5 pA when voltage-clamped at -40 mV, and were inhibited by picrotoxin, indicating that these were indeed GABAergic connections. In these pairs, the presynaptic cell was RS (47%), LF (35%) or FS (18%) whereas the postsynaptic cell was mostly LF (70%). Finally, the inhibitory connection was sufficient to halt firing in the postsynaptic cell. These results confirm that cells in the lateral portion of CeA form local inhibitory connections, which are capable of silencing the postsynaptic cell.

Title: Mechanisms of serotonergic 2A-receptor-mediated excitation in callosal projection neurons in the mouse prefrontal cortex

Authors: *E. K. STEPHENS, A. T. GULLEDGE;
Physiol. & Neurobio., Geisel Sch. of Med. At Dartmouth, Lebanon, NH

Abstract: Serotonin (5-HT) selectively excites subpopulations of pyramidal neurons in the neocortex via activation of $5HT_{2A}$ (2A) receptors. Classically, 2A and other G_q-coupled excitatory responses are thought to result from turning off potassium conductances, including those mediated by KCNQ channels. However, the precise mechanism underlying the 2A-dependent excitation in the cortex has not yet been established. We tested several potential mechanisms of serotonergic excitation in callosal projection neurons (COM neurons) in layer 5 of the mouse medial prefrontal cortex. Under baseline conditions, focally applied 5-HT increased the rate of action potential generation during suprathreshold DC somatic current injections. To confirm that potassium conductances are involved in serotonergic excitation, we measured 2A-excitation in control conditions and after reducing extracellular potassium from 3 mM to 0.5 mM. Surprisingly, increasing the driving force for potassium failed to enhance 2A-mediated excitatory responses (mean percent change in serotonergic excitation from baseline levels was -28 ± 22 %; n = 11, p = 0.24), even as the KCNQ channel blocker XE 991 (10 or 20 μM) reduced serotonergic excitation (by 32 ± 9%; n = 10, $p < 0.05$). These data suggest that serotonergic

excitation is mediated by combined suppression of KCNQ channels and activation of nonspecific cation channels permeable to potassium, similar to the G_q-mediated cholinergic excitation observed in these same neurons (see, for instance, Haj-Dahmane and Andrade, J. Neurosci., 1996). Indeed, we found that activation of muscarinic receptors with bath-applied carbachol (50 μM) occluded 2A-mediated excitation, confirming that both cholinergic and serotonergic excitation utilize the same G_q-pathway and effector mechanisms in COM neurons. Finally, we found that 2A-mediated excitation was not dependent on intracellular calcium, as responses were enhanced above control levels (by 176%), rather than reduced, when internal calcium was chelated with BAPTA (10 mM in patch pipette; $n = 12$, $p < 0.05$). Our results point to a role for multiple ionic effectors, including a nonspecific cation conductance and KCNQ-mediated M-current, working together to mediate serotonergic and cholinergic excitation in prefrontal pyramidal neurons.

Title: Peripheral nerve injury promotes emergence of acute, neuron-type-specific depressant actions of gabapentin in substantia gelatinosa and primary somatosensory cortex

Authors: *S. ALLES, N. BUKHANOVA, M. BANDET, I. WINSHIP, P. A. SMITH; Neurosci. and Mental Hlth. Inst., Univ. of Alberta, Edmonton, AB, Canada

Abstract: The effectiveness of the α2δ ligand gabapentin (GBP) in treatment for neuropathic pain is thought to develop over periods of 3-5 days. Acute mechanisms may also contribute as clinically-relevant doses (100 mg/kg) of intraperitoneal (IP)-injected GBP significantly increase paw withdrawal threshold to Von Frey filaments in rats subject to sciatic chronic constriction injury (CCI) within 30 min of injection. We used *ex vivo* whole-cell recording and confocal Ca2+ imaging of spinal cord slices and *in vivo* cortical Ca2+ imaging to identify the neuronal correlates of these acute drug actions. Excitatory substantia gelatinosa neurons were identified by their delay firing pattern and inhibitory neurons by their tonic firing pattern. When “neuropathic” rats (subject to 7-14 days of sciatic CCI) received an IP injection of 100 mg/kg GBP 30 min prior to euthanasia, excitatory drive to excitatory neurons was decreased compared to control saline-injected neuropathic rats. This involved a decreased frequency and amplitude of spontaneous excitatory post-synaptic currents (sEPSC). By contrast, excitatory drive to inhibitory neurons

increased as a result of increased sEPSC frequency. In excitatory neurons from neuropathic animals, rates of action potential discharge in response to depolarising current were decreased by prior GBP administration. These changes, which were not observed in sham-operated animals, led to an overall decrease in dorsal horn excitability as monitored by a decrease in K+-evoked Ca2+ responses. All experiments were blinded. *In vivo* imaging studies of neuropathic rat cortex in response to vibrotactile stimulation showed that there is a significant reduction in the neural mass (% of responsive neurons x mean normalized fluoresence) 10 min, 20 min and 30 min following IP injection of 100mg/kg GBP. This novel result implies that GBP is influencing cortical responses and may be affecting pain per se within 10 min of injection. In sham animals a significant effect is only observed after 20 min and 30 min of GBP injection. Most previous studies of the gabapentinoids have failed to identify any major acute effects since these studies have been mainly carried out on naïve animals or with no reference to effects on specific cell types. Elucidation of the mechanisms of these acute, cell-type specific actions of gabapentinoids may provide a basis for development of more effective therapeutic approaches.

Title: Mechanisms of long-term depression at electrical synapses in the thalamic reticular nucleus

Authors: J. SEVETSON, *J. S. HAAS;
Dept. of Biol. Sci., Lehigh Univ., Bethlehem, PA

Abstract: Long-term depression (LTD) of electrical synapses in the thalamic reticular nucleus (TRN) has been demonstrated following paired activity and following activation of metabotropic glutamate receptors by stimulation of corticothalamic afferents, but the interactions and downstream mechanisms of these two paradigms for LTD induction remain unclear. Using dual whole-cell recordings, we demonstrate that these two stimuli induce LTD by separable pathways. LTD following application of the mGluR agonist ACPD occludes further paired bursting in pairs of coupled TRN neurons, as do the stimuli in reverse order. We show that burst-induced LTD depends on calcium influx via T-type and L-type channels and calcium flux in in the intracellular

environment. However, ACPD-induced LTD can be induced independently of those sources of calcium. Together, these results provide support for a mechanistic model whereby activity-induced depression is mediated by calcium entry and dynamics, while afferent activity-induced depression is not; we hypothesize that the two induction mechanisms converge at a shared downstream pathway.

Title: Underlying mechanisms of intravenous administration of lidocaine on synaptic transmission in spinal dorsal horn neurons: An *in vitro* patch-clamp recording

Authors: M. KURABE[1], H. FURUE[2], *H. BABA[1], T. KOHNO[1];
[1]Niigata Univ, Sch. Med., Niigata, Japan; [2]Dept. of Information Physiol., Natl. Inst. for Physiological Sci., Okazaki, Japan

Abstract: Intravenous administration of lidocaine (IVL) has been used clinically for neuropathic pain or postoperative pain management. Many investigators have considered that voltage-gated sodium channel is a primary target for analgesic action of lidocaine. However, plasma concentration follwoing IVL is 1-5 μM, that concentration of lidocaine is not enough to block sodium channel. Moreover, several studies suggest that lidocaine has other potential targets (e.g., glycine transporter 1, muscarinic receptors) other than sodium channel. Therefore, the analgesic mechanisms of IVL have not been fully elucidated. We hypothesized that IVL would have an action on synaptic transmission in spinal dorsal horn neurons. We examined the effect of IVL using *in vivo* patch-clamp recordings in substantia gelatinosa neurons. Under urethane anesthesia, lumbar laminectomy was performed at the level of Th12-L2, and the animal was then placed in a stereotaxic apparatus. Blind whole-cell patch-clamp recordings were made with a resistance of 8-12 M Ω electrode. In the voltage-clamp mode (Holding potential = - 70 mV), IVL dose-dependently decreased the frequency, but not the amplitude, of spontaneous excitatory post synaptic currents (sEPSCs). IVL also decreased the frequency without changing the amplitude of miniature EPSCs in the presence of tetrodotoxin. We next examined the effect of IVL on inhibitory post synaptic currents (IPSCs) at a holding potential of 0 mV. IVL did not change the frequency and amplitude of spontaneous IPSCs. Furthermore, IVL decreased the area under the curve of currents induced by peripheral noxious pinch stimuli. However, bath-applied lidocaine

on the spinal cord surface did not affect the frequency and the amplitude of sEPSCs. Our results suggest that IVL inhibits the excitatory synaptic transmission presynaptically in spinal dorsal horn neurons, resulting in antinociceptive effect. Considering that intravenous, but not bath-applied, lidocaine affected the sEPSCs, lidocaine may not directly modulate excitatory synaptic transmission in the dorsal horn.

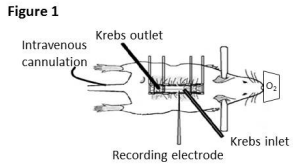

Figure 1. Schematic diagrams of in vivo rat preparation

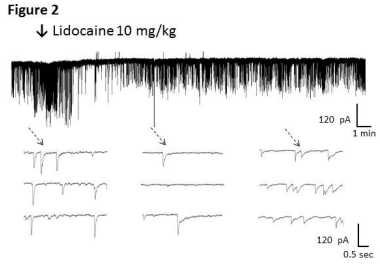

Figure 2. Continuous chart recording of sEPSCs before, during and after intravenous administration of lidocaine (10 mg/kg). The neuronal activity in this figure shows a typical response to lidocaine.

Title: Parkin is necessary for excitatory synaptic transmission in hippocampus

Authors: G. P. CORTESE, C. VOLLMER, *C. WAITES;
Pathology and Cell Biol., Columbia Univ., New York, NY

Abstract: The E3 ubiquitin ligase Parkin is highly expressed in glutamatergic neurons of the cortex and hippocampus, and is reported to interact with and/or ubiquitinate multiple synaptic proteins. Such findings suggest that Parkin could be an important regulator of glutamatergic synaptic transmission. However, few studies have examined Parkin's role in this context. Here, we have used shRNA-mediated knockdown combined with single-cell and paired-cell recordings to investigate the contribution of Parkin to excitatory synaptic transmission in hippocampal

neurons. Remarkably, we find that knockdown of Parkin leads to decreased spontaneous and evoked postsynaptic currents, as well as an increased synaptic failure rate. Moreover, AMPA- and NMDA receptor-mediated currents are dramatically reduced in knockdown neurons, indicating that Parkin is an important regulator of postsynaptic glutamate receptor expression and/or function. This study demonstrates Parkin's critical role in glutamatergic synaptic transmission, and highlights the need for additional studies to define the molecular mechanisms underlying these phenotypes.

Title: Regulation of GABA release by a synapsin llla phospho-switch

Authors: *S.-H. SONG[1,2], G. J. AUGUSTINE[1,2];
[1]Lee Kong Chian Sch. of Med., Singapore, Singapore; [2]Ctr. for Functional Connectomics, KIST, Seoul, Korea, Republic of

Abstract: We have examined the function of a MAPK phosphorylation site in synapsin IIIa, S470, in regulating GABA release from interneurons. The peak amplitude of electrically evoked inhibitory postsynaptic currents (IPSCs) was reduced in cultured hippocampal neurons from synapsin triple knockout (TKO) mice compared to neurons from wild-type (TWT) mice. This phenotype was rescued by synapsin IIIa, as well as by synapsin IIIa containing a schizophrenia-associated mutation in the MAPK phosphorylation site (S470N; Biol. Psych. 55: 118). As previously reported (Nature Comm. 4:1512), synapsins influence the time course of GABA release: IPSCs decayed more slowly in TKO neurons than in TWT neurons. Deconvolution analysis (J. Neurosci. 24: 6127) indicated that this is due to a prolongation of quantal GABA release following a stimulus, with the time constant of release slowing from 96+4.9 msec in TWT to 124+10 msec in TKO neurons. This desynchronization of GABA release was rescued by S470N (82+5.3 msec), but not by wild-type synapsin llla (127+9.7 msec). Thus, MAPK phosphorylation of synapsin IIIa controls the kinetics of GABA release but not the peak rate of GABA release. Because synapsin llla rescued the defect in peak rate, but not in release kinetics, there was a 2-fold increase in the total number of GABA quanta released in response to a stimulus. The S470 phosphorylation site also regulates the response to BDNF. While BDNF (100 ng/ml) had little effect on the frequency of miniature IPSCs (mIPSCs) in TWT neurons, there was a pronounced (1.4-fold) increase in mIPSC frequency in TKO neurons. Synapsin llla rescued the effect of BDNF on mIPSC frequency, but S470N did not. This indicates that

synapsin IIIa is a negative regulator of BDNF signaling and this action is also under the control of MAPK via phosphorylation of S470. In summary, synapsin llla serves unique roles in regulating GABA released in response to both electrical and chemical stimuli, with these roles controlled by MAPK phosphorylation of S470. These novel functions, and their disruption by S470N, could implicate synapsin IIIa in the etiology of schizophrenia.

Title: Investigating homeostatic plasticity at electrical synapses

Authors: *E. L. HECKMAN[1], S. FITTRO[1], Y. SONG[2], Y. BERDICHEVSKY[3], J. S. HAAS[1]; [1]Biol. Sci., [2]Bioengineering Program, [3]Dept. of Electrical and Computer Engin. and Bioengineering Program, Lehigh Univ., Bethlehem, PA

Abstract: Electrical synapses are specialized junctions that allow ionic current to flow directly between coupled neurons, thus allowing the rapid propagation of signals relevant to neural communication. They play a large role in synchronizing hippocampal oscillations and maintaining attention. Long-term depression of electrical synapses in the thalamic reticular nucleus (TRN) has been demonstrated following paired activity or activation of metabotropic glutamate receptors by stimulation of corticothalamic afferents. Whether electrical synaptic strength is regulated by homeostatic mechanisms that have been shown to up- or down-regulate synaptic strength in response to global activity modulation is unknown. Using dual whole-cell recordings in hippocampal slice cultures and acute horizontal slices containing the TRN, we investigated whether distributions of electrical synaptic strength varied after long-term exposure to tetrodotoxin used to block activity. Our results show that under these conditions, electrical synapses are not homeostatically plastic. However, coupling incidence was increased in acutely sliced TRN following exposure to tetrodotoxin; this was not true for coupling incidence in hippocampal cultures. These experiments gave us further insight into the modifiability and role of electrical synapses, which mediate interneuronal communication across the brain.

Title: Kv1.2 potassium channel role in Cerebellar learning and memory

Authors: ***S. C. MADASU**[1], M. L. SHIPMAN[2], J. T. GREEN[2], A. D. MORIELLI[3]; [1]Univ. of Vermont, Colchester, VT; [2]Dept. of Psychological Sci., [3]Dept. of Pharmacol., Univ. of Vermont, Burlington, VT

Abstract: Learning is regulated by synaptic and intrinsic plasticity. Synaptic plasticity in turn is regulated by ion channel function. Major contributors of neuronal excitability and intrinsic plasticity are voltage-gated ion channels. The regulation and surface expression of ion channels such as voltage-gated potassium channel Kv1.2 has been shown not only to govern Purkinje cell (PC) excitability in the cerebellum(1) but also cerebellum-dependent associative learning and memory such as eyeblink conditioning (EBC). Our lab has previously shown that inhibition of Kv1.2 in cerebellar cortex via infusion of the potent and selective Kv1.2 blocker tityustoxin-Kα facilitates EBC in rats (2). AMPAR endocytosis during mGluR1 stimulated long term depression (LTD) at parallel fiber-PC synapses has been proposed as a mechanism for EBC. mGluR1 knock out mice show impaired EBC and impaired LTD (3, 4). However, mutation studies in mouse that block AMPAR endocytosis and prevent LTD have no effect on EBC. (5). Thus, mGluR1, but possibly not AMPAR endocytosis, is important for cerebellar dependent learning. Here we show that mGluR1 stimulation via DHPG decreases surface expression of both Kv1.2 and AMPAR. We propose an alternative mechanism for mGluR1 involvement in EBC that involves modulation of surface expression of Kv1.2 in cerebellar cortex. References: 1. Title: Postsynaptic mechanism for progression of cerebellar long-term depression

Authors: *T. KIM, Y. YAMAMOTO, K. TANAKA-YAMAMOTO;
KIST, Seoul, Korea, Republic of

Abstract: Synapses can undergo changes in their efficacies by regulating the number of postsynaptic receptors, upon the external stimulus. Once the stimulus exceeds a certain threshold, synaptic efficacies are changed and maintained for long time, which is called long-term synaptic plasticity. Time course of long-term synaptic plasticity is characterized by stable baseline, induction of signaling activities, expression of changes in synaptic efficacies, and maintenance of resultant level of synaptic efficacies. Although many studies have discovered mechanisms of induction and expression, it remains unclear how synaptic plasticity can be maintained. In this study, we addressed this question by investigating one of the well-characterized long-term synaptic plasticity, long-term depression (LTD) at synapses between parallel fibers (PFs) and Purkinje cells (PCs) in cerebellar cortex. While synaptic transmission at PF-PC synapses is stably kept at the basal state, LTD is triggered when PF stimulation coincides with climbing fiber stimulation, and then is maintained. Experimental and theoretical studies showed that once net increase of intracellular calcium concentration reaches threshold to initiate PKC-MAPK positive feedback loop, activated PKC phosphorylates GluA2, the most abundant subunit of AMPAR in PC synapse, and consequently enhances the internalization of GluA2 by clatherin mediated endocytosis. These processes are responsible for LTD induction and expression, but not for LTD maintenance, as shown by our previous results. Early treatment of PKC inhibitor made LTD to be reversed back to basal level, whereas later treatment led two distinct responses; successful maintenance of LTD and restoration to baseline. This indicates that there is another sensitive bistable switch activated after PKC-MAPK positive feedback loop. The

current study demonstrates that Rab5-Rab7 conversion is the bistable switch responsible for the maintenance of LTD. Our computational model including the processes of induction and expression of LTD together with this conversion switch for sorting to late endosome successfully described the time course of LTD. Our experiments using dominant negative form of Rab7 (Rab7DN) showed that the conversion is indeed required for LTD. Further, photo-sensitive Rab7DN is newly developed and utilized to examine time course of LTD. Based on these results, we conclude that late endosome sorting of GluA2 works as the mechanism of LTD maintenance and there is variability in timing of each LTD progression phase.

Title: Cerebellar LTD induced in mice having mutated GluA2 C-terminus resolves discrepancy between motor learning and synaptic plasticity

Authors: *K. YAMAGUCHI[1], S. ITOHARA[2], M. ITO[1];
[2]Lab. for Behavioral Genet., [1]RIKEN BSI, Wako Saitama, Japan

Abstract: Long-term depression (LTD) of synaptic transmission between cerebellar parallel fiber (PF) and Purkinje cell has been considered to be essential for motor learning. As a molecular mechanism underlying LTD, it has been shown that coincidental activation of PFs and climbing fiber (CF) induces a sharp increase in [Ca2+]in, which activates PKCα. Then, PKCα phosphorylates Ser-880 at GluA2 C-terminus, and thereby detaches AMPA receptors containing the phosphorylated GluA2 from GRIP (a scaffold protein). Finally, the destabilized AMPA receptors are internalized via endocytosis. Mutated GluA2 lacking the C-terminal 7 amino acids (GluR2α7) and that having replaced Lys -882 to Ala (GluR2K882A) are not phosphorylated via PKCα, and LTD was not induced in knockin mice having these mutant GluA2 (Steinberg et al., 2006). Recently, motor learning ability of these mice lacking LTD was demonstrated to be normal (Schoneville et al., 2011), and these authors claimed that PF-PC LTD was not essential for cerebellar motor learning. However, LTD-inducibility was examined under only limited conditions. Here, we reassessed LTD-inducibility in these KI mice by using several types of protocols in slice of 3- to 6-month-old KI mutants, which were gift from Prof. R.L. Huganir. First, simultaneous stimulation of PF and CF at 1Hz for 5 min was applied under current-clamp condition. This pattern of conjunctive stimulation (CJ-stim) induced LTD in wild type (WT), but not in the two types of KI mice. Second, PFs were stimulated twice with 50 ms intervals and the second PF stimulus was synchronized with a single CF stimulus. This protocol induced LTD in

WT (EPSC-amplitude: 82.8±5.0%) and K882A (80.8±3.4%). EPSC-amplitudeof α7 (95.3±4.9%) was significantly larger than that of WT ($p<0.05$, Tukey-Kramer post hoc test) or K882A ($p<0.05$). Third, the CF stimulus was replaced with a single depolarizing pulse (50 ms) applied through the whole-cell patch pipette containing Cs+-based internal solution. This protocol induced LTD in WT (69.5±3.7%, n=5), K882A (71.3±3.6, n=7) and D7 (76.2±6.8, n=5). Thus, LTD is inducible in both mutant GluR2 KI mice under certain CJ-stim conditions. The discrepancy between motor learning and LTD raised in these mutant mice should be resolved.

Title: Role of the temporal pattern of conditioning stimulation on induction of synaptic plasticity in visual cortex after mild traumatic brain injury (mTBI)

Authors: *D. KALIKULOV, Q. S. FISCHER, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Traumatic brain injury can be accompanied by deficits of learning, memory and their underlying physiological processes - synaptic plasticity. We investigated a range of temporal patterns of conditioning stimulation of afferents on the induction of synaptic plasticity in visual cortex from control rats and from rats who had received mild impact TBI. Whole cell recordings were made from individual layer 2/3 pyramidal neurons in response to stimulation of layer 4 in acute slices of primary visual cortex from rats at 10-12 weeks postnatal age, including those who received an mTBI under anesthesia 2-3 weeks prior. Conditioning stimulation consisted of either a continuous train of 900 pulses at 10 Hz for 90s with an interstimulus interval (ISI) distribution coefficient of variation (CV) of 0.0 (perfectly regular ISIs), 0.2 (slightly irregular ISIs), or 1.0 (highly irregular ISIs) or of a discontinuous train of 9 bursts of 100 pulses each at 10 Hz with a pause between each burst. Baseline postsynaptic responses were evoked at 0.1 Hz for 10 minutes prior to the conditioning stimulus and for 20 minutes after the end of conditioning stimulus. We successfully recorded from 112 control and 101 mTBI cells. In controls, 10Hz continuous stimulation induced LTD in 58% (CV=1), 35% (CV=0.2) and 55% (CV=0) of the neurons. The incidence of LTP increased following increasing regularity of the conditioning stimulus (0%, 24% and 32% for CV=1, 0.2, 0, respectively). In mTBI rats, 10Hz continuous stimulation induced LTD in 42% (CV=1) , 61% (CV=0.2), and 44% (CV=0); and LTP in 29% (CV=1),

11%(CV=0.2) and 23% (CV=0) of the neurons. The plasticity outcomes were significantly different among certain different CV groups for mTBI: 10Hz, 90s, CV=0.2 vs CV=1 ($P<0.05$, t-test), and for certain groups between control vs. mTBI: 10 Hz, CV=1, 90s ($P<0.05$, t-test). In controls, discontinuous 10Hz stimulation produced LTD in 63%(CV=0), 56%(CV=0.2) and 82% (CV=1); and LTP in 16%(CV=0), 33% (CV=0.2) and 18% (CV=1) of the neurons. The distribution of plasticity outcomes for the CV=1 group was significantly different for control: 10Hz, 90s vs 900s ($P<0.005$, KS-test). In mTBI rats, the incidence of LTD increased with increasing conditioning stimulus regularity (53%, 44% and 33% for CV=0, 0.2, 1, respectively), while the incidence of LTP increased with increasing conditioning stimulus irregularity (20%, 28%, and 47% for CV=0, 0.2, 1, respectively). The distribution of plasticity outcomes for CV=1 stimulation was significantly different for control vs mTBI: 10Hz, 900sec ($P<0.005$, KS-test). Thus, stimulus pattern should be considered in selecting therapeutic approaches to chronic brain stimulation after mTBI.

Title: Effect of interstimulus interval regularity and mild traumatic brain injury (mTBI) on synaptic plasticity induced by 1Hz stimulation in visual cortex

Authors: *Q. S. FISCHER, D. KALIKULOV, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Typical protocols for inducing synaptic plasticity use stimulus patterns with constant interstimulus intervals (ISIs), while neurons *in vivo* receive synaptic input with irregular ISIs. A study of more physiologically salient stimulation patterns is important to understand the role that stimulus temporal pattern may play in synaptic plasticity induction. Here we evaluate how stimulus regularity influences synaptic plasticity induction in the visual cortex of 10-12 week-old normal rats and those which received a mTBI 2-3 weeks prior. We applied a defined pattern of stimulation to layer 4 in acute slices and made whole-cell recordings of evoked postsynaptic potentials (PSPs) from 116 layer 2/3 pyramidal cells. Conditioning stimulation consisted of 900 pulses at 1Hz with 1 of 3 different patterns of ISI regularity defined by the coefficient of variation (CV): regular (CV=0), slightly irregular (CV=0.2), or highly irregular (CV=1). PSP peak amplitudes evoked by 0.1Hz stimulation were measured before and after conditioning

stimulation, and the post- to pre-conditioning ratio was used to assess plasticity. In controls, long-term depression (LTD) occurred in 68% of cells for CV=0 (n=25) and 75% of cells for CV=0.2 (n=20) stimulation, but just 44% of cells for CV=1 stimulation (n=23). Plasticity (LTD or long-term potentiation=LTP) did not occur in 16% of cells for CV=0 or CV=0.2 stimulation, increasing to 39% of cells for CV=1 stimulation (remaining cells showed LTP). Notably, the distribution of plasticity outcomes was significantly different for CV=0.2 vs. CV=1 stimulation ($P<0.05$, KS test). In mTBI rats, LTD occurred in 93% of cells for CV=0.2 stimulation (n=15), but just 44% of cells for CV=1 (n=18) and 40% of cells for CV=0 (n=15) stimulation. Plasticity did not occur in 47% of cells for CV=0 stimulation, and 28% of cells for CV=1 stimulation (remaining cells showed LTP). Notably, the distribution of plasticity outcomes for CV=0.2 stimulation was significantly different from both CV=0 ($P=0.02$, KS-test) and CV=1 ($P=0.03$, KS-test) stimulation. We also compared the evoked PSP half width, rise time, decay rate, and latency before and after conditioning stimulation. In controls, CV=0.2 stimulation induced a significant increase in rise time and latency ($P<0.02$, t-test), while CV=1 stimulation induced a significant decrease in half width and decay rate ($P<0.03$, t-test). In contrast, cells from mTBI rats showed no change in these parameters for any stimulation pattern. These results suggest that stimulus regularity modifies the efficacy of synaptic plasticity induction and that mTBI can alter this interaction.

Title: Layer-specific involvement of endocannabinoid signaling in cholinergic-induced long-term depression of layer 2/3 pyramidal neurons in rat visual cortex

Authors: K. JOO[1], K.-H. CHO[1], H.-J. JANG[1,2], *D.-J. RHIE[1,2];
[1]Coll Med. Catholic Univ. Korea, Seoul, Korea, Republic of; [2]Catholic Neurosci. Inst., Seoul, Korea, Republic of

Abstract: Endocannabinoid, acting as a retrograde signal, is involved in some forms of long-term synaptic depression (LTD) in the cortex. In our previous study, the activation of muscarinic receptors induced cholinergic-dependent LTD in the visual cortex. Cholinergic facilitation of long-term potentiation (LTP) and LTD plays a important role of learning, memory and sensory

processing. In this study, we investigated whether endocannabinoid signaling is involved in muscarinic LTD (mLTD). In addition, we studied layer-specific involvement of endocannabinoid signaling on mLTD because modulation of synaptic transmission in different layers is important in the pathway-specific control of cortical information flow. We recorded excitatory postsynaptic potentials with whole-cell patch-clamp technique by alternating stimulation applied to layer 1 and layer 4 (every 20 s each) in layer 2/3 pyramidal neurons of the rat primary visual cortex. Application of muscarine (10 μM, 10 min) evoked LTD at both layers to similar extents (~70% of the baseline), which was inhibited by D-AP5 (50 μM), an N-methyl-D-aspartate (NMDA) receptor antagonist. Application of the non-competitive NMDA receptor antagonist MK801 (1 mM) into the pipette blocked the mLTD at both layers, as well. mLTD evoked by layer 4, but not layer 1, stimulation showed an increase in paired-pulse ratio of EPSPs, implying that mLTD at layer 4 is presynaptically expressed. Bath application of AM251 (5 μM), an inverse agonist of cannabinoid (CB1) receptors, blocked mLTD at layer 4 only. Hence, NMDA receptor-dependent induction of mLTD was expressed presynaptically via endocannabinoid signaling at layer 4 whereas mLTD at layer 1 was expressed in postsynaptic neurons. Our results suggest that layer-specific involvement of endocannabinoid systems in cholinergic-induced synaptic plasticity might be important for the pathway-specific modulation of information processing in the neocortex. This study was supported by the Basic Science Research Program (2014-055260) through the National Research Foundation of Korea funded by the Korea government (MSIP).

Title: Abnormal Retina -Specific Segregation at the dLGN of the Flailer - a myosin 5a mutant mice

Authors: *S. PANDIAN, M. CONSTANTINE-PATON;
McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: MyosinVa (MyoVA), is a widely distributed vesicular-cargo-binding actin motor known to deliver the major scaffold complex for glutamate receptors to spine synapses. In Flailer (Flr) mutant mice the cargo-binding domain of myo5a is driven by the brain specific promoter of Gnb5 (Jones et al 2000). When this truncated myo5a is expressed in 1:1 ratio reproducible abnormal behavior are seen (eg; early seizure, anxiety, repetitive whole body grooming (Pandian et al in prep)). In visual cortex neurons these mice have abnormally high AMPAR miniature current frequencies and their eAMPA/eNMDA ratio is significantly larger than in WT strain. Flr

shows no LTD at the layer 4 to layer 2/3 synapses although LTP is normal (Yoshii et al 2013). In developing rodent LGN the ipsilateral input arrives later than the contralateral input and there is a competition between the left and right eye axons (Huberman et al., 2008) Thus we hypothesized that if the retinogeniculate pathway also lacked LTD the ipsilateral territory might be unable to terminate in its normal region because the earlier contralateral innervating projections could not undergo LTD. Here we report that when both eyes of Flr pups are differentially labeled with CTB (555, 647) they show abnormally small and displaced ipsilateral zone while the contralateral projection occupies a larger territory. Monocular enucleation before eye-specific segregation in Flr causes the contralateral projection to spread throughout the dLGN with lowest density of input in region normally occupied by the ipsilateral eye. The ipsilateral projection is abnormally large with a shift towards the medial side of the nucleus. The results are consistant with the hypothesis that NMDAR LTD is also defective in the LGN of Flr and prevents displacement of early contralateral inputs by the later arriving axons.

Title: Gating of synaptic plasticity in the rodent primary auditory cortex by 17β-estradiol

Authors: *C. N. SOUTAR[1], S. G. RODIER[2], S. A. CHEE[1], N. PUN[2], H. C. DRINGENBERG[2]; [1]Ctr. for Neurosci. Studies, [2]Dept. of Psychology, Queen's Univ., Kingston, ON, Canada

Abstract: 17β-estradiol (E2) is an estrogenic hormone primarily synthesized in the ovary. Hormonal E2 has been shown to exert profound effects on both structural and functional synaptic plasticity, as well as learning. Interestingly, in males and females of several species, E2 is synthesized and released by forebrain neurons, including those in sensory regions such as the primary auditory cortex (A1). Thus, in addition to its role as a circulating hormone, E2 may also function as a modulator of synaptic activity and plasticity in the forebrain. Here we examined the role of E2 in synaptic plasticity (long-term potentiation and long-term depression; LTP and LTD, respectively) in A1 of adult, male rats under urethane-anaesthesia. In control animals, theta-burst stimulation (TBS) of the medial geniculate nucleus (MGN) resulted in only modest LTP of field postsynaptic potentials (fPSPs) in A1, while low-frequency stimulation (LFS) failed to induce LTD, data reflecting the high degree of resistance to plasticity induction in the mature A1.

Surprisingly, during local application of E2 in A1, both TBS and LFS resulted in the induction of LTD. Conversely, A1 application of Fadrozole, an aromatase inhibitor that suppresses local E2 synthesis, enhanced TBS-induced LTP, indicating that E2 functions as a potent inhibitor of LTP. E2 also resulted in a suppression of baseline fPSP amplitude in A1. Together, our experiments suggest that E2 exerts significant modulatory effects on synaptic transmission and plasticity in the mature A1. These findings hold important implications for the regulation of auditory processing and learning in adult mammals. Supported by NSERC and The Hearing Foundation of Canada.

Title: Hippocampal stratum radiatum interneuron plasticity type corresponds with cell subtype and mGluR5 expression

Authors: *T. M. NUFER[1], C. B. MERRILL[3], L. N. FRIEND[2], Z. H. HOPKINS[2,4], J. G. EDWARDS[2];
[1]Physiol. and Developmental Biol., [2]Brigham Young Univ., Provo, UT; [3]Univ. of California, Irvine, Irvine, CA; [4]Univ. of Utah Sch. of Med., Salt Lake City, UT

Abstract: Changes in synaptic strength in hippocampal CA1 pyramidal cells are thought to be responsible for the acquisition and retention of short-term memory. This plasticity is modulated by inhibitory interneurons in the stratum radiatum which are composed of many subtypes including, among others, parvalbumin-containing axo-axonic cells, calretinin-containing interneuron-selective cells, and cholecystokinin/calbindin positive basket cells. While radiatum interneurons induce long-term depression (LTD), short-term depression, or lack of plasticity (McMahon & Kauer, 1997, Neuron), it is not known whether these types of plasticity correlate to any specific interneuron subtype. Using whole cell electrophysiology and real time quantitative PCR, we characterized the plasticity expressed by different hippocampal interneuron subtypes in correlation with their mRNA expression patterns to determine cell subtype using calcium binding

proteins. We also assessed the expression of endocannabinoid (eCB) biosynthetic enzymes including diacylglycerol lipase α, N-acyl-phosphatidylethanolamine-specific phospholipase D, and 12-lipoxygenase, as well as metabotropic glutamate receptor subunits known to mediate stratum radiatum interneuron LTD. We identified a correlation in that cells that exhibited long-lasting depression tended to express mRNA for at least one of the eCB biosynthetic enzymes and the metabotropic glutamate receptor subunit mGluR5. Cells that exhibited short-term depression tended to express mRNA for at least one of the eCB biosynthetic enzymes, but not mGluR5. This suggests that stratum radiatum interneuron plasticity can be predicted based on cell subtype and mGluR expression, and that these different types of plasticity may have some importance in hippocampal function.

Title: Nanometer resolution imaging of Arc-mediated AMPA receptor endocytosis

Authors: *A. TAIBI[1], R. HOBSON[1], E. HUJBER[1], M. GUDHETI[2], E. JORGENSEN[1,3], J. SHEPHERD[1];

Abstract: The formation and storage of memory is mediated by a complex series of membrane and protein trafficking events at synapses. Activity Regulated Cytoskeletal protein (Arc) is necessary for long-term memory. *Arc* is an immediate early gene that is transcribed and translated in response to neural activity. Arc regulates multiple forms of synaptic plasticity, such as LTP, LTD, and homeostatic scaling, through the trafficking of α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs). How Arc regulates these different forms of synaptic plasticity remains unclear. We hypothesize that Arc facilitates endocytosis of AMPA receptors at the lateral margin of post-synaptic spines on excitatory neurons. Arc may, however, exhibit nanoscale variations in temporal and spatial dynamics that are specific to certain patterns of activity. To investigate this hypothesis we are developing novel super-resolution imaging methods for single fluorophore tracking of tagged or endogenous synaptic proteins. Since confocal microscopy cannot visualize proteins at the nanometer-scale, we are employing 3-

dimensional fluorescence photoactivation localization microscopy (3D-fPALM). This imaging platform allows single molecule tracking and colocalization analyses with 10-30nm resolution. Initial imaging of endogenous PSD95, Arc, and MAP2 using Alexafluor conjugated antibodies showed Arc is localized to discrete clusters along dendrites while confocal imaging shows a diffuse and nonspecific pattern of localization. PALM imaging of Arc with internalized GluA1 shows that Arc clusters around internalized GluA1 receptors. In order to visualize these events within the context of synaptic ultrastructure, we are also combining this method with high-pressure freeze electron microscopy. We are using EM-stable small molecule organic dyes to visualize HALO and SNAP tagged proteins such as Arc and GluA1 after induction of chemical LTD. This imaging method will allow us to definitively localize the site of AMPAR endocytosis and endosomal trafficking within the synaptic ultrastructure during synaptic plasticity. This cutting-edge imaging approach will allow the characterization of postsynaptic endocytosis at an unprecedented temporal and spatial scale.

Title: Dynamic nanoscale organization of ampa receptors during atp-mediated long term depression

Authors: *B. COMPANS, E. TOULMÉ, D. CHOQUET, E. HOSY;
Interdisciplinary Inst. For Neurosci. CNRS, Bordeaux Cedex, France

Abstract: AMPA-type glutamate receptors (AMPAR) mediate most of the fast excitatory transmission. The number of AMPARs at the synapse is a key determinant of synaptic strength. Long term changes in the efficacy of the synaptic transmission are thought to underlie learning and memory. Two major forms of long lasting plasticity, Long-Term Potentiation (LTP) and Long-Term Depression (LTD), are characterized by a long lasting increase or decrease in synaptic strength, respectively. LTD can be induced by Low Frequency Stimulation (LFS) or by chemical activation of appropriate receptors (cLTD). Recently, it has been demonstrated that stimulation of P2X receptors (P2XR), by ATP treatment or by a noradrenergic-dependent glial release of endogenous ATP, induces AMPAR endocytosis and long lasting depression of AMPAR currents through activation of phosphatases or CamKII. The dynamic and the nanoscale organization of AMPAR have both been shown to play an important role in synaptic activity and could be modified during long lasting plasticity. Using super resolution microscopy coupled to

electrophysiology, it has been that AMPARs are concentrated in clusters measuring around 80 nanometer and containing around 20 receptors. Most of dendritic spines contain 1 or 2 nanodomains which are composed by 60% of the synaptic AMPARs and could be responsible of quanta excitatory post synaptic currents. The other part of AMPARs are free to diffuse in and out the dendritic spines. Synaptic activity increases the percentage of mobile AMPAR and it is known that AMPAR lateral diffusion is important for responses in frequency of neurons. Here, we report the effect of ATP-mediated cLTD on nanoscale AMPAR dynamic organization. Single particle tracking microscopy (UPAINT) and d-STORM are applied to decipher the variation of AMPAR lateral diffusion and synaptic organization, respectively. AMPAR mobility seems to not be affected by a pharmacological activation of P2XRs whereas it organization is affected. Indeed, ATP induces a long lasting decrease of surface AMPAR number, and changes of the nanodomain organization. We observed a decrease of 40% of the number of surface AMPAR. This decrease is not observed with phospho-mutants of GluA1 subunit of AMPAR. We shown that ATP-mediated LTD correspond to a decrease of AMPAR number at synapses, leading to a reorganization of AMPARs without affecting their dynamic properties.

Title: Pin1 binding to PSD-95 regulates excitatory synapses

Authors: ***J. Y. DELGADO**[1], G. G. TURRIGIANO[1], D. CHOQUET[2];
[1]Brandeis Univ., Waltham, MA; [2]CNRS, Bordeaux, France

Abstract: Phosphorylation dependent peptidyl-propyl cis/trans isomerization by the peptidyl-prolyl cis/trans Isomerase 1 (Pin1) plays key roles in cell cycle progression, the pathogenesis of cancer, and age-related neurodegeneration. Most of our knowledge about Pin1 function is restricted to non-synaptic proteins and whether Pin1 regulates excitatory synapses is unknown.

We identified the Postsynaptic Density Protein 95 (PSD-95) as a novel Pin1 binding partner. Pin1 binds and isomerises phosphorylated threonine 19 and serine 25 at the N-terminus domain of PSD-95. Pin1 binding to phospho-threonine 19 prevents PP2A mediated dephosphorylation and ubiquitination of PSD-95. Pin1 down regulation increases the amount of ubiquitinated PSD-95 and decreases the number of PSD-95 positive dendritic spines, the amounts of surface AMPA receptors, and the frequency of mEPSCs. The decrease in mEPSC frequency by Pin1 down regulation was fully rescued by overexpressing wild type PSD-95. Thus, proline directed phosphorylation of PSD-95, Pin1 binding and peptidyl-prolyl isomerization regulates excitatory synapses by increasing PSD-95 protein lifetime at synapse.

Title: Neuronal network dynamics of n-methyl-d-aspartate-induced chemical long term depression in cultured rat hippocampal neurons

Authors: ***S. DJEMIL**[1], X. CHEN[1,2], R. DZAKPASU[1,2];
[1]Dept. of Pharmacol. and Physiol., [2]Physics, Georgetown Univ., Washington, DC

Abstract: During learning and memory, synapses, the conduits through which neurons “talk” to each other, can either be strengthened or weakened via long-term potentiation (LTP), or long-term depression (LTD) respectively. It is generally understood that both forms of synaptic plasticity, LTP and LTD, must be tightly regulated for correct memory storage to occur; therefore, the interference with the regulation of one or both would lead to incorrect memory storage. Since its discovery, many insights about LTD have been gained via studies performed at the single cell level. However, effects of LTD on neuronal network dynamics have yet to be explored. Within the hippocampus, chemical LTD (cLTD) can be induced via the activation of N-Methyl-D-aspartate (NMDA) receptors using NMDA. To assess the effects of cLTD on network activity, we utilize multielectrode arrays (MEA), an electrophysiological system that allows for simultaneous extracellular recordings from 59 electrodes. Preliminary data show that NMDA results in a decrease in spontaneous network activity of embryonic rat hippocampal cultures that is dose dependent, stable and long-lasting. Further experiments using pharmacological agents are needed to assess whether this effect can be attenuated.

Title: Actomyosin contraction mediates presynaptic long-term synaptic plasticity

Authors: M. H. MCFADDEN[1], H. XU[2], Y. CUI[2], R. A. PISKOROWSKI[3], V. CHEVALEYRE[3], L. VENANCE[2], *Z. LENKEI[1];
[1]ESPCI-ParisTech, Paris, France; [2]Ctr. for Interdisciplinary Res. in Biol., Col. de France, Paris, France; [3]Univ. Paris Descartes Sorbonne Paris Cité, Paris, France

Abstract: Long-term synaptic plasticity is critical for adaptive function of the brain, but presynaptic mechanisms of functional plasticity remain poorly documented. Here, we show that changes in synaptic efficacy during one of the most widespread forms of long-term presynaptic plasticity, i.e. endocannabinoid-mediated long-term depression (eCB-LTD), require contractility of the neuronal actomyosin cytoskeleton. First, we measured the effect of CB1R activation on synaptic vesicle release at individual axonal boutons by expressing synaptophysin-pHluorin (SpH) in rat hippocampal cultures. While CB1R activation led to a marked reduction in vesicle release as compared to control conditions, pharmacological inhibition of either non-muscular myosin II (NMII) or of its major activating kinase, Rho-associated protein kinase (ROCK), prevented this effect, as well as the increased number of silent boutons observed under CB1R activation. We then tested whether activity-dependent forms of plasticity mediated by endogenous cannabinoids (eCB) could engage similar mechanisms, by investigating two well-described eCB-mediated forms of plasticity both at inhibitory synapses in the hippocampus and at excitatory corticostriatal synapses. At both types of synapse, both NMII and ROCK inhibition prevented long-term forms of eCB-mediated synaptic depression, while short-term forms, such as depolarization-induced suppression of inhibition or of excitation, i. e. DSI or DSE, remained unaffected. Collectively, these results show that the long-term, but not short-term, blockade of the presynaptic release machinery under CB1R activation relies on ROCK-mediated actomyosin contraction, providing a novel mechanistic link relating changes in synaptic efficacy to one of the most widespread forms of presynaptic plasticity in the brain.

Title: Convergence of synaptic pathophysiology in the hippocampus of Fmr1 knockout and Syngap1 heterozygous mice

Authors: *S. BARNES[1], A. D. JACKSON[1,2], E. K. OSTERWEIL[1], P. C. KIND[1,2], D. J. A. WYLLIE[1];
[1]Univ. of Edinburgh, Edinburgh, United Kingdom; [2]Ctr. for Brain Develop. and Repair, inStem, Bangalore, India

Abstract: Genetically distinct causes of intellectual disability (ID) and autism spectrum disorder (ASD) may converge on common neuropathological mechanisms. For example, modulators of metabotropic glutamate receptor (mGluR)-dependent protein synthesis, for which ERK-MAPK is a key regulator, prevent and/or reverse many of the phenotypes associated with mouse models of Fragile X Syndrome (FXS) and Tuberous Sclerosis. Recently it was found that heterozygous *de novo* mutations in *SYNGAP1*, a negative regulator of the Ras/ERK pathway, results in ID with co-occurring ASD and epilepsy in approximately 4% of affected individuals, suggesting a similar prevalence to FXS. We have previously shown that, like *Fmr1*$^{-/y}$ mice, *Syngap*$^{+/-}$ mice show enhanced mGluR-dependent LTD that is independent of new protein synthesis. (Barnes et al., 2013; SFN abstract). Furthermore introduction of the *Fmr1* mutation in to *Syngap*$^{+/-}$ mice occludes a further increase in mGluR-LTD in *Syngap*$^{+/-}$*Fmr1*$^{-/y}$ double mutants indicating that mutations in *Fmr1* and *Syngap1* converge on a similar expression mechanism for this form of synaptic plasticity. We now show that direct measurements of protein synthesis in acute hippocampal slices from *Syngap*$^{+/-}$ mice reveal an elevation in basal protein synthesis that is saturated downstream of mGluR1/5 activation (Veh: WT 100 ± 7%; *SG*$^{+/-}$ 135 ± 7%; DHPG: WT 138 ± 14%; *SG*$^{+/-}$ 148 ± 15%; $n = 6$, $p < 0.05$). This is accompanied by an increase in steady-state activity levels of ERK (p-ERK/Total: WT 100 ± 7%; *SG*$^{+/-}$162 ± 15%, $n = 9$, $p = 0.004$) and p-S6 (Ser$^{235/236}$/S6: WT 100 ± 5%; *SG*$^{+/-}$ 121 ± 8%, $n = 8$, $p = 0.03$). Importantly, increased translation rates in *Syngap*$^{+/-}$ hippocampal slices can be corrected to WT levels by inhibiting mGluR5 (*SG*$^{+/-}$: Veh 125 ± 4%; CTEP 102 ± 8%; $n = 9$, $p = 0.06$), Ras (*SG*$^{+/-}$: Veh 142 ± 9%; Lovastatin 106 ± 9%; $p < 0.05$, $n = 7$) or ERK (*SG*$^{+/-}$: Veh 130 ± 9%; U0126 94 ± 9%; $p < 0.05$, $n = 9$). Furthermore we show that inhibition mTOR can reduce protein synthesis rates (*SG*$^{+/-}$: Veh 124 ± 6%; Rapamycin 109 ± 8%; $p < 0.05$; $n = 8$), normalize the magnitude of mGluR-LTD and restore the protein synthesis dependency of this form of LTD in the *Syngap*$^{+/-}$

hippocampus ($SG^{+/-}$: Veh 62 ± 5%, n = 15; Rapamycin 73 ± 5 %, n = 12; Rapamycin + Anisomycin 95 ± 4%, n = 9; $p < 0.05$). Together these findings raise the intriguing possibility that therapeutic strategies used in the treatment of FXS may also be of benefit for individuals with *Syngap1* haploinsufficiency.

Title: G9a governs metabotropic glutamate receptor dependent LTD (mGluR-LTD) by regulating N-ethylmaleimide-sensitive factor/GluR2 (NSF-GluR2) dependent trafficking of postsynaptic AMPA receptors

Authors: *M. SHARMA, S. GOPINADHAN, S. SAJIKUMAR;
Physiology, YLL Sch. of Med., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Synaptic plasticity mechanisms such as long -term potentiation (LTP) and long -term depression (LTD) are the cellular correlates of learning and memory. N-methyl-D-aspartate receptor dependent LTD (NMDAR-LTD) and metabotropic glutamate receptor dependent LTD (mGluR LTD) are the two forms of LTD that contribute to memory mechanisms at cellular level. The role of translation and transcription in LTP and LTD is well studied but the role of transcriptional regulators in memory is less well understood. G9a, a methyltransferase, has been reported to regulate the gene transcription in the hippocampus during memory consolidation. G9a controls a prominent Histone H3 lysine 9 dimethylation (H3K9me2). In the present study, we have investigated the role of G9a on mGluR-LTD in CA1 region of acute rat hippocampal slices using long-term functional plasticity methods and elucidated the mechanism of regulation of mGluR-LTD. Our preliminary results show that G9a inhibition prevents mGluR-LTD and increases the levels of protein kinase M zeta (PKMζ), a critical plasticity protein (PRP) necessary for the maintenance of LTP. Associated with the increased level of PKMζ, the phosphorylated GluR2 subunits of AMPA receptors were also high. Our results suggest that G9a is a negative regulator of plasticity that sets the stage for mGluR-LTD induction and maintenance by inhibiting PKMζ, thereby regulating the N-ethylmaleimide-sensitive factor/GluR2 (NSF-GluR2) -dependent trafficking of postsynaptic AMPA receptors.

Abstract: The superficial spinal dorsal horn serves a critical function in the relay and filtering of incoming nociceptive signals. Plastic changes in synaptic transmission between primary nociceptors and second order dorsal horn neurons have been implicated in many pathological pain conditions. Such plastic changes include among others long-term depression (LTD) or long-term potentiation (LTP) of synaptic transmission. Both forms of plasticity can be NMDA receptor-dependent, but in particular LTD can also involve other signaling molecules such as endocannabinoids (eCBs). In the present study, we were particularly interested in eCB-dependent synaptic plasticity in the spinal dorsal horn, because of the well-established role of eCBs in pain control. Using acute spinal cord slices and whole-cell patch-clamp recordings, we have previously demonstrated the presence of eCB-dependent primary nociceptor LTD in second order neurons of the superficial dorsal horn. The occurrence of this LTD was reduced by about half both in cannabinoid $(CB)_1$ receptor-deficient mice and in the presence of the NMDAR antagonist APV, suggesting a certain degree of heterogeneity in nociceptor LTD. To gain further insights into this heterogeneity, we investigated eCB-LTD separately in excitatory or inhibitory dorsal horn neurons visualized in “glutamatergic” vGluT2::eGFP or “GABAergic” $Gad67^{eGFP}$ transgenic mice, respectively. Although LTD occurred in both neuronal subpopulations, LTD in inhibitory neurons was resistant both to deletion of CB_1 and to blockade of NMDA receptors. Accordingly, neither deletion of NAPE-PLD nor of DGL-α, synthesizing enzymes of the major eCBs anandamide and 2-AG, respectively, could prevent LTD in inhibitory interneurons. In glutamatergic neurons, LTD was strongly reduced in CB_1 receptor-deficient mice and by pretreatment with APV, suggesting that NMDA and CB_1 receptors might act in series to induce primary nociceptor LTD in glutamatergic dorsal horn neurons. Our results demonstrate that the mechanisms of synaptic plasticity at primary nociceptor synapses differ between synapse types

and that this difference is at least partially determined by the neurotransmitter phenotype of the postsynaptic neuron.

Title: Operant ethanol self-administration affects the magnitude of LTD in D1 Medium spiny neurons in nucleus accumbens shell but not core

Authors: *T. A. MEYERS, R. A. MANGIERI, R. MORRISETT;
Univ. of Texas At Austin, Austin, TX

Abstract: Passive ethanol administration has been shown to induce alterations in synaptic plasticity within the nucleus accumbens (NAc) in the occlusion of NMDAR-dependent long-term depression (LTD) of D1 medium spiny neurons (MSN). It has also been shown that the core and shell subregions of the NAc encode different aspects of drug responding and have distinct dopamine responses to reinforcers. However, the effect on accumbal plasticity following operant ethanol self-administration has not been extensively studied and therefore, this study sought to examine the effects of volitional ethanol consumption via operant self-administration on accumbal plasticity in both the core and shell subregions of the NAc. Initially, male Drd1a-tdTomato(+) mice received limited access two bottle choice within their home cages of 15% ethanol (15E) or tap water (mean ethanol consumption: 2.08 ± 0.05 g/kg/session). They next were trained to respond for 15E over 15 daily operant sessions; training then continued for a minimum of 10 additional sessions with a fixed ratio (FR) 4 lever press requirement (mean consumption: 1.33 ± 0.18 g/kg/session). Whole cell patch clamp electrophysiology was performed to investigate plasticity induction of excitatory postsynaptic currents (EPSCs) within Tom(+) MSNs of both the core and shell twenty-four hours following the final operant session (final session consumption: 1.64 ± 0.22 g/kg). The induction of LTD in core neurons was apparently normal (~60% baseline amplitude), and there was no correlation between ethanol consumption and the magnitude of LTD ($R = 0.086$, $p=0.872$). In contrast, shell recordings showed a significant inverse relationship between ethanol consumption and magnitude of LTD (Spearman's $R=-0.928$, $p<0.01$). Taken together, these results indicate that the dose of ethanol

self-administered during operant sessions plays a role in accumbal plasticity in the shell, but not core of the NAc.

Title: Dopamine D2 receptors located on indirect pathway MSNs are not needed for high frequency stimulation-induced striatal long-term synaptic depression

Authors: *S. M. AUGUSTIN, M. I. DAVIS, D. M. LOVINGER;
NIAAA/Laboratory For Integrative Neurosci., Rockville, MD

Abstract: The dorsal striatum is a critical brain region for the integration of synaptic signals from cortex, thalamus, and midbrain. Plasticity at these afferent synapses contributes to action control and learning. The best understood form of synaptic plasticity in the striatum is endocannabinoid (eCB)-mediated long-term depression (LTD), which requires dopamine (DA) D2 receptors. Within striatum, there are different neuronal populations of which 90 percent are medium spiny projection neurons (MSNs) divided into two subpopulations, the “indirect” pathway MSNs (iMSNs) and “direct” pathway MSNs (dMSNs). The remaining 10 percent of striatal neurons are interneurons, including cholinergic interneurons (ChI). Both iMSNs and ChIs contain dopamine (DA) D2 receptors. For almost a decade, the site of the DA D2 receptors needed for the induction of LTD has been highly debated. Two different mechanisms for D2 involvement in LTD induction have been proposed; one involving the D2 receptors on the iMSNs and the other involving the D2 receptors on ChIs. Experimental evidence for these mechanisms is based on pharmacological experiments that could suffer from non-specific effects. Thus, the use of sophisticated gene-targeting strategy to selectively delete DA D2 receptors in the iMSNs and ChIs will allow for the dissection of DA D2 receptor roles in high frequency stimulation (HFS) induced eCB-mediated LTD in the dorsal lateral striatum. Mice carrying a “floxed” D2 allele were bred with mice expressing the Cre recombinase under the control of the iMSN-active A2A promoter to delete D2 receptors from iMSNs. There was a loss of D2 immunoreactivity in the MSNs, revealing somata of putative cholinergic interneurons in the iMSN knockout mice compared to control mice (D2 f/f) in dorsal striatum. In field potential recordings, HFS induces LTD of a similar magnitude in brain slices obtained from mice that lack DA D2 receptors on iMSNs in comparison to D2 f/f. This form of LTD was blocked by a DA

D2-class receptor antagonist and a cannabinoid receptor type 1 antagonist in both genotypes (DA D2 iMSN knockout and control). Whole cell recordings from iMSNs and dMSNs show that HFS induces LTD in both MSN subtypes, although DA D2 receptors are expressed on only iMSNs. HFS can induce a DA D2 receptor dependent LTD at synapses onto MSNs in the DA D2 iMSN knockout and control mice in whole cell recordings. These data indicate that D2 receptors on iMSNs are not necessary for LTD induction by HFS, and ongoing work will further assess this conclusion and allow us to determine the cellular locus of the D2 receptors that are most important for eCB mediated LTD induced using different stimulus protocols.

Title: Normalization of excitatory-inhibitory balance by cortical spike-timing-dependent plasticity

Authors: *J. A. D'AMOUR[1], R. C. FROEMKE[2];
[1]Mol. Neurosci., New York University, Sch. of Med., New York, NY; [2]NYU Sch. of Med., New York, NY

Abstract: Synapses are plastic and can be modified by changes of spike timing. While most studies of long-term synaptic plasticity focus on excitation, inhibitory plasticity may be critical for controlling information processing, memory storage, and overall excitability in neural circuits. Here we examine spike-timing-dependent plasticity (STDP) of inhibitory synapses onto layer 5 neurons in slices of young mouse auditory cortex (P10-25), together with concomitant STDP of excitatory synapses. Pairing pre- and postsynaptic spikes potentiated inhibitory inputs irrespective of precise temporal order within ~10 msec (162.2±15.3% n=34 for short positive spike timing intervals, and 133.7±15.8% n=26 for short negative intervals). This was in contrast to excitatory inputs, which displayed an asymmetrical STDP time window (132±6.2% n=46 for short positive intervals, and 81.9±2.8% n= 30 for negative intervals). These combined synaptic modifications both required NMDA receptor activation, and synergistically acted to normalize the excitatory-inhibitory ratio of events paired together with postsynaptic spiking. Finally, subthreshold events became suprathreshold, and the time window between somatically recorded excitation and inhibition became more precise, suggesting that these combined modifications also enforce spike-timing reliability. These findings demonstrate that cortical inhibitory plasticity requires interactions with co-activated excitatory synapses to properly regulate excitatory-inhibitory balance.

Title: Modulation of homosynaptic and heterosynaptic plasticity by adenosine receptors in rat visual cortex *in vitro*

Authors: ***N. M. BANNON**, M. CHISTIAKOVA, M. VOLGUSHEV;
Dept. of Psychology, Univ. of Connecticut, Storrs, CT

Abstract: In the rat neocortex, pairing presynaptic stimulation with postsynaptic bursts of spikes can lead to plasticity at both paired 'homosynaptic' inputs and at unpaired, 'heterosynaptic' inputs (which experience postsynaptic spiking but not presynaptic activation). Heterosynaptic plasticity can also be induced by intracellular tetanization: bursts of spikes in the postsynaptic cell induced in the absence of presynaptic stimulation (mimicking conditions experienced at unpaired inputs). The outcome of homo- and hetero-synaptic plasticity induced by these protocols is weight-dependent. Synapses with a high release probability (low initial paired-pulse ratio; PPR) tend to depress, while synapses with a low release probability (high PPR) tend to potentiate. Adenosine, which is released by neurons and glia in an activity-dependent manner, is an endogenous regulator of presynaptic release in the neocortex acting primarily via A1 receptors. We asked if manipulation of adenosine receptors can modulate long-term plasticity by altering baseline synaptic strength. To test this, we made *in vitro* whole-cell recordings from layer 2/3 pyramidal neurons in slices of rat visual cortex and studied synaptic responses evoked with stimulating electrodes placed in layer 4. We induced long-term plasticity by intracellular tetanization or a pairing protocol, with postsynaptic activity consisting of three trains (1/min) of ten bursts (1 Hz) of five pulses (5 ms, 100 Hz, 0.4-1.5 nA). We compared outcome of these plasticity protocols under conditions of normal artificial cerebral spinal fluid (control), and with 20uM adenosine or 30nM of the selective A1R antagonist 8-Cyclopentyl-1,3-dipropylxanthine (DPCPX) added to the bath. Adenosine suppressed synaptic responses and increased the baseline PPR, suggesting a reduction in release probability, while antagonism of A1 receptors decreased the PPR. Concurrent with changes in PPR were changes in plastic outcome predicted by the established weight-dependence relationship. In control solution, intracellular tetanization induced potentiation in 21% of cases, and depression in 29% of cases. Under adenosine, 44% of inputs exhibited potentiation and only 19% exhibited depression. Further, blocking endogenous adenosine tone with DPCPX restricted the range of initial synaptic strengths so that the weight-

dependent relationship was no longer observable. Thus, adenosine receptor manipulation modulates the outcome of weight-dependent plasticity by altering the baseline synaptic strength, and an endogenous adenosine tone is responsible for the full range of synaptic strengths which underlie this weight-dependence.

Title: History dependence of calcium dynamics at the larval fruit fly neuromuscular junction

Authors: ***M. CURRAN**, J. KRANS;
Western New England Univ., Springfield, MA

Abstract: Calcium (Ca^{2+}) is an essential ion for both pre- and post-synaptic function. Its actions as a second messenger and its contribution to synaptic plasticity are well described. Less is known about the history dependence of changes in free Ca^{2+} at the neuromuscular junction (NMJ), especially post-synaptically (i.e. muscle). However, previous research has shown that the decay rate of [Ca^{2+}] in muscle attenuates with constant rate synaptic activation over short intervals (< 1 min); Ca^{2+} is available for longer periods. It is also known that basal [Ca^{2+}] increases upon long-term stimulation of muscle (hours to days). Changes in [Ca^{2+}] that occur over intermediate time scales (~minutes) are not well described. Moreover, rarely is the NMJ activated in a physiologically relevant manner (e.g. rhythmic oscillation of synaptic activation). We investigated changes in [Ca^{2+}] in larval bodywall muscles of *D. melanogaster*. We employed a genetically encoded Ca^{2+} sensitive fluorophore (GCaMP5) to estimate the rate of calcium sequestration (decay of free Ca^{2+}) immediately following various stimulus trains. The NMJ was activated by multiple trains of stimuli, each of which was frequency modulated (FM) in a sinusoidal pattern to reflect peristaltic NMJ activation. Immediately after stimulation, [Ca^{2+}] was estimated by computing the change in relative fluorescence of select regions from each video (Stacks function, ImageJ). This decay in fluorescence – 0 to 0.5 s post stimulus train - was well fit by an exponential model (R= 0.98 +/- 0.002 SEM, n=28). We used this metric to evaluate the history dependence of post-synaptic [Ca^{2+}] decay rate. We presented multiple trains of stimuli separated by an inter-train interval (ITI). We hypothesized that history dependence would diminish with longer ITIs. When three stimulus trains were presented, 120 s apart from each other, the rate of fluorescence decay after each stimulus train decreased: stimulus train 2 exhibited 25% less decay than train 1, and train 3 was about 40% less decay than train 1. However, upon presentation of the fourth stimulus train the decay rate returned to it's initial

value (+/-5% decay rate of train 1). This return to initial decay rate upon presentation of the fourth train may represent a loss of history dependence, and was observed in all other ITIs. The time at which this 'reset' , or loss of history dependence, occurred was ~6 min. after initiation of the multi-train stimulus protocol. Interestingly, we also observed that decay rates changed less when ITI was short (ITIs = 45, 90, 120; N= 14) than when ITI was longer (ITIs = 150, 165, 180; N=14; $p < 0.01$), suggesting a maximal dependence upon history at ~ 180 s post stimulus initiation.

Title: Astrocytic glutamate uptake gates spike-timing-dependent plasticity and counteracts spurious plasticity

Authors: S. VALTCHEVA, *L. VENANCE;
Ctr. for Interdisciplinary Res. In Biol. (INSERM 1050/CNRS 7241), Paris, France

Abstract: Astrocytes constitute the major sink for released glutamate. Glutamate uptake is mainly operated by a high-affinity glutamate transporter, the excitatory amino acid transporter type-2 (EAAT2), expressed by astrocytes. Astrocytic glutamate uptake is crucial in shaping synaptic transmission by limiting glutamate spillover and therefore acting on the strength and the timing of synaptic inputs. Spike-timing-dependent plasticity (STDP) is a synaptic Hebbian learning rule, which relies on the precise order and timing of paired activity on either side of the synapse. EAAT2 is highly expressed in the striatum where it controls corticostriatal transmission and short-term plasticity (Goubard et al., 2011). The corticostriatal long-term plasticity provides a fundamental mechanism for the function of the basal ganglia in procedural learning. We investigated the impact of astrocytic glutamate uptake via EAAT2 on corticostriatal STDP. Here we show that proper function of EAAT2 is crucial for the temporal contingency necessary for STDP expression. Indeed, when EAAT2 was transiently blocked, STDP was replaced by another form of synaptic plasticity (GluN2B-mediated LTP) that invades the temporal windows in which STDP do not normally occur. When random patterns of pre- and postsynaptic activity were applied during EAAT2 transient blockade, plasticity could still be induced. It indicates that this form of plasticity depends neither on the timing nor on the order of pre- and postsynaptic activity and could be triggered even by highly uncorrelated events. In addition, this plasticity also occurred for unpaired activity consisting in postsynaptic spiking without presynaptic stimulation. Furthermore, overexpression of EAAT2 by ceftriaxone precluded STDP. We unravel a new role

of astrocytic glutamate uptake in synaptic plasticity. Indeed, astrocytic glutamate uptake favors the time-based coding at corticostriatal synapses over frequency-based and thus operates as a selector of learning rules. The novelty of our findings is that glutamate uptake selects the temporal coding paradigm at corticostriatal synapses. In this context, our report places astrocytes as a key player in the establishment of genuine Hebbian plasticity by gating STDP and in counteracting spurious plasticity.

Title: Optimization of deep brain stimulation parameters using computational models of the basal ganglia with spike-time dependent plasticity

Authors: ***L. GRADO**, M. JOHNSON, T. NETOFF;
Univ. of Minnesota, Minneapolis, MN

Abstract: Deep brain stimulation (DBS) of the basal ganglia is a widely used and effective treatment for patients with medication-refractory Parkinson's disease (PD). Current theories of DBS mechanisms propose that DBS suppresses pathological oscillations (15-35 Hz) that dominate the basal ganglia and filter information flow through the basal ganglia. Importantly, the effects of DBS are not instant, often taking minutes or more before an effect manifests. This time scale suggests DBS may induce a change in network architecture through synaptic plasticity, destabilizing oscillations in the network. In this study, we implemented spike-time dependent plasticity (STDP) mechanisms in a computational network model of the basal ganglia that exhibits emergent pathological 34 Hz oscillations following dopaminergic denervation (Hahn & McIntyre, 2010, J Comput Neurosci). The network model consists of biophysical single compartment models of STN, GPe, and GPi neurons. The neurons are organized into functional columns with excitatory connections from STN to GPe and GPi, and inhibitory connections from GPe to STN and GPi, driven by cortical beta rhythms. STDP was added to each synapse type present in the model: inhibitory-inhibitory, inhibitory-excitatory, and excitatory-inhibitory. For each STDP type, a separate curve was constructed relating the time between pre and post synaptic spike times and synaptic potentiation/depression. Simulations of the network model with STDP following DBS onset showed that these high-beta oscillations dissipate over time, fading out over the course of minutes. The model results also suggest that it may be possible to

automatically tune stimulation settings to take advantage of long-term potentiation and/or long-term depression within the network through reinforcement learning algorithms.

Title: The encoding of episodic memory via spike-timing-dependent plasticity: a computational model

Authors: ***P. THEODONI**, A. ROXIN;
Computat. Neurosci. Group, Ctr. De Recerca Matemàtica, Bellaterra (Barcelona), Spain

Abstract: It is well known that the hippocampus plays a major role in the formation and retrieval of episodic memories. In rodents, hippocampal cells called place-cells exhibit activity which is selective to the spatial location of the animal in a given environment. As the animal traverses the environment, a particular pattern of place-cell activity will be generated, corresponding to the specific trajectory taken. In this way, cells with spatially adjacent place fields will also fire in temporal proximity, potentially leading to changes in their recurrent synaptic weights via spike-timing-dependent plasticity (STDP) mechanisms [1]. Here we model this process with a computational model in which we consider both pairwise and triplet STDP rules in a recurrent network of hippocampal place cells. We study how the exploration of the animal over time can lead to the formation of low-dimensional attracting manifolds in the neuronal network, each one of which encodes the memory of a specific environment. For example, the traversal of a 1D ring-like environment leads, via STDP, to a so-called ring attractor [2]. Once formed, the presence of the attractor can explain the dynamics of so-called hippocampal replay, via spontaneous re-activation of spatially localized bump states [3]. In fact, the temporal compression of replay can be related to the details of the underlying STDP rule. Interestingly, once the memories of several distinct environments have been encoded, the correlation of replay activity with any given memory can be modulated by the level of external input. Title: Potentiation of synaptic connections among cortical neuronal groups via coactivation - an *in vitro* test of Hebb's cell

Authors: *D. ZHANG[1,2], X. YAN[3,2], M.-M. POO[3,2];
[1]Inst. of Neuroscience,Shangai Inst. For Bi, Shanghai, China; [2]CAS center for excllence in brain science, Shanghai, China; [3]Shanghai institutes for biological sciences,CAS, Shanghai, China

Abstract: Hebb proposed in 1949 that correlated firing of neurons strengthens their synaptic connections, and the perceptual memory is formed by establishing specific assembly of neurons with strengthened interconnections. Neuronal signals in the brain are often conveyed among co-activated neuronal groups rather than single neurons. We have tested the extended form of Hebb's cell assemble hypothesis by studying potentiation of interconnections among groups of cortical neurons in anesthetized mice. Cortical layer 2/3 pyramidal neurons were transfected with associated adenovirus coding for channelrhodopsin2 (ChR2), and coactivation of several groups of neurons was accomplished by simultaneous application of laser spots at multiple cortical locations. Laser spot-induced neuronal firing was detected by multiunit recording at co-activated locations to determine the strength of interconnections among coactivated neuronal groups. We found that coactivation induced persistent potentiation of connections among neuronal groups that depended on activation of N-methyl-D-aspartic acid (NMDA) subtype of glutamate receptors, consistent with activity-induced long-term potentiation (LTP) between individual neurons. This was confirmed by *in vivo* whole-cell recording of laser-evoked synaptic potentials in cortical neurons. Further studies showed that this potentiation was saturable and depended on the pattern of co-activation, with burst stimulation more effective than tonic stimulation at the same total number of stimuli. Similar coactivation-induced potentiation was observed in both visual and motor cortices. These results support the idea that Hebb's hypothesis could be applied to the assembly of neuronal groups by correlated activity, a situation more relevant to conditions of signal processing in the brain.

Title: An interplay between homosynaptic and heterosynaptic plasticity enforces synaptic competition and allows re-learning

Authors: *M. A. VOLGUSHEV[1], M. CHISTIAKOVA[1], V. ILIN[2], R. GOZ[1], J.-Y. CHEN[3], M. BAZHENOV[3];
[1]Dept Psychol, Univ. Connecticut, Storrs Manfld, CT; [2]Univ. Connecticut, Storrs, CT; [3]Univ. of California, Riverside, CA

Abstract: Homosynaptic Hebbian type plasticity provides a cellular mechanism of learning and refinement of connectivity during development in a variety of biological systems. However, Hebbian-type learning rules impose positive feedback on synaptic weight changes, and make learning systems with plastic synapses prone to runaway dynamics. An additional mechanism is necessary for preventing the runaway dynamics of synaptic weights and activity. We propose that this homeostatic role is played by heterosynaptic plasticity - changes that do not require activation of a pre-synapse, and thus can occur at synapses which were not active during the induction of homosynaptic plasticity. Here we show that in layer 2/3 pyramidal neurons in slices from rat visual cortex induction of homosynaptic plasticity with STDP-protocol is accompanied by heterosynaptic changes in un-paired synapses. The direction and magnitude of heterosynaptic plasticity correlated with initial paired-pulse ratio (PPR): inputs with initially high PPR tended to potentiate, while inputs with initially low PPR tended to depress or do not change. Because PPR is inversely related to release probability, this correlation suggests that heterosynaptic plasticity had a normalizing effect on synaptic strength. Using computer simulations we demonstrate that heterosynaptic plasticity with the observed experimental properties can indeed effectively prevent runaway dynamics of synaptic weights imposed by STDP learning rules. We further show that this form of heterosynaptic plasticity enhances synaptic competition in a model neuron and facilitates segregation of weights of synapses which differ by details of plasticity rules, frequency of presynaptic firing and level of correlation of activity of presynaptic neurons. Because heterosynaptic plasticity prevents saturation of synaptic weights but keeps them in the operation range, it also enables learning of new patterns on the background of existing memories (distributions of synaptic weights). We conclude that heterosynaptic plasticity is complementary to homosynaptic Hebbian-type plasticity and represents a necessary cellular component for homeostatic regulation of synaptic weights and maintaining the ability of neurons with plastic synapses for continuing learning.

Title: Presynaptic induction and expression of spike timing-dependent long-term depression in the CA1 region of the hippocampus

Authors: *A. RODRIGUEZ-MORENO[1], Y. ANDRADE-TALAVERA[1], P. DUQUE-FERIA[1], O. PAULSEN[2];
[1]Univ. Pablo de Olavide, Seville, Spain; [2]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Spike timing-dependent plasticity (STDP) is a model of synaptic plasticity that may underlie learning and memory. The aim of our research was to investigate the signalling pathway for the induction of spike timing-dependent long-term depression (t-LTD) in the hippocampus. Whole-cell recordings were made from individual CA1 cells in hippocampal slices prepared from P12-P18 mice. Two independent afferent pathways (Schaffer collaterals) were activated alternately by extracellular stimulation. We have previously shown in the hippocampus that a post-before-pre pairing protocol (pairing postsynaptic action potentials with EPSPs at 0.2 Hz) produced robust input-specific t-LTD and that the induction of this form of LTD was completely blocked by D-AP5, by the broad spectrum mGluR antagonist MCPG, as well as by group I mGluRs selective antagonists, phospholipase C (PLC) inhibitors and by the CB1 receptor antagonist AM251. The blockade of postsynaptic NMDARs by application of MK-801 (1 mM) through the patch pipette did not affect the induction of t-LTD (76 ± 8 %, n = 12), but abolished the induction of t-LTP induced by a pre-before-post pairing protocol (104 ± 7 %, n = 9, vs 152 ± 8 % in control experiments, n = 14). We have carried out pre-post and post-pre pairings in the same cell treated with MK-801. t-LTP was not observed after pre-post pairing (103 ± 6 %, n = 6, but subsequent post-pre pairing in the same pathway induced robust t-LTD (71± 7 %, n = 6). We have also determined that this t-LTD requires astroglial signalling as it is completely prevented by loading astrocytes with 20 mM BAPTA (129 ± 7 %, n = 5 vs interleaved slices 54 ± 6 %, n = 5). Fluctuation, failures and paired-pulse ratios analysis all indicated a presynaptic locus of expression of this t-LTD. These results show that whereas t-LTP induction depends on postsynaptic NMDARs, the induction of t-LTD is independent of postsynaptic activation of

NMDARs and likely requires presynaptic NMDA receptors. The results suggest that the induction and expression of t-LTD at CA3-CA1 synapses are presynaptic.

Title: $A\beta_{1\text{-}42}$ impairs metabotropic glutamate receptor-gated spike-timing dependent long-term potentiation of hippocampal CA3-CA1 synapse

Authors: ***J. LEE**, J. KWAG;
Dept. of Brain and Cognitive Engin., Korea Univ., Seoul, Korea, Republic of

Abstract: Alzheimer's disease is a neurodegenerative disease causing memory deficit, characterized by abnormal accumulation of amyloid-β oligomers ($A\beta_{1\text{-}42}$) in the hippocampus. We have recently reported that $A\beta_{1\text{-}42}$ impairs the induction of spike-timing dependent long-term potentiation (tLTP), which is considered a physiologically more realistic way to induce hippocampal LTP. Activation of metabotropic glutamate receptors (mGluR) is known to gate and enhance the hippocampal tLTP at the CA3-CA1 excitatory synapse but the effect of $A\beta_{1\text{-}42}$ on mGluR-gated tLTP is unclear. Therefore we investigated the effect of $A\beta_{1\text{-}42}$ on induction of mGluR-gated tLTP using whole-cell patch-clamp *in vitro*. tLTP was induced by pairing presynaptic CA3 input with postsynaptic CA1 pyramidal cell spike with a time window of +10 ms, 200 times at 1 Hz. Hippocampal slices were incubated in artificial cerebrospinal fluid (ACSF) containing 200 nM $A\beta_{1\text{-}42}$ or 0.02% dimethyl sulfoxide for 20 minutes prior to pairing for $A\beta_{1\text{-}42}$ or vehicle experiments, respectively. Group I mGluR agonist, dihydroxyphenylglycine (DHPG; 50 μM), or mGluR5 blocker, 2-methyl-6-(phenylethynyl)pyridine (MPEP; 10 μM) were dissolved in ACSF to modulate the activation of mGluR. tLTP induction protocol at CA3-CA1 synapse in the presence of DHPG could induce mGluR-gated tLTP reliably in the test pathway in vehicle experiment while mGluR-mediated long-term depression (LTD) was induced in the control pathway (test: 157 ± 25%, control: 79 ± 15%, paired *t*-test, $p < 0.05$, n = 5). In $A\beta_{1\text{-}42}$-treated slices, the induction of mGluR-gated tLTP failed in test pathway but LTD was induced in both the test and control pathways (test: 60 ± 15%, control: 66 ± 13%, paired *t*-test, $p = 0.72$, n = 6). Interestingly, stronger mGluR-mediated LTD was induced by $A\beta_{1\text{-}42}$ (vehicle control: 79 ± 15%, $A\beta_{1\text{-}42}$ control: 66 ± 13%). These results suggest that $A\beta_{1\text{-}42}$ impairs mGluR-gated tLTP

and enhances mGluR-mediated LTD. To confirm the role of mGluR, we repeated the experiments with MPEP. MPEP abolished both the mGluR-gated tLTP in the test pathway and mGluR-mediated LTD in the control pathway in vehicle experiments (test: 98 ± 34%, control: 97 ± 27%, paired *t*-test, $p = 0.96$, n = 6) while $A\beta_{1\text{-}42}$ induced strong LTD in both pathways (test: 24 ± 13%, control: 20 ± 7%, paired *t*-test, $p = 0.72$, n = 5). These results suggest that mGluR5 mediates the mGluR-gated tLTP induction and that $A\beta_{1\text{-}42}$ facilitates LTD. We demonstrate that $A\beta_{1\text{-}42}$ disrupts the induction of mGluR-gated tLTP at hippocampal CA3-CA1 synapse and enhances LTD induction. Further investigation on the interaction between $A\beta_{1\text{-}42}$ and mGluR is needed to better understand the $A\beta_{1\text{-}42}$-mediated impairment of synaptic plasticity.

Title: Retroactive effect of dopamine on spike timing-dependent plasticity

Authors: *Z. BRZOSKO, W. SCHULTZ, O. PAULSEN;
Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Spike timing-dependent plasticity (STDP) is a physiologically relevant form of Hebbian learning in which the order and precise timing of presynaptic and postsynaptic spikes determine the sign of synaptic change: pre–before-post spike pairings induce timing-dependent long-term potentiation (t-LTP) whereas post–before-pre pairings induce long-term depression (t-LTD). The quantitative rules of STDP are influenced by neuromodulators, including dopamine (DA). In light of the potential role of DA in reward learning, here we examined whether DA modulates STDP not only when applied during, but also – more importantly - when applied *after* the pairing event. The slope of excitatory post-synaptic potentials (EPSPs), evoked by extracellular stimulation of Schaffer-collateral-CA1 pathway, was monitored during whole-cell recordings of CA1 pyramidal cells in mouse hippocampal slices (postnatal days 12-18). Plasticity was induced by a pairing protocol that involved 100 pairings of a single postsynaptic spike and a single presynaptic EPSP at 0.2 Hz. In accordance with previous findings[1], we found that the presence of DA *during* the coordinated spiking activity widens the spike time window for induction of t-LTP. Crucially, we also found that DA applied *after* the post-before-pre pairing protocol (with the spike preceding the EPSP by 20 ms) converts t-LTD into t-LTP. This implies that DA can act retroactively to allow negative spike pairings to induce t-LTP. This effect of DA was activity-dependent, demonstrating that DA is capable of acting specifically on active inputs. In addition, the observed DA-induced conversion of t-LTD into t-LTP depends on the timing of

application following the post-before-pre protocol. Delayed application of DA (10 or 30 minutes after t-LTD pairing protocol) failed to convert t-LTD into t-LTP, suggesting that DA can convert t-LTD into t-LTP when acting within a short time window following the induction protocol. Finally, we explored possible mechanisms underlying the DA-induced conversion of t-LTD into t-LTP and showed that this effect is mediated in part through the activation of the cAMP/PKA cascade and requires synaptic NMDA receptors. Together our work demonstrates a retroactive effect of DA on STDP. This supports the concept of a slowly decaying synaptic *eligibility trace*, which is committed to memory by the occurrence of reward. It therefore provides a possible mechanism for associating specific experiences with behaviorally distant, rewarding outcomes.

Title: Stable assembly training and reinforcement through spike timing

Authors: ***G. K. OCKER**[1], B. DOIRON[2];
[1]Neurosci., [2]Mathematics, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Spike timing-dependent plasticity (STDP) leverages the temporal correlations between pre- and post-synaptic activity to shape synaptic strengths. It is a candidate mechanism for the formation of Hebbian assemblies, linking network structure to stimulus representation. Theories explaining the emergence of such macroscopic structure have either 1) relied on synaptic plasticity driven primarily by neurons' firing rates rather than precise spike timing or 2) have neglected internally generated spike-time correlations. We have recently developed a theory for spike timing-dependent plasticity in recurrent networks. This theory accounts for plasticity driven by spike-time correlations generated both by external inputs and by intra-network connectivity. We describe macroscopic structure at the level of average connection strengths while taking into account bidirectional connectivity between neurons. Using this theory we show that internally generated spike-time correlations can reinforce a diversity of macroscopic structures, including homogenous, clustered and feedforward architectures. External inputs can promote any of these, depending on their spatial profile. Furthermore, we study how rate-based homeostatis rules can stabilize the learned network structures and spiking activity. Such homeostatic rules control individual neurons'

firing rates. In contrast to previous studies, our network exhibits homogenous firing rates so that only precise spike-time correlations control plasticity, separating mechanisms supporting the formation of network structure from those responsible for homeostatic rate control.

Title: Toward a unifying plasticity model in extended dendrites

Authors: *C. EBNER[1,2], C. CLOPATH[3], P. JEDLICKA[4], H. CUNTZ[1,2];
[1]Ernst Strüngmann Inst. (ESI) for Neurosci., Frankfurt, Germany; [2]Frankfurt Inst. for Advanced Studies, Frankfurt, Germany; [3]Bioengineering Dept., Imperial Col. London, London, United Kingdom; [4]Inst. for Clin. Neuroanatomy, Goethe Univ. Frankfurt am Main, Frankfurt, Germany

Abstract: A wide variety of stimulation protocols have unraveled the complex relations governing synaptic plasticity. Neuronal firing rates, the precise timing of pre- and postsynaptic spikes and the location of synaptic inputs along the dendritic tree are just a few examples that modulate synaptic plasticity. Several computational models of synaptic plasticity exist that reproduce different aspects of the data obtained in these experiments. Here, we adapt a phenomenological voltage-based spike timing-dependent plasticity (STDP) rule (1) and combine it with a detailed compartmental model of a L5 pyramidal cell (2). The aim of this study was to investigate the mechanisms of plasticity in extended dendritic tree models that account for the exact attenuation of backpropagating action potentials and the genesis of dendritic calcium spikes. Our hypothesis based on simulations in (1) was that one unifying plasticity rule might exist that reconciles all stimulation procedures. We show that, in combination with the realistic dendritic morphology, the same STDP rule is able to account for a large number of experiments studying the dependence of synaptic plasticity on stimulation frequency, synapse location and stimulation timing. Consistent with experimental data, we find that low-frequency pairing using bursts of five pre- and postsynaptic spikes resulted in long-term potentiation (LTP) at positive (pre before post) and in long-term depression (LTD) at negative (post before pre) timings,

consistent with classical STDP assumptions, while the LTD component increases with distance from the soma (3, 4). We conclude that the voltage-based STDP rule (1) which does not vary with dendritic location is able to account for the observed LTP/LTD dendritic switch with distance from the soma (4). 1. C. Title: GABA driven circuit formation through heterosynaptic spike-timing-dependent plasticity

Authors: *N. HIRATANI[1,2], T. FUKAI[1];
[1]RIKEN Brain Sci. Inst., Saitama, Japan; [2]Dept. of Complexity Sci. and Engin., The Univ. of Tokyo, Tokyo, Japan

Abstract: A cortical neuron receives thousands of synaptic inputs through its dendrite, and the spatial distribution of the synaptic inputs on the dendrite is thought to significantly influence neural computation. Recent experimental results revealed that the relative spike timings among neighboring synapses on a dendritic branch have significant influence on changes in synaptic efficiency of these synapses, in addition to the spike time difference between presynaptic and postsynaptic neurons. Especially, the timing of GABAergic input exerts a great impact on synaptic plasticity at nearby Glutamatergic synapses. Here, we derived a simple yet biologically plausible computational model of this heterosynaptic form of spike-timing-dependent plasticity (h-STDP), by extending a previous model of homosynapic STDP, and investigated its functional role. In particular, we explored its contribution to dendritic computation. The model reproduces the several effects of h-STDP observed in the hippocampal CA1 area and the striatum of rodents. The model further predicts that h-STDP causes the detailed balance between excitatory and inhibitory inputs on a dendritic branch to enrich information capacity of a neuron through dendritic computation.

Title: The NMDA-spike as a fundamental mechanism in timing-dependent plasticity at hippocampal CA3 recurrent synapses

Authors: *F. BRANDALISE[1], S. CARTA[2], F. HELMCHEN[2], U. GERBER[2];
[1]Univerity of Zurich, Brain Res. Inst., Zurich, Switzerland; [2]Brain Res. Inst., Univ. of Zurich, Zurich, Switzerland

Abstract: Hippocampal CA3 pyramidal cells receive thousands of inputs onto their dendrites. It was previously shown that under certain conditions these inputs can trigger active integration leading to dendritic spikes, thereby enhancing the computational power of an individual neuron (Major et al. 2013). In CA3 pyramidal cells mainly two types of dendritic spikes have been described: the sodium dendritic spike and the NMDA spike (Kim et al. 2012; Makara and Magee 2013). As previously shown both *in vitro* (Golding et al. 2002; Brandalise and Gerber 2014) and *in vivo* (Gambino et al. 2014; Chicon and Gan 2015) dendritic spikes can induce synaptic plasticity. However, it is unclear whether the NMDA-spike is the ultimate effector in timing-dependent plasticity, as previously suggested (Lisman and Spruston 2005; Schiess et al. 2012) or if it represents a mechanism distinct from other forms of associative plasticity, e.g. spike timing dependent plasticity (STDP). We performed experiments to search for a causal relationship between the occurrence of NMDA spikes and the induction of LTP. We therefore obtained simultaneous double patch recordings from the soma and a dendrite of a CA3 pyramidal cell and applied an input-timing-dependent protocol (ITDP) as previously described (Brandalise and Gerber 2014). Focal hyperpolarization of a specific branch achieved through the dendritic patch pipette prevented the generation of an NMDA spike in those cases where the majority of the stimulated inputs targeted that same branch. Consequently LTP was not induced, consistent with a causal relation between the dendritic NMDA spike and synaptic plasticity. In contrast, in experiments where the stimulated inputs targeted dendritic branches other than the recorded branch, focal hyperpolarization through the patch pipette did not block LTP induction. We then confirmed the importance of extrasynaptic NMDA receptors in generating dendritic spikes (Chalifoux and Carter 2011) using a specific blocker for glutamate re-uptake (TBOA 70 μM). In this case, weak pairing stimulation that in control conditions failed to induce supralinear events and consequently did not induce LTP, evoked an NMDA spike during TBOA perfusion and CA3 EPSPs recurrent were potentiated. In a third set of experiments combining electrophysiological recording with calcium imaging we confirmed that subthreshold pairing of a CA3 EPSP

followed by an MF EPSP after 10 ms (ITDP) can evoke NMDA spikes manifesting as local, branch specific calcium transients. In conclusion our data support a mechanism whereby locally evoked NMDA spikes at excitatory dendritic synapses suffice to generate STDP.

Title: Optogenetic control of stimulus and background activity in spike-triplet and theta-burst plasticity in acute hippocampal slices

Authors: ***A. BHATIA**, U. S. BHALLA;
Neurobio., Natl. Ctr. For Biol. Sci. (NCBS), Bangalore, India

Abstract: We wish to understand plasticity mechanisms in the context of more natural stimuli and synaptic input. We addressed two aspects of this: the nature of the stimulus, and the presence of background activity. Of the known plasticity paradigms, Spike Timing Dependent Plasticity (STDP) seems physiologically more plausible. Unlike initial experiments done in hippocampal cultures (Bi and Poo, 1998), STDP has been shown not to elicit the same changes in acute hippocampal slices (Pike et al., 1999)(Buchanan and Mellor, 2007). This opens the possibility of some other rule existing in this system. In the current study we have examined spike triplets in adult mouse acute hippocampal slices. We further examined the influence of ongoing background activity on plasticity, using optogenetic stimulation to deliver pseudo-random input patterns as background to theta-burst stimulation. EPSPs were recorded from CA1 cells while optically stimulating CA3 region of CA3-cre mice injected with Channlelrhodopsin2(ChR2)-lox virus. Using optical stimuli makes the STDP and background activity specific to the CA3-CA1 pathway, allows us to titrate the number of inputs by scaling spot size and intensity and present rapidly varying patterned stimuli from a projector. We observed ~60% potentiation of EPSPs in case of post-pre-post triplet where the post spikes were separated by 10ms and pre spike happened between 5-7ms. 60 pairings were done in the induction protocol consisting of trains of 5 triplets at 5Hz, repeated 12 times at 0.1Hz. No change was seen when only post synaptic spike pairs were presented. We also observed robust theta-burst LTP in the presence of noisy background synaptic input which simulates background activity in awake animals. Our results show that spike triplets are able to induce plasticity in hippocampal slices, extending previous work in hippocampal cultures (Wang et al., 2005). Further, we show that plasticity using

conventional protocols can be elicited in the background of random activity. Together this preparation facilitates the investigation of synaptic plasticity in more in-vivo-like activity contexts.

Authors: ***H. KWON**[1,2], T. KIM[1,3];
[1]Max Planck Florida Inst., Jupiter, FL; [2]Max Planck Inst. of Neurobio., Martinsried, Germany; [3]MIT, Boston, MA

Abstract: During cortical circuit development in the mammalian brain, groups of excitatory neurons receiving similar sensory information form microcircuits. However, cellular mechanisms underlying cortical microcircuit development remain poorly understood. Here we implemented combined two-photon imaging and photolysis *in vivo* to monitor and manipulate neural activities in order to study processes underlying activity-dependent circuit changes. We found that repeated triggering of spike trains in a randomly chosen group of layer 2/3 pyramidal neurons in somatosensory cortex increased the probability that the members of this group exhibited correlated firing patterns in a long-term manner. The formation of this functionally correlated group of neurons was dependent on the time interval between spike trains, NMDA receptor, CaMKII activation. In addition, repetitive sequential trains of firing from a subset of neurons made functional circuit assembly uneven. Thus, our results demonstrate that the formation of functional microcircuits requires wide-ranging neural connectivity change whose directionality is essentially non-random.

Title: Examining the region-specific changes in plasticity and excitability in medial prefrontal cortex

Authors: B. OWEN, *M. BENVENISTE;
Neurosci. Inst., Morehouse Sch. of Med., Atlanta, GA

Abstract: The medial prefrontal cortex (mPFC), composed of the prelimbic (PL) and infralimbic (IL) areas, is a region associated with both memory and depression. These regions form connections with the hippocampus, amygdala, and raphe nucleus, and the PL and IL areas were observed to undergo region-specific changes in excitability. While others have examined the excitability changes within a specific network (i.e. mPFC-amygdala, hippocampus-mPFC) with regards to memory and fear conditioning, little work has been done to examine how serotonin, whose signaling is reduced in depressive states, modulates these network changes *in vitro*. Here, we examine the plasticity changes in the connections between layer V cells in the PL and IL areas using protocols which can induce long-term potentiation (LTP) and changes in EPSP-spike (E-S) coupling. Whole-cell current clamp recordings have been made from 300 μm brain slices containing the PL and IL areas from 8 - 12-week-old male C57Bl/6 mice. EPSPs were evoked by placing a stimulating electrode in layer V approximately 100 - 300 μm from the recorded cell. Preliminary data indicates that IL neurons undergo E-S potentiation following theta burst stimulation but do not show LTP. Yet, changes in the rheobase measured 30 minutes after the induction protocol were not observed. In contrast, PL neurons exhibit LTP but do not undergo E-S potentiation. These results lay the groundwork for examination of how serotonin input could influence neuronal plasticity, and yield insight into how depressive states influence memory acquisition.

Title: Cooperative coincidence detectors control mixed pre- and postsynaptic expression of spike-timing dependent plasticity at the cerebellar input stage

Authors: *F. PRESTORI[1], M. SGRITTA[1,2], E. D'ANGELO[1,3];
[1]Dept of Brain and Behavioral Sci., Univ. of Pavia, Pavia, Italy; [2]EBRI, Rome, Italy; [3]Brain Connectivity Ctr., IRCCS C.Mondino, Pavia, Italy

Abstract: Excitatory central synapses show a special form of persistent change, spike-timing dependent plasticity (STDP), in which long-term potentiation and depression (LTP and LTD) are related to the relative phase of occurrence of EPSPs and action potentials. At the cerebellar mossy fiber - granule cell synapse, LTP and LTD have been previously related to the duration and frequency of input busts but their EPSP-spike phase sensitivity was unknown. Here we show that EPSP-spike pairing on the 6Hz band can reliably induce STDP in this synapse. LTP was confined to the +5/+20 ms time-window, while LTD occurred at longer positive phases and at negative phases revealing a high temporal precision for LTP induction. STDP as a whole required NMDA receptor activation and calcium release from intracellular stores, but LTP also required mGluR activation and higher calcium levels. Importantly, STDP was 2-3 times larger than any forms of long-term synaptic plasticity previously reported at this same synapse (LTP:+61.4%± 20.2%, n=5, t<0.05; LTD:-50.6%±12.6%, n=5, t<0.05). While LTP and LTD induced by modulated burst duration and frequency were uniquely expressed by a release probability change, STDP showed a mixed pre- and postsynaptic expression attested by consistent changes in EPSC amplitude and coefficient of variation, EPSC paired-pulse ratio (PPR; LTP:-32.3%± 4.9%, n=5, t<0.001; LTD:+21.0%±14.9%, n=5, t<0.05) and minis amplitude (LTP:+23.4%± 9.9%, n=5, t<0.05; LTD:-16.1%±5.2%, n=5, t<0.05) and frequency (LTP:+18.1%± 8.7%, n=5, t<0.05; LTD:-30.7%±8.6%, n=5, t<0.05). Therefore STDP appears a powerful form of plasticity that binds LTP to the mossy fiber burst phase on the millisecond time-scale and could control granular layer functions binding it tightly to ongoing brain temporal dynamics.

Title: The interplay between exercise and dietary fat modulates myelinogenesis in the adult spinal cord

Authors: *I. A. SCARISBRICK[1], H. YOON[1], A. KLEVEN[1], P. STARSKI[1], A. PAULSEN[1], J. WU[1], L. KLEPPE[1], Z. YING[2], F. GOMEZ-PINILLA[2];
[1]Physical Med. and Rehabil., Mayo Clin., Rochester, MN; [2]Integrative Biol. and Physiol., UCLA, Los Angeles, CA

Abstract: Proper myelination is crucial for transmission of information and myelination is likely modulated by the interaction between lipid components and axonal activity. Here we test the hypothesis that dietary saturated fatty acids alone, or in combination with exercise training, can influence myelin homeostasis in the adult spinal cord. To test this hypothesis, 9 week old adult C57BL6/J male mice were fed a diet enriched in fat (60% total fat, 20% from saturated fat) for a period of 7 weeks, provided access to free wheel running for a corresponding period, or provided access to both interventions in combination. We used quantitative Western blot, real time PCR and immunohistochemical approaches to quantify myelin proteins, oligodendrocyte progenitor cells (OPCs), mature oligodendrocytes, associated growth factor systems, and signaling cascades in the lumbosacral spinal cord of mice under these conditions compared to those with a sedentary lifestyle. Results demonstrate that the abundance of the major myelin membrane proteins, proteolipid (PLP) and myelin basic protein (MBP), as well as NG2, a marker for OPCs, were significantly elevated in the spinal cord after 7 weeks of exercise training in combination with high dietary saturated fats. Expression of MBP and PLP RNA, as well that for Myrf1, a transcription factor driving oligodendrocyte differentiation, were also differentially increased with exercise and/or high dietary saturated fats. In conjunction with these findings however, consumption of a high fat diet alone resulted in a reduction in NG2 and Nkx2.2-OPCs present in the spinal cord white matter of adult mice. A parallel decrease in mature CC-1+-oligodendroglia and those labeled for the pan-OPC and oligodendrocyte marker Olig2 was also seen with consumption of high fat in the context of a sedentary lifestyle. Of potential clinical significance, seven weeks of exercise training completely reversed the deleterious effects of a high fat diet on OPC and oligodendrocyte numbers. Exercise and dietary fatty acid-induced changes in myelinogenesis occurred in parallel with increases in the expression of spinal cord IGF-1 and IGF-1 receptor. Parallel increases in phosphorylated-AKT, a signaling intermediate involved in the myelinogenic effects of IGF-1, was also observed in response to consumption of high dietary saturated fat alone or in combination with exercise. Together these data support a model in which exercise in combination with high dietary saturated fatty acids unleashes a pro-myelination program that supports myelin homeostasis in the adult spinal cord. These results are crucial for the design of rehabilitative programs to enhance CNS function.

Title: Lactate, a possible metabolite for remyelination by oligodendrocyte progenitor cells

Authors: *Y. ICHIHARA, T. DOI, Y. RYU, M. NAGAO, Y. SAWADA, T. OGATA;
Natl. Rehabil. Ctr. For Persons With Disabilities, Tokorozawa, Saitama, Japan

Abstract: Oligodendrocyte progenitor cells (OPCs) go through remarkable morphological changes to become mature oligodendrocytes, providing thick myelin sheaths to multiple axons. This process is thought to need extraordinary metabolic demands. Lactate has been reported to be used in primary oligodendrocytes as metabolites and rescue hypomyelination induced by low glucose in organotypic slice cultures. Although glycogen in astrocytes is regarded as the source of lactate in neural tissue, lactate usage derived from glycogen in oligodendrocytes *in vivo* is unclear. Therefore we tested the effect of 1,4-dideoxy-1,4-imino-d-arabinitol (DAB), inhibitor of glycogen phosphorylase, glycogen catabolic enzyme, in mice reversible demyelination model, named cuprizone model. A diet containing 0.2% cuprizone was given to mice to induce demyelination particularly in corpus callosum. After six weeks, when the diet was changed to normal chow, we started the administration of either DAB or saline (control) to the mice intracerebroventricularly for two weeks. From histological analysis, we found that the number of Glutathione S-transferase (GST)-π positive cells, indicating mature oligodendrocytes, was significantly decreased in corpus callosum of DAB injected mice compared to saline injected mice. To further examine the possibility whether lactate derived from glycogen affects proliferation or maturation of OPCs, we cultured primary OPCs and tested the effect of lactate. In high glucose condition (36.6 mM), myelin basic protein (MBP), mature oligodendrocyte marker, mRNA level was increased by addition of lactate (10 mM). The ratio of MBP positive cells was also increased by lacate. But BrdU positive cell ratio, proliferating cell marker, was not changed by lactate addition in high glucose condition. On the other hand, 10 mM lactate rescued decreased BrdU positive cell ratio in low glucose condition (0.4 mM). These results suggest that oligodendrocytes use metabolites derived from glycogen for remyelination *in vivo* and lactate might be used for proliferation and maturation in oligodendrocytes.

Title: Cathepsin D deficiency delays CNS myelination by inhibiting Proteolipid Protein trafficking from late endosome / lysosome to plasma membrane

Authors: *D. GUO[1], Y. LIU[2], L. XIAO[1], C. HE[3], S. DUAN[2];
[1]Navy Gen. Hosp., Beijing, China; [2]institute of neuroscience, zhejiang university, hangzhou, China; [3]department of neurobiology, second military medical university, shanghai, China

Abstract: Cathepsin D (CathD) deficiencies are fatal neurological diseases that in human infants, in sheep and in mice are characterized by extreme loss of neurons and myelin. However, how loss of CathD leads to the defect in myelination is still unclear. In the present study, we found surprisingly a selective dysmyelination in CNS but normal myelination in PNS of CathD -/- mice. Different from other proteins in myelin (MBP, MAG, et al), PLP is the most abundant protein present in CNS myelin of higher vertebrates, and only found in CNS myelin. PLP plays an important role in the formation and/or maintenance of multilayer myelin. Thus, we further examined intensity of the Fluoromyelin Green and PLP staining in corpus callosum from CathD -/- mice at P7, P14 and P24, we found that there was less extent increase in the level of Fluoromyelin Green staining and PLP expression with the growth of age, and compared with that in CathD+/+ mice, the extent of increasion in PLP expression was significantly delayed, and interestingly,PLP accumulated around nucleus. We also showed that the number of DAPI+ cells, oligodendrocyte lineage cells (olig2+) and postmitotic oligodendrocytes (CC1+) in corpus callosum from CathD -/- mice was significantly lower than from CathD -/- mice between P14 and P24, but there was no difference at P7, and the number of OPCs (NG2+) was normal, suggesting that CathD deficiency only lead to the delay of myelination and oligodendrocyte maturation. To further investigate the mechanisms of CathD deficiency in dysmyelination and defect of oligodendrocyte maturation, we used rat OPCs cultures with CathD antagonist, CathD-/- mouse OPC cultures, we found that CathD, PLP, and VAMP-7 could bind with each other, and CathD deficiency could induce the defect in the trafficking of PLP from LEs/Ls to the plasma membrane of oligodendrocyte, and more PLP gathered in LEs/Ls around nucleus. In addition, VAMP-7 was involved in the process, and delayed the MBP+ oligodendrocytes maturation and myelination in CNS. Together, our findings indicate that CathD may have important significance in the oligodendrocyte maturation and myelination of CNS mediated by protein-protein interation but not by proteolysis.

Title: Oligodendroglial expression of the inward-rectifying potassium channel Kir4.1 is not required for oligodendrocyte generation, survival, or myelination

Authors: *V. A. LARSON[1], A. AGARWAL[1], J. E. RASH[2], D. E. BERGLES[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]Dept. of Biomed. Sci., Colorado State Univ., Fort Collins, CO

Abstract: Oligodendrocytes are generated throughout life from a proliferative population of oligodendrocyte progenitor cells (OPCs). Both OPCs and oligodendrocytes have a highly negative resting potential due to their high resting potassium conductance. The inward rectifier potassium channel Kir4.1 is broadly expressed by CNS glia and is believed to be important in setting the resting membrane potential of these cells. Complete and glia-specific Kir4.1 knockout animals display a profound neurological phenotype that includes severe white matter pathology. This finding has led to the hypothesis that Kir4.1 is critical for the survival of oligodendroglia. However, cell type-specific manipulations of this channel have not been performed, and thus it is not known whether the defects observed in the knockout mice are due to cell-autonomous mechanisms in oligodendroglia, or to interactions among oligodendroglia and astrocytes. Here, we examined the role of Kir4.1 in oligodendroglia using conditional knockout (cKO) mouse lines in which Kir4.1 is selectively removed from OPCs or mature oligodendrocytes. PDGFRα-CreERxRosa-YFPxKir4.1f/f mice were given 4-hydroxytamoxifen at postnatal day 21, corresponding to the peak period of myelination in the brain, and analyzed at postnatal day 35. Whole-cell patch clamp recordings in the cortex, hippocampus, and corpus callosum showed that Kir4.1 cKO OPCs had significantly increased membrane resistance and less negative resting membrane potential than control OPCs. Despite these changes, BrdU incorporation studies and genetic fate tracing showed no change in the proliferation or differentiation of OPCs *in vivo* during this critical time period. We also examined the CNP-CrexKir4.1f/f and MOG-iCrexKir4.1f/f lines, in which Kir4.1 is selectively deleted from mature oligodendrocytes. We found no change in the number of oligodendrocytes, and no deficit in the formation of myelin or structure of myelin in these animals. These results demonstrate that Kir4.1 is not required for OPC proliferation, oligodendrogenesis, oligodendrocyte survival, or myelination. The hypomyelination phenotype observed in Kir4.1 knockout mice may therefore occur secondary to alterations in astrocytes and impaired astrocyte-oligodendrocyte communication.

Title: Dynamic and local remodeling of axon caliber during initial myelin ensheathment

Authors: A. J. TREICHEL, M. M. MARTELL, A. J. KAISER, A. G. TRUDEL, B. B. DUXBURY, *J. H. HINES;
Biol. Dept., Winona State Univ., Winona, MN

Abstract: A key feature of vertebrate neural development is the ensheathment of select axons with myelin. At the onset of myelination, oligodendrocytes extend exploratory membranous processes that sample numerous axons in anticipation of initial axon wrapping. How initial axon wrapping is restricted to specific axons is an important gap in our knowledge. In previous studies, we learned that activity-dependent secretion from axons biases axon selection by stabilizing nascent sheaths formed on select axons. To test whether activity also restricts which axons are initially wrapped, we first identified transgenic reporters labeling various myelin-fated and unmyelinated axon sub-types in the zebrafish spinal cord. Pharmacologic and genetic manipulations of neuronal activity did not cause ectopic myelination of axons that are normally unmyelinated, suggesting that activity-independent mechanisms must specify which axons are initially wrapped. We have begun to test the hypothesis that axon choice is determined by an axon's caliber immediately prior to initial wrapping. Supporting this hypothesis, average diameters of myelin-fated axon-sub-types were larger than unmyelinated axon sub-types. Also consistent with the hypothesis, reticulospinal axons that were wrapped first had larger average diameters than those not initially wrapped. However, a comparison of multiple myelin-fated axon types showed that the order of initial wrapping did not follow the order predicted by axon calibers. Rather than overall axon caliber, our findings support the notion that local and transient changes in axon caliber direct the initiation of axon wrapping. Time-lapse confocal microscopy revealed that axon morphology was highly dynamic both before and during initial wrapping. Short axon segments underwent brief and localized radial growth that was associated with interactions with oligodendrocyte membrane processes. Axon diameters at sites of initial wrapping were greater than adjacent unmyelinated segments, suggesting that dynamic and local changes in axon diameter may precede and instruct initial wrapping. Ongoing experiments are aimed to determine whether local axon enlargements precede initial wrapping, and whether changes in axon caliber act instructively during initial wrapping. Collectively, these data show that average axon caliber does not explain the order of axon selection, but raise the possibility that axon-glia interactions stimulate local radial growth of axons to direct initial wrapping, acting to specify select axons for myelination.

Title: Promotion of remyelination by Vitamin B12 in model with global demyelination, and the cell/s responsible

Authors: ***I. D. DUNCAN**[1], A. B. RADCLIFF[1], A. S. FIELD[3], G. MCLELLAN[2], J. N. VER HOEVE[4];
[1]Dept Med. Sci., [2]Dept Surg. Sci., Univ. Wisconsin Sch. Vet Med., Madison, WI; [3]Radiol., [4]Ophthalmol. & Vis. Sci., Univ. Wisconsin Sch. Med. Pub Hlth., Madison, WI

Abstract: The current understanding of remyelination is that the oligodendrocyte progenitor cell (OPC) is the primary or only cell capable of giving rise to remyelinating oligodendrocytes (OLs). While the data that supports this statement are strong, however it is both of biological interest and potentially of disease importance to know whether adult OLs might be recruitable in certain circumstances. We are using a large animal model of global demyelination-remyelination to explore this question. Feeding cats a diet irradiated at over 30 Kgrays results in delayed-onset progressive neurologic disease that resolves after return to non-irradiated food (Duncan *et al.* PNAS 2009, 106, 6832). Neurologic dysfunction is caused by generalized demyelination and ongoing remyelination of the CNS, most severe in the optic nerve and spinal cord. Extensive myelin vacuolation leads to myelin breakdown with no cell death of OLs apparent, suggesting that myelin is the primary target. Recovery results from total remyelination of these sites. The disorder has marked similarity to sub-acute combined degeneration in humans, which is caused by a deficiency in Vitamin B12. Early treatment of affected animals with B12 results in recovery while cessation of treatment resulted in relapse. Delay in treatment resulted in neurologic worsening and axon loss in the dorsal columns. Imaging of the brain and spinal cord by MRI, and physiologic evaluation of conduction in the optic nerve (visual evoked potentials) have more recently been performed. MRI showed T2-hyperintensity and reduced magnetization transfer (MT) ratio, primarily in the dorsal columns as well as in optic nerves and cerebral white matter. Recovery was accompanied by increased MT ratio and in one case disappearance of a focal T2-hyperintense lesion in the cerebral peduncle. Photopic flash VEPs and ERGs were recorded simultaneously. The flash VEP declined in amplitude and increased in latency while on diet and showed partial recovery after returning to a normal diet or after cats were given B12

supplementation. ERGs were not altered by the diet, implying the VEP changes are due to alteration in optic nerve and central visual pathway function. While our model does not demonstrate the biochemical hallmarks of B12 deficiency, it is responsive to B12 treatment associated with the promotion of remyelination. Certain aspects of the cellular milieu in areas of demyelination-remyelination suggests that adult OLs may be partaking in the remyelination process and we are exploring this further.

Title: Therapeutic use of microRNA mimics to promote remyelination

Authors: *A. L. MOYANO[1], A. HEBERT[1], H. LIPTON[2], E. R. BONGARZONE[1];
[1]Anat. and Cell Biol., [2]Microbiology and Immunol., Univ. of Illinois at Chicago, Chicago, IL

Abstract: MicroRNAs (miRs) are small (~22 nt) non-coding RNA molecules controlling gene expression by posttranscriptional regulation. miRs regulate the proliferation, survival and differentiation of oligodendrocytes (OLs). miRs also have functional roles in the pathogenesis of demyelinating diseases such as Multiple Sclerosis (MS). Therefore, there is an intrinsic potential for the therapeutic use of miR-related biology, especially considering that the regenerative capacity of the CNS (remyelination) in demyelinating diseases is generally impaired. The goal of this study is to examine the potential use of artificial miRs to promote remyelination by stimulating the number of functional OL precursor cells. We used an experimental model of demyelination, Theiler's Murine Encephalomyelitis Virus (TMEV), in susceptible SJL mice (*in vivo*) and its susceptible neuroglial progenitor cultures (*in vitro*). We found that miR-17, -19b, and -138 (involved in oligodendrogenesis) were decreased in TMEV-infected cells and TMEV-infected mice. These results were correlated with an increase in caspase-1 mediated death of OL progenitor cells. To test our hypothesis that complementation with miR mimics protects OLs, miR-17 and miR-19a were transfected in TMEV-infected cells. Our results showed that complementation of glial cultures with miR-17 exerted a protective effect on OL progenitor cells. Our results showed that levels of OL-related miRs were significantly decreased during demyelination and these molecules have the potential to exert therapeutic effects by *in vivo*

complementation. This study has an intrinsic clinical value for improving therapies in the treatment of myelin diseases such as MS and highlights the importance of miRs biology in myelinating cells.

Title: Neuroanatomically distinct vulnerability and response to remyelinating factors in the mouse forebrain of the cuprizone-induced demyelination model: new insights into the progression patterns of demyelination and responses to remyelinating therapy

Authors: ***E. PAVLOPOULOS**, Y. WANG, C. CUI, E. TROY, T. J. PARRY, A. O. CAGGIANO, R. W. COLBURN;
Acorda Therapeut., Ardsley, NY

Abstract: Remyelination is a central focus of a growing number of therapeutic candidates for the treatment of demyelinating diseases, such as multiple sclerosis (MS). However, little is known about whether demyelination or remyelination and their mechanisms are differentially affected by location within the brain, and whether this might lead to a differential response to remyelination therapies. To address these questions, we used the cuprizone mouse model of induced demyelination and spontaneous remyelination and examined the corpus callosum, critical for motor function and a range of cognitive processes, and the hippocampus, the center of learning and memory. Both of these regions and their associated functions are markedly affected in MS and demyelinating diseases. Seven-week old mice were fed with 0.3% cuprizone-containing food for 6 weeks, and their brains were examined immediately after the end of the cuprizone diet as well as 4 weeks later (recovery period), and compared with those of age-matched control mice, fed only regular food. Another group of mice underwent a similar cuprizone diet but they were treated with thyroid hormone T3, a known facilitator of remyelination, beginning at cuprizone cessation. We examined the brains of these mice after 4 weeks of recovery and compared them with those of placebo control animals, as well as mice fed with regular food. We found that cuprizone induced substantial and comparable demyelination in both the corpus callosum and the hippocampus, as measured by 1) myelin detection using the Black Gold and Fluoro-Myelin tracers, and 2) fluorescence-based immunohistochemical examination of myelin proteins, such as the Myelin Basic Protein (MBP) and the Myelin Associated Glycoprotein (MAG). All of these markers were significantly reduced at the end of

the cuprizone diet. Four weeks later, black gold-stained myelin, fluoro-myelin and MBP in the corpus callosum remained unaltered. MAG, however, had returned to control levels, indicating initiation of remyelination. This process was faster in the hippocampus, as, in addition to MAG, MBP was also restored. T3 facilitated remyelination in the corpus callosum, as evidenced by reinstatement of MBP and fluoromyelin after 4 weeks of recovery. The effect of T3 was greater in the hippocampus, as there was also recovery of black-gold stained myelin. These results support the idea that the brain differentially responds to demyelinating insults and facilitators of remyelination depending on the brain area, providing potential new insights into the pathophysiology of demyelinating diseases and the importance of considering regional sensitivity to therapeutic interventions.

Title: Physical exercise promotes remyelination and alters the composition of the lesion extracellular matrix

Authors: *S. K. JENSEN, M. B. KEOUGH, C. BRIDEAU, V. YONG;
Univ. of Calgary, Calgary, AB, Canada

Abstract: Physical exercise is considered a critical component of a healthy lifestyle and is known to have efficacy in treating/controlling many systemic disorders. In the central nervous system, physical exercise is known to promote wellbeing in a number of neurological conditions, including the demyelinating disorder Multiple Sclerosis. Notably, a strong positive correlation between physical activity and white matter integrity (as determined by diffusion tensor imaging) in patients with MS has been described. However, whether physical exercise is capable of promoting repair processes, particularly remyelination, has not been directly established. In the current study, we investigated the ability for physical exercise to promote remyelination. We induced a focal demyelinating lesion via injection of lysolecithin into the ventrolateral white matter of the murine spinal cord. Mice were singly housed and given free access to an electronically monitored running wheel, which were locked in control animals, at the day of injury until sacrifice at either 7 or 14 days post lesion (representing peak demyelination and early remyelination, respectively). Immunohistochemical analysis of day 14 lesions revealed a 47.6% increase in lesion myelin basic protein expression and a 35.9% increase in CC1+ mature oligodendrocytes as a result of access to a running wheel. When examined at the semithin level, we observe a 2.74 fold increase myelinated axons in exercising animals when compared to sedentary controls. Interestingly, lesion versican and chondroitin sulfate A (CSA) expression is altered in the exercise group, and may result in microenvironment more permissive to remyelination in exercising animal. Our previous data has implicated lesion-accumulated chondroitin sulfate proteoglycan (CSPGs) as inhibitors of oligodendrocyte migration, maturation and remyelination (Lau et al., Ann Neurol 72:419, 2012; Nature Rev Neurosci 14:722, 2013). These results indicate that physical exercise can improve white matter regeneration and may be an important tool for the treatment of demyelinating disorders, such as multiple sclerosis.

Title: NESTORONE treatment after chronic cuprizone intoxication stimulates the production of transcription factors involved in remyelination in the corpus callosum

Authors: *M. EL-ETR[1], M. RAME[1], A. M. GHOUMARI[1], M. SCHUMACHER[1], R. SITRUK-WARE[2];
[1]INSERM UMR 1195 (ex U 788), Le Kremlin Bicêtre, France; [2]Population Council and Adjunct Fac. at Rockefeller Univ., New York, NY

Abstract: We have previously demonstrated that Progesterone and Nestorone®, a synthetic 19-norprogesterone derivative, were able to favor callosal myelin repair, when administered for 3 weeks after a 12-week cuprizone-induced chronic demyelination (El-Etr M et al, GLIA 2015;63:104-117). We also observed that Progesterone exerts its effect via the brain Progesterone receptors (PR), since it was less efficient in heterozygous mice lacking one allele of the PR and had no effect on remyelination in PR-knockout mice. Here we show that after only one week of steroid treatment, Nestorone is already able to enhance the callosal production of some mRNAs coding for transcription factors known to be involved in the proliferation and early differentiation of Oligodendrocyte Progenitor Cells (OPC). Indeed, Myelin transcription factor 1 (Myt1) mRNA expression increases equally after a 1-week treatment with 8 µg/d Nestorone alone, or combined with Estradiol 1µg/d. Myt1 is a zinc-finger DNA binding protein which regulates OPC differentiation and binds to the promoter region of Proteolipid Protein PLP, the most important myelin gene in the CNS (Nielsen JA et al, Mol Cell Neurosci 2004, 25:111-123). While cuprizone alone decreases their mRNA levels, steroid treatments also stimulate the production of Sox17 mRNA, and to the largest extent of Olig2 mRNA. These results are consistent with the increase in NG2 mRNA, a marker of OPCs, after a 1-week treatment and with the increase of mature oligodendrocytes density observed using immunohistological techniques at the end of the 3-week treatment with Nestorone ± Estradiol. However, there is no effect of Nestorone alone or combined with Estradiol on the cuprizone-induced changes of mRNA levels of two other transcription factors which might play a role in OPC differentiation, Sox10 and Ascl1. We are currently investigating the protein levels of the responding transcription factors in order to quantify these responses.

Title: The neuronal mitochondrial metabolite NAA supports myelination

Authors: ***N. K. SINGHAL**[1], H. HUANG[2], S. LI[1], R. CLEMENTS[1], J. GADD[1], A. DANIELS[1], E. E. KOOIJMAN[1], F. GUO[3], D. PLEASURE[3], L. SHRIVER[2], E. FREEMAN[1], J. MCDONOUGH[1];

Abstract: Mitochondrial changes including decreased expression of nuclear encoded electron transport chain subunit genes, inhibition of electron transport chain activity, and decreased levels of the neuronal mitochondrial metabolite N-acetylaspartate (NAA) have been implicated in multiple sclerosis (MS) neuropathology. NAA is synthesized in neuronal mitochondria by the enzyme N-acetyltransferase (NAT8L) and broken down in oligodendrocytes by aspartoacylase (ASPA) into acetate and aspartate. We have hypothesized that NAA links the metabolic activity of axons and oligodendrocytes to support myelination. In the present study we have performed shot-gun lipidomic analysis by mass spectrometry and high performance thin layer chromatography (HPTLC) to identify changes in myelin lipid composition that are correlated with decreased NAA levels in postmortem MS and control brains and in NAT8L knockout (NAT8L-KO) mice. We found that the myelin lipid sphingomyelin was depleted in MS normal appearing white matter (-1.4 fold) compared to controls and was correlated with NAA levels measured by HPLC in adjacent gray matter in the same tissue block. Sphingomyelin and sulfatides were also decreased in myelin lipids isolated from NAT8L-KO brains by 7 and 1.6 fold respectively compared to controls. Metabolomic analysis of primary cultures of oligodendrocytes treated with NAA revealed changes in tricarboxylic acid (TCA) cycle intermediates and increased α-ketoglutarate. Levels of α-ketoglutarate have been shown to regulate histone demethylases. Consistent with this, we found that NAA treatment also resulted in decreased levels of histone H3 trimethylation on lysine 4 (H3K4me3) in the nucleus of oligodendrocytes. H3K4me3 marks promoters of actively transcribed genes and reductions in H3K4me3 result in slowed metabolism and growth, and increased differentiation. These data suggest that dysfunction of neuronal mitochondria and reduced NAA in MS may contribute to defects in oligodendrocyte metabolism and myelin lipid composition.

Title: Regulatory role of the thrombin receptor in spinal cord myelination

Authors: *H. YOON, M. RADULOVIC, K. L. DRUCKER, J. WU, I. A. SCARISBRICK; Physical Med. & Rehabilitation, Rehabil. Med. Res. Ctr., Mayo Clin., Rochester, MN

Abstract: Myelination in the CNS is achieved through a delicate balance of extrinsic and intrinsic signaling mechanisms with aberrations in the perinatal period resulting in white matter injury and profound sensorimotor and cognitive disabilities. Leakage of blood-derived serine proteases such as thrombin into the CNS is a common feature of infectious, traumatic, hypoxic and hemorrhagic injuries occurring perinatally. In addition to its roles in thrombostasis, elevations in thrombin have been identified as a powerful neurotoxic agent and possible new target for neuroprotection. Thrombin mediates its cellular effects by activation of a G-protein coupled receptor referred to as Protease Activated Receptor 1 (PAR1). Here we use PAR1 knockout mice to evaluate the role of PAR1 in the process of murine spinal cord myelination at a cellular, molecular and ultrastructural level. PAR1 exhibits peak expression levels in the spinal cord at term, including expression by platelet derived growth factor receptor oligodendrocyte progenitor cells (OPCs) and newly generated CC-1+ oligodendroglia. A critical role for PAR1 in the process of myelination is suggested by findings demonstrating that PAR1 gene deficient mice exhibit an earlier onset of spinal cord myelination, including substantially more Olig2-positive oligodendrocytes, more myelinated axons and higher proteolipid protein (PLP) levels at birth. *In vitro*, the highest levels of PAR1 were observed in OPCs, being reduced with differentiation. In parallel, the expression of PLP and myelin basic protein (MBP), in addition to Olig2, were all significantly higher in cultures of PAR1-/- oligodendroglia. Moreover, application of a small molecule inhibitor of PAR1 (SCH79797) to OPCs *in vitro*, resulted in higher levels of expression of both PLP and MBP upon differentiation. Enhancements in myelination associated with PAR1 deficient mice were also observed in adults, including higher levels of MBP and significantly thicker myelin sheaths across large, medium and small diameter axons. Increases in spinal cord myelination in PAR1-/- mice were coupled to developmental increases in the pro-myelination signaling intermediates, extracellular-signal-regulated kinase 1/2 and AKT. Nocturnal ambulation and rearing activity were also elevated in PAR1-/- mice. These studies identify the thrombin receptor as a powerful extracellular regulatory switch that could be readily targeted to improve myelin production in the face of white matter injury and disease. Title: Low density lipoprotein receptor-related protein 1 (LRP1) is a positive regulator of cns myelin development and repair

Authors: ***J.-P. LIN**[1], R. GIGER[1], Y. MIRONOVA[1], P. SHRAGER[2];
[1]Univ. of Michigan, Ann Arbor, MI; [2]Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: LRP1 is a large cell surface protein best known for its role in receptor-mediated endocytosis. In the nervous system, LRP1 is broadly expressed and is required in Schwann cells for proper myelination in the peripheral nervous system. Whether LRP1 participates in CNS myelin development or repair following white matter injury, however, has not yet been determined. In our study, deletion of *Lrp1* in the oligodendrocyte (OL) lineage results in a hypomyelination phenotype. At postnatal-day (P) 10, 21 and 56, optic nerve myelination is greatly reduced compared to wildtype littermate controls. Electrophysiological studies revealed that the propagation of compound action potentials (CAPs) in acutely isolated P21 optic nerves is compromised. Compared to controls, conduction velocity and amplitude of CAPs is reduced in *Lrp1*$^{flox/flox}$*; Olig2-Cre* nerves, and the fraction of abnormally formed nodes of Ranvier is increased. Biochemical studies of membrane extracted from control and *Lrp1*$^{flox/flox}$*; Olig2-Cre* brain tissue revealed reduced levels of proteolipid protein (PLP). Compared to control optic nerves, a decrease in the number of mature OLs was observed in *Lrp1*$^{flox/flox}$*; Olig2-Cre* mice *in vivo*. Primary oligodendrocyte progenitor cells (OPCs) isolated from P6 brains showed normal viability and proliferation. However, in the absence of *Lrp1*, differentiation into mature OLs was significantly attenuated. At P56 inducible deletion of *Lrp1* (*Lrp1*$^{flox/flox}$*; CMV-ER Cre*) does not lead to any overt defects in CNS white matter. However, our data suggests in the adult brain LRP1 is required for white matter repair. Stereotaxic injection of lysophosphatidyl choline (LPC) into the corpus callosum leads to focal axon demyelination. At 21 days after LPC injection, remyelination in the lesion core is significantly more robust in control mice than in *Lrp1* inducible knockout mice. Collectively, these studies show that *Lrp1* functions cell-autonomously

in the OL-lineage during myelin development, and demonstrate that LRP1 is a positive regulator of myelin repair in the adult CNS.

Title: Regulation of central nervous system myelination by the ATRX chromatin remodeling protein

Authors: M. W. EDWARDS[1], *N. G. BERUBE[2];
[1]Biochem., Univ. of Western Ontario, London, ON, Canada; [2]Univ. Western Ontario, London, ON, Canada

Abstract: The myelin sheath is a specialized plasma membrane that encompasses axons of neurons, and is necessary for efficient firing of action potentials, along with providing protection and trophic support to the axonal cell body. In the central nervous system, myelin arises via differentiation of oligodendrocyte precursor cells (OPCs) into oligodendrocytes (OLs). The latter then undergo an additional maturation step into mature OLs, which then extend membraneous fibres and enwrap axons creating the myelin sheath. This is a tightly regulated process, however the mechanisms involved have yet to be fully elucidated. Alpha thalassaemia mental retardation, X-linked (ATR-X) syndrome is a developmental disorder caused by hypomorphic mutations in the ATRX gene, and is characterized by severe cognitive deficits, seizures, microcephaly, loss of white matter, as well as myelin sheath abnormalities. ATRX is an ATP-dependent translocase involved in organizing chromatin structure to influence transcriptional regulation and genomic stability. Microarray analysis from our group revealed that loss of ATRX from the mouse forebrain results in decreased expression of several genes implicated in myelination; therefore, the objective of this study is to determine the mechanism by which ATRX regulates myelin production in the brain. We identified that conditional inactivation of Atrx in the mouse forebrain results in decreased expression of critical components of the myelin sheath at the transcriptional and proteomic level, indicating a decrease in myelination. The observed hypomyelination phenotype was not due to a defect in OPC production, proliferative capacity, or the ability to differentiate into OLs. Moreover, OL-specific deletion of ATRX did not perturb myelination. Together, these results suggest that the myelination defect does not result from abnormalities in the oligodendrocyte lineage and implies that ATRX influences OL maturation in

a cell non-autonomous manner. We are currently testing the hypothesis that neuronal-specific activities of ATRX influence the myelination process using conditional mutant mice and neuron/oligodendrocyte myelinating co-cultures. Clarifying the role of ATRX in myelination presents a novel mechanism that regulates myelin sheath formation, and findings stemming from this study will undoubtedly benefit future treatments of myelin disorders such as ATR-X syndrome.

Title: Myelin remodeling in the adult brain

Authors: *E. G. HUGHES, J. L. ORTHMANN-MURPHY, D. E. BERGLES;
Dept. of Neurosci., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Oligodendrocytes generate myelin sheaths that accelerate action potential propagation and provide metabolic support to axons in the CNS. Although most oligodendrocytes are generated in early postnatal life, the development of myelin continues into adulthood, and recent studies indicate that the characteristics of myelin (number and length of myelin internodes, thickness of myelin sheaths, and myelin protein expression) can be modified by experience. Moreover, axons in the cortical gray matter exhibit discontinuous myelination, and blocking the formation of new oligodendrocytes impairs motor learning, raising the possibility that myelin is continually adjusted to modify the information processing capabilities of cortical circuits. However, these studies have all been performed during early adulthood, when developmental myelination is still ongoing. It is unclear whether the ability to remodel myelin is retained with age. To explore how myelination changes with age, we performed histological analysis and *in vivo* two-photon time-lapse imaging in the somatosensory cortex of transgenic mice in which EGFP is expressed specifically in mature oligodendrocytes (MOBP-EGFP mice). Immunohistological analysis revealed that EGFP is expressed by nearly all myelinating oligodendrocytes in the CNS of MOBP-EGFP mice, and the expression of EGFP was high enough to visualize oligodendrocyte cell somata and myelin sheaths in living tissue. Our studies

indicate that the period of oligodendrogenesis in the cortex is very prolonged, with more than half of the oligodendrocytes produced after 3 months of age. However, isolated myelin internodes were still observed in the upper layers of cortex in animals 12 months of age, indicating that discontinuous myelination is not a transient developmental phenomenon. To determine whether the ability to remodel myelin is retained with age, we used *in vivo* two-photon time-lapse imaging to repeatedly image individual myelin internodes for up to 1.5 months in mice 11-14 months old. Although most oligodendrocyte myelin internodes remained stable over this period, approximately 6% of internodes were dynamically remodeled, either increasing or decreasing in length, and some internodes were completely removed. Together, these results indicate that the myelination state of axons in the adult CNS is not continuous and that some internodes can be remodeled. This ongoing reorganization of existing myelin in the adult CNS may help to alter the pattern of myelination with life experience and perhaps contribute to the plasticity of adult cortical circuits.

Abstract: Multiple sclerosis (MS) is a chronic neurodegenerative disease characterized by the occurrence of many pathophysiological hallmarks like de- and remyelination, axonal and neuronal degeneration and immune cell infiltration and proliferation in the CNS. Important steps forward have been done in understanding consequences of demyelination in the peripheral nerve but little is known about neuronal effects at the central nervous system. Here, by combining *in vivo* and *in vitro* techniques we aim to understand the mechanism underlying de- and

remyelination processes and their consequences in a topographically highly organized neuronal network, namely the auditory thalamocortical system. General demyelination was induced in C57BL6J mice by feeding them with a cuprizone-based diet (0.2%) and then the functionality of the neurons of the primary auditory cortex (AC1) was tested *in vitro* by electrical stimulation and the number of elicited action potentials and changes in the resting membrane potential were taken as read-out. Moreover, the neuronal population properties were tested *ex vivo* by means of field potential and voltage-sensitive dye recordings and, *in vivo* by single unit activity analysis in freely behaving animals exposed to various auditory stimuli. Cuprizone treatment significantly impaired cortical functionality by reducing system' excitability and rendering the network unable to respond to any electrical or auditory stimulus. The latency to response was significantly increased suggesting an altered stimulus conductance. Moreover, *in vivo* electrophysiological data demonstrate single-unit activity to be stimulus-independent after cuprizone-treatment, strongly suggesting demyelination to permanently disrupt AC1-tonotopy. Finally, these alterations of cortical structures have been shown to result in a complete loss of stimulus-discrimination abilities in behavioral experiments after auditory pavlovian conditioning. The very same effect is observed during early and late phases of remyelination. Taken together our data show a severe effect of cortical demyelination on neuronal network activity and it suggests a permanent alteration of cortical processing which may be relevant for MS patients which are often diagnosed with early cortical or thalamic lesions and it may play a crucial role as target in therapeutic approaches.

Title: Promoting oligodendrocyte survival with creatine: implications for multiple sclerosis

Authors: ***K. A. CHAMBERLAIN**, K. S. CHAPEY, J. K. HUANG;
Georgetown Univ., Washington, DC

Abstract: Oligodendrocytes are glial cells of the central nervous system that enable rapid saltatory conduction by ensheathing neuronal axons with a lipid rich membrane known as the myelin sheath. Expansion of myelin membranes during development requires rapid lipid synthesis and is a highly energy consuming process. Indeed, defects in energy production are associated with oligodendrocyte dysfunction in numerous mitochondrial diseases. Interestingly, genetic mutations affecting the organic energy compound creatine, which maintains intracellular energy supplies via rapid regeneration of ATP, present with delayed myelination and severe cognitive disability. Previous work has shown that the final enzyme in the creatine biosynthetic pathway, guanidinoacetate N-methyltransferase (GAMT), is expressed during oligodendrocyte differentiation and remyelination following experimental demyelination in rodents. Therefore, we investigated the effect of creatine on oligodendrocyte lineage cells following lysolecithin-mediated experimental demyelination of mouse spinal cord at 5,10, and 20 days post lesion (dpl). Our preliminary data suggest that creatine supplementation increases the number of mature oligodendrocytes in lesioned spinal cord compared to control. Conversely, creatine deficient transgenic mice lacking GAMT have significantly less mature oligodendrocytes in lesioned spinal cord. Our *in vitro* studies suggest that creatine may modulate oligodendrocyte cell survival, possibly through mitochondria, as mitochondria distribution and density are altered following creatine treatment of purified mouse oligodendrocytes. Investigating the role of creatine in oligodendrocyte lineage cells may have important implications for the development of novel therapeutics for diseases in which oligodendrocytes are lost or dysfunctional, including multiple sclerosis (MS).

Abstract: Amyloid precursor protein (APP) is the parent protein for amyloid plaques, the pathological hallmark of Alzheimer's disease (AD) with an abundance of plaque in the brain. Here, we decouple the effects of the overexpressed protein itself from the subsequent plaque that it produces. We used a transgenic mouse carrying a human APP with both Swe/Ind mutations, with expression driven by a tetracycline-sensitive promoter. Three groups were studied. Group 'A' (no doxy, +plaques, +APP); group 'B' (doxy at 8 days before sacrifice, +plaques, no APP), and group 'C' (doxy prior to conception, and stopped 8 days before sacrifice, no plaques, +APP). We used manganese-enhanced magnetic resonance imaging (MEMRI) to observe differences in axonal transport dynamics between the three groups. Mn^{2+} was injected into CA3 of the hippocampus. Mn^{2+} enters the neuron through voltage-gated calcium channels. Mn^{2+} travels by kinesin-dependent axonal transport to distal projections. MR images were taken at several time points before and after injection. Mn^{2+} gives a hyperintense signal in T_1-weighted MRI, thus tracing transport over time. Histopathology revealed well-developed plaques in Groups A and B, and Western blots showed human APP expressed 3.2-fold over WT in Groups A and C. Our preliminary results show increased transport in A and C, with APP Swe/Ind expression when compared with B, where expression is suppressed. Transport is increased with APP overexpression independent of plaques, but decreased in the presence of plaques alone in this circuit. Cholinergic neurons in the medial septal nucleus were decreased as determined by anti-ChAT staining in Group C ($p=0.0006$ by one-way ANOVA, $n=15$). These effects could be model-specific. Phospho-tau was present in the dystrophic neuritis surrounding the plaques. In conclusion, we observe separable effects between APP and plaque.

Title: Cell-specific function of amyloid precursor protein during neural development

Authors: *R. K. BANOTE[1], M. EDLING[1], F. ELIASSEN[2], P. KETTUNEN[1], H. ZETTERBERG[1,3], A. ABRAMSSON[1];
[1]Inst. of Neurosci. and Physiol., Univ. of Gothenburg, Gothenburg, Sweden; [2]Dept. of Chem. and Mol. biology, Univ. of Gothenburg, Gothenburg, Sweden; [3]UCL Inst. of Neurology, Queen Square, WC1N3BG, London, United Kingdom

Abstract: The amyloid hypothesis comprised that the amyloid plaques are the core cause of neurodegeneration in Alzheimer's disease (AD), which produces from amyloid precursor protein (APP) by proteolytic processing. APP is a transmembrane glycoprotein that has been the subject of intense research because of its implication in Alzheimer's disease pathogenesis. However, its physiological function in the development and maintenance of the central nervous system remains elusive. In this study, we address the role of zebrafish APP homologue, Appb, in the formation of specific hindbrain neurons. We demonstrate that knockdown of appb affects the development of Mauthner neurons, hence plays an essential role for the escape response. Loss of Appb results in increased Notch signaling and decreased neural proliferation and differentiation in the hindbrain. Remarkably, the development defect of the Mauthner cell can be rescued by repression of Notch1a signaling in appb morphants. Furthermore, Appb expression is required to maintain proliferation and differentiation of neural progenitors. In conclusion, we show that Appb negatively regulates Notch1a activity, which is essential for Mauthner cell development and neuronal differentiation. Collectively, our study provides evidence in support of zebrafish model for studying the function of amyloid precursor protein in an *in vivo* framework. We believe that this study may transmit significant information for APP function and its role in neurodegenerative diseases.

Title: Contactins as regulators of Amyloid Precursor Protein-dependent neuronal guidance

Authors: *P. F. COPENHAVER[1], J. A. ZWEIG[2], T. L. SWANSON[2], J. M. RAMAKER[2];
[2]Cell and Developmental Biol., [1]Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Although Amyloid Precursor Protein (APP) is best known as the source of beta-amyloid peptides associated with Alzheimer's disease (AD), factors that disrupt the normal functions of APP may also provoke neurodegeneration. Numerous studies have shown that APP can modulate different aspects of neuronal growth and plasticity, while *in vitro* assays have shown that APP can affect cellular behavior via activation of the heterotrimeric G protein Gαo. However, the mechanisms underlying APP-dependent responses in the nervous system are still controversial. Using Manduca and *Drosophila* as model systems, we have shown that the sole insect ortholog of APP (APPL) co-localizes with Gαo in the leading processes and synaptic terminals of developing neurons, and that the two proteins directly interact *in vivo*. Using both cultured Manduca embryos and rat hippocampal neurons, we also found that stimulating APP/APPL activation inhibits different aspects of neuronal motility in a Gαo-dependent manner. Stimulating Gαo also causes a reduction in Gαo-APPL interactions, supporting the model that APP family proteins can function as unconventional Gαo-coupled receptors. Previous studies by other groups identified members of the Contactin family as potential binding partners for APP that can either induce signaling responses or stimulate proteolytic cleavage of the holoprotein. Recently, we found that insect Contactin represents a promising candidate ligand for APPL. Within the developing nervous system, Manduca Contactin (msContactin) is expressed by proliferating glial cells as they ensheath populations of migratory neurons that express APPL. Short-term treatment with msContactin-Fc fusion proteins selectively labeled the migratory neurons, while more prolonged treatment inhibited their motile behavior, similar to the effects of stimulating APPL-Gαo signaling. Knocking down APPL expression with antisense morpholino oligonucleotides demonstrated that these effects are APPL-dependent. Intriguingly, our initial studies suggest that msContactin-Fc stimulation also promotes the cleavage of APPL by endogenous secretases. These results support the model that Contactins can function as authentic ligands for APP/APPL, regulating neuronal motile responses in a Gαo-dependent manner. Given recent evidence that APP-Gαo signaling may be misregulated in AD, we are currently exploring whether altered Contactin-APP interactions are similarly associated with neurodegenerative responses in the brain.

Title: Opposite dysregulation of fragile-x mental retardation protein and heteronuclear ribonucleoprotein c protein associates with enhanced app translation in Alzheimer's disease

Authors: *A. BORRECA[1], K. GIRONI[2], G. AMADORO[3], M. AMMASSARI-TEULE[4]; [1]CNR-IBCN, Rome, Italy; [2]Univ. of Rome- Sapienza, Rome, Italy; [3]Inst. of Translational Pharmacol. (IFT) -National Res. Council (CNR), Rome, Italy; [4]Inst. of Cell. Biol. and Neurobio. (IBCN), Consiglio Nazionale delle Ricerche, Rome, Italy

Abstract: Amyloid precursor protein (APP) is overexpressed in familiar and sporadic Alzheimer Disease (AD) patients suggesting that, in addition to abnormalities in APP cleavage, enhanced levels of APP full length might contribute to the pathology. Based on data showing that the two RNA binding proteins (RBPs) Fragile-X Mental Retardation Protein (FMRP) and heteronuclear Ribonucleoprotein C (hnRNP C) exert an opposite control on APP translation, we have analyzed whether expression and translation of these two RBPs vary in relation to changes in APP protein and mRNA levels in the AD brain at 1, 3 and 6 months of age. Here we show that, as expected, human APP is overexpressed in hippocampal total extract from Tg2576 mice at all age points. APP overexpression, however, is not stable over time but reaches its maximal level in 1-month old mutants in association with the stronger (i) reduction of FMRP and (ii) augmentation of hnRNP C. APP levels then decrease progressively as a function of age in close relationship with the gradual normalization of FMRP and hnRNP C levels. Consistent with the mouse data, expression of FMRP and hnRNP C are respectively decreased and increased in hippocampal synaptosomes from sporadic AD patients. Our findings identify two RBP targets that might be manipulated for reducing abnormally elevated levels of APP in the AD brain, with the hypothesis that acting upstream of amyloidogenic processing might contribute to attenuate the amyloid burden.

Title: Increased accumulation of APP-C99 in mitochondria-associated ER membranes triggers early events in the pathogenesis of Alzheimer's disease

Authors: *E. AREA[1], M. PERA[1], D. LARREA[1], R. B. CHAN[1], G. DI PAOLO[1], M. F. MEHLER[2], E. A. SCHON[1];
[1]Columbia Univ., New York, NY; [2]Albert Einstein Col. of Med., New York, NY

Abstract: The pathogenesis of Alzheimer disease (AD) is associated with aberrant proteolytic processing of the amyloid precursor protein (APP) - first by β-secretase to generate a 99-aa C-terminal fragment (C99) and then by γ-secretase (containing presenilins-1 [PS1] or -2 [PS2]) that cleaves C99 to generate the APP intracellular domain and the β-amyloid (Aβ) that is found in extraneuronal plaques - but the relationship of the former to the latter is unclear. Whereas plaques typically form late in disease progression, early events include aberrant lipid metabolism and mitochondrial dysfunction. We recently showed that PS1, PS2, and γ-secretase activity itself are highly enriched in a subdomain of the endoplasmic reticulum (ER) that communicates with mitochondria, called mitochondria-associated ER membranes (MAM), and that ER-mitochondrial connectivity and MAM function are highly upregulated in presenilin-mutant cells and in cells from AD patients. However, the relationship of perturbed APP processing to MAM-related AD phenotypes has also been unclear. MAM, which is a lipid raft rich in cholesterol and sphingomyelin, is a key regulator of lipid metabolism and of mitochondial dynamics, among other processes. We now show that C99 is highly enriched in the MAM, and that it plays a central role in regulating cellular cholesterol and sphingolipid homeostasis and mitochondrial bioenergetics. Furthermore, in cells from AD patients and in cell and animal models of AD, C99 levels are increased significantly, resulting in a disruption of lipid homeostasis that is triggered by the unregulated uptake of extracellular cholesterol, with downstream consequences that mimic the biochemical features of AD, including the bioenergetic deficits. We propose that MAM-localized C99 is a component of the cell's lipid sensing machinery and that its accumulation is a key and early event in AD pathogenesis that can explain many of the biochemical and morphological features of the disease.

Title: Atxn1, spinocerebellar ataxia type-1 protein, regulates bace1 expression and beta-amyloid pathology in the cerebrum

Authors: *J. SUH[1], D. M. ROMANO[2], J. D. SCHMAHMANN[3], R. E. TANZI[4];

Abstract: Abnormal expansion of CAG repeat in the ataxin-1 gene (ATXN1) causes the degeneration of Purkinje cells and spinocerebellar ataxia type 1 (SCA1), a neurodegenerative movement disease. Previously our laboratory has reported ATXN1 is associated with Alzheimer's disease (AD) and knockdown of ATXN1 increases Abeta generation in the cultured mammalian cells. Here, we investigate whether ATXN1 expression affects the processing of amyloid precursor protein (APP) and the pathogenesis of AD. We examined the levels of APP cleavage products and the expression of secretases in the brains of ATXN1 knockout (KO) mice. APP processing and Abeta pathology were further analyzed after crossing the ATXN1 KO mice with APPswe/PS1deltaE9 AD mice. We found ATXN1 KO increases the levels of beta-secretase BACE1, but not alpha-secretase ADAM10 in the cortex and hippocampus. No change of BACE1 expression was detected the cerebellum. The increase of BACE1 in cerebrum is concordant with the shift of APP processing into the beta-secretase cleavage pathway along with an increase in Abeta levels and plaque load in the brains of AD mice. In addition, both the proliferation of neural progenitor cells and the dendritic development of immature neurons, the two markers of adult neurogenesis, were severely impaired in the hippocampus of ATXN1 KO mice. Together, these findings suggest that the loss of ATXN1 function potentiates beta-amyloid pathology through the increase of BACE1 expression and the subsequent beta-secretase cleavage of APP.

Title: Transcription factor Specificity Protein 1 (Sp1) modulation of the amyloid-β precursor protein (APP) and β-site APP Cleaving Enzyme (BACE1) activity as a drug target in Alzheimer's disease (AD)

Authors: *B. L. BAYON[1], K. NHO[2], N. CHOPRA[3], B. MALONEY[4], D. K. LAHIRI[5]; [1]Dept. of Med. & Mol. Genet., [2]Radiology and Imaging Sci., [3]Neurosci., [4]Psychiatry, [5]Psychiatry and Med. & Mol. Genet., Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: The Latent Early-life Associated Regulation (LEARn) model posits that environmental agents epigenetically disturb gene regulation in a long-term manner, but that the pathology may not manifest until much later in life. The LEARn model's molecular mechanisms include changes in DNA methylation within the promoters of specific genes. Expression levels of some transcription factors (TFs) such as Sp1 are perturbed in this latent fashion. Expression of Sp1 parallels expression levels of disease associated genes in AD. BACE1 is the β-secretase responsible for the rate-limiting cleavage of APP to amyloid-β (Aβ), which can reach the pathological levels seen in AD. Sp1 positively regulates APP and induces BACE1 via their respective promoters. We chose single nucleotide polymorphisms (SNPs) within the Sp1 gene from the AD Neuroimaging Initiative GWAS data, performed an association analysis with an AD-specific imaging biomarker (entorhinal cortex thickness), and identified a significant SNP (rs11170553) associated with entorhinal cortex thickness. rs11170553 was also associated with cerebral amyloid deposition. We tested Sp1-mediated regulation of APP with Mithramycin A (MTM), a selective inhibitor of Sp1, and Tolfenamic acid (TA), an inducer of Sp1 degradation, and with siRNAs in mammalian cell lines (rat neuronal PC12 and human glioblastoma U373), a primary human fetal neuron culture (HFN) and mixed cultures derived from human fetal neurospheres (NSPc). Treatment of PC12 reveals minimal changes in confluence, cytotoxicity, neurite length, and neurite outgrowth after Sp1 knockdown via siRNA or treatment with Sp1 modulating drugs. Morphology and cell death tracking studies from U373 reveal increasing cytotoxicity in MTM concentrations above 10 μM after 36 hours. Treatment of HFN with TA did not affect cell viability with doses up to 5 μM. Western blotting shows a significant decrease in expression of BACE1 after MTM treatment in NSPc and U373. Treatment with TA does not significantly decrease APP or BACE1 in NSPc or U373. APP siRNA knocks down expression of APP in both of these cell types. APP expression is not altered by treatment with TA in NSPc, perhaps due to disparate mechanisms of these Sp1-inhibiting drugs. MTM reduces APP and BACE1 expression. Neither treatment with Sp1-inhibiting drugs nor transfection with Sp1 siRNA affects cell viability of primary neurons nor differentiated NSPc. Compounds that can

modify Sp1 binding to sites on the BACE1 and APP promoters could provide a means to limit the production of Aβ peptide and may slow the symptoms of AD. These results show that appropriate modulation of a specific TF could potentially be a novel drug target for AD.

Title: Understanding the neurobiology of Alzheimer's disease (AD) by correlating specific AD-associated miRNAs and the MMSE cognitive scale

Authors: *D. K. LAHIRI[1], B. MALONEY[1], J. M. LONG[1], N. CHOPRA[1], K. SAMBAMURTI[2], B. L. BAYON[1];
[1]Dept. of Psychiatry, Indiana Univ. Sch. of Med., Indianapolis, IN; [2]Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: Alzheimer's disease (AD) is characterized by excess amyloid-β (Aβ) peptide in neuritic plaques. The rate-limiting step in Aβ production is proteolytic cleavage of amyloid- β precursor protein (APP) by β-secretase (BACE1). Dysregulation of such proteins contributes to Aβ deposition. Both APP and BACE1 are regulated by specific microRNAs (miRNAs). E. g., miR-101, miR153, and miR-346 regulate APP, and miR-339-5p lowers BACE1 levels (Long et al-*JBC*, 2012; 2014). The Mini Mental State Examination (MMSE) is a common clinical measure of cognitive decline. We examined relationships between miRNA regulation of AD-associated genes and the MMSE cognitive scale. Levels of APP, BACE 1 expression, and miRNA in brain specimens (BA9, frontal cortex) from AD and age-matched control patients (Dr. Peter Nelson, University of Kentucky) were measured as previously described (Long, et al-JBC 2014). Quantitative RT-PCR was performed on isolated RNA samples and normalized to three control RU-RNAs. The resulting data were modeled as follows: "MMSE ~ (−*APOE*ε4 + miR101+ miR153 + miR346)^2"; where "^2" indicates all two-way interactions, and "−*APOE*ε4" indicates lack of any *APOE*ε4 allele. Our results showed a significant ($p \leq 0.05$)

association between MMSE and miR101 and between MMSE and −*APOE*ε4. A negative relationship between MMSE and miR153 was observed as well as interaction of *APOE* status with each individual miRNA. Interestingly, interactions miR101× miR346 and miR153×miR346 were also significant. Cook's D identified one extreme influential point (D = 7.31). Deleting this point maintained the same relationships except for the association with *APOE* status. *APOE* status interactions were maintained. In summary, we compared levels of miRNAs with MMSE and identified significant relationships between miRNA levels and MMSE scores. Our findings suggest a potential role for specific miRNA activities and cognitive decline measured by MMSE.

Title: Loss of BACE1 polarization in GGA3 null hippocampal neurons

Authors: *S. LOMOIO, G. TESCO;
Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: We have previously reported that GGA3, a clathrin adaptor protein highly expressed in the brain, plays a pivotal role in the degradation and stabilization of BACE1, the rate limiting enzyme in the production of Alzheimer's disease (AD)-associated Aβ protein. It has been described that BACE1 localizes at the presynaptic terminals and accumulates in dystrophic neurites around Aβ plaques in AD. Other studies suggested that high BACE1 levels in AD brains might be due to alterations of its degradation as a result of abnormal cellular trafficking. Our previous findings have shown that the depletion of GGA3 results in increased BACE1 level and activity *in vitro* and *in vivo* owing to accumulation of BACE1 in early endosomes and that the levels of BACE1 and Aβ are increased in GGA3 null hippocampal neurons. More importantly we have previously demonstrated that GGA3 levels are decreased and inversely correlated with BACE1 in post-mortem AD temporal cortex. In spite of compelling studies showing that GGA3 regulates BACE1 trafficking, the role of GGA3 in BACE1 neuronal polarized sorting has not being studied before. Moreover, while increasing evidence is accumulating for a role of the AP

complexes in neuronal sorting, the function of GGA3 in neurons remains poorly understood. Exploring the subcellular localization of GGA3 and BACE1 in cultured hippocampal neurons, we found that BACE1 and GGA3 highly colocalized and are targeted both to the somatodendritic and axonal compartment with a preference for dendritic targeting. As far as we know this is the first study demonstrating the presence of the clathrin adaptor protein GGA3 into the axon. Moreover, live imaging experiments have shown that both BACE1 and GGA3 undergo a bidirectional trafficking along the axon. In fact, while GGA3 trafficking appears slow and saltatory, BACE1 moves with a rapid and constant pace both anterogradely and retrogradely. More interestingly we observed a loss of BACE1 polarization leading to accumulation and increase levels of BACE1 into the axons of GGA3 null hippocampal neurons. To further address the role of GGA3 in BACE1 axonal sorting we performed co-transfection experiments of the two proteins. The results clearly demonstrated that GGA3 reintroduction in GGA3 null hippocampal neurons is sufficient to rescue the polarized distribution of BACE1 to the wild type conditions. Together, these results suggest that GGA3 is able to control and modulate the axonal targeting and the polarized sorting of BACE1. Thus, the depletion of GGA3 observed in AD brains is a leading candidate mechanism underlying BACE1 accumulation in peri-plaque dystrophic axons observed in AD brains.

Title: The role of elevated calcium and microtubule destabilization in BACE1 and Aβ accumulation around amyloid plaques in Alzheimer’s disease

Authors: *K. R. SADLEIR[1], A. SOMASUNDARAM[2], V. BUGGIA-PREVOT[3], P. KANDALEPAS[1], G. THINAKARAN[3], M. PRAKRIYA[2], R. VASSAR[1];

Abstract: β-Secretase, β-site APP Cleaving Enzyme1 (BACE1) initiates the production of the β-amyloid (Aβ) peptide involved in Alzheimer's disease (AD). Genetic reduction of BACE1 levels inhibits Aβ generation and amyloid plaque formation. BACE1 protein and activity are elevated in the brains of Alzheimer's patients and mouse models of AD, accumulating in presynaptic neuronal dystrophies around plaques. These accumulations of BACE1 and APP, lead to increased Aβ production. Immunostaining with antibodies specific to neoepitopes of APP and Aβ created by BACE1 cleavage show accumulation of sAPPβ, β-CTF and Aβ species in dystrophic axons along with BACE1, indicating active processing of APP to Aβ in these areas. Blocking the BACE1 increase could be therapeutically useful for decreasing Aβ generation and in slowing or preventing AD without reducing baseline levels of BACE1, which may cause mechanism-based side effects due to deficient processing of numerous BACE1 substrates. Currently, the mechanism of the BACE1 increase is not clear. We observe that in the brains of 5XFAD mice and AD patients, tubulin is mostly absent in BACE1-containing dystrophic axons around plaques, and remaining tubulin accumulates into spheroidal aggregates. We hypothesize that impaired retrograde transport of BACE1 and other proteins leads to accumulation in swollen dystrophic axons,. We see tubulin beading, varicosity formation, and neurite degeneration in primary neurons exposed to Aβ42, and loss of microtubules in dystrophic axons by EM. Also, some components of the kinesin and dynein-dynactin axon transport complexes are decreased and disorganized in dystrophic axons, while others are enriched. Additionally, Aβ42 disrupts anterograde and retrograde axon transport in primary neurons *in vitro*. High intracellular calcium can depolymerize microtubules and disrupt microtubule-based transport. Elevated resting calcium is observed in dystrophic neurites and in neurons exposed to Aβ42. Calcium channel blockers inhibit the calcium influx observed in Aβ42-treated neurons, implicating a calcium channel as the source of increased resting calcium. We hypothesize that Aβ plaques cause increased resting calcium, disrupted microtubule networks, and impaired BACE1 retrograde transport from dystrophic axons for degradation. We will focus on identifying the calcium channel(s) responsible for increased resting calcium, and using pharmacological methods to inhibit calcium increase and/or microtubule destabilization. Through these approaches we hope to decrease BACE1 accumulation in dystrophic axons around plaques, which we predict will slow Aβ42 generation and amyloid pathology.

Abstract: Presenilins play essential roles in memory formation, synaptic function, and neuronal survival. Mutations in the Presenilin-1 (PSEN1) gene are the major cause of familial Alzheimer's disease (FAD). How PSEN1 mutations cause FAD is unclear, and pathogenic mechanisms based on gain or loss of function have been proposed. Here, we generated Psen1 knockin (KI) mice carrying the FAD mutation L435F or C410Y. Remarkably, KI mice homozygous for either mutation recapitulate the phenotypes of Psen1-/- mice. Neither mutation altered Psen1 mRNA expression, but both abolished γ-secretase activity. Heterozygosity for the KI mutation decreased production of Aβ40 and Aβ42, increased the Aβ42/Aβ40 ratio, and exacerbated Aβ deposition. Furthermore, the L435F mutation impairs hippocampal synaptic plasticity and memory and causes age-dependent neurodegeneration in the aging cerebral cortex. Collectively, our findings reveal that FAD mutations can cause complete loss of Presenilin-1 function *in vivo*, suggesting that clinical PSEN mutations produce FAD through a loss-of-function mechanism. We are continuing the analysis of these mutant mice and the new results will be presented.

Title: Identification of γ-secretase substrate-binding sites suggests altered substrate positioning as a core mechanism of pathogenic Aβ generation

Authors: *A. FUKUMORI[1], H. STEINER[2];
[1]German Ctr. for Neurodegenerative Dis., Muenchen, Germany; [2]Biomed. Ctr. - BMC, Metabolic Biochem., Ludwig-Maximilians-University Munich and German Ctr. for Neurodegenerative Dis., Muenchen, Germany

Abstract: The failures of Alzheimer´s disease trials with γ-secretase inhibitors to lower Aβ have raised discussions as to whether the enzyme remains a viable drug target. Since lack of substrate selectivity for the Aβ precursor C99 is one likely cause for the failures, a deep understanding of how the enzyme recruits substrates, which has been strikingly understudied, is needed. To address this long-standing unresolved question, we set out to identify the key residues of C99 interacting with the protease complex and to unambiguously identify its substrate-binding subunit(s). By using a tRNA suppressor approach, we site-specifically incorporated the photocrosslinkable amino acid analog para-benzoyl-phenylalanine at every single residue of the Aβ domain of C99 up to the intracellular juxtamembrane domain. Following UV-mediated photoactivation, key substrate residues binding to γ-secretase, such as Val44, were identified as well as the target subunits including the presenilin 1 N-terminal fragment as major substrate-binding site. Strikingly, clinical presenilin 1 mutants displayed altered substrate-binding patterns suggesting that altered substrate positioning is one molecular cause that underlies the pathogenic generation of longer Aβ peptides. By providing a detailed C99 substrate-enzyme interaction map, our photoaffinity-labeling data fill a major gap of basic knowledge of γ-secretase that might also be key for the development of improved γ-secretase-targeting drugs.

Title: Single-cell detection of Aß and sAPPα secreted from human iPSC-derived neurons and glia

Authors: *M.-C. LIAO[1], T. YOUNG-PEARSE[1], J. C. LOVE[2];
[1]Harvard Med. School/Brigham and Women's Hosp., Boston, MA; [2]Chem. Engin., MIT, Cambridge, MA

Abstract: Secreted factors play a central role in normal and pathological processes in every tissue in the body. The brain is composed of a highly complex milieu of different cell types, and few methods exist that can identify which individual cells in a complex mixture are secreting specific analytes. By identifying which cells are responsible, we can better understand neural physiology and pathophysiology, more readily identify the underlying pathways responsible for analyte production, and develop and test novel therapeutic strategies that target the cell types of relevance. Accumulation of amyloid beta (Aß) in senile plaques is a pathological hallmark of Alzheimer's disease. Aß is generated from sequential processing of Amyloid Precursor Protein (APP) by ß-secretase followed by γ-secretase. APP also can be cleaved by α-secretase to generate sAPPα, which precludes Aβ generation. We present here the method of microengraving to detect Aβ and sAPPα secreted from single hiPSC-derived neural cells. Through these single cells studies, we have found: 1) unexpectedly heterogeneous responses to secretase inhibitors in putatively "homogeneous" stable clonal cell lines; 2) a previously unappreciated subpopulation of cells that secrete high levels of Aβ in the absence of detectable sAPPα; 3) that cell state can affect the relationship between α- and β-secretase cleavage of APP; 4) that during the time of neural differentiation, the number of cells secreting detectable levels of Aβ and sAPPα increases; and intriguingly 5) that cells expressing forebrain GABAergic neuronal markers are overrepresented in subpopulations of cells that secrete high levels of Aβ and sAPPα, although a variety of cell types can secrete high levels of each. Finally, while there is a widespread belief that neurons are the major source of Aβ in the CNS, the results presented here show that astrocytes are competent to secrete high levels of Aβ and may therefore be a significant contributor to pathology in Alzheimer's disease. Taken together, these results using APP as a model protein describe a novel methodology to examine and quantify analyte secretion from hiPSC-derived neural cells at a single cell level, and they demonstrate the utility of such a system with studies directly relevant to unsettled questions regarding AD pathobiology.

Title: Glycelaldehyde-3-phosphate dehydrogenase (GAPDH) aggregates contribute to the pathogenesis of Alzheimer's disease via the acceleration of Aβ amyloidogenesis

Authors: *M. ITAKURA, H. NAKAJIMA, T. KUBO, Y. SEMI, S. KUME, S. HIGASHIDA, A. KANESHIGE, A. KITA, K. SATO, Y.-T. AZUMA, T. INUI, T. TAKEUCHI;
Osaka Prefecture Univ., Osaka, Japan

Abstract: Glycelaldehyde-3-phosphate dehydrogenase (GAPDH) has been identified as a critical enzyme in glycolysis. In addition to this classical role, GAPDH possesses diverse functions including cell death. It is well known that GAPDH is highly sensitive to reactive oxygen species and oxidatively modified GAPDH forms disulfide-bond related aggregation, leading to cell death. Alzheimer's disease (AD) is a progressive neurodegenerative disorder that is characterized by memory loss and cognitive deficit. Although the exact cause of AD remains to be elucidated, numerous studies have demonstrated the involvement of Amyloid-β peptide (Aβ) in the pathogenesis of AD; Aβ amyloidogenesis is known to be responsible for neuronal dysfunction and cell death. Recently, several reports suggest the relationship between GAPDH and AD, but the underlying mechanism has not been revealed. In the present study, our observation using 3xTg AD mice clarified the co-localization of GAPDH aggregates with Aβ aggregates both in senile plaques and inside neurons in the hippocampal CA3 region, which makes us hypothesize that GAPDH aggregates are involved in Aβ amyoidogenesis. *In vitro* assay using purified GAPDH and Aβ40 revealed that GAPDH aggregates enhanced Aβ40 amyloidogenesis assessed quantitatively and morphologically by Thioflavin-T fluorescence intensity, Congo red birefringence, far-ultraviolet CD spectrum and atomic force microscopy. Further investigation at the cellular level showed that GAPDH aggregates augmented Aβ40-induced mitochondrial dysfunction, causing enhanced cell death. Moreover, the test using intracerebroventricularly Aβ40-injected mice demonstrated that Aβ40-induced neuronal cell death in the hippocampal CA3 region was potentiated by the co-incubation with GAPDH aggregates via the increased cytochrome-c release and nuclear translocation of apoptosis inducing factor. These data indicate that aggregated GAPDH augments Aβ amyloidogenesis and increases neuronal cell death both *in vitro* and *in vivo*, which suggests that GAPDH play an important role for AD pathogenesis.

Title: Partial purification of amyloid-beta oligomers from human Alzheimer's disease brain lysates

Authors: *D. L. BRODY, H. JIANG, T. J. ESPARZA;
Dept Neurol, Washington Univ., Saint Louis, MO

Abstract: Senile plaques constitute a key pathological hallmark of Alzheimer's disease (AD), yet the extent of plaque deposition only moderately correlates with the progression of dementia. In contrast, various forms of soluble amyloid-beta (Aβ) oligomers have demonstrated a stronger correlation with dementia status and exhibit significantly greater toxicity than isolated fibrils, plaques or peptide monomers. We used our plate-based Aβ oligomer assay (Esparza et al, Annals of Neurology, 2013) to quantitatively guide extraction and partial purification of Aβ oligomers from frozen cortical AD brain tissue. Tissue was dounce homogenized in phosphate-buffered saline containing 0.5% CHAPS. Oligomeric Aβ was separated from monomers by 35% ammonium sulfate precipitation followed by size exclusion chromatography. To prevent non-specific loss, tubes and pipet tips were pre-coated with 0.0075% albumin. Immunoprecipitation was performed with combined N-terminal and mid-domain specific Aβ monoclonal antibody-conjugated sepharose beads. After 20 saline washes, immunoprecipitated material was eluted with pH 11 ammonium hydroxide. CHAPS extraction increased yield of Aβ oligomers to approximately 10 ng per gram of frozen cortical tissue. CHAPS extraction and did not result in artifactual oligomerization based on control experiments involving spiking 2 ng/ml AD-brain derived monomeric Aβ into non-demented control brain tissue prior to homogenization. In contrast, triton X-100 and SDS extractions resulted in substantial artifactual Aβ oligomerization. Ammonium sulfate precipitation also did not result in artifactual oligomerization and did not change the predominant size of oligomers: >500 kDa based on Superdex 200 size exclusion chromatography in physiological saline running buffer. In contrast, size exclusion chromatography using ammonium acetate pH 8.5 running buffer produced a heterogenous array of smaller oligomers, suggesting dissociation into sub-assemblies. Ammonium sulfate precipitation produced approximately 10-fold purification, and immunoprecipitation resulted in an additional 1000-fold purification. We have achieved approximately 10,000 fold purification of native Aβ oligomers from human Alzheimer's disease cortex with <30% loss of starting material. Our immediate goal is to test the hypothesis that post-translational modifications and co-associated proteins contribute to the development and accumulation of synaptotoxic Aβ assemblies.

Title: CLAC alters the plaque morphology and dynamics of amyloid-β peptides in the brain

Authors: *T. HASHIMOTO, Y. NAKA, D. FUJII, M. KASHIWAGI, T. WAKABAYASHI, T. IWATSUBO;
The Univ. of Tokyo, Tokyo, Japan

Abstract: Massive deposition of amyloid-β peptides (Aβ) as senile plaques (SPs) characterizes the pathology of the brains of patients with Alzheimer's disease (AD), although the role of SPs in the pathophysiology of AD remains unclear. A variety of SPs in different morphology are observed in AD brains, whereas specific components of SP that determine their morphology are unknown. We examined the role of collagenous Alzheimer amyloid plaque component (CLAC), a non-Aβ proteinaceous component of SP amyloid identified in AD brains, in the formation of SPs and dynamics of Aβ in the brains of AD model mice. To this end, we generated transgenic (tg) mice overexpressing CLAC precursor (CLAC-P) in neurons and crossed them with APP tg mice. Overexpression of CLAC in the brains of APP tg mice caused a remarkable reduction in diffuse-type Aβ plaques and increased well-demarcated and middle-sized Aβ plaques, which were occasionally laden with thioflavin S-positive amyloid cores. Biochemically, the levels of insoluble Aβ in the brains of APP/CLAC-P double tg mice were comparable to those in APP tg mice. These data implicate CLAC in the remodeling of Aβ plaque morphology into maturated form. To further investigate the role of SPs in the dynamics and metabolism of Aβ in brains, we measured the levels of Aβ42 in the interstitial fluid (ISF) of hippocampus by *in vivo* microdialysis using a 1,000 kDa molecular weight cut-off probe. Interestingly, we found a negative correlation between the Aβ plaque burden and the ISF Aβ42 levels in 18-month-old APP tg mice, which may suggest the role of Aβ plaques as a pool of soluble extracellular Aβ in brains. In the APP/CLAC-P double tg mice, however, the levels of hippocampal ISF Aβ42 was significantly lower than those in APP single tg mice, and the negative correlation between Aβ burden and ISF Aβ42 was attenuated. These results altogether suggest that association of CLAC may play an important role in the maturation of Aβ plaques, resulting in an alteration in the dynamics and metabolism of Aβ in AD brains

Title: Endothelin-converting enzyme-2 is expressed by somatostatin GABAergic interneurons and modulates intraneuronal Aβ

Authors: *J. PACHECO-QUINTO, E. ECKMAN;
Biomed. Res. Inst. of New Jersey, Cedar Knolls, NJ

Abstract: One of the key features of Alzheimer's disease (AD) is the accumulation of the neuronally-produced amyloid β peptide (Aβ) in the form of aggregates in the brain. These Aβ aggregates, specifically in their soluble states, can cause synaptic toxicity and neuronal loss. Enzymatic degradation is crucial to maintain Aβ homeostasis and endothelin-converting enzyme-2 (ECE-2) is one of the known physiologically important Aβ degrading enzymes. We have previously shown that ECE-2 knockout mice have a significant 1.3 fold elevation in endogenous Aβ. However, ECE-2 has an acidic pH optimum, cannot modulate extracellular Aβ and only degrades Aβ along the endosomal/lysosomal pathway, suggesting that in ECE-2 knockout mice Aβ accumulates intracellularly. To understand better the role that ECE-2 plays in Aβ catabolism, we characterized which cell populations express ECE-2 in CNS and the consequence of ECE-2 inhibition on Aβ accumulation and aggregation. Experiments were performed on brain tissue from wild-type and TgCRND8 APP transgenic mice, as well as temporal cortex from AD patients and non-demented control patients. By combining fluorescence immunohistochemistry with multiplex fluorescence *in situ* hybridization we observed that ECE-2 mRNA was abundantly expressed by somatostatin positive GABAergic interneurons in the soma and along axons. In addition, ECE-2 was found active in synaptosomal preparations, suggesting that it degrades either internalized Aβ in presynapses or Aβ produced along the retrograde transport pathway. We did not observe ECE-2 expression in activated astrocytes or microglia surrounding amyloid plaques, in either APP transgenic mice or in patients with AD. In SH-SY5Y cells overexpressing human wild type APP and in primary neuronal cultures from TgCRND8 mice, ECE-2 inhibition led to increased intracellular Aβ accumulation and the intracellular formation of Aβ aggregates.Our data suggest that somatostatin positive GABAergic interneurons contribute to Aβ homeostasis by degrading Aβ along the retrograde transport pathway. Failure in ECE-2 activity could lead to the formation of Aβ aggregates and represent one of the first steps in the amyloidogenic process.

Title: Aβ(1-42) fibril structure illuminates self-recognition and replication of amyloid in Alzheimer's disease

Authors: *Y. ISHII[1], Y. XIAO[2];
[1]Univ. Illinois At Chicago, Dept of Chem., Chicago, IL; [2]Dept of Chem., Univ. Illinois At Chicago, Chicago, IL

Abstract: Increasing evidence suggests that formation and propagation of misfolded aggregates of 42-residue amyloid β (Aβ(1-42)), rather than the more abundant Aβ(1-40), provokes the Alzheimer's cascade. To date, structural details of misfolded Aβ(1-42) have remained elusive. Here we present the atomic model of Aβ(1-42) amyloid fibril based on solid-state NMR (SSNMR) data. It displays triple parallel-β-sheet segments that are different from reported structures of Aβ(1-40) fibrils. Remarkably, Aβ(1-40) is not compatible with the triple-β motif, as seeding with Aβ(1-42) fibrils does not promote conversion of monomeric Aβ(1-40) into fibrils via cross-replication. SSNMR experiments suggest that the Ala42 carboxyl terminus, absent in Aβ(1-40), forms a salt-bridge with Lys28 as a self-recognition molecular switch that excludes Aβ(1-40). The results provide insight into Aβ(1-42)-selective self-replicating amyloid propagation machinery in early-stage Alzheimer's disease. Other topics such as interactions with a pathogenic mutant of Aβ will be also discussed.

Title: Hyperinsulinemia modulates extracellular amyloid-beta *in vitro*

Authors: *M. STANLEY[1], S. L. MACAULEY[2], E. E. CAESAR[2], G. ROBINSON[2], D. M. HOLTZMAN[2];

Abstract: Type 2 diabetes (T2D) is a risk factor for developing late-onset Alzheimer's disease (AD), the most common form of dementia. T2D is characterized by high blood insulin (hyperinsulinemia), high blood glucose (hyperglycemia), and insulin resistance. Hyperinsulinemia, specifically, has been associated with an increased risk for developing AD and amyloid plaques. Levels of extracellular amyloid-beta (Aβ) in the brain influences Aβ deposition in a concentration-dependent manner and *in vitro* experiments suggest that high insulin can lead to higher concentrations of extracellular Aβ. However, the effects of high insulin on extracellular Aβ *in vivo* are currently unknown. To determine if insulin can modulate brain levels of interstitial fluid (ISF) Aβ in awake, freely-behaving PS1dE9/APPswe mice, insulin was delivered directly into the hippocampus through a microdialysis probe at different concentrations. The response in males was more variable than females, but overall there was a significant increase in ISF Aβ in response to 40nM insulin. T2D is characterized by peripheral hyperinsulinemia and since it is known that blood insulin crosses the blood brain barrier through a saturable transport mechanism, we also determined the effects of peripherally high insulin on ISF Aβ. To manipulate blood insulin levels in awake, freely-behaving PS1dE9/APPswe mice, we performed acute hyperinsulinemic-euglycemic clamps while simultaneously collecting ISF from the hippocampus using microdialysis. We found that moderate hyperinsulinemia (4mU/kg/min) increased ISF Aβ in both young mice without amyloid plaques and old mice with significant amyloid pathology of both genders. We also found that extreme hyperinsulinemia (20mU/kg/min) also modulates ISF Aβ to a similar extent. Our results suggest that increases in peripheral and central insulin can increase the concentration of ISF Aβ both before and after amyloid plaque deposition, suggesting that insulin levels may affect the onset or progression of AD by affecting Aβ aggregation *in vivo*. Abstract: Background Alzheimer's disease (AD) is the most common form of dementia in the aging population and affects millions of people worldwide. Aggregation and toxicity of the amyloid β-peptide (Aβ) are considered as critical events in the initiation and progression of AD. Several familial AD (FAD) mutations that cause early onset AD are found within the Aβ and result in alterations of peptide conformation and promote oligomerization. However, such mutations are very rare and molecular mechanisms that induce the formation or stabilization of oligomers of the wild-type Aβ remain unclear. Methods We applied cell biological, biochemical, biophysical and neuropathological methods to characterize the effect of Aβ phosphorylation in cell culture models as well as in brains of human AD cases and transgenic mice. Results We demonstrate that Aβ undergoes phosphorylation at different sites and identified potential protein kinases. Phosphorylated Aβ shows increased propensity to form oligomeric and fibrillar aggregates and adopt β-sheet conformation. By using highly specific phosphorylation site specific antibodies, we demonstrate abundant presence of phosphorylated Aβ (pAβ) in transgenic mouse models of AD and human brain. Phosphorylated Aβ shows different spatio-temporal distribution as compared to non-phosphorylated Aβ (npAβ). Importantly, pAβ oligomers exert increased toxicity in human neurons. Conclusions Our studies reveal the effect of site-specific

phosphorylation on Aβ conformation, oligomerization and toxicity. We hypothesize that phosphorylation of Aβ seems to act as a conformational switch and modulate aggregation and toxicity of Aβ peptides. Phosphorylated Aβ species are present in human AD brains and transgenic mouse models. The detection of these variants could be further explored as targets for AD therapy and prevention as well as markers for AD pathogenesis.

Title: Nominal amyloid-beta (Aβ) levels, and reduction of Aβ by exogenous neprilysin, in mouse eye tissues

Authors: *R. PARTHASARATHY[1,2], M. K. CHOW[3], Z. DERAFSHI[2], M. P. FAUTSCH[4], J. R. HETLING[2], D. W. RODGERS[3], L. B. HERSH[3], D. R. PEPPERBERG[1,2];

Abstract: Amyloid-beta (Aβ), an aggregation-prone peptide, is a suspected culprit in Alzheimer’s disease. Recent studies have raised the hypothesis that excessive Aβ build-up in eye tissues may contribute to retinal degenerative diseases such as age-related macular degeneration. Neprilysin (NEP) is a native membrane-anchored endopeptidase that cleaves Aβ into inactive products, and this activity is retained by a recombinant soluble protein (sNEP) that includes

NEP's catalytic domain. We have examined whether sNEP delivered intravitreally to the mouse eye can decrease ocular levels of Aβ40 and Aβ42 (40 and 42 amino acids in length, respectively). Anesthetized 10-month old wild-type C57BL/6J mice and 2-3-month old 5XFAD mice received intravitreal injections (2 μL) of phosphate-buffered saline (PBS) containing 10 μg sNEP. Twenty-four hours after injection, animals were euthanized and the eyes dissected to separately yield (i) combined lens and vitreous, (ii) neural retina, and (iii) combined retinal pigment epithelium and choroid. PBS extracts of homogenized samples were analyzed for Aβ and protein to yield protein-normalized Aβ40 and Aβ42 concentrations. Samples of types (i-iii) from untreated eyes of C57BL/6J and 5XFAD mice exhibited readily measurable Aβ concentrations. For C57BL/6J mice (n=12), Aβ40 concentrations in (i-iii) did not differ significantly from one another ($p>0.3$), and the sum of levels in (i-iii) (43.8 ± 6.9 pmol/g protein) did not differ significantly from Aβ40 levels determined in experiments that involved the recovery of combined samples (i-iii) followed by homogenization, PBS extraction and analysis of the combined eye tissues ($p>0.05$). Similar results were obtained for 5XFAD mice (n=8), where no significant differences were noted between separate-tissue (i-iii) concentrations for either Aβ40 or Aβ42 ($p>0.09$), and where, for both Aβ40 and Aβ42, summed concentrations in (i-iii) did not differ significantly from those determined in combined-eye-tissue experiments ($p = 0.57$ and 0.21, respectively). Treatment with sNEP produced significant Aβ40 reductions in compartments (i-iii) in C57BL/6J mice. In 5XFAD mice, sNEP treatment significantly reduced Aβ40 in all three compartments, and these reductions exceeded those for Aβ42 in each compartment. The results indicate that intravitreal sNEP treatment reduces Aβ levels in multiple compartments of the mouse eye *in vivo*. The data encourage further investigation of the effect of sNEP-mediated Aβ degradation *in vivo* on eye tissue structure and function, with potential for therapeutic application.

Title: Altered vascular morphology and tight junction proteins in presence of oligomeric amyloid-beta in the hippocampus

Authors: *M. VARGHESE[1], T. WARDA[2], A.-L. MANDENGUE SOSSO[2], A. SOWA[2], D. DICKSTEIN[2], M. EHRLICH[3], D. L. DICKSTEIN[2];

[1]Neurosci., Mount Sinai Sch. of Med., New York, NY; [2]Neurosci., [3]Neurol. & Pediatrics, Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Vascular amyloid-beta deposits and cerebral vascular pathology are observed in Alzheimer's disease and in cerebral amyloid angiopathy. The amyloid-beta peptide can exist in soluble oligomeric or fibrillar forms. While oligomeric amyloid-beta is hypothesized to initiate neurotoxicity, it is unclear which of these amyloid-beta species is responsible for vascular changes in disease. We investigated whether soluble oligomeric amyloid-beta alone can trigger cerebral vascular pathology using an experimental model, the Thy-1/hAPP^{E693Q} mouse. These mice express the human amyloid precursor protein with the E693Q Dutch mutation, produce the soluble species of the peptide and do not have visible fibrillar deposits. To identify changes in vascular morphology in Thy-1/hAPP^{E693Q} mice as compared to wild-type (WT) controls, we used collagen IV immunohistochemistry and quantitative stereology. We also quantified the expression of tight junction proteins in the vascular endothelial cells using Western blot, followed by densitometry. Stereological analyses revealed no changes in vascular length density in the hippocampal CA1/2 and CA3 areas of Thy-1/hAPP^{E693Q} mice as compared to WT. However, analysis of vascular morphology revealed that Thy-1/hAPP^{E693Q} mice had more pathological vessels as compared to WT controls. Specifically, we observed increased number of string vessels, with a trend towards increased twisted vessels in the Thy-1/hAPP^{E693Q} mice. Ultrastructural analysis of vessels also revealed changes in the vessel diameters of Thy-1/hAPP^{E693Q} mice. We then investigated the expression of tight junction proteins in various brain regions and found altered expression of the tight junction protein zonula occludens-1 in the hippocampus of Thy-1/hAPP^{E693Q} mice as compared to controls. Taken together, our results indicate that oligomeric amyloid-beta alone, in the absence of fibrillar and amyloid plaque pathology, causes cerebral vascular pathology, reminiscent of those observed in patients with Alzheimer's disease and cerebral amyloid angiopathy.

Abstract: Accumulation of the β-amyloid (Aβ) protein in the brain as senile plaques is a signature lesion of Alzheimer's disease (AD). The mechanism of Aβ accumulation that fosters its deposition is a subject of intense study and has been considered as the basis for most drug development efforts in the field. However, we still have a poor understanding of the degradation pathways that are responsible for maintaining Aβ homeostasis in normal people. We have previously determined that partial γ-secretase inhibition works through an Aβ degradation bypass mechanism to Aβ levels. In neuronal cells, intracellular (ic)Aβ40 levels are very low and nearly undetectable. Treatment with low doses (25 μM) of a γ-secretase inhibitor -DAPT - increases secreted (s)Aβ40 secreted in the medium substantially, but does not seem to affect icAβ40. High doses of DAPT that completely inhibits sAβ, increases intracellular Aβ40 significantly. Phosphoramidon (PA), an inhibitor of some metalloproteases such as endothelin-converting enzyme (ECE) substantially increase icAβ40 to about 1 ng/mg protein. Inhibiting major protease classes by treatment with E64 and Leupeptin to block serine proteases and cysteine proteases or pepstatin A to inhibit acid proteases did not increase icAβ40 or sAβ40 levels. Treatment with 4-(2-Aminoethyl) benzenesulfonyl fluoride (AEBSF) completely inhibits sAβ40 and icAβ40. However, it only reduces PA-stimulated Aβ40 by 40%. We have used extracts of a popular neuronal cell line - SH-SY5Y - to characterize the Aβ degrading pathways *in vitro*. The studies show that two pools of proteases that are active at acid and neutral pH rapidly degrade Aβ in these lysates. Inhibitor sensitivity profile suggests that metalloproteinase(s) are major contributors to the turnover process at neutral pH, but multiple redundant acid proteases appear to be responsible for its degradation in acid pH. A combination of protease inhibitors fails to substantially block the loss of Aβ at acid pH, suggesting that other uncharacterized activities play a key role under these conditions. The studies suggest that a large redundant process normally prevents amyloid accumulation and the process that overwhelms this safety net needs to be studied in detail to understand the mechanisms of amyloidosis in AD. We are currently examining the miRNA profiles for putative AB-degrading enzymes, including Neprilysin.

Title: Role of ESCRT dependent mutivesicular bodies in intracellular beta-amyloid accumulation and exosomal secretion in Alzheimer's disease

Authors: *K. WILLÉN, G. K. GOURAS;
Lund Univ., Lund, Sweden

Abstract: Objectives Alzheimer's-linked beta-amyloid (Aβ) accumulates in endosomal vesicles near synapses with the onset of synaptic dysfunction in Alzheimer's disease (AD). Previous evidence suggested that sorting via the multivesicular body (MVB) pathway is impaired by endosomal Aβ accumulation in cultured AD-transgenic primary neurons. Our aim was to investigate the trafficking and processing of APP and its cleavage products in the endocytic pathway with a focus on the role of ESCRT (endosomal sorting complex required for transport)-mediated sorting. Methods Different steps in the endocytic pathway, including MVB formation, lysosome acidification, autophagy, and exocytosis, were modulated in neuroblastoma cells and primary mouse neurons. APP and its metabolites including Aβ , as well as synaptic proteins, were analysed using WB and immunofluorescence. Differences in the endocytic pathway between wt and AD-transgenic primary neurons (AD-neurons) and neurons treated with synthetic Aβ were also investigated. Results Inhibition of VPS4A, a key component in the ESCRT machinery and the only energy-consuming enzyme that promotes disassembly and recycling of ESCRT-III oligomers, leads to elevated intracellular levels and reduced secretion of Aβ in N2a cells and primary neurons. Inhibition of VPS4A also affects the release of exosomes. Dysfunctional MVBs increase markers of autophagy and chemical stimulation of autophagy partially rescues the dominant negative VPS4A induced rise of intracellular Aβ. Conclusions AD-neurons were shown to have impaired MVB sorting as well as progressive intraneuronal Aβ accumulation and reduced Aβ secretion with time in culture. We now show that inhibition of VPS4A, a critical component of ESCRTs involved in MVB formation, mimics these cellular changes in AD-neurons. Further, our results provide novel insights into the role of MVBs in autophagy and lysosomal degradation, both of which are altered in AD.

Title: Function and regulation of APP and Alcadeinα cargoes transported by kinesin-1 in neuron

Authors: *Y. SHIRAKI, K. CHIBA, S. HATA, T. SUZUKI;
Lab. of Neuroscience, Grad. Sch. of Pharmaceut. Sci., Sapporo/Hokkaido, Japan

Abstract: Kinesin-1 is the major anterograde motor to transport vesicles in axon. The kinesin-1 is a heterotetramer with two heavy chains (KHC) and two light chains (KLC). Various types of cargos and organelle can be associated with kinesin-1 through the binding to distinct adapter proteins or cargo receptor proteins. Alzheimer's β-amyloid precursor protein (APP) and Alcadeinα (Alcα)/Calsyntenin-1 are major cargo receptor in neuron (EMBO J. [2007] 26, 1475). KLC of kinesin-1 binds APP largely by mediation with JIP1b and Alcα directly (Traffic [2012] 13, 834; Mol. Biol, Cell [2014] 25, 3569). However, cargos transported by APP or Alcα are still controversial. In this study, we showed that APP and Alcα vesicles are largely independent for axonal transport using live cell imaging, and found that the respective cargos transport distinct types of components by proteome analysis. We previously reported that a complex formation of APP with Alcα mediated by X11L neural adaptor protein suppressed both APP and Alcα protein transport to cell surface and overexpression of Alcα intracellular domain fragment (Alcα ICD), which can be generated physiologically by γ-secretase cleavage of Alcα, released APP from the complex to increase APP vesicle transport (J. Biol. Chem. [2015] 290, 987). Taken together with this observation, present results propose a novel insight that APP and Alcα transport a distinct type of vesicular cargo, but the transport of both cargos is regulated ingeniously by an associated mechanism.

Abstract: Alzheimer's disease is pathologically characterized by the accumulation of beta-Amyloid (Aβ) plaques in brain, the result of metabolic processing of the Amyloid Precursor Protein (APP). While a definitive function for APP in healthy brains has remained elusive, the series of metabolic events leading to Aβ pathology has been well characterized. APP is a type I integral membrane protein, metabolized by alternative pathways that release either the disease-associated beta-amyloid peptide or the non-pathological p3 peptide. Both pathways ultimately result in the release of a C-terminal fragment into the cytosol - the APP Intracellular Domain (AICD). AICD has been implicated in nuclear signaling, particularly in the regulation of gene expression related to APP processing. This theorized pattern of self-regulation by an intracellular fragment is seen in other metabolic pathways, and AICD protein interactions could be determining factors of the metabolic fate (amyloidogenic or non-) of APP. In this way, AICD and its network of interacting proteins have become an inroad to study, and hopefully translationally influence, APP. The biological role of AICD, if any, remains controversial due to its short half-life and modest effects in *in vitro* gene expression studies. Thus, there is a need to discover potential AICD interacting proteins and to clarify potential functions for this metabolic fragment. Towards this goal, identification of the AICD interactome by affinity purification of a tagged AICD followed by mass spectrometry (MS) and bioinformatic analysis was performed. Affinity tagged AICD fragment were stably expressed in cultured cells. Affinity purification was performed under native conditions on lysates cleared of nuclei to yield extranuclear interaction partners of AICD. We performed both a complete interactome screen as well as targeted proteomics to confirm interactors of interest. Among the targets identified are proteins implicated in nuclear signaling, APP regulation, processing enzymes, and modulation of AICD levels. The post discovery phase will include co-localization studies, transcriptional analysis and *in vivo* analysis with vetted animal models to better comprehend the role of AICD's role in Pathogenesis of Alzheimer's Disease. Title: Translational control of the amyloid precursor protein by a guanine quadruplex

Authors: *E. M. CRENSHAW[1], B. LEUNG[2], C. K. KWOK[3], P. C. BEVILACQUA[4], M. R. AKINS[1], A. J. SAUNDERS[1];
[1]Drexel Univ., Philadelphia, PA; [2]USC, Los Angeles, CA; [3]Chem., Univ. of Cambridge, Cambridge, United Kingdom; [4]Penn State Univ., University Park, PA

Abstract: The single stranded nature of RNA enables this molecule to adopt different structural conformations. Guanine rich RNAs can fold into a guanine quadruplex structure through Hoogsteen hydrogen bonding. Guanine quadruplexes are further stabilized by monovalent cations such as potassium or sodium. The involvement of guanine quadruplexes in RNA has shown to be of importance because it can affect translation for a given protein. Recently, we have identified a guanine quadruplex in the 3 prime untranslated region (3' UTR) of the Amyloid Precursor Protein (APP). APP plays a major role in Alzheimer's disease. Neuropathologically, Alzheimer's disease is defined by the accumulation of the β-amyloid (Aβ) peptide. Aβ is produced by the sequential, proteolytic cleavage of the amyloid precursor protein by the β- and γ-secretases. While most Alzheimer's disease cases occur after the age of 65 years (late-onset), there are a small number of cases that occur before the age of 60 years (early-onset). Alzheimer's disease can be caused by genetic changes that result in increased production of the Amyloid Precursor Protein. The increase in APP expression can lead to increased Aβ production and accumulation as seen in Individuals with Down's syndrome (Trisomy 21) who invariably develop AD. This information strongly suggest that dysregulation of APP expression could play a role in the pathogenesis of AD. Therefore it is imperative to identify mechanisms underlying the regulation of APP expression. Given that guianine quadruplexes within the 3' UTR of mRNAs have been shown to play a role in repressing translation, we decided to test what effects this secondary structure would have on regulating the Amyloid Precursor Protein. We first confirmed the presence of the 3 prime untranslated region guanine quadruplex within the APP mRNA by using Circular Dichroism in which we compared the wild type and mutant guanine quadruplex sequence. To address the involvement of the APP 3'UTR guanine quadruplex on translation, we used luciferase reporter constructs and APP reporter constructs to detect changes in mRNA levels (for transcription) or protein levels (for translation). Our results demonstrate that the guanine quadruplex in the 3'UTR of APP negatively regulates APP translation. Moreover, we show that disrupting the guanine quadruplex lead to higher APP protein levels as well as an increase in Aβ levels.

Abstract: Alzheimer's disease (AD) is characterized by the deposition of amyloid β (Aβ), a peptide generated from proteolytic processing of its precursor, amyloid precursor protein (APP). Canonical APP proteolysis occurs via α-/ β- and γ-secretases. APP is also actively degraded by protein degradation systems. By pharmacologically inhibiting protein degradation with ALLN, we observed an accumulation of several novel APP C-terminal fragments (CTFs). The two major novel CTFs migrated around 15 and 25 kD, and can be observed across multiple cell types. The process was independent of cytotoxicity or protein synthesis. We further determine that the accumulation of the novel CTFs is not mediated by proteasome or calpain inhibition, but by cathepsin L inhibition. Moreover, these novel CTFs are not generated by increased amount of BACE. Here, we name the CTF of 25 kD as η-CTF (eta-CTF). Our data suggests that under physiological conditions, a subset of APP undergoes alternative processing and the intermediate products, the 15 kD- and the η-CTFs get rapidly degraded/ processed via the protein degradation machinery, specifically, cathepsin L.

Title: Modeling CD74 directed APP trafficking for Alzheimer's disease

Authors: *T. KIYOTA[1], C. M. MORRISON[1], Y. LU[1], W. DONG[1,3], B. DYAVARSHETTY[1], H. E. GENDELMAN[1,2];

Abstract: Control of amyloid-β (Aβ) precursor protein (APP)/Aβ trafficking represents an exciting therapeutic directive in harnessing β-amyloidosis. If successful it could positively affect the tempo of Alzheimer's disease (AD). The current work is based on our prior observations that recombinant adeno-associated virus (AAV)-mediated gene delivery of CD74, the major histocompatibility complex class II-associated invariant chain, reduces Aβ production in the mouse hippocampus and improves learning performance when measured by Morris water maze tasks. To elucidate how CD74 effects APP/Aβ modification, we investigated its trafficking pathways. Stereotaxic injection of the AAV-tet-response element (TRE)-green fluorescent protein (GFP) or CD74 into the hippocampi of AD mice [TgCRND8 strain x CamKII (calmodulin-dependent protein kinase II derived promoter)-tet-controlled transactivator (tTA, binding to TRE to regulate gene expression) double-transgenic mice] demonstrated hippocampal expression of GFP and CD74. Neuronal production of CD74 reduced intraneuronal Aβ accumulation when compared to GFP-controls. Immunoprecipitation tests demonstrated that CD74 binds to neuronal APP in neural progenitor cell (NPC)-derived neurons co-infected with adenovirus expressing human APP Swedish mutant (APPsw) and AAV-CD74. Endolysosomal trafficking of APP was shown from NPC-derived neurons co-infected with AAV-tTA, AAV-TRE-APPsw and AAV-GFP or CD74. Here immunofluorescence studies for Rab5 and 7 and Lamp1 showed that APPsw was co-localized with Rab5 and Lamp1, but not Rab7 in CD74 expressing neurons. These results support the idea that CD74 reduces Aβ production by endolysosomal trafficking and promotes APP degradation. This previously undisclosed pathway opens a new therapeutic window for AD.

Title: A novel role for amyloid precursor protein in the endocrine pancreas

Authors: *J. KULAS, K. L. PUIG, C. K. COMBS;
Basic Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: Amyloid Precursor Protein (APP) has been widely studied due to its role in the formation of Aβ plaques in Alzheimer's disease (AD) patients. Despite rigorous examination the endogenous function of this protein has remained elusive. Epidemiological data has indicated a link between AD and type II diabetes, with recent evidence of insulin resistance occurring in the hippocampi of AD patients. Our lab has focused on documenting the expression and function of APP in peripheral tissues. We have observed APP expression within human and murine pancreatic Islets of Langerhans, the site of peripheral insulin production, with abundant overexpression in the pancreatic islets of APP/PS1 transgenic mice. In order to gain a mechanistic understanding of APP within this tissue, we have compared pancreatic function and protein expression across a variety of transgenic mice, including C57BL/6 wild type, APP -/- and APP/PS1 animals. Our data suggests a novel role for APP in the regulation of both BACE2 and Insulin Degrading Enzyme (IDE) expression as revealed by western blotting. Additionally, our assessments of isolated murine pancreatic islets indicate APP as a regulator of both islet glucose uptake and insulin secretion. Together, these data suggest a previously unknown function for APP within the endocrine pancreas.

Title: The role of FE65 phosphorylation in regulating Alzheimer's disease amyloid precursor protein processing

Authors: *K.-F. LAU, W. LI, J. C. NGO, H. E. CHAN, W. V. CHOW;
The Chinese Univ. of Hong Kong, Shatin, NT, Hong Kong

Abstract: Alzheimer's disease (AD) is a fatal neurodegenerative disease affecting 36 million people worldwide. Genetic and biochemical research indicated that the excessive generation of amyloid-β peptide (Aβ) from Amyloid Precursor Protein (APP), is essential to AD pathology. A number of APP-interacting proteins have been implicated in modulation of APP processing, including FE65. FE65 is a neuronal adaptor protein with multiple protein-protein interaction domains. It has been shown that FE65 interacts with APP to alter APP processing and Aβ generation. Evidence indicates that FE65 is a phospho-protein with a number of phosphorylation sites. However, the role of FE65 phosphorylation in APP metabolism is still not fully understood. In our work, we found a number of phosphorylated residues in FE65 that could modulate APP processing. Moreover, the kinases for the sites were identified. We therefore provide evidence that FE65 phosphorylation plays important role in the regulation of FE65-mediated APP processing.

Title: Homeostatic coupling between surface trafficking and cleavage of amyloid precursor protein

Authors: *C. DELBOVE[1], C. E. STROTHMAN[2], K. E. KITKO[2], R. M. LAZARENKO[1], Q. ZHANG[1];
[1]Pharmacol., [2]Vanderbilt Univ., Nashville, TN

Abstract: Amyloid precursor protein (APP) is a ubiquitously expressed neuronal membrane protein with multiple routes of proteinase processing involving different secretases in different lipid membrane compartments. Among those routes, only intracellular cleavages of APP by β- and γ-secretases contribute to the production of amyloid beta peptides (Aβ). Due to its pathological association with Alzheimer's disease (AD), the expression, trafficking, and processing of APP have drawn tremendous attention and effort in the field of neurodegeneration.

Recent studies have revealed that APP trafficking and processing are influenced by synaptic activity. Despite tremendous interest and research effort, a few major questions about APP remain unanswered: (1) the distribution of APP in different lipid compartments at neuronal synapses, (2) the role of synaptic transmission in APP trafficking between the surface membrane and intracellular compartments, and (3) the regulation of APP allocation to different cleavage pathways. These issues are not only important for the understanding of Aβ generation but also precede any therapeutic strategies targeting APP cleavage. To directly address these questions in live neurons, we devised a multicolor fluorescent probe as a ratiometric reporter for APP trafficking and processing. Using immunocytochemistry and quantitative measurements, we confirmed that this probe is a faithful proxy for endogenous APP. In combination with an optically separable reporter for synaptic activity, we evaluated the activity-driven APP shuttling between surface and internal membrane compartments. Pharmacological inhibition of selected secretases revealed an unexpected homeostatic coupling between different APP cleavage processes and APP trafficking. Homeostatic mechanisms maintain a constant level of APP on the synaptic surface and α- and/or β-secretase inhibitors cause an intracellular APP accumulation. Unexpectedly, this homeostasis heavily depends on γ-secretase activity. As those secretases become major drug targets for AD treatment, tools to quantify APP allocation, trafficking, and cleavage in live neurons are indispensible. More importantly, a mechanistic understanding of APP distribution and trafficking among different subcellular locations, between major secretase pathways and under the influence of neuronal activity is essential for designing effective therapeutic strategies to prevent Aβ accumulation and neurodegeneration.

Abstract: Diverse and extensive data sets indicate disturbances in energy metabolism in Alzheimer's disease (AD), including mitochondrial deficits and a comorbidity with type-2 diabetes. The amyloid precursor protein (APP) is genetically and biochemically connected to AD, and we have begun to assess its role in glucose regulation and other aspects of energy utilization through the analysis of APP-knockout mice. We examined glucose maintenance via glucose- and insulin-tolerance tests, and we explored other aspects of metabolism through the use of a Comprehensive Laboratory Animal Monitoring System (CLAMS). We also assessed cell-autonomous respiration via Seahorse assays of cultured astrocytes. Wild-type mice fed a western (high-fat, high-sucrose) diet developed an impaired ability to respond to glucose and insulin challenges, and they exhibited hyperinsulinemia; their APP-KO littermates were resistant to these effects. These results appear to involve both reduced food consumption and elevated metabolism in the APP-KO mice. Moreover, respiratory changes were apparent at the cellular level, as APP-KO astrocytes showed elevated oxygen consumption rates. These findings indicate fundamental roles for APP in cellular metabolism that are translated to global physiological effects. This illuminates yet another caveat for disease models that involve overexpression of APP.

Title: Alternative processing of APP through the rhomboid protease RHBDL4

Authors: *S. PASCHKOWSKY[1], M. HAMZÉ[1], F. OESTEREICH[2], B. MICHALSKI[3], M. FAHNESTOCK[3], L. M. MUNTER[1];
[1]Pharmacol., [2]Integrated Program in Neurosci., McGill Univ., Montreal, QC, Canada; [3]McMaster Univ., Hamilton, ON, Canada

Abstract: Alzheimer's disease (AD) is the most common neurodegenerative disease, with 44 million affected patients in 2014 and numbers increasing. So far, no FDA-approved treatment is able to halt or prevent disease progression. With molecular changes occurring as early as 25 years prior to manifestation of clinical symptoms, preventive treatment strategies seem very promising. One major hallmark of AD pathology is the toxic amyloid-beta (Aβ) peptide, which is generated from the larger amyloid precursor protein (APP) in two sequential cleavage events. Reducing Aβ production is one of the main goals of AD therapeutics. Rhomboid proteases are a highly conserved class of intramembrane serine proteases, which cleave their substrates within the transmembrane and ectodomain regions. The human rhomboid-related protein 4 (RHBDL4) resides in the endoplasmic reticulum (ER) and is involved in essential cell processes such as ER-associated degradation (ERAD) of proteins and apoptosis. We found that RHBDL4 efficiently cleaves APP when expressed in HEK 293T cells. Cleavage of APP by RHBDL4 occurs in the ectodomain, leading to the generation of stable, 75 kDa N-terminal fragments and multiple 15-25 kDa C-terminal fragments, as determined by Western blot analysis. All fragments were detected in the cell lysate, while the N-terminal fragment was additionally observed in the supernatant. Co-immunoprecipitation of APP and RHBDL4 indicated an interaction between both proteins. Furthermore, an inactive form of RHBDL4 caused accumulation of the immature, ER-residing form of APP, but not mature APP in cell lysates. In addition, inhibition of other known APP-processing enzymes such α-,β- and γ-secretase did not affect production of RHBDL4-specific APP fragments, indicating that fragment generation is independent of other proteases. Most importantly, RHBDL4-mediated degradation of APP led to a drastic reduction in Aβ peptide levels, presumably by preventing APP from reaching the cell surface. Finally, analysis of human brain tissue from AD cases and age-matched controls revealed an increase in RHBDL4 mRNA and protein. This may be a protective, compensatory response to accumulating Aβ. Thus, our results suggest a new metabolic pathway for APP, which removes it from amyloidogenic processing and therefore reduces Aβ levels. We conclude that RHBDL4-mediated APP processing is a new potential mechanism to reduce Aβ peptide levels that could be exploited as novel drug target for AD.

Abstract: Objectives: Beside its crucial role in Alzheimer's disease (AD) pathogenesis, different functions have been attributed to the amyloid precursor protein (APP) but its pivotal role is difficult to depict. Here, we show that APP regulates the transcription of the Glial cell line-Derived Neurotrophic Factor (GDNF). Our work aims at investigating the role of APP-dependent GDNF expression in neuromuscular junctions. Methods: Following transcriptome analysis, qRT-PCR, ELISA and reporter gene assays were performed on APP knock-out mouse embryonic fibroblasts (APP -/- MEFs) stably re-expressing APP695 and APP751 isoforms. APP and GDNF expression have been monitored throughout skeletal muscle differentiation (C2C12 cells) upon APP silencing (small interfering RNA) and/or GDNF plasmid expression. We performed grip strength tests, mechanic measurements on isolated muscles and immunohistochemistry (IHC) of neuromuscular junctions (NMJs) on APP -/- mice. We set up a nerve-muscle co-culture model to generate NMJs *in vitro* and to analyze the effects of APP silencing or GDNF expression on NMJs formation and neuronal maturation by immunocytochemistry (ICC). Results: GDNF mRNA and protein levels together with GDNF transcriptional activity are down-regulated in APP -/- MEFs and restored specifically by APP751 isoform. GDNF and APP levels increase during muscular differentiation. Their overexpression or silencing favors or affects the process, respectively. APP-dependent regulation of GDNF expression affects muscles strength, muscular trophy and both neuronal and muscular differentiation fundamental for neuromuscular junctions (NMJs) maturation *in vivo*. Silencing of muscular APP induces a significant decrease in secreted GDNF levels, in the total number of NMJs, in the density of acetylcholine vesicles at the presynaptic site and in neuronal maturation. These defects are rescued by GDNF expression in muscle cells. Conclusions: Our findings highlight for the first time that APP-dependent GDNF expression drive the process of neuronal and muscular differentiation contributing to a better understanding of APP gene regulatory network and physiological functions.

Abstract: Generation of β-amyloid (Aβ), by cleavage of APP in endosomes has been postulated as a central event in AD pathogenesis. Both β- and γ-secretase have been localized to endosomes, and the acidic environment favors β-secretase activity. On the other hand, cleavage of APP by α-secretase is thought to take place at the plasma membrane. Accumulation of enlarged endosomes is one pathological finding in Alzheimer's disease (AD), indicating that disturbances in the endocytic pathway could contribute to disease progression in AD. We have earlier identified a novel pathway of APP cleavage, generating short Aβ fragments by β- followed by α-secretase cleavage. However, the localization of this type of cleavage is still unknown. The aim of this study was to investigate how inhibition of endocytosis (in general and of recycling endosomes) affects APP cleavage and generation of different Aβ peptides in a human, iPSc derived, cortical cell model. Human IPS cells were differentiated into cortical neurons [1]. Endocytosis was inhibited using dynasore, as well as siRNA knockdown of specific proteins in the endocytosis machinery. Transferrin uptake was analyzed to confirm inhibition of dynamin dependent endocytosis. After 24 hours of endocytosis inhibition, cell culture media and cells were collected. Cell culture media was analyzed for Aβ 38/40/42 and sAPPα/β using the Meso Scale Discovery system. Aβ peptides were analyzed using immunoprecipitation followed by mass spectrometry (IP-MS). IP-MS analysis of Aβ fragments ranging from 14 to 42 amino

acids (aa) showed a change in the ratio of secreted peptides when cells were treated with dynasore. Shorter fragments (ending at aa 14 to 20), were generally increased whereas longer fragments (ending at aa 34 to 40) tended to be decreased upon inhibition of endocytosis. Cleavage pattern, secretion and intracellular accumulation of Aβ were also analyzed upon Rab11B siRNA treatment, successfully inhibiting expression of Rab11B protein. The cleavage patterns of Aβ peptides, analyzed with IP-MS, seem to be affected by endocytosis inhibition. These results indicate two different cellular localizations for APP cleavage into Aβ, and this could have implications for the understanding on APP processing in healthy neurons, as well as in AD. 1. Title: Memory deficits in rats using a model of Alzheimer’s disease with an overexpression of APP21 and the presenilin 1 transgene

Authors: D. KLAKOTSKAIA[1], R. A. RICHARDSON[1], T. A. LARSON[1], E. WOODALL[1], K. PATEL[1], M. K. BURRUS[1], K. M. CLARK[1], C. AGCA[2], *T. SCHACHTMAN[3], Y. AGCA[2]; [1]Psychological Sci., [2]Vet. Pathology, [3]Univ. of Missouri, Columbia, MO

Abstract: The accumulation of amyloid plaques in the brain due to aggregate forms of amyloid beta (Aβ) peptides is known to lead to Alzheimer’s disease. Previous studies have found that the cleavage of beta amyloid precursor protein (APP) is the mechanism by which Aβ peptides are released. In this study, spatial memory performance in the Barnes maze was assessed in two strains of transgenic rats that overexpress human beta amyloid precursor protein (APP) in comparison to Fischer controls. All animals received eight 5-min acquisition trials over the course of four days, after which 3-day retention was evaluated, and subsequently followed by three days of reversal training trials. The number of nose-poke errors made and latency to enter the target hole were recorded. No significant group or sex differences were found during acquisition or reversal training, but there were significant group differences during the retention interval test. It was found that APP21 rats with an additional presenilin 1 transgene (APP21-PS1) made significantly more errors than both singly transgenic APP21 rats and control rats. Doubly transgenic (APP21-PS1) rats also took longer to enter the target hole than control rats, as

measured by their significantly longer latency scores. These results suggest a larger spatial memory deficit for APP21-PS1 rats than the singly transgenic APP21 rats.

Title: Characterization of amyloid precursor protein-dependent brain changes in a murine model of high fat diet-dependent obesity

Authors: ***K. L. PUIG**, S. A. BROSE, M. Y. GOLOVKO, C. K. COMBS;
Basic Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: Mid-life obesity has been implicated as a significant risk factor for AD. This suggests that the relationship between AD and obesity may be more than correlative and involve a common pathophysiology. It is well known that mutations in the gene coding for amyloid precursor protein, APP, are responsible for autosomal dominant forms of AD and our prior work has demonstrated a role for APP in regulating monocyte/microglial activation. Therefore, we tested whether APP is involved in inflammatory changes that occur in brain tissue during high fat diet-induced obesity. Six week old male wild type (C57BL/6) and $APP^{-/-}$ mice were maintained on either a control or high fat diet for 22 weeks. As we and others have reported, neuronal APP and reactive microglia immunoreactivity did appear to have slight increases in the temporal cortex region of high fat diet fed wild type mice. $APP^{-/-}$ brains exhibited reduced microglial immunoreactivity on a control diet but noticeably increased staining in high fat diet fed mouse brains. High fat diet fed brains had significantly increased protein levels of phosphorylated tau, CFABP, and APOE in wild type but not $APP^{-/-}$ cortex. $APP^{-/-}$ mice on high fat diet also showed reduced CD36, TLR2, TLR4, LRP, CD68, Iba-1, Cox-2, GFAP, CFABP, and APOE protein levels compared to wild type mice on high fat diet. On either diet, $APP^{-/-}$ mice had significantly less PGE_2, PGD_2, thromboxane B_2 and 6-*keto*$PGF_{1\alpha}$ compared to their diet-matched wild type mice. $APP^{-/-}$ neurons demonstrated attenuated 16:0 uptake ability whereas $APP^{-/-}$ astrocytes demonstrated attenuated 16:0, 20:4n6, and 22:6n3 uptake ability. A cytokine array analysis of temporal cortex lysate revealed a significant increase in eotaxin-2,fractalkine, IL-2, IL-13, IL-17, I-TAC, KC, MIP-1γ, RANTES, and TCA-3 in $APP^{-/-}$ mouse brains. This data

demonstrated a fundamental role for APP in regulating brain immune and lipid-metabolism associated events particularly during high fat diet feeding.

Title: Phospholipid transfer protein (PLTP) deficiency accelerates memory dysfunction through altering amyloid precursor protein (APP) processing in a mouse model of Alzheimer’s disease

Authors: *D. CHUI;
Peking Univ., Beijing, China

Abstract: Disordered lipid metabolism is increasingly recognized in the pathogenesis of several neurodegenerative diseases, such as Alzheimer’s disease (AD). As a widely expressed lipid transfer protein, phospholipid transfer protein (PLTP) participates in the transport of cholesterol and other lipids in the plasma and peripheral tissues. Recently, elevated amyloid β (Aβ) in young and aged PLTP-deficient brains had been reported. However, the role of PLTP in amyloid precursor protein (APP) processing and AD pathology remains elusive. Here we first found that deficiency of PLTP accelerated memory dysfunction in APP/PS1ΔE9 AD model mice at the age of 3 months. Further characterization showed that PLTP deficiency increased soluble Aβ peptides, and intracellular accumulation of Aβ was illustrated, which might be due to disrupted APP turnover and the enhanced amyloidogenic pathway. Besides, reduced brain-derived neurotrophic factor (BDNF) was found in PLTP deficient APP/PS1ΔE9 mice, and BDNF level was negatively correlated with Aβ42 content, instead of Aβ40 content. In addition, autophagic dysfunction was found in the PLTP deficient APP/PS1ΔE9 mice. Our data suggested that PLTP played an important role in APP processing and PLTP deficiency could increase susceptibility to early onset of AD. Title: Using an unnatural amino acid to fluorescently label amyloid beta generated de novo from amyloid precursor protein expressed within cells

Authors: *L. R. CZERNIEWSKI, S. L. CRICK, J.-M. LEE;
Washington Univ. In St. Louis, Saint Louis, MO

Abstract: Amyloid beta (Aβ) plays a fundamental role in Alzheimer's disease pathogenesis, but its production, trafficking, degradation, and eventual aggregation into extracellular plaques is poorly understood. A key reason for our inability to study these processes in cells and *in vivo* is that there is no method for specifically labeling and subsequently monitoring Aβ, endogenously produced from its amyloid precursor protein (APP). Current trafficking studies utilize APP fused with fluorescent proteins at either terminus to study its intracellular trafficking. In this work, we will present a method for labeling the Aβ segment within APP, so that we can track *de novo* Aβ production within a cell using an unnatural amino acid (UAA). We generated an APP construct mutated at a single codon within Aβ to allow for incorporation of an UAA. The seventh amino acid in Aβ was mutated to a stop codon to prevent translation in the absence of an UAA. In the presence of an UAA and its cognate tRNA/tRNA-synthetase pair the UAA is inserted at the stop codon in Aβ outside of the transmembrane domain. This allowed us to use two alternative UAA variants to label Aβ: 1) an intrinsically fluorescent UAA could be used to label Aβ within APP from the start of translation; and 2) a different UAA harboring a strained dienophile could also be incorporated—with a subsequent click chemistry reaction at the cell surface linking fluorescently tagged tetrazine molecules to the UAA incorporated in APP as it is trafficked to the plasma membrane (figure 1). APP was also fused at its C-terminus to the mClover fluorescent protein in order to visualize cleavage events. The incorporation of an unnatural amino acid allows for direct visualization of Aβ through use of an intrinsically fluorescent unnatural amino acid or an unnatural amino amenable to click-chemistry labeling. This strategy of unnatural amino acid incorporation can be used to site-specifically label endogenous Aβ within the amyloid precursor protein.

Title: The effect of oligomeric aβ42 on app processing and aβ40 generation in cultured u373 astrocytes

Authors: *D. I. OURDEV[1], B. V. FOROUTANPAY[2], Y. WANG[2], S. KAR[3];

Abstract: Background: Amyloid-β (Aβ) peptides are a family of proteins that are considered to be a principal aspect of Alzheimer's disease (AD), the most common cause of senile dementia affecting elderly. These peptides result from the proteolytic processing of Amyloid precursor protein (APP) by the sequential cleavage mediated via β- and γ-secretases. Evidence suggests that an overproduction and/or a lack of degradation may increase brain Aβ levels which, in turn, contribute to neuronal loss and development of AD. **Objectives:** In this study, we seek to determine what effect Aβ has on APP processing in cultured astrocytes. **Methods:** Using human astrocytoma cell line U373, we investigated the effects induced by $A\beta_{42}$ treatment on the cellular expression of APP and its products, αCTF, βCTF, and $A\beta_{40}$. In conjunction with these experiments, we examined the relative levels and activity of β- and γ-secretases in Aβ-treated astrocytes. **Results:** We report here that $A\beta_{42}$ treatment of astrocytes increased the expression of APP and its cleaved products including $A\beta_{1\text{-}40}$ in a time-dependent manner. **Conclusions:** These results suggest that astrocytes following activation can contribute to the development of AD by enhancing levels and processing of APP leading to increased production/secretion of Aβ-related peptides.

Title: Effects of Aβ1-42 on APP processing in cultured N2a cells

Authors: *B. V. FOROUTANPAY[1], T. J. REVETT[2], D. VERGOTE[2], D. WESTAWAY[2], S. KAR[1];

Abstract: Alzheimer's disease (AD), the most common cause of senile dementia and a growing global medical concern, is characterized by neuronal loss, tau-positive neurofibrillary tangles and amyloid-β (Aβ) containing neuritic plaques in selected brain regions. Aβ peptides are a family of proteins that are considered to contribute to AD pathogenesis. These peptides are derived from Amyloid Precursor Protein (APP) via sequential processing by β- and γ-secretases. Although much work has been focused on the interactions between Aβ peptide and neurons, the potential role of Aβ in APP processing is relatively unclear. Here we aimed to elucidate the effects of Aβ peptide on APP processing using cultured neuronal N2a cells. Through use of RT-PCR, we have shown that APP transcription is increased after Aβ treatment. Further analysis indicates an increase in APP and APP-CTFs levels in a time- and dose-dependent manner; however, the levels of secretases do not appear to alter following Aβ treatment. Similarly, our ELISA results have shown an increase in Aβ levels both in cell lysates and conditioned media. As a follow up, we will examine activity of β- and γ-secretases, as well as the subcellular localization of the various components involved in the cellular processing of APP and clearance of Aβ. These experiments will provide an insight into the molecular mechanisms by which Aβ can regulate the proteolytic processing of APP that can influence the loss of neurons and subsequent development of AD pathology.

Title: Scanning ultrasound opening of the blood-brain-barrier reduces amyloid pathology and improves memory in APP23 transgenic mice

Authors: *G. LEINENGA[1], J. GOETZ[2];
[1]Queensland Brain Inst., Brisbane, Australia; [2]Clem Jones Ctr. for Ageing Dementia Research, Queensland Brain Inst., The Univ. of Queensland, Brisbane, Australia

Abstract: The brain of Alzheimer's disease (AD) patients is characterized by plaques, with the amyloid-β (Aβ) peptide being a major constituent. Here, we aimed to establish whether a transient opening of the blood-brain barrier (BBB) by 'scanning' the brain with focused ultrasound could assist in Aβ clearance. The protocol we developed caused neither edemas nor erythrocyte extravasation, nor upregulation of inflammatory markers associated with tissue

damage. We found, however, that repeated scanning ultrasound (SUS) treatments of the brain of Aβ plaque-forming APP23 mice, without the need for any additional therapeutic agents, significantly reduced Aβ levels and Aβ plaque load. Moreover, memory functions were restored to wild-type levels, as shown with three complementary memory tasks, spontaneous alternation in the Y-maze, novel object recognition and active place avoidance. Spinning disk confocal microscopy, histology and high-resolution 3D-reconstruction revealed an increased activation of microglia, but no increase in microglial numbers. Microglia in SUSed brains were found to fragment and engulf plaques. Moreover, Aβ was internalized into microglial lysosomes. Cleared plaques were observed in 75% of the SUSed mice but never in the sham-treated animals. Given that repeated SUSing and caused no overt damage to brain tissue, our study highlights the potential of this non-pharmacological approach, including as a possible vehicle for drug delivery, given that the BBB remains a major obstacle for the brain uptake of therapeutic agents.

Title: Annexin A1 restores Aβ1-42- induced blood brain barrier disruption

Authors: ***J. PARK**, H. CHO, S. BAIK, S.-H. HAN, A. KIM, I. MOOK-JUNG;
Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: The blood brain barrier (BBB) is composed of capillary endothelial cells, which are connected by tight junctions with a high selective permeability. It has an important role in maintaining homeostasis of the brain separated the blood from the parenchyma of the central nervous system (CNS). It is widely known that disruption of the BBB occurs in various neurodegenerative diseases, including Alzheimer’s disease (AD). Annexin A1 (ANXA1), an anti-inflammatory messenger, is expressed in brain endothelial cells and there was some reports that it can regulate BBB integrity. However, its role and mechanisms for protecting BBB in AD have not been identified. We found that Aβ1-42 induced BBB disruption was rescued by human recombinant ANXA1 (hrANXA1) in the murine brain endothelial cell line bEnd.3. Also, ANXA1 was reduced in human serum of AD patients. In addition, we attempted to find out what is the mechanism that ANXA1 recovers BBB integrity in AD. These data propose that ANXA1 is a therapeutic agent, protecting against the breakdown of the BBB in AD.

Title: Effects of MRK-016 on amyloid-beta induced learning deficits in mice in a contextual conditioning paradigm

Authors: *S. L. HODGES[1], M. J. EIMERBRINK[2], J. D. WILES[2], J. D. WHITE[2], M. J. CHUMLEY[2], G. W. BOEHM[2];
[1]Baylor Univ., Waco, TX; [2]Texas Christian Univ., Fort Worth, TX

Abstract: Alzheimer's disease pathology is associated with cognitive decline, the presence of amyloid-beta (Aβ) plaques, and disruption of gene expression related to BDNF. Previously, our lab has demonstrated that repeated bouts of peripheral inflammation are sufficient to significantly increase central Aβ peptide in the dorsal hippocampus, and that this elevation is congruent with cognitive deficits in learning and memory. In the present study, we examined the protective effects of the inverse benzodiazepine agonist MRK-016 on the cognitive deficits associated with inflammation-induced accumulation of amyloid-beta (Aβ). Animals were injected (i.p.) with either LPS (250μg/kg) or saline, once per day, for seven consecutive days to increase central Aβ. On day eight, 24 hours after the last injection, animals were trained in a contextual fear conditioning paradigm, and received either an i.p. injection of either MRK-016 (2mg/kg) or saline to create 4 treatment groups. The following day, animals were returned to the conditioning chamber for testing to evaluate freezing behavior. Analysis of the behavioral data identified a significant interaction between MRK and LPS treatments, such that animals treated with MRK and LPS exhibited freezing behavior comparable to controls, while animals treated with Saline and LPS froze significantly less than all other conditions. After testing, hippocampi were collected to evaluate levels of central Aβ. In a comparable set of animals, dorsal hippocampus sections were collected both prior to training as well as 4 hours after training to identify the influence MRK-016 and LPS has on BDNF-related gene expression, using qRT-PCR. Between-groups analysis of the qRT-PCR data showed that animals treated with MRK and LPS had unique, and significantly different, expression of BDNF-related genes. Overall, results from this study support the hypothesis that MRK-016 can prevent Aβ-induced cognitive deficits, and alter gene expression related to BDNF activity in the hippocampus.

Title: Chronic low level beta1-adrenergic receptor activation decreases amyloid beta, modulates the neuroimmune response and improves neurocognitive function in two models of Alzheimer's disease

Authors: *A. K. EVANS, P. M. ARDESTANI, B. YI, M. SHAMLOO;
Neurosurg., Stanford, Stanford, CA

Abstract: Severe degeneration of noradrenergic (NA) neurons has been reported in Alzheimer's Disease (AD) and may contribute to progression of pathology, neuroinflammation and cognitive dysfunction. In addition to a neuronal role in learning and memory, beta adrenergic receptors (ADRB1 and ADRB2) on microglia and astrocytes regulate neuroinflammation and govern compensatory and protective mechanisms for neuronal function and survival. Pharmacological and genetic ablation of NA neurons has been shown to exacerbate amyloid beta deposition, markers of neuroinflammation, and behavioral deficits in mouse models of AD. We have previously implicated acute activation of ADRB1 in restoration of cognitive deficits in mouse models of AD. In a series of studies we aimed to determine effects of chronic low level activation of the ADRB1 receptor on behavioral, pathological, and neuroimmune endpoints in 2 different mouse models of AD. Using 2 different transgenic models in which mice either express 5 mutations related to Familial Alzheimer's Disease, [5XFAD; 3 mutations in the amyloid precursor protein and 2 in presenilin 1] or 2 mutations in amyloid precursor protein (T41B), transgenic and wildtype male mice were chronically dosed with vehicle or with the specific ADRB1 partial agonist, xamoterol (5XFAD, 6 mg/kg daily oral gavage or 3 mg/kg subcutaneous pump; T41B, 0.3-1.0 mg/kg daily subcutaneous injection). Mice were dosed for 3 months and run through a series of behavioral tests during the last 6 weeks of dosing (Activity Chamber, Y-maze, Novel Object Recognition, Morris Water Maze, Elevated Plus Maze, Fear Conditioning). At conclusion (6-9 months of age in respective studies), plasma was collected and brains were perfused with saline and were either fresh frozen or paraformaldehyde fixed for neurobiological analyses. Chronic dosing with the specific ADRB1 partial agonist, xamoterol, improved novel object recognition and spatial learning in 5XFAD mice, and reduced hyperactivity and improved contextual fear conditioning in T41B mice. Chronic dosing with xamoterol decreased amyloid beta in both models and modulated indices of neuroimmune activation in both models (microglia/macrophage immunoreactivity, and immune-related mRNA and protein expression). Chronic dosing with an ADRB1 partial agonist attenuated upregulation of mRNA expression for several markers of neuroimmune activation while having a unique potentiating effect on CD68 mRNA expression in 5XFAD mice. These data support the hypothesis that ADRB1 activation

improves pathology and cognitive function in mouse models of AD and may do so by modulating the neuroimmune response.

Abstract: Alzheimer’s disease (AD) is an irreversible progressive neurodegenerative disease among older people. Although the cause of AD remains unknown, Amyloid-β (Aβ) is thought to play a crucial role in the AD pathology. Aβ interferes different cell types through different mechanisms. Cerebral endothelial cells (CECs) are integral components of the blood brain barrier (BBB), which is important for maintaining neuron function. The BBB regulates transportation of materials between peripheral blood and brain parenchyma. Aβ has been reported to disrupt calcium homeostasis and increase oxidative stress in CECs resulting in alterations of CEC functions. In this project, azelnidipine (ALP), an anti-hypertension drug, was examined for its ability to attenuate Aβ-altered CEC function with immortalized mouse cerebral endothelial cells (bEnd.3). We found that Aβ oligomers triggered calcium influx in cells within 15 min and lasted for at least 45 mins, and calcium influx was suppressed by ALP treatment. Aβ also induced production of superoxides activation of ERK, cytosolic phospholipase A2 and NF-κB activity, and all these events were suppressed by ALP. Taken together, these results demonstrate that ALP is capable of reducing Aβ-induced calcium influx, and downstream

oxidative and inflammatory pathways in CEC, and may be potentially useful for development of therapeutic treatment for AD.

Title: Trigonelline is effective in scopolamine induced memory deficits in mice due to its anti-acetylcholinesterase and anti-oxidative properties

Authors: ***A. JUVEKAR**, A. CHOWDHURY, N. GAWALI, P. KOTHAVADE, P. DESHPANDE;
Dept. of Pharmaceut. Sci. and Technol., Inst. of Chem. Technol., Mumbai, India

Abstract: Background: Alzheimer's disease (AD) is a progressive, neurodegenerative disease of the brain, and is the most common form of dementia among the elderly population. It is a chronic disease characterized symptomatically by progressive decline of daily living activities, behavioral disturbances and loss of cognition. Trigonelline, a pyridine alkaloid is commonly found in coffee beans and Trigonella foenum-graecum L. (fenugreek) seeds. Recent reports have emerged regarding the beneficial effects of trigonelline in β- amyloid induced memory impairment in rats. Also, Trigonelline demonstrated *in vitro* neurite outgrowth in rats and human neuronal cells. However detailed mechanism of the neuroprotection has not been explored yet. Therefore present study was conducted to explore the neuroprotective mechanism of Trigonelline in scopolamine induced amnesia mice model. Methods: Scopolamine (2.5 mg/kg) was used to induce amnesia in male swiss albino mice. Donezepil (1 mg/kg i.p) was used as positive control. Animals were divided into 5 groups (n=6) and Trigonelline (50 and 100 mg/kg) was administered by oral gavage for 2 weeks. Memory performance was evaluated by Morris water maze test and elevated plus maze. Post treatment, the mice were euthanized, brains isolated and extent of oxidative stress (elevated malionaldehyde, nitrite concentration, reduced glutathione, superoxide dismutase and catalase) was estimated. Histopathology studies were carried out to corroborate the neuroprotective effect of Trigonelline. Results: Administration of Trigonelline (50 and 100 mg/kg) resulted in improved cognitive performance in both, Morris water and elevated plus maze models as compared to negative control. Further pretreatment with Trigonelline caused significant attenuation of brain acetyl choline esterase activity and strengthened the oxidative defense. Moreover the neuroprotective effect of Trigonelline was well supported by photomicrographs of the hippocampus of brain where minimal vacuolar

degeneration of neurons were observed as compared to negative control. Conclusions: In conclusion, these results indicate that Trigonelline may exert anti-amnesiac effects which may be mediated, at least in part due to its anti-acetylcholinesterase and anti-oxidant properties.

Title: Cerebrospinal fluid and plasma ceramides are modified by dietary intervention in adults with mild cognitive impairment and healthy controls

Authors: *B. J. NETH[1], J. L. BAYER-CARTER[2], A. HANSON[3], L. D. BAKER[1], K. S. NAIR[4], S. CRAFT[1];
[1]Wake Forest Sch. of Med., Winston Salem, NC; [2]Veterans Affairs Puget Sound Hlth. Care Syst., [3]Div. of Gerontology and Geriatric Med., Univ. of Washington Sch. of Med., Seattle, WA; [4]Metabolomics Resource Core, Mayo Clin., Rochester, MN

Abstract: Background: Sphingolipid-derived ceramides play an important role in cell signaling and disease pathology. Serum ceramides are higher in insulin resistance, Type 2 Diabetes and other metabolic conditions, and are modulated by diet in rodent studies (Haus et al., 2009; Turpin et al., 2014). Moreover, recent studies have described elevated blood ceramide concentrations in adults with Alzheimer's disease (AD) and other neurologic conditions (Mielke et al., 2012; Filippov et al., 2012). Interestingly, several cerebrospinal fluid (CSF) ceramides are lower in adults with Mild Cognitive Impairment (MCI) and AD and correlate with AD biomarkers (Fonteh et al., 2015). Modification of ceramide levels through diet and other metabolic manipulations may reveal therapeutic targets to alleviate AD pathology. Methods: Data from 49 participants were used in this analysis. Twenty participants (13F, 7M) were cognitively normal (CN) with a mean [SD] age of 69.3 [7.4] and 29 participants (13F, 16M) were adults with amnestic MCI with a mean [SD] age of 67.6 [6.8]. Participants were randomized to one of two equicaloric dietary interventions (High Saturated Fat/Glycemic Index – "High Diet" & Low Saturated Fat/Glycemic Index – "Low Diet") for 4 weeks. All meals were supplied during the study period. Blood (plasma) and CSF samples were collected prior to starting diet (week 0) and ending diet (week 4). CSF and plasma ceramide concentrations were measured with Liquid Chromatography–Mass Spectrometry, and subjected to analysis of covariance adjusting for age,

gender, and APOE-e4 status. Results: In CSF, adults with MCI showed decreased concentrations of C16:0 ($p<0.05$) and C22:0 ($p<0.05$) on the Low relative to the High diet. The ceramide C18:0 trended toward significance ($p=0.08$). Conversely, concentrations of C16:0 ($p<0.05$) for CN were increased on the Low relative to the High diet. In plasma, concentrations of 5 ceramides (C14:0 ($p<0.0001$), C16:0 ($p<0.0001$), C18:0 ($p<0.0001$), C20:0($p<0.0005$), C24:1($p<0.001$)) decreased significantly after consumption of the Low diet relative to the High, with exception to C24:1, which showed an opposite pattern. Conclusions: Our results demonstrate both plasma and CSF ceramides are modified after a 4-week dietary intervention in cognitively normal adults, as well as in adults with amnestic MCI. Further study is needed to fully understand the role of ceramides in AD and whether dietary intervention is an effective therapeutic or preventative approach.

Title: Effects of high fat diet on cognition and neurodegeneration in APOE3 and APOE4 mice

Authors: *V. L. REEVES, A. Y. CARTER, N. F. FITZ, I. LEFTEROV, R. KOLDAMOVA; Envrn. and Occup. Hlth., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Multiple genes, metabolic stimuli, and environmental factors control the variation in susceptibility to Alzheimer’s disease (AD). The inheritance of ε4 allele of *APOE* (APOE4) is the major genetic risk factor for late-onset AD; however, the mechanisms underlying this association remain elusive. Notably, high fat diet (HFD) and related metabolic stimuli are associated with increased risk of AD. Recently, we have demonstrated the detrimental effects of HFD on cognitive performance and cerebral amyloidosis in animal models of AD. Gene-environment interactions are critical for the development and progression of AD. We hypothesize that high fat

diet results in changes in transcriptional activity and expression level of genes important for developing AD, accelerating the course of the disease, or aggravating AD phenotypes. We have utilized the targeted replacement humanized APOE3 and APOE4 mouse models and a HFD to simulate typical Western diet. The mice were compared for behavioral, amyloid deposition, and transcriptional profiles in the brain. Our data demonstrate that HFD aggravate behavioral deficits in an isoform-specific manner with APOE4 and mice fed HFD having worse cognitive performance than APOE3 mice, and mice fed control diet. The results of this study will reveal transcriptional changes instigated by HFD nutritional signals and how these modifications contribute to AD pathology. The ability to associate changes at gene expression level, or transcript enrichment within gene networks and clusters, to pathogenic features of AD will have a significant impact on defining various molecular mechanism of AD pathogenesis. This study further defines how diet and dietary patterns influence epigenetic mechanisms relevant to neurodegeneration.

Title: Insulin and Insulin-Like Growth Factors (IGFs) may protect against susceptibility to brain atrophy and dementia in Late-Onset Alzheimer’s disease (LOAD) and diabetes

Authors: *D. N. ISHII;
Colorado State Univ., Fort Collins, CO

Abstract: It is herein proposed that insulin and IGFs are age-dependent, environmentally-responsive growth factors that normally protect against weak susceptibility genes to prevent brain atrophy, synapse loss and dementia in LOAD. Age is a major risk factor for LOAD (comprises 95% of Alzheimer's cases; onset arises after age 65; dementia and brain atrophy with loss of up to 1/3 brain mass). Irrespective of presence or absence of susceptibility genes, subjects are protected against disease onset for 65+ years. Indeed, two decades after onset of amyloid-beta plaques and neurofibrillary tangles (P&T) as well as dementia in LOAD patients, their identical twins can be free of P&T and cognitively normal (Brickell et al., 2007). Environmental factors can clearly prevent or delay disease onset for decades in subjects with identical genetic

susceptibility. Autopsy confirmed LOAD brains have an 81% association with mid-life diabetes or insulin resistance. Obesity, insulin resistance, and diabetes are each correlated with brain atrophy and cognitive disorder in mid-life. Elderly diabetic patients have increased risk of dementia even after correcting for cerebrovascular disease. Neither learning/memory nor glucose utilization are altered following conditional knock-out of the neuronal insulin receptor in mice. LOAD, clinical diabetes, and diabetic rats share brain atrophy, impaired learning/memory, and reduced insulin and IGF levels in brain. IGFs are neurotrophic factors required for synapse formation and learning, IGF levels decline with age, and IGF treatment prevents impaired learning in diabetic rats independently of hyperglycemia (Lupien et al., 2003). The combination of insulin and IGF restoration is discovered to prevent massive brain atrophy, including loss of total brain protein and DNA involving both neurons and glia (Serbedzija et al., 2009). Disease onset may be delayed for decades by a) lifestyle modifications that prevent obesity, insulin resistance, and diabetes, and/or b) pharmacologic interventions that increase both insulin and IGF levels in the CNS, but not systemic glucose levels. The safe doses of insulin and IGF are known, and clinical trials should explore whether the combination of insulin and IGF can prevent brain atrophy and subsequent dementia.

Title: 3-iodothyronamine rescues β-Amyloid-dependent inhibition of long-term potentiation in the entorhinal cortex

Authors: *A. ACCORRONI[1], C. CRISCUOLO[2], M. SABATINI[3], R. DONZELLI[3], A. SABA[3], R. ZUCCHI[3], N. ORIGLIA[2];
[1]Scuola Superiore Sant'Anna - CNR, Pisa, Italy; [2]Inst. di Neuroscienze, Consiglio Nazionale delle Ricerche, Pisa, Italy; [3]Dept. of Pathology, Univ. of Pisa, Pisa, Italy

Abstract: Entorhinal cortex (EC) is a parahippocampal region involved in learning and memory that is early affected in Alzheimer’s disease (AD). Beta-Amyloid (Aβ) oligomers have been proven to be involved in the inhibition of long-term potentiation (LTP) in the EC. Thyroid hormones (TH) have been demonstrated to regulate cognitive function and there is evidence that TH cerebral metabolism may be altered, with an increased production of the inactive form of TH, in AD patients. Furthermore, the acute administration of 3-iodothyronamine (T1AM), a

derivative of TH, has been shown to stimulate memory acquisition in the mouse. To investigate whether T1AM can restore Aβ-induced impairment of synaptic plasticity, we performed extracellular *in vitro* recordings in EC slices taken from wild type (WT) mice and treated with Aβ oligomers. In addition, we evaluated T1AM restorative effect on LTP in EC slices taken from AD mice expressing human mutations of APP gene (hAPP-J20 line), which show EC-LTP impairment at a very early stage (2months). Field Potentials (FPs) were evoked in layer II after stimulation of the same layer and LTP was elicited by high frequency stimulation (HFS), consisting of three trains of 100 pulses at 100 Hz. In addition to electrophysiological evaluations, T1AM endogenous levels were assayed in the EC by HPLC coupled to tandem mass spectrometry. First, we identified a concentration (5μM) of T1AM that did affect neither basal synaptic transmission nor LTP induction and maintenance in WT EC slices. T1AM was administered for 10 minutes starting 5 minutes before the delivery of HFS. To verify its protective effect, T1AM (5μM) was administered in combination with Aβ oligomers at 200 nM, a concentration that has been previously demonstrated to inhibit EC-LTP. The results indicate that T1AM perfusion completely restores LTP in Aβ-treated WT slices. Moreover, T1AM confirmed its protective efficacy in slices from hAPP-J20 mice. Indeed, LTP was completely rescued in hAPP-J20 slices perfused with T1AM, with respect to transgenic untreated slices and was comparable to LTP recorded in WT control slices. Furthermore, T1AM endogenous concentration was reduced in 2 month old mhAPP EC slices when compared to age-matched WT controls. Our results suggest that T1AM plays a neuroprotective effect, rescuing Aβ-induced neuronal dysfunction, and that its reduced levels may contribute to EC vulnerability in AD. A more thorough understanding of the neuroprotective properties of T1AM and the underlying mechanisms of its effect, may be beneficial for clinical research and might lead to the identification of new pharmacological targets to delay disease progression.

Title: Protective effects of Anthocyanins against Amyloid beta-induced neurotoxicity *in vitro* and *in vitro*

Authors: *T. KIM, H. BADSHAH, M. KIM;
Gyeongsang Natl. Univ., Jinju, Korea, Republic of

Abstract: Alzheimer's disease (AD) is one of the most common neurodegenerative disorders in recent world, characterized by increased production of amyloid beta in the nervous system with an ultimate effect of apoptotic neurodegeneration. This study was aimed to investigate the neuroprotective effect of black soybean anthocyanins in a neurodegenerative model of amyloid beta 1-42 (Aβ1-42). Aβ1-42 was treated to HT22 cell lines or adult male rats via intra-cerebro-ventricular injection to induce neurotoxicity in these experimental models. Anthocyanins were treated 0.2mg/kg in case of cell lines or 4mg/kg intragastrically to adult rats to protect against Aβ-induced neurodegeneration. Assay for cell viability, mitochondrial membrane potential (Ψm), intracellular free Ca2+ and apoptotic cells (Fluorojade-B and TUNEL) were performed *in vitro* while western blot analysis were performed to the hippocampal proteins of adult rats. Our results showed that Aβ1-42 treatment reduced cell viability, disturbed the Ψm and Ca2+ homeostasis in and out of the cell, and increase neuronal apoptosis. Treatment with anthocyanins for 12 hr retained the cell viability, normalized Ψm and Ca2+ level, and decreased the neuronal cell death. In accordance, anthocyanins reversed Aβ-induced effect on proteins expression of mitochondrial apoptotic pathway (Bax, cytochrome c, caspase-3 and caspase-9) and major Alzheimer's markers i.e. Aβ, APP, P-tau and BACE-1. Overall, our results showed that anthocyanins are potential candidates to treat neurodegenerative disorders like AD.

Title: The neuroprotective action of a hexapeptide core sequence within beta amyloid

Authors: *K. FOREST, J. LAWRENCE, N. ALFULAIJ, R. NICHOLS;
Univ. of Hawaii, Manoa, Honolulu, HI

Abstract: PURPOSE: Alzheimer's disease (AD) is a progressive neurodegenerative disease, characterized by memory loss as well as cognitive decline and language dysfunction. To date, there is no effective cure for the disease. Identifying and characterizing the cellular mechanisms underlying AD will potentially elucidate a target pathway for potential treatment. One possible pathway is the neurotoxicity triggered by the accumulation of beta amyloid (Aβ), a short peptide found in the brains of individuals with Alzheimer's disease. Aβ was originally identified in dense neuritic plaques which are one of two histopathological hallmarks in AD. However, considerable

evidence has shown that in normal healthy brains, soluble, oligomeric Aβ functions as a neuromodulator. Our laboratory has recently shown that at low concentrations (pM-nM) the N-terminal Aβ fragment (N-Aβ) is twice as effective as full-length Aβ as a neuromodulator, stimulating receptor-linked increases in Ca^{2+}, enhancing long-term potentiation (LTP) and enhancing contextual fear conditioning. In addition, we have shown that N-Aβ inhibits the synaptotoxicity triggered by full-length Aβ ($Aβ_{42}$). Preliminarily, we have found that N-Aβ also protects against $Aβ_{42}$-induced neurotoxicity. We have further identified a hexapeptide core sequence within N-Aβ ($Aβ_{core}$), YEVHHQ, encompassing a putative metal binding site, which is equally as effective as N-Aβ in Ca^{2+} signaling. We have therefore postulated that the $Aβ_{core}$ would have neuroprotective potential. DESIGN METHODS: We investigated the extent of neuroprotection of $Aβ_{core}$ and mutants against full-length Aβ toxicity by measuring oxidative stress (as production of reactive oxygen species, ROS), nuclei and DNA fragmentation, and cell death in an *in vitro* $α_4β_2$-nicotinic receptor (nAChR)-transfected neuroblastoma-based model nerve cell culture system. The presence of target nAChRs was previously shown to sensitive nerve cells to Aβ toxicity. In addition, we assessed the neuroprotective action of $Aβ_{core}$ and mutant peptides on synaptic plasticity in rodent hippocampal slice LTP. RESULTS and CONCLUSION: Through mutational analysis, we have identified residues in the $Aβ_{core}$ essential for functional regulation. In addition, co-treatment with the $Aβ_{core}$ was shown to protect against $Aβ_{42}$-induced ROS and cellular toxicity in $α_4β_2$-nAChR-transfected neuroblastoma cells. SIGNIFICANCE: The neuroprotective action of the $Aβ_{core}$ suggests the possibility of using this core sequence as a scaffold for optimization of a potential biologic for protection against Aβ-induced toxicity.

Title: Neuroprotection by a n-terminal fragment of beta amyloid

Authors: ***N. ALFULAIJ**, G. YOSHIKAWA, J. CHENG, K. ARORA, R. NICHOLS; Dept. of Biol., Univ. of Hawaii At Manoa, Honolulu, HI

Abstract: Amyloid-beta (Aβ) is the primary component of plaques associated with Alzheimer's disease (AD). In normal brain, Aβ is present in soluble oligomeric form at low picomolar levels

where it appears to have a neuromodulatory role. We have previously shown that the presence of nicotinic receptors (nAChRs) sensitizes neurons to Aβ neurotoxicity. We recently discovered that a N-terminal Aβ fragment, $A\beta_{1-15,}$ has neuromodulatory activity but is not toxic. We have been able to show that picomolar levels are able to enhance fear memory and increase long-term potentiation (LTP). We postulated therefore that $A\beta_{1-15}$ may have a neuroprotective action against full-length Aβ neurotoxicity. Changes in reactive oxygen species (ROS) and nuclear disintegration are early measures of toxicity and apoptosis. Using a ROS assay as a measure of toxicity, we examined the potential neuroprotective action of $A\beta_{1-15}$ on a hybrid neuroblastoma cell line, NG108-15, expressing α4β2 nAChRs as compared to α7 nAChRs or controls, subjected to treatment with full-length $A\beta_{1-42}$ at 100nM for 3 days. We also examined effects of withdrawing $A\beta_{1-42}$ after varying lengths of treatment to assess the time-dependency of receptor stimulation for toxicity. To confirm this in an *ex vivo* model, we utilized organotypic hippocampal slice cultures subjected to full-length Aβ or combination treatment of $A\beta_{1-42}$ and $A\beta_{1-15}$. We assessed cell viability using a propidium iodine stain and then homogenized the tissue and extracted proteins to examine cell death signaling proteins in each treatment group. Electrophysiology was performed on acute slices to examine the effect of $A\beta_{1-15}$ on the inhibitory effects of $A\beta_{1-42}$ on LTP. While we've previously shown that $A\beta_{1-15}$ enhanced LTP, we now examined how various combinations of $A\beta_{1-42}$ and $A\beta_{1-15}$, or delayed $A\beta_{1-15}$ perfusion after $A\beta_{1-42}$ affects LTP. Following $A\beta_{1-42}$ early withdrawal, ROS production continued, approaching levels found for 3 days of Aβ treatment, indicating that the neuroprotection window is in the early phase of $A\beta_{1-42}$-induced toxicity. With co-incubation, $A\beta_{1-15}$ blocked $A\beta_{1-42}$-induced ROS and nuclear disintegration in cultures expressing α4β2 nAChRs. In contrast, α7 nAChRs may not sensitize the cultures to Aβ neurotoxicity, precluding a neuroprotective action of $A\beta_{1-15}$ via this pathway. Further confirming neuroprotection by $A\beta_{1-15}$, *ex vivo* slice cultures show significantly less cell death in combination-treated slices compared to high levels of cell death when treated with $A\beta_{1-42}$ alone. The action of the $A\beta_{1-15}$ fragment indicates that it may serve a competitive, neuroprotective role via α4β2 nAChRs at the synapse in the context of accumulating Aβ in AD.

Title: Cyanidin-3-glucoside protects against amyloid beta (25-35)-induced neuronal cell death in cultured rat hippocampal neurons

Authors: J. YANG[1], K. YOON[2], *S. YOON[3];
[1]Dept. of Physiology,College of Med., [2]Col. of Pharm., [3]Col. of Med., Catholic Univ. of Korea, Seoul, Korea, Republic of

Abstract: Increasing evidences implicate changes in $[Ca^{2+}]_i$ and oxidative stress as causative factors in amyloid beta (Aβ)-induced neuronal cell death. Cyanidin-3-glucoside (C3G), a component of anthocyanin, has been reported to protect against glutamate-induced neuronal cell death by inhibiting Ca^{2+} and Zn^{2+} signaling. The present study was investigated to determine whether C3G has a protective effect against Aβ-induced neuronal cell death in cultured rat hippocampal cells and pure hippocampal neurons from embryonic day 17 fetal Sprague-Dawley rats using digital imaging methods for Ca^{2+}, Zn^{2+}, MMP and ROS, and MTT assay for cell survival. Pretreatment with C3G (10 μg/ml) for 30 min inhibited Aβ-induced $[Ca^{2+}]_i$ increases in the cultured rat hippocampal neurons**.** C3G significantly inhibited Aβ-induced mitochondrial depolarization. C3G blocked Aβ-induced formation of ROS. C3G also significantly inhibited Aβ-induced $[Zn^{2+}]_i$ increases. Treatment with C3G (10 μg/ml) for 48 h attenuated Aβ-induced neuronal cell death in cultured rat pure hippocampal neurons. Taken together, all these results suggest that cyanidin-3-glucoside inhibits Aβ-induced Ca^{2+} signaling, mitochondrial depolarization, formation of reactive oxygen species and Zn^{2+} signaling in cultured rat hippocampal neurons, which is involved in neuroprotection.

Title: LMTX reduces tau-pathology in transgenic mice and restores microtubule stabilisation and synaptic transmission

Authors: *K. SCHWAB[1,2], S. FRAHM[1,2], V. MELIS[2,3], M. MAGBAGBEOLU[1,2], G. RIEDEL[3,2], C. M. WISCHIK[3,2], C. R. HARRINGTON[3,2], F. THEURING[1,2];
[1]Inst. of Pharmacol., Charite Berlin, Berlin, Germany; [2]TauRx Therapeut. Ltd., Singapore, Singapore; [3]Univ. of Aberdeen, Aberdeen, United Kingdom

Abstract: Alzheimer’s disease (AD) is an irreversible neurological disorder characterised by cognitive and motor impairments and the microtubule-associated protein tau is believed to drive the underlying pathology. We recently reported beneficial effects of LMTX, a reduced form of

methylthioninium, on pathology and motor skills in an AD transgenic mouse model overexpressing mutated human tau (P301S/G335D). We have used a proteomics approach to identify signaling networks responsible for the mediation of beneficial actions of LMTX. Brain tissue from untreated and LMTX-treated transgenic mice was subjected to large scale two-dimensional electrophoresis and nano-LC-ESI-MS (orbitrap). We found that oral LMTX administration affects biological processes involved in microtubule stabilisation and synaptic transmission, protein ubiquitination and response to oxidative stress, as well as metabolic processes associated with energy generation. Ingenuity Pathway Analysis revealed tau to be a highly significant upstream regulator of the observed changes. We conclude that LMTX specifically targets tau aggregation and that tau represents a reasonable therapeutic target for the treatment of AD and other tauopathies.

Title: Effects of U18666A on APP metabolism in cultured N2a cells

Authors: *J. CHUNG[1], A. MOHAMED[2], M. MAULIK[3], G. THINAKARAN[4,5,6], E. POSSE DE CHAVES[2], S. KAR[1,3];
[1]Dept. of Psychiatry, [2]Dept. of Pharmacol., [3]Ctr. for Prions and Protein Folding Dis., Univ. of Alberta, Edmonton, AB, Canada; [4]Dept. of Neurobio., [5]Dept. of Neurol., [6]Dept. of Pathology, The Univ. of Chicago, Chicago, IL

Abstract: Amyloid β (Aβ) peptides originating from β-amyloid precursor protein (APP) are considered to play a critical role in the development of Alzheimer's disease (AD). Multiple lines of evidence suggest that elevated levels of cholesterol can influence amyloidogenic processing of APP, leading to increased production of Aβ peptides. However, it remains unclear how sequestration of cholesterol within endosomal-lysosomal (EL) system, the major site of Aβ production, can regulate APP metabolism. In this study we investigate how alteration in cholesterol level/distribution following treatment with U18666A, a class II amphiphile that triggers redistribution of cholesterol to the EL system, can influence the levels/processing of APP in cultured N2a cells grown in media containing 0%, 5% or 10% fetal bovine serum (FBS). The N2a cells used in the study includes wild type N2a cells ($N2a_{wt}$), N2a cells transfected with

either wild type human APP ($N2aAPP_{wt}$) or human APP containing Swedish mutation ($N2aAPP_{sw}$). Our results indicate that U18666A treatment in 0% FBS, but not in 5% or 10% FBS, decreases the levels of total and free cholesterol in all categories of N2a cells. Changes in SREBP2 activation reflect this decrease in cholesterol. The levels of APP, APP-CTFs and intracellular Aβ1-40/42 are not markedly altered in $N2a_{wt}$ cells but are differentially increased in $N2aAPP_{wt}$ and $N2aAPP_{sw}$ cells. However, levels of α-secretase ADAM10, β-secretase BACE1 and components of γ-secretase (PS1, Nicastrin, PEN2 and APH1) remain unaltered in all three types of N2a cells following U18666A treatment. We are currently evaluating levels of secreted Aβ and activities of APP processing enzymes in U18666A treated N2a cells. Our results, obtained so far, suggest that redistribution of cholesterol into the EL system differentially alters the levels/processing of APP depending on the cultured conditions and endogenous levels of APP.

Abstract: Microgliosis is a major hallmark of Alzheimer's disease (AD) brain pathology. Aβ peptide is hypothesized to act as a stimulus for microglia leading to activation of non-receptor tyrosine kinases and subsequent secretion of pro-inflammatory cytokines. Therefore, the signaling pathways mediating microglial activation may be important therapeutic targets of anti-inflammatory therapy for AD. Four novel compounds were chosen after high throughput screening kinase activity assays determined them as potential Lyn kinase inhibitors. Their kinase inhibitory and anti-inflammatory effect on Aβ-stimulated activation was assessed using the murine microglial cell line, BV2. Cells were treated with the compounds determine effects on active, phosphorylated levels of Src family kinases, Src and Lyn, as well as an unrelated Ser/Thr

kinase, ERK. This study identifies a novel small molecule Src family tyrosine kinase inhibitor with anti-inflammatory effects in response to Aβ stimulation of microglia. Further *in vitro*/*in vivo* characterization of LDDN-0003499 as well as structural modification may provide a new tool for attenuating microglial mediated brain inflammatory conditions such as that occurring in AD.

Title: Unexpected receptors interactions in striatal neurons during a rodent model of Parkinson´s disease

Authors: *E. RENDON-OCHOA, T. HERNANDEZ-FLORES, O. HERNANDEZ-GONZALEZ, M. PEREZ-RAMIREZ, M. PALOMERO-RIVERO, R. DRUKER-COLÍN, E. GALARRAGA, J. BARGAS;
Univ. Nacional Autónoma De México, Ciudad DE Mexico, Mexico

Abstract: The "two pathways model" of the basal ganglia (BG) proposes that the direct pathway facilitates whereas the indirect pathway inhibits movement execution. Half of striatal projection neurons (SPNs) belong to the direct (dSPNs) and the other half to the indirect (iSPNs) pathway. dSPNs express D1-type dopamine (DA) receptors while iSPNs express D2-type DA receptors. D1-receptors facilitate neuronal discharge while D2-receptors repress neuronal discharge in part by enhancing or reducing, respectively, CaV1 Ca2+ currents. Adenosine A1 receptors are located in both neuron classes, while adenosine A2A receptors are preferential expressed in iSPNs. A1-type receptors in the SPNs reduce CaV2.2 Ca2+ currents, increasing neuronal excitability. A2A-type receptors enhance CaV1 Ca2+ currents in iSPNs, increasing neuronal excitability. However, A2A receptors need the previous occupation of A1 receptors to modulate Ca2+ channels. Here, we asked whether another receptor type could facilitate A2A receptors activation. Using voltage-clamp recordings in acutely dissociated SPNs we found that activation of D2-type receptors also facilitate A2A receptors activation in iSPNs. These interactions (A1-A2A and D2-A2A) are preserved in the 6-OHDA rodent model of Parkinson´s disease (PD).

Currently, L-DOPA and dopamine agonists are used therapeutically. While antagonists of A2A receptors are being tested as adjuvants. However their efficacy has been lower than expected. One reason is that D2-receptors induced activity may be counteracting antagonists actions on A2A -receptors.

Title: An in silico analysis of α-synuclein interactions using seed

Authors: *J. J. MORRISON, III, J. W. RYAN, K. MCLAUCHLAN, A. M. GREEN, L. SCHAPPELL, K. S. INMAN, A. D. LEE, B. BEHROUZ;
Neuroinitiative, Jacksonville, FL

Abstract: Parkinson's Diseases (PD) is a progressive neurodegenerative disorder with debilitating symptoms and unknown etiology. The protein α-synuclein has been at the forefront of PD research for two main reasons: aggregated forms of the protein within Lewy Body inclusions are a hallmark pathology of sporadic PD and gain of function mutations and multiplications in the gene encoding for α-synuclein cause autosomal dominant PD. Since the discovery of α-synuclein's involvement in PD in 1997, over four thousand peer reviewed manuscripts have described numerous interactions with other proteins and involvement in multiple subcellular pathways. Although the complexity of the neuronal system and the heavy interplay between biochemical pathways within the cell make it incredibly difficult to derive meaningful conclusions, recent computational advances open the door to organizing, visualizing and analyzing this data in a comprehensible manner. In these experiments, we used the Simulation Environment for Experimental Design (SEED) to model molecular interactions that affect or are impacted by α-synuclein. These in Silico experiments allow for manipulation of proteins in such a way that can model aspects of disease, for example by accumulation and aggregation of α-synuclein. These models can be used as a platform to test potential therapeutics cheaply and efficiently, reducing negative data and highlighting important molecular pathways that can be further exploited using laboratory research.

Title: In silico visualization of the endosomal pathway in Parkinson's disease using SEED

Authors: *J. W. RYAN, J. J. MORRISON, A. M. GREEN, L. SCHAPPELL, K. S. INMAN, A. D. LEE, B. BEHROUZ;
Neuroinitiative, Jacksonville, FL

Abstract: Recent genetic findings have implicated the endosomal pathway as a contributor in the development of Parkinson’s disease. Much is known about the molecular interactions that occur within this and other pathways involved in the pathogenesis of this disease. However, the heavy interplay between endosomal proteins, their neuronal locations, organelle associations, and associated feedback loops make it difficult to predict downstream effects of genetic alterations. Recent computational advancements provide a unique opportunity to create *in silico* models of these known interactions, and to predict downstream events associated with abnormalities within these pathways. Using the Simulation Environment for Experimental Design (SEED), we consolidated, simplified, and visualized available data on known molecular interactions. Using video game technology, we created a 3D environment in which to visualize the interplay between multiple molecules within the endosomal pathway in virtual space, in real time. Further, we manipulated expression of these molecules, including VPS35 to alter downstream molecular interactions within a virtual test tube. These *in silico* models can serve as a platform to quickly and inexpensively obtain detailed insight into the spatio-temporal behaviors of molecules inside the cell.

Title: Structural plasticity of the GABAergic pallidothalamic system in MPTP-treated Parkinsonian monkeys

Authors: *A. J. SULLIVAN[1], A. SHIBATA[1], C. KATONA[1], T. WICHMANN[1,2], Y. SMITH[1,2];
[1]Udall Ctr. of Excellence for Parkinson's Dis. Res., Yerkes Natl. Primate Res. Center, Emory Uni, Atlanta, GA; [2]Dept. of Neurol., Sch. of Med., Atlanta, GA

Abstract: Parkinson's disease is characterized by progressive loss of the dopaminergic neurons of the substantia nigra pars compacta, and manifests clinically with severe motor impairments including slowness of movement, resting tremor, rigidity, loss of balance and gait problems. Although the decreased motor activity seen in PD is thought to result from an abnormally increased inhibitory outflow from the internal globus pallidus (GPi) onto the thalamus, structural and functional data to support such a network change remain scarce. While studies have reported parkinsonism-associated changes in thalamic metabolism, neurochemistry and GABA receptor binding, the findings were inconsistent. Our preliminary light microscopic data from 3 control and 3 MPTP-treated parkinsonian monkeys suggest ~20% increase in vesicular GABA transporter (vGAT) immunoreactivity in the GPi-receiving region of the ventral motor thalamic nuclei in parkinsonian animals. In order to determine the source of this increased immunolabeling, we undertook an ultrastructural analysis of the morphology and prevalence of GABAergic terminals from the GPi in the anterior portion of the ventrolateral nucleus (VLa), known as the main target of sensorimotor pallidal projections in primates. Based on data about structural changes of pallidal terminals in the subthalamic nucleus (Fan et al. J Neurosci 32, 13718. 2012) and other GPi-like GABAergic terminal subtypes in the thalamus (Bodor et al. J Neurosci 28, 3090. 2008), we hypothesize that the synaptic microcircuitry of the GABAergic connections between the GPi and the anterior portion of the VLa undergoes major plastic reorganization in the parkinsonian state so that the GPi is capable of over-inhibiting its thalamic targets through an increased release of GABA. Data obtained so far demonstrate that GPi terminals have a large size, contain numerous mitochondria and form multiple symmetric synapses with large dendrites of VLa neurons. Some also contact vesicle-filled dendrites of GABAergic interneurons. A quantitative analysis is in progress to determine changes in the relative density, pattern of connectivity and number of synapses formed by individual GPi terminals in parkinsonian monkeys. The results of this study will help us to gain a better understanding of the complex network changes that affect the pallidothalamic system in the parkinsonian state, thereby contributing to our knowledge of the development of PD pathophysiology and the refinement of antiparkinsonian therapies.

Title: Glutamatergic denervation of striatal cholinergic interneurons in MPTP-treated Parkinsonian monkeys

Authors: *R. M. VILLALBA[1], S. LEE[1], J.-F. PARE[1], Y. SMITH[1,2];
[1]Yerkes Resch Ctr. and Udall Ctr. of Excelence For Parkinson's Disease, Emory Un, Atlanta, GA; [2]Dept Neurol., Sch. of Med., Atlanta, GA

Abstract: The thalamus is a major source of glutamatergic innervation to the striatum. The caudal intralaminar nuclei, namely the centre median (CM) and parafascicular (Pf) nuclei, are the main sources of thalamic inputs to the putamen and caudate nucleus, respectively. Previous tract-tracing studies have shown that both striatal projection neurons and cholinergic interneurons are the main targets of CM/Pf inputs in the monkey striatum (Sidibe and Smith, 1999, Neuroscience 89:1189). Recent behavioral data indicate that the CM/Pf plays a critical role in regulating the physiological responses of cholinergic interneurons to reward-related salient sensory stimuli (Matsumoto et al., 2001, J Neurophysiol 85: 960). The CM/Pf undergoes severe degeneration in Parkinson's disease and MPTP-treated monkeys (Henderson et al., 2000, Ann Neurol 47:345; Villalba et al., 2014, Brain Struct Funct 219:381). This neuronal death is associated with a significant loss of vGluT2-immunoreactive thalamostriatal terminals in the putamen of parkinsonian monkeys (Villalba et al., 2013, Soc Neurosci Abstr 240.02). However, the impact of this breakdown of the thalamostriatal system on the thalamic innervation of specific neuronal populations in the striatum remains unknown. To address this issue, we performed a double immunolabeling study for the vesicular glutamate transporter 2 (vGluT2) (specific marker of thalamostriatal terminals) and choline acetyltransferase (ChAT) at the electron microscopic level to determine if striatal cholinergic interneurons undergo thalamic denervation in the caudate nucleus and putamen of MPTP-treated parkinsonian monkeys. Three control and three MPTP-treated adult rhesus monkeys were used in this study. The pre-embedding immunogold method was used to localize vGluT2-positive profiles, while ChAT-containing elements were labeled with immunoperoxidase. Quantitative electron microscopic analysis revealed ~30% reduction in the prevalence of unlabeled terminals forming asymmetric synapses with ChAT-containing dendrites in both the caudate nucleus and putamen of parkinsonian monkeys. In contrast, there

was no significant difference in the proportion of ChAT-positive dendrites contacted by vGluT2-positive terminals between the two groups of animals. In conclusion, these findings demonstrate that striatal cholinergic interneurons undergo glutamatergic synaptic denervation that largely affects non-vGluT2-positive terminals in parkinsonian monkeys. Studies are in progress to determine the exact source of these terminals.

Title: Direct impact of dopaminergic and noradrenergic systems on adult-hippocampal neurogenesis in adult rats and the relevance to dementia in Parkinson's disease

Authors: ***C. ERMINE**[1,2], J. L. WRIGHT[1,2], C. L. PARISH[1,2], L. H. THOMPSON[1,2];
[1]The Florey Inst., The Florey, Parkville, Australia; [2]Univ. of Melbourne, Parkville, Australia

Abstract: A key pathological feature of Parkinson's disease (PD) is the progressive degeneration of midbrain dopaminergic neurons, causing motor dysfunction. However there are a range of 'non-movement' related features (including cognitive dysfunction, dementia and sleep disorder), which are not alleviated by dopamine replacement therapy. We are currently investigating the hypothesis that reduced hippocampal neurogenesis contributes to cognitive dysfunction in PD. We aim to characterise the effect of the dopaminergic and noradrenergic system on the adult-hippocampal neurogenesis in order to identify potential targets for the treatment cognitive impairments related to neurogenesis. We induced lesions of the different systems in adult rats using stereotaxic injections of toxins: 6-hydroxydopamine (dopaminergic system) and anti-dopa-β-hydroxylase-saporin (noradrenergic system). Four weeks later, the new cells were marked by pulses of bromodeoxyuridine (Brd-U) twice daily for 1 week. The animals were then sacrificed 4 weeks later for tissue collection. A high-performance liquid chromatography has confirmed that both lesions were successful: dopamine level in the striatum dropped to 20% and noradrenaline level in the hippocampus dropped to 8.3%. Surprisingly there was no difference in the number of Brd-U positive cells or in the number of double positive Brd-U/NeuN cells between our groups. The results show that while both noradrenergic and dopaminergic systems are implicated in the onsets of non-motor symptoms, they may not act through the regulation of adult-hippocampal neurogenesis like it was previously thought. Importantly our project has allowed reconsideration

of how neurogenesis is involved in PD and redirected the therapies to better potential targets for treatment.

Abstract: The striatum is essential for many aspects of mammalian behavior including motivation and movement and is dysfunctional in motor disorders such as Parkinson's disease. Previous studies have suggested a key role for the vesicular glutamate transporter (VGLUT) 3 in regulating locomotor activity, a canonical measure of basal ganglia output, through its expression by striatal cholinergic interneurons. Here we show that the hyperlocomotor activity observed in mice lacking VGLUT3 occurs during the waking cycle and is accompanied by increased dopamine synthesis, packaging and release in the striatum. We also show that contrary to the prevailing hypothesis, locomotor activity and striatal dopamine levels are surprisingly unaffected by the loss of the transporter from cholinergic neurons. The mice do however show defects in sensorimotor gating and habituation. Importantly, we find that loss of VGLUT3 prevents the development of motor deficits and markedly diminishes the appearance of L-dopa mediated dyskinesias in a model of Parkinson's disease. VGLUT3 thus profoundly regulates striatal function through multiple mechanisms, opening new avenues for understanding the regulation of

basal ganglia circuitry and potentially finding new treatment options for Parkinson's disease and related disorders.

Title: Combined D1-D3 dopamine receptor stimulation synergistically exacerbates dyskinesia in L-DOPA-primed hemi-Parkinsonian rats

Authors: ***S. M. MEADOWS**, L. GROSS, E. NUSS, N. CHAMBERS, C. BISHOP; Binghamton Univ., Binghamton, NY

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder characterized by motor deficits that result from the loss of nigro-striatal dopamine (DA) cells. Thus exogenous stimulation of DA receptors with direct and/or indirect DA agonists is standard treatment for early stage PD patients. However, chronic treatment often results in a loss of efficacy and abnormal involuntary movements (AIMs), known as dyskinesia. Recent evidence has shown that D1R and D3R co-localize in the striatum and may augment G-protein independent signaling implicated in dyskinesia. Therefore, the present study tested the behavioral effects of individual and combined D1R and D3R agonists in L-DOPA-primed hemi-parkinsonian rats. Adult male Sprague-dawley rats were given unilateral 6-hydroxydopamine lesions to the medial forebrain bundle. Three weeks later, rats were given daily L-DOPA (6 mg/kg; s.c.) for 2 weeks to establish stable dyskinesia expression. Using a within-subjects, counterbalanced design, dose-response AIMs testing was performed with the D1R agonist SKF38393 (0, 0.3, 1.0, 3.0 mg/kg; s.c.) followed by dose-response AIMs testing with the D3R agonist (+)PD128907 (0, 0.1, 0.3, 1.0 mg/kg; s.c.). Results demonstrated that both D1R and D3R agonists alone dose-dependently induced AIMs. Rats were then administered threshold doses of either SKF38393 (0.3 mg/kg; s.c.), (+)PD128907 (0.1 mg/kg; s.c.), or both after which AIMs were rated. The results showed that D1R-D3R co-activation produces significantly greater dyskinesia than individual stimulation of either receptor alone. Thus, the present study elucidates the pronounced contribution of combined D1R-D3R signaling to dyskinesia, suggesting a potential pharmacotherapeutic target for the attenuation of dyskinesia.

Title: Early repetitive transcranial magnetic stimulation intervention exerts neuroprotective effects and ameliorates motor deficits on Parkinson's disease model of rats

Authors: ***T.-H. HSIEH**[1,2], Y.-Z. HUANG[4], A. ROTENBERG[5], Y.-H. CHIANG[3], J.-J. CHEN[6]; [1]Dept. of Physical Therapy and Grad. Inst. of Rehabil. Sci., Chang Gung Univ., Taoyuan, Taiwan; [2]Grad. Inst. of Neural Regenerative Med., [3]Dept. of Neurosurg., Taipei Med. Univ., Taipei, Taiwan; [4]Dept. of Neurol., Chang Gung Mem. Hosp. and Chang Gung Univ. Col. of Med., Taipei, Taiwan; [5]Dept. of Neurol., Boston Children's Hosp. and Harvard Med. Sch., Boston, MA; [6]Dept. of Biomed. Engin., Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: Non-invasive repetitive magnetic stimulation (rTMS) technique, including theta burst stimulation (TBS) paradigm, has been proven to be able to effectively modulate motor cortical plasticity which might have potential for the novel treatment of Parkinson's disease (PD). However, the therapeutic benefits in PD are still controversial. The severity of dopamine depletion could be critically involved for the expression of motor plasticity induced by rTMS and might further interfere the improvement of motor performance. Accordingly, we conducted the PD animal model for elucidating the possible therapeutic effects after early and long-term intervention of rTMS. An acute hemiparkinsonian rat model, generated by unilateral injection of 6-hydroxydopamine (6-OHDA) into the medial forebrain bundle (MFB), was applied to evaluate therapeutic potential of rTMS in neuroprotective effects and motor behaviors following an intermittent theta burst stimulation (iTBS) protocol. The detailed gait analysis, akinesia, apomorphine-induced turning behavior as well as dopaminergic neurons degeneration level were evaluated up to 4 weeks after daily administration of iTBS over the motor cortex. Under rTMS intervention over the course in acute PD rats, we found that the long-term and daily iTBS significantly reduced and postponed the 6-OHDA induced motor deficits in gait, akinesia and rotational behavior. Immunohistochemically, tyrosine hydroxylase (TH)-positive neurons and fibers in the substantia nigra and striatum were significantly preserved, respectively. Taken

together, these results suggest that early and daily iTBS exerts neuroprotection and reduces the aggravation of PD symptoms in PD rats model. Also, our data further highlight the potential therapeutic effects of rTMS and confirm the existence of a long-term effect of consecutive daily applications of iTBS that might be relevant to the clinical effect and useful for further potential application of human PD subjects.

Title: Pharmacological blockade of mTORC1 or genetic deletion of Rhes inhibit levodopa-induced dyskinesia along with GABA and glutamate release in mice substantia nigra reticulata

Authors: ***A. BRUGNOLI**[1], A. USIELLO[2,3], M. MORARI[1];
[1]Med. Sci. - Pharmacol., Univ. of Ferrara, Ferrara, Italy; [2]CEINGE Biotecnologie Avanzate, Naples, Italy; [3]Second Univ. of Naples (SUN), Caserta, Italy

Abstract: Evidence that levodopa-induced dyskinesia (LID) is mediated by activation of mammalian target of rapamycin complex-1 (mTORC1) has been provided (Santini et al, Sci Signal 2: 1-10, 2009). mTORC1 signaling cascade in striatum is modulated by both Rheb (Ras homolog enriched in brain) and Rhes (Ras homolog enriched in striatum). It was recently proved that Rhes gene deletion significantly reduces LID in 6-hydroxydopamine (6-OHDA) hemilesioned mutant mice (Subramaniam et al, Nat Neurosci 15: 191-193, 2012). In order to investigate whether mTORC1 pathway activation is involved in the modulation of direct pathway medium-sized spiny neurons (MSNs), we performed *in vivo* microdialysis in C57BL/6J 6-OHDA-hemilesioned mice subacutely treated with rapamycin and levodopa. The levodopa-induced rise of GABA and glutamate levels in substantia nigra reticulata (SNr), a neurochemical marker of LID (Bido et al, J Neurochem 118: 1043-1055, 2011; Mela et al, Neurobiol Dis 45: 573-582, 2012), was monitored simultaneously with abnormal involuntary movements. Subacute rapamycin attenuated LID development by about 50%, without compromising the therapeutic effect of levodopa. Different from control animals, acute levodopa challenge in rapamycin-treated mice did not evoke the rise of nigral amino acids. To investigate whether lack of Rhes replicated the effect of pharmacological blockade of mTORC1, microdialysis was performed in knockouts (Rhes-/-) 6-OHDA-hemilesioned mice and wild-type controls (Rhes+/+). Rhes-/-

mice developed less severe dyskinesia upon subacute levodopa treatment compared with controls (~40%), without showing changes of levodopa therapeutic effect. Different from Rhes+/+ mice, Rhes-/- mice undergoing microdialysis did not show the increase of nigral GABA and glutamate levels upon acute levodopa challenge. These data suggest that mTOR activity alterations induced either by rapamycin administration or Rhes gene targeting prevent the sensitization of striato-nigral MSNs to levodopa, further pointing to Rhes protein as a promising target in LID therapy.

Title: Increased striatal acetylcholine and dopamine efflux is associated with L-DOPA-induced dyskinesia in hemi-Parkinsonian rats

Authors: ***M. CONTI**, N. PALUMBO, J. A. GEORGE, N. CHAMBERS, C. BISHOP; Psychology, Binghamton Univ., Binghamton, NY

Abstract: The dopamine (DA)-acetylcholine (ACh) balance hypothesis describes an antagonistic balance in the striatum where increased DA reduces ACh efflux and vice versa. Parkinson’s disease (PD) is typically characterized by the progressive loss of nigrostriatal DA resulting in elevated striatal ACh and hypokinetic motor symptoms. Replacing depleted DA levels with L-DOPA is the standard PD treatment, but chronic L-DOPA typically leads to the development of abnormal involuntary movements (AIMs) referred to as L-DOPA-induced dyskinesia (LID). However, it is unclear how L-DOPA treatment affects ACh neurotransmission in the PD brain. Thus, the current study sought to examine L-DOPA-induced changes in extracellular striatal DA and ACh following systemic L-DOPA treatment in L-DOPA-primed, hemi-parkinsonian rats. Adult male Sprague-dawley rats received either sham or unilateral 6-hydroxydopamine lesions of the left medial forebrain bundle and microdialysis guide cannulae into the DA-lesioned striatum. Animals were then primed with daily L-DOPA (6 mg/kg + benserazide 15 mg/kg; s.c.) for 2 weeks to establish stable AIMs. Lesion and L-DOPA-mediated striatal DA and ACh efflux was monitored with *in vivo* microdialysis while concurrent AIMs and rotations were quantified in response to L-DOPA. Surprisingly, both DA and ACh efflux positively and temporally correlated with severe LID expression and rotations in DA-lesioned rats. These findings shed new light on DA-ACh interactions in the context of L-DOPA treatment and point to novel therapeutic targeting of the ACh system.

Title: Contribution of muscarinic acetylcholine receptors to L-DOPA-induced dyskinesia

Authors: ***N. E. CHAMBERS**[1], M. CONTI[1], C. NAMBA[1], N. PALUMBO[1], C. FELDER[2], D. MCKINZIE[2], C. BISHOP[1];
[1]Binghamton Univ., Binghamton, NY; [2]Eli Lilly & Co., Indianapolis, IN

Abstract: Parkinson's disease (PD), a neurodegenerative disorder caused by a depletion of dopamine (DA) cells in the substantia nigra, is characterized by motor symptoms that eventually necessitate the use of L-DOPA DA replacement therapy. However, chronic L-DOPA treatment results in L-DOPA-induced dyskinesia (LID), characterized by abnormal involuntary movements (AIMs). The exact cause of LID is unknown, but recent evidence has suggested that an L-DOPA-induced imbalance in striatal DA and acetylcholine (ACh) may contribute. With improved drug discovery and synthesis, muscarinic ACh receptors (mAChRs) have been identified as potential therapeutic targets for attenuating LID. In order to better understand the contribution of ACh and mAChRs to LID, the current study examined the potential for a panel of mAChR agonists and antagonists to modulate LID in unilateral 6-OHDA-lesioned Sprague-Dawley rats. After 3 weeks of recovery from surgery, rats were primed with L-DOPA, and monitored for AIMs to ensure stable expression of LID. Selective and non-selective mAChR agonists and antagonists were administered subcutaneously before L-DOPA in a counterbalanced within-subjects design, after which rats were then tested for AIMs as well as motor performance using the forepaw adjusting steps test. The results of this study suggest that mAChRs can modulate LID and preliminarily implicate the promise of the mAChR 4 subtype for the treatment of LID.

Title: Involvement of phospholipase C in the dopaminergic treatment of Parkinson's disease: effects on dyskinetic behaviors and ERK1/2 signaling activation

Authors: *I. SEBASTIANUTTO, N. MASLAVA, M. A. CENCI;
Exptl. Med. Science; Basal Ganglia Pathophysiology Unit, Lund Univ., Lund, Sweden

Abstract: In animal models of Parkinson's disease (PD) treated with L-DOPA, a large striatal activation of extracellular signal-regulated kinases 1 and 2 (ERK1/2) is associated with the development of dyskinesia. Antagonists of metabotropic glutamate receptor type 5 (mGluR5) reduce the striatal activation of ERK1/2 by L-DOPA and have antidyskinetic effects. In the dopamine (DA)-denervated striatum *ex vivo*, the ERK1/2 activation induced by SKF38393 (a D1/D5 receptor agonist) can be inhibited by antagonizing mGluR5 or its downstream signaling mediator, phospholipase C (PLC) (Fieblinger et al. J. Neurosci. 2014). Based on these results, we set out to examine the effects of PLC inhibition *in vivo*. Rats sustained unilateral 6-OHDA lesions of the nigrostriatal DA pathway followed by chronic treatment with either L-DOPA or SKF38393. Thereafter, animals that had developed dyskinesia received challenge injections of the PLC inhibitor U73122 (10 or 30 mg/kg) or its inactive analogue, U73343, together with the dopaminergic treatment. U73122 dose-dependently reduced the severity of peak-dose dyskinesia without altering the rats´ performance in tests of forelimb use and general motor dexterity. The effects of U73122 were more potent when the dyskinesia-inducing agent was SKF38393. By contrast, U73122 was ineffective on dyskinesias evoked by the D2/D3 agonist, Quinpirole. The dose of U73122 exerting significant antidyskinetic effects blunted the striatal activation of ERK1/2 and the phosphorylation of histone 3 (pH3) induced by either L-DOPA or SKF38393 (Quinpirole did not induce these markers). In keeping with previous findings *ex vivo*, these results demonstrate that the striatal activation of ERK1/2 downstream of supersensitive D1 receptors requires PLC activity. These results will hopefully inform the development of novel antidyskinetic treatments that selectively target an abnormal communication between D1 receptors and PLC-dependent signaling.

Title: A small molecule ligand for TrkB/TrkC neurotrophin receptors improves motor dysfunction and pathology in cellular and mouse MPTP-induced Parkinson's models

Authors: *F. M. LONGO[1], T. YANG[1], K. C. TRAN[1], N. PHELPS[1], C. J. CONDON[1], D. A. SIMMONS[1], S. M. MASSA[2,3];
[1]Dept. of Neurol. and Neurolog. Sci., Stanford Univ. Med. Ctr., Stanford, CA; [2]San Francisco Veterans Affairs Med.Ctr., San Francisco, CA; [3]Neurol., Univ. of California, San Francisco, CA

Abstract: Multiple lines of evidence suggest that the neurotrophin receptors TrkB, which selectively binds brain-derived neurotrophic factor (BDNF), and TrkC, the cognate NT-3 receptor would be particularly effective therapeutic targets for PD. Both receptors are expressed by substantia nigra (SN) dopaminergic (DA) and striatal neurons, their survival depends on BDNF and NT-3, and loss of BDNF may occur in the SN of PD patients. TrkB and/or TrkC mutations cause hypersensitivity of nigrostriatal DA neurons to MPTP and BDNF/TrkB protects against MPTP-induced degeneration. These findings suggest that deficiencies in Trk receptor signaling contribute to PD pathogenesis and that compounds which restore this signaling could be important therapeutic candidates. Our laboratories have developed a small molecule, non-peptide ligand, BC-2, that binds to and activates both TrkB and TrkC, but not TrkA or p75 receptors. We hypothesized that BC-2 would have positive effects on morphological, behavioral and biochemical deficits in cell culture and/or mouse MPTP-induced PD models. In *in vitro* studies, BC-2 at nanomolar concentrations rescued mouse embryonic DA neuron degeneration induced by MPTP and promoted human stem cell differentiation into TH-positive neurons. In normal mice, BC-2 from 10-150 mg/kg (intraperitoneal, IP) achieved significant brain levels, and activated TrkB and TrkC and their downstream targets. 50mg/kg was determined to be an optimal dose for *in vivo* studies. In a neuroprotection study in mice, daily IP BC-2 began 3 days before and continued throughout MPTP injections and behavior testing for 14 days. In a neurorestoration study, BC-2 treatment was begun one day after the last MPTP injection and continued throughout behavioral testing until mice were euthanized at 28 days. In both studies, BC-2 significantly improved motor outcomes, reduced the loss of SN TH-positive neurons and neurites, inhibited decreases in striatal dendritic spine density, and reversed deficits in the levels of phosphorylated Trks and their downstream signaling components. Overall, these results support the idea that concomitant targeting of TrkB and TrkC might offer a novel, pharmacologically feasible small molecule strategy for treatment of PD patients.

Title: A small molecule mediates co-activation of TrkB/TrkC neurotrophin receptors, and promotes novel signaling patterns and bioactivities including neurite outgrowth on inhibitory surfaces

Authors: *T. YANG[1], S. M. MASSA[2,3], K. C. TRAN[1], D. A. SIMMONS[1], J. RAJADAS[1], T. JANG[1], S. CARSANARO[1], F. M. LONGO[1];
[1]Neurol. and Neurology. Sci., Stanford Univ., Stanford, CA; [2]San Francisco Veterans Affairs Med.Ctr., San Francisco, CA; [3]Neurol., Univ. of California, San Francisco, CA

Abstract: These authors made equal contributions to this work. Neurotrophin receptors are coupled to numerous signaling cascades that play critical roles in neuronal survival and plasticity. Several non-peptide small molecule ligands have recently been reported that bind to and activate specific tyrosine-receptor kinase (Trk) neurotrophin receptors, stimulate their downstream signaling and cause biologic effects similar to, though not completely overlapping, those of the native protein ligands. Using *in silico* screening coupled with low-throughput neuronal survival screening (Massa et al., JCI. 2010), a new compound has been identified, BC-2, that unlike prior small molecule compounds is capable of: selectively binding to and activating two of the three Trk receptors, TrkB and TrkC; promoting neurite outgrowth superseding maximal levels obtainable with brain derived neurotrophic factor (BDNF), neurotrophin 3 (NT-3) or a combination of the two in cultured mouse hippocampal neurons; and unlike BDNF or NT-3, supporting neurite outgrowth in an inhibitory environment consisting of myelin-associated glycoprotein (MAG) and chondroitin sulfate proteoglycans (CSPGs). In young and aged mice, the compound activates hippocampal and striatal TrkB and TrkC, and their downstream signaling AKT, ERK and PKC, and increases hippocampal dendritic spine density and synaptic markers in aged mice. Thus, BC-2 constitutes a new tool for the study of TrkB and TrkC signaling, and supports the possibility of developing ligands that stimulate unique combinations of Trk receptors and activity patterns applicable to neuronal populations and deficits present in various disease states.

Title: Lasting spontaneous negative motor effect of dopamine synthesis blocker alpha-methyl-para-tyrosine (AMPT) in common marmosets

Authors: *H. S. PEREIRA[1,2], K. COSTA[1], M. F. P. ARAÚJO[1];
[1]Edmond and Lily Safra Intl. Inst. of Neurosci., Inst. Santos Dumont, Macaiba, Brazil; [2]Dept. of Biomed. sciences, State Univ. of Rio Grande do Norte, Mossoró, Brazil

Abstract: The most prominent symptom in many pathological states, such as Parkinson disease, is motor disability. Most animals models of motor system impairments either induce chronic irreversible deficits or highly acute deficits lasting just a few hours. Alpha-methyl-para-tyrosine (AMPT) injections have been previously used in chronic animal models to enhance the motor impairments for a few hours. In the present study we evaluated the effects of AMPT injections in four normal marmosets. The common marmoset (Callithrix jacchus) is a New world primate used extensively in biomedical and behavioral research which have many brain structures similarities with humans allowing for better translational inferences. Four marmosets were injected subcutaneously with AMPT (2 doses of 240 mg/kg, dissolved in physiological saline, with a 3 hours interval between them). The animals daily spontaneous locomotion 3 days before and 6 days after AMPT injections were measured by an actimeter (Actiwatch Mini©, CamNtech Ltd) placed inside a bag attached to the torso of each animal. Motor disabilities following AMPT were also evaluated in 2 animals using the Manual Parkinson Disease Scoring (MPDS) developed by Santana (adapted from Fahn's UPDRS). The MPDS adapted scale consists of 16 categories scored from zero to three, which corresponds to absence of altered state to more intense symptomatology, respectively. Some categories involve symptoms that were evaluated for each body part individually (i.e., limbs, trunk, head). Hence, the maximum total score of the scale is 48 points. The motor examination was performed daily in the animal's home cage. The daily spontaneous locomotion decreased during days 1-3 after AMPT injection in all 4 animals. In addition, the MDPS score increased during 3 days after AMPT injection in both marmosets evaluated. These results suggest that subcutaneous injection of AMPT can be used as an acute model to study motor disabilities in commom marmosets.

Title: Characterization of D3 receptor agonists with atypical signaling and receptor trafficking properties

Authors: *S. KORTAGERE[1], W. XU[2];
[1]Microbiology and Immunol., [2]Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Dopamine D3 receptor (D3R) has been evidenced to play a critical role in the etiology of both the Parkinson's disease (PD) and levodopa (L-dopa)-induced dyskinesia (LID). A number of dopaminergic agents from partial agonists to antagonists have been tested either as L-dopa replacement agents or as adjuvants with L-dopa therapy with limited success. Our previous results showed that compound SK609, a novel selective D3R agonist with atypical properties such as biased-ERK signaling, did not induce desensitization of D3R *in vitro*. SK609, significantly improved motor impairments associated with PD-like symptoms in a 6-OHDA induced hemiparkinson rat model of PD. Chronic treatment of SK609 did not induce abnormal involuntary movements (AIMs) but significantly reduced AIMs induced by L-dopa when used adjuvantly with L-dopa. In our quest to identify novel analogs of SK609 that possess similar atypical properties but with improved affinity for D3R, we have identified SK608, a selective D3R agonist. SK608, like its parent compound does not induce desensitization of D3R stably expressed in CHO cells and dose- and time-dependently induces internalization of D3R. These results are in complete contrast with the signaling properties of other known D3R agonists such as Dopamine and PD128907, which significantly induce desensitization but not internalization of D3R. D3R are only known to undergo pharmacological sequestration in response to these known D3R agonists. Our preliminary results suggest that the internalization induced by SK608 contributes to the re-sensitization of D3R signaling and receptor trafficking which may explain its novel therapeutic efficacy observed in alleviating the symptoms of PD and LID in rodent model.

Title: Pharmacological rescue of defective mitophagy in PINK1 deficiency

Authors: J. KIM, *S. YANG, J. HAN, M. KANG, J. H. SON;
Ewha Womans Univ., Seoul, Korea, Republic of

Abstract: At present, no effective therapeutic measures are available to alleviate mitochondrial deficits in Parkinson's disease (PD), despite the implication of mitochondrial dysfunction as one of the major pathological mechanisms underlying the dopaminergic neuronal loss. Mitophagy is the selective autophagy of mitochondria, which is a critical quality control mechanism involved in removal of damaged or excess mitochondria. The failure in mitophagy is implicated in the mitochondrial dysfunction observed in familial PD that is caused by PINK1 or Parkin gene mutations. According to the PINK1-Parkin signaling model, mitophagy is promoted by the mitochondrial translocation of Parkin, an essential PINK1-dependent step. We have identified that low levels of nitric oxide (NO), produced by phospho-nNOS on damaged mitochondria, was sufficient to induce the mitochondrial translocation of Parkin even in PINK1 deficiency (Han J. et al. J. Biol. Chem. (2015)) Especially, optimum levels of NO treatment enabled PINK1-null cells to regain the mitochondrial translocation of Parkin, which appeared to be significantly suppressed by both NAAN, an nNOS inhibitor, and nNOS-null mutation in wild type cells. Moreover, nNOS-null mutation resulted in the similar mitochondrial OXPHOS enzyme deficits as PINK1-null mutation. A functional significance of nNOS activation in mitophagy was further confirmed by demonstrating the increased interaction of the full-length PINK1 with nNOS on mitochondria, which was accompanied by mitochondrial accumulation of phospho-nNOS during mitophagy. Of interest, L347P PINK1 mutant, a causal monogenic mutation of familial PD, failed to interact with nNOS and to mediate subsequent induction of mitophagy. Furthermore, NO-induced mitophagy help recover from the mitochondrial OXPHOS deficits in PINK1-null cells. Therefore, we first demonstrate a novel functional role for NO in induction of Parkin translocation and mitophagy, suggesting the feasibility of pharmacotherapy for defective mitophagy in PINK1 deficiency.

Title: Oxi-alpha and Oxi-beta as potential therapeutic targets in autophagic dysregulation caused by oxidative stress in a dopaminergic neuron model

Authors: *J.-S. KIM, Y. JANG, J. H. SON;
Ewha Womans Univ., Seoul-City, Korea, Republic of

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder which is characterized by specific cell death of dopaminergic (DA) neurons in the substantia nigra. Both altered autophagy and oxidative stress (OS) are considered as major pathogenic factors contributing to DA neurodegeneration, but it is largely unknown how autophagy is disrupted by OS. We have characterized the autophagy regulator gene family including Oxi-alpha and Oxi-beta (Choi et al., J. Neurochem. 2010). Oxi-alpha and Oxi-beta exhibited the opposing actions towards mTOR phosphorylation, one of the critical regulatory steps of autophagy and translation. Oxi-alpha was down-regulated by OS, and overexpression of Oxi-alpha increased mTOR phosphorylation via unknown mechanism, subsequently suppressing the accumulation of autophagosome. In contrast, Oxi-beta was up-regulated during OS-induced dopaminergic cell death. Oxi-beta inhibited mTOR phosphorylation and subsequently induced autophagy. We have identified that Oxi-β acted to stabilize tuberous sclerosis complex 2 (TSC2) through competitively interacting with FBXW5, E3-ubiquitin ligase (Ha et al., J. Neurochem. 2014), resulting in decreased mTOR phosphorylation and increased autophagy under OS. Our results suggest that, under pathogenic OS condition, the altered expression of Oxi-α and Oxi-β may act synergistically to increase autophagy in dopaminergic neurons, and they might be potential therapeutic targets in dysregulated autophagy under OS condition observed in PD.

Title: Photobiomodulation in aged nonhuman primates

Authors: *J. H. KORDOWER[1], S. MULLER[2], K. MAREK[4], G. TAMAGNAN[4], R. HARKER[3], B. HILLER[3], K. OH[3], B. LOVISA[5], A. PITZSCHKE[5], G. WAGNIERES[5];
[1]Dept Neurol Sci., [2]Neurolog. Sci., [3]Rush Univ. Med. Ctr., Chicago, IL; [4]Inst. or Neurodegenerative Disorders, New Haven, CT; [5]École polytechnique fédérale de Lausanne, Lausanne, Switzerland

Abstract: The purpose of this study was to develop a medical device capable of altering the progression of Parkinson's disease through photobiomodulation (PBM) using near-infrared light in the substantia nigra pars compacta (SNpc) region of aged Rhesus monkeys. Four aged (≥19 yrs) rhesus monkeys were unilaterally implanted with a hollow catheter into the substantia nigra,

through which an optical fiber was later introduced to illuminate the target region. Pre- and post-operative MRIs were taken to confirm positioning of the catheter. Monkeys received illumination for 100 seconds with near-infrared light at 808 nm once every other day for four weeks with irradiances ranging between 1 and 100 mW/cm^2 to determine dose-response. *In vivo* PE2I (DAT) SPECT scan results were variable across animals and dose levels. Relative to the unimplanted and unilluminated side, reductions in the dopaminergic nigrostriatal system on the implanted/illuminated side were seen with tyrosine hydroxylase (TH)-immunoreactive stereological cell counts, (Monkey 1: -29.73%, Monkey 2: -29.92%, Monkey 3: -40.25%, Monkey 4: 52.67%), TH optical density in the putamen (Monkey 1: +1.71%, Monkey 2: -42.44%, Monkey 3: +9.46%, Monkey 4: -29.60%) and caudate nucleus (Monkey 1: 18.78%, Monkey 2: -34.79%, Monkey 3: + 4.85%, Monkey 4: -27.33%), and striatal dopamine via HPLC (Monkey 1: -41.72%, Monkey 2: -51.66%, Monkey 3: +1.26%, Monkey 4: 67.24%). This pilot data suggests that surgical implantation of the catheter plus near-infrared illumination of the SNpc can, in certain conditions, induce a degeneration of nigrostriatal neurons in aged nonhuman primates. Caution should be employed prior to clinically using this approach until parameters can be established that induce a positive influence on this system, as is the case in separate studies performed in rodent models.

Title: Effects of mesenchymal stem cell differentation to DA induced by linear micro and nano-topology for Parkinson`s disease

Authors: ***L. QI**, X. ZHANG;
Xi'An Jiaotong Univ. Suzhou Acad., Jiangsu, China

Abstract: Precursor cell differentiation of Dopamine (DA) neural is the most feasible way for Parkinson`s disease (PD) treatment. Mesenchymal Stem Cells (MSC) have potentiality into DA neuron differentiation which was influenced by many factors. Physics factor was focused on the

MSC proliferation and differentiation. We used processing technique of micro and nano-meter topology to get 0.7um and 2um substrates with linear pattern (LMP) for MSC culturing. We found that LMP depressed adult neural stem cells proliferation when compared to non-patterned substrates. Thus, this finding has led us to the rational for the proposed research, which will validate LMP to regulate MSC into DA differentiation. The aims of study are: 1) Improve the LMP substrates and choose optimal substrates to increase MSC into DA differentiation; 2) To verify the effects of LMP on differentiation to DA in MSC. The present data showed LMP depress ANSC proliferation when compared to non-patterned substrates (control). Meanwhile, LMP can significantly enhance MSC differentiation to DA. The smaller the feature size is, the better upregulation applies to the differentiation; 3) The underlying mechanisms of topography-enhanced DA differentiation are further revealed by directing suppression of mitogen activated protein kinase/extracellular signaling-regulated kinase (MAPK/Erk) signaling pathway in MSC using U0126, known to inhibit the activation of Erk. The currently data suggest MAPK/ Erk pathway is partially involved in topography-induce differentiation. Furthermore, the therapeutic effect with DA induced by LMP will be investigated in PD animal model. Taken together, successful completion of these studies will therefore form a basis for algorithms to help elucidate mechanism of MSC regulating DA neuron differentiation by nano-substracts, to provide the strategies aimed at laying the foundation for further PD clinical studies.

Title: Reducing C-terminal truncation mitigates synucleinopathy and neurodegeneration in a transgenic model of multiple system atrophy

Authors: *W. MEISSNER[1], F. BASSIL[1], P.-O. FERNAGUT[1], E. BEZARD[1], Q. HOANG[2], D. RINGE[3], G. PETSKO[4];
[1]Inst. Des Maladies Neurodégénératives, Bordeaux, France; [2]Sch. of Med., Indiana Univ., Indianapolis, IN; [3]Rosenstiel Basic Med. Sci. Res. Ctr., Brandeis Univ., Waltham, MA; [4]Weill Cornell Med. Col., New York, NY

Abstract: Multiple system atrophy (MSA) is a sporadic orphan neurodegenerative disorder. No treatment is currently available to slow down the aggressive neurodegenerative process and patients die within a few years after disease onset. The cytopathological hallmark of MSA is the accumulation of alpha-synuclein (α-syn) aggregates in affected oligodendrocytes. Several studies point to α-syn oligomerization and aggregation as a mediator of neurotoxicity in synucleinopathies including MSA. C-terminal truncation by the inflammatory protease caspase-1 has recently been implicated in the mechanisms that promote aggregation of α-syn *in vitro* and in neuronal cell models of α-syn toxicity. We here present an *in vivo* proof of concept of the ability of the caspase-1 inhibitor prodrug VX-765 to mitigate α-syn pathology and to mediate neuroprotection in PLP-SYN mice, a transgenic mouse model of MSA. PLP-SYN and age-matched wild-type mice were treated for a period of 11 weeks with VX-765 or placebo. VX-765 prevented motor deficits in PLP-SYN mice compared to placebo controls. More importantly, VX-765 was able to limit the progressive toxicity of α-syn aggregation by reducing its load in the striatum of PLP-SYN mice. Not only did VX-765 reduce truncated α-syn but also decreased its monomeric and oligomeric forms. Finally, VX-765 showed neuroprotective effects by preserving tyrosine hydroxylase positive neurons in the substantia nigra of PLP-SYN mice. In conclusion, our results suggest that VX-765, a drug that was well tolerated in a six-week-long phase 2 trial in patients with epilepsy, is a promising candidate to achieve disease modification in synucleinopathies by limiting α-syn accumulation.

Abstract: Cell replacement therapy in Parkinson's Disease still miss a study addressing electrophysiological properties of human grafted neural stem cells and its correlation with behavioral recovery after transplantation in parkinsonian animal models. Here we study the electrophysiological profiles of two grafted ventral mesencephalic (VM) human Neural Stem Cells (hNSCs) clonal lines that are forced to overexpress Bcl-XL to preserve their neurogenic capacity, named C30-Bcl-XL and C32-Bcl-XL, onto the parkinsonian model of coronal striatal slices. Electrophysiological recordings show that these C30-Bcl-XL and C32-Bcl-XL cells integrate, mature and are able to achieve a complete A9-subtype phenotype 6 weeks after grafting into the striatal slice. Their electrophysiological properties include spontaneous pacemaker-like action potentials, highly regular firing pattern, long duration action potentials, high spike threshold and a sag component. This result is the first communication of a complete A9-subtype electrophysiological profile of DAn derived from any human stem cell in a PD model. In addition, we transplanted C30-Bcl-XL and C32-Bcl-XL cells in hemiparkinsonian animals to study behavioral recovery at 7 weeks post grafting and immune reaction of the host tissue towards the transplanted cells up to 12 weeks post grafting. A significant behavioral improvement was observed for C30-Bcl-XL transplanted animals at the short time point of 7 weeks. Our data also show a low immune reaction that would allow migration and integration of our human cell lines in the host tissue in future long-term studies.

Laval, Québec, QC, Canada; [3]Dept. of cellular and molecular medicine, Fac. of Medicine, Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Although the mechanisms underlying the loss of neurons in Parkinson's disease are not well understood, impaired mitochondrial function and pathological protein aggregation are suspected as playing a major role. Why dopamine (DA) neurons and a select small subset of brain nuclei are particularly vulnerable to such ubiquitous cellular dysfunctions is presently one of the key unanswered questions in Parkinson's disease research. One intriguing hypothesis is that their heightened vulnerability is a consequence of their elevated bioenergetic requirements. Here we used mouse DA neurons in primary culture to show for the first time that vulnerable nigral DA neurons differ from less vulnerable DA neurons such as those of the VTA (ventral tegmental area) by having a higher basal rate of mitochondrial OXPHOS (oxidative phosphorylation) and a smaller reserve capacity, as measured using a Seahorse bioanalyzer. We also find that nigral DA neurons have a higher density of axonal mitochondria, an elevated level of basal oxidative stress and a considerably more complex axonal arborization. Furthermore, we demonstrate that reducing axonal arborization by acting on axon guidance pathways with semaphorin 7A reduces in parallel the basal rate of mitochondrial OXPHOS and the vulnerability of nigral DA neurons to the neurotoxic agents MPP+ (1methyl4phenylpyridinium) and rotenone. Blocking L-type calcium channels with isradipine shows a similar effect, although it does not protect against rotenone. Our data provide the most direct demonstration to date in favor of the hypothesis that the heightened vulnerability of DA neurons in Parkinson's disease is directly due to their particular bioenergetic and morphological characteristics.

Title: A role for Nlrp3 in mediating rotenone-induced neuroinflammation

Authors: *M. C. HAVRDA[1], J. SULLIVAN[2], L. WANG[3], Y. PATANKAR[1], B. BERWIN[1], S. LEE[1], M. FELDMAN[1], A. YOUNG[1];
[1]Geisel Sch. of Med. at Dartmouth, Lebanon, NH; [2]Geisel Sch. of Med. at Dartmouth, Lebanon NH, NH; [3]Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Pathologic examination of post-mortem tissues obtained from Parkinson's disease (PD) patients, animal models of PD and large scale epidemiologic studies implicate neuroinflammation in the development and progression of PD. Exposure to the pesticide rotenone is associated with the development of PD in agricultural workers and is the basis of rodent models of PD. In spite of these findings, the cellular and molecular mechanisms of rotenone-induced neuroinflammation remain unclear. Zhou and others identified a pro-inflammatory function for rotenone in blood cells where rotenone induced ROS-dependent activation of the Nlrp3 inflammasome. The Nlrp3-inflammasome is an intracellular mediator that can initiate an inflammatory cascade in response to cellular stress that is known to be active in Alzheimer's disease. We do not yet know if the Nlrp3 inflammasome mediates neuroinflammation associated with rotenone exposure in mice or during the progression of PD. To understand whether ingestion of small doses of rotenone could translate into neuroinflammation we exposed mice to rotenone, using intragastric gavage, over an extended time period. Using this model system, we observed progressive behavioral and histopathologic symptoms of Parkinsonism. Associated with PD symptomology we identified neuroinflammatory changes including an elevated pro-inflammatory cytokine profile and evidence of leukocyte recruitment in the CNS. Implicating *Nlrp3* in these neuroinflammatory changes, flow cytometry and immunohistologic studies indicated that peripheral innate immune cells, specifically $CD11b^{+}$, $Ly6G^{-}$, $Ly6C^{lo}$ "patrolling" monocytes, were recruited into the CNS of WT mice ingesting rotenone but not into the brains of rotenone-treated $Nlrp3^{-/-}$ mice. Further implicating Nlrp3 in mediating rotenone-induced neuroinflammation, we observed a sustained elevation of the canonical *Nlrp3*-dependent cytokines IL1b and IL6 in brain extracts obtained from wild-type mice ingesting rotenone but not in similarly treated $Nlrp3^{-/-}$ mice. Seeking a cellular origin for these cytokines in the CNS, we observed that in primary mixed glial cultures, $CD11b^{+}$ microglia were the sole source of rotenone-induced Nlrp3-dependent IL1b. Planned studies will extend these findings to evaluate the activation of the NLRP3 inflammasome in post-mortem tissues obtained from patients diagnosed with sporadic PD. The completion of these studies is expected to have broad reaching implications for our understanding of neuroinflammation occurring as the result of both long-term exposure to environmental toxins and PD.

Title: Impaired mitochondria trafficking and autophagy in hiPSC-derived dopaminergic neurons harboring three copies of SNCA gene

Authors: *M. FERRARI[1], T. Q. MELO[1,2], K. C. VAN ZOMEREN[2], S. C. V. M. COPRAY[2], E. W. G. M. BODDEKE[2];

Abstract: Background: Protein aggregates containing α-synuclein, increased oxidative stress due mitochondria dysfunction and disturbances in autophagy are hallmarks of Parkinson's disease. The increased levels of α-synuclein can impair mitochondria function and autophagy. Mitochondria are essential organelles for neuronal function; their dynamics is dependent of proper trafficking to cell body and terminals. Alterations in the mitochondria transportation can precede the presence of aggregates and contribute to cell death. However, the link between alteration in mitochondrial transport and protein aggregation involved in neurodegenerative diseases is still unresolved. Human induced pluripotent stem cells (iPSCs) derived from patients suffering from neurodegenerative disorder allows the investigation of the cell pathogenesis process. Objective: The objective of this study is to analyze mitochondrial trafficking and autophagy in the human dopaminergic neurons derived from iPSCs of a Parkinson patient with a triplication of the alpha-synuclein gene (SNCA3) and of a healthy age matched control. . Design/methods: hiPSCs were differentiated into dopaminergic neurons based on dual SMAD inhibition following the protocol of Kriks et al. in 2011 (doi: 10.1038/nature10648.). Dopaminergic neurons were analyzed by immunocytochemistry to confirm the phenotype. Mitochondrial mobility and autophagy were analyzed in living cells using Mitotracker and Lyso-tracker respectively using confocal microscopy and 63x objective after 60 and 90 days of differentiation. Parallel to the differentiation of hiPSCs into dopaminergic neurons, neuroblastoma cells (SHSY5Y) containing α-synuclein wild-type or A30P or A53T were differentiated into DA neuron-like cells by exposure to retinoic acid during 5 days. Mitochondria mobility was analyzed using pDSRED2-mito after 4, 6 and 8 days of differentiation. Results: Mitochondria trafficking was decreased (50%) after 90 days of differentiation in human dopaminergic neurons derived from iPSC expressingSNCA3. In addition, lisossomes were accumulated (100%) after 90 days of differentiation in human dopaminergic neurons derived

from iPSC containing SNCA3. Retrograde trafficking was preferentially decreased (50%) after 6 days of differentiation in SHSY5Y containing α-synuclein A53T. Mitochondria is also fragmented after 8 days of differentiation in SHSY5Y containing α-synuclein A53T. Conclusion: The overexpression of alpha-synuclein as well as the expression of the mutant A53T can disturb mitochondria dymanics and autophagy, which is a mechanism that may trigger cell death during the course of Parkinson's disease.

Title: Loss of mitochondrial chaperone protein mortalin in a *Drosophila* model of Parkinson's disease causes functional defects which are rescued by downregulation of Autophagy

Authors: *S. B. HANNAN[1], J. Y. ZHU[2], T. M. RASSE[3];
[1]Hertie Inst. of Clin. Brain Res., Tübingen, Germany; [2]Hertie Inst. of Clin. Brain Res., Tuebingen, Germany; [3]German Cancer Res. Inst., Heidelberg, Germany

Abstract: Impairments in mitochondrial function, lysosomal degradation pathways and synaptic transmission are cardinal features of Parkinson's disease (PD) pathogenesis. Genetic studies have identified mutations in mitochondrial chaperone protein Mortalin/Hsc70-5/GRP75 in PD patients. Mortalin levels are reduced in the brains of PD patients and disease-associated rare mutated genetic variants failed to rescue impaired mitochondrial integrity in cellular mortalin knockdown models. Recent studies in a *Drosophila* model of PD showed that pan-neuronal knockdown of Mortalin *in vivo* causes synaptic mitochondrial depletion due to enhanced mitophagy, reduced ATP levels, shortening of lifespan as well as demonstrating cardinal features of *Drosophila* models of PD including impaired body posture and climbing defects. In order to gain an insight into the physiological consequences of mortalin-knockdown, we performed electrophysiological analysis at the *Drosophila* neuromuscular junction following pan-neuronal knockdown of Mortalin. Our studies reveal that knockdown of Mortalin causes functional impairments in synaptic transmission characterized by defects in basal synaptic transmission as well as increased failure rates following sustained stimulation at a high frequency compared to control animals. Next, by utilizing *Drosophila* genetic tools, we performed an RNAi screen to identify genes that can modify loss-of-mortalin associated phenotypes. Our screen revealed a

number of enhancers and suppressors that could modify the pattern of temperature dependent paralysis caused by mortalin knockdown. Interestingly, 5 members of the autophagy machinery were identified as modifiers namely Atg1, Atg5, Atg7, Atg12, and Atg101. These genes are involved in autophagy induction (Atg1 and Atg101) and expansion (Atg5, Atg7 and Atg12). Down regulation of Atg1, Atg5, Atg7, Atg12, and Atg101 respectively ameliorated the temperature-sensitive paralysis in flies impaired for mortalin function. Protective effects of knocking down of Atg1, Atg5, Atg7, Atg12, and Atg101 were also observed to rescue mortalin-knockdown associated climbing defects, abnormal wing posture and importantly ATP levels suggesting the rescue of mitochondrial function.

Title: Mitochondrial impairment-induced Ser129-phosphorylation of alpha-synuclein through intracellular calcium concentration change

Authors: A. SASAKI[1], H. SATO[1], T. KATO[1], *S. ARAWAKA[2];
[1]Dep. of Neurology, Hematology, Metabolism, Endocrinol. and Diabetology, [2]Yamagata Univ. Fac. of Med., Yamagata, Japan

Abstract: One of the characteristic findings in the Parkinson’s disease (PD) pathology is the presence of intracellular α-synuclein (a-syn) aggregates, called Lewy bodies (LBs), in the surviving neurons. In the PD brains, a-syn deposited in LBs is known to be highly phosphorylated at the Ser129 residue. In contrast, only 4%, or less, of the total amount of a-syn is phosphorylated in the normal brains. This difference suggests that Ser129-phosphorylation of a-syn is a pathological event in the neurodegenerative process of PD. However, it is unknown what factors accelerate this event. In this study, we first tested whether alteration in intracellular calcium concentration affects Ser129-phosphorylation of a-syn using human dopaminergic SH-SY5Y cells stably expressing wild-type a-syn (wt-aS/SH) and rat primary cortical neurons. When cells were treated with calcium ionophore A23187, the amounts of Ser129-phosphorylated a-syn were significantly increased in an A23187 concentration- or incubation time-dependent manner. This increase was suppressed by addition of calcium chelator, EGTA or BAPTA-AM. In addition, the A23187-induced elevation was inhibited by addition of calmodulin inhibitor, W-7 or calmidazolium. Then, we tested whether mitochondrial complex I inhibitors alter Ser129-

phosphorylation of a-syn. In wt-aS/SH cells, treatment with MPP^+ or rotenone enhanced the phosphorylation of a-syn in a concentration-dependent manner. In rat primary cortical neurons, treatment with rotenone also enhanced the phosphorylation of a-syn. These increases were blocked by addition of either EGTA or BAPTA-AM. Our results showed that intracellular calcium concentration and calmodulin were factors to modulate Ser129-phosphorylayion of a-syn. The results also suggested that mitochondrial impairment enhanced Ser129-phosphorylation of a-syn by causing influx of extracellular calcium, because EGTA is a non-membrane permeable chelator and decreases extracellular calcium. Calcium dysregulation may link mitochondrial impairment to a-syn neurotoxicity in PD.

Title: Mitochondrial dysfunction and ER stress response in human iPSC-derived neurons carrying LRRK2 G2019S mutation

Authors: ***J. A. KORECKA**[1], S. LEVY[1], M. L. TERPSTRA[1], D. C. DINESH[1], D. P. CHRISTENSEN[1], T. M. OSBORN[1], P. J. HALLETT[1], F. M. JODELKA[2], M. L. HASTINGS[2], O. ISACSON[1];
[1]Neuroregeneration Res. Inst., McLean Hospital/Harvard Med. Sch., Belmont, MA; [2]Dept. of Cell Biol. and Anat., Chicago Med. School, Rosalind Franklin Univ. of Med. and Sci., Chicago, IL

Abstract: The Leucine-Rich Repeat Kinase (LRRK2) G2019S gain of function gene mutation can contribute to Parkinson disease (PD) pathogenesis. Previous work from our lab (Cooper et al., 2012, Sanders et al., 2014) and others indicate that the LRRK2 G2019S mutation can influence mitochondrial health, axon outgrowth, intracellular trafficking and autophagy. To further explore the function of LRRK2 and G2019S mutation-driven increased kinase activity we aim to investigate the neuronal ability to cope with 1. mitochondrial dysfunction induced by mitochondrial membrane depolarization (through valinomycin toxicity) and 2. endoplasmic reticulum (ER) stress response induced by inhibition of ER calcium influx and increase in

cytosol calcium concentration (through thapsigargin toxicity). We detected 2-fold higher nitric oxide levels but no elevated super oxide production in induced pluripotent stem cell (iPSC)-derived neurons from PD patients carrying the LRRK2 G2019S mutation when compared to healthy controls. In addition, we found a decreased ER stress response in these neurons by using lentiviral reporter constructs driven to quantitatively assess the activation of ER stress signal transduction pathways. Preliminary live cell imaging data showed altered mitochondrial subcellular distribution and translocation in LRRK2 G2019S neurons after mild mitochondrial toxicity. To determine the rate of mitochondrial lysosome dependent clearance, we are now exploring the real time dynamics of mitophagy in neurons using a lentiviral driven overexpression of a dual-fluorescence mitophagy specific bio-probe. As controls for our experiments we are using isogenic zinc finger nuclease based gene corrected neurons, antisense oligonucleotides targeting LRRK2 G2019S mutation, or pharmacological LRRK2 kinase inhibition. The altered mitochondrial function and ER stress response in neurons derived from patients carrying LRRK2 G2019S mutation sheds more light on the increased LRRK2 kinase activity and our understanding of the specific subcellular organelle dysfunction in PD pathogenesis.

Title: S-Nitrosylation of divalent metal transporter 1 increases Iron deposition and contributes to loss of dopaminergic neurons after LPS-induced inflammation

Authors: ***C. LIU**[1], C.-W. ZHANG[2], K. C. CHEW[1], B. TAN[1], A. SUPPERMPOOL[1], K.-L. LIM[2], T. SOONG[1];

Abstract: Iron elevation in substantia nigra is constantly reported in Parkinson’s disease (PD). Recently, a selective iron chelator was reported to improve PD-motor outcomes in a randomized clinical trial. Nitrosative stress has also been proposed as a major upstream event in PD pathogenesis. Nitric oxide has been linked with iron metabolism, while DMT1 has been

implicated in neurodegeneration via iron transport in animal models of PD. However, whether DMT1 function is modulated by nitrosative stress is unknown. Here we report that DMT1 could be nitrosylated when heterologously expressed in HEK 293 cells, and the DMT1 currents were increased by nitrosylation. The iron uptake and calcein quenching assays showed that nitrosylation of DMT1 increased its iron transport function. Using LPS-induced nigral inflammation model, we showed that DMT1 was nitrosylated *in vivo*. Iron uptake was increased in the LPS-injection site, which led to loss of dopaminergic neurons. Thus we showed a potential role of NO-mediated increase in iron uptake via DMT1 in inflammation related neurodegeneration.

Title: MicroRNA-7 inhibits mitochondrial permeability pore function and confers neuroprotection

Authors: *A. DATTA CHAUDHURI, D.-C. CHOI, S. KABARIA, E. JUNN;
Rutgers Biomed. and Hlth. Sci., Piscataway, NJ

Abstract: Mitochondrial dysfunction and electron transport chain failure are major contributors to neurodegeneration in Parkinson’s disease (PD). Voltage dependent anion channel 1 (VDAC1) is a transmembrane protein located on the outer mitochondrial membrane, which forms the mitochondrial permeability transition pore (PTP) along with cyclophilin D and adenine nucleotide translocase (ANT). Under conditions of cellular stress, mitochondrial depolarization leads to opening of the PTP, triggering mitochondrial swelling, release of pro-apoptotic proteins, ultimately resulting in cell death. MicroRNA-7 (miR-7) is a small non-coding RNA that has been found to be protective in several cellular models of PD. In the present study, we performed gene ontology (GO) analysis of proteomic profiles that are downregulated by miR-7, revealing that mitochondrial proteins are significantly overrepresented. Accordingly, miR-7 overexpression prevented MPP+-induced mitochondrial depolarization, increase in mitochondrial calcium and cytochrome c release from mitochondria as well as ROS generation. Among the mitochondrial proteins that were downregulated by miR-7, we found that VDAC1 3’UTR harbors a conserved miR-7 target site. Overexpression of miR-7 led to downregulation of VDAC1 mRNA and protein

levels, while inhibition of endogenous miR-7 led to an increase. Additionally, we demonstrated that miR-7 directly targets VDAC1 3'UTR by performing 3'UTR luciferase reporter assays. Similar to miR-7 overexpression, knockdown of VDAC1 by siRNA led to neuroprotection and prevention of pathological changes in the mitochondria upon exposure to MPP+. Furthermore, knockdown of VDAC1 reversed the anti-miR-7-induced sensitization of cells to MPP+ toxicity. Therefore this study identifies VDAC1 as a direct miR-7 target that contributes to its neuroprotective effect.

Title: Effects of acute neurotoxicant administration on ubiquitin carboxy-terminal hydrolase L1 (UCH-L1) activity in MN9D cell line and mouse striatal synaptosomes

Authors: ***B. M. WINNER**[1], K. J. LOOKINGLAND[1], J. L. GOUDREAU[2];
[1]Pharmacol. and Toxicology, [2]Michigan State Univ., East Lansing, MI

Abstract: In Parkinson disease (PD), relatively selective degeneration of the substantia nigra pars compacta (SN) results in a loss of dopamine (DA) released in the striatum (ST) and leads to the motor disturbance symptoms in PD. We can recapitulate the loss of DA by administering acute 1-methyl-4-phenyl -1,2,3,6-tetrahydropyridine (MPTP). With acute MPTP administration, ubiquitin carboxy-terminal hydrolase L1 (UCH-L1) protein is decreased in the SN after 24 h while mRNA for UCH-L1 is unchanged. UCH-L1 is a deubiquitinating enzyme linked to inheritable PD which functions in the ubiquitin proteasome system (UPS), a major pathway for protein degradation. UCH-L1 removes ubiquitin (Ub) from small proteins and thereby replenish the pool of monomeric Ub to be reused in the UPS. The loss of UCH-L1 protein is postulated to be associated with susceptibility of the SN to acute neurotoxic insult and perhaps neurodegeneration in PD. Similarly, in MN9D cells (a mesencephalic-derived DA cell line), UCH-L1 protein decreases in a time and concentration-dependent manner with administration of MPP+, the active form of MPTP which is readily taken up by dopamine transporter. Decrease in UCH-L1 protein in MN9D cells with MPP+ is also associated with loss of intracellular DA in the cells without significant cytotoxicity. Although the decrease in UCH-L1 protein in the SN and MN9D cells suggests that UCH-L1 may play an important role in susceptibility to neurotoxicant, the activity of the enzyme has not been determined in MN9D cells or striatal

synaptosomes isolated from mouse brain. It is currently unknown whether UCH-L1's hydrolase activity is compromised with acute MPTP treatment, and so the goal of the current study was to establish an assay to measure activity of UCH-L1 using an *in vitro* fluorogenic probe conjugated to ubiquitin (Ub-AMC). This substrate allows for kinetic readings to measure UCH-L1 activity *ex vivo* and determine if UCH-L1 function is impaired in MPTP-treated mouse brain. For this study, crude synaptosomes isolated from the ST of mice were collected at 4, 6, 8 12, and 24 h post-MPTP and UCH-L1 hydrolase activity was measured. The results of this study reveal an association between expression of UCH-L1 protein and hydrolase activity as a function of time after MPTP exposure in mouse brain and MN9D cell extracts.

Abstract: Mutations in genes encoding Parkin (PARK2) and PINK1 (PARK6) cause autosomal recessive forms of Parkinson's disease. These proteins regulate jointly several processes relevant to maintenance of mitochondrial quality. We previously showed that Parkin interacts with PINK1 at the TOM machinery (Translocase of the Outer Membrane), a protein complex responsible for the mitochondrial import of the vast majority of the mitochondrial proteins. We provided evidence that the degradation of key subunits of the TOM complex initiates Parkin-dependent mitophagy. Here, we explored the relevance of these findings in primary cortical neurons from wild type and PARK2 KO mice. By confocal and FRET microscopy, we show that following mitochondrial depolarization triggered by the protonophore CCCP, PINK1 accumulates and recruits Parkin in proximity of the TOM complex. These events were impaired in PARK2 KO cells, suggesting that Parkin plays a role in stabilizing PINK1 on the outer mitochondrial membrane. Using an image-based quantitative analysis of markers of different mitochondrial subcompartments at various time points after CCCP treatment, mitochondrial loss was observed in wild type but not PARK2 KO cells. Components of the TOM complex were lost earlier than other markers, confirming that this machinery is an early target for Parkin-dependent

degradation. In parallel, we investigated the relationship between PINK1/Parkin-mediated mitochondrial degradation and other mitochondrial stress response pathways, including mitochondrial biogenesis and the unfolded protein response (mtUPR). We explored expression of master genes of these processes, as well as downstream targets, by quantitative RT-PCR. Our results show different transcriptional activation profiles between wild type and PARK2 KO mice after CCCP treatment. We also describe the development and validation of a genetically encoded reporter for the evaluation of mitochondrial import efficiently through the TOM complex. Our preliminary results suggest alteration of this aspect of mitochondrial biogenesis in cells with PARK2 mutations. Altogether our studies suggest that loss of mitochondrial protein import efficiency is coupled with other mitochondrial quality control mechanisms that respond to Parkin deficiency in primary neurons.

Title: Genome-wide epigenomic alterations in Parkinson’s disease

Authors: ***A. I. BERNSTEIN**, M. GEARING, J. MULLE;
Emory Univ., Atlanta, GA

Abstract: Parkinson’s disease (PD), the most common neurodegenerative movement disorder, is characterized by degeneration of the nigrostriatal dopaminergic pathway and other monoaminergic regions and the formation of cytoplasmic inclusions. The majority of cases of PD are sporadic (not caused by an inherited monogenic mutation). While the etiology of these sporadic cases remains unclear, it is thought to involve an interaction between genetic and environmental factors. Environmental risk factors have been identified and epidemiological studies suggest that exposure to environmental toxicants, especially persistent organic pollutants, increase the risk of PD. Many of these compounds have been found in post-mortem human PD brains and many groups have shown that these compounds cause oxidative stress and disrupt expression and function of dopaminergic-related and PD-related proteins, resulting in increased

susceptibility of dopaminergic neurons. It has been proposed that epigenetic modulations could serve as an intermediate process that imprints dynamic environmental experiences on the "fixed" genome, resulting in stable alterations in phenotype. Therefore, it is likely that these factors converge upon the epigenome. Recent work has also revealed a role for regulation of the transcriptome and the epigenome in PD and in the response to toxic exposures. Many lines of evidence suggest a role for epigenetic regulation, and, in particular, cytosine modifications in PD. Methylation of cytosine to 5-methylcytosine in genomic DNA is carried out by DNA methyltransferases. 5hmC, highly enriched in the nervous system, is generated from 5mC by Tet proteins. 5hmC displays temporal and spatial changes during neurodevelopment and aging. Aberrant gene methylation of PD-related genes and deficiencies in microRNAs have been observed in post-mortem PD brains. However, these studies have largely focused on the individual genes responsible for familial PD and not genome-wide changes or in regions or tissues not affected in PD. Moreover, it is not known how these changes in the epigenome are related to changes in neuronal vulnerability. It is possible that epigenomic changes contribute to neuronal vulnerability by altering the expression of proteins within the dopaminergic system. Here, we mapped genome-wide changes in cytosine modifications using DNA isolated from cingulate and parietal cortices of post-mortem early- and late-stage PD and age-matched controls. We identified regions that are differentially modified in PD and analyzed the genes they map to. Together, this analysis suggests that cytosine modifications play an important role in PD pathogenesis.

Title: Mitochondrial accumulation of α-synuclein in Parkinson's disease causes impaired protein import via tom40 release/degradation

Authors: ***V. VASQUEZ**[1,2,3], J. MITRA[3], P. M. HEGDE[3], K. S. RAO[1], M. L. HEGDE[3,4]; [1]INDICASAT-AIP, Panama, Panama; [2]Biothecnology, Acharya Nagarjuna Univ., Guntur, India;

Abstract: α-synuclein is a presynaptic protein, whose intracellular aggregation in brain has been etiologically implicated in Parkinson's disease (PD), a progressive neurodegenerative disorder, affecting 4.9-19 per 100,000 people per year worldwide. Accumulation of mis-folded α-synuclein in the substantia nigra of the brain leads to the formation of Lewy body deposits, one of the histopathological features of PD, which also involves oxidative stress, pro-oxidant metal toxicity and increased nuclear genome damage. More recent studies have implicated significant mitochondrial pathology in PD brain, including accumulation of dysfunctional mitochondria with high levels of mitochondrial DNA (mtDNA) deletions/damage, and altered outer mitochondrial membrane (OMM) proteins, which also correlates with increased α-synuclein in mitochondria. However, the role of α-synuclein toxicity in mitochondria is unclear. Here we demonstrate that α-synuclein stably interacts/co-localizes with mitochondrial membrane translocases involved in the import of nuclear-coded proteins into mitochondria, TOM40 (outer membrane) and TOM20 (inner membrane) in normal neurons. Furthermore, we made a surprising observation that in α-synuclein overexpressing iPSC-derived neuronal cell model of PD, TOM40 is distinctly released/degraded in mitochondria, while TOM20 is not affected. Thus α-synuclein pathology in PD causes defective protein import via TOM40 release in mitochondria of dopaminergic neurons leading to imbalance in mtDNA damage/repair and anti-oxidant machinery. These data are consistent with evidence of increased mitochondrial DNA damage in PD affected human brain. Comprehensive molecular events involved in this phenomenon and potential prevention strategies will be discussed.

Title: Sensitivity of complex I to rotenone is activity-dependent in neurons

Authors: *C.-H. J. CHIANG[1], L. SANDERS[2], J. CALLIO[3], E. HOWLETT[2], C. T. CHU[3]; [1]UPMC Neuropathology, Pittsburgh, PA; [2]Pittsburgh Inst. for Neurodegenerative Dis., Pittsburgh, PA; [3]Univ. of Pittsburgh Sch. of Med. Dept. of Pathology, Pittsburgh, PA

Abstract: Neuronal and systemic decrease in the activity of mitochondrial respiratory complex I, the main entry point of the electron transport chain for oxidative phosphorylation, has been identified in both sporadic and hereditary forms of Parkinson disease (PD) and animal models of PD. More interestingly, systemic complex I inhibition by toxins such as rotenone generates parkinsonism in both human and model organisms. It remains unclear why neurons are particularly sensitive to complex I dysfunction and why certain populations of neurons are more severely affected to generate specific phenotypes such as parkinsonism. Mammalian complex I consists of 14 core subunits and 31 accessory subunits. Although complex I has been extensively studied in non-neuronal systems including heart, liver and muscle, its regulation is largely unknown in the nervous system. Here we show that in primary mouse cortical neurons the sensitivity of complex I to toxin inhibition was changed in response to neuronal and electron transport chain activities and substrate availability. There was a positive correlation between the oxygen consumption rates of the neurons and the sensitivity to rotenone, the commonly used complex I inhibitor. Furthermore, excitatory NMDA receptor (NMDAR) activation increased the activity of immunocaptured complex I from neurons. The changes induced by NMDAR activation correlated with the presence of significantly increased oxidative stress within the neurons. Our previous studies have implicated mitochondrial dysregulation in LRRK2 mutation-linked PD. Here we also show that neurons with LRRK2 R1441G mutation had decreased complex I activity and the capacity of oxidative phosphorylation. Ongoing studies are aimed at identification of activity-dependent changes in subunit composition and/or post-translational modifications of complex I in the nervous system, and how PD-linked LRRK2 mutations exert negative impacts. Understanding the regulation of complex I in neurons and the impacts of genetic risk factors may shed light on novel therapeutics for neurodegenerative diseases.

Abstract: Parkinson's disease (PD) is characterized by the progressive degeneration of dopaminergic neurons in the substantia nigra (SN) and the presence of intraneuronal aggregated alpha-synuclein (a-syn) in Lewy bodies. Among other factors, inflammation seems to play a role in PD neurodegeneration. CD163 is a scavenger receptor normally expressed on peripheral monocytes/macrophages, which increases with inflammation. In brain, CD163 expression is limited to perivascular macrophages. We have observed infiltration of CD163+ macrophages into the area of neurodegeneration in the 6-hydroxydopamine (6-OHDA) PD model and the alpha-synuclein viral vector based PD model. We hypothesized that the migration of CD163+ macrophages into the brain-injured area in PD may influence local microglia. Therefore we aimed to deplete selectively the CD163+ macrophages vs. unspecific circulating macrophages. To do so we used CD163-targeted liposomes, via a specific antibody, loaded with doxorubicin vs clodronate untargeted liposomes, a well-known macrophages depletion strategy used by many before. Animals were injected twice per week for three weeks starting the day of the intra-striatal toxin injection. We are currently analyzing dopaminergic degeneration as well as the microglia response in the animals in order to determine the specific role of the circulating macrophages in the 6OHDA-induced toxicity. To complement our animal studies; in parallel we immunostained human brain tissue (posterior putamen) from PD patients and we are evaluating possible CD163+ cells infiltration during disease.

Title: Chronic L-DOPA administration induces astrogliosis in rats with intra-nigral 6-OHDA-lesion

Authors: *G. RAMÍREZ GARCÍA[1,2], V. PALAFOX SÁNCHEZ[2], I. LIMON PEREZ DE LEON[2];

Abstract: Parkinson's disease (PD) is characterized by the death of dopaminergic neurons in the substantia nigra pars compacta (SNpc) with the consequent decrease of dopamine (DA) in the striatum and prefrontal cortex (PFC). L-3,4-dihydroxyphenylalanine (L-DOPA) is administered for long term to restore DA levels and improve motor functions in PD patients. Is widely known that chronic L-DOPA could establish an oxidant environment for neuron, however, currently the impact of the L-DOPA treatment on astrogliosis is unknown. Besides has been showed that astroglia activation could relate with an inflammatory process. In this work, we evaluated the effect of chronic L-DOPA administration in rats with intra-nigral 6-hydroxydopamine (6-OHDA)-lesion on astrogliosis induction in the nigro-striatal-cortical pathway. After lesion, the animals were divided into four experimental groups, two groups received orally isotonic saline (SSI) administration and another two groups received orally L-DOPA/Carbidopa (100 mg/kg) for 20 days. After administration period, tyrosine hydroxylase (TH) and Glial Fibrillary Acidic Protein (GFAP) immunoreactivity was evaluated by immunohistochemistry in the SNpc, dorsal striatum and PFC. Our results showed that lesion with 6-OHDA induce a substantial astrocytic activation but the chronic L-DOPA administration induced an increment of immunoreactivity of GFAP. Also, the astrogliosis occurs in areas with great dopaminergic denervation, where the DA release is deregulated, making impossible DA reuptake, which contributes to induce an oxidative stress and inflammatory process. These facts suggest that astrogliosis in the striatum and PFC increased by L-DOPA treatment may be related with motor and cognitive complications that occur in PD patients. Title: Behavioral characterization of mice lacking of PKR-like endoplasmic reticulum kinase (PERK) in dopaminergic neurons

Authors: *F. LONGO, E. SANTINI, E. KLANN;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Several neurodegenerative disorders, including Parkinson's Disease (PD) are associated with protein misfolding and the formation of distinct aggregates. Accumulation of misfolded proteins results in the endoplasmic reticulum (ER) stress and leads to the activation of an intracellular signaling pathway termed the unfolded protein response (UPR), which typically has a neuroprotective role. As a crucial component of the UPR, PERK activation results in phosphorylation and inhibition of eukaryotic initiation factor 2α (eIF2α), a translation factor that controls the initiation step of protein synthesis and has been implicated in long-term synaptic plasticity and memory formation. Paradoxically, the phosphorylation of eIF2α also results in the increased synthesis of transcription factors that contain unread open reading frames (uORF) in the 5'UTR of their mRNAs, including activating transcription factor 4 (ATF4), which is involved in the expression of several UPR target genes. Although the UPR serves a neuroprotective role via regulation of general and gene-specific translation, it also is responsible for promoting apoptotic cell death following sustained activation, which occurs in neurodegenerative disorders, such as PD. Growing evidence from studies on post-mortem tissue has shown expression of PERK and increased phosphorylation of eIF2α in dopaminergic neurons of PD patients compared to age-matched controls. Our central hypothesis is that a prolonged UPR results in inhibition of general protein synthesis via PERK-dependent phosphorylation of eIF2α, resulting in the loss of synaptic proteins, synaptic failure, and ultimately, neuronal death in dopaminergic neurons. To investigate the involvement of PERK in neurodegeneration and to determine whether the deletion of PERK in dopaminergic neurons results in motor disturbances and cognitive symptoms observed in PD, we generated mice selectively lacking either one or both copies of the PERK gene in dopaminergic neurons (DAT-PERK+/- and DAT-PERK -/-, respectively). We examined the DAT-PERK mutant mice in a set of complementary motor behavioral tests specific for akinesia (BAR test), bradykinesia (DRAG test), and overall gait ability (rotarod test, foot print test, and open field test), as well as in a series of cognitive tasks (water maze test, novel object recognition test, and associative fear conditioning). We found that the reduction of PERK in dopaminergic neurons results in the alteration of multiple motor and cognitive abilities in mice. These results support our overall hypothesis and are consistent with previous studies (Ma et al. 2013; Moreno et al., 2013).

Title: Fipronil-induces apoptosis via modulation of mitochondrial function and alteration in protein degradation machinery in SH-SY5Y cells

Authors: S. KANURI[1], H. JIN[1], A. VELLAREDDY[1], A. KANTHASAMY[1], *A. KANTHASAMY[2];

Abstract: Chronic environmental exposure to pesticides and insecticides had been implicated in the etiopathogenesis of Parkinson's Disease (PD). Wide spread application of insecticides can gain entry into the food chain thereby increasing the risk of potential toxic effects. In this context fipronil (FPN), a broad spectrum insecticide has been shown to elicit its effects via the disruption of Gamma aminobutyric regulated chloride (GABA) channel thereby leading to the impairment in neuromuscular transmission. Recent studies have demonstrated that fipronil-induces neurotoxicity; however, the cellular mechanisms underlying fipronil-induced neurotoxicity remain poorly understood. In this study we systematically characterized the mechanistic basis of FPN-induced neurotoxicity using human neuroblastoma SH-SY5Y cells. Exposure of SH-SY5Y cells to FPN-induced a dose and time dependent increase in apoptotic cell death as assessed via DNA fragmentation assay. Additionally a similar scenario was evidenced when cell viability was assessed via MTT assay. Furthermore FPN-induced neuronal cell death was preceded by the dissipation of mitochondrial membrane potential (MMP), depletion of GSH levels and activation of caspase 3. Additionally, Western blot analysis revealed that FPN (60 uM)-induced a time dependent increase in beclin-1 expression, phosphorylation and cleavage of PKC-delta; and accumulation of ubiquitin positive aggregates. Collectively, these findings suggest that FPN can induce dopaminergic neurotoxicity by promoting caspase-3 mediated mitochondria dependent cell death signaling with a concomitant impairment in protein degradation machinery.

Abstract: Parkinson's disease (PD) is a chronic neurodegenerative disorder characterized by the preferential loss of dopaminergic neurons stemming from the midbrain's substantia nigra pars compacta (SNpc) and innervating the dorsal striatum. The substantial decreases in striatal dopamine (DA) result in devastating hypokinetic movements and motor disturbances. Demonstrating an absence in understanding what initiates and drives this degeneration, the standard treatment strategy of dopaminergic replacement therapy via administration of Levodopa (L-DOPA; L-3,4 dihydroxyphenylalanine) has remained unchanged for several decades, despite a majority of patients exhibiting "off-peak" undesirable hyperkinetic and dyskinetic motor complications. One potential contributor to processes involved in the initiation, progression, and maintenance of Parkinsonian symptoms is increased generation of reactive oxygen species, such as hydrogen peroxide (H2O2). We aim to investigate how striatal H2O2 and DA dynamics underlie behavioral changes that result from chronic L-DOPA administration in a rodent model of PD (unilateral 6-OHDA lesion) using fast-scan cyclic voltammetry (FSCV), an electrochemical technique that affords precise spatial and temporal resolution. Specifically, carbon-fiber microelectrodes are used to simultaneously quantify rapid H2O2 and DA fluctuations at single recording sites in the dorsal striatum over several weeks of L-DOPA administration. These studies will aid in our understanding of how oxidative stress modulates nigrostriatal DA signaling, and will demonstrate how these signals correspond with the development of dyskinetic movements in the treatment of PD.

Abstract: Parkinson´s disease (PD) is characterized by the selective loss of dopaminergic neurons, in which the mitochondrial dysfunction seems to play an important role. In this context, one of the first evidences appeared when it was found that long exposure to MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine), an inhibitor of complex I of mitochondrial electron transport chain, generated parkinsonism in humans and monkeys. However, it is not entirely clear yet the effects induced by the chronic exposure to this inhibitor not only on the density and function of mitochondrial electron transport chain proteins but also on the lipid composition of the cellular membrane. For this purpose, the density of the complex I (using [3H]-Dihydrorotenone), the succinate dehydrogenase activity (complex II) and the cytochrome c oxidase activity (complex IV) were evaluated in different brain areas and tissues of control and MPTP-treated non-human primate (Macaca fascicularis) using cell membrane microarrays. To determine the lipid profile, MALDI imaging mass spectrometry (MALDI-IMS) was combined with cell membrane microarrays and artificial neuron networks were employed to data handling and analysis. MPTP treatment induced an increase of the succinate dehydrogenase activity in olfactory bulb, putamen, caudate and substantia nigra, where it was observed a decrease in cytochrome c oxidase activity. This treatment also produced an alteration of the lipid profile in these areas, being especially relevant the reduction in the phosphatidylserine (38:1) content. However, in the cerebellum, where a decrease of both enzymatic activities was recorded, this phosphatidylserine (38:1) was enhanced. Therefore, the MPTP treatment not only modulates the mitochondrial electron transport chain enzymes, but also seems to alter other mitochondrial enzymes that regulate the lipid metabolism such as the phosphatidylserine decarboxylase.

Title: Mitochondrial quality control in microglial cells and astrocytes and their regulation by the Parkin-dependent pathway

Authors: *F. MOUTON-LIGER, M. JACOUPY, J. SEPULVEDA, F. BONELLO, S.-M. HASSOUN, A.-L. PRIVAT, Z. ERPAPAZOGLOU, P. MICHEL, A. BRICE, J.-C. CORVOL, O. CORTI;
ICM Brain & Spine Inst., PARIS, France

Abstract: Parkinson's disease (PD) is a common, severe neurodegenerative disorder due to the preferential and progressive degeneration of the dopaminergic neurons of the substantia nigra, which may be intrinsically vulnerable to oxidative stress. The loss of these neurons is associated with a glial response composed mainly of activated microglial cells and, to a lesser extent, of reactive astrocytes. This glial response may be the source of trophic factors and can protect against reactive oxygen species. On the other side, the glial response can induce deleterious events related to the production of pro-inflammatory cytokines. Although most cases of PD appear to be sporadic, several gene mutations have been linked to familial forms of PD. The discovery of some of the proteins encoded by these genes, including Parkin (PARK2) and PINK1 (PARK6), at the mitochondria offered a new perspective on the involvement of mitochondria in PD. Specifically, these proteins are involved in the maintenance of a healthy pool of mitochondria by regulating their turnover by mitochondrial autophagy, also known as mitophagy. Most studies have examined this process in immortalized cell lines overexpressing high levels of Parkin. More recently, few researches have addressed the role of Parkin/PINK1-dependent mitophagy in primary cultured neurons. However, whether or how endogenous Parkin contributes to mitophagy in central nervous system glial cells remain unclear. In this study, by using new innovative protocols for highly-enriched isolation of astrocytes and microglia, we have observed in primary cultured cells derived from Parkin knockout (Parkin-/-) and wild-type (WT) mice, the impact of mitochondrial membrane depolarization induced by 24 or 48 hours of CCCP (Carbonyl cyanide m-chlorophenyl hydrazine) on the mitochondrial quality control mechanisms mediated by Parkin. Our results show that astrocytes and microglial cells derived from WT mice undergo strong mitophagy following CCCP treatment and that this process is significantly impaired in cells from PARK2-/- mice. Interestingly, these defects are associated with alteration of glial cells morphology, activation and in pro-inflammatory cytokines production. Finally, to analyze whether the functionally and morphologically mitochondrial impairment in astrocytes or microglia exhibit a disturbed interaction with neurons and contributes to neuronal loss, Parkin-/- and WT glial cells are currently being co-cultured with WT neurons. These results should allow a better understanding of Parkin-dependent mitochondrial dysfunction in neuronal and glial physiology and their impact on neurodegeneration in PD.

Title: Lysosomal glycolipid changes in Parkinson's disease are mirrored by normal aging of the human and mouse brain

Authors: *P. HALLETT[1], E. N. ROCHA[1], M. HUEBECKER[2], G. A. SMITH[1], D. A. PRIESTMAN[2], F. M. PLATT[2], O. ISACSON[1];
[1]Ctr. Neuroregeneration Res., McLean Hospital/Harvard Med. Sc, Belmont, MA; [2]Dept. of Pharmacol., Univ. of Oxford, Oxford, United Kingdom

Abstract: *GBA1* encodes for glucocerebrosidase (GCase), a lysosomal lipid hydrolase involved in glycosphingolipid metabolism, and mutations in *GBA1* cause Gaucher disease (GD), which is the most common autosomal recessive lysosomal storage disease. A reduction in lysosomal GCase activity causes accumulation of the corresponding glycosphingolipid substrates, glucosylceramide (GluCer) and glucosylsphingosine (GluSph). *GBA1* haploinsufficiency can result in a 30-50% reduction in GCase activity and increases the risk for developing PD dramatically. We recently made the observation that there is a reduction of GCase in sporadic PD patients without the *GBA1* mutation (nonGBA1-PD), and a progressive age-dependent reduction in GCase activity and increase in glycolipids in healthy subjects in the brain regions most affected in PD (Rocha EN et al., 2015 *Ann. Clin. Trans. Neurol.* doi: 10.1002/acn3.177). This age-dependent decline in GCase activity and rise in GluSph eventually becomes similar to sporadic nonGBA1-PD patients, and by the time an individual reaches the 7^{th}-8^{th} decade of life, GCase levels in the substantia nigra and putamen are reduced to the same extent as subjects with sporadic PD. We therefore hypothesize that aging mirrors changes to the GBA pathway similar to those that occur in genetic (*GBA1* haploinsufficiency) and sporadic (nonGBA1) forms of PD, and that disrupted GBA and lysosomal homeostasis occurring with normal aging may accelerate degenerative processes in vulnerable neurons and lower the threshold for developing PD. In order to further explore and model these age-dependent changes in the GBA pathway in animals, we have measured levels of glycosphingolipids in whole brain homogenates from wildtype (FVB) mice aged between 7-17 months of age. Our results show that levels of GluCer are significantly correlated with age ($r=0.3732$, $p<0.05$) and that by the latest timepoint studied (17 months), GluCer is increased to 136% of younger (7 month) mice, whereas levels of gangliosides GD1b ($r=-0.5054$, $p<0.01$) and GT1b ($r=-0.3442$, $p<0.05$), are negatively correlated with age. Measurements of GCase activity and other lysosomal hydrolases, as well as alpha-synuclein

levels, will further determine alterations in GBA and protein degradation pathways. Determining changes in the activity of GCase and other lysosomal hydrolases and their associated glycosphingolipids in normal aging and in PD, will shed light on underlying pathophysiological mechanisms. Furthermore, assays for specific lysosomal hydrolases and glycosphingolipids may in the future be essential both as biomarkers and pharmacodynamic for PD.

Title: Mito-function of DJ1 in Parkinson's disease

Authors: *R. CHEN, J. WU, P. MIRANDA, K. N. ALAVIAN, E. A. JONAS;
Dept. of Intrnl. Med., Yale Sch. of Med., New Haven, CT

Abstract: Parkinson’s disease (PD), which includes Familial PD (10%) and Sporadic PD (90%), is a progressive neurodegenerative disorder with limited therapeutic options. PD is characterized by loss of dopaminergic (DA) neurons in the substantia nigra pars compacta (SNpc). Genetic studies of PD have identified several related genes, including LRRK2, Parkin/PINK-1 and DJ1. Most PD genes are necessary for normal mitochondrial function. However, the functional mechanism of DJ1 is poorly understood. Here, we investigated the function of DJ1 and its two disease-associated point mutants, M3 (A104T) and M5 (L166P). We found that overexpression of WT but not M3 or M5 in HEK293 cells significantly increased ATP levels. Recombinant WT DJ1 protein also strikingly enhanced ATPase activity of purified ATP synthase complex, measured as the rate of decrease in NADH fluorescence, whereas mutants had no effect. In response to ATP hydrolysis, WT but not mutant DJ1 protein efficiently decreased the inner membrane leak, measured during the movement of the H+ ions into sub-mitochondrial vesicles enriched in F1FO ATP synthase complex (SMVs). Patch clamp recordings of WT SMVs and SMVs from DJ1 -/- mice confirmed that WT DJ1 but not mutant DJ1 protein decreases inner membrane conductance. Our evidence indicates that the differences in activity between WT and mutant DJ1 proteins was not due to differences in interaction with Bcl-xL or with the F1FO ATP synthase beta-subunit. Interestingly, we found that DJ1 depletion affected the expression of several mitochondrial-related genes in mice, especially in midbrain and in tissues with high ATP demand. We also established methods for efficient dopaminergic (mesDA) neuronal culture of

WT and DJ1-/- mouse midbrain cells. We found that DJ1-/- mesDA neurons have low survival rate. Thus, our study uncovered an important role of DJ1 in Parkinson's disease by affecting mitochondrial inner membrane properties, cell metabolism and death.

Title: Rescue of neuromuscular junction integrity in two SOD1 mice models by chronic *in vitro* blockade of glial muscarinic receptors

Authors: ***D. ARBOUR**, É. MARTINEAU, E. TREMBLAY, R. ROBITAILLE;
Univ. De Montréal, Montréal, QC, Canada

Abstract: Amyotrophic lateral sclerosis (ALS) is a non-cell autonomous neurodegenerative disease characterized by progressive loss of motoneurons and the destruction of the neuromuscular junctions (NMJ). Despite the importance of NMJ malfunction and the reported involvement of other glial cells in ALS, the contribution of glial cell at the NMJ remains unknown. Perisynaptic Schwann cell (PSCs), glial cells at the NMJ, influence structural stability, integrity and repair of the NMJ and synaptic activity. Of particular importance is the PSCs muscarinic signaling that must be reduced to allow morphological plasticity and repair of the NMJ. However, our recent data suggest that this signaling is enhanced in a SOD1 mouse model. Hence, we hypothesize that enhanced PSC muscarinic receptor (mAChRs) function may deter NMJ repair and remodelling in ALS and that chronic *in vivo* blockade of PSC mAChRs should restore the state of NMJ repair in ALS and allow glial rescue to proceed. SOD1 mice (G93A or G37R) were injected 3 times a week to target the soleus muscle either with a saline solution or pirenzepine, an antagonist of M1, 3 and 5 subtypes known to be present on PSCs. A combination of techniques was used in the SOD1G37R mice to obtain a good read-out of the PSCs functions. More specifically, we performed Ca2+ imaging to assess PSCs properties, electrophysiological recordings for synaptic properties and immunostaining for the NMJs morphological analysis. Pirenzepine treatment was efficient at reducing PSC mAChRs activation since the Ca2+ response evoked by the nerve stimulation or local muscarine application were significantly reduced, while Ca2+ responses evoked by local application of ATP were unchanged. Interestingly, the synaptic properties (quantal release and spontaneous activity) were unchanged. Importantly, reduction of

the mAChRs activity in PSCs restored their ability to repair and maintain NMJs structural integrity as suggested by the reduction in the level of denervation in the pirenzepine-treated mice. An NMJ healthyness index reflecting the quality of innervation also revealed a better general condition of the NMJs in the pirenzepine group. Taken together, these results suggest that reducing PSCs mAChRs activation could be beneficial in a context of ALS. This intrinsic PSC property could represent an important and novel therapeutic target in ALS.

Title: Morpholino antisense oligomer against SOD1 for amyotrophic lateral sclerosis therapy

Authors: C. SIMONE, M. NIZZARDO, F. RIZZO, G. ULZI, A. RAMIREZ, M. BUCCHIA, A. BORDONI, G. COMI, *S. CORTI;
Univ. of Milan, Milan, Italy

Abstract: Neurotoxicity from accumulation of misfolded/mutant proteins is thought to drive pathogenesis in neurodegenerative diseases. Mutations in superoxide dismutase 1 (SOD1) are linked to familial amyotrophic lateral sclerosis (FALS) resulting in progressive motor neuron death through one or more acquired toxicities. Interestingly wild-type SOD1 has been associated also to sporadic ALS (SALS), as misfolded SOD1 has been reported in affected tissues of sporadic patients. For these reasons, it represents a promising therapeutic target for antisense oligonucleotides. We now report slowed disease progression, ameliorated neuromuscular function and increased survival in an ALS *in vivo* model following therapeutic delivery of morpholino (MO) oligonucleotides designed to reduce the synthesis of ALS-causing human SOD1. Neuropathological analysis demonstrated an increased motor neuron and axon number, an ameliorated muscle trophism and a reduced micro and macrogliosis-mediated inflammation. Moreover, MO yield robust SOD1 suppression, in particular of misfolded form, not only *in vivo* in ALS rodent, but also in human patient samples, setting the stage for MO-mediated therapy in human clinical trials.

Abstract: The application of adeno-associated virus (AAV) in gene therapy has multiple advantages due to its long-term expression in the central nervous system (CNS) and low immunoreactivity in humans. Gene therapy strategies in CNS include Canavan's disease, Alzheimer's disease and motor neuron diseases such as amyotrophic lateral sclerosis (ALS). Targeting only the vulnerable neuron populations without affecting other neuron types within the cerebral cortex is a major obstacle for translational neuroscience. This applies to ALS, in which the corticospinal motors neurons (CSMN; a.k.a upper motor neurons) show selective vulnerability and progressive degeneration. In this study, seven different AAV serotypes that harbor the eGFP gene were tested for their ability to transduce CSMN upon direct injection into the layer V of the motor cortex. CSMN transduction was confirmed by Ctip2 immunocytochemistry and by presence of red fluorescent microsphere in the CSMN after retrograde labeling by injection into the corticospinal tract (CST). Large pyramidal neurons located in layer V showed higher tropism for AAV2-2. In an effort to increase the selective transduction of CSMN by AAV, we used capsid proteins that are engineered, and different promoters to drive the eGFP expression. Our results suggest that the choice of the promoter is critically important to enhance selectivity of gene expression in CSMN. Furthermore, specific

transduction of CSMN was feasible in mouse models with progressive CSMN degeneration. Identification of AAV serotypes that transduce only a select set of neuron populations at symptomatic stage of disease is critically important to develop effective and long-term gene therapy approaches in the cerebral cortex.

Title: Expression of glial cell line-derived neurotrophic factor (GDNF) in the muscle using AAV does not slow disease progression the G93A SOD1 rat model of ALS

Authors: ***V. J. GARCIA**, G. GOWING, M. GODOY, P. SUEZAKI, P. AVALOS, D. RUSHTON, O. SHELEST, L. GARCIA, C. CHIU, I. ORELLANA, C. N. SVENDSEN; Regenerative Med. Institute/ Biomedica Sci., Cedars-Sinai, West Hollywood, CA

Abstract: Amyotrophic lateral sclerosis (ALS) is a complex and devastating disorder characterized by the degeneration of motor neurons in the cortex, brainstem and spinal cord leading to muscle weakness, paralysis and death within 1-5 years of diagnosis. Numerous studies have demonstrated a direct beneficial effect of growth factors, such as glial cell line-derived neurotrophic factor (GDNF) on motor neuron survival and function in experimental models of ALS. Specifically, the expression of GDNF at the muscle has been shown to promote motor neuron survival and function. Here, we performed direct intramuscular injection of Adeno-Associated Virus (1, 5, 6 or 9) encoding GDNF in the SOD1G93A rat model of ALS. Surprisingly, despite high expression of GDNF in injected muscles, the administration of AAV-GDNF had no effect on motor function when compared to controls. Quantification of motor neurons and muscle innervation are currently underway to determine the effect, if any, of AAV-GDNF on motor neuron pathology.

Abstract: Physicians frequently require an incredible degree of accuracy when they perform surgical procedures around anatomical sites, especially in and around the spine. There is a need for stabilized surgical instruments and advanced work to optimize safety and usability during surgery. To meet this need, research was conducted in order to design a minimally invasive stereotactic surgical device that provides a stable and easily controlled interface for precise positioning of surgical instruments, such as a cannula or needle, within a surgical space. For this application, the minimally invasive stereotactic surgical device was designed for research relating to spinal cord injections. As such, an accessory cannula was designed to attach to the minimally invasive stereotactic surgical device to help deliver therapeutics, such as stem cells, to the dorsal horn of the spinal cord. Further, the minimally invasive stereotactic surgical device attaches to a third-party surgical retractor system, such as the Mast Quadrant Retractor, which is placed into a small incision site. To ensure steadiness of the surgical retractor system, stabilizing arms of the retractor system are affixed to the surgical table, which secures the surgical retractor in place. Design development of the minimally invasive stereotactic surgical device and accessory cannula included bench testing using a surrogate model of a spine, simulation testing including observational analysis related to human factors using a synthetic human model and animal testing including observational analysis related to usability. During simulation and animal testing, the minimally invasive stereotactic surgical device and accessory cannula were shown to move with the breathing motions of the animal and/or simulation model without invasively attaching the device beyond its connection to the surgical retractor.

Title: Environmental enrichment after transplantation of mesenchymal stem cells enhance angiogenic effect in chronic hypoxic-ischemic brain injury

Authors: *S. WI[1,2], J. SEO[1,2], J. YU[1,2], Y. SHIN[1,2], S. CHO[1,2,3,4];
[2]Brain Korea 21 PLUS Project for Med. Sci., [3]Rehabil. Inst. of Neuromuscular Dis., [1]Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [4]Yonsei Stem Cell Res. Ctr., Avison Biomed. Res. Ctr., Seoul, Korea, Republic of

Abstract: Objective: Recent studies have shown that transplantation of mesenchymal stem cells(MSCs)have paracrine effects. Some studies are shown that environmental enrichment(EE)results in improved sensory motor function and stimulated endothelial cell proliferation. Astrocytes are activated by both MSCs and EE. Activated astrocytes produce not only angiogenic factors but also neurogenesis factors. We investigated angiogenic effects of astrocyte activation by EE and MSCs transplantation on neurobehavioral function in an animal model of chronic HI brain injury. **Methods:**HI brain damage was induced in 7-day-old CD-1®(ICR) mice by unilateral carotid artery ligation and exposure to hypoxia(8% O_2 for 90min). At 6 weeks of age, the mice were randomly injected with either MSC ($1x10^5$/2μl) or phosphate buffered saline(PBS) into the striatum and assigned to either EE or standard cages(SC), comprising MSC-EE, MSC-SC, PBS-EE, PBS-SC. Whereas SC controls were housed for the same duration in a standard cag(27×22.5×14 cm), EE mice were housed in a huge cage(86×76×31 cm) containing novel objects for up to 2 months. Rotarod, forelimb-use asymmetry, grip strength, and openfield tests were performed to evaluate neurobehavioral function. We confirmed the fate of transplanted cells, the levels of endogenous angiogenesis, activated astrocytes and glial scar using immunohistochemistry. To identify growth factors that are regulated by MSC transplantation and/or EE, neostriata separated from brain, a array-based multiplex ELISA assay was used to determine which of the following 10 cytokines were detectable in the neostriata. Expression of angiogenic and neurotrophic factors using western blot. **Results:**EE and MSCs transplantation synergistically improved rotarod latency, forelimb-use asymmetry, and grip strength compared to those of the other groups. The number of engrafted MSCs and $CD31^+$ endothelial cells were significantly higher in mice in EE than those in SC. Two weeks after EE and MSC transplantation increased density of $CD\text{-}31^+$ and a-smooth muscle $actin^+$ cells coupled with increased $GFAP^+$ astrocytic density and fibroblast growth factor-2 (FGF-2) but not the level of $CS\text{-}56^+$ glial scarring in the striatum. The fate of transplanted cells and the levels of endogenous angiogenesis, astrocyte activation and angiogenic factors were also measured. **Conclusions:**EE and MSC transplantation synergistically improved neurobehavioral functions. The underlying mechanisms of this synergism included enhanced repair processes such as higher engraftment of the transplanted MSCs, increased endogenous angiogenesis and astrocyte activation coupled with upregulation of FGF-2.

Title: Genotype specific impact of nuclear factor E2-related factor 2 (Nrf2) treatment in animal models of amyotrophic lateral sclerosis

Authors: ***W. NANDAR**[1], E. B. NEELY[1], Z. SIMMONS[2], J. R. CONNOR[1];

Abstract: H63D HFE gene variant, found in approximately 30% of ALS patients, impacts disease processes implicated in amyotrophic lateral sclerosis (ALS). We generated double transgenic mice (SOD1/H67D) and show the addition of H67D HFE (homologous to human H63D) to the SOD1 mice shortens survival and accelerates disease progression. We found elevated oxidative stress associated with decreased Nrf2 levels is one mechanism contributing to accelerated disease in double transgenic mice. The Nrf2 signaling pathway is the major cellular defense mechanism against oxidative stress and regulates expressions of many endogenous antioxidant genes. Neuroprotective effects of the Nrf2 activator (2-Cyano-3,12-Dioxooleana-1,9-Dien-28-Oic acid trifluoroethylamide or CDDO-TFEA) are reported in preclinical models of neurodegenerative disease. We evaluated the impact of HFE genotype on the effect of CDDO-TFEA using double transgenic and SOD1 mice. We hypothesize a genotype-dependent response to treatment in ALS. At 97 days of age, double transgenic and SOD1 mice were fed either control or diet supplemented with CDDO-TFEA (400mg/kg body weight). We evaluated effects on disease onset, disease progression and survival. Disease onset was determined by motor performance on the rotarod apparatus. A gripstrength meter that measures forelimb and hindlimb strength was used to evaluate disease progression. Disease end-stage was defined as the inability of an animal to right itself within 30 seconds after being placed on its side. We found diet supplemented with CDDO-TFEA significantly prolonged survival in double transgenic mice, but had no effect in SOD1 mice. The CDDO-TFEA had no effect on age at onset and disease duration in double transgenic or SOD1 mice. Moreover, we separately evaluated nutritional effects and found mice fed an animal-based diet containing cholesterol survived longer than those fed a vegetarian-based diet lacking cholesterol, an effect more pronounced in double transgenic mice. Thus, nutritional interventions including specific nutritional supplements could have therapeutic values in ALS. Our findings indicate a genotype specific response to treatment

in ALS and provide support for stratifying patients by genotype. Therefore, findings from double transgenic mice, which are relevant to the 30% of ALS patients carrying H63D HFE, could impact clinical practice and evaluation of treatment strategies.

Title: The role of nuclear export in TDP43-mediated neurodegeneration

Authors: *H. ARCHBOLD[1], X. LI[1], S. TAMIR[4], S. BARMADA[1,2,3];
[1]Dept. of Neurol., [2]Cell. & Mol. Biol. Program, [3]Neurosci. Program, Univ. of Michigan, Ann Arbor, MI; [4]Karyopharm Therapuetics, Newton, MA

Abstract: Nuclear exclusion and cytoplasmic deposition of the RNA binding protein TDP43 (transactive response element DNA binding protein of 43 kDa) is a pathological hallmark of the related neurodegenerative disorders amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Mutations in the TDP43 gene associated with familial ALS cause a redistribution of the protein from the nucleus to the cytoplasm, and we have previously shown that cytoplasmic TDP43 deposition closely predicts cell death, making the nucleocytoplasmic shuttling of TDP43 an attractive therapeutic target. TDP43 contains putative nuclear export signal (NES) and nuclear localization signal (NLS) motifs, as well as an M9-like domain, which is sufficient for karyopherin-mediated transport of related RNA binding proteins. Here, we find that selective inhibitors of nuclear export (SINE) compounds - designed to inhibit the interaction of exportin 1 (Xpo1/CRM1) with its cargo substrate proteins - improve cellular survival in primary neuron models of ALS and FTD involving TDP43. Preliminary data indicate that SINE compounds decrease levels of endogenous, but not exogenously expressed, TDP43. TDP43 negatively regulates its own production at the RNA level, suggesting that nuclear sequestration of TDP43 may promote a negative feedback loop that protects neurons from death by decreasing nuclear and whole cell levels of TDP43. In support of this hypothesis, steady state TDP43 levels are dose-dependently related with neurodegeneration, and alternative methods for reducing TDP43 protein levels have proven to be potent neuroprotective therapies in cellular models of

ALS and FTD. However, SINE compounds affect the distribution and activity of several transcription factors important for neuronal survival, and an indirect effect upon TDP43 levels and/or neurodegeneration remains a possibility. Given that related SINE compounds are currently undergoing evaluation in clinical trials for other indications, we expect that validation of their neuroprotective effects in neuronal models of ALS and FTD such as these will facilitate and accelerate their translation to humans with disease.

Abstract: Neuronal degeneration in amyotrophic lateral sclerosis (ALS) appears to begin as a focal process that spreads contiguously through the upper and lower motor neurons. Such disease progression leads to increasing paralysis. It likely implicates an acquired pathogenic mechanism maintained by interaction of damaged neurons and inflammatory cells including astrocytes, microglia, mast cells and T cells. We have previously showed evidence for aberrant glial cells (AbA cells) emerging around damaged motor neurons. Because AbA cells exhibit a high toxicity for motor neurons, they may be considered as a cell type specifically associated to disease progression in ALS. As part of the ALS neuroinflammatory reaction, mast cells appear as a key

cell type associated to chronic inflammation. In this context, two studies have shown evidence for increased mast cell infiltration in the postmortem samples of ALS patients. Masitinib mesilate (Mb) is a selective, tyrosine kinase inhibitor that targets c-Kit, Lyn and Fyn pathways. By combined targeting of c-Kit, Lyn and Fyn, Mb is particularly efficient in controlling mast cell survival, differentiation, and degranulation. Our hypothesis establishes that Mb indirectly decrease the appearance of inflammatory AbA cells through the down-regulation of activated mast cells. To further explore our hypothesis we assessed whether Mb can slow disease progression in the SOD1G93A rat model of ALS. Mb (30 mg/kg/day) was orally administered from disease onset until complete paralysis. Mb treatment significantly prolonged life span of ALS SOD1G93A rats. To further determine the mechanism of action of Mb we analyzed the neuroinflammatory components in the degenerating spinal cord after the treatment. The histopathological analysis performed suggested that Mb provided a significant protection against progressive motor neurons loss and degeneration when compared with control animals. Furthermore, all parameters of neuroinflammation, including the degree of astrocytosis, the number of AbA cells and microgliosis were dramatically reduced in Mb-treated rats with respect to control. Taken together, the present findings provide convincing evidence for a protective role of Mb in an inherited model of ALS. Additionally, the treatment regime implemented by these studies reflects a clinically plausible scenario, i.e. therapeutic settings. Mb is currently being evaluated in two phase 3 clinical trials for ALS, administered as either a single-agent or in combination with riluzole.

Title: Pur alpha: a potential therapy for ALS due to the C9ORF72 expanded repeat

Authors: *E. W. GODFREY[1], J. W. ORIANS[2], T. E. CRIST[2], E. M. JOHNSON[3], D. C. DANIEL[3];
[2]Pathology and Anat., [3]Microbiology and Mol. Cell Biol., [1]Eastern Virginia Med. Sch., Norfolk, VA

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that results in paralysis due to loss of motor neurons in the cortex and spinal cord. The most common genetic cause of ALS is an expanded hexanucleotide repeat (GGGGCC) in a non-coding region of the C9ORF72 gene, which encodes a protein involved in endocytosis and autophagy. Patients with this mutation have hundreds to thousands of copies of this repeat sequence. Repeat sequence RNA aggregates in nuclear foci that can be detected by fluorescent *in situ* hybridization (FISH). The mechanism by which the C9ORF72 repeat causes ALS is unknown, but the repeat sequence in the RNA sequesters RNA-binding proteins. Disturbing the content of RNA-binding proteins in the cell can affect transcription, translation, and splicing of many mRNAs, resulting in expression of altered RNAs and reduction in RNA content. Pur-alpha, an abundant RNA- and DNA-binding protein that binds to GGGGCC repeats, or a peptide with a generic Pur family repeat, may be therapeutic in C9ORF72 ALS. Pur alpha binds to the GGGGCC sequence with high affinity and has been colocalized with the nuclear RNA foci. Overexpression of Pur alpha in *Drosophila* or neuronal cells with 30 copies of the repeat resulted in a reduction in neurodegeneration (Xu et al., 2012). We used virally transformed lymphocytes from C9ORF72 ALS patients to test the ability of Pur alpha to reduce cellular pathology. We labeled autophagosomes of cells from patients and controls with an antibody to p62, a protein in the autophagosome membrane. These organelles are involved in removal of proteins that misfold and aggregate in the cytoplasm of neurons in ALS. We also quantitated the number of autophagosomes and autolysosomes using a fluorescent LC3 probe. Lymphoblasts from C9ORF72 patients had significantly more autophagosomes and p62 protein than control cells. Transfection of Pur alpha or treatment of cells with the Pur peptide resulted in a significant reduction in p62-positive puncta in C9ORF72 lymphoblasts. Pur alpha and the Pur peptide reduced the number of autophagosomes almost to the level in control cells. Our results suggest that Pur proteins and the peptide stimulate autophagy and ameliorate cellular pathology in this form of ALS. Experiments are underway to test the efficacy of the peptide in reducing cellular pathology in neurons differentiated from iPS cells of C9ORF72 ALS patients.

Abstract: Guillain-Barré syndrome (GBS) is a serious autoimmune disease affecting the peripheral nervous system. Majority of the GBS patients experienced neurological symptoms such as paresthesia, muscle weakness, persistent pain and areflexia. In GBS, immune cells start attacking the major complex gangliosides present on the peripheral nerves resulting in nerve injury or demyelination. Clinical studies showed that high levels of anti-ganglioside antibodies were detected in the sera of the GBS patients. Our previous studies reported that heat shock protein (Hsp) 27 accelerated the axonal regeneration in mice after peripheral nerve injury. In the current *in vitro* and *in vivo* experiments, we showed that forced expression of a human (h) Hsp27 could overcome anti-ganglioside mediated nerve regeneration inhibition. Passive transfer of anti-ganglioside antibodies (GD1a/GT1b-2b) into transgenic (Tg) mice overexpressing hHsp27 and their littermates (LM) to study their functional recovery. Sensory function recovery assessed by pinprick test was ten days earlier in hHsp27 Tg mice as compared to LM controls. Motor function recovery was restored to baseline in Tg mice as observed by grip strength, toe spread and sciatic functional index. Our electromyography and histology data showed that Tg mice demonstrated a mark improvement of muscle function in terms of increasing compound muscle action potential and neuromuscular junction reinnervation. Taken together, our data indicates that Hsp27 could be a potential therapeutic target for GBS prevention. Further investigation is needed to elucidate the molecular mechanism involved by examining some of the key genes in axonal regeneration by single cell PCR.

Title: Neural progenitor cells secreting glial cell line-derived neurotrophic factor (GDNF) for the treatment of amyotrophic lateral sclerosis

Authors: *G. M. GOWING, B. SHELLEY, P. AVALOS, J. LATTER, A. HURLEY, L. GARCIA, K. STAGGENBORG, M. CHEN, M. GODOY, P. SUEZAKI, D. RUSHTON, R. PARADIS, J. ZELAYA, A. LIN, L. SHUE, C. CHANG, C. CHIU, K. NISHIMORI, J.-P. VIT, C. N. SVENDSEN;
Cedars-Sinai, West Hollywood, CA

Abstract: Astrocytes releasing the powerful growth factor glial cell line-derived neurotrophic factor (GDNF) have been shown to slow motor neuron degeneration in the SOD1G93A rat model of amyotrophic lateral sclerosis (ALS). In the current study we have generated a process comparable line of human neural progenitors engineered to secrete GDNF (hNPC-CNS10GDNF). These have been used to perform full dose ranging, bio-distribution studies, along with preliminary toxicity and tumorogenicity studies in a rodent model of ALS, immune compromised animals and pigs. We show that at all doses the transplanted cells survive, migrate, release GDNF and do not form tumors. Grafted cells provided significant protection to dying motor neurons in this model, although no dose could protect the motor neuron connection to muscle and thus did not prevent paralysis in the animals. Together this body of work shows that hNPC-CNS10 GDNF can be grown under Good Manufacturing Procedure (GMP)-like conditions and safely delivered to both rodents and pigs where they protect dying motor neurons. This combined stem cell and gene therapy approach is now being moved forward into final pre-clinical enabling studies and submitted as an investigational new drug (IND) to treat ALS.

Title: Tempol treatment reduces microglial reaction in late stages of disease in SOD1 mutant mice

Authors: *G. CHIAROTTO, A. B. SPEJO, A. L. R. OLIVEIRA;
Univ. of Campinas, Campinas, Brazil

Abstract: A hallmark of amyotrophic lateral sclerosis (ALS) is the progressive loss of motoneurons. Preservation of synapses together with modulation of gliosis may contribute to decrease or delay neuronal degeneration. This may not be achieved with riluzole alone, that is the only drug currently available. Thus, new substances must be evaluated, given the fact that the oxidative stress greatly contributes to the disease progression. In this scenario, 4-hydroxy-TEMPO (tempol) is a potent nitric oxide scavenger and superoxide dismutase (SOD) mimetic, putatively capable of neuroprotection. Therefore, we investigated neuroprotection and glial reaction in SOD1 G93A mice orally treated with tempol. Male and female siblings were distributed in the following groups: control (absence SOD1 mutation); vehicle treated SOD1 mutant mice; riluzole (8mg/kg) treated; tempol (24mg/kg) treated. Treatment began in 70 days old mice and was kept every other day for twenty days. From that point, drug administration was carried out twice a week until euthanasia at degree four of disease. Following fixative perfusion, the lumbar spinal cord was dissected out and processed for Nissl staining (neuronal survival) and immunohistochemistry, to evaluate glial reaction (GFAP and Iba1) and spinal synapse preservation (synaptophysin, GAD65 and VGLUT1). Immunolabeling was accessed in three spinal cord regions: ventral horn (lamina IX), intermediated region and dorsal horn (laminae I to III). The body weight, onset of the disease, motor score and survival were also analyzed. Nissl staining revealed that ALS led to degeneration of more than fifty percent of all motoneurons, and different treatments were unable to reverse such scenario. SOD 1 mutant mice also displayed loss of more than half of synapses in the ventral horn, being more prominent in glutamatergic (VGLUT1-positive, 87%) than in GABAergic inputs (55%). Uniform loss of such inputs took place in other spinal cord regions. Astrogliosis, evaluated by GFAP labeling, was increased in all SOD1 mutant groups, appearing more intense in the ventral horn. Tempol and riluzole were effective in decreasing microglial reaction, seen by Iba1 labeling, particularly in the dorsal region, that receives most of the primary afferent inputs, contributing, among other functions, to the sensorimotor integration. Nevertheless, no statistical differences among groups regarding the onset of the disease, loss of body mass, progression and survival endpoint were achieved. Taken together, the results indicate that tempol is unable to reverse the fate of SOD1 mutant mice, although it shows potentially beneficial effects regarding microglial reaction.

Title: Identification of novel inducers of SMN2 expression using the Privileged Structure Platform

Authors: *M. E. R. BUTCHBACH[1,2,3], A. W. HARRIS[1], A. PESYAN[4];
[1]Ctr. for Applied Clin. Genomics, Nemours Biomed. Research/A. I. duPont Hosp. For Children, Wilmington, DE; [2]Pediatrics, Thomas Jefferson Univ., Philadelphia, PA; [3]Biol. Sci., Univ. of Delaware, Newark, DE; [4]AurimMed Pharma, Inc., Park City, UT

Abstract: Spinal muscular atrophy (SMA), a leading genetic cause of infant death worldwide, is an autosomal recessive motor neuron disease caused by the loss of *SMN1* but retention of *SMN2*. The number of copies of *SMN2* inversely correlates with disease severity in both SMA patients as well as in mouse models for SMA. There is currently no successful treatment for SMA; however, much attention has been focused on *SMN2* as a target for therapeutics development. AurimMed Pharma, Inc. has developed a focused library of potent central nervous system (CNS) active compounds based on their Privileged Structure Platform (PSP). In this study, we screened this PSP library for compounds that modulate *SMN2* expression using reporter assay cell lines as well as fibroblasts derived from SMA patients. To monitor changes in *SMN2* promoter activity in response to drug treatment, we used a β-lactamase reporter construct under the control of the 3.4 kb *SMN2* promoter expressed in motor neuron-like NSC-34 cells. 64 compounds from the PSP library were screened for SMN2 promoter induction activity; 26 of these compounds showed enhanced *SMN2* promoter activity relative to vehicle (DMSO)-treated cells. In fact, 3 of these compounds induced *SMN2* promoter activity at a level similar to that for our positive control, the C5-substituted 2,4-diaminoquinazoline D156844. We also tested 7 PSP compounds for their ability to increase SMN localization to subnuclear gems in SMA cells. Type II SMA fibroblasts were treated with these compounds for 5 days and then immunolabeled for SMN. Of the 7 test compounds, 6 increased gems counts relative to vehicle-treated SMA fibroblasts in a dose-dependent manner. 2 of these compounds increased gem counts to those observed in healthy, carrier fibroblasts. Some of the gem inducing compounds did not significantly increase *SMN2* promoter activity. We have identified CNS active compounds that increase *SMN2* promoter activity and/or SMN protein localization to gems. Because some of the gem inducing PSP compounds did not increase *SMN2* promoter activity, different compounds may be regulating SMN2 expression at different levels of gene regulation. Future work will determine the

mechanisms by which these compounds are increasing *SMN2* expression. Furthermore, these compounds will be moved forward into preclinical drug studies in mouse models of SMA.

Title: Monoacylglycerol lipase inhibiton is therapeutically effective in chronic mouse models of amyotrophic lateral sclerosis and Parkinson's disease

Authors: N. PASQUARELLI[1], C. PORAZIK[1], J. HANSELMANN[1], P. WEYDT[1], B. FERGER[2], *A. WITTING[1];
[1]Univ. Ulm, Ulm, Germany; [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach/Riß, Germany

Abstract: For the development of therapeutic strategies towards neurodegenerative diseases, the endocannabinoid system is a valuable approach. Especially the 2-arachidonoyl glycerol (2-AG)-degrading enzyme monoacylglycerol lipase (MAGL) represents a promising target as inhibition of MAGL may induce neuroprotective and anti-inflammatory effects by increasing 2-AG and decreasing arachidonic acid and prostaglandins. To study the therapeutic potential of MAGL in neurodegenerative diseases, we pharmacologically inhibited MAGL by the highly selective inhibitor KML29 in chronic mouse models of amyotrophic lateral sclerosis (ALS) and Parkinson's disease (PD). For ALS, we orally treated 150-day-old low-copy B6SJL-Tg(SOD1*G93A)dl1Gur/J (SOD1G93A) mice with KML29 (0, 0.5, 5, 10 mg/kg, 3x/week) and monitored disease onset, progression and survival as well as running wheel activity and body weight. For PD, we orally treated mice from the chronic 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine/probenecid (MPTP, 10 mg/kg; probenecid 250 mg/kg; 2x/week) mouse model of PD with KML29 and the fatty acid amide hydrolase (FAAH) inhibitor PF3845 (10

mg/kg, 5x/week) over five weeks and quantified dopamine and metabolites by HPLC/ECD in the striatum. In addition we quantified the expression of cannabinoid receptors and MAGL on mRNA and protein level and of endocannabinoids, arachidonic acid and prostaglandins by LC-MS/MS. To investigate the effect of MAGL inhibitors on neuroprotection and inflammation, we quantified cytokines and neurotrophins on mRNA and protein level and performed immunohistochemistry. In SOD1G93A mice, KML29 delayed the disease onset, the occurrence of first pareses and the disease end-stage in a dose-dependent manner. Furthermore, KML29 significantly delayed the disease-associated loss in body weight and running wheel activity. Post mortem, KML29 increased 2-AG levels in a cumulative manner during the disease course and decreased arachidonic acid without enhancing anandamide levels. In addition, KML29 induced an increase in MAGL, CB1 and BDNF expression, suggesting a neuroprotective mechanism. In MPTP mice, KML29, but not PF3845, was able to restore striatal dopamine levels by 20 %, further highlighting a neuroprotective mode of action of KML29. In conclusion, our therapeutic application of KML29 evidences MAGL as a valuable target for the treatment of neurodegenerative diseases like ALS and PD and warrants further investigation on a mechanistic level.

Title: Use of a new minimally invasive intraparenchymal spinal delivery system for the injection of stem cells into the spinal cord

Authors: ***P. AVALOS**[1], G. GOWING[1], B. C. SHELLEY[1], D. DRAZIN[2], L. GARCIA[1], M. J. BAKER[3], S. SUCKOW[3], B. EDIN[3], C. N. SVENDSEN[1];

Abstract: A number of novel treatment approaches for diseases, such as amyotrophic lateral sclerosis (ALS) and spinal cord injury, require intraparenchymal delivery of a therapeutic into the spinal cord. ALS is a neurodegenerative disease that affects motor neurons leading to

paralysis and death 1 to 5 years following diagnosis. There is no effective treatment for ALS. Direct transplantation of stem cells into the spinal cord parenchyma has been shown to have beneficial effects in ALS animal models. However, spinal transplantation is a relatively new procedure and currently available systems require extensive training, involve cumbersome and complex devices and use delivery systems that may lead to increased risk of injury. We have developed a new spinal delivery system that can safely, successfully and precisely target the injection of human neural progenitor cells (hNPC) secreting the powerful growth factor glial cell line-derived neurotrophic factor (GDNF) to the spinal cord of Yucatan mini-pigs. Preliminary studies have shown survival and appropriate targeting of grafted cells. Moreover, evaluation of post-operative locomotor function of mini-pigs shows that they return to the pre-surgical baseline within 5 days post-surgery, demonstrating the safety of this approach. In conclusion, this new device appears efficient, safe and simple to use. As such, an extensive Good Laboratory Practice (GLP) safety study in Yucatan mini-pigs is ongoing in order to validate the device for use in a Phase I trial for the transplantation of hNPC secreting GDNF into the lumbar spinal cord of ALS patients.

Title: CSF1R signalling has a pivotal role in amyotrophic lateral sclerosis

Authors: ***A. MARTÍNEZ-MURIANA**[1], R. MANCUSO[1], I. FRANCOS-QUIJORNA[1], A. OLMOS-ALONSO[2], R. OSTA[3], V. PERRY[2], X. NAVARRO[1], D. GOMEZ-NICOLA[2], R. LÓPEZ-VALES[1];
[1]Cell Biology, Physiol. and Immunol., Univ. Autònoma de Barcelona, Bellaterra, Spain; [2]Ctr. for Biol. Sciences, Univ. of Southampton, Southampton, United Kingdom; [3]Univ. de Zaragoza, Zaragoza, Spain

Abstract: Inflammation is a common neuropathological feature in many neurological disorders, including amyotrophic lateral sclerosis (ALS). In the present work we studied the contribution of CSF1R signalling to inflammation in ALS. We found that microglial cell expansion in the spinal cord of SOD1G93A transgenic mice showed a similar progression than the expression of CSF1R

and its ligand CSF1. Administration of GW2580, a selective CSF1R inhibition, reduced microglial cell proliferation in this ALS mouse model suggesting the importance of CSF1-CSF1R signalling in microgliosis in ALS. Moreover, GW2580 slowed disease progression and death of SOD1G93A mice. Electrophysiological assessment revealed that that GW2580 reduced muscle denervation prior to its effects on microglial cells. Interestingly, we found that macrophages invaded the peripheral nerve of ALS mice before microgliosis occurred, and that treatment with GW2580 attenuated macrophages influx into the nerve, in part, due to the difficulty of bone marrow cells to produce monocytes upon CSF1R inhibition. Overall, our findings provide clear evidence that CSF1R signalling regulates inflammation in the central and peripheral nervous system in ALS, and highlight the importance of nerve macrophages in the course of ALS pathology, supporting therapeutic targeting of CSF1R in ALS

Title: Assessing the neuroprotective effects of MicroNeurotrophins in the SOD1 mouse model of Amyotrophic Lateral Sclerosis

Authors: *K. E. GLAJCH[1], K. MUELLER[1], L. RYCYNA[1], C. VANDERBURG[1], A. GRAVANIS[2], G. SADRI-VAKILI[1];
[1]Dept. of Neurol., Massachusetts Gen. Hosp., Charlestown, MA; [2]Univ. of Crete, Crete, Greece

Abstract: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder caused by loss of motor neurons. ALS patients experience rapid deterioration in muscle function with an average lifespan of 3-5 years after diagnosis. Currently, the most effective therapeutic for the treatment of ALS only extends lifespan by a few months. Neurotrophic factors (NTFs) are a group of molecules involved in neuronal development, maintenance, and survival. NTF treatment has previously shown efficacy in pre-clinical ALS models. However, clinical trials using NTFs produced no major improvements in ALS patients, due in part to the limited penetration of NTFs across the blood brain barrier (BBB). Microneurotrophins (MNTs) are small neurotrophic-like compounds that cross the BBB and bind to tyrosine kinase receptors mimicking the pro-survival effects of endogenous neurotrophic factors. In this study, we sought

to determine the potential therapeutic efficacy of the MNT BNN27 in a mouse model of ALS expressing the G93A mutation in the superoxide dismutase (SOD1) gene. Previous preliminary studies from our group showed that administration of BNN27 resulted in trends towards the improvement of disease phenotypes, delayed disease progression, and increased motor neuron number in the lumbar spinal cord in male and female mutant SOD1 mice. We will present results from our large pre-clinical study on the effects of BNN27 treatment on motor neuron survival, motor behavior, disease progression, and survival. These findings could reveal a novel potential therapeutic for the treatment of ALS.

Title: Intra spinal delivery of human neural progenitors releasing ciliary neurotrophic factor (CNTF) ameliorate functional decline in the G93A rat model of amyotrophic lateral sclerosis

Authors: *M. GODOY, G. GOWING, P. SUEZAKI, D. RUSHTON, K. STAGGENBORG, P. AVALOS, L. GARCIA, O. SHELEST, R. PARADIS, C. CHIU, C. CHANG, C. SVENDSEN; Board of Governors Regenerative Med. Inst., Cedars-Sinai Med. Ctr., Los Angeles, CA

Abstract: Amyotrophic lateral sclerosis (ALS) is a complex and devastating disorder characterized by the degeneration of motor neurons in the cortex, brainstem and spinal cord, resulting in muscle weakness, paralysis and death within 1-5 years of diagnosis. Glial cells, specifically Schwann cells and astrocytes in the CNS and PNS, express ciliary neurotrophic factor (CNTF), which has been demonstrated to protect neurons, including motor neurons, following injury. Here we used an ex-vivo gene therapy approach with the transplantation of human neural progenitors expressing CNTF into the spinal cord of G93A SOD1 rats in order to see if they could extend motor neuron survival and function. We have demonstrated that neural progenitors expressing CNTF survive unilateral transplantation into the lumbar spinal cord and secrete CNTF. Preliminary behavioral results have shown that female rats treated with CNTF-expressing neural progenitor cells show a significant difference in rate of motor function decline on the ipsilateral versus contralateral side. Further analysis is underway to confirm the effect of transplanting CNTF-expressing neural progenitor cells on motor neuron survival and function. In conclusion, our results suggest a therapeutic benefit of CNTF in the ALS rodent animal model.

Title: Alternative anaplerotic fuel in the hSOD1G93A mouse model of Amyotrophic Lateral Sclerosis

Authors: ***K. BORGES**, T. TEFERA, Y. WONG, K. TAN, T. MCDONALD, S. NGO; Univ. of Queensland, St Lucia, Australia

Abstract: Amyotrophic lateral sclerosis (ALS) is characterized by degeneration of motor neurons in the motor cortex and spinal cord resulting in muscle weakness and degeneration, paralysis and ultimately death usually due to respiratory failure. There is mounting evidence that there is impaired energy metabolism in patients with ALS and in animal models that contributes to the disease. There is an increased energy requirement as a result of hypermetabolism (higher energy expenditure), reduced food intake and weight loss. Alternative metabolic substrates such as triheptanoin, the triglyceride of heptanoate, are ideally suited to alleviate many of the known metabolic problems in ALS. Triheptanoin is already being tested in clinical trials for energy metabolism and other neuromuscular disorders. Being tasteless, it is mixed with food and quickly provides heptanoate, which diffuses freely into the mitochondria of all tissues, including motor neurons and muscle. Heptanoate is beta-oxidized to acetyl-CoA, the main substrate for the tricarboxylic acid (TCA) cycle, and propionyl-CoA. Propionyl-CoA refills C4 intermediates of the TCA cycle (anaplerosis) as it is metabolized to succinyl-CoA and then oxaloacetate. Our quantitative real time PCR data show that when compared to healthy wild type mice, the mRNA levels of several enzymes involved in glycolysis and the TCA cycle were significantly reduced in the gastrocnemius muscle of $hSOD1^{G93A}$ mice at 10 and 25 weeks of age, including the dehydrogenases for pyruvate (Pdha1), 2-oxoglutarate (Ogdh) and succinate (Sdha) and the main muscle glutamic pyruvic transaminase 2. 35% of calories provided as triheptanoin prevented the reduction in Pdha1 and Sdha mRNA levels seen in $hSOD1^{G93A}$ mice, illustrating protective effects of triheptanoin on the TCA cycle. Also, we found several differences in maximal activities for glycolytic and other enzymes in muscle at different disease stages in $hSOD1^{G93A}$ mice, indicating impaired energy metabolism. Initiating triheptanoin to $hSOD1^{G93A}$ mice at P35

delayed the onset of motor symptoms by 2.5 weeks, as well as onset of body weight loss and motor balance loss (all $p<0.01$**)** and seems to delay motor neuron loss at 10 weeks.

Title: Atypical electropherogram patterns are observed among C9orf72 (G4C2) expansion carriers in a familial and sporadic ALS and ALS/FTD North American cohort study

Authors: *J. L. LOWRY, J. YAN, L. KINSLEY, N. SIDDIQUE, H.-X. DENG, T. SIDDIQUE; Neurol., Northwestern Univ., Chicago, IL

Abstract: A hexanucleotide (G_4C_2) repeat expansion mutation on Chromosome 9 open reading frame 72 (C9orf72; C9) is currently identified as the most common cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). We have been actively genotyping one of the largest North American ALS and ALS/FTD cohorts since originally establishing genetic linkage at chromosome 9p21.3–9p21.1 in families with concomitant FTD and ALS (Yan J., *et al.* (2006) *Neurology* 67, 186). To date, we have screened more than 500 FALS and 1400 SALS cases with and without FTD for the C9 expansion mutation using the repeat primed-polymerase chain reaction (RP-PCR) method. This cohort consisted of patients that have not been previously found to carry other known ALS-causing mutations. Of those, ~50% FALS and ~5% SALS cases appear to be C9 expansion carriers evident by >23 repeats. Typically, electropherograms from expanded C9 carriers are described as displaying a characteristic saw-tooth pattern with ≥21 peaks, where each successive peak differs in one (G_4C_2) unit that decreases in signal intensity (SI) as fragment size increases. Interestingly, we identified that ~40% of our expanded C9 cases do not generate electropherograms displaying a typical saw-tooth pattern. Instead, we detect an unreported atypical pattern that is characterized by a series (<21) of equally robust peaks, followed by several additional peaks (>21) of low SI that requires manipulation of the SI range for adequate detection. We have confirmed that these samples are indeed expanded using a

non-radioactive Southern blot method that utilizes a digoxigenin-labeled C9 probe. What causes a difference in electropherogram pattern among C9 expansion carriers is currently unknown and is being investigated by our lab. It is possible that atypical expansion carriers have interruptions present in the (G_4C_2) tract as seen in other expansion disorders. Additionally, several other labs have reported the presence of mutations in the low complexity sequence region immediately following the (G_4C_2) tract. Mutations with in or following the (G_4C_2) tract may prevent efficient primer annealing and/or elongation of the product during the PCR reaction resulting in premature reaction termination. It is interesting to speculate whether variances in the expansion pattern correlate with differences in disease phenotype. Ultimately, the overarching goal of our studies is to gain a more thorough understanding of the pathogenic mechanisms associated with the C9 (G_4C_2) repeat expansion mutation, with the intention of identifying disease-causing pathways that may one day be exploited for therapeutic intervention.

Title: Identification of modifiers of C9orf72-associated dipeptide toxicity in a new *C. elegans* model

Authors: *S. T. LAMITINA[1], J. MONAGHAN[2], U. PANDEY[2], K. MARSHALL[1], C. SNOZNIK[1];
[1]Dept of Pediatrics and Cell Biol., [2]Dept of Pediatrics, Childrens Hosp. of Pittsburgh of UPMC, Pittsburgh, PA

Abstract: Nucleotide repeat expansions are a common cause of multiple age-related neurodegenerative diseases. An expansion of the intronic hexanucleotide repeat GGGGCC in the C9orf72 gene was recently found to be associated with two major neurodegenerative diseases – amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). Both repeat containing RNA and repeat encoded dipeptide proteins are associated with neurotoxicity and death in *Drosophila* and mammalian cell culture. To gain additional insights into the mechanisms of C9orf72 associated dipeptide toxicity, we generated transgenic *C. elegans* expressing dipeptides fused to GFP. We focused solely on the effects of dipeptide toxicity by varying codon usage, which preserves the dipeptide coding sequence but eliminates potential RNA repeat induced toxicity. Dipeptide expression was controlled by promoters that are active in muscle, all neurons, or specific motor neurons. Similar to previous reports, expression of GR

and PR, but not GA and PA, was extremely toxic under all conditions, producing various phenotypes (lethality, short lifespan, motility defects) depending on the site of expression. Since there are no known modifiers of dipeptide toxicity, we used these phenotypes to perform biased and unbiased modifier screens. One such modifier was a mutant that activates the insulin signaling pathway, an evolutionarily conserved modifier of longevity and proteotoxicity from *C. elegans* to humans. This pathway is known to reduce toxicity in other *C. elegans* ALS models, suggesting that dipeptide toxicity and other forms of ALS may share a common mechanism(s) of toxicity that is opposed by the target(s) of insulin signaling. Genetic screens to identify additional modifiers of C9orf72-associated dipeptide toxicity are ongoing.

Title: iPS astrocytes derived from amyotrophic lateral sclerosis patients up regulate efflux transporters in endothelial cells

Authors: *H. QOSA, S. MARKANDAIAH, J. LICHTER, P. PASINELLI, D. TROTTI; Thomas Jefferson Univ., Philadelphia, PA

Abstract: Previous studies showed that riluzole, the only FDA-approved drug for treatment of amyotrophic lateral sclerosis (ALS) and other investigational ALS therapeutics are substrates for drug efflux transporters; P-glycoprotein (P-gp) and breast cancer resistance protein (BCRP). These transporters can restrict the brain access of ALS therapeutics and enhance their extrusion from the brain. In addition, gradual increase in the expression and activity levels of these transporters over disease progression have been observed in the spinal cord of mouse model of ALS. Upregulation of P-gp and BCRP was also observed in postmortem spinal cord tissues of ALS patients, supporting the premise of development of pharmacoresistance in ALS. Therefore, the overall goal of this research is to identify the CNS-specific mechanisms of P-gp/BCRP overexpression that are activated in ALS in order to develop a therapeutic approach that can decrease the activity of these transporters and enhance ALS therapeutics brain level. First specific aim of this work is to evaluate the effect of astrocytes on endothelial expression of P-gp and BCRP. To achieve this aim, we used in-vitro blood-brain barrier (BBB) model that is

composed from endothelial cells and astrocytes derived from human induced pluripotent stem cells (iPS) that are obtained from ALS patients. Second specific aim is the identification of the signaling cascade(s) that contribute significantly to P-gp/BCRP up-regulation in ALS. We used our in-vitro BBB model to evaluate the activity of NF-κB-dependent pathways and xenobiotic-nuclear receptors pathways in endothelial cells after exposure to ALS-astrocytes. Our results showed significant increase in the endothelial expression of P-gp but not BCRP after co-culture with ALS-astrocytes. Increase of P-gp expression was associated with activation of NF-κB-dependent pathway but not xenobiotic-nuclear receptors in endothelial cells. Our findings suggest the contribution of ALS-astrocytes to the development of drug pharmacoresistance through activation of NF-κB-dependent pathways.

Abstract: Subtle variations amongst different cell types in the central nervous system (CNS) remain undefined, which has complicated the successful discovery of disease-modifying therapies for neurodegenerative diseases. There is a critical need to define the state and predict the behavior of healthy and diseased human cells in the CNS. Our knowledge of the CNS and the ability to intervene rationally in disease would be dramatically advanced by generating quantitative molecular phenotypes_essentially cell signatures_of human neurons, astrocytes and oligodendrocytes from healthy people and from patients with CNS disorders such as the motor neuron diseases. Despite this desperate need, the inaccessibility of human brain cells has made

studying them difficult until the hallmark discovery of cellular reprogramming and the induced pluripotent stem cell (iPSC) technology. The NeuroLINCS consortium has generated 16 total iPSC lines from amyotrophic lateral sclerosis (ALS) patients with the C9orf72 (4) or SOD1 mutations (4), spinal muscular atrophy patients (4) and control subjects (4). Motor neurons, the primary cell type affected in these diseases, were generated from the iPSCs under specific differentiation protocols. Transcriptomics, epigenomics, whole genome sequencing, proteomics, high content imaging, high throughput longitudinal single cell analysis and other cell-based assays are all in progress using standardized and parallel cultures. Specific "omics" profiles are associated with these different motor neuron diseases (or "genetic perterbagens"). Integrated signatures are currently being generated using bioinformatics, statistics and computational biology to establish patterns that may lead to a better understanding of the underlying mechanisms of disease. We are also developing innovative software tools and approaches that will make the comprehensive signature generating process faster, and more reliable. All of this data will be made available through the NIH LINCS program for the entire scientific community to utilize.

Title: The environmental neurotoxin β-methylamino-L-alanine: Modeling mother-to-infant transfer using human cell lines

Authors: *L. ERSSON[1], M. ANDERSSON[2], U. BERGSTRÖM[2], I. BRANDT[2], E. B. BRITTEBO[1];
[2]Envrn. Toxicology, [1]Uppsala Univ., Uppsala, Sweden

Abstract: The environmental neurotoxin β-N-methylamino-L-alanine (BMAA) has been implicated in the etiology of human neurodegenerative disease, presumably following dietary exposure. BMAA is a developmental neurotoxin that induce long-term learning and memory deficits, as well as neurodegeneration and intracellular fibril formation in the hippocampus of adult rats exposed neontally.We have also reported that BMAA is rapidly transported into the mammary gland of lactating mice, secreted in breast milk and subsequently transported to the

brain of the suckling pups, reaching higher concentrations in the neonatal than the maternal brain. Mother's milk is consequently proposed as a major exposure pathway for BMAA in neonatal rodents. Being a zwitterion, BMAA needs specific transporters to be transported via mammary epithelium, neonatal intestinal epithelium, and through cell membranes of neurons and glia cells to enter the neonatal brain. To model this transport in humans, we examined the uptake of ^{14}C-BMAA in four human cell lines; i.e. MCF7 mammary epithelial cells, Caco 2 intestinal cells, SH-SY5Y neuroblastoma cells and U343 astroglioma cells. BMAA was transported in all cell types. The uptake of BMAA was more rapid in the neuronal and astrocyte cell lines than in the mammary cell line and the Caco 2 cells. Competition experiments with other amino acids indicated that BMAA is taken up by transporters other than the large amino acid transporters 1 and 2 (LAT 1 and LAT 2) in SH-SY5Y and U343 cells. Taken together, the results suggest that mother-to-infant transport of BMAA to neonatal brain will occur also in humans.

Title: Investigating the contribution of β-amyloid1-42 mediated toxicity to motor neuron degeneration in models of amyotrophic lateral sclerosis (ALS)

Authors: *J. BRYSON[1], D. BUI[1], C. BARCELLOS-MACHADO[2], I. LIEBERAM[2], L. GREENSMITH[1];
[1]Sobell Dept. of Motor Neurosci. and Movement Disorders, UCL Inst. of Neurol., London, United Kingdom; [2]MRC Ctr. for Developmental Neurobio., King's Col. London, London, United Kingdom

Abstract: Motor neuron degeneration is the primary pathological hallmark underlying the progressive deterioration of motor function that occurs in patients with amyotrophic lateral sclerosis (ALS). Importantly, recent evidence indicates that motor neurons also undergo degeneration in other neurological disorders in which amyloid precursor protein (APP) has been implicated, including Niemann Pick type-C (NPC) disease[1] and Alzheimer's disease (AD)[2]. In animal models of AD, overexpression of human β-amyloid$_{1-42}$ (Aβ$_{42}$), a neurotoxic cleavage product of APP, has been shown to be sufficient to cause motor neuron degeneration. Previous research from our group demonstrated that genetic ablation of APP in the SOD1^{G93A} mouse

model of ALS resulted in a significant improvement of multiple disease parameters, including muscle innervation, motor function and motor neuron survival[3]. Additionally, we demonstrated a ~3-fold upregulation of endogenous murine $A\beta_{42}$, which accumulates within motor neurons and astrocytes in $SOD1^{G93A}$ mice. Taken together, this evidence strongly suggests that APP contributes to pathology in $SOD1^{G93A}$ mice and that the toxicity may be caused by enhanced amyloidogenic processing of APP in the setting of an ALS-like environment. In the current study, we have developed a long-term culture system using a combination of mouse embryonic stem cell (ESC) derived motor neurons (ESC-MNs) and astrocytes (ESC-ACs), which enables functional maturation of motor neurons *in vitro*[4]. Traditional methods of culturing primary motor neurons do not permit long-term maintenance and maturation of motor neurons, which typically remain viable for only 1-2 weeks. Using this ESC-derived system, we investigated the direct toxicity of oligomeric $A\beta_{42}$ ($_oA\beta_{42}$) to 'mature' motor neurons. Our results show that mature motor neurons are indeed susceptible to $_oA\beta_{42}$-mediated toxicity. We are now examining whether elevated levels of human $_oA\beta_{42}$ (as opposed to endogenous murine $A\beta_{42}$ which is thought to be less toxic) exacerbate motor neuron degeneration in $SOD1^{G93A}$ mice. Given the enormous efforts to develop pharmacological inhibitors of $A\beta_{42}$ production as a therapy for AD, evidence of a direct contribution of $A\beta_{42}$ to motor neuron degeneration in ALS could lead to new therapeutic approaches for this devastating disease. **References:** 1 Maulik M, Ghoshal B, Kim J, et al. Abstract: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder characterized by progressive degeneration and death of motoneurons. It is a fatal disorder with no effective therapy and patients have only 2 to 5 years of life expectancy after diagnosis. The majority of ALS cases are sporadic while around 10% are familial cases. Until recently, only one mouse model recapitulated the disease, but this model represented only 1% of all ALS cases. Despite several hypotheses regarding the mechanisms leading to ALS, little is known today and this is mostly due to disease heterogeneity and the impossibility to have access to human affected motoneurons. By providing such an access to human cells, induced pluripotent stem cells (iPSc) offers today a unique opportunity to study motoneurons of patients and to learn more about what triggers their death. In the present study, we have investigated the electrophysiological properties of iPS-derived motoneurons generated from ALS patients with mutations in one of the three main genes responsible for ALS (C9ORF72, SOD1, TDP-43) and healthy subjects of different ages (11, 33 and 69 years old). Motoneuron differentiation was performed as described in Maury et al. (Nat. Biotechnol., 2015) allowing the production of synchronized differentiated motoneuron cultures devoid of proliferative cells. HB9-positive and Islet1-positive motoneurons were produced as soon as day 17 and both control and ALS motoneurons survived in the presence of neurotrophic factors for more than 13 weeks. We currently analyze the formation of protein aggregates in these aged motoneurons. To examine electrophysiological properties of individual motoneurons, cultures were transduced with a lentiviral vector expressing RFP under the control of the HB9 promoter and only the largest RFP-positive neurons were recorded at 7 and 12 weeks after plating. We observed that at both time points all recorded control and ALS neurons were electrically active and able to fire at least one action potential in response to a pulse of depolarizing current. These data are in contrast with the recently published results by Devlin et al. (Nat Commun., 2015) and need to be confirmed. We then compared the Na+ and K+ currents developing during voltage steps of various amplitudes and could not find evidence for a decrease of INa+, with the cells aging from 7 to 12 weeks. The electrical behavior of the three cell lines of ALS-iPSc-derived motor neurons was comparable but a small tendency towards reduced excitability with respect to the aged-matched control iPSc-derived motor neurons was observed. Experiments are in progress to validate these results.

London, London, United Kingdom; [5]Med. Res. Council Ctr. for Neurodegeneration Res., King's Col. London, London, United Kingdom

Abstract: Background: Recent advances in the genetics of amyotrophic lateral sclerosis (ALS) show that GGGGCC hexanucleotide repeat expansion on C9ORF72 is the most common genetic cause of ALS. Understanding the pathogenic mechanisms underlying this mutation may hold the key to developing potential therapeutic treatments. In addition, accumulating experimental and human pathological evidence implicates non-cell autonomous mechanisms in the aetiopathogenesis of ALS. Astrogliosis and glial pathology has long been described in ALS but until recently has been assumed to be secondary and / or reactive. Human stem cell technologies allow the *in vitro* study of cellular autonomy with a focus on astrocytes. Results: Induced pluripotent stem cells (iPSCs) were generated from 3 patients carrying the GGGGCC hexanucleotide expansion on C9ORF72 as well as 2 healthy controls. Highly enriched (>90%) functional astrocytes were derived from all iPSC lines following a well-established protocol. Expansion carrying astrocytes recapitulate pathological features of C9ORF72 mediated ALS: a) dysregulation of C9ORF72 transcripts and b) presence of GGGGCC RNA foci in nuclei. Additionally, using longitudinal live imaging and Kaplan-Meier survival analysis, an increased risk of cell death was revealed in expansion carrying astrocytes when compared to controls. Mutant astrocytes also showed increased cell vulnerability under autophagy inhibition. In order to assess the non-cell autonomous contribution of repeat expansion carrying astrocytes, cell viability as well as electrophysiological profile of motor neurons cocultured with astrocytes is currently being examined. Discussion and Conclusion: Our work has established a platform to investigate the glial pathology and potential non-cell autonomous toxicity of astrocytes in C9ORF72 repeat expansion related ALS.

Title: C9orf72 repeat-associated non-atg (ran) translation products induce tdp43 mislocalization and neurodegeneration in models of als and ftd

Authors: *B. FLORES[1], M. IVANOVA[2], A. KRANS[2], P. TODD[2], S. BARMADA[2];
[2]Neurol., [1]Univ. of Michigan, Ann Arbor, MI

Abstract: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease characterized by a loss of motor neurons and muscle weakness. Patients with ALS may also present behavioral, personality, or language abnormalities that are associated with frontotemporal dementia (FTD). The most common cause of mutation familial forms of both FTD and ALS is a hexanucleotide (GGGGCC) expansion in a noncoding region of the chromosome 9 open reading frame 72, or *C9ORF72*. Expanded *C9ORF72* transcripts undergo a unique mechanism of translation, known as repeat associated non-ATG (RAN) translation, in all reading frames, but the significance of these RAN translation products in ALS and FTD pathogenesis is unknown. For the majority of patients with ALS and FTD, including *C9ORF72*-mutation carriers, the most striking pathologic characteristic is the cytoplasmic accumulation of TDP43, a nuclear RNA binding protein. The connection between C9ORF72 RAN peptides, TDP43 metabolism, and neurodegeneration remains fundamentally unclear. Our goals are to investigate the association between C9ORF72 mutations, abnormal TDP43 deposition, and their respective contributions to neuronal toxicity and disease pathogenesis. Here, we show that synthetically-derived C9ORF72 RAN products — glycine-arginine (GR), glycine-alanine (GA), and glycine-proline (GP) dipeptides, depending on the translational reading frame of the (GGGGCC) repeat — aggregate *in vitro*, and they reduce viability in a mammalian cell line. To determine if the RAN products are neurotoxic, we utilized fully-automated longitudinal fluorescence microscopy to prospectively visualize large populations of live neurons and track their survival. We show that short (6mer) GR dipeptides selectively increase the risk of death in rodent primary cortical neurons, but as the length increases both GA and GR dipeptides display neurotoxicity. Consistent with their negative effects on survival, both GA and GR dipeptides are internalized by neurons, but not GP dipeptides. In primary neurons expressing constructs containing hexanucleotide *C9ORF72* expansion mutations associated with RAN translation are more toxic than those that do not support RAN translation. Furthermore, in neurons treated with the short (6mer) GA dipeptide, we observed a reduction in the nuclear/cytoplasmic ratio of TDP43, suggesting that neurotoxic RAN dipeptides accentuate TDP43 mislocalization. These initial findings are an important, first step, in making the connection between *C9ORF72* mutations, RAN dipeptides, and neurodegeneration in ALS and FTD.

Title: Arginine-rich sense and antisense dipeptides in post-mortem human tissues of c9orf72-als/ftd patients

Authors: ***T. R. WESTERGARD**[1], X. WEN[1], N. A. SCHNEIDER[2], P. PASINELLI[1], D. TROTTI[1];
[1]Thomas Jefferson Univ., Philadelphia, PA; [2]Dept. of Neurology, The Ctr. for Motor Neuron Biol. and Dis., Columbia Univ. Med. Ctr., New York, NY

Abstract: The non-coding GGGGCC hexanucleotide repeat expansion in the C9ORF72 gene is the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). The expansion sense and anti-sense RNA transcripts can be translated through repeat associated non-ATG (RAN) translation to form five dipeptide repeat proteins (DRPs). We, as well as other labs, have shown that the arginine-rich dipepetides, particularly Proline-Arginine (PR), are highly toxic. We have demonstrated this toxicity in primary cortical and motor neuron cultures, transgenic fly models, and in human iPS-derived neurons. Toxicity of these arginine-rich dipeptides is associated with aggregate formation of the dipeptides in the nucleus, with strong co-localization with nucleolin and fibrillarin, both nucleoli proteins. To further determine the human relevance of the observed dipeptide toxicity, we performed immunofluorescence (IF) imaging techniques on post mortem human tissues. Human tissues were collected from mutant C9ORF72 positive ALS patients, mutant C9ORF72 negative ALS patients, and non ALS patients. Analyses of the human tissue showed robust paranuclear and nuclear PR positive cells specifically in mutant C9ORF72 ALS positive patients. Interestingly, PR staining primarily showed aggregation in the nucleus that co-localized in nucleoli, similar to toxicity factors seen in the primary cell cultures.

Title: Does MAO-A play a role in the development of depression for individuals with Alzheimer's disease

Authors: *Z. WEI[1], B. CHAHARYN[1], K. FEHR[1], K. CHEN[2], J. C. SHIH[2], D. D. MOUSSEAU[1];
[1]Univ. of Saskatchewan, Saskatoon, SK, Canada; [2]USC, Los Angeles, CA

Abstract: The exact association between Alzheimer's disease (AD) and depression is unknown. One possibility is the biological changes caused by AD may predispose to depression. Another possibility is that depression-related changes in the brain occur first and subsequently lead to AD. Our research program focuses on monoamine oxidase- A (MAO-A), an enzyme that has been associated independently with both depression as well as AD. We chose to examine relevant mouse models for any evidence of the direction of causality. We first used a transgenic mouse model of AD, the 'J20' strain that expresses the human Amyloid Protein Precursor (APP) (Cg-Tg PDGF-APP SwInd). The mutated form of APP (carries the Swedish and Indiana mutations) is an aggressive model of amyloidosis. We tested these mice and their wildtype littermates in the Tail Suspension Test (TST), a test used as a reflection of depression-like behavior. The time the mice spent immobile (i.e. despaired) decreased in the wildtype mice as they aged: i.e. 179.4 sec ± 35.1 (at three months of age) and 147.3 sec ± 49.7 at 12-months of age. In contrast, immobility time was increased in older J20 mice: i.e. 143.8 sec ± 57.4 (at three months) and 183.4 sec ± 36.6 at 12 months of age. We then crossbred J20 mice with a strain of mice bearing a spontaneous mutation in the mao-A gene that results in a truncated and inactive MAO-A protein (a functional knock-out: KO). The four genotypes studied were MAO-A WT/APP-, MAO-A WT/APP+, MAO-A KO/APP-, and MAO-A KO/APP+. Using the TST, we observed that immobility time increased in MAO-A WT/APP+ mice as they aged when compared with their age-matched MAOA WT/APP- mice, and immobility time decreased in MAO-A KO/APP- mice compared with mild type mice. We did not observe any of the expected difference between MAO-A KO/APP- and MAO-A KO/APP+ mice. However, preliminary studies using the Novel Object Recognition revealed that the cognitive decline associated with the APP genotype was accelerated in an MAO-A KO background. Our data indicate that the expression of an AD-related APP mutation could predispose to a depression-like phenotype, and that the loss of MAO-A could accelerate the AD process. We continue to examine the mechanism(s) underlying this intriguing observation.

Title: Guanine nucleotide exchange factor OSG-1 confers functional aging via dysregulated Rho signaling in Caenorhabditis elegans neurons

Authors: *F. SESTI, Z. DUAN;
Neurosci. and Cell Biol., Rutgers, Piscataway, NJ

Abstract: Rho signaling regulates a variety of biological processes, but whether it is implicated in aging, remains an open question. Here we show that a guanine nucleotide exchange factor of the Dbl family, OSG-1, confers functional aging by dysregulating Rho GTPases activities in *C. elegans*. Thus, gene reporter analysis revealed widespread OSG-1 expression in muscle and neurons. Loss of OSG-1 gene function was not associated with developmental defects. In contrast, suppression of OSG-1 lessened loss of function (chemotaxis) in ASE sensory neurons subjected to conditions of oxidative stress generated either during natural aging or by oxidative challenges or by genetic mutations. RNAi analysis showed that OSG-1 was specific toward activation of RHO-1 GTPase signaling. RNAi further implicated actin-binding proteins ARX-3 and ARX-5, thus the actin cytoskeleton, as one of the targets of OSG-1/RHO-1 signaling. Taken together these data suggest that OSG-1 is recruited in conditions of oxidative stress, a hallmark of aging and contributes to promote loss of neuronal function by affecting the actin cytoskeleton via altered RHO-1 activity.

Abstract: Mitochondria are dynamic and tubular organelles essential for normal neuronal physiology, and their dysfunction leads to the metabolic abnormalities observed in diabetes. In diabetic neuropathy, mitochondrial dysfunction is marked by decreased electron transport chain (ETC) activity, suboptimal rates of respiration and impaired calcium homeostasis. Although mitochondria normally produce ROS as by-products of ATP biosynthesis, hyperglycemia drives excessive electron donation to the ETC, resulting in the further production of ROS and leading to mitochondrial and cellular damage. Hyperglycemia also leads to the formation of advanced glycation endproducts (AGEs) which bind to their membrane receptor, RAGE. We have recently shown that RAGE signaling is required for malfunction of autonomic neurons in diabetes, and we hypothesize that RAGE signaling is linked to mitochondrial dysfunction. To test this hypothesis we investigated changes in mitochondrial dynamics in cultured autonomic neurons from the autonomic superior cervical ganglion (SCG) of mice and we exposed them to either control or high glucose conditions. To investigate the potential role of RAGE we used SCG neurons from RAGE knock-out mice(RAGE-/-) mice. To visualize and study live mitochondria, neurons were transfected with a vector containing enhanced green fluorescent protein (EGFP) fused to a mitochondrial signal peptide (MITO-EGFP). Our findings revealed that high glucose induces morphological changes in mitochondria in SCG neurons. Electron micrographs revealed an abundance of damaged mitochondria cristae and mitochondrial swelling in sections from STZ-diabetic mice, while control mice had preserver mitochondrial ultrastructure. Moreover, *in vitro* observation along neurites, showed that high glucose disrupted compensatory changes in mitochondrial dynamics in neurons from WT when compared to RAGE-/- mice. These changes in the WT neurons included a significant increase in the density and proportion only of mitochondria moving anterogradely, while in the RAGE-/- neurons there was a significant increase in the density and proportion of mitochondria moving both anterogradely and retrogradely. In addition, we found a significant reduction in the size of stationary mitochondria in neurons from WT but not from RAGE-/- mice. Therefore, since mitochondria in RAGE-/- neurons do not show changes in size/morphology, our data suggest that the observed changes in mitochondrial dynamics may be part of a compensatory response to high glucose, a task that is impaired by the activation of RAGE signaling.

Title: Iron restriction induces alterations in dopamine metabolism and PrPC expression

Authors: *J. M. PINO[1], H. K. M. ANTUNES[2], S. Q. D. GIAMPÁ[2], K. S. LEE[3];
[2]Psicobiologia, [3]Biologia Mol., [1]Univ. Federal De São Paulo UNIFESP, Sao Paulo, Brazil

Abstract: Neurodegenerative diseases can be characterized by protein aggregation, and reactive oxigen species (ROS) seems to contribute to this fenomenon. ROS can be produced by several metabolic pathways including dopamin metabolism. Dopamine (DA) can be enzimatically degraded generating hydrogen peroxide (H_2O_2) or auto-oxidated generating dopamine quinone. Celular príon protein (PrP^C) is one of the proteins that can directly react with dopamine metabolites *in vitro*, but the physiological meaning of this reaction is not clear. PrP^C is highly expressed glycoprotein that carries out important physiological functions in central nervous system. Several studies showed neuroprotective effects of PrP^C against oxidative stress. Thus the reaction between PrPC and oxidative metabolites of dopamine might be one of the protective mechanisms to neutralize ROS and alteration of dopamine metabolism might influence PrPC expression. Therefore in this study, we disturbed the dopamine metabolism by iron restriction in diets to investigate the expression levels of PrP^C. Male C57/BL6 mice were divided in two groups, one treated with normal diet (CTL) and the other treated with iron restricted diet (IR) for one month. Iron deficiency in IR group was verified by reduced iron and ferritin levels in liver, serum and hippocampus. Iron restriction also reduced the level of DA and its metabolites, dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) in striatum. However this decrease doesn't seem to be caused by a diminished DA synthesis, as the expression of tyrosine hydroxylase (TH) was not altered. In the prefrontal cortex, the HVA levels were augmented in IR group. Moreover, HVA concentration was correlated with the TH levels, suggesting that this increase was due to the enhanced DA synthesis and its rapid metabolization. Interestingly both HVA and TH showed a positive correlation with the PrP^C expression in prefrontal cortex. Our data show that PrP^C expression was influenced by DA metabolism in a brain region-specific manner.

Title: Effects of intermittent fasting on lipopolysaccharide-induced changes on glutamate-nitric oxide-Na,K-ATPase pathway during brain aging

Authors: *A. R. VASCONCELOS[1], P. F. KINOSHITA[2], L. M. YSHII[2], A. M. M. ORELLANA[2], A. E. BÖHMER[2], L. DE SÁ LIMA[2], R. ALVES[2], D. Z. ANDREOTTI[2], T. MARCOURAKIS[2], C. SCAVONE[2], E. M. KAWAMOTO[2];

Abstract: Introduction: Chronic neuroinflammation is a common characteristic of neurodegenerative disorders, such as Alzheimer's and Parkinson's diseases, that may contribute to loss of function and cell death. The signaling of the endotoxin Lipopolysaccharide (LPS) is linked to glutamate-nitric oxide (NO)-Na,K-ATPase isoforms pathway in the central nervous system (CNS) and also causes neuroinflammation. Intermittent fasting (IF, every other day feeding) induces adaptive responses in the brain that can suppress inflammation, but the age-related effect of IF on LPS modulatory influence on NO-Na,K-ATPase isoforms pathway is unknown. Methods: This work compared the effects of an inflammatory stimulus induced by LPS (1mg/kg, i.v. bolus, 2 hours before euthanasia) on α1,α2,3-Na,K-ATPase activity, nitric oxide synthase (NOS) gene expression and/or activity, cyclic guanosine monophosphate (cGMP), 3-nitrotyrosine (3-NT)-containing proteins, and levels of thiobarbituric acid-reactive substances (TBARS) in CNS of young (4 months) and older (24 months) male Wistar rats submitted to the IF protocol for 30 days. Results: LPS induced an age-related effect in neuronal nitric oxide synthase (nNOS) activity, cGMP, and TBARS levels in rat hippocampus that was linked to changes in α2,3-Na,K-ATPase activity, 3-NT proteins, and inducible NOS gene expression. IF induced adaptative cellular stress-response signaling pathways that reverts LPS effects in rat hippocampus of young and older rats. Conclusion: The results suggest that IF in both ages would reduce the risk for brain function deficits and neurodegenerative disorders linked to inflammatory response in the CNS.

Title: The effects of LRRK2 genetic mutations on mitochondrial dynamics in Parkinson's disease model

Authors: ***J. KIM**, J. KIM, J. JANG, H. SEO;
Hanyang Univ., Ansan, Korea, Republic of

Abstract: Parkinson's disease (PD) is progressive neurodegenerative disease that shows substantial loss of dopaminergic neuron in substantia nigra pars compacta (SNpc). Genetic mutation, oxidative stress, mitochondrial abnormalities and aging are main cause of PD. From previous studies, it is known that leucine-rich repeat kinase 2 (LRRK2), which contains GTPase and kinase domains, controls mitochondrial fission-fusion proteins. In this study, we focused on the effects of LRRK2 genetic mutations on mitochondrial function depending on age. LRRK2 G2019S and R1441G mice at old age showed significant decrease in the latency to fall in rotarod test. Mitochondria complex II/III activity was decreased in LRRK2 R1441G mutant mice compared to littermates (LM). The expression levels of mitochondrial fusion-fission related genes were determined in the striatum of LRRK2 G2019S and R1441G PD model mice. Our results suggest that mitochondrial dynamics can be applied for future therapeutic approach for PD.

Title: Age-dependent effects of RCAN1 overexpression on memory and synaptic plasticity

Authors: *H. WONG[1], J. LEVENGA[2], B. ROTHERMEL[3], E. KLANN[1], C. HOEFFER[2]; [1]Neural Sci., New York Univ., New York, NY; [2]Inst. for Behavioral Genet., Univ. of Colorado, Boulder, CO; [3]Dept. of Cardiol., UT Southwestern Med. Ctr., Dallas, TX

Abstract: Patients with Down syndrome (DS) and DS model mice display symptoms consistent with early onset Alzheimer's disease (AD), suggesting that factors involved in DS may also play a role in AD onset. DS is caused by trisomy of all or part of chromosome 21, resulting in overexpression of genes within this region. One such gene is Regulator of calcineurin 1 (RCAN1). RCAN1 is a potent regulator of the calcium/calmodulin-dependent phosphatase calcineurin and is required for long-lasting memory and synaptic plasticity. Interestingly, overexpression of RCAN1 has been observed in brain tissue from not only DS patients but also AD patients. To understand the potential contribution of chronically high RCAN1 levels in the progression of neurodegenerative disease, we generated transgenic mice that overexpress RCAN1 in the brain using the cre/lox system. We found that selective overexpression of a human RCAN1 isoform in the mouse forebrain leads to the development of behavioral and plasticity deficits with age. Aged but not young RCAN1-overexpressing mice display impaired hippocampus-dependent memory and synaptic plasticity. To explain these age-dependent effects, we investigated the biochemical differences between young and aged transgenic mice and found a role for oxidative stress. Overall, this work should provide insight into the molecular basis of the cognitive phenotypes and neurodegeneration associated with DS and AD and whether RCAN1 may be a therapeutic target for treatment of these neurological disorders.

Title: HMGB1 sensitizes microglia in the aged brain causing prolonged inflammation and cognitive impairments following infection

Authors: *L. K. FONKEN, M. M. KITT, M. G. FRANK, R. M. BARRIENTOS, L. R. WATKINS, S. F. MAIER;
Univ. of Colorado, Boulder, CO

Abstract: Healthy aged individuals can experience precipitous cognitive decline, typically following events that induce peripheral inflammation (e.g. infection, surgery, or injury). Peripheral immune stimuli cause exaggerated and prolonged inflammatory responses in the aged brain and these changes likely underlie increased susceptibility to cognitive impairments. However, the mechanisms that prime the inflammatory response in the aged brain are poorly understood. Here we propose that HMGB1 activates the NLRP3 inflammasome in the aged brain, resulting in neuroinflammatory priming. Following an E. coli injection, young rats (3 mos FBN) resolve neuroinflammatory responses within 24 h, whereas at 4 d post-E. coli aged rats (24 mos) still show cognitive deficits and elevated pro-inflammatory cytokines (including IL-1β and IL-18) in the hippocampus. Mature IL-1β and IL-18 are produced by the NLRP3 inflammasome, which is basally elevated in the aged brain along with other key inflammatory genes such as MHCII, toll-like receptors, and HMGB1. Previous research indicates that sub-septic levels of HMGB1 do not necessarily induce a pro-inflammatory cytokine response in the brain; rather, HMGB1 potentiates the effects of a subsequent neuroinflammatory challenge. Thus, to test whether increased HMGB1 in aged rats elicits neuroinflammatory priming, we blocked endogenous HMGB1 activity with the antagonist Box-A. Intra-cisterna magna (ICM) injection of Box-A down-regulated expression of several inflammatory pathway genes - including NLRP3 - in the hippocampus of aged rats. Importantly, Box-A did not alter gene expression in young rats, suggesting it may not interfere with non-pathological immune responses in young animals. The administration of ICM Box-A to aged rats 24 h prior to an E. coli injection prevented the protracted hippocampal inflammatory response. Furthermore, aged rats displayed cognitive impairments in a fear-conditioning paradigm 4 days following E. coli injection, and these impairments were reduced by Box-A pretreatment. Finally, we investigated whether HMGB1 mediates inflammatory priming through action on microglia, the primary innate immune cells of the central nervous system. ICM pretreatment with Box-A prevented priming in *ex vivo* microglia stimulated with LPS. Overall, these experiments indicate that elevated HMGB1 in the aged brain may prime the NLRP3 inflammasome in microglia, thereby driving an exaggerated and prolonged neuroinflammatory response following peripheral immune challenge. Ongoing experiments will identify the cellular source of increased HMGB1 in the aged brain.

Title: Differences in plasma and CNS cytokine levels in adult and ageing rats

Authors: ***I. P. JOHNSON**[1], V. KATHARESAN[1], M. D. LEWIS[2], R. VINK[3];
[1]Univ. of Adelaide, Adelaide, Australia; [2]Mind and Brain theme, South Australian Hlth. and Med. Res. Inst., Adelaide, Australia; [3]Div. of Hlth. Sci., Univ. of South Australia, Adelaide, Australia

Abstract: It has been proposed that an increase in inflammatory cytokines in the blood and the central nervous system (CNS) explains many aspects of ageing, including age-related neurodegeneration. In this study, we distinguished age-related changes in CNS cytokines from those occurring in the blood (systemically), by analysing CNS after flushing the blood from its vessels. Groups of 3-5 female Sprague-Dawley rats aged 3 months, 12-18 months and 24 months were used. The open-field test measured exploratory behaviour and general anxiety levels as total distance travelled using the Stoelting "ANY-maze" software. Rats were deeply anaesthetised and blood plasma was obtained and stored at -80°C. Transcardial perfusion with saline followed immediately, brainstem was then removed, trimmed at the mid-pons level, homogenised and the supernatant stored at -80°C. Protein estimation assays ensured the same amount of protein was loaded for each sample. The Bio-Plex Pro Rat 12plex cytokine assay kits were used to measure the concentration of twelve cytokines (IL-1α, IL-β, IL-2, IL-4, IL-5, IL-6, IL-10, IL-12p70, IL-13, TNFα, IFN-γ and GM-CSF) in both plasma and brainstem samples as duplicates for 3m and 12-18m rats and triplicates for 24m rats. The Magpix Luminex multiplexing platform was used to quantitate cytokines. A general linear model generated descriptive statistics following by multivariate ANOVA and Dunnett's post-hoc test to report statistical significance of $p<0.05$, $p<0.01$ and $p<0.001$. Both 3m- and 12-18m old rats showed significantly larger exploratory behaviour and higher anxiety levels compared to 24m old rats. 3m old rats had higher mean concentrations of IL-5, IL-6 and IFNγ compared to 12-18m rats in the brainstem with no significant differences in the plasma. However, 3m old rats had lower mean concentrations of IL-1α, IL-2, IL-4, IL-10 and TNFα compared to 24m old rats in the brainstem. Interestingly, 3m old rats had higher mean concentrations of IL-12p70 and TNFα in plasma compared to 24m old rats. In addition, 24m old rats have higher levels of IL-1α, IL-4, IL-

6, IL-13, TNF-α, IFNγ and GM-CSF in the brainstem compared to 12-18m old rats with no differences in plasma. Contrary to current assumptions, our results indicate that ageing is associated with a general decline in peripheral inflammatory cytokines but a general increase in central inflammatory cytokines. This may reflect an intrinsic loss in competency of peripheral immunity with age or alternatively be the result of a regulatory system where increased levels of central inflammation negatively feedbacks to the periphery.

Title: Ameliorating age-related deficits in hippocampal function through viral overexpression of CREB protein

Authors: *X.-W. YU[1], D. M. CURLIK, II[1], M. M. OH[1], J. C. P. YIN[2], J. F. DISTERHOFT[1]; [1]Feinberg Sch. of Med., Northwestern Univ., Chicago, IL; [2]Genet., Univ. of Wisconsin, Madison, WI

Abstract: Humans and animals often display learning and memory impairments as they age, however the underlying mechanisms of these impairments are poorly understood. Identifying the molecular pathways that mediate these impairments will allow us to design therapeutics to prevent or reverse these deficits. One important brain region for learning and memory is the hippocampal CA1 region. The Disterhoft laboratory has shown that CA1 pyramidal neurons from cognitively-impaired aged rats are less excitable than those from young and cognitively-unimpaired aged animals. These and many other experiments suggest that an age-related decrease in the excitability of CA1 pyramidal neurons mediates age-related cognitive impairments. Of note, the nuclear transcription factor cAMP response element binding protein (CREB) has been found to be a modulator of neuronal excitability. Additionally, our recent experiments have revealed that basal levels of phosphorylated CREB (pCREB) are decreased in dorsal hippocampus with age, and that pCREB levels correlate with behavioral performance during a hippocampal-dependent spatial learning task. Previous studies in young adult animals have shown that increasing CREB levels can enhance both excitability of CA1 pyramidal

neurons, and learning and memory. Together, these results suggest that elevating CREB levels in aged animals will ameliorate deficits in both excitability, and learning and memory. Therefore, this project used an adeno-associated virus to overexpress CREB in CA1 of young and aged rats. Levels of CREB mRNA were increased in infected regions of CA1, confirming virally mediated overexpression of CREB. As predicted, we found that infected cells were more excitable than control cells. On-going experiments are being conducted to confirm that increases in total and activated CREB protein will ameliorate age-related learning and memory deficits. This work is supported by NIH R37 AG008796 and T32 AG020506, and the Glenn/AFAR Scholarship for Research in the Biology of Aging.

Title: Effects of the anti-aging hormone Klotho on AKT/FoxO signaling in the central nervous system

Authors: ***C. MAZUCANTI**, M. CARARO, T. SALA, L. YSHII, C. SCAVONE;
Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: INTRODUCTION: Klotho gene, a senescence associated gene, was originally identified by insertional mutagenesis in mice and codifies a single pass type I transmembrane protein, known as Klotho. Klotho protein has been considered an aging phenotype repressor, since its suppression in mice precipitates age-related characteristics, such as arteriosclerosis, osteoporosis, skin atrophy, infertility, early thymus involution and pulmonary emphysema, as early as 4 weeks old. Life expectancy of these mice is very low, normally not greater than 8 weeks. Membrane-bound Klotho acts as an obligatory FGF23 co-receptor, hence playing a crucial role on phosphate metabolism. By suffering a shedding process Klotho can be cleaved from its transmembrane domain and act as a regulatory hormone, acting upon ion channels (e.g. TRPV5 and ROMK1) and repressing Wnt and Insulin/IGF signaling. FoxO is a class of transcription factors known to be regulated by insulin signaling and that has been for quite some time related to anti-aging properties. OBJECTIVES: The objective of this work is to study the influence of Klotho protein upon insulin signaling in the hippocampus of mice lacking Klotho protein, tracking its effects on FoxO phosphorylation and activation state. METHODS: 2 months

old, male klotho knockout mice (and its genotype variants), were euthanized and its hippocampi dissected and collected for western blotting analysis. AKT, mTOR, FoxO1a and FoxO3 phosphorylation states were assessed by calculating the ratio between phosphorylated form and total form of such proteins. For astrocyte-rich cultures, 3 days old pups were decapitated and its cerebral cortices dissected and digested (both enzymatically and mechanically) for primary cell culture. Culture was maintained in a humidified CO2 incubator, in DMEM supplemented with FBS 10% until they reach 100% confluence. At this point, cultures were shaken in an orbital shaker, at 37oC, 180 RPM for 15 hours. Astrocytes, strongly attached to the bottom, were then pre-treated with recombinant Klotho (0,5nM) for 24 hours, and then challenged with H2O2 500µM for 30 minutes. Cell viability was assessed via MTT reduction. RESULTS: It is clear that in the hippocampi of Klotho knockout mice, AKT signaling is enhanced and its phosphorylation on Ser473 induces inactivation of both Foxo1a and FoxO3. Klotho-treated astrocytes displayed higher viability when challenged with H2O2, linking FoxO activity with anti-oxidant defense. CONCLUSIONS: Klotho can modulate insulin signaling and therefore modify FoxO activity. Anti-oxidant properties of this transcription factor may be correlated to its effects as an aging suppressor.

Title: Activation of the A2A adenosine receptor protects PC12 cells from the H2O2-induced DNA damage by TRAX

Authors: *Y. CHERN[1], T. CHIEN[2], S.-Y. CHANG[3], H.-L. LAI[3];
[1]Inst. Biomed Sci., Taipei, Taiwan; [2]Inst. of Life Sci., National Defense Medical Center, Taipei, Taiwan; [3]Inst. of Neuroscience, Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Adenosine has been implicated in a wide variety of physiological functions via four adenosine receptors (A1, A2A, A2B and A3). The A2A adenosine receptor (A2AR) is a G-protein coupled receptor, which is located in many brain areas with the highest level in the striatum. We previously reported that the translin- associated protein X (TRAX) is an interacting protein of the C terminus of A2AR. TRAX was first identified as an interacting protein of a DNA/RNA binding protein (translin), which functions in controlling mRNA transport,

translation, DNA repair, and DNA recombination. It was shown earlier that, upon γ-irradiation, TRAX interacts specifically with C1D (an activator of DNA- dependent protein kinase), and might play an important role in DNA repair of double-strand breaks. In the present study, we demonstrated that stimulation of A2AR by an A2AR-selective agonist (CGS21680) markedly ameliorated the DNA double-strand breaks evoked by elevated oxidative stress through TRAX in a neuronal cell line (PC12). Moreover, stimulation of A2AR might facilitate the non-homologous end joining (NHEJ) repair activity by enhancing the activation and phosphorylation of DNA-dependent protein kinase (DNA-PK) at T2609. Collectively, TRAX might contribute to the activation of DNA-PK in the detection of DNA double-strand breaks induced by oxidative stress.

Title: Pattern recognition receptor activity increases NF-κB signaling in cerebellar granule cells: A potential mechanism for age-associated alterations in neuronal structure and function

Authors: ***N. W. DEKORVER**, J. ARIKKATH, S. J. BONASERA;
Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: In a mouse model of age-associated locomotor decline, pattern recognition receptor (PRR) and immune molecule expression is increased in a region specific manner in the aging brain, and these changes do not localize to microglia. Many PRRs signal through conserved cellular pathways, one of which is nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB). NF-κB dysregulation is involved in numerous disease processes and has been implicated in aging. We hypothesize that increased PRR expression and subsequent activation in the aging brain leads to dysregulation of NF-κB signaling and thereby alterations in neuron structure and function. To test this hypothesis we developed an enriched primary cerebellar granule cell culture (pCGC) system that we then characterized for PRR expression. The effect of PRR activity on NF-κB signaling was tested by stimulating pCGC cultures with agonists for select pattern recognition receptors expressed in culture and increased in the aging cerebellum. Stimulation of the PRR toll-like receptor 2 (Tlr2) with synthetic triacylated lipoprotein (Pam3CSK4) led to a time dependent increase in nuclear p65 and increased phosphorylated p65, both markers of active NF-κB. Additionally, stimulation of Tlr2 led to time dependent increases in NF-κB regulated transcriptional products including Tlr2, complement 3, beta-2 microglobulin,

Fc fragment of IgE, and nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor alpha (IκBα), further demonstrating increased activation of NF-κB signaling. There was no increase observed in toll-like receptor 4 transcript, suggesting specificity for NF-κB mediated transcripts. Additionally, pretreatment of primary cerebellar granule cells with pyrrolidine dithiocarbamate (PDTC), an inhibitor of NF-κB activity, attenuates Pam3CSK4 mediated increases in phosphorylated p65 and partially attenuates transcriptional changes. These results demonstrate that stimulation of specific PRRs in cerebellar granule cell cultures leads to increased p65 translocation, phosphorylation, and production of NF-κB regulated transcriptional products. Many of the transcriptional products that increased with stimulation of Tlr2 are present at increased levels in the aged C57BL6 mouse and human cerebellum. It is our goal to use this system to further characterize the pathway from PRR stimulation to NF-κB activation, including mechanisms of NF-κB regulation in cerebellar granule cells. Understanding these mechanisms may provide neuron specific targets for pharmacological intervention in diseases with known NF-κB dysregulation.

Title: Changes in nutrient sensing pathways alter bio-energetics and are upstream of age dependent changes in microglial phenotype

Authors: *A. FLOWERS[1], H. BELL-TEMIN[1], L. DALY[1], S. M. STEVENS[2], P. BICKFORD[3]; [1]Mol. Pharmacol. and Physiol., Univ. of South Florida, Tampa, FL; [2]Biochem., [3]Mol. Pharmacol. and Physiol., Univ. of South Florida, tampa, FL

Abstract: Microglia play a pivotal role in the homeostasis of the brain and their proper functioning requires dynamic control over migration, expansion/contraction, and proper response to environmental signals. The objective of this study was to identify age dependent changes in microglial cellular components that could potentially contribute to priming, a state where microglia are over-responsive to pro-inflammatory and under responsive to anti-inflammatory signals. To accomplish these objectives we used SILAC labeled mass spectrometry. We attained primary microglia from brains of 5 month and 22 month C57BL/6 mice. 250 proteins were differentially expressed ($p<0.05$) between young and old. Ingenuity Pathway Analysis was performed on all differentially expressed proteins with at least a 1.5 fold change and a $p<0.05$

statistical cut-off. Top canonical pathways were EIF2 signaling, Isoleucine degradation, ketolysis, ketogenesis, and Gluataryl-CoA Degradation. Analysis of upstream regulators predicted an inhibition of RICTOR, PSEN2, PSEN1, and MAPK1. Alterations in Rictor an essential component of the mTORC2 signaling complex were one explanation for the observed changes in amino acid metabolism. To further investigate we used siRNA specific for RICTOR and knocked down mTORC2 activity in a microglial cell line. Decreasing mTORC2 activity recapitulated the aged microglial phenotype resulting in an increased M1 polarization and a decreased response to M2 activators. We followed this experiment by examining the activity of the mTORC1 and mTORC2 pathway in young and aged microglia by examining phosphorylation of their downstream targets. Our findings indicate that Impairments in amino acid metabolism may represent a first hit to the downstream disruption bioenergetics. This disruption likely leads to an increased reliance on glycolysis for energy production, resulting in an increase in M1 polarization. Because chronic inflammation contributes to the progression of degenerative disease, understanding age-induced impairments in microglial polarization are key to the development of therapeutics. Our findings suggest that nutrient sensing pathways are altered with age and contribute to loss of immune homeostasis.

Title: Neuroinflammation, dopaminergic neurodegeneration and behavioral impairment in hyperglycemic rats

Authors: K. DUFRESNE[1], J. RENAUD[1], N. ST-AMAND LUNA[1], C. LAVOIE[1], G. COSTA[2], N. SIMOLA[2], M. MORELLI[2], *M. MARTINOLI[1];

Abstract: It is now well known that hyperglycemia is a cause of oxidative stress reported to be harmful for the nervous system. Epidemiological evidence displays a relationship between diabetes and neurodegenerative disorders, including Alzheimer's disease [1] and Parkinson's disease [2]. We have recently shown that dopaminergic neurons in culture are vulnerable to physiologically sustainable high levels of glucose by exhibiting increased production of reactive

oxygen/nitrogen species, expression of pro-apoptotic markers and cell death [3,4]. In light of these results, this study aimed to characterize dopaminergic neurodegeneration in a streptozotocin-nicotinamide rat model of chronic hyperglycemia and metabolic impairment. Male Sprague-Dawley rats were injected with nicotinamide followed by streptozotocin, and metabolic parameters were monitored for five months. During the last three weeks, ultrasonic vocalizations and social behavior were recorded in pairs of unacquainted rats in a novel environment. At 5 months, rats were sacrificed, and brain and intestinal tissues were harvested for immunoblotting or immunohistochemical analyses. Metabolic measurements show that streptozotocin-nicotinamide-injected rats were hyperglycemic and metabolically impaired, as demonstrated by modulation of weight, glucose tolerance, plasma insulin levels, polyuria, polydipsia and polyphagia, as compared with control rats. In addition, ultrasonic vocalization patterns, which are critically regulated by dopaminergic pathways [5], were disrupted in pairs of hyperglycemic rats compared to pairs of control rats. Freezing and aggressive incidents were also notably increased in these rats compared to control animals. Further experiments were performed to detect dopaminergic neurodegeneration in hyperglycemic rat midbrains and mesenteric plexus, which houses up to 50% of total dopamine in the body. Our results show a definite modulation of dopaminergic function and neurodegeneration accompanied by neuroinflammation in hyperglycemic rats. Altogether, our data evoke a correlation between hyperglycemia and dopaminergic neurodegeneration with a component of neuroinflammation, which provides new insight on the higher occurrence of PD in diabetic patients. 1. Title: Establishing an animal model to study the neurobiology of obesity and ageing

Authors: ***J. K. SINHA**, S. GHOSH, M. RAGHUNATH;
Natl. Inst. of Nutr. (NIN), Hyderabad, India

Abstract: Purpose: Proportion of aged individuals is on the rise in general population and non-communicable diseases like obesity is a leading cause of death in older individuals. Wistar of National Institute of Nutrition obese (WNIN/Ob) rat is a novel strain developed at NIN, Hyderabad, India. These rats have significantly reduced average lifespan of 15-18 months in contrast to 36 months in normal WNIN rats. Elucidation of various molecular and biochemical characteristics in these rats would help to establish it as an appropriate model to study the neurobiology of ageing and obesity. Methods: Different growth characteristics were studied and the lifespan analysis was performed using OASIS software. The neuronal and glial changes were studied using Nissl staining and immunohistochemistry. Levels of oxidative stress, antioxidant enzyme activity and extent DNA damage were studied in various brain parts. Results: The brain weights were significantly decreased and there was a 60% decrease in the total lifespan in the WNIN/Ob obese rats as compared to the lean littermates as well as WNIN normal rats. Neuronal and glial changes that were observed in these rats were in line with other brain ageing studies. In addition, oxidative stress levels and extent of DNA damage were observed to be significantly high in the brain of young WNIN/Ob obese rats as compared to age-matched rats and it was as high as that observed in 15 months old WNIN normal rats. The levels of antioxidants enzyme activity were also significantly low in the WNIN/Ob obese rats. Conclusion: Onset of various degenerative features like increased oxidative stress, astrogliosis, DNA damage and decreased antioxidant levels in different brain regions of WNIN/Ob obese rats at a much younger age is a plausible cause of reduced longevity observed in this novel obese rat model. This model may be used to study the connecting link between obesity and ageing.

Title: Modulation of metabolic parameters and antioxidant enzymes in diabetic aging female rat brain: Beneficial role of Metformin

Authors: *P. KUMAR, N. BAQUER;
Jawaharlal Nehru Univ., New Delhi, India

Abstract: Objective: The objective of this study was to investigate beneficial effects of metformin on membrane bound enzymes (monoamine oxidase, Na^+ K^+ ATPse,) and antioxidant enzymes (sueroxidase dismutase, glutathione S-transferases), lipid peroxidation, neurolipofuscin, DNA degradation in diabetic aging brain of female rats. Methods: Young (3 months) adult (12 months) and aged (24 months) rats will be diabetic by using alloxan monohydrate. Metformin

was administered i.p. at a dose of 200 mg/kg/day for 30 days to both control and diabetic aging rats. Learning was tested in a Morris water maze. A detailed study was carried on membrane linked enzymes, membrane fluidity, neurolipofuscin, antioxidant enzymes and DNA degradation to identify the antidiabetic and antiaging role of metformin using biochemical ,molecular and histiochemical study. Results: Present study shows that there was a similar pattern of increased lipid peroxidation, neurolipofuscin, DNA degradation and monoamine oxidase activity and a decrease in membrane fluidity, Na^+ K^+ ATPse, antixodant enzymes activities in brain of both aging and diabetes. Metformin was found to be an effective treatment in stabilizing and normalizing the membrane functions; therefore this therapy can be considered an alternative to be explored further as a means of diabetic and aged related disorders control. Metformin treatment also reversed the age related changes studied, to normal levels, elucidating an anti-aging, antidiabetic and neuroprotective action. Conclusions: The results of this study will be useful for pharmacological modification of the aging process and applying new strategies for control of age related disorders including metabolic syndrome.

Title: Longevity manipulations differentially affect serotonin/dopamine level and behavioral deterioration in aging caenorhabditis elegans

Authors: *J.-A. YIN, X. LIU, J. YUAN, S. CAI;
Inst. of Neuroscience, SIBS, CAS, Shanghai, China

Abstract: Aging is accompanied with behavioral and cognitive decline. Changes in the neurotransmitter level are associated with the age-related behavioral deterioration, but whether well-known longevity manipulations affect the function of neurotransmitter system in aging animals is largely unclear. Here we report that serotonin (5-HT) and dopamine (DA) level decrease with age in *C. elegans*. The reduction results in down regulation of the activity of neurons controlled by 5-HT/DA signaling, and deterioration of some important behaviors, including pharyngeal pumping, food-induced slowing responses, and male mating. Longevity manipulations differentially affect the age-related decline in neuronal level of 5-HT/DA. The reduction and resultant behavioral deterioration occur in long-lived worms with defective insulin signaling [daf-2(e1370), age-1(hx546)] or mitochondria function [isp-1(qm150), tpk-1(qm162)], but not in long-lived worms with dietary restriction eat-2(ad1116). A reduced expression level of dopa decarboxylase BAS-1, the shared enzyme for 5-HT/DA synthesis, is responsible for the

decline in 5-HT/DA levels. RNAi assay revealed that the sustained 5-HT/DA level in neurons of aged eat-2(ad1116) worms requires PHA-4 and its effectors superoxide dismutases and catalases, suggesting the involvement of reactive oxygen species in the 5-HT/DA decline. Furthermore, we found that elevating 5-HT/DA ameliorates age-related deterioration of pharyngeal pumping,food-induced slowing responses,and male mating in both wild-type and daf-2(e1370) worms.Together,dietary restriction preserves healthy behaviors in aged worms at least partially by sustaining a high 5-HT/DA level, and elevating the 5-HT/DA level in wild-type and daf-2(e1370) worms improves their behaviors during aging.

Title: Inhibition of dopamine transporter by arachidonic acid oxidation is associated with γ-ketoaldehyde adduct formation in PC12 cells

Authors: ***J. A. PINO**[1], N. OSSES[2], T. B. BAUST[1], C. A. VALLE[3], J. G. REYES[2], G. E. TORRES[1];
[1]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA; [2]Pontifical Catholic Univ. of Valparaiso, Valparaiso, Chile; [3]Univ. of Viña del Mar, Viña del Mar, Chile

Abstract: Oxidative stress and dysfunction of the dopamine transporter (DAT) underlie pathologies such as Parkinson's disease, a brain associated disorder where arachidonic acid (AA) is abundant as an acyl chain in phospholipids. AA oxidation produces γ-ketoaldehydes (γ-KAs) species, that can modify protein structure and function by forming adducts. Although, previous reports have shown that AA produces a decrease in DAT activity, the impact of AA lipid peroxidation, possible γ-KA-DAT adduct formation and the resulting effects on DAT functionality have not been examined. In this study, PC12 cells overexpressing DAT were incubated under different experimental conditions and the γ-KA-DAT adducts formation and DAT function were evaluated. When PC12 cells were incubated with AA under oxidative conditions or with synthetic γ-KAs, a significant increase in the amount of γ-KA-DAT adducts was observed compared to the control condition. In addition, the formation of γ-KA-DAT

adducts was associated to a significant decrease in the maximal velocity (Vmax) of DAT, an effect that could be reversed by the specific γ-KA scavenger, salicylamine. Consequently, our results strongly suggest that γ-KAs are covalent modifiers and inhibitors of DAT function in cells, and support a novel mechanism for oxidative stress-related DAT protein dysfunction and altered dopaminergic transmission.

Abstract: Mitochondria are the 'power-houses' of all cells, generating ATP to fuel numerous pathways which are vital for cellular form and function [1]. Neuronal processes and synapses present a constant demand for ATP to maintain ionic gradients and neurotransmission events [2], promoting sub-populations of mitochondria to be enriched pre- and post-synaptically [3, 4]. These mitochondria display unique enzymatic [5], calcium buffering [6, 7] and antioxidant properties [8] and have thus been associated in the pathogenesis of a variety of neurodegenerative diseases where the synapse is the primary target. We have used label-free proteomics to characterise the proteomes of these synaptic and non-synaptic mitochondria at a basal level after following early biochemical isolation methods [5]. By utilizing this methodology we have generated a species-specific molecular fingerprint and demonstrated distinct proteomic profiles between the two sub-populations of mitochondria, dependent upon sub-cellular localisation. Quantitative fluorescent western blotting was used to validate the proteomic studies in a range of species, suggesting that the data may be an accurate reflection of the fingerprint for distinct mitochondrial populations. These results also suggest that mitochondrial neuronal sub-populations and their relative protein abundances are likely conserved between mammals. Following this, *in vivo* assays of mitochondrial candidates using

Drosophila larval fillet preparations were performed. Our data demonstrates that selective knock-down of intrinsic mitochondrial proteins alter synaptic morphology which may contribute to pathological processes during ageing and disease.

Title: The role of STK3 in neurodegeneration : Brain region-specific alterations in the aging process

Authors: *M. LESSARD-BEAUDOIN[1,3], M.-J. DEMERS[1,3], M. LAROCHE[1,3], G. GRENIER[2], R. GRAHAM[1,3];
[1]Dept. of pharmacology and physiology, [2]Dept. of Surgery, Univ. of Sherbrooke, Sherbrooke, QC, Canada; [3]Res. Ctr. on Aging, Sherbrooke, QC, Canada

Abstract: Neurodegenaration is observed in several neurological diseases including Alzheimer disease, and Huntington disease (HD), and in the aging process. Caspase-6 (casp6) activation and cleavage of several casp6 substrates is a key pathological event in many neurodegenarative diseases. In HD, casp6 cleavage of mutant huntingtin produces a neurotoxic fragment essential to the development of HD. Characterization of the casp6 interactome will improve our understanding of the causes and consequences of its overactivation and identify novel therapeutic targets for neurodegenerative diseases. Preliminary results reveal cleavage of Serine/Threonine Kinase 3 (STK3) by casp6. As a fragment of STK3 has previously been shown *in vitro* to have proapoptotic functions, the generation of a caspase cleaved STK3 fragment *in vivo* could influence neurodegenerative pathways.In order to define the function of STK3 and characterise its potential role in neurodegeneration and in aging process, the expression of STK3 and

caspases were analysed in the cortex, cerebellum and striatum of C57BL6 wild type male mice at 3,12,23-28 and >30 months of age. STK3 mRNA increases in the cerebellum ($p=0.057$) and striatum ($p<0.0001$), and decreases in the cortex ($p=0.003$) of C57BL6 male mice with age. STK3 protein expression (full-length and fragment levels) increases in all brain regions with age. Interestingly, a 2-3 fold increase is observed for the full-length ($p=0.0006$) and the fragment ($p=0.0002$) of STK3 in the cortex. Casp6 mRNA decreases in the cortex ($p=0.04$) and increases in the striatum ($p=0.0006$) and the cerebellum ($p=0.0009$) with age. However, casp6 protein expression increases in the cortex ($p=0.03$) and cerebellum ($p=0.012$) and decreases in the striatum ($p=0.06$) with age. Protein expression of caspase-3, which has previously been shown to also cleave STK3, decreases in the cerebellum ($p=0.03$) with aging. These results suggest that important dysregulation occurs in the expression and post-translational modifications of STK3 with aging. Moreover, the caspases known to cleave STK3 are dysregulated in a region-specific manner. This provides important information regarding their understanding in the aging process, and can serves as comparative data for HD and other age-associated diseases.

Title: Glyceraldehyde-3-phosphate dehydrogenase regulates c-jun N-terminal kinase activation under oxidative stress conditions

Authors: *K. SATO, M. ITAKURA, Y.-T. AZUMA, T. TAKEUCHI, H. NAKAJIMA; Osaka Prefecture Univ., Izumisanoshi, Japan

Abstract: Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) has diverse functions and introduce of cell death under oxidative stress. Mitogen-activated protein kinase (MAPK) is also established as a candidate of an important signaling pathway under oxidative stress. MAPK pathways lead to various cellular responses including cell proliferation, differentiation, and apoptosis. Recently, it has been reported that GAPDH interacts with apoptosis signal-regulating kinase1 (ASK1) which is upstream kinase of MAPK pathway. In addition, it is revealed that oxidative stress-induced ASK1 activation emerges cellular dysfunction evoked by oxidized GAPDH. It is, however, not clear how oxidized GAPDH is involved in MAPK pathways. Therefore, we examined the activation level of each typical MAPK such as an Extracellular Signal-regulated kinase, p38, or c-jun N-terminal Kinase (JNK) in GAPDH-knockdown HEK cells under exposure of oxidative stress. While treatments of cells with GAPDH-siRNA reduced

significantly the hydrogen peroxide (H2O2)-induced JNK activation, there is no influence of both Extracellular Signal-regulated kinase and p38 activation. We next investigated the protein-protein interaction between GAPDH and JNK using an immunoprecipitation assay. The GAPDH-JNK interaction was observed only by the treatment with H2O2, suggesting that its interaction is likely to depend on oxidized GAPDH. Moreover, we conducted an experiment using human GAPDH-knockdown cells transiently expressing rabbit wild type (WT) or the active site cysteine-substituted mutant GAPDH that lacks the ability to bind JNK. In GAPDH-knockdown cells, decline of JNK activation was restored by conducting exogenous rabbit WT-GAPDH, but was not by that of its mutant. Thus, oxidized GAPDH is essential for H2O2-induced JNK activation. Together, these findings suggest that GAPDH binds to JNK in an oxidative stress-dependent manner, resulting in JNK activation.

Title: Role of surface MHCI in mediating negative effects of B2M and old blood on cognitive and regenerative function

Authors: *C. SNETHLAGE, L. SMITH, K. LIN, G. GONTIER, K. PLAMBECK, J. UDEOCHU, E. WHEATLEY;
Anat., UCSF, San Francisco, CA

Abstract: Aging drives cognitive and regenerative impairments in the adult brain, increasing susceptibility to neurodegenerative disorders in healthy individuals. Experiments using heterochronic parabiosis (in which the circulatory system of a young and old animal are joined) have demonstrated that age-related changes in the systemic environment drive aging phenotypes in the brain, indicating pro-aging factors in old blood. Previously we identify β2-microglobulin (B2M), a component of major histocompatibility complex class 1 (MHC I) molecules, as a pro-aging factor that negatively regulates cognitive and regenerative function in the adult hippocampus in an age-dependent manner. However, the specific mechanism by which B2M and old blood act on cognitive and regenerative function in the hippocampus is still unknown. We hypothesized that surface MHC I mediates the negative effects of B2M and old blood on

cognitive and regenerative function. Here we report that local hippocampal administration of exogenous B2M results in impairments in spatial learning and memory, as well as contextual fear conditioning following short-term recovery. Moreover, the negative effects of B2M on cognitive function were reversed after long-term recovery. To test if surface MHC I is involved in mediating cognitive effects of B2M, we used a genetic mouse model expressing reduced levels of surface MHC I (Tap1-/-), and detected no impairments in these mice after hippocampal B2M administration. Next we investigated the effects of B2M on regenerative function, and detected an MHC I-dependent decrease in neurogenesis after local exposure to B2M. Subsequently, we investigated whether reduced surface MHC I could also mitigate the negative effects of old blood elicited by heterochronic parabiosis. Consistent with previous reports we observed a decrease in neurogenesis in young wild type heterochronic parabionts. However, decreased neurogenesis was in part mitigated in young Tap1-/- heterochronic parabionts expressing reduced surface MHC 1. Collectively, these data show that surface expression of classical MHC I molecules plays an important role in regulating the negative effects of pro-aging factors in old blood, including B2M. Our work now identifies MHC I molecules as potential future therapeutic targets aimed at counteracting age-related cognitive and regenerative impairments.

Title: Role of classical MHC I molecules H2-Kb and H2-Db in regulating adult neurogenesis and cognitive function with age

Authors: *K. LIN, L. K. SMITH, S. A. VILLEDA;
Anat., UCSF, San Francisco, CA

Abstract: Aging in the brain is a multifaceted process in which changes in regenerative capacity and functional integrity lead to cognitive decline and susceptibility to neurodegenerative diseases. Identifying methods to prevent or even reverse the effects of aging in the brain is thus

critical. Adult neural stem cells (NSCs) have been at the center of exciting attempts to curb age-related cognitive dysfunction. However, in order to use regenerative therapeutics to restore cellular and cognitive functions in the aging brain, we must first understand the mechanisms underlying changes in NSC function with age. Previously, using heterochronic parabiosis (in which the circulatory systems of young and old animals are joined) we have shown that age-related changes in the systemic environment can induce aging phenotypes in the brain; furthermore, we have identified β2-microglobulin (B2M), a component of the major histocompatibility class 1 (MHCI) molecules, as a pro-aging factor affecting the hippocampal neurogenic niche. Here, we implicate a specific subset of classical MHCI molecules, H2-Kb and H2-Db, in negatively regulating adult neurogenesis and associated hippocampal-dependent functions. Absence of H2-Kb and H2-Db in young adult MHCI knockout mice resulted in a decreased pool of Tbr2-positive intermediate progenitors while increasing neurogenesis and neuronal survival in the hippocampus *in vivo*. This robust increase in neurogenesis at young age ultimately led to stem cell exhaustion and decreased neurogenic output in aged MHCI knockout mice. At a cognitive level, adult MHCI knockout animals also exhibited differences in their performance in the radial arm water maze and contextual fear conditioning paradigms, indicating changes in hippocampal-dependent learning and memory. Collectively, this work reveals a novel role for classical MHCI molecules in regulating the age-related decline in adult neurogenesis and cognitive function. Given MHCI expression increases in the aging hippocampus, it now becomes an exciting prospect to examine whether temporally controlled abrogation of MHCI in the aged brain can enhance neurogenesis and cognitive functions at old age.

Title: A role for Nrf2 in neural stem cell function during aging

Authors: ***L. MADHAVAN**[1], M. J. CORENBLUM[1], S. RAY[2], M. LONG[3], B. HARDER[3], D. ZHANG[3], C. BARNES[4];
[1]Neurol., [2]Neurosci. and Cognitive Sci. Program, [3]Pharmacol. and Toxicology, [4]Psychology, Univ. of Arizona, Tucson, AZ

Abstract: Although it is known that the regenerative function of neural stem/progenitor cells (NSPCs) declines with age, causal mechanisms underlying this phenomenon are not understood. In this context, we have systematically analyzed subventricular zone NSPCs in various groups of rats across the aging spectrum, using *in vitro*, *in vivo*, and behavioral techniques. These studies indicate that although NSC function continuously declines with advancing age, there is a critical time period during middle-age (13-15 months) when a striking reduction in NSPC survival and regeneration (proliferation and neuronal differentiation) occurs. We also find that this specific temporal pattern of NSPC deterioration correlates with the decreasing expression of the redox-sensitive transcription factor nuclear erythroid factor 2 like 2, or Nrf2, in the NSPCs. When Nrf2 expression was suppressed in 'young' NSPCs, using short interfering RNAs, the survival and regeneration of the NSPCs was significantly compromised and their behavior mirrored 'old' NSPCs. Conversely, Nrf2 overexpression in 'old' NSPCs rendered their behavior similar to `young' NSPCs and they showed increased survival and regeneration. Furthermore, examination of NSPCs in young Nrf2 knock-out (Nrf2 -/-) mice revealed a lower number of NSPCs in the subventricular zones of these animals, when compared to age-matched wild type controls. In addition, the proliferative potential of the NSPCs, and their ability to produce new neurons, was also notably compromised in the Nrf2 -/- mice. These results identify a novel regulatory role for Nrf2 in NSPC function during aging, and have important implications towards developing NSPC based strategies to support healthy aging and to treat age-related neurodegenerative disorders.

Abstract: Accumulation of mitochondrial DNA (mtDNA) mutations resulting in mitochondrial dysfunction has been heavily implicated in mitochondrial diseases as well as aging and age-related diseases, such as Alzheimer's and Parkinson's disease. To study the effects of progressive mitochondrial dysfunction, homozygous knock-in mice expressing a proof-reading deficient version of the nucleus-encoded catalytic subunit (*PolgA*) of mtDNA polymerase-γ has been developed (Trifunovic *et al., Nature,* 2004). The mtDNA mutator mice ($PolgA^{mut/mut}$) have very high levels of point mutations (20-30 mutations per mtDNA molecule) and linear deletions (~25% of total mtDNA), and show many signs of premature aging such as reduced life span (42-43 wks), alopecia, weight loss, anemia, sarcopenia, loss of subcutaneous fat, reduced fertility, impaired hearing, osteoporosis, and organ enlargement. Elevated lactate levels in brain and other tissues have been described as a hallmark and a pre-symptomatic marker of aging in both prematurely aging mtDNA mutator and normally aging mice (Ross *et al., PNAS*, 2010). Recently, it has also been shown that germline mtDNA mutations cause anticipation of impaired fecundity, produce stochastic brain malformations when maternal mtDNA mutations are combined with homozygosity for the *PolgA* mutation, and aggravate aging phenotypes and lifespan in homozygous mtDNA mutator mice as well as in mice with a wild-type nuclear DNA background (Ross *et al., Nature,* 2013; *Sci Rep,* 2014). Investigating lipid metabolism, we found increased serum and hepatic cholesterol levels, but no change in triglycerides in >40 wk-old mtDNA mutator mice. Liver size and weight were increased. Cytochrome *c* oxidase (COX) enzyme histochemistry showed deficiency in COX (Complex IV) activity and Oil Red O staining indicated increased lipid droplets in liver sections. We are now investigating key genes involved in the formation and breakdown of cholesterol, such as HMG CoA Synthase, HMG CoA Reductase, LDL-Receptor, and CYP7A1, in order to explain the increased cholesterol levels. Additionally, we found an overall decrease in mtDNA mutator brain size with minimal difference in weight. We are now using histological and biochemical approaches to determine if there is a loss in both grey and white matter and if there are brain-specific changes in lipid metabolism. These findings could provide insights into dyslipidemia and disorders of lipoprotein metabolism, both commonly described among elderly patients.

Title: Age-dependent high copper contents and expressions of copper regulatory proteins in the subventricular zone and choroid plexus

Authors: *X. FU, W. JIANG, W. ZHENG;
Purdue Univ. Sch. of Hlth. Sci., West Lafayette, IN

Abstract: Copper (Cu) is an essential element for normal brain development and function. Our recent data by X-ray fluorescent microscopy suggest that Cu is highly concentrated along the lateral walls of brain lateral ventricles where subventricular zone (SVZ) is located. Anatomically, SVZ is in direct contact with cerebrospinal fluid (CSF), which is secreted by a neighboring tissue choroid plexus. Changes in Cu regulatory gene expressions in the SVZ and choroid plexus as the function of aging may determine Cu levels in the CSF and SVZ. This study was designed to investigate the associations between age, Cu levels, and Cu regulatory genes in SVZ and plexus. The SVZ and choroid plexus were dissected from brains of 3-week, 10-week or 9-month old male rats. Analyses by atomic absorption spectroscopy revealed that the SVZ of adult and old animals contained the highest Cu level compared with other tested brain regions. Significant positive correlations between age and Cu levels in SVZ and plexus were observed; the SVZ Cu level of old animals was 7.5- and 5.8-fold higher than those of young and adult rats ($p<0.01$), respectively. Quantitation by qPCR of the transcriptional expressions of Cu regulatory proteins showed that the SVZ expressed the highest level of Cu storage protein MTs, while the choroid plexus expressed the high level of Cu transporter protein Ctr1. Noticeably, Cu levels in the SVZ were positively associated with type B slow proliferating cell marker Gfap ($p<0.05$), but inversely associated with type A proliferating neuroblast marker Dcx ($p<0.05$) and type C transit amplifying progenitor marker Nestin ($p<0.01$). Dmt1 had significant positive correlations with age and Cu levels in the plexus ($p<0.01$). These findings suggest that Cu levels in all tested brain regions are increased as the function of age. The SVZ shows a different expression pattern of Cu-regulatory genes from the choroid plexus. The age-related increase of MTs and Gfap, and decrease of Ctr1 in the SVZ may contribute to the high Cu level in this neurogenesis active brain region. In addition, the inverse correlations between SVZ Cu content and Nestin expression, as well as Dcx, may imply a potential role of Cu in regulating the adult neurogenesis activity in this region.

Title: Aging-vulnerable and -resilient activity patterns in an identified *Drosophila* motor neuron: Acceleration by high temperature and distortion by oxidative stress

Authors: *A. IYENGAR[1], H. RUAN[2], C.-F. WU[2];
[2]Biol., [1]Univ. of Iowa, Iowa City, IA

Abstract: In *Drosophila*, molecular pathways influencing longevity have been extensively studied. However, corresponding neurophysiological changes underlying aging-related behavioral deterioration remains to be explored. To elucidate salient features in functional decline of neural circuit function, we examined the activity of an identified motor neuron (DLMn5), which drives DLM flight muscle, but also actuates additional motor circuit outputs including giant-fiber (GF) mediated jump-and-escape reflex and electroconvulsion seizure activity in the CNS. The convergence of these motor outputs on DLMn5 enables dissections of age- and stress-vulnerable circuit components and their physiological parameters within the same individual. We studied the extent of decline for a number of motor functions progressing across the lifespan and found both age-sensitive and age-resilient trajectories. For example, we observed relatively little deterioration in GF components responsible for the escape reflex across the lifespan (latency changes less than 15 %, threshold changes less 5%, between 1 and 95% mortality). Conversely, markers of age-dependent plasticity were observed in central inputs to the GF pathway (doubling of refractory period, and a 2 - 4 fold increase in habituation rate), flight motor circuits (doubling of firing rate), and seizure discharges (30 % reduction in threshold) over the same period. Manipulations of specific environmental or mutational stressors could result in drastically different effects on the progression of specific motor patterns and physiological parameters. Interestingly, the age-resilient properties identified above remain intact where as the age-vulnerable counterparts revealed stress-specific responses. Importantly, we found a relatively straightforward compression of the characteristic age-progression of ageing-vulnerable circuit properties when individuals were reared at increased temperature (29°C). This finding provides experimental evidence justifying the common practice in *Drosophila* aging studies conducted at 29°C for expedited experiments. Another important factor recognized in aging processes is oxidative stress. We examined the effects of increased reactive oxygen species (ROS) in Sod1 mutants due to reduced Cu/Zn superoxide dismutase activity. We found distinct effects on age-trajectories when compared with the responses to high temperature rearing. Our study juxtaposes the relative age-resilience of the GF circuit (including the GF, PSI interneuron,

and DLMn5) with the age-vulnerability in other central circuits driving motor activities through DLMn5 directly or mediated by GF input.

Title: Shank3-mutant mice lacking exon 9 show altered excitation/inhibition balance, enhanced rearing, and spatial memory deficit

Authors: ***J. LEE**[1], C. CHUNG[1], S. HA[1], D. LEE[2], D.-Y. KIM[1], H. KIM[2], E. KIM[1,3]; [1]Dept. of Biol. Sci., KAIST, Daejeon, Korea, Republic of; [2]Korea Univ., Seoul, Korea, Republic of; [3]Inst. for Basic Sci. (IBS), Daejeon, Korea, Republic of

Abstract: Shank3 is a scaffolding protein important for organizing the postsynaptic signaling complex at excitatory synapses. Mutations in *SHANK3* gene are implicated in autism spectrum disorders (ASDs) in humans. Several *Shank3* knockout mouse models have been generated in order to study the mechanisms underlying *SHANK3* mutation-induced ASDs. In this study, we generated $Shank3^{\Delta 9}$ mice, in which exon 9 of *Shank3* is deleted to induce gene knockout. Among the major *Shank3* transcript variants, $Shank3^{\Delta 9}$ mice lacked the longest variant (Shank3a), which contains the ankyrin-repeat domain, but other major variants were intact. We thus analyzed the temporal and spatial expression patterns of Shank3a variant. Behaviorally, $Shank3^{\Delta 9}$ mice showed increased rearing in a novel environment, and mild deficit in Morris water maze task. However, they did not show autistic-like phenotypes. Interestingly, we found increased inhibitory synaptic transmission in the hippocampus, but decreased inhibitory transmission in the medial prefrontal cortex of $Shank3^{\Delta 9}$ mice. These results suggest that ankyrin repeat-containing Shank3 variants are important for E/I (excitation/inhibition) balance, rearing behavior, and spatial memory.

Title: Behavioral characterization of SHANK3-deficient rats on an 8-arm radial maze

Authors: *M. YOUNG[1,2], M. L. SHAPIRO[3];
[1]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]The Seaver Autism Ctr. for Res. and Treatment, New York, NY; [3]Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Phelan-McDermid syndrome is a developmental disorder caused by deletions or mutations in chromosome 22q13.3 that lead to the loss of one functional copy of the gene for SHANK3, a postsynaptic scaffolding protein. This single mutation is a highly penetrant cause of autism, with ~70% of affected individuals meeting the criteria for autism and ~80% meeting criteria for autism spectrum disorders. To investigate how SHANK3 mutations lead to behavioral impairments in autism, we tested SHANK3 heterozygotes and knockouts on an 8-arm radial maze. Initial acquisition, reversal and strategy switching tasks were evaluated. Additionally, we investigated whether rats lacking SHANK3 are capable of performing slow, medium, and fast reversals of the spatial goal arm. Preliminary results suggest that SHANK3 heterozygosity has no effect on the ability of rats to acquire an initial spatial goal arm, to reverse to a different goal arm, or to switch to a body turn strategy, or to remember any of these tasks after 24 hours. Further analysis will determine the effect of full SHANK3 knockout on these measures.

Title: Pten is necessary to establish normal numbers of GABAergic cortical interneurons

Authors: *D. VOGT, K. K. A. CHO, A. T. LEE, V. S. SOHAL, J. L. R. RUBENSTEIN; Dept. of Psychiatry, Univ. of California San Francisco, San Francisco, CA

Abstract: Cortical GABAergic interneurons, primarily derived from the medial and caudal ganglionic eminences (MGE and CGE), are highly diverse in morphology, and function. Their dysfunction has been implicated in neuropsychiatric disorders, including schizophrenia, epilepsy, and autism spectrum disorder (ASD). One hypothesis of ASD is that an imbalance in excitation/inhibition in the brain underlies some ASD phenotypes and a functional understanding of candidate genes associated with ASD biology is needed. MGE and CGE-derived interneurons migrate long distances and distinct subgroups will express parvalbumin and somatostatin (MGE-derived) as well as by vasoactive intestinal peptide and reelin, lacking somatostain, (CGE-derived) as they integrate into the cortex. We examined the function of the ASD candidate gene Pten in cortical GABAergic interneuron development using different spatial and temporal Cre-driver mouse lines. Pten inhibits PI3K/Akt/mTor signaling and interacts with other ASD candidate genes through this pathway. We found that Pten inhibits Akt signaling in MGE cells and is necessary for interneuron survival, with somatostatin+ interneurons showing the greatest loss. Interestingly, this only occurs if Pten is deleted in progenitor cells. In addition, Pten differentially regulates parvalbumin+ interneurons, and its loss results in ectopic projections in the cortex, altered behavior and increased cortical inhibition. To understand the impact of human ASD mutations, we developed an *in vivo* complementation assay to determine the function of PTEN ASD mutant alleles in cortical interneuron development. We found that these human ASD alleles were hypofunctional compared to wild type PTEN and did not act in a dominant-interfering manner. Together, these results suggest an important role for Pten and PI3K/Akt/mTor signaling in cortical interneuron development.

Title: Conditional deletion of autism risk gene PTEN in the dopaminergic system leads to morphological, neurochemical, and behavioral abnormalities; can it be rescued?

Authors: K. T. E. KLEIJER, A. HOYER, M. J. H. KAS, *J. H. BURBACH;
Brain Ctr. Rudolf Magnus, UMC Utrecht, Utrecht, Netherlands

Abstract: Autism spectrum disorder (ASD) is a severe neurodevelopmental disorder, which presents with impairments in social behavior, communication and increased repetitive and restrictive behavior as core symptoms. In the last decade, hundreds of genes have been associated with ASD. Although the field has made much progress in delineating functions of ASD risk-genes, the origins of ASD symptomatology remains elusive. One major ASD risk-gene is phosphatase and tensin homolog (PTEN), which is found to be mutated in circa 10% of ASD-patients with macrocephaly. PTEN is hierarchically on top of signal transduction pathways, which regulate other genes that are strongly connected to ASD dysfunctions, such as FMR1, TSC1/2. To examine the role of PTEN in a specific brain system and its association with neurodevelopmental symptoms, a conditional knockout (cKO) mouse was generated, in which Pten was deleted in the midbrain dopaminergic (mDA) system during development (E11.5) using a Pitx3-Cre driver. The morphological, behavioral and neurochemical character of the cKO mouse are being analyzed to gain insight into the neuronal functions of PTEN and to provide robust mouse phenotypes allowing to test novel therapeutics for their ability to ameliorate the phenotypes. Morphologically, the fields of mDA neurons in the Substantia Nigra pars compacta (SNc) and Ventral Tegmenal Area (VTA) were enlarged at three stages; embryonic day (E) 18.5, postnatal day (P) 8 and adulthood. At all three ages, cell size was enlarged and thickened dendrites and enhanced axonal projections towards the striatum and prefrontal cortex were found. Behaviorally, the cKO mouse showed increased baseline locomotor activity (at adult age), which suggests enhanced DA signaling. To analyze the effect of PTEN on neurotransmission and organization of the DA system, neurochemical studies are currently in progress. The data show developmental phenotypes in the midbrain DA system which will be used to test compounds interfering with downstream pathways of PTEN for their ability to ameliorate or reverse ASD-related symptoms.

Title: Treatment with novel erk inhibitor rescues pathophysiology associated with 16p11.2 chromosomal deletion in mice

Authors: *J. PUCILOWSKA[1], J. VITHAYATHIL[2], C. KELLY[2], J. C. KARLO[2], R. BRAMBILLA[3], G. E. LANDRETH[2];
[1]Neurosci., [2]Case Western Reserve Univ., Cleveland, OH; [3]San Raffaele Scientific Inst., Milan, Italy

Abstract: Autism Spectrum Disorders (ASDs) are complex, highly heritable neurodevelopmental disorders affecting approximately 1 in 100 children. Copy number variations (CNVs) are associated with 5-10% of children with ASDs and the 16p11.2 variation is genetically linked to approximately 1% of all ASDs. Even though the human 16p11.2 deletion is one of the most common CNVs in autism, the causative pathophysiology associated with this chromosomal abnormality is largely unknown. The 593-kb deletion contains the ERK1 gene as well as other genes that regulate the ERK/MAPK pathway. It has recently been appreciated that perturbations in signaling through the ERK MAP kinase pathway are a significant genetic cause of a range of neurodevelopmental disorders including autism. In fact, data from preclinical and clinical studies strongly suggests that changes in ERK signaling are central to the pathophysiology associated with ASDs. We have previously shown that a murine model of 16p11.2 deletion exhibits a reduction in brain size and perturbations in cortical cytoarchitecture. These changes are largely due to altered progenitor proliferation dynamics and premature cell cycle exit, which resulted in premature depletion of progenitor pools and deficits in the number and birth frequency of neurons populating cortical lamina. Importantly, the 16p11.2del mice exhibit a paradoxical increase in ERK signaling during neurogenesis, which is coincident with the development of aberrant cortical cytoarchitecture. Therefore, we postulated that treatment with ERK inhibitors may correct the pathophysiology observed in these mice. We treated the 16p11.2del mice with ERK inhibitors during a critical window at the start of neurogenesis. We administered a BBB permeant ERK inhibitor for 5 consecutive days starting on embryonic day 10 and evaluated the ERK inhibitor and vehicle treated 16p11.2del and control mice at E14.5 and P2. We observed a rescue of the developmental deficits associated with the 16p11.2 deletion at E14.5 by IHC and western blot analysis. Furthermore, we verified the embryonic rescue by counting the number of lamina-specific neurons at P2, showing restoration of neuronal numbers and cortical cytoarchitecture in the inhibitor treated deletion mice. Importantly, we tested the mice in a battery of behavioral tests including elevated plus maze, open field, NOR and maternal behavior and report rescue of the behavioral deficits associated with the 16p11.2 chromosomal deletion. In conclusion, our data suggests that ERKs may represent a therapeutic target since

MAPK inhibitors have been previously investigated for treatment of other developmental syndromes.

Title: Autism-related shank3 exon 13 stop mice exhibit altered behavior and synaptic dysfunction in striatum and hippocampus

Authors: ***T. C. JARAMILLO**, H. SPEED, Z. XUAN, S. LIU, C. POWELL;
Neurol. & Neurotherapeutics, UT Southwestern Med. Ctr., Dallas, TX

Abstract: Mutations/deletions in the Shank3 gene are associated with autism spectrum disorders (ASD) and intellectual disability (ID). Here we present electrophysiological and behavioral consequences in heterozygous and homozygous mice with targeted disruption of the PDZ domain in Shank3 (exon 13 STOP mutant mice, Shank3E13). Insertion of a transcriptional stop cassette prior to exon 13 leads to a loss of the two highest molecular weight isoforms of Shank3. Behaviorally, both Shank3E13 heterozygous (HET) and knockout (KO) mice display increased repetitive grooming, deficits in social interaction tasks, and decreased rearing. Shank3E13 KO mice also display deficits in spatial memory in the Morris water maze. Baseline hippocampal synaptic transmission and short-term plasticity are preserved in Shank3E13 HET and KO mice, while both HET and KO mice exhibit impaired hippocampal long-term plasticity. Additionally, Shank3E13 HET and KO mice display impaired striatal glutamatergic synaptic transmission. These results demonstrate that this novel Shank3 mutant model leads to ASD-associated behavioral abnormalities along with widespread synaptic dysfunction. The conditionally reversible nature of this model allows for future studies to examine the temporal and regional nature of Shank3's involvement in these phenotypes.

Title: Autism related stress circuits exhibit enhanced norepinephrine system activity in the Engrailed-2 (En2) knockout model of neurodevelopmental disorders

Authors: J. W. LUNDEN[1], M. GENESTINE[1], C. C. PENG[1], V. MIRABELLA[1], S. PREM[1], J. H. MILLONIG[1], *E. M. DICICCO-BLOOM[2];
[1]Neurosci. and Cell Biol., Rutgers-Robert Wood Johnson Med. Sch., Piscataway, NJ; [2]Dept Neurosci & Cell Biol/ Pediatrics (Neurology & Developmental Disabilities), Rutgers Robert Wood Johnson Med. Sch., Piscataway, NJ

Abstract: Autism spectrum disorder (ASD) is a pervasive neurodevelopmental disorder characterized by impairments in social interactions and the presence of repetitive/restricted behaviors. The neural patterning transcription factor En2 is involved in development of the embryonic mid-hindbrain region, where monoamine neurons emerge, and has been associated with ASD. Our previous studies indicate that En2 knockout (KO) mice exhibit deficits in social interactions, depression related tasks (forced swim, tail suspension), fear conditioning and spatial learning, all associated with diminished hippocampal neurogenesis and norepinephrine (NE) fiber innervation. While these deficits in hippocampal neurogenesis and NE systems suggest likely abnormalities in stress system structures and function, nothing is known about NE fiber innervation and neural activity in limbic regions such as amygdala and paraventricular nucleus of the hypothalamus (PVN). To examine this issue, postnatal day 60-70 wild type (WT) and KO mice (N=4-6/genotype) were assessed immunochemically for protein levels of NE transporter (NET) and tyrosine hydroxylase (TH, the rate-limiting enzyme for NE biosynthesis) in brain regions using western blotting and numbers of fibers expressing NET on tissue sections. Functional activity in the amygdala and PVN is being assessed using c-Fos immunostaining. En2 KO mice exhibited 1.7-fold ($p<0.02$) and 1.5-fold ($p<0.002$) increases in NET and TH protein levels respectively in amygdala compared to WT controls. NET fiber counts were increased 2.6-fold ($p<0.004$) in the basolateral amygdala and 1.7-fold ($p<0.016$) in the PVN. Preliminary nuclear c-Fos staining suggests that the increased NET innervation in the En2 KO PVN is associated with increased neural activation. These observations indicate that NE fiber innervation is increased in some En2-KO limbic system regions, a result that contrasts with the reduced fibers in the dorsally localized hippocampus. This region-specific dysregulation of fiber growth may contribute to abnormalities in depression-related tasks, fear conditioning and social interactions. More broadly, these studies of a neurodevelopmental animal model are defining a surprising array of monoamine system abnormalities in the forebrain that may be a consequence of disordered early development of hindbrain regulatory pathways.

Title: Autism-relevant social communication deficits and aberrant cognitive phenotypes in mice lacking the post-synaptic scaffolding protein SHANK1: a developmental perspective

Authors: ***A. Ö. SUNGUR**, M. C. E. JOCHNER, T. M. REDECKER, R. K. W. SCHWARTING, M. WÖHR;
Philipps-University of Marburg, Marburg, Germany

Abstract: Autism spectrum disorders (ASD) are a class of neurodevelopmental disorders characterized by persistent social communication deficits across multiple contexts, together with repetitive patterns of behavior. Among the most promising ASD candidate genes is the *SHANK* gene family, including *SHANK1*. To study the contribution of *SHANK1* mutations to ASD symptoms throughout development, *Shank1+/+, Shank1+/-,* and *Shank1-/-* mice were compared in behavioral assays developed to detect social communication deficits and aberrant cognitive phenotypes as pups, juveniles, and adults. When assessing isolation-induced ultrasonic vocalizations as a measure for communication during early development, call rate exhibited the typical inverted U-shaped developmental pattern in all genotypes. However, *Shank1-/-* pups were found to be developmentally delayed and characterized by a less prominent inverted U-shaped call emission pattern, reflecting an overall reduction in ultrasonic calling. Furthermore, testing under social conditions revealed genotype-dependent deficits even more prominently, regardless of the familiarity of the social context. As juveniles, social approach and recognition were evident irrespective of genotype. In contrast, object recognition was affected by the *Shank1* deletion, with *Shank1-/-* mice being severely impaired, not showing a preference for the novel object. In adulthood, *Shank1-/-* males and controls displayed normal social approach, but impaired social recognition. Object recognition was additionally impaired in adult *Shank1-/-* males. Conversely, adult *Shank1-/-* females exhibited deficits in social recognition only. At the neuroanatomical level, reductions in brain volume of adult *Shank1-/-* mice were detected by means of magnetic resonance imaging (MRI), consistent with findings obtained in other *Shank* mouse models and some individuals with ASD. In summary, the present findings indicate that *Shank1* deletions lead to communication deficits and an aberrant cognitive phenotype, together with age- and sex-dependent effects on social behavior.

Abstract: Mutations in the transcription factor *FOXP1* are causative for neurodevelopmental disorders such as autism. However, the function of FOXP1 within the brain remains largely uncharacterized. Here, we identify the gene expression program regulated by FoxP1 in both human neural cells and patient-relevant heterozygous *Foxp1* (*Foxp1*$^{+/-}$) mouse brain. We demonstrate a role for Foxp1 in the transcriptional regulation of autism- and Fragile X-related pathways as well as genes involved in neuronal activity. We show that Foxp1 regulates the excitability of medium spiny neurons in the striatum and that reduction of Foxp1 correlates with defects in ultrasonic vocalizations. Finally, we demonstrate that FoxP1 has an evolutionarily conserved role in regulating pathways involved in striatal neuron identity through manipulation of FOXP1 levels followed by genome wide expression studies in human neural progenitors. These data support an integral role for FoxP1 in regulating signaling pathways vulnerable in autism and the specific regulation of striatal pathways important for vocal communication.

Title: Neurodevelopmental mTORC1 activity predicts cell size and the effect of mutations in autism risk genes

Authors: *W.-C. HUANG, D. PAGE;
The Scripps Res. Inst., Jupiter, FL

Abstract: PTEN and FMR1 are two susceptibility genes for autism spectrum disorder (ASD) that encode regulators of the PI3K-mTOR pathway. Phosphorylation of ribosomal protein S6 (p-S6) is a downstream readout of mTOR activity. Altered levels of p-S6 have been reported in the postmortem cerebral cortex of individuals with autism and in mouse models of autism risk genes. However, it is not known when during development and in which cell types dysregulation of p-S6 signaling occurs and whether this contributes to the symptoms of ASD. Our goal is to identify common cell types and time windows in which p-S6 is dysregulated across two mouse models of autism risk genes, Pten and Fmr1, and to study the relationship between p-S6 dysregulation and social behavioral deficits. We report that in the developing brain of wild type mice, p-S6 immunoreactivity is differentially enriched in large versus small cell types during the first two postnatal weeks, and that developmental levels of p-S6 predict cell size across cortical layers. We find that p-S6 levels are particularly enriched in layer V neurons in the cerebral cortex, and levels of p-S6 are transiently elevated during early postnatal life in both Pten+/- and Fmr1-/y mice. Consistent with p-S6 being an indicator of cell growth, we find developmental overgrowth of layer V neuronal soma and dendrites in these models. Strikingly, we do not observe increased cell soma size in neurons of layers II/III or VI (which have relatively low levels of p-S6), indicating that cell types that have high level of p-S6 in the developing brain display the greatest magnitude of overgrowth in response to Pten or Fmr1 mutations. We predict that this non-uniform overgrowth will have considerable consequences on circuit assembly and synchronization, particularly given that cortical layer V neurons project to numerous subcortical

areas important for social behavior. Consistent with this, we find that selectively suppressing mTORC1 signaling in the cerebral cortex is sufficient to rescue both overgrowth of layer V neurons and social behavioral deficits in Pten+/- mice. Moreover, S6K1 inhibitor treatment during early postnatal life results in lasting rescue of these phenotypes in Pten+/- mice. Taken together, our study suggests that p-S6 enriched cells (e.g. layer V neurons) are particularly vulnerable to alterations in growth caused by mutations in ASD risk genes that regulate mTOR signaling, and that inhibition of S6K1 during early postnatal life is a therapeutic strategy relevant for individuals with ASD who have been exposed to risk factors associated with dysregulated mTOR signaling.

Title: Association of single-nucleotide polymorphisms of the CD157/BST1 gene with autism spectrum disorders in a Japanese population

Authors: *S. YOKOYAMA, N. A. MAHMUDA, T. MUNESUE, H. HIGASHIDA; Kanazawa Univ., Kanazawa, Japan

Abstract: CD157, also referred to as bone marrow stromal cell antigen-1 (BST-1), is a glycosylphosphatidylinositol-anchored protein that facilitates pre-B-lymphocyte growth. Previous studies have reported associations between single-nucleotide polymorphisms (SNPs) in the CD157/BST1 gene with Parkinson's disease. In addition, we have recently demonstrated that mice deficient in the CD157/BST1 gene exhibited anxiety-related and depression-like behaviors (Lopatina, O. et al., Front. Neurosci. 8, 133, 2014). It is unclear, however, whether SNPs of the CD157/BST1 gene is related to other brain disorders. We therefore carried out a case-control study to test polymorphisms of the CD157/BST1 gene for association with autism spectrum disorders (ASDs). DNA samples obtained from 147 ASD patients at Kanazawa University Hospital in Japan and 150 unselected Japanese volunteers were examined by the sequence-specific primer-polymerase chain reaction method combined with fluorescence correlation spectroscopy. This study was approved by the ethics committees of Kanazawa University School of Medicine. Of 121 SNPs, two SNPs exhibited significantly higher allele frequencies in the ASD cases than in the unselected controls [rs4301112, odds ratio (OR) = 6.4, 95% CI = 1.9 to

22, p = 0.0007; and rs28532698, OR = 6.2, 95% CI = 1.8 to 21, p = 0.0012; Fisher's exact test; p < 0.002 was considered significant after multiple testing correction]. In addition, CT genotype in rs10001565 was more frequently observed in the ASD group than in the control group (OR = 15, 95% CI = 2.0 to 117, p = 0.0007; Fisher's exact test). Haplotype analysis revealed that 13 cases (9.0%, n = 145) carried all the minor alleles of the three SNPs (AG/AG/CT for rs4301112-rs28532698-rs10001565), whereas only one (0.7%, n = 141) did in the control group (OR = 14.2, 95% CI = 1.4 to 110). In LD analysis of these SNPs, two haplotype blocks were identified: a 5-kb one comprising the ASD-associated rs4301112, rs28532698 and rs10001565, and a 12-kb one including the SNPs associated with Parkinson's disease. These data suggest that genetic variations of the CD157/BST1 gene might serve as a risk factor for ASDs.

Title: Functional characterization of coding FOXP1 variants found in individuals with intellectual disability, autism and language impairment

Authors: *P. DERIZIOTI[1], E. SOLLIS[1], A. VINO[1], C. GILLISEN[2], H. FROHLICH[3], S. GRAHAM[1], R. PFUNDT[2], D. DIMITROPOULOU[1], H. BRUNNER[2,4], G. RAPPOLD[3], S. FISHER[1,5];

Ctr., Maastricht, Netherlands; [5]Donders Inst. for Brain, Cognition and Behaviour, Radboud Univ., Nijmegen, Netherlands

Abstract: In recent years, next-generation DNA sequencing approaches have uncovered heterozygous variants disrupting the FOXP1 transcription factor in a number of patients with sporadic autism spectrum disorder (ASD), intellectual disability (ID), global developmental delay, and moderate to severe speech delay. The presence of speech and language deficits in this emerging FOXP1-deficiency syndrome is of particular interest because FOXP1 is the closest paralogous gene to FOXP2, which is disrupted in a rare form of speech and language disorder.

To date, FOXP1 variants include whole gene deletions, translocations, nonsense variants, missense variants and frameshift variants. The detection of whole gene deletions suggests that haploinsufficiency is the main pathogenic mechanism. Furthermore, the probands carrying FOXP1 variants are often severely affected, suggesting that these mutations are not inherited and in all cases where parental DNA has been tested the variants have been found to occur de novo. We have previously performed functional analyses on de novo frameshifting variants identified in cases of ASD/ID to assess the biological significance of these variants and gained significant insights into the molecular pathways underlying this syndrome. In this study, we report novel de novo FOXP1 variants detected using clinical whole-exome sequencing in three unrelated individuals with ASD/ID and language impairment. To understand their role in disease etiology, we performed extensive functional analyses in human cellular models, testing the effects of de novo FOXP1 variants on several aspects of protein function, including subcellular localization and transcriptional repression properties. In addition, because FOXP1 and FOXP2 directly interact with each other in several brain regions, with the potential to co-regulate downstream targets, including those involved in language development (such as CNTNAP2), we tested the effect of the FOXP1 variants on protein-protein interactions with FOXP2. We then compared the functional effects of the variants detected here to those conferred by FOXP1 variants previously detected in cases of ASD, ID and/or language impairment. Our findings support the hypothesis that de novo variants represent significant causal factors in severe sporadic disorders. Moreover, our data highlight the importance of performing functional characterisation to help uncover the biological significance of variants identified by genomics approaches, thereby providing insight into pathways underlying complex neurodevelopmental disorders.

Title: Autism phenotype and megalencephaly in zinc transporter 3 (ZnT3) null mice: Possible involvement of MMP activation and BDNF upregulation

Authors: *M. YOO, T.-Y. KIM, J.-Y. KOH;
Asan Life Sci. Res. Inst., Seoul, Korea, Republic of

Abstract: Synaptic zinc in the forebrain plays diverse roles in synaptic transmission and plasticity. For instance, it may contribute to polymerization of Shank3, a postsynaptic density protein, mutations of which gene have been linked to autism spectrum disorder (ASD). Hence, synaptic zinc in brain may play certain roles in ASD. In the present study, using ZnT3 null mice that are devoid of synaptic zinc, we examined social behaviors, brain sizes and cytoarchitectures, MMP activities, BDNF expression, and possible relationships among these. At 4-5 weeks of age, male ZnT3 null mice, but not female ones, exhibited reduced scores on 3-chamber sociability and social novelty tests as compared with wild-type control mice. In the reciprocal social interaction test, open field test, and marble-burying test, male ZnT3 null mice exhibited autistic behaviors. At 1-5 weeks of age, the size of frontoparietal cortex and the density of neurites were significantly greater in male ZnT3 null mice than in WT mice. Consistent with enhanced neurotrophic stimuli in ZnT3 null mice, levels of BDNF and TrkB in neurons and astrocytes were upregulated in male ZnT3 null mouse brains. Moreover, activities of MMP2 and MMP9 were also increased. Although it is unclear how the ZnT3 null state caused increases in MMP activities, BDNF levels, and megalencephaly in male mice, the absence of synaptic zinc or ZnT3 mRNA/protein during the critical period of brain development may contribute in a gender-dependent fashion to changes associated with ASD.

Title: Purkinje cells-restricted expression of mutant DISC1 in anterior cerebellum produces neurobehavioral abnormalities relevant to schizophrenia and autism spectrum disorders

Authors: *A. V. SHEVELKIN[1,2], B. N. ABAZYAN[2], C. YANG[2], O. A. MYCHKO[2], G. L. RUDOW[2], J. C. TRONCOSO[2], M. V. PLETNIKOV[2];
[1]P.K.Anokhin Inst. Norm Physiol, Moscow, Russian Federation; [2]Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Disrupted-In-Schizophrenia-1(DISC1) and its variants have been associated with neurodevelopmental disorders, including schizophrenia and autism spectrum disorders (ASD). Purkinje cells (PC) express DISC1. We generated a mouse model of inducible and selective expression of mutant DISC1 in PC of anterior lobuli of the cerebellum (II-V and internal side of VI). We sought to analyze the brain and behavioral alterations in this mouse model. We evaluated volume of the cerebellum and PC in mice at postnatal (P) day 21 and 150 after assessing behavioral phenotypes in male and female mice in novelty-induced activity, elevated plus maze, Y maze, object and place recognition, fear conditioning and rotarod. Conventional western blotting and electrophysiological technics were used in the experiments. All protocols were approved by the Animal Care and Use Committee at Johns Hopkins University. We found a significant decrease in PC soma size at P21 but not at P150. Analysis of soma PC size showed presence of small and big soma PC size in the anterior cerebellum of control mice, but we observed only small soma PC size in mutant DISC1 mice at P21. Neither total number of PC nor volume of the cerebellum were significantly altered in mutant DISC1 mice. No up-regulation of cellular markers of inflammation was observed in mutant mice. Mutant male but not female mice demonstrated abnormal social interaction, hyperactivity and deficient novel object recognition. We observed no group differences in elevated plus maze, spontaneous alteration or spatial recognition in Y maze. Preliminary electrophysiological experiments found no changes in excitability and Rinput of PC in mutant DISC1 mice. Evaluation of potential synaptic alterations is in progress. Mutant DISC1 mice had comparable expression of NR1 and NR2A but significantly more expression of SNAP-25 and PSD-95 in the cerebellum but not in the cortex. Our findings indicate that mutant DISC1 affects PC morphology at P21 and produces cognitive and social abnormalities in adult mice. This may have the potential to advance our knowledge of the role of DISC1 in maturation and function of the cerebellum related to neurodevelopmental disorders.

Abstract: Behavioral and cognitive impairments observed in autism spectrum disorder (ASD) are thought to arise from abnormal neuronal connectivity in the developing brain, but the molecular basis of these deficits is largely unknown. Protocadherin 10 (Pcdh10) is a protocadherin superfamily neural cell adhesion molecule that has been associated with ASD in human genetic studies. Mouse Pcdh10 is expressed highly in olfactory, limbic, and striatal regions, including the basolateral amygdala, and plays an important role in activity-dependent synaptic pruning. Juvenile male mice lacking a single allele of Pcdh10 display reduced social approach behavior, but no difference in social behavior was observed in female Pcdh10+/- mice. Social approach behavior strongly activates neurons in the basolateral amygdala, a brain region that expresses high levels of Pcdh10. To determine whether abnormal neural connectivity may underlie the behavioral deficits we observed, we measured dendritic length and spine density in Golgi stained lateral and basolateral amygdala neurons from Pcdh10+/- males. We found that neurons of male but not female Pcdh10+/- mice have increased spine density, with increases specifically observed in thin elongated filopodia-type spines. In the amygdala of Pcdh10+/- male mice, we found reduced levels of NMDAR subunit NR1 in the post-synaptic density. These data suggest that abnormal regulation of synapse formation and NMDAR function in the lateral and basolateral amygdala may underlie the social approach deficits observed in male Pcdh10+/- mice.

Title: Evaluation of r-baclofen in novel object recognition in the Fmr1 knockout mouse model of Fragile X syndrome

Authors: *T. M. KAZDOBA[1], P. T. LEACH[2], J. N. CRAWLEY[2];
[1]Univ. of California, Davis, Citrus Heights, CA; [2]Univ. of California, Davis, Sacramento, CA

Abstract: Fragile X syndrome (FXS) is one of the most commonly inherited forms of intellectual disability. Autism spectrum disorder (ASD) is comorbid in approximately 25% of diagnosed FXS cases. Clinically, FXS symptoms can include cognitive impairments, hyperactivity, seizures, social phobia, anxiety and repetitive behaviors. FXS is caused by a CGG repeat mutation on the X chromosome, which expands a region containing the FMR1 gene, which encodes FMRP, an RNA-binding protein that regulates protein translation. The Fmr1 knockout (KO) mouse is a well-characterized rodent model of FXS that has been used as a tool to further understand the consequences of FMRP loss, as well as evaluate putative therapeutic compounds to reverse FXS-relevant symptoms, including modulators of excitatory and inhibitory neurotransmission. Early clinical trials with STX209 (Arbaclofen), a selective GABAB receptor agonist, showed promise on measures of social avoidance and social responsiveness in FXS and autism (Berry-Kravis et al., 2012, Erickson et al., 2014). In Fmr1 KO mice, r-baclofen administration restored abnormal protein synthesis, improved dendritic spine abnormalities and reduced audiogenic seizures (Henderson et al., 2012). Here, we evaluated the efficacy of r-baclofen in Fmr1 KO male mice on the FVB genetic background in two behavioral phenotypes, novel object recognition and hyperactivity in the open field. Normal novel object recognition was confirmed in Fmr1 wildtype littermates (WT), and the absence of significant novel object recognition was confirmed in Fmr1 null mutants, after administration of a saline vehicle. Acute treatment with 1 and 3 mg/kg of r-baclofen, administered intraperitoneally 60 minutes before testing, restored novel object recognition in Fmr1 null mutants, while having no detrimental effects in WT littermates. During the initial habituation phase, neither dose of r-baclofen significantly affected locomotor activity in either Fmr1 WT or KO mice. Our findings suggest that in addition to having beneficial effects on protein translation, dendritic morphology and seizure activity, r-baclofen may improve cognitive deficits associated with FXS.

Title: Shank3B knockout mice display unusual adult reciprocal social interactions, ultrasonic vocalizations, repetitive self-grooming, seizure activity and EEG gamma-power

Authors: *J. L. SILVERMAN[1], M. C. PRIDE[1], N. A. COPPING[1], J. E. HAYES[1], S. H. T. LAMMERS[2], S. C. DHAMNE[2], A. ROTENBERG[2], E. CHADWICK[2], D. G. SMITH[3], M. SAHIN[2], J. N. CRAWLEY[1];
[1]UC Davis Sch. of Med., Sacramento, CA; [2]Boston Children's Hospital, Harvard Med. Sch., Boston, MA; [3]Autism Speaks, New York, NY

Abstract: Translocation and breakpoint mutations in *SHANK3* have been implicated in autism spectrum disorder (ASD). Mutant mouse models have been generated to evaluate the biological and behavioral consequences of *Shank3* gene mutations, including targeted mutations in the ankyrin (*Shank3A*), PDZ (*Shank3B*) or Homer binding domains within the *Shank3* gene (Bozdagi et al., 2010; Peca et al., 2011; Bangash et al., 2011; Wang et al., 2011; Kouser et al., 2013). The present experiments in *Shank3B* mice were designed to (a) evaluate replicability of published phenotypes and (b) evaluate novel behavioral and physiological phenotypes of high relevance to ASD. Social approach and repetitive behavior assays were conducted as previously described (Silverman et al., 2010, 2012). In addition, an analysis of male-female reciprocal social interactions and ultrasonic vocalizations was conducted in male subjects paired with freely moving unfamiliar estrus C57BL/6J females. By continuous wireless video telemetry, we also recorded EEG seizures, gamma oscillations and circadian rhythms in independent cohorts. Separate cohorts were also challenged with pentylenetetrazole (PTZ), a GABA-A antagonist and potent convulsant. Adult male-female social interactions were lower in *Shank3B* null mutants than wildtype littermates on several key social parameters. Fewer ultrasonic vocalizations were emitted during the male-female interaction session. Self-grooming was higher in the null mutants than in their wildtype controls, in both sexes, replicating and extending earlier findings. Relative to wildtype controls, *Shank3B* null mutant males exhibited more frequent and longer spontaneous electrographic seizures at night. In contrast, during daytime, these mice did not have seizures and had increased power in the gamma (30-80 Hz) frequency band on EEG. Upon PTZ-challenge, in daytime, the *Shank3B* null mutants showed a significantly reduced number of myoclonic seizures. These results confirm the robustness of elevated self-grooming in *Shank3B* null mutant mice, and confirm social deficits using sensitive assays, supporting the use of this line as a mouse model of autism. Moreover, our EEG and video seizure analyses point to a possible discrepancy in seizure vulnerability such that these mice are more prone to seizures at night, and yet are seizure-resistant during the day. The increase in gamma power on EEG

suggests a plausible increase in GABAergic reserve in this phenotype that may account for the seizure resistance. These EEG and behavioral abnormalities may represent quantitative, translational biological markers of pathophysiology associated with mutations in the *Shank3* gene.

Title: 16p11.2 mouse model of autism demonstrates impaired novel object recognition with intact spatial object recognition and contextual fear conditioning

Authors: ***S. L. FERRI**[1], W. O'BRIEN[2], J. WALSH[3], N. BOWMAN[2], R. HAVEKES[1], T. ABEL[1];
[1]Biol., [2]Neurosci., Univ. of Pennsylvania, Philadelphia, PA; [3]Swarthmore Col., Swarthmore, PA

Abstract: The 16p11.2 deletion is the most common copy number variant (CNV) associated with autism spectrum disorders (ASD). Humans with ASD and some mouse models of ASD exhibit social and cognitive deficits, including impairments in object categorization and identification tasks. Using mice with a 0.39 Mb deletion on chromosome 7, a region that shares conserved synteny with the critical interval on chromosome 16 associated with ASD, we tested males and females in novel object recognition (NOR), spatial object recognition (SOR) and contextual fear conditioning (CFC) tasks. Mice with the 16p11.2 deletion exhibited a deficit in a long-term memory paradigm of novel object recognition, suggesting impaired perirhinal cortex function. However, no deficits were found in spatial object recognition or contextual fear conditioning, suggesting intact hippocampal function. Interestingly, deficits in novel object recognition are age- and sex-dependent, showing greatest impairment in young males. Thus, our findings provide insight into the neural circuitry most severely affected by 16p11.2 deletion and may serve to guide future investigations of molecular and cellular mechanisms that underlie ASD-associated cognitive deficits.

Title: Touchscreen visual discrimination learning deficits in the Ube3a mouse model of Angelman syndrome

Authors: *P. T. LEACH[1], T. M. KAZDOBA[2], K. SISON[2], C. M. GALL[3], G. S. LYNCH[4], J. N. CRAWLEY[2];
[1]Psychiatry, MIND Institute, Univ. of California Davis Sch., Citrus Heights, CA; [2]Psychiatry, MIND Institute, Univ. of California Davis Sch., Sacramento, CA; [3]Dept. of Anat. and Neurobio., Univ. of California Irvine, Irvine, CA; [4]Dept. of Psychiatry and Human Behavior, Univ. of California Irvine Sch. of Med., Irvine, CA

Abstract: Angelman syndrome is a monogenic neurodevelopmental disorder with intellectual impairments. Angelman syndrome is caused by mutations within the maternally-derived UBE3A gene, which is a paternally imprinted region of chromosome 15. The Ube3a mouse model of Angelman syndrome, harboring the heterozygous maternal deletion, m-/p+, has been previously reported to show significant cognitive deficits in tasks including Morris water maze reversal and fear conditioning. Here we investigate cortically dependent learning in Ube3a mice and their wildtype (WT) littermates, employing a forefront touchscreen-based operant task with high face validity to human cognitive testing paradigms. We trained WT and Ube3a m-/p+ male and female mice in a pairwise visual discrimination task. Subject mice were trained with images presented randomly at the left or right locations and touches to the image location were rewarded while touches to the blank location were punished with a 20 sec timeout period. Training commenced for each mouse until individual performance was ≥ 80% correct for 2 days. Pairwise visual discrimination training trials consisted of two images, an X symbol and an = symbol, of matched illumination. Images were simultaneously presented on the front panel, randomly alternating at the left and right image locations. Mice were randomly assigned to be rewarded for pressing the X or the = image. Pressing the incorrect image led to a 20 sec timeout period. The primary dependent measure was the number of days required for each subject to reach the criterion of ≥ 80% correct for 2 days. Data were analyzed using a parametric unpaired t-test and

a nonparametric survival/completion curve analysis, as well as trials to criterion and daily % correct performance. WT completed acquisition in 14 ± 3 days, while heterozygous m-/p+ Ube3a mice completed acquisition in 27 ± 4 days. Both parametric and nonparametric statistics revealed that Ube3a subjects took significantly longer to reach criterion as compared to WTs. These results demonstrate that the Ube3a mutation results in cognitive deficits observable in an operant task that is dependent on intact cortical function. In addition, rotarod motor learning deficits were detected in Ube3a mice, providing a confirmation of consistency with previous reports of rotarod deficits in Ube3a mutant lines of mice. Our findings lend support to using touchscreen assays to evaluate cognitive phenotypes in mouse models of neurodevelopmental disorders, and for preclinical evaluation of pharmacological agents, in a task with high face validity to human cognitive testing methods.

Title: Hyperactivity and male-specific sleep deficits in the 16p11.2 deletion mouse model of autism

Authors: *C. C. ANGELAKOS[1], A. J. WATSON[2], K. S. KRAINOCK[2], W. T. O'BRIEN[1], T. ABEL[2];
[1]Dept. of Neurosci., [2]Dept. of Biol., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Sleep disturbances are prevalent in several neurodevelopmental disorders, including autism spectrum disorders (ASDs) and attention deficit-hyperactivity disorder (ADHD). Evidence from genome-wide association studies indicates that chromosomal copy number variations (CNVs) are significantly associated with increased prevalence of these neurodevelopmental disorders. In particular, CNVs in chromosomal region 16p11.2 profoundly increase the risk for ASD and ADHD, disorders which are more common in males than females. We hypothesized that mice hemizygous for the 16p11.2 deletion (16p11.2 del/+) would exhibit sex-specific sleep and activity deficits. To test his hypothesis, we recorded activity patterns using infrared beam breaks in the home cages of male and female 16p11.2 del/+ and wildtype littermates. Activity was monitored under standard conditions (12:12 light-dark cycle) as well as

under continuous darkness in order to assess circadian rhythms. We found that both male and female 16p11.2 del/+ mice exhibit robust home cage hyperactivity in comparison to controls, which persisted in 24-hour darkness. In additional experiments, male and female mice were implanted with electroencephalography (EEG) and electromyography (EMG) electrodes, and sleep was assessed during a 24-hour period. 16p11.2 del/+ male, but not female mice, exhibited significantly more time awake and significantly less time in non-rapid-eye-movement (NREM) sleep during the 24-hour period. Analysis of bouts of sleep and wakefulness revealed that 16p11.2 del/+ males, but not females, showed significant changes in the distribution of wake time. Specifically, in the males a greater proportion of wake time was spent in long bouts (greater than 42 minutes in duration) compared to controls, and a significantly lower proportion of wake time was spent in shorter bouts. These changes in hyperactivity, wake time, and wake time distribution in the males are similar to the sleep disturbances observed in human ADHD and ASD patients, suggesting that the 16p11.2 del/+ mouse model may be a useful genetic model for studying human neurodevelopmental disorders.

Title: Characterization of neuronal phenotypes in the 15q13.3 microdeletion mouse model

Authors: *B. K. UNDA[1], M. UDDIN[2], S. WHITE[1], A. FORSINGDAL[3], J. NIELSEN[3], S. W. SCHERER[2], K. K. SINGH[1];

Abstract: Copy number variations (CNVs) are chromosomal deletions or duplications that confer high risk for many neuropsychiatric conditions. The 15q13.3 CNV microdeletion has been associated with high risk for epilepsy, intellectual disability, schizophrenia and autism spectrum

disorder (ASD). However, it remains unknown what neurodevelopmental abnormalities underlie the clinical phenotypes. To study this, we are utilizing a 15q13.3 microdeletion mouse model that displays characteristic behavioural features of 15q13.3 syndrome, including epilepsy, increased stereotyped behaviour and deficits in spatial learning and memory, supporting its validity as a translational model. To better understand how these behavioural abnormalities arise, we are performing morphological analysis of different brain regions. Preliminary analysis of postnatal neuronal morphology revealed alterations in dendritic morphology in excitatory cortical pyramidal neurons. We are following up with electrophysiological experiments to determine if the morphological abnormalities lead to functional deficits in neural connectivity. To understand the pathophysiology of 15q13.3 syndrome, we are dissecting candidate disease-causing genes using patient exome and transcriptome data to determine if there are discrete mutations in specific genes within this CNV, or genes that have a higher burden of missense variants. Preliminary exome sequencing of ASD probands revealed inherited and de novo variants in specific genes within the 15q13.3 region. Future work will focus on determining whether loss of these genes can account for the observed morphological defects in the mouse model and elucidating the role of these genes and associated signaling networks in neurodevelopment.

Title: Deficits in learning operant associations, but not motivation, in CNTNAP2 and Shank3b mouse models of autism

Authors: *N. M. GRISSOM[1], S. E. MCKEE[1], L. WALSH[1], M. R. MARINI[1], T. M. REYES[1,2], T. ABEL[1];
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Univ. of Cincinnati, Cincinnati, OH

Abstract: Autism spectrum disorders (ASD) are characterized by disruptions in behavior including restricted interests, repetitive behaviors, and difficulties performing appropriate social

interactions. Several theories have been put forward to reconcile how these disparate symptoms might be related. The Social Motivation Hypothesis suggests that ASD symptoms are related to insufficient motivation to pursue reinforcers. In contrast, the Predictive Impairment in Autism Hypothesis suggests that ASD symptoms are related to difficulties in being able to predict the outcomes of events, including ones own actions, that might lead to reinforcement. A number of mouse models of genetic lesions associated with autism spectrum disorders (ASD) have been developed, making it possible to directly test whether loss of function at these ASD-associated genes impact the ability to form action-outcome predictions or to maintain motivation. We have recently tested knockouts of contactin-associated protein-like 2 (CNTNAP2) and Shank3b, both of which are important to synaptic function. Both mouse lines have been demonstrated to have cognitive deficits including elevated repetitive behaviors and problems with reversal learning. However, whether there are specific deficits in motivation or outcome prediction have not been tested. Male and female adult wildtypes and knockouts were tested in 9-hole mouse operant chambers for both the acquisition of a simple Fixed Ratio task, and following acquisition, for motivation using a Progressive Ratio task. CNTNAP2 null males were significantly delayed in learning the association between the operant response and reinforcement in the Fixed Ratio task, while CNTNAP2 null females were unaffected. In Shank3b null mice, both sexes were impaired in acquiring the action-outcome association in the Fixed Ratio task. However, neither genotype showed any impairment in motivation as assessed by Progressive Ratio following training in the Fixed Ratio task. Therefore, the deficits CNTNAP2-/- males and Shank3b -/- animals of both sexes displayed in learning the Fixed Ratio task are unlikely to be attributable to impairments in motivation. Instead, operant deficits in mouse models of ASD may be due to difficulty predicting reinforcement as an outcome of the operant response. Deficits in outcome prediction may be a common phenotype related to genetic lesions associated with ASD.

Title: Characterization of prenatal zinc deficient animals regarding possible autism like behavior

Authors: *A. M. GRABRUCKER[1], G. EHRET[2], T. BOECKERS[3], S. GRABRUCKER[3]; [1]Neurocenter of Ulm Univ., Ulm, Germany; [2]Dept. of Neurobio., [3]Inst. for Anat. and Cell Biol., Univ. Ulm, Ulm, Germany

Abstract: Autism is a neurodevelopmental disorders characterized by impairments in communication and social behavior, and by repetitive behaviors. The idea that many genes implicated in Autism might converge on a single pathway present at excitatory glutamatergic synapses has recently been raised by multiple studies. For instance, our recent data provide evidence that a common synaptic pathway (Nrxn-Nlgn-Shank) found at excitatory synapses is disrupted in ASD. However, although genetic factors might be largely responsible for the occurrence of autism they cannot fully account for all cases and it is likely that in addition to a certain combination of autism-related genes, specific environmental factors might act as risk factors triggering the development of autism. On such environmental risk factor might be zinc deficiency. Zinc is one of the most prevalent metal ions in the brain and participates in processes such as neurogenesis, neuronal migration and differentiation, thereby shaping brain development and function. Here, we show the impact of maternal zinc deficiency on the behavior of the offspring later in life regarding a possible ASD phenotype. To that end, we generated a mouse model for prenatal zinc deficiency and examined the mice for their general health and neurological reflexes, muscle strength and motor coordination, juvenile play, anxiety, hyperactivity, sociability and social novelty with and without object and in male-male and female-female reciprocal social interactions, olfactory habituation, ultrasonic vocalizations, and memory and learning. Our results show that prenatal zinc deficient mice later in life display deficits in vocalization, increased aggression and slight abnormalities towards social stimuli and in social situations. Thus, given that maternal zinc deficiency alone is sufficient to alter the behavior of the adult offspring towards a more “autistic-like” behavior, it is likely that prenatal zinc deficiency together with a specific genetic predisposition might act as important risk factor for the development of Autism.

Title: Local information influences visual shape perception in autism spectrum across different developmental periods

Authors: *A. PERREAULT[1,2], C. HABAK[4], L. MOTTRON[3], F. LEPORE[5], A. BERTONE[2,6,3]; [1]Psychology Dept., Univ. De Montréal, Outremont, QC, Canada; [2]Perceptual Neurosci. Lab. for Autism and Develop. (PNLab), [3]Ctr. d'excellence en Troubles envahissants du développement de l'Université de Montréal (CETEDUM), Hôpital Rivière-des-Prairies, Montreal, QC, Canada; [4]Educational Neurosci. Res. Abstract: Background. Although studies have identified altered visual perception in autism at early and higher levels of visual analysis, much less is known about whether alterations at each level are related at different periods of development. Objectives. To assess whether the types of local information, mediated by early (local) level perception, differentially affect intermediate level (global) visual perception in autism at different periods of development. Methods. 40 autistic and 44 non-autistic participants, matched for full-scale IQ and age, were placed into school-aged (7-12 years), adolescent (13-17 years) and adult (18-27) age groups. All participants were asked to discriminate between perfect circles and RFP, whose contours (a) contained either 3, 5, or 10 bumps, and (b) were either luminance- or texture-defined. Depending on the number of bumps surrounding the contour, both local and global visual analysis can be targeted. The size (or amplitude) of the bumps was varied: the larger the amplitude, the easier it was to discriminate a RFP from a perfect circle. RFP discrimination thresholds were measured using a method of constant stimuli and a 2-ATFC procedure. Results. Separate 2 (group) X 3 (age group) X 3 (# of RF) mixed factorial ANOVAs were conducted for luminance- and texture-defined RFP conditions. For luminance-defined RFP, no group-differences were identified at any RFP condition for any of the developmental periods assessed. For texture-defined RFP, group-differences were identified for adolescent and adult groups, with decreased performance across both global (3 and 5 bumps) and local (10 bumps) RFP conditions in autism. Conclusions. The differential effect of type of local attribute (luminance vs texture) on global shape discrimination supports the hypothesis that decreased global perception in autism, when present, may have early (local) visual origins. Specifically, manipulating the complexity (from luminance to texture) of local contour elements affected global shape perception to a greater extent in autism. Based on the present results, it can be argued that alterations at early levels of analysis can in part contribute to the atypical perception of objects in autism, and this is especially evident later in development.

Title: Sensory filtering and cognitive impairments in a VPA rat model of autism

Authors: A. DE SILVA[1], *S. SCHMID[2];
[1]Anat. & Cell Biol., [2]Univ. of Western Ontario, London, ON, Canada

Abstract: Autism is a highly prevalent neurodevelopmental disorder with approximately 70-90% of individuals displaying an atypical response to sensory stimulation. Studies have shown that patterns of abnormal sensory filtering in autistic children have been associated with poor attention, impaired academic performance and high anxiety levels. This emphasizes a correlation between sensory filtering mechanisms and cognitive function. We tested sensory filtering and related cognitive impairments in an established valproic acid (VPA) rat model of autism. 600 mg VPA (or saline) was injected in a pregnant rat at gestation day 12.5. We hypothesized that sensory filtering impairments in the offspring is correlated with disruptions in cognition. We used startle boxes to assess sensory filtering processes and locomotor boxes to measure exploration behavior, anxiety, and habituation during adolescence and adulthood. We then assessed learning and attention in these animals through the 5-choice-serial-reaction-time-task (5-CSRTT) using Bussey touch screen boxes. Preliminary results reveal a lower startle response amplitude in VPA animals of both sexes compared to control animals. VPA animals showed less short-term and long-term habituation of startle, which was more prominent in female animals. In contrast, male VPA animals showed less prepulse inhibition of startle at different prepulse levels and interstimulus intervals between prepulse and pulse. VPA animals also showed a trend to lower exploratory behavior in the locomotor boxes, and both male and female animals spent significantly less time in the centre of the boxes than their control counterparts, indicating a higher level of anxiety in VPA animals. Interestingly, testing in the 5-CSRTT showed both extremely low performers and some rare extremely high performers in the VPA group in both task learning during training and in attention testing. Systemic injections of the acetylcholine esterase inhibitor galantamine showed no effect on performance in the 5-CSRTT. We conclude that the VPA rat model is a valid model for autism spectrum disorders and that there is a correlation of sensory filtering disruption and low cognitive performance. Future studies will also involve injections of Riluzole and Ritalin which are currently used for treatment in autism spectrum disorders in clinical trials, and of an allosteric BK channel opener, in order to determine its effectiveness in enhancing attention.

Title: Lower anisotropy and higher diffusivity in limbic system white matter in the autism spectrum

Authors: *M. J. ALSHIKHO[1,3,4], N. SHETTY[1,3,4], S. GHOSH[1,3,4], E. M. RATAI[2,3,4], M. R. HERBERT[1,3,4];
[1]Neurol., [2]Radiology, Massachusetts Gen. Hosp., Boston, MA; [3]Neurol., MGH/HST Martinos Ctr. for Biomed. Imaging, Charlestown, MA; [4]Neurol., Massachusetts Gen. Hospital/TRANSCEND, Charlestown, MA

Abstract: Objective: To evaluate the relationship between white matter volume (WMV) and the physical patterns of diffusion tensor imaging (DTI) in an effort to better characterize white matter (WM) microstructure in autism spectrum disorders (ASDs). Background: ASDs are biologically based and behaviorally defined neurodevelopmental disorders characterized by impairments in social communication, and social interaction, as well as by restricted and repetitive patterns of behavior, interests, and activities. Children with ASD often find it hard to recognize facial expressions, interpret the emotions behind them or manage their own emotions. We hypothesized that increased white matter volume in the limbic system, a critical mediator of emotion, could be a result of abnormalities in the extracellular space and not just in the cells themselves. The neuroinflammation identified in ASDs can not only enlarge glial cell size and alter glial cell function but also increase the space outside the cells, leading structurally to increased WMV and functionally to disturbances in limbic system activity. Methods and Materials: Magnetic resonance volumetric and diffusion tensor imaging were performed on 50 males, 23 ASD (10.43y± 1.77, NVIQ 99.77±17.11), 27 typically developing (TD; 9.94y± 2.49, NVIQ 113.34±16.59). Subjects were ASD diagnosed using ADOS and clinical assessment. WMV and DTI metrics (FA, MD, AD, RD) were generated by Freesurfer. General linear model analysis was carried out to study the relationship between WMV, subject age and DTI metrics in the amygdala, hippocampus, hypothalamus, putamen and cingulate gyrus. Results: WMV was significantly different between the groups in the right and left thalamus, caudate, putamen, amygdala, accumbens-areas and the cingulate gyrus. We found positive and significant correlation between WMV and diffusivity and negative correlation between WMV and anisotropy in ASD group in the right and left amygdala, right thalamus, right and left putamen and in the right anterior cingulate. The correlation between WMV and age in the right and left thalamus, caudate, putamen and amygdala was significantly positive in the ASD group. Conclusions: The positive correlation of WMV with diffusivity and the negative correlation between WMV and anisotropy in ASD invite a more serious investigation of the possible contribution of an expansion of the fluid space between the cells to the increase in WMV. Such

microstructural changes in the limbic system would likely arise from neuroinflammation and could help mediate the social and behavioral aspects of ASD.

Title: Novel approaches to the reconstruction of transcriptomic and epigenomic networks underlying dysfunction in CNV-dependent neurodevelopmental disorders

Authors: *G. TESTA[1], P.-L. GERMAIN[2], A. ADAMO[2], M. ZANELLA[2], G. D'AGOSTINO[2], A. VITRIOLO[2], V. ALBERTIN[2], C. FASANO[3], S. TEMPLE[3], K. BENNETT[4];
[1]Univ. of Milan and European Inst. of Onco, Milan, Italy; [2]European Inst. of Oncology, Milan, Italy; [3]The Neural Stem Cell Inst., Rensselaer, NY; [4]Rensselaer Polytechnic Inst., Rensselaer, NY

Abstract: The critical challenge for induced Pluripotent Stem Cell (iPSC)-based disease modeling is to trace the effect of molecular dysregulations through successive layers of biological complexity to ultimately map them up onto clinical phenotypes. We recently described the thus far largest cohort of disease-specific, transgene-free iPSC, focusing on two neurodevelopmental disorders caused by symmetrical copy number variations (CNV) of 7q11.23, Williams syndrome and 7q-microduplication syndrome, that display a striking combination of shared and symmetrically opposite neurodevelopmental phenotypes (Adamo et al. *Nature Genetics* 2015). We found that already in iPSC 7q11.23 CNV disrupt transcriptional circuits across disease-relevant pathways, a dysregulation that is selectively retained upon differentiation. Importantly, we further uncovered that transcriptomic dysregulation in the pluripotent stage was enriched for genes that peak in the proneural differentiation stages or in the deep-layer formation stage of cortical development, further supporting the idea that the malleable chromatin of iPSCs offers also an experimental window of opportunity to gauge disease-relevant neurodevelopmental trajectories. We now present the dissection of transcriptomic and epigenomic profiles observed *in vitro* into distinct regulatory pathways, thereby offering mechanistic insights and targets of intervention. To this end, we introduce a novel methodology to the reconstruction of gene networks, which overcomes the key limitations of current reverse

engineering-based methods, namely the difficulty of their interpretation and their poor reproducibility, especially across small sample sizes. Our novel approach leverages the power of larger, external datasets to yield more robust networks. On the basis of several hundreds of ChIP-seq experiments, predicted and curated transcription factor binding sites, and relevant transcriptomic datasets, we assembled a cell-type-specific probabilistic model of regulator-target interaction. By calculating the shortest probabilistic path that connects differentially-expressed genes to genes of the CNVs underlying the diseases under study, we obtained robust and highly actionable networks that revealed important dysregulations that had escaped differential expression analysis and offer compelling mechanistic hypotheses explaining the transcriptional effect of these CNVs, with far-reaching implications for the field of iPSC-based neurodevelopmental disease modeling.

Title: Neuregulin1 modulation of experimental autoimmune encephalomyelitis

Authors: ***F. SONG**[1], H. DEOL[1], J. A. LOEB[1], E. ALLENDER[1], E. H. SIMPSON[2]; [1]Dept. of Neurol. and Rehabil., Univ. of Illinois at Chicago, Chicago, IL; [2]Columbia Univ., New York, NY

Abstract: Background: The mechanisms that modulate disease severity and progression in multiple sclerosis (MS) are poorly understood. One potential mediator is neuregulin1 (NRG1) which is a membrane bound and secreted growth and differentiation factor that regulates glial development, survival, synaptogenesis, axoglial interactions, and microglial activation. We developed a targeted NRG1 antagonist called HBD-S-H4 that given intrathecally reduces microglial activation in a rat spinal cord pain model, suggesting that it may have similar effects in other diseases. Here we test the hypothesis that blocking NRG1 in the central nervous system (CNS) could be a therapeutic approach to reduce neuroinflammation and demyelination in MS. Objective: To determine the effects of a NRG1 antagonist (HBD-S-H4) on myelin oligodendrocyte glycoprotein (MOG)-induced experimental autoimmune encephalomyelitis (EAE). Design/Methods: HBD-S-H4 is a novel humanized fusion protein consisting of a decoy

Her4 receptor fused to NRG1's heparin-binding, targeting domain. MOG-induced EAE was induced in transgenic mice that were developed to express this fusion protein in the CNS, and compared to control mice. More and less potent EAE disease induction models were compared as well as gender-specific differences. Results: Transgenic expression of HBD-S-H4 in the CNS did not result in any significant neurological or other overt phenotypes. With induction of less potent EAE disease, female HBD-S-H4 mice were less severely affected compared to their male HBD-S-H4 littermates. However, with more potent disease induction, female HBD-S-H4 mice were affected more than the males of the same genotype, suggesting complex interaction between NRG1 signaling and gender. Measurements of the gene and cellular pathology of microglia in male and female HBD-S-H4 Tg mice with EAE are currently underway. Conclusions: Blocking NRG1 is protective in female mice in mild disease, but this effect was not seen in more severe disease, suggesting a complex interplay between NRG1 and sex hormones in EAE that is dependent on disease severity. One possible explanation for this may be from combined effects of NRG1 and estrogens on microglia. Future studies of gender and hormonal influences on NRG1 signaling in microglia will be important to understand the heterogeneity of disease pathology and the therapeutic potential of targeting microglial activation in human MS in men and women.

Title: Epimedium flavonoids ameliorate neuroinflammatory and neuropathological changes in rodents

Authors: *L. YIN[1], Z. QU[3], M. LIANG[3], L. ZHANG[2], L. LI[2];
[2]Dept. of Pharmacol., [1]Xuan Wu Hosp. of Capital Med. Univ., Beijing, China; [3]Dept. of Pharmacol., Beijing Geriatric Med. Res. Ctr., Beijing, China

Abstract: The present study was designed to determine whether epimedium flavonoids (EF) had effect on the development of experimental autoimmune encephalomyelitis (EAE) in rats and cuprizone (CPZ)-induced neuropathological changes in the corpus callosum of C57BL/6 mice. EAE was induced by immunization of adult female Lewis rats with partially purified myelin basic protein (MBP) prepared from guinea-pig spinal cord homogenate. EF was administrated intragastrically once a day after immunization until day 14 post immunization (p.i.). Administration of EF (20 and 60 mg/kg) significantly reduced clinical score of neurological deficit in EAE rats; alleviated demyelination and inflammatory infiltration; and inhibited astrocytes activation, production of proinflammatory molecules such as interleukin-1β (IL-1β), tumour necrosis factor-α (TNF-α), nitric oxide (NO) and nuclear transcription factor (NF-κB) in the spinal cord of EAE rats. Treatment with EF also enhanced the expression of 2', 3'-cyclic nucleotide 3'-phosphohydrolase (CNPase) and nerve growth factor (NGF), increased the number of oligodendrocytes and protected the ultrastructure of myelin sheaths and axons in the spinal cord of EAE rats. To induce demyelination, 8 week old mice were fed with 0.2% CPZ for a maximum period of 6 weeks. EF treatment for a period of 3 weeks effectively decreased the breakdown of myelin, OL loss, and oligodendrocyte precursor cell (OPC) accumulation in CPZ-fed mice. In addition, EF administration significantly increased the cortical expression level of insulin-like growth factor 1 (IGF-1). Our results showed that EF inhibited the development of partial MBP-induced EAE in rats and protected against CPZ-induced neuropathological changes. These effects involved reducing neuroinflammation and enhancing myelination and neurotrophins and our findings suggest that EF may be useful for the treatment of multiple sclerosis.

Title: Phasic treatment with IFNγ stimulates release of CNS exosomes that protect against spreading depression

Authors: *A. D. PUSIC, K. M. PUSIC, R. P. KRAIG;
Univ. of Chicago, Chicago, IL

Abstract: Migraine is a common headache disorder characterized by unilateral, intense headaches that are preceded by an aura in one-third of patients. Spreading depression (SD), the most likely cause of migraine aura and perhaps migraine pain, is a self-propagating wave of transient depolarization accompanied by a transient negative shift of the interstitial direct current potential.1,2 In prior work, we found that SD elevates IFNγ production, and increases production of pro-inflammatory cytokine and reactive oxygen species production in the CNS. Conditions of inflammation have deleterious effects on myelin integrity, including decompaction of myelin sheaths. This decompaction of myelin is relevant to SD, wherein increased production of reactive oxygen species and inflammatory cytokines causes transient demyelination that increases susceptibility to subsequent SD perhaps via ephaptic transmission.3 Though existing therapies offer only modest benefits, environmental enrichment (EE; volitionally increased physical, social, and intellectual activity) has been clinically shown to reduce migraine frequency and SD.4 This effect may involve adaptive responses initiated by phasic production of IFNγ during EE. Accordingly, we focused on the potential for physiological levels of IFNγ to protect against SD. In contrast to the detrimental effects of elevated IFNγ from SD3, IFNγ applied phasically or as a 12-hour pulse (equivalent to a single cycle of phasic treatment) to mimic EE produced opposite effects - myelin basic protein (MBP) significantly increased, SD threshold significantly increased, and OS was significantly reduced. IFNγ-stimulated slice cultures produced exosomes that conferred adaptive changes comparable to those evoked by phasic or pulsed IFNγ treatment. Furthermore, we found that exosomes produced by IFNγ-stimulated primary microglia produced the same effect, suggesting that these cells are the source of nutritive exosomes harvested from intact slice cultures. microRNA profiling of exosomal contents revealed the presence of a number of miRNA species involved in myelination and anti-inflammatory pathways, that may account for these effects. Thus, our results support further research on exosomes produced by IFNγ-stimulated immune cells (including microglia) as a possible therapeutic target for prevention of SD, and by extension, migraine.

Title: Siponimod - direct CNS effects of a 2nd generation immunomodulatory drug?

Authors: *P. EHLING, M. CERINA, V. NARAYANAN, A. M. HERRMANN, S. PANKRATZ, S. BOCK, K. GOEBEL, S. G. MEUTH;
Neurol., Univ. of Muenster, Muenster, Germany

Abstract: Introduction: Siponimod (BAF312) is a selective sphingosine 1-phosphate1,5 receptor modulator currently under clinical development for the treatment of secondary progressive multiple sclerosis. Its precursor drug fingolimod is approved for the treatment of relapsing-remitting multiple sclerosis, an autoimmune, neurodegenerative disease. Both drugs are shown to inhibit peripheral lymphocyte egress thereby reducing pathological immune cell invasion into the brain. However, non-immunological central nervous system (CNS) effects of S1PR modulatory drugs are still a matter of debate. Here, we test the hypothesis that beside its immunomodulatory effect siponimod exerts a direct effect in the CNS. Methods: We stereotactically induce lesions targeted to either white or grey matter regions by injection of proinflammatory cytokines in mice that were immunized with myelin oligodendrocyte glycoprotein 10 days earlier (focal experimental autoimmune encephalomyelitis, EAE). To allow distinction between peripheral and central drug effects siponimod was administered either systemically (3 mg/kg) or directly to the brain lesion site via implantable osmotic pumps and brain infusion cannulae (1 µg/day). Behavioural, histological, flow cytometric analyses were performed both 2 and 5 days after focal EAE induction. Results: Siponimod induced lymphopenia and attenuated EAE symptoms in systemically treated mice. Flow cytometry revealed reduced immune cell infiltrates at both grey and white matter lesions compared to sham-treated controls. After systemic siponimod treatment locomotor activity was slightly increased in the open field arena 2 days and 5 days after focal EAE induction. In the rotarod setup, treated mice with white matter lesions revealed less locomotor deficits 5 days after focal EAE induction. In first experiments with direct drug application to the brain lesion via osmotic pumps, lymphocyte counts in peripheral blood and lymph nodes were indifferent between treated and non-treated mice. Conclusion: Systemic siponimod ameliorates the EAE disease course by inhibiting lymphocyte egress from lymphoid organs. However, drug application directly to the brain lesion site does not affect peripheral immune cell counts. Investigations concerning central drug effects are still ongoing work.

Title: Evaluation of nefiracetam as a regenerative therapeutic in an animal model of demyelinating Charcot Marie Tooth disease

Authors: *L. ALVEY[1], R. P. MURPHY[2], K. J. MURPHY[2], K. H. KEANE[1], J. F. X. JONES[1], M. PICKERING[1];

Abstract: Demyelinating Charcot Marie Tooth disease (CMT) is an inherited progressive peripheral neuropathy characterised by degeneration of the myelin sheath that surrounds the axons of peripheral nerves, and to date there are no pharmacological interventions to treat them. The trembler-J mouse is used as a model for investigating peripheral nerve demyelination. As previous studies indicated that nefiracetam was capable of accelerating remyelination after injury in the central nervous system, we set out to evaluate the efficacy of the drug to induce repair in a model of peripheral demyelination. Adult trembler-J mice were treated with nefiracetam (30mg/kg ip) for 30 days, and motor function was assessed with rotarod testing. While no differences in motor phenotype were detected between control and treatment groups, we examined nerve structural pathology for evidence of any impact of nefiracetam treatment. Myelin thickness and fibre calibre were significantly reduced in trembler-J mice relative to wild type, and no difference was seen between nefiracetam and vehicle treated animals. We have recently described previously unreported feature of nerve pathology in these animals (Power et al, Muscle & Nerve 51: pg246-522, 2015), where axon length relative to nerve length is increased in the trembler-J mouse. This pathology was also unchanged by nefiracetam treatment. Nodal density was also assessed as an indicator of intermodal distance. While the trembler-J mice exhibited a higher nodal density (suggesting shorter intermodal distance) as expected, nefiracetam treatment significantly reduced this to the same level as seen in the wild type nerves. While the drug appeared to be ineffective on the disease phenotype, we noted a loss of large calibre fibres in the trembler-J mice, suggesting a loss of motor neurons, which would imply our intervention at the late stage of disease was inappropriate. Because there seemed to be a normalisation of internodal distance, we then investigated whether there was evidence for a direct effect of the drug on Schwann cells. Using a novel aligned dorsal root ganglion explant culture system, we found treatment with 1 μM nefiracetam significantly increased Schwann cell density and migration away from the ganglion, and also increased axon growth at the same time. We conclude that, while nefiracetam is unlikely to be an effective intervention in advanced CMT, we cannot rule out that it may act directly on Schwann cells and be an effective therapeutic for earlier intervention.

Title: Amantadine ameliorates gait deficits and disease severity in an animal model of multiple sclerosis

Authors: J. NGUYEN[1], *B. BRIGHAM[1], J. OKSMAN[2], T. AHTONIEMI[2], B. SAVA[3], B. BUISSON[3];

Abstract: Multiple Sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system (CNS). MS is characterized by the impairment of axonal transmission and the reduction in nerve conduction velocity, resulting in neurological and motor deficits. Dalfampridine is approved as a treatment to improve walking in MS. It is thought that dalfampridine improves walking in MS patients by blocking potassium channels, thereby improving nerve impulses across regions of demyelination in axons. In a mouse model of MS, dalfampridine has been shown to ameliorate gait deficits but did not alter the disease course (Gobel et al 2013). Amantadine HCl is an NMDA receptor (NMDAr) antagonist approved for the treatment of influenza infection and Parkinson's disease. In addition to its glutaminergic activity, amantadine has also been shown to modulate other neurotransmitter systems, inhibit microglial activation, and elevate levels of brain-derived neurotrophic factor (BDNF). Amantadine has been shown in clinical trials to reduce fatigue in MS, but its effects on gait and walking have not been evaluated. Here, we characterize the *in vitro* effects of amantadine on potassium channel activity and the efficacy of amantadine in a mouse model of MS. First, we compared the effects of amantadine to dalfampridine on the blockade of potassium currents in rat coronal brain slices. Both amantadine and dalfampridine blocked potassium leak currents and delayed rectifying currents in a concentration-dependent fashion, but potassium current blockade occurred at 10-100 fold lower concentration with amantadine compared to dalfampridine. Next, we assessed the effects of amantadine in experimental autoimmune encephalomyelitis (EAE), a mouse chronic model of MS. EAE was induced in female C57BL/6 mice by subcutaneous injection of myelin oligodendrocyte glycoprotein (MOG35-55), and disease severity and gait parameters were measured over 28 days. We found that chronic administration of clinically relevant doses of amantadine reduced the severity of clinical disease, improved gross motor function and improved walking following EAE in mice. Together, the data suggest that amantadine may have clinical utility as treatment in MS, and provide a framework for further clinical evaluation. References: Gobel et al. Title: Dendritic cell-derived exosomes containing miR-219 are effective after nasal administration to rat brain - implications for treatment of multiple sclerosis and migraine

Authors: ***J. SCHUMER**, A. D. PUSIC, R. P. KRAIG;
Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Environmental enrichment (EE) consists of increased intellectual, physical and social activity, and is known to reduce brain disease. In previous work, we have shown that exosomes derived from the serum of EE animals increased myelination and reduced oxidative stress (OS). These effects are, in part, due to increased exosomal miR-219, which has been shown to be necessary and sufficient to promote differentiation of oligodendrocyte precursors into myelinating cells.1 We have also shown that the effects of EE can be mimicked ex-vivo by IFNγ stimulated dendritic cell-derived exosomes (IFNγ-DC-Exos). IFNγ-DC-Exos increase remyelination and reduces OS in hippocampal brain slice cultures.2 This led us to propose IFNγ-DC-Exos as a novel therapeutic for demyelinating diseases, which include multiple sclerosis and migraine [modeled here by spreading depression (SD)]. We are exploring the efficacy of nasally delivered1,2,6 IFNγ-DC-Exos on *in vivo* models of MS (using lysolecithin injections into corpus callosum) and migraine (using SD threshold, SDT). Nasal delivery of IFNγ-DC-Exos followed by lysolecithin injection significantly ($p < 0.019$; $n = 3$/group) improved recovery from

demyelination three days later (lysolecithin alone: 1.00 ± 0.14; lysolecithin+ IFNγ-DC-Exos: 0.4 ± 0.07). Also, nasal treatment IFNγ-DC-Exos significantly ($p < 0.001$) increased SDT [sham: 1.00 ± 0.14; unstim-DC-Exo: 1.10 ± 0.28; IFNγ-DC-Exos: 57.0 ± 4.27 (n = 3-5/group)] a day later. The nutritive exosomes were equivalently effective ($p < 0.001$) in brain slice cultures (control: 1.00 ± 0.45; IFNγ-DC-Exos: 12.5 ± 1.52; n = 8/group). One day after nasal treatment, CNS protein carbonylation (as an indicator of OS) was significantly ($p = 0.035$) reduced (sham: 7.25 ± 0.83, n = 7; IFNγ-DC-Exos: 4.58 ± 0.55, n = 5). This led us to ask if miR-219 plays a role in OS reduction. Transfection of exosomes with a miR-219 inhibitor significantly ($p < 0.0001$) abrogated the reduction in OS seen with IFNγ-DC-Exo-treated slice cultures. As a negative control, exosomes were transfected with a non-targeting miRNA inhibitor, which had no effect (control: 1.00 ± 0.1; IFNγ-DC-Exos: 0.28 ± 0.002; +inhibitor: 1.06 ± 0.17; +negative control: 0.13 ± 0.02; n = 9/group). Thus, we have shown that nasal administration sucessfully delivered IFNγ-DC-Exos to the CNS, and had a functional effect on both myelin content and oxidative status. Furthermore, we have identified miR-219 as an important mediator of these effects. Title: Combinatorial treatment strategies attenuate EAE

Authors: *K. P. KOENIG, J. C. NISSEN, S. E. TSIRKA;
Mol. and Cell. Pharmacol., Stony Brook Univ. Med. Sch., Stony Brook, NY

Abstract: Multiple sclerosis (MS) is a chronic demyelinating disease of the central nervous system characterized by inflammation and neurodegenerative processes. Currently, MS therapy involves the long-term use of immunomodulators, which tend to have numerous side effects and varying efficacies among MS patients. Additionally, these immunomodulators do not aid in promoting remyelination, which is essential to the return of neuronal function. Benztropine, a FDA-approved drug used for treatment of Parkinson's disease, was recently identified as an effective inducer of oligodendrocyte precursor cell differentiation *in vitro* and in experimental autoimmune encephalomyelitis (EAE), the most common animal model used to study MS. Thus,

we sought to study the effects of a combinatorial therapy of benztropine and tuftsin, an immunomodulatory tetrapeptide shown to polarize microglia to the M2 phenotype, on the MOG-induced EAE disease course, demyelination, and microglial infiltration and polarization. Here we show that combinatorial treatment with both benztropine and tuftsin seem to markedly ameliorate the EAE disease course. Further, this treatment strategy reduces the pathological hallmarks of MS as well, as these animals have reduced demyelination and decreased microglial activation, with an overall anti-inflammatory immune phenotype.

Title: Triacetin therapy alters spinal cord lipid metabolism in mice subjected to experimental autoimmune encephalomyelitis (EAE)

Authors: *A. C. CHEVALIER, T. A. ROSENBERGER;
Univ. of North Dakota, Grand Forks, ND

Abstract: Triacetin therapy increases brain acetyl-CoA metabolism, increases phosphocreatine levels, alters the expression of adenosinergic enzymes and receptors, increases histone and non-histone protein acetylation, and inhibits neuroglia activation. However, it is unknown if triacetin therapy alters lipid metabolism within the central nervous system. To begin to address this question, we quantified the effect treatment had on spinal cord lipid content and phospholipase levels in mice subjected to experimental autoimmune encephalomyelitis (EAE), a mouse model of multiple sclerosis. EAE was induced with myelin oligodendrocyte glycoprotein peptide (MOG 35-55, 50μg per mouse), and prophylactic triacetin therapy was maintained for 40 days (glycerol triacetate, 4g/kg via oral gavage daily). We found that treatment attenuated the onset of clinical symptoms in EAE mice treated with GTA compared to control-treated mice. Further, triacetin therapy prevented the loss of ethanolamine and choline glycerophospholipid, phosphatidylserine, esterified fatty acids, and cholesterol in these mice. Triacetin therapy did not alter cholesteryl esters, but EAE injury did result in a significant decrease in these molecules within the spinal cord. With regard to enzymes involved in the metabolism of membrane phospholipids, treatment increased phosphorylated cytosolic phospholipase A2 (cPLA2) and non-phosphorylated cPLA2 levels but did not alter the levels of phospholipase C (PLC) β and PLC δ. Both phosphorylated and non-phosphorylated cPLA2 levels increased significantly with injury but were returned to

baseline levels following treatment. In addition, β-actin was significantly increased in mice subjected to EAE compared to control animals suggesting that EAE disrupts actin polymerization and/or metabolism. In conclusion, these data suggests that triacetin therapy may alter spinal cord lipid metabolism in mice subjected to EAE.

Title: Environmental enrichment stimulates immune cell secretion of exosomes that promote CNS myelination and reduce inflammation

Authors: *K. M. PUSIC, A. D. PUSIC, R. P. KRAIG;
Dept. of Neurol., Univ. of Chicago, Chicago, IL

Abstract: Grey matter demyelination is an important component of multiple sclerosis (MS) pathogenesis, particularly in the secondary progressive disease phase. Extent of damage is strongly correlated with neurological dysfunction. Aging likewise occurs with cognitive decline from myelin loss, and age-associated failure to remyelinate significantly contributes to MS progression. In prior work, we show that serum exosomes from young animals can increase oligodendrocyte precursor cell (OPC) differentiation into mature myelinating oligodendrocytes - both under normal conditions and after acute demyelination.1 Environmental enrichment (EE) of aging animals produced exosomes that mimicked this effect. We found that both young and EE serum-derived exosomes were enriched in miR-219, which is necessary and sufficient for OPC differentiation.2 Exosomes found in the blood can originate from a multitude of sources, and it is precisely this attribute that makes them ideal candidates as biomarkers of disease. For example, in a variety of solid organ cancers, tumor-derived exosomes can be isolated from blood.3 However, based on work showing that the properties of serum-derived EE exosomes could be reproduced ex-vivo using primary dendritic cell cultures4, we focused on immune cells. Given

the broad beneficial effects of EE on immune function5, it is likely the pro-myelinating effect is not due to a specific cell type, but a common property of many immune cells. In support of this, we found that exosomes produced by all EE immune cell types significantly increased MBP in slice cultures, whereas those from immune cells of non-enriched animals had no effect. This suggests that EE globally alters immune function in a way that supports brain health. However, circulating blood cell exosomes produced a more robust effect than those derived from cells of the spleen and lymph nodes. miRNA expression profiling showed that all circulating blood cell exosomes examined contained miR-219, but it is interesting to note other miRNA species present at high levels in a subset of EE exosome types: miR-9 and miR-17, which are involved in OPC proliferation; miR181a, which has an anti-inflammatory function; and miR-665, which may affect brain immune function in a manner that dysregulates neuronal excitability. Thus, we have begun to explore the impact of these exosome on oxidative status and resolution of inflammation. This may help us determine the role of additional enriched miRNAs; information that could be useful in engineering more effective and specific exosomes as therapeutics against brain demyelination and oxidative stress.

Title: Prolonged electrical stimulation of a hindbrain raphe region attenuates experimental autoimmune encephalomyelitis in mice

Authors: S. S. SLOLEY[1], P. M. MADSEN[1,2], M. M. CARBALLOSA[1], A. VITORES[1], R. BRAMBILLA[1], *I. D. HENTALL[1];
[1]Miami Project Cure Paral, Univ. Miami Schl Med., Miami, FL; [2]Dept. of Neurobio. Res., Inst. of Mol. Med., Odense, Denmark

Abstract: Interactions between the nervous and immune systems are critical in various chronic neurological diseases, such as multiple sclerosis (MS). MS is an immune-mediated inflammatory disease of the central nervous system characterized by widespread demyelination and axonal loss

in the brain and spinal cord, which ultimately account for disease severity and irreversible disability. Strategies aimed at reducing inflammation and promoting remyelination are the two most promising interventions to improve function and slow disease progression in MS therapy. Since electrical stimulation targeting a raphe nucleus has proved efficacious in promoting myelin sparing in models of CNS trauma, we explored whether this treatment may also be beneficial in experimental autoimmune encephalomyelitis (EAE), a model of MS. EAE was induced in mice by injection of MOG35-55 peptide. Eight days after EAE symptoms emerged (mean onset 17 days after induction), a self-powered encapsulated stimulator, controlled and read wirelessly, was implanted on the mouse's skull, and an integral microelectrode stereotaxically positioned in the hindbrain's nucleus raphe magnus (NRM). Stimulation (-30 μA, 1 ms pulses, 8 Hz) was given during 12 daylight hours, alternating 5 minutes on and off, over 5-29 days. Controls had inactive stimulators. EAE severity, scored daily on a 0 to 6 scale by a blinded observer, was reduced by about 0.5 points in stimulated mice compared to controls, starting around 20 days after EAE onset. The number of days of stimulation was linearly correlated with later EAE improvement. Mice were sacrificed and histological analyses performed 4-5 weeks after EAE onset. The numbers of degenerated collapsed axons and infiltrating immune cells in the thoracic spinal cord were significantly reduced in stimulated mice, while myelinated axons showed a trend toward increase. In conclusion, NRM activity improves EAE clinical symptoms and reduces axonal pathology in spinal cord, suggesting it may have neuroprotective effects in neuroinflammation. Ascending midbrain raphe nuclei may have similar effects, given the disseminated nature of MS. Hence activation of neurons in raphe areas or their input regions, such as by deep brain stimulation (DBS) or drugs, could offer a potential MS therapy.

Title: FTY720 (Gilenya) stimulates neurotrophic factor expression in oligodendroglial cells

Authors: I. SEGURA, *R. G. PEREZ;
Biomed. Sci., Texas Tech. Univ. HSC El Paso, El Paso, TX

Abstract: Multiple system atrophy (MSA) is a rare and rapidly progressing demyelinating neurodegenerative disorder with no effective treatments. Most MSA patients progress from diagnosis to death in 10 years. Postmortem analyses of MSA brains reveal accumulation of the protein α-synuclein (aSyn) in glial cytoplasmic inclusions (GCI) of oligodendroglia cells (OLGs), the myelinating cells of the brain. MSA brains show reduced levels of glial cell line derived neurotrophic factor (GDNF) and brain derived neurotrophic factor (BDNF). Supplementation of MSA cell and mouse models with these factors decreases MSA-related dysfunction. Nerve growth factor (NGF) is another protective molecule for OLGs and neurons. It protects against neuroinflammation, promotes axon extension and neuronal survival, induces differentiation of oligodendrocyte precursor cells (OPCs) and stimulates myelination by OLGs. Hence, therapies that increase expression of NGF, GDNF or BDNF should be beneficial for MSA. Research shows that histone deacetylase (HDAC) inhibitors increase the levels of acetylated histone 3 (AcH3) and acetylated histone 4 (AcH4), which up-regulates GDNF, BDNF and/or NGF expression in neuronal and/or glial cells. FTY720 (Gilenya), an FDA-approved oral drug for multiple sclerosis, stimulates BDNF and GDNF expression in neurons and microglia. Recently, phosphorylated FTY720 (FTY720-P) was shown to inhibit HDACs; however, HDAC inhibition and effects on neurotrophic factor expression are mostly unexplored and have never been assessed in OLGs. To assess this we treated an OLG cell line, OLN-93, with FTY720 or vehicle for 6 - 24 hr, then measured levels of AcH3 and AcH4 using immunoblotting. We also measured NGF, GDNF and BDNF expression by quantitative real time PCR. FTY720 treatment caused a significant increase in the levels of AcH3 and AcH4 by 6 hr, but by 24 hr only AcH3 was significantly increased. OLN-93 NGF expression was significantly increased at 6 and 24 hr after FTY720, and neither GDNF nor BDNF were significantly changed in OLGs. This increased NGF expression in OLGs is another protective mechanism elicited by FTY720 that may prevent demyelination and associated neurodegeneration in MSA. Furthermore, FTY720-induced changes in NGF expression seem to mirror those of global histone acetylation. Further exploring HDAC inhibition by FTY720 and the role of aSyn in MSA will help determine if changes in histone acetylation are responsible for altered expression of neurotrophic factors in MSA.

Title: Effect of Vitamin D replacement on cognition in Multiple Sclerosis patients

Authors: *H. J. DARWISH, R. HADDAD, S. OSMAN, S. GHASSAN, B. YAMOUT, S. KHOURY;
American Univ. of Beirut, Beirut, Lebanon

Abstract: Multiple Sclerosis (MS) is a chronic inflammatory disease of the central nervous system with genetic and environmental risk factors including low serum vitamin D. Recent studies correlated low serum 25(OH)D levels with cognitive dysfunction in adults. In this study we evaluated the change in cognitive function after vitamin D supplementation in MS patients with low serum 25(OH)D (<25μg/ml) compared to subjects with normal 25(OH)D levels (serum level >35 μg/ml). A total of 113 adult MS patients with relapsing-remitting disease stable on interferon-beta therapy were recruited. Demographic and health behavior information were collected, depression and anxiety were assessed using the Arabic- Hopkins Symptoms Checklist (HSCL-25), cognitive performance was measured, at baseline and 3 months after vitamin D supplementation (10,000 IU daily for 3 months or 50,000 IU weekly for 3 months), using the Arabic-Montreal Cognitive Assessment (MoCA), Stroop Test, Symbol Digit Modalities Test (SDMT) and Brief Visual Memory Test delayed recall (BVMT-DR). Of the recruited subjects, 89 were found eligible with low (<25, n=41) or normal (>35, n=48) 25(OH)D . After 3 months, anxiety scores decreased significantly in those with low baseline 25(OH)D and showed a significant improvement on the BVMT immediate (10 and 30 sec), DR (20 min) and MoCA. Yet, those with normal 25(OH)D level improved on Stroop test and BVMT (10 and 20 sec). At baseline, the low 25(OH)D group scored less on all cognitive tests except Stroop; this difference was significant for SDMT and BVMT-DR. Serum 25(OH)D level correlated positively and significantly with BVMT-DR. Exercise was positively associated with cognitive performance in all tests except the Stroop[BVMT, 10 sec r=. 61, 20 sec r= .64, 30 sec, r=.70, DR, r= .54, SDMT, r= .56, MoCA= .46; $p < 0.05$], and correlated strongly with cognitive performance in those with low 25(OH)D [BVMT, 10 sec r=.946, 20 sec r= .80, 30 sec, r=.891, DR, r= .81, SDMT, r= .747, MoCA= .614; $p < 0.01$]. The normal 25(OH)D group had lower anxiety scores at baseline. Alcohol consumption correlated positively with SDMT, BVMT and MoCA in the group with low 25(OH)D and BVMT and SDMT in the normal group. Age and years of education correlated positively with all cognitive tests regardless of 25(OH)D level. Cognitive performance and anxiety in MS seem to be affected by low 25(OH)D level. There is a positive correlation between exercise and cognitive performance in all subjects; but is stronger in the group with low 25(OH)D suggesting compensatory exercise role in this group. Of interest is the positive alcohol effect on cognitive performance that needs further exploration.

Title: Recognising the role of hypoxia in neuroinflammatory disease, and the effects of oxygen as a therapy

Authors: *M. AMATRUDA[1], A. MATIS[1], A. DAVIES[1], R. DESAI[1], M. LINDNER[2], C. LININGTON[2], K. J. SMITH[1];
[1]Inst. of Neurology, Univ. Col. London, London, United Kingdom; [2]Univ. of Glasgow, Inst. of Infection, Immunity and Inflammation, Glasgow, United Kingdom

Abstract: The mechanisms responsible for the neurological deficits and demyelination in relapsing-remitting multiple sclerosis (MS) are complex, and remain unclear. Here we focus on the potential role of tissue hypoxia in contributing to the loss of neurological function, and the possibility that oxygen therapy may ameliorate the deficits. We examine the presence of tissue hypoxia in passive transfer EAE, where paralysis occurs in absence of demyelination, and the role of oxygen therapy in active EAE, a model in which we have previously described a correlation between hypoxia in the spinal cord and the severity of the neurological deficits. In passive EAE, an oxygen-sensitive probe inserted into the spinal cord revealed tissue hypoxia at the time of expression of neurological deficit. Indeed, the oxygen partial pressure (PO2) was comparable with the PO2 values we have observed in rats with active EAE and the same disease severity. Histologically there was a significantly higher expression of hypoxia-related markers. The findings suggest that hypoxia contributes to the neurological deficits in passive EAE, as we have found in active EAE. In active EAE we have now extended our observations to examine the consequences of oxygen therapy. We report that treatment with 95-100% oxygen improved neurological function in 50% of the treated rats within only one hour of exposure, and the improvement reversed upon return to room air for the following hour. To explore the time-dependence of oxygen therapy, oxygen (75%) was applied for 24 hours either at the first, second or third day of disease expression. Oxygen significantly reduced the neurological deficit; notably the greatest improvement occurred when administered on the first day. We then tested the optimal duration for oxygen treatment (24, 48 and 72 hours at 75% oxygen) from onset of disease, and found the greatest benefit was achieved with 48 hours exposure ($p < 0.05$). Interestingly, when administered at the onset of deficit, oxygen reduced the severity of the disease progression for up to two additional days once returned to room air. We conclude that tissue hypoxia is an important but currently overlooked cause of neurological deficits in neuroinflammatory disease, and that oxygen administration can promptly ameliorate the deficits.

Title: Fingolimod sustains neuronal and electrophysiological function in a mouse model of myelin oligodendrocyte glycoprotein (MOG) induced experimental autoimmune encephalomyelitis (EAE)

Authors: *S. S. POPP, P. SCHLEESE, B. K. MÜLLER, K. WICKE;
Pharmacol., AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany

Abstract: Fingolimod is a sphingosine-1-phosphate receptor modulator and is approved for treating multiple sclerosis. It prevents an autoimmune reaction in MS by sequestering lymphocytes in lymph nodes. Here, we demonstrate that prophylactic therapy protected against the emergence of experimental autoimmune encephalomyelitis EAE symptoms in a rotarod performance test and against abnormalities to the H-reflex, a marker for spasticity since spasticity is a common manifestation in multiple sclerosis. Fourty female C57BL/6 mice were randomly assigned to three treatment groups (sham (n=10), vehicle (n=15) and fingolimod (n=15)). Vehicle and fingolimod mice received MOG emulsified in complete Freund's adjuvant containing heat-inactivated Myobacterium tuberculosis and pertussis toxin injections. The sham mice did not receive any treatment. Three days after MOG injection all groups received daily peroral treatment injection for three weeks (sham and vehicle mice: water and fingolimod mice: 1mg/kg fingolimod in water). Eight days after MOG treatment the mice were scored daily for neurological signs by a person blinded to the treatment. Twenty-one and twenty-two days after MOG treatment the H-reflex was measured; 22 days after the MOG injection the rotarod test was performed, as well. We observed a significant difference between the fingolimod treated animals and the vehicle treated animals in the H/M wave ratio as well as in the rotarod performance test. The sham animals were also significantly different from vehicle treated animals in both tests. Interestingly, we did not find a significant difference in the EAE scores between the fingolimod and vehicle group. This may be due for being a subjective test whereas rotarod and H-reflex are two objective tests. The two objective tests seem to be more sensitive than the subjective one. Our results clearly demonstrate that prophylactic treatment with fingolimod at a clinically relevant concentration prevents the development of neurological disability. Here we show for the first time that the H-reflex can be used as measurement for the assessment of the efficacy of substances used in an animal model of disseminated EAE. This result correlates with the behavioral finding. Disclosures: All authors are employees of AbbVie. The design, study conduct, and financial support for this research was provided by AbbVie. Abstract: Experimental Autoimmune Encephalomyelitis (EAE) is an animal model of multiple sclerosis (MS). We characterized the impairments associated with EAE in female C57BL/6 mice. Mice were immunized subcutaneously with 100 μg of myelin oligodendrocyte glycoprotein emulsified in incomplete Freund's adjuvant supplemented with 500ug mycobacterium tuberculosis H37RA and 200 ng of intraperitoneal pertussis toxin on days 0 and 2. Tail paralysis was observed daily. In Experiment 1, we found that caloric restriction (CR) and chronic oral administration of riluzole, a glutamate release inhibitor, delayed the onset and severity of EAE. CR and riluzole both reduced nociceptive behavior. Array and protein analysis revealed alterations in inflammatory and regulatory cytokines. Moreover, we found altered expression of STAT3, GFAP, and Foxp3 which are notable determinants involved in the immune response. Altered immunological function was indicated by reduced inflammation in the spinal cords of mice treated with chronic oral riluzole. In Experiment 2, we found that acute oral administration did not delay the onset or severity of EAE. These findings indicate a compelling need to delineate the roles of glutamate, the immune response, and CR in EAE.

Title: Activation of NF-κB protects oligodendrocytes against inflammation

Authors: ***W. LIN**[1], W. WISESSMITH[1], S. JAMISON[1], R. SCHMIDT-ULLRICH[2]; [1]Neurosci., Univ. of Minnesota, Minneapolis, MN; [2]Max-Delbrueck-Center for Mol. Med., Berlin, Germany

Abstract: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS), characterized by inflammation, demyelination, and oligodendrocyte loss. Transcription factor Nuclear Factor κ B (NF-κB) plays a critical role in inflammatory diseases by regulating inflammation and cell viability. Activation of NF-κB has been observed in oligodendrocytes in MS lesions. Although *in vitro* studies suggest that NF-κB activation promotes oligodendrocyte survival in response to inflammatory mediators, the effects of NF-κB activation on oligodendrocytes in MS and its animal models remain unknown. Interferon-γ (IFN-γ) is regarded as a key proinflammatory cytokine in MS. The presence of IFN-γ in the CNS during development results in inflammation, oligodendrocyte death, and myelin loss. Interestingly, our previous study shows that IFN-γ activates NF-κB in oligodendrocytes *in vitro* and *in vivo*. In this study, using a mouse model that expresses IκBαΔN, a super-suppressor of NF-κB, specifically in oligodendrocytes, we found that NF-κB inactivation in oligodendrocytes exacerbated IFN-γ-induced cell death and myelin loss in young, developing mice, but did not alter inflammation elicited by this cytokine in the CNS. Thus, this finding implies the cytoprotective effects of NF-κB activation on oligodendrocytes in neuroinflammatory diseases such as MS.

Abstract: Neuronal degeneration underlies the progressive and chronic disability in MS and is currently untreatable. Emerging evidence indicates that myelin is important not only for neuronal function but for the survival of axons, suggesting that remyelination therapies may represent a promising approach to preserve axonal integrity in MS. Muscarinic receptor (MR) antagonists significantly promote oligodendrocyte differentiation and remyelination, however the receptor target(s) of these compounds is currently unknown. The non-selective antagonism of all MR subtypes (M1R-M5R), as well as other off-target receptors, limits the utility of these compounds for MS therapy. As oligodendrocyte precursor cells (OPCs) express all five MR subtypes, we used MR knockout mice to identify the receptor subtype responsible for the beneficial actions of MR antagonists in MS. Here we identify one MR subtype as the specific receptor that inhibits oligodendrocyte differentiation and myelination and mediates the effects of MR antagonists. Deletion of the MR phenocopies the effects of the anti-muscarinic compounds resulting in

enhanced differentiation and myelination. More importantly, disruption of the MR function reduces the severity and enhances recovery from experimental autoimmune encephalomyelitis (EAE) with robust remyelination and subsequent preservation of axonal integrity. Additionally, enhanced remyelination in the lysolecithin-induced focal demyelination model suggests that the MR acts to inhibit the kinetics of remyelination of endogenous oligodendroglia. To determine enhanced remyelination is sufficient to protect axons against degeneration, the MR in oligodendroglia is conditionally deleted under the control of CNPase promoter. We will assess remyelination and axonal integrity in the MR conditional knockout EAE mice. Together, our findings indicate that the MR mediates potent inhibition of oligodendrocyte differentiation and myelination and antagonizing the MR may represent a promising therapeutic approach to stimulate remyelination and preserve axonal integrity in MS.

Title: Oligodendroglial TNFR2 mediates membrane TNF-dependent repair in neuroimmune disease by promoting oligodendrocyte differentiation and remyelination

Authors: *P. MADSEN[1,2], D. MOTTI[3], D. E. SZYMKOWSKI[4], J. R. BETHEA[5], R. BRAMBILLA[1,6];
[1]Univ. of Miami Miller Sch. of Med., Miami, FL; [2]Dept. of Neurobio. Res., Univ. of Southern Denmark, Institute of Molecular Medicine, Odense, Denmark; [3]Nationwide Children's Hosp., Columbus, OH; [4]Xencor Inc., Monrovia, CA; [5]Dept. of Biol., Drexel Univ., Philadelphia, PA; [6]The Neurosci. Program, Miller Sch. of Medicine, Univ. of Miami, Miami, FL

Abstract: Tumor necrosis factor (TNF) has been associated with the pathophysiology of multiple sclerosis (MS) as patients have elevated concentration of TNF in serum, CSF and within active lesions. TNF exists in two forms, transmembrane (tmTNF) and soluble (solTNF), whose

functions are mediated by TNFR1 and TNFR2. Due to differential binding affinities of the ligands solTNF signals only via TNFR1 and tmTNF through both TNFR1 and TNFR2. The cellular processes activated by the two receptors are often opposite: TNFR1 mediates apoptosis and inflammation, TNFR2 mediates cell survival, resolution of inflammation and myelination. Numerous studies have underscored the importance of distinguishing between the functions of solTNF and tmTNF and have associated MS and its animal model experimental autoimmune encephalomyelitis (EAE) to the detrimental effects of solTNF via TNFR1, while tmTNF is important for repair and remyelination. Here we demonstrate that TNFR2 expressed in the oligodendrocyte lineage is a key mediator of the protective functions of tmTNF in EAE. CNP-cre:TNFR2fl/fl mice with conditional ablation of TNFR2 in oligodendrocytes showed exacerbation of EAE with increased axonal damage and myelin pathology, as well as reduced remyelination. The EAE clinical profile was not improved by treatment with the solTNF inhibitor XPro1595, which suppresses EAE in TNFR2fl/fl control mice, indicating that for tmTNF to be beneficial a functional TNFR2 in oligodendrocytes is required. Lack of oligodendroglial TNFR2 also resulted in increased loss of oligodendrocyte precursor cells and mature oligodendrocytes after EAE. In oligodendrocyte cultures from WT and TNFR2-/- mice we demonstrated that TNFR2 promotes differentiation, but is not required for proliferation or survival. Finally, in oligodendrocyte-enriched spinal cord suspensions from naïve and acute EAE TNFR2fl/fl and CNP-cre:TNFR2fl/fl mice differential expression of microRNAs that are known regulators of oligodendrocyte differentiation and inflammation, such as members of the miR-219, miR-138 and miR-338 clusters. Taken together our data provide the first direct evidence that TNFR2 in oligodendrocytes is important in driving differentiation, thereby sustaining the tmTNF-dependent repair process in neuro-immune disease. Our studies identify TNFR2 in the CNS as a viable molecular target for the development of remyelinating agents for progressive MS, addressing the most pressing need in MS therapy today.

Title: Immunophenotyping and cytokine expression in MOG_{35-55} induced experimental autoimmune encephalomyelitis mouse model

Authors: M. VIHMA, M. TAAVITSAINEN, J. OKSMAN, *S. KIM, R. HODGSON, P. J. SWEENEY, A. NURMI;
Charles River Discovery Services, Kuopio, Finland

Abstract: Multiple sclerosis (MS) is an autoimmune disease causing a wide range of symptoms by demyelination in central nervous system (CNS). To study mechanisms of MS by using preclinical *in vivo* models, there are several of options but one of the most common models is an MOG_{35-55} induced experimental autoimmune encephalomyelitis (EAE) in mice. In addition to using behavioral, histological and immunohistochemical read outs to assess disease burden and tissue pathology, evaluation of molecular mechanisms and relationship between peripheral and central resident immune cells in the EAE is important. In this study our aim was to characterize MOG_{35-55} mouse model immunological profile by immunophenotyping different subsets of cells in CNS and in peripheral lymph nodes during the course of EAE phenotype. Mice were inoculated with MOG_{35-55} containing adjuvant and disease progression was followed up until day 14 or 21 after which mice were terminated. Cells were harvested and processed from CNS and lymph nodes after which immunophenotyping of subsets of CD45+ cells (CD4+, CD8+, CD11b+ and B-cells) were evaluated by flow cytometry . In addition, cytokine expression of inflammatory cytokines, such as TNF-a, in plasma and CSF were evaluated by Luminex multiplexing assay. Taken together, this study describes immunophenotypic characteristics of resident and infiltrated subsets of CD45+ cells in the CNS as well as profile for cells extracted from lymph nodes during different stages of the disease (EAE) and in relation to naïve mice. Immunophenotypic profile of CNS and lymph nodes is supplemented with cytokine expression levels in plasma and CSF extracted from EAE mice at corresponding time-points. Data will provide insight to this model characteristics through understanding the dynamics of infiltrated and resident immune cells and inflammatory cytokine signals in circulation during the disease progression.

Title: Characterization of the MOG_{35-55} induced experimental autoimmune encephalomyelitis mouse model for multiple sclerosis by behavior and immunohistochemistry

Authors: *J. OKSMAN, S. KIM, L. TÄHTIVAARA, A. NURMI;
Charles River Discovery Services, Kuopio, Finland

Abstract: One of the most common preclinical *in vivo* models used in the study of mechanisms of multiple sclerosis (MS) is the MOG_{35-55} induced experimental autoimmune encephalomyelitis (EAE) in mice. This technique involves inoculation with MOG_{35-55} protein, which is emulsified to complete Freud's adjuvant, to evoke inflammatory responses against proteins. Further, an injection of pertusis toxin (PTx) allows immune cells access to the CNS trough the blood brain barrier (BBB) causing T cell related demyelination. Fingolimod (FTY-720), an immune modulating drug approved by FDA for treatment of MS, is commonly used as a positive control in MOG_{35-55} induced EAE in mice. FTY-720 is a sphingosine-1-phosphate receptor modulator, which can isolate the lymphocytes in lymph nodes to prohibit immune cells from reacting against antibodies. In the current study, mice were inoculated with MOG_{35-55} on Day 0 and followed until Day 35. FTY-720 served as a positive control compound with therapeutic and prophylactic therapy. The clinical status of the mice was scored and body weights were measured daily. At the study end-point, the mice were terminated for tissue sample collection. Cervical segments of spinal cord were collected and fixed for immunohistochemical (IHC) analyses. Demyelination was analyzed by myelin basic protein staining; microglia activation was analyzed by Iba-1 staining; and inflammation was analyzed with CD68 staining. MOG_{33-55} induced mice start to develop disease symptoms at around two weeks after immunization. After which the disease progression is either primarily dominant or relapsing and remitting type. Mice can reach complete or partial paralysis which also causes muscle atrophy and loss of body weight. After the period of 35 days, IHC analyses of spinal cord cervical segment reveals demyelination, microglia activation and macrophage expression in MOG_{35-55} inoculated mice. In the light of the model phenotype, mouse MOG_{35-55} EAE model is a useful model to study novel compounds against MS. In addition to models disease related behavioral and tissue pathological outcomes and their relationships, model is also useful to examine molecular mechanisms and therapeutic targets in detail to understand human disease better and to develop more effective therapies against MS.

Title: Cuprizone model in mice: characterization of white matter, tissue pathology and inflammation by mri and spect

Authors: K. LEHTIMÄKI, T. HUHTALA, A.-M. ZAINANA, R. HODGSON, *A. J. NURMI; Charles River Discovery Res. Services, Kuopio, Finland

Abstract: Understanding the pathology and processes that are involved in animal models of demyelinating diseases such as multiple sclerosis is a critical component of assessing the utility of the model as a tool to develop novel treatments or biomarkers. . The mouse cuprizone model was developed to produce a wide range of pathological and symptomatic endpoints that recapitulate clinical aspects of MS.To understand better changes that are underlying the phenotype observed in cuprizone model mice, we sought to apply noninvasive imaging techniques to understand the magnitude of demyelination and inflammation over time in the model. Given that many of the symptomatic endpoints demonstrate recovery following discontinuation of cuprizone treatment, we also examined tissue pathology that coincides with reversal of behavioral deficits. To address these questions we used magnetic resonance imaging (MRI), and single photon emission computer tomography (SPECT) and analysis of brain and spinal cord to determine if mice exhibit pathology that could be linked to the observed phenotype of the model both during and following cuprizone exposure. C57Bl/6 female mice were subjected to diet induced cuprizone (0.3% w/w) exposure or regular powdered diet in their home cage. Exposure was 6 weeks on cuprizone following which the cuprizone diet was discontinued and switched to normal diet for 3 weeks. Diffusion tensor magnetic resonance imaging (DTI-MRI) was performed at 3 and 6 weeks after the onset of cuprizone diet. [123I]-TSPO SPECT for inflammation was examined after 6 weeks of exposure with cuprizone. In this presentation we describe tissue pathology end-points (white matter changes, inflammation) in mouse cuprizone model that dynamically evolves during and after cuprizone challenge. Observed tissue changes are compared with behavioral data to identify which imaging markers correlate with phenotypic changes in the model. Taken together, data presented in this presentation provide further insight to the relationship between tissue pathology and the observed behavioral phenotype of cuprizone-exposed mice.

Title: Cuprizone model in mice: characterization of tissue pathology by immunohistochemistry and flow cytometry

Authors: M. VIHMA, *L. TAHTIVAARA, A.-M. ZAINANA, R. HODGSON, A. NURMI; Charles River Discovery Res. Services Finland Ltd, Kuopio, Finland

Abstract: Chronic cuprizone treatment produces a CNS-wide demyelination in mice that is used to model MS and other demyelinating diseases. The construct validity of this model is a function on the extent to which the pathology in the animal recapitulates the pathology in MS. Here we use immunohistochemical and immunophenotyping methods to characterize the effects of cuprizone on demyelination and inflammation and to compare those results to symptomatic endpoints measured using behavioral methods. C57Bl/6 female mice were subjected to diet induced cuprizone (0.3% w/w) exposure or regular powdered diet in their home cage. Exposure was 6 weeks on cuprizone following which the cuprizone diet was discontinued and switched to normal diet for 3 weeks. Brains were harvested from mice at 3, 6 and 9 week time-points for histological/immunohistochemical analysis of brain and spinal cord, with emphasis on demyelination (anti-myelin basic protein (anti-MBP) staining) and inflammatory markers (Iba-1, CD4+, CD8+ CD68+). Finally, we characterized key cell surface markers from cells extracted from CNS and lymph nodes with flow cytometry. In this presentation we describe tissue pathology end-points (white matter changes, inflammation) in mouse cuprizone model that dynamically evolves during and after cuprizone challenge. Observed tissue changes are linked with behavioral data to identify which histological, immunohistochemical and immunophenotype markers correlate with behavioral phenotype of the model. Taken together, data presented in this presentation provide further insight to the relationship between tissue pathology and the observed behavioral phenotype of cuprizone-exposed mice.

Title: Behavioral Characterization of the Cuprizone Model of demyelination in mice

Authors: A.-M. ZAINANA, *S. HÄTINEN, J. PUOLIVÄLI, T. HEIKKINEN, R. HODGSON, A. NURMI;
Charles River Discovery Res. Services, Kuopio, Finland

Abstract: Demyelination is a key factor involved in many neurological diseases including multiple sclerosis (MS). There have been multiple attempts to create novel models that will broaden our understanding of demyelinating disease such as MS and allow for the development of novel treatments. One such model involves the delivery of cuprizone in the diet, which produces a clear demyelination across the CNS in mice. Much has been done to describe the pathology in the brain following cuprizone treatment, but there has been relatively little to

determine the clinical relevance of the model using behavioral endpoints. In this presentation we describe the characterization of the cuprizone model in mice, which shows clear and highly reproducible behavioral changes during and after the cuprizone exposure. C57Bl/6 female mice were given cuprizone (0.3% w/w) in their diet or regular powdered diet. Exposure lasted 6 weeks after which the cuprizone supplementation of the diet was discontinued and the animals were switched to normal diet for 3 weeks. The mice were assessed usinga neurological index, locomotor activity (LMA), and rotarod (RR) during week 3, 6 and 9 as well as elevated plus maze (EPM) and contextual fear conditioning (CFC) test on week 6. In addition, the mice were subjected fine motor gait analysis by MotoRater (MR) assay to evaluate in depth motor performance of the mice on week 6. When LMA was evaluated after 3 weeks of cuprizone exposure, locomotor speed was reduced, but there was no significant difference in distance traveled when compared to vehicle. At 6 weeks the mice clearly showed differences in LMA (distance, rearings, time in center, speed and inactivity time) when compared to controls. However, at 3 weeks after discontinuation of cuprizone , the cuprizone-treated mice were not different from controls in LMA measures with exception of locomotive speed. Mice that had been 6 (but not 3) weeks on cuprizone diet mice showed significant decrease in fall latency in RR. MR analysis showed clear gait impairment in mice that had been 6 weeks on the cuprizone diet. In the EPM, the mice showed anxiety-like behavior with decreased time spent in open arms when compared to control mice at 6 weeks. In CFC, the mice showed freezing behavior for context and cue similar to controls, but also significant freezing behavior in an altered context. These data describe multiple motor and cognitive behavioral deficits while mice were on cuprizone diet during the 3-week follow-up period. Taken together the results described herein provide a better understanding of how to use the cuprizone model for research and drug development.

Title: Mechanisms of myelin loss in copper depleted mice: implications for Progressive MS

Authors: ***A. V. CAPRARIELLO**, K. W. C. POON, J. R. PLEMEL, L. LU, J. F. DUNN, P. K. STYS;
Clin. Neurosciences, Univ. of Calgary, Calgary, AB, Canada

Abstract: Copper is an essential trace element and co-factor for myriad enzymes involved in fundamental biological processes ranging from cellular respiration to anti-oxidation. That copper is also important for myelin physiology is suggested by reduced myelination in genetic diseases of copper transport, and strengthened by decades of rodent studies in which stereotyped demyelination follows ingestion of the copper chelator cuprizone (CPZ). Despite its widespread use as a rodent model of demyelinating diseases such as multiple sclerosis (MS), the precise mechanistic connections between CPZ and demyelination remain unexplained, as does the extrapolation of findings from CPZ-fed mice to relevant neurological diseases. The current study seeks to elucidate mechanistic links between copper deficiency and demyelination. Building on the lab's findings in cultured neurons that copper is an important regulator of NMDA receptor (NMDAR) activity, the hypothesis is that copper chelation causes demyelination through an indirect mechanism involving excitotoxic injury to the oligodendrocyte and myelin directly, both of which express glutamate receptors. Given our recent findings that copper also controls desensitization of the AMPA receptor (AMPAR), the demyelinating action of CPZ may also reflect AMPAR-dependent excitotoxicity. To test these possibilities, various strains of wild-type and NMDAR knockout mice were CPZ-treated and the effects of copper chelation on subcellular as well as systems-level processes were analyzed by a combination of NMR, laser-scanning fluorescence, and CARS imaging modalities in both *in vivo* and *in vitro* preparations. *In vivo*, the absence of GluR3A conferred partial protection from CPZ-mediated demyelination, while GluR3A/2D double knockout mice were fully protected. Current studies seek to clarify the *in situ* expression of glutamate receptors within affected white matter regions and to determine the relative susceptibilities of the oligodendrocyte soma versus its myelin processes to glutamate excitotoxicity. Understanding the link between copper chelation and demyelination carries important implications not only for evaluating the relevance of the CPZ mouse model to MS but for treating the white matter damage that occurs in copper diseases such as Menkes or Wilson's Disease.

Title: Cell intrinsic and microenvironmental etiologies of chemotherapy-induced white matter injury

Authors: *E. M. GIBSON, L. S. WOOD, S. CARTMELL, A. K. GOLDSTEIN, J. LENNON, S. NAGARAJA, S. E. MILLER, P. J. WOO, A. OCAMPO, M. MONJE;
Stanford Univ., Stanford, CA

Abstract: An unintended consequence of cancer chemotherapy is thought to be depletion or dysfunction of the oligodendroglial precursor cells (OPCs) present throughout the central nervous system that give rise to the myelinating oligodendrocytes necessary for fast saltatory conduction of neural impulses. The resultant injury to the myelinated infrastructure of the brain may underlie chemotherapy-associated symptoms of slowed information processing, deficits in attention, concentration, fine motor skills, working memory and learning. OPCs are necessary for developmental myelination, as well as for ongoing myelin remodeling throughout life. Cancer therapy-induced damage to the OPC pool is thus particularly devastating for children who have not yet completed developmental myelination. To confirm the extent of OPC population depletion in children receiving chemotherapy, we examined post-mortem brain samples from the frontal lobes of children treated with multi-agent traditional chemotherapy. We found that OPCs are depleted specifically in subcortical white matter. In contrast, grey matter OPCs are preserved in comparison to age-matched control subjects. Methotrexate, an antimetabolite chemotherapeutic, is a commonly used agent in pediatric cancer therapy and is particularly associated with white matter injury and cognitive dysfunction. We have developed a mouse model of juvenile methotrexate (MTX) chemotherapy exposure in which mice are treated with MTX or PBS (one dose each week from P21-35 for a total of three doses). One month following the last dose of MTX, mice exhibit behavioral deficits in motor speed as measured by the CatWalk gait system, as well as depletion of deep cortical grey matter and subcortical white matter OPCs. As in human subjects, superficial grey matter OPC density was preserved. Concomitant with deep cortical and subcortical OPC depletion, we observed an increase in immature oligodendrocytes, suggesting increased but incomplete differentiation of OPCs. Experiments allografting healthy, GFP-labeled OPCs into the environment of the previously chemotherapy-treated brain to probe the gliogenic microenvironment are ongoing. OPCs isolated from whole brain exhibit an IC_{50} less than the measured MTX concentration achieved in the brain with this paradigm, suggesting that a direct cytotoxic effect on OPCs plays a role in depletion of the subcortical OPC population. Collectively, these data suggest both direct and microenvironmental MTX toxicity on oligodendroglial lineage cells.

Title: Understanding neuronal gene expression changes induced by distal demyelination or inflammatory insult

Authors: *B. CLARKSON, K. MIRCHIA, H. KIM, B. SAUER, R. LAFRANCE-COREY, C. HOWE;
Mayo Clinic, Rochester, MN

Abstract: MR imaging suggests an anatomic correspondence between WM and GM lesions in progressing MS patients, suggesting an underlying neuronal-signaling or neurodegenerative element to the progressive disease state. While retrograde signals evolving from stressed axons that alter soma gene expression have been previously described in models of axonal transection or crush injury, those resulting from inflammation and demyelination are unknown. Using microfluidic chambers that segregate neuronal soma and axons, we have previously demonstrated increased axonal MHC I following treatment with IFNg, a cytokine prominent in demyelinating MS lesions. Furthermore, expression of antigen-loaded MHC I predisposed axons to injury by antigen-specific CD8+ T cells *in vitro*. Here we report that neurons also upregulate expression of MHC class Ib mRNAs in response to axonal stimulation with IFNg. Genes most highly upregulated following cytokine treatment included H2-M3, H2-Q5, H2-Q6, H2-Q7, H2-Q8, H2-T10 , and H2-T23. We further report the development of an *in vivo* model system for measuring axonal vulnerability to antigen-specific immune attack following demyelination using an AAV vector to induce neuronspecific expression of axonally-targeted neoantigen (ovalbumin) tagged with cleavable eGFP. We also present optimized methods using AAV vectors in mice for infecting retinal, motor cortex, and hippocampal neurons to induce target gene expression in axons projecting to optic nerve and corpus collosum.

Title: Multiple sclerosis patients have increased levels of the uremic toxin 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid (CMPF)

Authors: *F. MIR, D. BLEMUR, S. A. SADIQ;
Tisch MS Res. Ctr. of NY, New York, NY

Abstract: We found the uremic toxin 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid (CMPF) to be significantly elevated in the cerebrospinal fluid (CSF) of untreated progressive multiple sclerosis (MS) patients in comparison to normal healthy controls, using global metabolomics profiling. CMPF is an endogenous metabolite of furan fatty acids in humans. CMPF is excreted into the urine via organic anion transporters but accumulates at very high concentrations in the serum of uremic patients. CMPF is mostly albumin bound and has previously been reported to inhibit cellular transport, erythropoiesis and mitochondrial respiration. It has also been implicated in the induction of beta cell dysfunction in diabetes; thyroid irregularities and neurologic dysfunction. We next sought to validate these results in a larger independent cohort of MS patients. CSF and blood was obtained from healthy controls and MS patients with informed consent under an IRB-approved protocol. Samples were immediately processed and stored at -80 degree until use. Data obtained was analyzed using Graphpad Prism. CMPF levels were quantitated using a competitive ELISA from NovaTein Biologicals, USA as per the manufacturer's instructions. Indeed serum CMPF levels were found to be significantly elevated in the MS patients (0.857±0.044μM) (n = 183) as compared to the normal healthy controls (0.0178±0.02 μM) (n = 38) with a p value of < 0.0001. Furthermore, the results show a more pronounced increase in CMPF levels in progressive MS patients as compared to the relapsing remitting patient group. On a cellular level, we have localized the CMPF transporter - solute carrier family 22 member 8/organic anion transporter 3 (SLC22A8), to the glia and neurons in the central nervous system. Functionally, high doses of CMPF were found to be toxic to neuroblastoma cells in culture, in part through an increase in reactive oxygen species generation. The results are the first report of increased CMPF levels in MS and clearly warrant further investigation of its role in the pathogenesis of MS.

Title: Cortical spreading depression induces hemodynamic mini-strokes: a potential cause of white matter leisons in migraine

Authors: *B. DONMEZ-DEMIR[1], M. YEMISCI[1,2], K. KILIC[1], Y. GURSOY-OZDEMIR[1,2], M. MOSKOWITZ[3], T. DALKARA[1,2];
[1]Inst. of Neurolog. Sci. and Psychiatry, Hacettepe Univ., Ankara, Turkey; [2]Dept. of Neurology, Hacettepe Univ., Ankara, Turkey; [3]Massachusetts Gen. Hosp. Harvard Univ., Boston, MA

Abstract: White matter lesions (WMLs) are prevalent in patients with migraine with aura (MA). The mechanisms underlying these putatively ischemic lesions are unknown. As suggested by observations in CADASIL patients, brief hypoperfusion attacks in cortical/subcortical areas supplied by penetrating arteries (PAs) may initiate a cortical spreading depression (CSD) wave and, hence, MA attack and; when hypoperfusion is prolonged, an ischemic lesion may emerge at subcortical areas supplied by long PAs that are particularly vulnerable to perfusion deficits. Alternatively, the source of PA hypoperfusion in MA patients could be the prolonged oligemia accompanying CSDs aggravated by unfavorable hemodynamic conditions. We have tested these possibilities in the intact mouse brain. Mice were anesthetized with ketamine/xylazine or isoflurane. The body temperature, pulse rate and tissue oxygen saturation were monitored and kept within physiological limits. A glass pipette filled with FeCl3 was gently touched the dura over a PA for 3 minutes to induce thrombosis. DC potentials were recorded with Ag-AgCl pellet electrodes placed over the thinned skull. We also monitored the blood flow changes with laser speckle contrast imaging. After 1 or 2 weeks, mice were perfused transcardially with 4% PFA and 5 μm-thick paraffin sections were stained with luxol-fast blue or hematoxylene and eosin staining or labeled with anti-myelin basic protein (to detect demyelination) or anti-CD68 antibodies (to detect activated microglia). We found that occlusion of a single cortical PA consistently (10 out of 10 mice) triggered a CSD originating from the tissue around the PA and, induced a slowly evolving ischemic injury. However, the ischemic lesion was generally confined to the cortex unlike the deep demyelinating WMLs seen in MA patients. In contrast, the cortical oligemia and PA constriction induced by a CSD caused ischemic histological changes in the deep paraventricular zone supplied by hemodynamically vulnerable long medullary arteries. When the unfavorable hemodynamic conditions were further compromised during recurrent CSDs, ischemic histological changes emerged in the cortical watershed areas between the middle-anterior and middle-posterior cerebral arteries. In conclusion, CSD has the potential to cause a delayed ischemic injury at hemodynamically vulnerable brain areas although majority of the cortex and subcortical areas remain histologically intact as generally accepted. This finding may account for the WMLs seen in MA.

Title: Clinical difference between idiopathic optic neuritis and viral optic neuritis

Authors: *S. KIM;
Ophthalmology, Kangwon Natl. Univ. Hosp., Chuncheon-Si, Gangwon-Do, Korea, Republic of

Abstract: Introduction Optic neuritis (ON) is a demyelinating disease of the optic nerve. Most of the ON cases in the Asian population are classified as idiopathic. Idiopathic ON may be associated with a variety of systemic autoimmune disorders, such as multiple sclerosis (MS). But in some cases, especially ON in children, viral infection is known to be associated. A previous study by the optic neuritis study group (ONTT) showed that 26.1% of ON patients had a viral syndrome preceding visual loss, but the characteristics of the viral infection-associated group were not presented. In this context, our study was conducted to analyze the features of ON associated with viral infection. Method A retrospective chart review was performed on 124 patients with ON over 15 years old who visited a tertiary referral center in Korea from 2004 to 2014. Demographics, symptoms, signs and laboratory results were reviewed. Magnetic resonance images (MRI) and cerebrospinal fluid findings were also analyzed. Result Seventeen out of 124 ON patients had history of viral infection. Ten patients had history of upper respiratory infection symptoms, 2 patients had myalgia, 2 patients had fever, 2 patients had history of vaccination (for epidemic hemorrhagic fever and influenza) and one patient had history of herpes simplex infection on lips. There were 9 males (52.9%) and mean (±SD, range) age of onset was 36.0 7(±12.82, 18-64) years. Ten (76.9%) patients initially presented with poor visual acuity, equal or worse than counting finger. Ocular pain or headache was accompanied in 82.4% of cases. The optic disc swelling was observed in 41.2% of the patients. Good visual outcome, equal or better than 20/40, was observed in 84.6%. Bilateral optic neuritis was observed in 3 cases and recurrent optic neuritis was observed in 3 cases. CSF analysis was evaluated in 12 patients and none of them showed significant abnormal result. Antinuclear antibody was positive in 3 out of 12 patients. Central scotoma was observed in 7 patients, and other variable field defects were also observed. Optic nerve enhancement in MRI was observed in 8 out of 15 cases. Spine MRI was evaluated in 3 patients, and 2 patients showed increased signal intensity in T2 weighted image. Conclusion We focused on a group of viral infection-associated optic neuritis (VON) patients and compared it with idiopathic ON. VON showed distinct characteristics: (1) Lower female ratio (2) Poor initial visual acuity (3) Lower recurrence. Some similar features were also observed: (1) Headaches (2) Good visual prognosis (3) Optic disc swelling. These findings suggest that VON may differ in the cause itself but share similar pathophysiological pathways with other types of ON.

Title: Single cell analysis of multiple sclerosis cerebrospinal fluid B cells shows predominant IgM response in some MS patients

Authors: *J. LIN, P. H. AU, S. A. SADIQ;
Tisch MS Res. Cntr NY, New York, NY

Abstract: Introduction: B cells are more and more recognized as an important immune component in the pathogenesis of MS. Traditionally CSF IgGs (oligoclonal bands) have always been a diagnostic biomarker of MS, and the subject of much research because the IgG is thought to represent an antigen driven response; CSF IgMs have not been as widely investigated. Recent publications indicate that the presence of CSF IgMs may be involved in more aggressive forms of MS, or may be a predictor of future conversion to clinical definite MS. In our study, we attempt to determine the isotype of the MS B cell response. Methods: CSF cells from MS patients were stained for CD19 and CD138. Single cells were sorted via FACS for CD19 or CD138 positivity. Gene specific primers for immunoglobulin gamma (IgG) and immunoglobulin mu (IgM) were used for reverse transcription. Nested PCRs were performed to amplify the variable region and a small portion of the constant region. Sequence analysis identified the immunoglobulin isotype. Results: Twenty of 47 patients who had single B-cell sequence analysis revealed a predominant IgM isotype (at least 50% or greater IgM cells). This predominant IgM response does not appear to correlate with disease type, disease activity, or even disease duration. In 3 patients with longitudinal samples, the relative amounts of IgM expressing B cells appear relatively consistent across samples: patient 1, 80% and 63%; patient 2, 40% and 38%; patient 3, 2% and 19%. Conclusion: IgM expressing B cells appear to be the main B cell repertoire in some MS patients. This result does not appear to correlate with disease type, disease phase and/or disease duration. Longitudinal data suggest that this IgM response is not a transient phenomenon and appears to be specific to that patient. Our results suggest different immune mechanisms in some MS patients affecting their B cells other than the classic antigen driven IgG response and should lead to further investigation.

Title: Ultrastructure of the lower motor system in a mouse model of Krabbe disease (KD)

Authors: *V. CAPPELLO[1], P. PARLANTI[2,3], L. MARCHETTI[3], I. TONAZZINI[4], M. CECCHINI[4], V. PIAZZA[2], M. GEMMI[2];
[2]Ctr. for nanotechnology innovation @NEST, [1]Inst. Italiano Di Tecnologia, Pisa, Italy; [3]Scuola Normale Superiore, Pisa, Italy; [4]NEST, Scuola Normale Superiore and Inst. di Nanoscienze - CNR, Pisa, Italy

Abstract: Krabbe disease (KD) is a devastating pathology (Krabbe, 1916), caused by the deficiency of lysosomal enzyme GALC activity that induces the accumulation of the lipid-raft-associated neurotoxin psychosine. KD is characterized by the apoptosis of myelinating cells, axonopathy and activation of inflammatory processes. A treatment for KD is still missing; for this reason the identification of new hallmarks could be a key aspect for the development of therapies. In this study we used a transmission electron microscopy approach to study the lower motor system (LMS) of the Twitcher mouse (TWI), homozygous for the inactive form of GALC and adopted as KD experimental model, at a late pathological stage (P30). We collected information of pathological condition in the central and in the peripheral nervous system (CNS and PNS) and correlated, for the first time, those observations with the architecture of skeletal muscle. Our data clearly demonstrate that alterations, mild or absent in the bodies of motor neurons in the spinal cord (CNS), grow stronger moving towards the PNS and towards the gastrocnemius muscle (GM) which was found to suffer from denervation and showed evident signs of inflammation. These observations allow us to claim unambiguously that in TWI mice the pathology follows a dying-back progression. Furthermore, in TWI sciatic nerves we identified a peculiar sub-population of myelinating cells that wrap more than one axon contrarily to the usual behavior of SC. Multiple myelination processes were observed in the all the TWI sciatic nerves observes but the same phenomenology could not be found in any of the WT nerves. Due to their morphology and to the proximity to Remak bundles, it is possible to speculate that non-myelinating SCs implement a compensatory mechanism to restore, at least partially, the level of myelination in the sciatic nerve of TWI mice. In the sciatic nerve both motorneurons and the Schwann cells (SC) are affected and the number of myelinated axons is significantly reduced. The morphometric evaluation of those remaining showed larger axons with a disorganized cytoskeleton and thicker myelin sheaths. In the GM we identified a reduced percentage of innervation of the neuromuscular junctions accompanied to strong signs of tissue inflammation affecting both the mitochondrial pool and the sarcoplasmic reticulum. In conclusion, we performed a complete ultrastructural analysis of the LMS identifying the progression of the disease and observing for the first time other alterations that can be exploited as targets for novel therapies and for testing their effectiveness.

Title: Three cases of osmotic demyelination syndrome with an unusual onset and a favorable outcome

Authors: A. FUKUI, X. CAO, M. TAJITSU, J. NAGAI, T. YAMADA, Y. YAMBE, *T. MURASE;
Endocrinol. and Diabetes, Nagoya Med. Ctr., Nagoya-Shi, Japan

Abstract: [Background] Osmotic demyelination syndrome (ODS) is a demyelinating brain disease resulting from a rapid increase in plasma osmolality. We present three cases with an unusual onset and a favorable outcome. [Patients] Case 1: An HIV-infected 49-year-old man became infected with influenza virus. One week later, his serum Na+ was 106 mEq/L. Two weeks later, he was admitted to hospital because of malaise, gait disturbance, dysarthria and cognitive dysfunction, and his serum Na+ was 139 mEq/L. MRI revealed T2-hyperintense lesions in his central pons, bilateral basal ganglia, and caudate nuclei, leading to a diagnosis of extra and central pontine myelinolysis (CPM). Although subsequent MRI showed demyelinating lesions more clearly, his neurological deficits were gradually improved by rehabilitation, and recovered almost completely within 4 months of admission. Case 2: A 59-year-old man was admitted to hospital because of acute renal failure resulting from pneumonia and dehydration. His serum Na+ was 133 mEq/L, which increased to 161 mEq/L in 4 days. Dysarthria, disorientation, and orthostatic hypotension persisted. Three weeks after admission, MRI showed a T2-hyperintense lesion in his central pons, indicating CPM. His neurological symptoms were gradually improved by rehabilitation. Five months later, he almost completely recovered, but the MRI lesion in his pons remained. Case 3: A 60-year-old man was admitted to hospital because of malaise and impaired consciousness. His blood glucose was 667 mg/dL, HbA1c 16.6%, Na+ 132 mEq/L, plasma osmolality 318 mOsm/kg. CT showed a hypointense lesion in his central pons. After admission, disorientation persisted and he showed dysphagia. MRI 7 days after admission revealed a T2-hyperintense lesion in his pons, indicating CPM. Thereafter, his neurological symptoms gradually improved. MRI 5 months after hospitalization showed an improved hyperintense lesion, and his neurological symptoms had almost completely disappeared. [Discussion] These findings suggest that it remains difficult to prevent the onset of ODS. In Case 1, hyponatremia, possibly caused by the syndrome of inappropriate antidiuretic hormone secretion as a result of influenza virus infection, spontaneously resolved, resulting in ODS. In Case 2, it is remarkable that ODS occurred despite the not so low initial serum Na+ level. In Case 3, ODS appears to have occurred because of hyperglycemia before admission. An almost complete improvement of neurological symptoms occurred in all cases, consistent with reports

that a prognosis of ODS is not as dismal as previously thought. We note that neurological symptoms did not correlate with the changes in MRI lesions.

Abstract: Multiple sclerosis (MS) is a chronic inflammatory disease affecting the central nervous system. Clinical observations suggest that hormonal level alterations might modify disease progression and incidence. Specifically, decreased levels of testosterone are permissive for disease onset in male subjects. Accordingly, in the experimental autoimmune encephalomyelitis (EAE) model of MS, testosterone seems to exert protective effects. In this context, it is important to highlight that testosterone may be further metabolized into 17beta-estradiol or dihydrotestosterone (DHT). Based on this, the effects of DHT treatment in EAE Dark Agouti rats (i.e. an experimental model showing a protracted relapsing EAE) were analyzed. After 45 days from EAE induction, DHT treatment exerts beneficial effects on clinical score, on gliosis (i.e., decreased glial fibrillary acidic protein and major histocompatibility complex of class II staining) and on inflammation (i.e., decreased Translocator Protein 18kDa, interleukin-1beta, Toll Like Receptor 4 and nuclear factor kappa B expression) in spinal cord. Moreover, parameters linked to oxidative stress and tissue damage, like thiobarbituric acid-reactive substances levels and Bcl-2 associated X protein expression, and to mitochondrial activity (i.e., content of mitochondrial DNA and proteins), were improved after DHT administration. Furthermore, the metabolism of DHT into 3alpha- or 3beta-diol was analyzed. Indeed, assessment of the levels of these metabolites after DHT treatment seem to suggest that the protective effects here observed are due to DHT itself. Altogether, the present results indicate that DHT was effective in reducing the severity of chronic EAE and, consequently, may represent an interesting perspective for MS treatment.

Title: Blood plasma measurements of oxidative stress show phenotype specificity in x-linked adrenoleukodystrophy

Authors: B. R. TURK[1], C. TIFFANY[1], J. MARX[1], R. JONES[1], A. B. MOSER[1], *A. FATEMI[2]; [1]Kennedy Krieger Institute, Johns Hopkins Univ., Baltimore, MD; [2]Neurol., Johns Hopkins Univ., Baltimore, MD

Abstract: Background The disease process of X-linked adrenoleukodystrophy (ALD), a hereditary peroxisomal disorder is attributed to the mutation and dysfunction of the ALD protein, which leads to the accumulation of very long chain fatty acids (VLCFA), in turn leading to oxidative stress and cell death. Clinically, ALD is characterised by an unpredictable phenotypic variance and shift, even between monozygotic twins. Common presentation phenotypes are progressive spinal axonopathy, adrenomyeloneuropathy (AMN) or rapid cephalic demyelination, cerebral ALD (cALD). In this study, oxidative stress parameters were assessed in cALD, AMN, heterozygote female carriers. Methods Total antioxidant content (TRAP), glutathione (GLT), superoxide dismutase (SOD) and prostaglandin E2 (PGE2) were assessed in human plasma and fibroblast cell culture media. Results cALD patients (n=8) showed significantly lower ($p<0.0003$) plasma SOD levels than AMN patients (n=15), who in turn showed a lower tendency than both female heterozygote carriers (n=10) and age matched control subjects (n=9). No significant difference in glutathione was found in plasma. Cell culture media showed significantly higher PGE2 in cALD patients (n=6) compared to AMN patients (n=6), who in turn had lower levels than in controls and female heterozygotes. This differential in PGE2 content was mirrored by levels of phospholipase A2. Discussion SOD functions as an initial antioxidant barrier to the highly reactive radical superoxide anion in the brain. The decreased levels of SOD and increased proinflammatory cytokines in plasma and culture media of cALD patients may reflect higher levels of oxidative stress and/or inflammation, allowing insight into previously unreported phenotypic specific pathology as well as supporting biomarker development for future clinical trials.

Title: The effects of psychosocial stress during the remyelination phase in an animal model of multiple sclerosis

Authors: *M. MAKINODAN, K. YAMAMURO, D. IKAWA, Y. YAMASHITA, M. TORITSUKA, T. YAMAUCHI, S. FUKAMI, T. KISHIMOTO;
Fac. of Medicine, Nara Med. Univ., Nara, Japan

Abstract: Recent findings have shown that psychosocial factors are implicated in the pathobiology of multiple sclerosis. Most of studies regarding psychosocial stress have focused on the onset or the relapse of the symptoms, that is, have aimed to examine the effects on the "demyelination". In this study, we sought to investigate whether psychosocial stress affects the biology in the remyelination phase since our previous study revealed that psychosocial stress dramatically changes myelination only during the developing phase of myelin (Makinodan et al., 2012). Myelin in the medial prefrontal cortex was depleted with cuprizone-treatment for four weeks and we observed whether the subsequent psychosocial differences for four weeks affect remyelination in the medial prefrontal cortex following the termination of cuprizone-treatment. We employed social isolation as a psychosocial stress and the four groups were compared; four mice in a cage (regular environment, RE) after no demyelination, one mouse in a cage (isolation, IS) after no demyelination, RE after demyelination, and IS after demyelination. Interestingly, remyelinatoin in the medial prefrontal cortex was severely impaired only in the group of IS after demyelination, and the medial prefrontal cortex-dependent behaviors were also altered only in the same group.

Title: Relating white matter "potholes" to polygenic risk for Multiple Sclerosis

Authors: *D. RINKER[1], G. PRASAD[2], M. RENTERIA[3], N. JAHANSHAD[2], D. P. HIBAR[2], K. L. MCMAHON[4], G. I. DE ZUBICARAY[5], G. MONTGOMERY[3], N. G. MARTIN[3], M. J. WRIGHT[3], P. M. THOMPSON[2];

Abstract: The pathogenesis of multiple sclerosis (MS) is currently unknown. Complex polygenic influence is thought to play a substantial role in disease risk. Previous analyses have looked at the relationship between polygenic risk scores and white-matter status as defined by voxel-wise fractional anisotropy. However, because MS lesions do not follow a predictable pattern in the white matter, we wanted to assess if there is any explanatory effect of polygenic risk scores on white matter status in healthy subjects. We analyzed data diffusion tensor imaging (DTI) and genotyping data from 528 healthy Australians (mean age 23.6 ± 2.2 years) scanned for the Queensland Twin Imaging Study. To calculate MS polygenic risk scores, the 102 most significant SNPs from the largest known MS GWAS [1] were LD pruned to leave 76 unique variants. Scores were then calculated from each subject's total number of risk alleles weighted by the GWAS-reported SNP effect, and controlled for missing SNPs. White-matter 'potholes' [2] were quantified for each subject by creating z-transformed FA maps, where a pothole was defined as any voxel with a preset number of standard deviations away from the subject's mean (.5-3). Data were split into two separate groups for analysis and replication; linear regression was used to relate potholes to polygenic risk scores, controlling for age and sex. In one subset, number of potholes (SD=.5) was significantly related to polygenic risk score (P=.03), but the replication set failed to reach significance (P=.3). With a more stringent definition of potholes (SD=2) the results failed to reach significance in each group (p=.08 and p=.1), but trended in the same positive direction relating polygenic risk scores to number of potholes. Similar results were found across thresholds. This preliminary analysis is an attempt to assess subtle genetic effects on white matter where consistent spatial differences between subjects are not hypothesized.

Abstract: Multiple sclerosis (MS) is an inflammatory demyelinating disease of the central nervous system and alteration of the metabolism of immune cells is an attractive strategy to modify their function during autoimmunity in MS. We investigated the effect of modulating fatty acid metabolism in an animal model of multiple sclerosis, myelin oligodendrocyte glycoprotein (MOG)35-55-induced, chronic progressive, experimental autoimmune encephalomyelitis (EAE) in C57/BL6 mice. Alpha-methylacyl-CoA racemase (AMACR) converts R-configurated branched fatty acids into the S-configuration, thereby preparing them for metabolic β-oxidation. We observed significant, selective, disease-dependent elevation of AMACR expression in various immune cells (monocytes, T Cells) isolated from blood, draining lymph nodes and spleen in EAE mice during the preclinical phase. *In vitro* studies revealed that genetic deletion of AMACR inhibits the proliferation of T Cells. Furthermore, activated T Cells isolated from AMACR KO mice are characterized by a higher production of IFN-γ, IL-17 and IL-10 and a lower production of IL-4 in comparison to T Cells with a wild type background. However, AMACR KO mice showed only a slight worsening of early clinical symptoms of EAE and no alteration in cognitive behavior in comparison to wild type mice. Interestingly, in the lymph nodes of AMACR KO EAE mice the cytokines are similar regulated as in *in vitro* activated T

Cells. AMACR was not regulated in white blood cells of MS patients. In conclusion, our data suggest that AMACR is regulated in immune cells during EAE but it is not essential for the development of EAE.

Title: Brain galanin is regulated in an animal model of multiple sclerosis

Authors: *P. LOPRESTI;
Dept. of Physiol. and Biophysics, Univ. of Illinois At Chicago, Chicago, IL

Abstract: The neuropeptide Galanin has been implicated in both neuroprotection and neurodegeneration. Galanin is overexpressed in the basal forebrain during Alzheimer's disease; an excess of Galanin has been implicated in cognitive impairment during the progression of this disease. Galanin is known to be expressed in inflammatory and non-inflammatory cells. Furthermore, Wraith et al., (2009) showed that Galanin expression is specifically and markedly up regulated in microglia in multiple sclerosis lesions and shadow plaques; whereas oligodendrocytes in the spinal cord upregulated Galanin in an animal model of multiple sclerosis, i.e. Experimental Autoimmune Encephalomyelitis (EAE). This study examined brain tissues during the second week post EAE induction, and found an increased in Galanin-positive fibers. Furthermore, our studies found that Galanin was not expressed in brain astrocytes and oligodendrocytes. Since Galanin-positive nerves can normally be detected only in a few dorsal root ganglion neurons and they are dramatically up regulated after peripheral nerve injury in both rat and monkey (Zhang et al., 2006), the upregulation of brain Galanin-positive nerves during EAE may be secondary to the nerve injury taking place during this disease. Experiments are in progress to establish time course of brain Galanin regulation and whether brain Galanin has a protective or a deleterious role. Title: Effects of brief aquatic exercise on cardiovascular fitness and cerebral oxygenation in Multiple Sclerosis

Authors: J. PETERSEN[1], D. CALVO[2], H. GERHART[1], M. SPITZNAGEL[2], *A. L. RIDGEL[1]; [1]Exercise Physiol., [2]Psychology, Kent State Univ., Kent, OH

Abstract: Multiple Sclerosis (MS) is the leading cause of non-traumatic neurologic disability in adults. Demyelination of neuronal axons results in inflammation, focal plaque formation, decreased oxygen utilization, and reduced absolute cerebral blood flow. As a result, people with MS are less physically active and deconditioned which further compromises activities of daily living. Although physical rehabilitation and exercise are an important treatment component in MS, fatigue and overheating limit the abilities of this population. The impact of high intensity exercise on fitness and cerebral oxygenation has not been well studied in MS. We examined the effects of seven consecutive days of aquatic aerobics on cardiovascular fitness, assessed with the two minute step test, and cerebral oxygenation, measured with near-infrared spectroscopy (NIRS). Although fitness improvements were minimal, there was a 45-65% increase in cerebral oxyhemoglobin after the seven day intervention. In addition, there was a 35-55% decrease in cerebral deoxyhemogloblin. These findings suggest that a high intensity aquatic aerobics program can increase cerebral blood flow, and potentially improve quality of life in Multiple Sclerosis.

Title: The birth seasonality in multiple sclerosis: Implications from a similar seasonality found among gay men and an opposite seasonality found among both lesbian women and powerful baseball hitters

Authors: *G. MARZULLO;
Per Aspera Res. Fndn., New York, NY

Abstract: Multiple sclerosis, which occurs 2 or 3 times more often in women than in men and more often at higher (darker) than at lower latitudes, has also shown a birth seasonality with an excess around May and an equally significant deficit six months later around November. We recently found this same birth seasonality among gay men and a diametrically opposite seasonality among both lesbian women and more powerful classes of professional baseball hitters (Marzullo, 2014). Based on evidence that two major maternal messengers of short day-lengths (which are also major antioxidants), melatonin (MEL) and reduced glutathione (GSH), can both suppress fetal testosterone (T) formation and/or function in mammalian species, we proposed a sunlight hypothesis prompted by the coincidence of 17th or 18th-week peak stages of T-dependent fetal male-female differentiation with the summer solstice (SS) in early-Nov births and the winter solstice (SW) in early-May births. This held that the seasonality of sexually-dimorphic development in the newborn reflected the sunlight-dependent seasonality of T activity in fetus. A more in-depth version of this same "solstitial" hypothesis may also explain the MS birth seasonality. This follows from evidence that the processes of neuronal myelination (NM) are intertwined in time as well as in cell death-dependent mechanisms with those responsible for sexually dimorphic neurogensis (SDN). NM was thus found to peak in the human fetus around the same 18th post-conceptional week as the peaks in T formation and sexual differentiation. NM and SDN were also both found to be critically dependent on apoptotic cell death and therefore on the action of Bax proteins in triggering the apoptotic reaction cascade. Bax-/- mice mutants thus failed to properly myelinate as well as to sexually differentiate. Most interestingly, GSH and MEL were found to play critical roles in, respectively, the first and the last event in the apoptotic cascade. The cascade was thus found to be triggered by a precipitous extrusion of intracellular GSH with a resulting relative rise in oxidized GSH (GSSG). Higher extracellular levels of GSH were found to oppose this sudden loss of cellular redox potential and cause apoptotic resistance. Lower extracellular GSH levels did the opposite. MEL was found to inhibit the last reaction in the chain, one that activates fatal mitochondrial caspases. GSH and Mel thus appeared to act synergistically in ways that minimized apoptosis near the WS and maximized it near the SS. Such "sunlight messenger" functions of MEL and GSH in multicellular species appeared derived from their primary functions as sunlight-protective antioxidants in earlier species.

Title: Immunointervention in experimental autoimmune encephalomyelitis by targeting the protease site of endothelial NMDA receptor

Authors: ***R. M. MACREZ**[1], C. ORTEGA[2], A. FOURNIER[1], S. VAN DER POL[3], A. MERHA[1], E. MAUBERT[1], F. LESEPT[1], A. CHEVILLEY[1], B. HAELEWYN[4], F. DE CASTRO[2], E. DE VRIES[3], D. VIVIEN[1], D. CLEMENTE[2], F. DOCAGNE[1];
[1]GIP Cyceron Inserm U919, Caen, France; [2]Hosp. Nacional de paraplejicos, Toledo, Spain; [3]Neurosci. campus, Amsterdam, Netherlands; [4]Univ. of Caen, Caen, France

Abstract: Background: Recent advances suggest a role for NMDAR in immunological mechanisms of brain diseases. Here, we tested an original therapeutic strategy of immunointervention in animal models of multiple sclerosis (MS) based on a newly developed therapeutic anti-NMDAR antibody. This antibody targets a regulatory site of the GluN1 subunit sensitive to the protease tPA (tissue plasminogen activator). We aimed at identifying the cell targets with a particular focus on immune cells and components of the blood brain barrier (BBB). Methods: Antibody was injected in C57/Bl6 mice subjected to EAE, a model of MS. Neurological assessment was performed via clinical score scale, and using automated activity measurement. Inflammation in animals was studied by 3D-T2* molecular MRI. Immune cells were analysed by flow cytometry (FACS) and immunohistology. Modulation of NMDAR function by our antibody was characterized by Ca2+ videomicroscopy in HEK cells expressing NMDAR. Its impact was evaluated *in vitro* on splenocytes and leukocyte transcytosis assay. Findings: We show that our antibody blocks tPA-induced potentiation of NMDA-R function without affecting basal NMDA-R activity. In EAE animals, it reduced neurological impairments (delayed onset and reduced clinical score) and inflammation (reduced signal void in MRI, reduced leukocyte infiltration, BBB preservation and switches in splenic cell populations). *In vitro*, our antibody reduces leukocyte transmigration, and we investigated its effects on lymphocyte activation, proliferation and survival. This study argues for a critical function in MS of NMDAR expressed outside the nervous system, and highlights the therapeutic potential of anti-NMDA-R based immunointervention.

Title: Galectin-3 is a possible target molecule for anti-brain microvascular endothelial cell antibodies in patients with secondary progressive multiple sclerosis

Authors: *H. NISHIHARA, F. SHIMIZU, Y. SANO, Y. TAKESHITA, M. ABE, T. MAEDA, T. KANDA;
Dept. of Neurol. and Clin. Neurosci., Yamaguchi Univ. Grad. Sch. of Medicine,, Ube/Yamaguchi, Japan

Abstract: Objective: We previously reported that autoantibodies against human brain microvascular endothelial cells (hBMECs) from secondary progressive multiple sclerosis (SPMS) patients could compromise the blood-brain barrier (BBB). In this study, we investigate a target for anti-brain microvascular endothelial cell antibodies in patients with SPMS. Methods: Proteins from hBMECs were separated by 2-dimentional electrophoresis. Two dimentional immunoblots were used to compare serum reactivities from pooled sera of 7 SPMS patients and those of controls (9 relapsing-remitting MS (RRMS), 14 neuromyelitis optica (NMO), 9 amyotrophic lateral sclerosis (ALS), 10 myositis patients, and 20 healthy controls). Proteins were identified by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Afterwards individual serum reactivities against target antigens were confirmed by western blot analysis. Identified protein functions in hBMECs were examined using small interfering RNA (siRNA)

method. Result: We identified galectin-3 as a target antigen in SPMS patients group. Positivity of the anti-galectin-3 antibodies was significantly higher in patients with SPMS (90 %, 9 of 10) than in patients with RRMS (30 %, 3 of 10). The anti-galectin-3 antibodies were not found in all the patients with NMO, ALS, myositis, or in healthy controls. Protein and mRNA levels of NFκB and ICAM-1 in hBMECs were elevated after the downregulation of galectin-3. Sera from the patient with SPMS also increased the protein amounts of NFκB and ICAM-1 in hBMECs. Conclusion: In SPMS patients, anti-galectin-3 antibody might compromise BBB by upregulating NFκB and downstream target of NFκB like ICAM-1.

Title: Diverse nicotinic mechanisms in a model of multiple sclerosis

Authors: *R. J. LUKAS[1], Q. LIU[1], L. LUCERO[1], A. R. SIMARD[2], P. WHITEAKER[1], B. J. MORLEY[3], F.-D. SHI[1];
[1]Barrow Neurol Inst., Phoenix, AZ; [2]Dept. of Chem. and Biochemsitry, Univ. of Moncton, Moncton, NB, Canada; [3]Boys Town Natl. Res. Hosp., Omaha, NE

Abstract: Several lines of evidence implicate acetylcholine (ACh) in modulation of immune system as well as nervous system function. This testifies to progressive specialization of ACh from its primordial roles in chemical signaling early in the evolution of life forms. Focusing on nicotinic mechanisms, our earlier work defined nicotinic ACh receptor (nAChR) subunit gene expression patterns in mouse and human immune system cells and demonstrated nicotinic suppression of T cell development and differentiation. This suggested that nicotine could have

immunomodulatory and anti-inflammatory effects. Further studies using experimental autoimmune encephalomyelitis (EAE) in mice as a model for multiple sclerosis (MS), coupled with exploitation of a range of nAChR subunit knock out mice, suggests that different nAChR subtypes play disease exacerbating or protective roles in different stages in disease progression and recovery, building upon initial observations that nicotine protects against EAE. We have extended our characterization of nAChR subunit mRNA levels in different immune cell types in the periphery or infiltrating into the brain, including T cells, B cells, dendritic cells, macrophages, and microglia, finding remarkably widespread expression that changes with disease stage and cell microenvironment. Results continue to support the hypotheses: (1) that peripheral immune cell nAChR containing α9 subunits (α9*-nAChR) play disease initiating/exacerbating roles as revealed by their attenuation in α9 subunit knockout mice or via nicotine's antagonism of α9*-nAChR, (2) that there are neuroprotective roles of α7-nAChR, probably expressed by brain cell types, and made particularly evident in α7/α9 double knock out mice, and (3) that β2-nAChR are involved in recovery from EAE, which is absent in β2 subunit knock out mice. Adoptive transfer studies support these hypotheses, and additional nAChR subunits and subtypes also could play roles. Taken together, our results suggest that modulation of disease-exacerbating or disease-ameliorating inflammatory and/or immune processes is possible through therapeutic approaches targeting nicotinic signaling. There are exciting possibilities that improved treatment of hyperimmune and inflammatory disorders such as MS, lupus and arthritis, and even stroke, brain cancer or neurodegenerative diseases, could result from nAChR modulation.

Title: Oligodendrocyte death in the DTA mouse model results in late-onset immune-mediated CNS demyelination

Authors: ***M. TRAKA**[1], J. R. PODOJIL[2], D. P. MCCARTHY[2], S. D. MILLER[2], B. POPKO[1]; [1]Univ. of Chicago, Chicago, IL; [2]Microbiology-Immunology and Interdepartmental Immunobiology Ctr., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Multiple sclerosis (MS) is an inflammatory neurodegenerative disease characterized by CNS demyelination induced by myelin-specific T lymphocytes. Although the primary etiology of MS remains unknown, the main hypothesis suggests that a primary dysregulation of the immune system exists that leads to an autoreactive response against myelin-sheath components, which secondarily leads to a breakdown of the blood-brain barrier. This is followed by infiltration of the CNS by T cells, leading to the focal inflammation and demyelination that characterize MS lesions. An alternative hypothesis is based on pathological evidence showing that oligodendrocyte loss and myelin defects occur in the brains of MS patients even in the absence of apparent signs of inflammation. Thus, the loss of oligodendrocytes and subsequent demyelination might trigger the autoreactivity against myelin antigens and, secondarily, lead to inflammation and demyelination in the CNS. To investigate the second hypothesis, we used the DTA (PLP/CreERT;ROSA26-eGFP-DTA) mouse model (Traka et al., Brain 2010 Oct;133(10):3017-29), in which activation with tamoxifen causes pervasive oligodendrocyte loss resulting in widespread CNS demyelination, that peaks at 5 weeks and resolves by 10 weeks. Strikingly, a fatal, secondary demyelinating disease follows the early disease around 40 weeks post-activation. The late-onset disease in DTA mice is characterized by the presence of focal, MS-like, actively demyelinating lesions that progress to extensive myelin and axonal loss at later disease stages and is associated with increased numbers of activated CD4+ T cells in the CNS and myelin oligodendrocyte glycoprotein (MOG)-specific T cells in peripheral lymphoid organs. We confirmed the pathogenic potential of the MOG-specific DTA-derived T cells by adoptively transferring them to naïve Rag1-deficient mice that produce no mature T cells and B cells; this approach resulted in neurological defects in the DTA cell-recipient mice that correlated with CNS white matter inflammation. Furthermore, we significantly ameliorated the late-onset disease symptoms in the DTA mice by immune tolerization against MOG. Overall, these data suggest that primary oligodendrocyte death is sufficient to trigger an adaptive autoimmune response against myelin, raising the possibility that a similar process can occur in the pathogenesis of MS, consistent with the 'inside-out' hypothesis.

Title: Visuomotor delay adaptation reduces intention tremor in multiple sclerosis: a case series

Authors: *M. HEENAN[1], R. SCHEIDT[1,2,3], S. BEARDSLEY[1,4,5];
[1]Biomed. Engin., Marquette Univ., Milwaukee, WI; [2]Physical Med. and Rehabil., Northwestern Univ., Chicago, IL; [3]Neurol., [4]Clin. and Translational Sci. Inst., Med. Col. of Wisconsin, Milwaukee, WI; [5]Biomed. Engin., Boston Univ., Boston, MA

Abstract: We have previously shown that intention tremor in MS may be due to an inability to adapt to increased visual processing time. This inability creates a prediction error that the neuromotor controller attempts to minimize, which results in tremor. We characterized and simulated neuromotor feedback control in compensatory and pursuit tracking tasks. Preliminary results suggest that subjects with intention tremor may be trapped within locally-optimal region of control space and are unable to minimize error further because doing so would require accepting an initial increase in movement error. Simulations suggest that adaptation to gradually increasing feedback delays may induce subjects to learn an internal model of the visual response delay that matches their actual response delay. We now examine whether a visual delay adaptation task - as our simulations suggest - can be used to reduce tremor by gradually shifting subjects' expected delays. Subjects used a 1-D robot to track a target during a series of random step displacements. Cursor position had no added feedback delay (Sham Adaptation Session) or was delayed from hand position (Adaptation Session) using 3 delays that were specific to subjects' deficits. Tremor was examined before, immediately after, and 24-48 hours after the Sham Adaptation and Adaptation Sessions using spiral tracing, handwriting, the Nine Hole Peg Test (9HPT), and a step-tracking task. For three subjects with MS and moderate to severe intention tremor, no significant improvements across subjects were seen before and after the Sham Adaptation Session. Sumulations suggest that during the Adaptation Session, three additional feedback delays would be sufficient to induce adaptation of predicted visual response delay. Subjects adapted to each new feedback delay (ranging from 50-300 ms of additional delay) for approximately 15 minutes, followed by an "adaptation" to a no delay condition. After this time, submovement interval (a proxy for predicted visual delay) increased by 55.6±15.7% (mean±SE) but fell short of subjects' actual response delays by 25.2±7.2%. Tremor power decreased by 65.7±12.3% Movement endpoint error decreased by 22.7±13.4%. 9HPT scores improved by 7.5±4.5% in the dominant hand and by 23.2±3.2% in the non-dominant hand. Although there were not significant improvements in handwriting speed, handwriting quality improved in 2/3 subjects. In all subjects, at least one of these improvements persisted into the following day. These results suggest that visual delay adaptation can be used therapeutically to increase predicted visual delay and decrease intention tremor in MS.

Title: Dominant influence of mood on neurophysiological responses to exercise in people with multiple sclerosis

Authors: ***L. M. KOSKI**[1], A. YUSUF[2];
[1]Neurol. and Neurosurg., [2]Psychiatry, McGill Univ., Montreal, QC, Canada

Abstract: BACKGROUND: Multiple sclerosis (MS) is associated with increased fatigability during exercise, which can have a significant impact on functional outcome. Neurophysiological studies of changes in corticomotor excitability during exercise may yield insights into potentially modifiable causes of this fatigability. This study aimed to identify predictors of abnormal motor evoked potentials (MEPs) responses to exercise among patients with relapsing-remitting MS. METHODS: Muscle strength, MEP amplitudes, and recovery of motor threshold were assessed in 36 MS patients and 14 healthy age- and sex-matched controls (HC) before and after a series of 30 maximum voluntary contractions (3-s on, 3-s off). Age, sex, self-reported fatigue, MS Functional Composite test, Hospital Anxiety and Depression Scale, and measures of cortical excitability (motor threshold, cortical silent period duration, short-interval intracortical inhibition) were also obtained at baseline. RESULTS: The difference in electromyographic activity during exercise was comparable in both groups (HC: -10.6 =/- 18.7; MS: -11.4 +/-38.6), as was the time to recovery of motor threshold post-exercise. After recovery of motor threshold, MEPs were facilitated in the HC group but not in the MS group. Among all potential contributing variables, only depressive symptoms predicted post-exercise facilitation, with higher depressive symptoms predicting lower post-exercise facilitation in the MS group ($r = 0.39$, $p = 0.04$). CONCLUSIONS: Similar results have been reported in the depression literature, highlighting the need to control for mood when investigating neurophysiological contributors to fatigue in MS.

Title: Brain endothelium differs between mouse and humans with adrenoleukodystrophy

Authors: J. M. T. SNYDER[1], *P. L. MUSOLINO[3], Y. GONG[1], J. LOK[2], E. LO[2], F. S. EICHLER[1];
[1]Neurol., [2]Massachusetts Gen. Hosptial, Boston, MA; [3]MGH/Harvard, Boston, MA

Abstract: Cerebral X-linked adrenoleukodystrophy (ALD) is a progressive inflammatory demyelinating disease caused by mutations in the ABCD1 gene. A prominent perivascular infiltrate at the leading edge suggests that blood brain barrier disruption plays an important role in lesion progression. Recent in-vitro cell work indicates that ABCD1 deficiency causes upregulation of adhesion molecules and decreased tight junction protein expression, resulting in increased adhesion and permeability of human brain endothelium. A major barrier to progress in the field is that the current ALD mouse model, an ABCD1 KO mouse, never develops the cerebral form of the disease. Therefore, we set out to determine what molecular differences exist between human and mouse brain endothelium and between human brain and other organ specific endothelium. Using primary human brain microvascular (HBMEC), human umbilical vein (HUVEC) and human dermal microvascualar (HDMEC) endothelial cells, ABCD1 was silenced via siRNA. Molecular characterization was performed using RT-PCR arrays, western blot, CL-CTMS. Adhesion and transmigration assays were used to assess monocyte-endothelial cells interactions. We found that silencing ABCD1 in HUVEC and HDMEC does not cause significant changes in adhesion molecules, tight junction protein expression and adhesion of monocytes, suggesting that the molecular and functional changes in human endothelium due to ABCD1 deficiency are brain specific. Moreover, unlike human brain endothelium, ABCD1 deficiency in mouse brain endothelium results in an increase in tight junction protein expression and no change in adhesion molecule expression as compared to controls, even following endothelial activation with inflammatory cytokines. Together these data demonstrate that endothelial dysfunction characterized by increased adhesion and permeability to monocytes caused by the deficiency of ABCD1 is selective to human brain. Our findings also provide potential molecular targets for future intervention as well as creating an improved mouse model and functional assays for the cerebral form of ALD.

Title: Enhanced GABAA receptor-mediated tonic conductance in hippocampal CA1 pyramidal neurons in experimental autoimmune encephalomyelitis

Authors: *W. WEI[1], L. KAMMEL[1], R. R. VOSKUHL[1], T. J. O'DELL[2];
[1]Dept Neurol, [2]Dept Physiol, UCLA Sch. Med., Los Angeles, CA

Abstract: A number of recent studies have found that phasic inhibitory synaptic transmission mediated by synaptic $GABA_A$ receptors ($GABA_ARs$) is altered in experimental autoimmune encephalomyelitis (EAE), a mouse model of Multiple Sclerosis (MS). Importantly, persistent activation of extrasynaptic $GABA_ARs$ by ambient levels of GABA gives rise to a distinct form GABAergic inhibition known as tonic inhibition and it is unclear whether this form of inhibition is also altered in EAE. Here we investigated $GABA_AR$-mediated inhibitory transmission in hippocampal CA1 pyramidal neurons using whole-cell patch-clamp recordings to determine whether tonic inhibition is altered in EAE. We find that the $GABA_AR$-mediated tonic conductance is significantly enhanced in EAE (0.43 ± 0.07 pA/pF, n = 13 in control vs. 0.76 ± 0.06 pA/pF, n = 28 in EAE, $p < 0.01$). To determine whether reduced GABA transporter function and elevated levels of extracellular GABA might contribute to enhanced tonic inhibition in EAE, we examined tonic currents in the presence of the GABA transporter inhibitor nipecotic acid (10 μM). Although nipecotic acid strongly enhanced tonic inhibition, tonic inhibitory currents were still significantly larger in pyramidal cells from EAE mice (5.60 ± 0.49 pA/pF, n = 10 in control vs. 7.93 ± 0.62 pA/pF, n = 10, in EAE, $p < 0.01$). This suggests that reduced GABA transporter function is unlikely to account for enhanced tonic inhibition in EAE. In contrast, L-655,708 (5 μM), an inverse-agonist of the α5 subunit-containing $GABA_ARs$ responsible for tonic inhibition in CA1 pyramidal cells, reduced tonic inhibition to a greater extend in pyramidal cells from EAE mice (tonic inhibition was reduced by 6.8 ± 1.4% in control cells, n = 9 compared to 34.6 ± 8.1% in cells from EAE mice, n = 11, $p < 0.01$). However, the delta subunit-containing $GABA_AR$ agonist DS2 (2 μM) had a similar effect on tonic inhibition in both control and EAE cells ($p > 0.05$, n = 14 and 11, respectively). This suggests that enhanced tonic inhibition in EAE may be due to increased expression and/or function of α5 subunit-containing $GABA_ARs$. We also find that phasic inhibitory synaptic transmission is enhanced in EAE (spontaneous IPSC frequency was 18.13 ± 1.11 Hz, n = 12 in control vs. 24.64 ± 1.06 Hz, n = 28 in EAE, $p < 0.01$). Together our results indicate that multiple forms of inhibitory synaptic transmission are altered in EAE and identify additional targets for pharmacological interventions aimed at restoring normal synaptic and circuit function in MS.

Title: Increased GABAergic inhibition contributes to impaired hippocampal synaptic plasticity in experimental autoimmune encephalomyelitis

Authors: *L. G. KAMMEL[1], W. WEI[2], S. W. THORNTON[1], T. J. O'DELL[2], R. R. VOSKUHL[1];
[1]Neurol., [2]Physiol., David Geffen Sch. of Medicine, UCLA, Los Angeles, CA

Abstract: Hippocampal synaptic dysfunction contributes to cognitive impairment experienced by multiple sclerosis (MS) patients. A number of findings, both in post-mortem MS brain tissue and from mouse models of MS (experimental autoimmune encephalomyelitis or EAE) indicate that GABAergic neurotransmission may be particularly vulnerable to disruption in MS. However, the functional consequence of impaired GABAergic neurotransmission in MS remains poorly understood. Thus, using electrophysiological techniques we examined inhibitory synaptic transmission in the CA1 region of hippocampal slices prepared from control and EAE mice. Although the number of parvalbumin positive cells in the hippocampal CA1 region is reduced in slices from EAE mice (44.5 ± 1.8 in control, n=5, compared to 37.1 ± 2.2, n=5 in EAE, $p < 0.05$), we find that the frequency of spontaneous IPSCs in CA1 pyramidal cells is significantly enhanced in EAE (n = 28) compared to control mice (n = 12, $p < 0.01$ compared to control). Moreover, tonic inhibition mediated by extrasynaptc GABA receptors was strongly enhanced in CA1 pyramidal cells from EAE mice (currents were 0.43 ± 0.07 pA/pF in controls, n = 13 and 0.76 ± 0.06 pA/pF in cells from EAE mice n = 28, $p < 0.01$). Based on these findings we hypothesize that the inflammatory, demyelinating milieu in MS generates changes in GABAergic inhibition that could strongly oppose the induction of activity-dependent forms of synaptic plasticity at excitatory synapses, such as long-term potentiation (LTP). Consistent with this, the induction of LTP by 150 pulses of 5 Hz presynaptic fiber stimulation was significantly reduced in hippocampal slices from EAE mice (fEPSPs were potentiated to 137.2 + 4.4% of baseline in control, n = 5, compared to 120.8 + 3.0% in slices from EAE mice, n = 6, $p < 0.05$). We conclude that decreased synaptic plasticity seen in hippocampal synapses during EAE may be due to increased GABAergic inhibition. Together these data suggest that targeting GABAergic neurotransmission may be a strategy for treating cognitive impairments in MS associated with impaired hippocampal synaptic plasticity.

Title: Pathological involvement of astrocyte-derived lipocalin-2 in the rodent model of demyelinating optic neuritis

Authors: *J.-H. KIM[1], B. CHUN[2], K. SUK[1];
[1]Brain Sci. and Engin. Institute, and Depar, Daegu, Korea, Republic of; [2]Dept. of Ophthalmology, Kyungpook Natl. Univ. Sch. of Med., Daegu, Korea, Republic of

Abstract: The current study was carried out to determine the role of lipocalin-2 (LCN2) in the pathogenesis of demyelinating optic neuritis using an experimental autoimmune optic neuritis (EAON) model. EAON was induced by subcutaneous immunization with an emulsified mixture of myelin oligodendrocyte glycoprotein (MOG_{35-55}) peptide in mice. LCN2 expression was examined in the optic nerve after MOG peptide injection. The expression of LCN2 was notably increased in the optic nerve after EAON induction and colocalized with reactive astrocytes. In comparison of degree of demyelination, inflammatory infiltration, glial activation, and expression profile of inflammatory mediators in the optic nerve between LCN2 knockout (KO) animals and wild-type littermates by histological analysis and real-time PCR following EAON induction, a significant reduction of demyelination, inflammatory infiltration, and gliosis was demonstrated in the optic nerve of LCN2 KO mice. In addition, LCN2 KO mice also showed markedly reduced gene expression associated with the M1-polarized glia phenotype and toll-like receptor signaling in the optic nerve. Their visual ability measured by photopic Flash VEP Recording showed that VEPs of EAON-induced WT mouse were diminished or not recordable but the impaired conductivities were attenuated in EAON-induced LCN2 KO mouse. Next, plasma levels of LCN2 in patients with optic neuritis were measured by ELISA. The LCN2 levels in plasma were significantly higher in optic neuritis patients (71.6 ± 10.6 ng/ml) compared to healthy controls (37.4 ± 9.1 ng/ml) ($p=0.0284$). In this study, we demonstrated a significant induction of LCN2 expression in astrocytes of the optic nerve following EAON induction. Our results imply that astrocyte-derived LCN2 may play a pivotal role in the development of demyelinating optic neuritis, and LCN2 can be a therapeutic target to alleviate immune and inflammatory damage in optic nerve.

Myelin Repair Foundation

Title: Opposing roles of astrocytes in developmental myelination and early myelin repair

Authors: *R. TOGNATTA[1], M. KARL[1], C. KANTOR[2], R. R. DIGIACOMO[2], G. SHANO[2], P. LEAHY[2], S. L. FYFFE-MARICICH[3], R. H. MILLER[1];
[1]George Washington Univ., Washington, DC; [2]Case Western Reserve Univ., Cleveland, OH; [3]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Understanding the mechanisms regulating oligodendrocyte development and myelination in the vertebrate CNS is becoming increasingly important, not only to facilitate myelin repair but also to further define the roles of oligodendrocytes and myelin in the maintenance of axonal integrity and neuronal connectivity. *In vitro* studies have implicated astrocytes in influencing the development of oligodendrocytes and myelination, however their roles *in vivo* remain poorly defined. In this study we utilize GFAP-iCP9 transgenic animals that allow us for the first time to selectively eliminate non-proliferative GFAP+ astrocytes. In these animals the GFAP promoter drives coordinated expression of DsRed and iCP9 in greater than 90% of GFAP+ astrocytes. Localized delivery of CID results in selective loss of DsRed+/GFAP+ cells. Astrocyte ablation during postnatal spinal cord development results in a transient loss of astrocytes and a concomitant delay in myelination, demonstrating a critical role for astrocytes in promoting the timing of developmental myelination. By contrast, in the adult CNS localized ablation of astrocytes 2 days after the induction of a demyelinating lesion resulted in myelin repair in both the spinal cord and the corpus callosum, although through fundamentally different cellular pathways. In spinal cord, remyelinating cells exhibited a characteristic Schwann cell phenotype, while in the corpus callosum preservation of CC1+ OLs was seen. The proportion of BrdU+ OPCs was actually somewhat decreased in astrocyte depleted lesions compared to controls suggesting the higher number of OLs reflects either enhanced survival or differentiation rather than increased OPC proliferation. The potential preservation of oligodendrocytes in astrocyte depleted lesions is consistent with the diminished immune response in such lesions. This protection against demyeliantion was associated with increased numbers of oligodendrocytes that persisted for at least 1-month post lesion, providing axonal support. Microarray analysis reveals astrocytic NF-kB signaling pathway as a major contributor to the pathological events compromising myelin repair in the brain, suggesting cellular responses to astrocyte loss are temporally and regionally specific.

Abstract: Taiep rat has a failure in myelination and remyelination processes leading to a condition of hypomyelination throughout its life. Chemokines, which are known to play a role in inflammation, are also involved in the remyelination process. We aimed to demonstrate that remyelination-stimulating factors are altered in the brainstem of 1- and 6-months old taiep rats. We used a rat RT2 Profiler PCR array to assess mRNA expression of 84 genes coding for cytokines, chemokines and theirs receptors. We also evaluated protein levels of CCL2, CCR1, CCR2, CCL5, CCR5, CCR8, CXCL1, CXCR2, CXCR4, FGF2, and VEGFA by ELISA. Sprague-Dawley rats were used as a control. Our results using PCR Array procedure showed that pro-inflammatory inflammatory cytokines were not upregulated in the taiep rat. In contrast, some mRNA levels of beta- and alpha chemokines were upregulated in 1-month old rats, but CXCR4 was downregulated at their 6 months of age. ELISA results showed that CXCL1, CCL2, CCR2, CCR5, CCR8 and CXCR4 protein levels were decreased in brainstem at age of 6 months. These results suggest the presence of a chronic neuroinflammation process with deficiency of remyelination-stimulating factors (CXCL1, CXCR2 and CXCR4), which might account for the demyelination in the taiep rat.

Title: Notch ligand-selective activation in CNS demyelination-remyelination

Authors: P. MATHIEU, L. GÓMEZ PINTO, F. ALMEIRA GUBIANI, *A. M. ADAMO; Facultad De Farmacia Y Bioquímica. Univ. of Buenos Aires. IQUIFIB-CONICET, CABA, Argentina

Abstract: In the CNS, myelination is a physiological process driven by oligodendroglial cells, while demyelination is a pathological process characterized by myelin loss around axons. Demyelination is followed by remyelination, which solves functional deficits. This work focuses on Notch1 ligands and their role in the demyelination-remyelination process in a cuprizone (CPZ)-induced demyelination model. Twenty-one-day-old Wistar rats were fed a diet containing CPZ during 2 weeks. Demyelinated and control animals were sacrificed 7d before CPZ withdrawal (-7d), the day of CPZ withdrawal (0d), 7, 14 and 21d (+7d, +14d and +21d) after CPZ withdrawal and experiments were conducted for each survival time. The levels of F3/contactin and Jagged1 were determined by Western blot in the subventricular zone (SVZ) and corpus callosum (CC) of control and CPZ animals. To evaluate the participation of SVZ in the remyelination process in the CC, primary neurosphere cultures from SVZ dissected from control and CPZ animals were carried out. The cellular populations in these cultures were characterized with specific markers, i.e. Nestin for neural precursor cells, GFAP for astrocytes and NG2 for oligodendroglial progenitor cells (OPCs). Notch signaling activation and ligands F3/contactin and Jagged1 expression were determined. Results show an increase in F3/contactin expression at -7d, +7d and +21d in CC of CPZ animals as compared to controls, whereas in the SVZ the increase in F3/contactin was observed at +14d. In addition, a greater proportion of Nestin+ cells was detected in neurosphere cultures from SVZ of demyelinated and spontaneously remyelinating animals (0d, +7d) as compared to controls, which indicates an increase in OPC proliferation in response to injury. Notch signaling activation (NICD levels) was observed in

NG2+ OPCs, together with an increase in the percentage of Jagged1-expressing cells, which suggests that the pool of OPCs remains preserved in these cultures. In turn, the increase observed in the percentage of F3/contactin+ cells and the concomitant decrease in NG2+ OPCs in neurosphere cultures carried out at 0d and +7d might prove F3/contactin participation in inducing OPC maturation. Worth pointing out, F3/contactin was found to colocalize with OPC marker NG2 but went undetected in GFAP+ cells. Finally, co-immunoprecipitation experiments prove F3/contactin binding to Notch, thus confirming its role as a non-canonical ligand.

Title: Vitamin C facilitates pluripotent stem cell maintenance of MSCs and promotes its neurotrophic functions

Authors: Y. LIU, B. ULLOA, M. ALAHIRI, *S. A. SADIQ;
Tisch MS Res. Ctr., New York, NY

Abstract: Background: Ascorbate (Vitamin C) is best known for its role in scurvy, in which the hydroxylation of collagen catalyzed by dioxygenases is incomplete due to ascorbate deficiency. DNA methylation is a heritable epigenetic modification involved in gene silencing. In early embryo and the germ line, global DNA demethylation were mediated by Tet (ten eleven translocation) enzymes, which convert 5-methylcytosine (5mC) to 5-hydroxymethylcytosine (5hmC). Vitamin C (Vit C), a potential cofactor for Tet enzymes, could promote the generation of induced pluripotent stem cells (iPSCs) and facilitates pluripotent stem cell maintenance. Objective: In this study, we added Vit C into the culture media of mesenchymal stem cells (MSCs) to investigate its role on the morphology, proliferation, differentiation and function of MSCs. Methods: MSCs from human multiple sclerosis patients were cultured and treated with Vit C at 50μg/ml. Genomic DNA extracted from MSCs were quantified and used for dot-blot . FACS was carried out to detect the cell surface or intracellular markers of MSCs after Vit C treatment. RNA was extracted and quantitative PCR was performed using 7900HT fast real-time PCR system and relative quantification was determined using RQ manager software. Adipocytes and osteocytes were differentiated by induction media with or without Vit C added. Results: Vit C significantly enhanced Tet -mediated generation of 5hmC. Vit C did not significantly increase the proliferation of MSCs and did not alter the pluripotent markers of MSCs. Vit C did not induce MSC differentiation into adipocytes and osteocytes. Treatment with Vit C significantly

increases the levels of MSC expression of HGF and IGF. Conclusion: Our study provides the indirect evidence of Vitamin C on production of HGF and IGF which are important in the neurotrophic function of MSCs without inducing the unwanted mesodermal differentiation. Vit C should be investigated further for its role on MSCs used for transplantation to treat multiple sclerosis.

Title: Pericyte deficiency leads to white matter tract damage, demyelination and axonal degeneration

Authors: *A. M. NIKOLAKOPOULOU, A. MONTAGNE, G. SI, A. P. SAGARE, Z. ZHAO, B. V. ZLOKOVIC;
Physiol. and Biophysics, USC, Los Angeles, CA

Abstract: White matter damage is a characteristic of a plethora of neurodegenerative diseases, such as Alzheimer's disease (AD) and Multiple Sclerosis (MS). Pericytes, the vascular mural cells located within the basement membrane of blood microvessels, regulate blood brain barrier (BBB) permeability and cerebral blood flow while they participate in clearance of toxic byproducts. Pericyte loss has been implicated in BBB breakdown, neuronal degeneration, cognitive impairment, inflammation, synaptic loss and effects on cerebral blood flow (CBF). In this study, we used $Pdgfr\beta^{F7/F7}$ mice to examine the effects of pericyte-deficiency on white matter tracts and more specifically in the corpus callosum. Our data show that pericyte-deficiency leads to early BBB leakage and CBF deficits, which precede demyelination and axonal degeneration; one-month-old animals show no defects in myelin and axonal integrity, although accumulation of blood byproducts is visible (IgG and fibrin). However, young adult $Pdgfr\beta^{F7/F7}$ mice (2-4m old) exhibit white matter volume reduction and demyelination as determined by diffusion tensor magnetic resonance imaging (DTI-MRI) and by trace weighted imaging (TWI) compared to neurologically-intact controls. In particular, radial diffusivity, axial diffusivity and fractional anisotropy are increased, and fiber tract maps are significantly impaired

in *Pdgfrβ*$^{F7/F7}$ mice compared to controls. Furthermore, *Pdgfrβ*$^{F7/F7}$ mice show impaired fiber tract integrity that affects brain connectivity, as demonstrated by reduction in projection length. In addition, immunohistological, flow cytometry, and electron microscopy data show a decrease in myelin thickness and myelin-protein expression both in young adult and old animals. Taken together, our results show that pericyte-deficiency causes BBB leakage and CBF abnormalities at very early stages, followed by myelin destruction and axonal degeneration, thus emphasizing the importance of the neurovascular unit.

Title: Studying lipocalin 2 as a novel player in the pathophysiology of the disease

Authors: ***F. MARQUES**, S. NEVES, C. FERREIRA, S. MESQUITA, C. SERRE-MIRANDA, L. BELARD, M. CORREIA-NEVES, J. SOUSA, J. CERQUEIRA, J. PALHA;
Life and Hlth. Sci. Res. Inst. (ICVS), Braga, Portugal

Abstract: Multiple sclerosis (MS) is an immune-mediated demyelinating disease of the central nervous system (CNS), characterized by the presence of demyelination plaques, inflammation and gliosis that consequently lead to axonal damage. The sequence of events that leads to demyelination remains unclear and the pathophysiological mechanisms are diverse. Recently we found that lipocalin 2 (LCN2), an acute phase protein that is a part of the defense system against bacteria by binding to iron-loaded siderophores, was increased in cerebrospinal fluid (CSF) and serum of MS patients, when compared to control subjects. Similarly, using the experimental autoimmune encephalomyelitis (EAE) mouse model, LCN2 was detected in brain parenchyma astrocytes, in regions typically affected in MS patients. This expression by astrocytes, together with an increased LCN2 level in the CSF, occurs during the active phases of the disease, which could point towards a role for LCN2 secreted by astrocytes in the mediation of inflammatory responses in the EAE model. To further understand the role of LCN2 in MS pathology we are using the EAE mouse model and inducing EAE both in LCN2-null mice and in WT littermate controls. Non-induced EAE animals are being used as controls. LCN2-null mice induced with EAE do not show major alterations in terms of the clinical score when compared with WT littermate controls also induced with EAE. Regarding the activation of astrocytes, we quantified the percentage of area GFAP+ and did a 3D morphology reconstruction of astrocytes, in the white matter of the cerebellum of LCN2-null mice and WT littermates induced with EAE. The

EAE animals present an increase in the GFAP+ area, but we only detected on tendency to decreased activation in LCN2-null mice. We also evaluated the role of LCN2 in demyelination, in the cerebellum, using the histochemical coloration luxol fast blue, and the LCN2-null mice with EAE show a tendency to present less demyelination than their induced WT littermates.

Title: ROS-initiated calcium-influx drives axonal degeneration in an animal model of multiple sclerosis

Authors: ***M. WITTE**[1], A.-M. SCHUMACHER[2], C. MAHLER[2], J. BEWERSDORF[2], P. R. WILLIAMS[3], O. GRIESBECK[4], T. MISGELD[3], M. KERSCHENSTEINER[2];

Abstract: Multiple sclerosis (MS) is a neuroinflammatory disorder driven by an autoimmune response against myelin components in the central nervous system (CNS). Besides demyelination, infiltration of immune cells into the CNS also leads to axonal degeneration, which in turn causes irreversible neurological disability. Previously, we identified a shared mechanism of axonal degeneration in MS and its animal model, experimental autoimmune encephalomyelitis (EAE), which we termed focal axonal degeneration (FAD). Essentially, FAD is a two-step process of focal axonal swelling followed by axonal fragmentation. Interestingly, a substantial proportion of swollen axons recovered and returned back to normal morphology. Here we set out to identify the underlying molecular mechanism of neuroinflammation-induced FAD.First, we investigated intra-axonal calcium levels in EAE mice *in vivo*, by using two-photon microscopy in the spinal cord of transgenic mice expressing a FRET-based ratiometric calcium sensor in neurons. This revealed that many axons in neuroinflammatory lesion have elevated levels of intracellular calcium, whereas calcium levels were tightly controlled in healthy animals. Importantly, high-calcium levels were also found in axons with normal morphology, suggesting that a rise in intra-axonal calcium precedes and perhaps initiates FAD. To address this

question, we followed changes in axonal calcium levels and morphology over time in a large number of axons in EAE animals. Our results indicate that intra-axonal calcium levels predict both swelling and fragmentation of axons in a neuroinflammatory environment. Next, we set out to identify potential causes for this rise in intra-axonal calcium. Of the previously implicated damage mechanisms in MS/EAE, only oxidative/nitrosative stress was able to directly induce an increase in axonal calcium levels and a FAD-like process in the spinal cord of healthy mice, while glutamate excitoxicity and acidosis did not markedly alter axonal calcium levels *in vivo*. Taken together, our experiments point to a crucial role for reactive oxygen/nitrogen species (ROS/RNS) in increasing intra-axonal calcium levels and, driving axonal degeneration in MS and EAE. We are currently exploring pathways involved in the ROS/RNS-induced rise in intra-axonal calcium.

Title: Exosomal protein changes of cerebrospinal fluid from neuromyelitis optica and multiple sclerosis patients

Authors: *S. HWANG[1], J. LEE[1], K. Q. MCKINNEY[1], A. J. PAVLOPOULOS[1], J. M. CONWAY[2], H.-J. KIM[3];
[2]Neurol., [1]Carolinas Healthcare Syst., Charlotte, NC; [3]Neurol., Res. Inst. and Hosp. of Natl. Cancer Ctr., Goyang-si, Korea, Republic of

Abstract: Microvesicles including exosomes are believed to play a significant role in intercellular signaling by delivering molecules via membrane vesicle trafficking. These processes then influence immune system cells, such as dendritic cells and B cells, and mediate adaptive immune responses to pathogens and tumors. Cerebrospinal fluid (CSF) is the most valuable biological specimen for the determination of neurodegenerative diseases since it contains corresponding molecular mediators being kept separated from systemic circulation. Comparative proteomics profiling of CSF exosomes isolated from neuromyelitis optica (NMO) and multiple sclerosis (MS) patients detected potential distinctive disease markers capable of discriminating NMO from MS. Differential centrifugation provided good yields of exosomes from CSF pooled by cytokine expression pattern. Immunological pre-classification of CSF by cytokine level gave advantages in target molecule identification by providing enhanced fold

change ratio and lower p-values when the subsets with high-cytokines were compared to each other. In this study, proteomics profiling of the exosomes isolated from the CSF of NMO patients identified disease specific molecular markers by comparison to the CSF exosome profiles of control and MS subjects. A SEQUEST search employing Swiss-Prot protein database (Human, reviewd) identified 470 proteins from the technical duplicate LC-MS/MS analysis of CSF exosomal proteins from control, NMO and MS subjects. The refined proteomic datasets identified putative disease specific markers, glial fibrillary acidic protein (GFAP) for NMO and fibronectin for MS. Among the target proteins, GFAP was observed from intact exosomes by flow cytometry and transmission electron microscopy (TEM) analysis in combination with immunogold staining and its expression level was measured by label-free quantification, which were in good agreement with western blot analysis results. The ELISA assay measurement of target proteins from individual CSF demonstrated their diagnostic applicability by clustering disease groups successfully. The current comprehensive study also suggests that this approach may be utilized to detect other neuronal diseases involved in inflammation, degeneration, demyelination, differentiation of oligodendrocytes, and neurofilament remodeling, etc.

Title: CHOP knockdown protects oligodendrocytes in mouse models of immune-mediated demyelination

Authors: ***Y. DZHASHIASHVILI**[1], H. BOMMIASAMY[2], R. B. KUNJAMMA[1], B. POPKO[1]; [1]Neurol., Univ. of Chicago, Chicago, IL; [2]Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS), characterized by focal demyelination. A central feature in the development of MS lesions is the death of oligodendrocytes, the cells responsible for generating and maintaining the myelin sheath. We have previously shown that genetic impairment of the integrated stress response (ISR), a cytoprotective mechanism that maintains cellular homeostasis, significantly exacerbates oligodendrocyte death and demyelination during an inflammatory attack. In addition, we have shown that the genetic or pharmacological enhancement of the ISR provides increased

protection against inflammatory demyelination. CHOP (C/EBP homologous protein) is a key ISR pro-apoptotic transcription factor that becomes activated under conditions of sustained endoplasmic reticulum (ER) stress, which has been implicated in MS lesion formation. We demonstrate here that genetic CHOP deletion protects oligodendrocytes against inflammatory demyelination, and alleviates disease in experimental autoimmune encephalomyelitis (EAE), a mouse model of MS. Our results implicate CHOP as a potential target for therapeutic intervention in MS, aimed to prevent oligodendrocyte loss and demyelination in the inflammatory CNS environment.

Abstract: The roles of various immune cells in the pathogenesis of experimental allergic encephalomyelitis (EAE), a rodent model widely used for multiple sclerosis study have been previously investigated with different methodologies. However, the relative roles of different immune cells have not been studied with the same model system. Here, we utilized intermedilysin (ILY)-mediated cell ablation model to compare the pathogenic roles of immune cells in EAE. ILY, secreted by *Streptococcus intermedius* (SI), binds exclusively to human membrane protein CD59 (hCD59) but not to CD59 of any other species. Once bound, ILY rapidly and potently lyses the targeted cells. Using this unique feature, we previously developed a novel cell ablation method. To streamline this approach, we recently generated the floxedSTOP-hCD59 or inducible hCD59 knock-in mice (ihCD59) where hCD59 expression only occurs following Cre-mediated recombination. To express the hCD59 in each type of the T cells, monocytes, and B cells, we crossed ihCD59 with Lck-Cre, Lyz-Cre or CD19-Cre mice respectively to generate three different strains of the mice: ihCD59/Lck-Cre, ihCD59/CD19-Cre

or ihCD59/Lyz-Cre. As expected, the specific Cre expression in T cells, monocytes, or B-cells mediated the hCD59's expression in each strain of these mice. Systemic ILY administration to each strain specifically ablated the corresponding cells. ILY administration was initiated 3 days after immunization with myelin oligodendrocyte glycoprotein peptide and continued for 14 days (daily i.p.) to ablate T cells, monocytes and B cells, respectively. By monitoring the clinical EAE scores in these mice, we demonstrated that ablation of T cells completely prevented EAE development and that ablation of monocytes largely attenuated the EAE scores, in contrast to moderate reduction of EAE scores in B-cell ablated mice. Therefore, for the first time, we have successfully dissected the roles of different immune cells with the same approach and demonstrated their distinct functions in EAE's pathogenesis.

Title: Exosomal secretion of a lipid neurotoxin from neural progenitors

Authors: ***G. SCESA**, A. L. MOYANO, L. D'AURIA, K. PITUCH, M. I. GIVOGRI, E. R. BONGARZONE;
Anat. & cell biology, Univ. of Illinois At Chicago, Chicago, IL

Abstract: Exosomes are small vesicles secreted from most mammalian cells via the multivesicular endosomal pathway. Multiple functions have been associated with this secretory pathway. It is unknown whether exosomes contribute to detoxification and also to the mobilization of neurotoxins. Krabbe's disease is an autosomal recessive genetic disorder affecting central and peripheral nervous systems, due to mutations in beta-galactosyl-ceramidase gene (GALC). As a result of GALC deficiency, the normal degradation pathway of several galactosyl-sphingolipids is impaired. One of these lipids, galactosyl-sphingosine or psychosine, exerts cytotoxic effects on neurons and myelin forming cells. Considering that psychosine is associated with lipid rafts in plasma membranes and that raft components are secreted via exosomes, we hypothesized that the neurotoxin psychosine may be secreted through this mechanism. Using a neural stem cell (NSC) *in vitro* paradigm, we show that NSC deficient in GALC (GALC-/- NSC) accumulate psychosine significantly more than wild-type cells upon

differentiation into the main three neural lineages. Upond differentiation GALC+/+ and GALC-/- cultures released detectable levels of exosomes to the medium, but psychosine was only detected in exosomes derived from deficient cells. Furthermore, levels of psychosine correlate with days of *in vitro* differentiation, suggesting an intracellular accumulation prior to exosomal release. Medium containing exosomes from differentiated GALC-/- NSC was sufficient to impair the differentiation of wild-type primary cultures of oligodendrocytes, suggesting a mechanism of trans-toxicity. These results suggest that mammalian cells have mechanisms to secrete toxic metabolites associated with lipid raft microdomains like psychosine through the exosomal pathway. This process may contribute to long-range toxicity in disease conditions and may also be part of a more general detoxifying mechanism.

Title: Psychosine causes cellular toxicity by downregulating the PI3K/Akt pathway in motoneurons

Authors: *T. SURAL-FEHR, L. CANTUTI-CASTELVETRI, H. ZHU, M. MARSHALL, E. R. BONGARZONE;
Dept. of Anat. & Cell Biol., Univ. of Illinois At Chicago, Chicago, IL

Abstract: Deficiency of the lysosomal galactosyl-ceramidase (GALC) enzyme results in the accumulation of the toxic lipid psychosine, and is the underlying cause for the hereditary Krabbe's disease. Psychosine causes fast axonal transport defects through abnormal activation of GSK3b and results in a dying-back pathology in neurons. However, the exact mechanism leading to this activation and the associated cellular toxicity is unknown. We previously showed that psychosine preferentially accumulates in lipid rafts within cell membranes disrupting their structure. Lipid rafts are essential platforms for cellular signaling pathways, therefore we hypothesized that psychosine accumulation would lead to a deregulation of intracellular signaling pathways affecting key mediators of integrity in neuronal axons. Using the neuronal-

like NSC34 cell culture system, we have systematically analyzed the downstream effects of psychosine, particularly on cellular signaling. We have found that exogenous psychosine administration causes a significant downregulation of the PI3K/Akt and MAPK pathways downstream of the IGF receptor. Inhibition of phospho-Akt takes place mainly at the plasma membrane and can be fully recovered through either stimulation of the IGF receptor by IGF-1, or using a small molecule activator (SC-79) of Akt, implying that the short-term effects of psychosine toxicity may be reversible. We conclude that the mechanism of psychosine toxicity in motoneurons goes through modulation of the cell's ability to sense growth factor availability in its environment and appropriately adjust its intracellular response. This effect possibly goes through perturbing the structure within membrane lipid rafts, thereby altering associated survival signals that depend on them, such as Akt activation coupled to IGF receptor signaling. Therefore, the use of Akt activators such as IGF-1 or SC-79 may represent potential therapies to alleviate the aspects of this disease regulated by this pathway.

Title: Functional characterization of IPSC-derived brain cells as a model for X-linked adrenoleukodystrophy

Authors: *I. SINGH[1], A. SINGH[2], M. KHAN[2], M. BAARINE[2];
[1]Developmental Neurogenetics, Med. Univ. South Carolina, Charleston, SC; [2]Med. Univ. of South Carolina, Charleston, SC

Abstract: X-linked Adrenoleukodystrophy (X-ALD) is an inherited neurodegenerative disorder where mutations in ABCD1 gene result in clinically diverse phenotypes, the fatal disorder of cerebral ALD (cALD) or a milder disorder of adrenomyeloneuropathy (AMN). The different models used to study the pathobiology of X-ALD disease lack the appropriate presentation for different phenotypes of cALD vs AMN. This study demonstrates that induced pluripotent stem

cell derived brain cells astrocytes (Ast), neurons and oligodendrocytes (OLs) express morphological and functional activities of the respective brain cell types. The excessive accumulation of saturated VLCFA a “hallmark” of X-ALD was observed in both AMN OLs and cALD OLs but higher levels were in cALD OLs than AMN OLs. The levels of ELOVL1 parallel the VLCFA load in these cell types. Secondly, cALD Ast expressed higher levels of proinflammatory cytokines than AMN Ast and control Ast with or without stimulation with lipopolysaccharide. These results document that IPSC-derived Ast and OLs from cALD and AMN fibroblasts mimic the respective biochemical disease phenotypes and thus provide an ideal platform to investigate the mechanism of VLCFA load in cALD OLs and VLCFA-induced inflammatory disease mechanisms of cALD Ast and thus for testing of new therapeutics for AMN and cALD disease of X-ALD.

Title: Deletion of signal transducer and activator of transcription 3 (STAT3) in myeloid cells confers resistance to experimental autoimmune encephalomyelitis

Authors: *H. LU, A. STEELMAN, S. KIM, B. ZHOU, J. LI;
Texas A&M Univ., College Station, TX

Abstract: Multiple sclerosis (MS) is a debilitating disease characterized by demyelination and neurodegeneration in the CNS. Both activated microglia and infiltrating myeloid cells are thought to contribute to disease initiation and progression of experimental autoimmune encephalomyelitis (EAE), a widely used animal model of MS that involves immunization of animals with a myelin antigen. STAT3 regulates multiple cellular functions including cell differentiation, survival, and inflammation and is a critical signaling molecule for the interleukin-6 family of cytokines. To investigate the role of STAT3 in myeloid cells and neuroinflammation, we generated conditional knockout mice with STAT3 selectively disrupted in myeloid cells and investigated their susceptibility to myelin oligodendrocyte glycoprotein (MOG)-induced EAE. Whereas $STAT3^{f/f}$ control mice developed typical signs of EAE with characteristic tail and hind limb paralysis, myeloid-specific STAT3 deficient mice were resistant to MOG-induced EAE. In contrast to $STAT3^{f/f}$ mice that elicited MOG-specific T_H1 and T_H17 responses at disease onset,

myeloid STAT3 deficient mice did not develop MOG-specific T cell responses. However, at later time points, the STAT3 mutant mice developed MOG-specific specific T_H1 and T_H17 responses in the peripheral lymphoid organs comparable to that of $STAT3^{f/f}$ mice, but failed to develop classic EAE and had minimum leukocyte infiltration into the CNS even after the peak disease phase. Our results suggest a duo role of myeloid STAT3 signaling in T cell polarization and myeloid cell function in modulating CNS autoimmunity. *Supported in part by NIH R01NS060017 and the National Multiple Sclerosis Society research grant RG3975*

Title: Indomethacin effect on BMMC migration: Prostaglandin synthesis inhibition or PPARɣ activation?

Authors: V. USACH, C. I. CASALIS, G. M. PIÑERO, L. PARRA, K. WEBER, P. A. SOTO, M. FERNÁNDEZ-TOMÉ, *P. C. SETTON-AVRUJ;
Sch. of Pharm. and Biochem, Buenos Aires, Argentina

Abstract: Demyelination is one of the hallmarks of the Wallerian degeneration (WD) process and cell therapy is among the strategies under study to induce remyelination. Results from our group obtained in a reversible model of WD induced by the crush of the rat sciatic nerve demonstrated the spontaneous migration of endogenous or transplanted bone marrow mononuclear cells (BMMC) exclusively to the injured nerve. Once in the ipsilateral nerve, some BMMC colocalized with Schwann cell markers and nerve fiber markers, which accelerated the regeneration process. On the basis of these results, the aim of the present work was to evaluate whether prostaglandins (PGs), one of the molecules generated during the inflammatory process associated with injury, is one of the signals involved in the migration and recruitment of BMMC to the demyelinated nerve. To this end, adult Wistar rats were submitted to sciatic nerve crush and one group of animals was immediately transplanted BMMC through the sacra artery. The presence of BMMC in the injured nerve was evaluated through confocal microscopy 24 h, 3 and 5 days post injury; the expression of ciclooxygenase 2 (Cox-2) was evaluated at 24 and 72 h and the synthesis of PGs was evaluated between 0 and 24 h post crush, through Western blot and PG radioconversion, respectively. Besides, the effect of a non-steroidal anti-inflammatory drug as

indomethacin on the migration of BMMC and PG biosynthesis was analyzed by treating animals with a subcutaneous injection of indomethacin 50 mg/kg/day the day of the lesion and the previous day, and 5 mg/kg/day the subsequent days. The results obtained show that, as soon as 24 h post injury, BMMC arrived at the edges of the ipsilateral nerve, and after 3 days they became part of it. Our results demonstrate the biosynthesis of PGE2, PGD2 and PGJ2 in sciatic nerve homogenates, and that their levels did not change significantly as a consequence of the lesion. Although indomethacin inhibited the migration of transplanted BMMC to the injured sciatic nerve, the biosynthesis of PGE2 and PGD2 was not affected. Surprisingly, indomethacin promoted a significant increase in PGJ2 both in the contralateral and the ipsilateral nerves as well as in the control nerve. This increase was dose-dependent, as rats treated with 12.5 or 25 mg/kg showed a smaller increase in PGJ2 synthesis. In the light of these results, indomethacin action on BMMC migration may be thought to occur through an independent PG-mediated mechanism such as the PPARɣ pathway. Further experiments are necessary to more precisely elucidate indomethacin effect on BMMC migration and on the degeneration-regeneration process.

Title: Aging exaggerates myelin disruption in an experimental model of demyelination

Authors: ***N. MICHAELS**, K. RAWJI, M. B. KEOUGH, J. R. PLEMEL, V. W. YONG; Univ. of Calgary, Calgary, AB, Canada

Abstract: Multiple sclerosis (MS) is an inflammatory and degenerative condition that destroys the myelin and axons of the central nervous system (CNS). It clinically begins most commonly with a relapsing-remitting (RRMS) disease course in young adults with the majority of these cases becoming progressively disabling. Age has been identified as an independent predictor for the time to the onset of the progressive stage of the disease; therefore, age-associated differences in the response to acute demyelination may underlie the progressive compromise of axons (neurodegeneration) and myelin (demyelination) with aging. We sought to test the hypothesis that the extent of early myelin disruption to a demyelinating injury would be greater in aging compared to young mice; if so, this would provide a model to examine the proximal mechanisms

of aging-enhanced neural injury. We have used the toxin lysophosphatidylcholine (LPC, lysolecithin) to induce demyelination, and have focused on myelin disruption over the first 72h in order to model aspects of an early MS lesion. LPC (0.5 µl of 1% solution) was deposited into the ventral column of the mouse spinal cord as described previously (Keough et al., JOVE 2015). Young (6 weeks old) and aging (8 month) mice were compared. At 3h post-LPC, disruption of myelin detected by eriochrome cyanine staining was apparent but not obviously different in both age groups. However, at 24h post-LPC, we found an exaggerated amount of myelin disruption in aging compared to young animals, and this exacerbation of lesion was still evident at 3 days. Current results indicate that the older animals after demyelination have greater microgliosis, as evaluated using Iba1 immunoreactivity. These results not only emphasize a greater demyelinating injury in aging compared to young mice in response to LPC, but they also provide a model to identify mechanisms that contribute to exaggerated myelin disruption in an effort to develop neuroprotective therapeutic strategies to delay progression in MS patients.

Title: Increased levels of colony stimulating factor-1 and its receptors in mouse spinal cords with experimental autoimmune encephalomyelitis

Authors: *X. BO[1], S. GUSHCHINA[2], W. J. B. ATKINS[2], G. PRYCE[2], G. GIOVANNONI[2], D. BAKER[2];
[1]Queen Mary, Univ. London, London, United Kingdom; [2]Ctr. for Neurosci. and Trauma, Queen Mary Univ. of London, London, United Kingdom

Abstract: Multiple sclerosis (MS) is generally considered as a chronic autoimmune disease, resulting from the attack of autoaggressive T cells on the myelin sheath or oligodendrocytes in the brain and spinal cord. Recently the contribution of microglia to various stages of the development of MS is being recognized. It is known that activated microglia are involved in antigen presentation, phagocytosis, and release of various pro-inflammatory molecules. Colony stimulating factor-1 (CSF-1) and interleukin-34 (IL-34) are two crucial molecules responsible for proliferation and activation of microglia. The main aim of the project was to study whether the expression levels of CSF-1, IL-34, and their receptors (CSF1R) were increased in the mouse spinal cords with experimental autoimmune encephalomyelitis (EAE). Using ELISA we found that the level of CSF-1 was significantly higher in the spinal cords of acute and chronic EAE

mice than the control mice, while the levels of CSF-1 in the plasma of the three groups were not significantly different, which may indicate increased local synthesis of CSF-1 in the spinal cords of EAE mice. The level of IL-34 in the spinal cords of the control group was not significantly different from the acute EAE group, but significantly higher than the chronic group, implicating that IL-34 may play a lesser important role in microglia activation in the EAE mice. IL-34 levels in the plasma of the three groups were also not significantly different. Preliminary data from immunohistochemistry showed that there were more CSF-1R positive microglia in the spinal cords of the acute and chronic EAE mice than the control group. The results from the current study implicate that locally synthesized CSF-1 in the central nervous system may play an important role in the activation of microglia in EAE, contributing to neuroinflammation and neurodegeneration.

Title: Notch-1 signaling in a mouse model of metachromatic leukodystrophy

Authors: *F. MAROTTOLI;
Anat. & Cell Biol., Univ. of Illinois At Chicago, Chicago, IL

Abstract: Metachromatic leukodystrophy (MLD) is an inherited lysosomal storage disease caused by a deficiency in the catabolic enzyme arylsulfatase-A (ARSA). This deficiency leads to the accumulation of sulfatides in glial and neuronal cells, resulting in demyelination in the central and peripheral nervous systems. The pattern of sulfatide accumulation seen in this disease has been recapitulated in a knock-out (KO) mouse model, in which a delay in the onset of myelination has been observed. The molecular mechanism behind this delay is unknown. While the process of myelination is governed by a number of pathways working in concert, previous work from various groups including ours indicates that activity of Notch signaling pathway represses the differentiation of oligodendrocytes. Importantly, previous studies in *Drosophila* have also found that this highly conserved signaling pathway is positively stimulated by glycosphingolipids under certain conditions. Therefore, we hypothesized that sulfatides

aberrantly activate the Notch1 pathway, contributing to block oligodendrocyte differentiation and to the delayed onset of myelination in the MLD mouse. We have been testing this hypothesis by measuring the levels of the various signaling components of the Notch pathway, including its downstream targets (Hes genes). This was done via RT-qPCR and western blot in the cortex and corpus callosum of MLD KO and wild-type mice during the peak of myelination. We found a significant increase in the notch intracellular domain (NICD) in our western blot analysis at P21 in MLD KO mice accompanied by a significant increase in Hes 5 mRNA expression, which correlates with the delay in myelin gene expression. Currently we have incorporated a sensitive luciferase-based reporter system to specifically measure the effect of sulfatides on the activity of Hes1 and Hes5 promoters in primary glial cultures. Abberant Notch activation during the period of oligodendrocyte maturation in the MLD mouse appears to be a possible mechanism contributing to the observed delay in myelination.

Title: Elimination of mitochondrial anchoring protects dysmyelinating shiverer: implications for progressive MS

Authors: *D. C. JOSHI[1], C.-L. ZHANG[1], T.-M. LIN[1], A. GUSAIN[2], M. G. HARRIS[3], Z.-H. SHENG[4], Z. FABRY[3], R. J. DEMPSEY[2], S. CHIU[1];

Abstract: The demyelinating disease multiple sclerosis (MS) has an early inflammatory phase followed by a late phase with subdued inflammation. Unlike the first phase, the late phase resists all known treatments and has poorly understood mechanisms for neurodegeneration. Recent studies have suggested an emerging role for mitochondria in the pathogenesis of MS. In particular, demyelination/dysmyelination triggers an increased axonal mitochondrial density and numbers at lesion sites which is said to a beneficial adaptive response to match an increase in

metabolic demand in demyelinated axons. Further, it has been suggested that mitochondrial anchoring contributes to the increased axonal mitochondrial content in demyelination, evidenced by increased expression of a neuron specific protein Syntaphilin (SNPH). However it is not well studied if the increased mitochondrial contents and SNPH expression are beneficial or detrimental. To examine whether a SNPH-mediated increase in axonal mitochondrial content is beneficial in MS, we genetically eliminated SNPH from the *Shiverer* mice, a dysmyelinating mutant that approximates the late phase of MS in lacking inflammation, show increased mitochondrial density / SNPH expression and cerebellar degeneration. We generated a *Shiverer*-SNPH knock out (Shi-SNPH-KO) mice by crossbreeding *Shiverer* into SNPH-KO mice anticipating worsen of disease course and life span of *Shiverer*. Surprisingly, SNPH-KO significantly prolonged the survival of *Shiverer* and reduced the cerebellar grey and white matter degeneration in these mice. Biochemical and fluorometric analysis revealed an improved mitochondrial health and decreased oxidative stress in Shi-SNPH-KO mice. In contrast, SNPH deletion did not benefit clinical symptoms in experimental autoimmune encephalomyelitis (EAE), a model for early-phase MS. Our results provide the critical link of mitochondrial mobility to MS mice model. Further, because SNPH deletion exerts neuroprotection in the non-inflammatory *Shiverer* model, we suggests that mitochondrial anchoring is a novel site for therapeutic intervention in late phase MS.

Title: Effects of anti-AQP4 and co-existing autoantibodies at the Blood-Brain Barrier in Neuromyelitis optica

Authors: ***Y. TAKESHITA**[1], B. OBERMEIER[2], F. SHIMIZU[2], A. COTLEUR[2], S. SPAMPINATO[3], T. KRYZER[4], V. LENNON[4], Y. SANO[1], T. KANDA[1], R. M. RANSOHOFF[2]; [1]Neurosci., Yamaguchi Univ. Grad. Sch. of Med., Ube, Japan; [2]Biogen, Cambrige, MA; [3]Univ. of Catania, Catania, Italy; [4]Mayo Clin., Rochester, MN

Abstract: [Background] Neuromyelitis optica (NMO), an autoimmune inflammatory astrocytopathy, is caused by antibodies to the astrocyte water channel aquaporin 4 (AQP4). AQP4 is expressed widely on astrocytes. The IgG plasma fraction of NMO patients (NMO-IgG)

contains AQP4 antibodies. 30% of NMO patients also have well-known co-existing autoantibodies (like anti-phospholipid antibody). It is suggested that NMO-IgG might contain some unknown co-existing autoantibodies to disrupt the blood-brain barrier (BBB) (Shimizu F et al., 2011). It remains uncertain how AQP4 and these co-existing autoantibodies affect on the BBB. [Aim] We examined effects of anti-AQP4 and these co-existing autoantibodies on endothelial cells and astrocytes. [Method] We prepared the total NMO-IgG (T-NMO-IgG) and individual NMO-IgG (I-NMO-IgG). T-NMO-IgG was pooled from therapeutic plasma exchange from total 50 NMO patients and I-NMO-IgG came from each NMO patient (N=5). All NMO-IgG were purified by IgG prep. Conditionally immortalized human brain microvascular endothelial cell line (EC) or human astrocyte cell line which express AQP4 (A4) or don't express AQP4 (A) were cultured on the slide chamber. After exposing NMO-IgGs, we evaluated ICAM-1 expression of EC by quantity PCR and immunocytochemistry, IL-6 expression of EC, A4 and A by ELISA. We also demonstrated immunocytochemistry with T-NMO-IgG or I-NMO-IgG as primary antibodies. [Results] T-NMO-IgG and some I-NMO-IgG increased ICAM-1 of EC and IL-6 of EC and A4 but not A and recognized unknown molecules on EC. The other I-NMO-IgGs didn't induce ICAM-1 expression and detect anything on EC although they elevated IL-6 in A4. [Conclusion] These results indicate that 1) co-existing autoantibodies clearly exerts vascular effects, causing upregulation of ICAM1 and IL-6; and 2) Anti AQP4-IgG itself induces IL-6 in astrocytes via AQP4.

Title: Role of Caspase-8 in multiple sclerosis

Authors: *S. J. KIM[1], F. LU[1], A. STEELMAN[1], J. LI[1], B. ZHOU[2];
[1]Vet. Integrative Biosci., [2]Dept. of Vet. Physiol. and Pharmacol., Texas A&M Univ., College Station, TX

Abstract: Recent studies suggested non-canonical functions of caspase-8 in immune cells. To investigate the role of caspase-8 in regulating immune reactions, we generated conditional

knockout mice with Casp8 selectively disrupted in myeloid cells including activated microglia through lysozyme M-driven Cre recombination, and subjected these mice to experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis (MS). We report here that caspase-8 is activated in microglia/macrophages in active MS lesions and that myeloid specific Casp8 deletion (Casp8LysM) exacerbates neuroinflammation and clinical symptoms of EAE with enhanced Th1 specific T cell responses in the CNS. Mice with Casp8 selectively ablated in microglial cells (Casp8CX3CR1-CerERT) failed to show enhanced EAE progression when compared to their littermate controls, suggesting that caspase-8 activation in peripheral myeloid cells restricts EAE progression. Consistent with our *in vivo* findings, Caspase-8 deficiency in bone-marrow-derived macrophages and dendritic cells produced significantly more IL-1β after innate challenges, which was independent of any cell death. The heightened IL-1β production in Casp8-deficient macrophages/dendritic cells further promoted Th1 cell activation and production of interferon gamma (IFN-γ). The enhanced IL-1β production by caspase-8 deficient macrophages and dendritic cells was completely abolished in Rip3/Casp8 LysM double knockout cells or by necrostatin-1 that prevents RIP1 and RIP3 dimerization, suggesting a function link between RIP3 and IL-1β processing that is negatively regulated by caspase-8. Moreover, exaggerated neuroinflammatory responses and clinical EAE symptoms were ameliorated by Casp8 LysM/Rip3-/-double deletion. Taken together, our studies provide the first evidence that caspase-8 negatively regulates IL-1β production and neuroinflammation during autoimmune demyelination, and suggest potential targets for developing therapeutics in the acute phase of relapsing remitting MS.

Title: Simultaneous measurement of hnRNP A1 fibril formation by dynamic light scattering (DLS)

Authors: ***M. MOTIWALA**[1], S. LEE[2], H. SALAPA[3], Y. SHIN[2], J. DOUGLAS[3], H. CHO[3], M. LEVIN[2];
[1]Neurol., VA Med. Ctr., Memphis, TN; [2]Neurol., [3]Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Heterogeneous nuclear ribonucleoprotein (hnRNP) A1 is a functionally variable RNA-binding protein (RBP). It affects transcription and mRNA splicing using both RNA interactions and nuclear pore transport. HnRNP A1 is required by neurons for normal functioning, and moreover, inadequate levels of the RBP, whether caused by transcription errors or as a result of autoimmune reactions, result in the dysregulation of normal RNA processing. Indeed, this type of dysregulation is well established. It plays an important role in several neurodegenerative conditions, but its link to hnRNP A1 represents a fairly novel insight and may involve other associated proteins. Notably, when stress granules form as a result of mutations in genes coding for stress granule-associated RNA binding proteins such as hnRNP A1, fused in sarcoma (FUS), transactive response DNA-binding protein (TDP43), etc., the aggregation of proteins is exacerbated. This dysregulated aggregation caused by genetic mutations in RBPs can initiate degenerative disease. Furthermore, depleted hnRNP A1 is associated with a symptomatological increase in numerous neurodegenerative diseases, including Alzheimer's disease (AD), amyotrophic lateral sclerosis (ALS), multiple sclerosis (MS) and HTLV-I associated myelopathy/tropical spastic paraparesis (HAM/TSP). In the context of our own research, point mutations in the genetic sequence for hnRNP A1 are shown to inhibit normal binding by transportin-1 at the M9 region, and this condition eventually contributes to the pathogenesis of MS. In this study, we utilized the dynamic light scattering (DLS) method to examine the protein-protein interaction between transportin-1 and hnRNP A1. DLS measures intensity fluctuations of scattering light in order to calculate the molecular radius of protein complexes in solution. Successful application of this method confirmed normal function of the RNA-binding proteins, demonstrating proof of concept for DLS as a higher throughput approach to evaluate protein binding. Because defective and aggregated cellular proteins are a feature of a number of neurodegenerative diseases, DLS represents a novel technique to explore their significance without the costly and time consuming constraints of the standard protein-protein interaction assays (GST pull- down assay, co-immunoprecipitation, proximity ligation assay (PLA), etc.). By utilizing the DLS approach, numerous samples of abnormal hnRNP A1 could be quickly screened for binding with transportin-1 or other proteins, further clarifying the functional significance of these defects in the context of MS.

Title: Cross-talk between astrocytes and mast cells is a neuro-immune mechanism for disease exacerbation in neuromyelitis optica

Authors: *M. CAULFIELD, Y. GUO, H. KITA, C. HOWE, C. LUCCHINETTI;
Mayo Clin., Rochester, MN

Abstract: Neuromyelitis optica (NMO) is an inflammatory CNS autoimmune disorder characterized by recurrent attacks of the optic nerve, spinal cord, and brain. The identification of a putative pathogenic autoantibody, NMO IgG, has enabled reliable diagnostic distinction between NMO and other similar disorders. Pathogenesis is likely initiated by binding of NMO IgG to the surface of target cells expressing aquaporin-4 (AQP4), the principle CNS water channel. Astrocytes are a primary target in NMO due to the high expression of AQP4 on perivascular and peripial endfeet. In addition to lytic events, we have found immunopathological evidence of a spectrum of early, sublethal, non-lytic, widespread astrocytic alterations in NMO human tissues including early granulocytic infiltration, even in the absence of terminal complement deposition and demyelination, suggesting that early astrocyte responses to NMO IgG may drive recruitment. In an *in vitro* culture system, stimulation of astrocytes with NMO IgG drives a rapid and robust pro-granulocytic cytokine and chemokine response. Strikingly, mast cells, members of the innate immune system, co-localize with both astrocyte foot processes and AQP4 expression throughout the CNS. Mast cells are early responders to insults in both infectious and autoimmune settings where they act to recruit other innate immune cells to sites of inflammation. Recent studies have shown that mast cells and astrocytes interact directly via CD40:CD40L interactions or via soluble mediators that induce the release of histamine, leukotrienes, and numerous cytokines and chemokines. Therefore, we asked if cross-talk between astrocytes and mast cells contributes to the exacerbation of inflammation in NMO. Microarray analysis revealed that astrocyte cultures upregulate a variety of mast cell-associated transcripts within 24 hours of stimulation by NMO IgG. Preliminary examination of mast cells in human tissue using H&E and tryptase immunohistochemistry in 4 NMO cases (29 regions) and 7 healthy controls revealed: i) increased frequency of mast cells in NMO meninges and periplaque white and gray matter (PPWM/PPGM); ii) mast cells in early non-destructive, vacuolated NMO lesions with AQP4 loss; iii) mast cell degranulation in meninges, PPWM, PPGM and NMO lesions; and iv) mast cells co-localized with granulocytic infiltrates. Together these data suggest that mast cells are actively involved in early NMO lesions where they may play a pivotal role in granulocyte recruitment, and suggest that cross talk with astrocytes may provide the impetus for this novel mechanism of early NMO pathogenesis.

Title: A1 reactive astrocytes are strongly neurotoxic inducing apoptosis of neurons and oligodendrocytes and are induced by M1 microglia via IL1α, TNFα and C1q signaling

Authors: *S. A. LIDDELOW[1,2], A. E. MÜNCH[1], L. E. CLARKE[1], B. A. BARRES[1]; [1]Neurobio., Stanford Univ., Stanford, CA; [2]Pharmacol. and Therapeut., The Univ. of Melbourne, Melbourne, Australia

Abstract: Astrocytes undergo profound changes in morphology and gene expression in response to brain injury and disease. But whether reactive astrocytes are harmful or helpful has been unclear. We recently found that the genes induced in reactive astrocytes depends on the nature of the inducing injury. After ischemia, reactive astrocytes upregulate neurotrophic factors suggesting they may be beneficial, whereas after systemic injection of lipopolysaccharide (LPS) they strongly upregulate multiple complement cascade components needed to drive synapse destruction suggesting they may be detrimental. These findings suggest that, like macrophages which exist on a spectrum from bad (M1) to good (M2) states, reactive astrocytes also exist in bad (A1) and good (A2) states. Here we show that LPS-induced M1 microglia are sufficient to induce A1 reactive astrocytes. M1 microglia do this by releasing IL1α, TNFα and C1q, which together are sufficient to induce A1 (bad) reactivity in purified astrocytes within 24h and are all required for M1 microglia to induce the A1 state. Using IL1α, TNFα and C1q together, allowed us to create the first defined serum-free cultures of pure A1 reactive astrocytes enabling us to investigate their function. By directly comparing the function of normal astrocytes with A1 astrocytes *in vitro*, we found that A1 astrocytes are unable to promote neuronal survival, axon outgrowth, synapse formation or synapse function, and have lost the ability to phagocytose synaptosomes and myelin debris. In addition to loss of their normal functions, A1 reactive astrocytes gained a powerfully neurotoxic function, releasing a toxic protein that specifically induces apoptosis of neurons and oligodendrocytes. Drugs that prevent the formation of A1 reactive astrocytes or inhibit this toxic protein may have great potential to treat neurodegenerative diseases such as Alzheimer's disease, Parkinson's disease and Multiple Sclerosis.

Title: Ultrastructural analysis of hippocampal synapses following demyelination

Authors: ***S. JAWAID**[1], G. J. KIDD[1], R. DUTTA[1], L. ROHOLT[1], S. DECKARD[1], E. BENSON[1,2], A. CHOMYK[1], B. D. TRAPP[1];
[1]Dept. of Neurosci., Lerner Res. Inst., Cleveland, OH; [2]Renovo Neural, Inc., Cleveland, OH

Abstract: Memory dysfunction and hippocampal demyelination is common in Multiple Sclerosis (MS) patients. Hippocampal demyelination has been associated with significant decrease in expression of pre- and post-synaptic proteins specific for glutamatergic synapses and neuronal proteins that modulate synaptic plasticity and memory without obvious loss of neurons. To investigate how demyelination impacts synaptic function, we utilized a rodent animal model of hippocampal demyelination/remyelination that uses the oligodendrocyte toxin cuprizone (C) and rapamycin (R), an inhibitor of oligodendrocyte differentiation. C/R treatment for 12 weeks led to ~95% reduction of myelin staining; followed with 6 weeks of normal diet led to myelin levels ~63% of control. Remyelination of the hippocampus in this model completely reversed the memory dysfunction observed following demyelination. To understand the ultrastructural changes associated with hippocampal demyelination and remyelination, we used a serial blockface electron microscopy (SBF-SEM) and investigated synaptic alterations in the distal stratum radiatum of CA1 pyramidal neurons. Dendrites in this region produce excitatory synaptic spines which are highly dynamic and are involved in learning and memory. Imaging and reconstruction of primary dendrites from chronic demyelinated hippocampus showed increase (almost double) in median spine volume, spine lengths (35%) and larger post synaptic densities (PSD area/Spine area; 25%) compared to Rap-only control. These changes were a response to chronic demyelination as the dendritic spine morphology showed reversal towards control levels following remyelination. As astrocytes are integral part of synaptic functioning, we determined extent of astrocyte contacts in CA1 synapses. In demyelinated hippocampus, the frequency of astrocyte processes at synaptic cleft doubled and recovered towards Rap-only control after 6w remyelination. Larger spines participated more in the formation of these tripartite synapse. Collectively, our results suggest that demyelination affects synaptic plasticity in rodent

hippocampus through alteration of the dendritic spine morphology and increased astrocyte-synapse interactions.

Title: Myelin disruption leads to targeted behavioral deficits

Authors: *E. A. GOULD, N. BUSQUET, D. RESTREPO, W. MACKLIN;
Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: Myelin is required for proper nerve conduction and has an important role in normal axonal function. Alteration in myelin structure and quantity is observed in various neurological diseases. Polymorphism in myelin genes is associated with conditions including depression, schizophrenia, and bipolar disorder. However, little is known about the neuronal and behavioral consequences of myelin disruption alone and the role of myelin genes in pathology. To address the contribution of myelin function to behavioral and cognitive deficits, we used a mouse line lacking the myelin proteolipid protein (PLP). These mice generate myelin but exhibit progressive myelin dysfunction and eventual axonal degeneration. We tested 3 and 8 month-old PLP knockout PLP(-/Y) male mice in a battery of behavioral tests. No motor deficits were observed in 3 and 8 month old PLP(-/Y) mice on the Rotarod, a classical test of motor function. Altered emotionality was observed in 3 and 8 month PLP(-/Y) mice. 3 month PLP(-/Y) mice spent more time in open arms of the zero maze (175 ±17 vs 92±21 seconds, $p<0.05$), a test of anxiety, while no change was observed at 8 months (126±27 vs 117 ±26 s, $p=0.81$). 8 month PLP(-/Y) mice spent less time in the center of an open field (159±23 seconds vs. 239±25 seconds, $p <0.05$), while exploration of the walls was increased (105.3±9 vs 74.1±10 seconds, $p<0.05$). PLP(-/Y) mice demonstrated a decrease in the motivation to bury marbles in the marble burying task (mean number of marbles buried: 3 month = 2.9±0.3 vs. 6.1±0.6; 8 month = 0.3±0.2 vs. 4.2±0.9, $p<0.001$). Performance on the Y maze, a test of spatial memory and hippocampal function, was normal in 3 and 8 month old PLP(-/Y) mice. In the Puzzle Box, a test of problem-solving and executive function, 3 and 8 month PLP(-/Y) mice displayed longer latency to reach the goal box when presented with a new challenge (repeated measure ANOVA, $p=0.02$), indicating deficits in higher cognition. Intriguingly, a significant increase in immobility and a lack of coordinated

swimming was observed when 8 month PLP(-/Y) mice were placed in water (distance moved = 140 ± 5 vs 339 ±11 in 30 second swimming trial, $p<0.01$). Our data indicate that myelin dysfunction results in targeted behavioral deficits and cognitive dysfunction even long before significant axonal degeneration can be observed. This suggests that there could be a myelin-specific dimension to certain neurological disorders, which may warrant specific therapeutic interventions. Ongoing investigation aims at better characterizing those deficits and linking them to structural alteration of myelin in specific parts of the brain, in order to understand the underlying mechanisms.

Title: Correlation of spinal cord and CSF biomarkers to clinical and radiological measures of CNS injury in a mouse model of multiple sclerosis

Authors: *F. A. GILLI[1], X. CHEN[2], A. R. PACHNER[1], B. GIMI[2];
[1]Dept. of Neurol., Geisel Sch. of Med. At Dartmouth,, Lebanon, NH; [2]Radiology, Geisel Sch. of Med. at Dartmouth, Lebanon, NH

Abstract: OBJECTIVE: To develop biomarkers relevant to inflammatory, demyelinating CNS injury in the Theiler's encephalomyelitis virus-induced demyelinating disease (TMEV-IDD) model of MS by correlating gene expression in the spinal cord and CSF with MRI and clinical measures of spinal cord injury. BACKGROUND: A major gap in our understanding of MS is a lack of information about the pathogenesis of demyelination and axonal injury that are the pathological hallmarks of the disease. This has led to the lack of availability of useful clinical biomarkers of inflammation and disease. The TMEV-IDD model of MS reproduces both the progressive spastic disability and the pathology of MS, and thus serves as an ideal model to improve our understanding of mechanisms of CNS injury in MS. DESIGN/METHODS: We used gene expression measures of spinal cord tissue and CSF to correlate potential biomarkers to spinal cord injury as measured by MRI (T2 and diffusion tensor imaging) and Rotarod. SJL/J mice with TMEV-IDD with varying levels of clinical disease and anti-TMEV antibodies in the serum were serially imaged using a 9.4T horizontal bore small animal MRI scanner. Mice were then necropsied; blood, CSF, and spinal cord tissue were obtained. Gene expression of a range of host and viral proteins were analyzed by real time RT-PCR for mRNA of tissue, and multiplex

bioassay for proteins in the CSF. Correlation was then performed between potential biomarkers and MRI and Rotarod. RESULTS: A number of potential biomarkers, including molecules upregulated in CNS antibody production, were identified using this approach. Many of these potential biomarkers are classified as innate immune molecules. CONCLUSIONS: Correlation of CNS tissue and CSF biomarkers to clinical and MRI measures of disease in the spinal cord in TMEV-IDD represents a sound approach to development of clinically useful biomarkers in MS.

Title: Long-term psycho-affective outcomes in male athlete with a history of concussion

Authors: ***W. SAUVE**, R. D. MOORE, D. ELLEMBERG;
Kinesiology, Neurodevlab, Montreal, QC, Canada

Abstract: Mild or concussive brain injuries are known to cause psycho-affective changes (Jorge, 2004). However, these disturbances are believed to resolve within 7 to 10 days of injury (McCrory, 2013), and few studies have evaluated the persistent psycho-affective outcomes of concussion in collegiate athletes. As such, this study evaluated the long-term psycho-affective outcomes of concussions in collegiate athletes and the relation between the number of injuries and their psycho-affective functioning. Seventy-seven collegiate male athletes (43 concussed, age = 21.23 ± 1.43; 34 controls, age = 21.82 ±1.83) completed the Beck's Depression Inventory-II (BDI-II) and the Profile of Mood States (POMS). All participants were asymptomatic at the time of testing and those with a concussion history were 1+ year post-injury (26.58 months ± 14.67). Analyses revealed that athletes with a concussion history has significantly higher scores on the BDI-II (5.72 ± 3.92) relative to controls (3.91 ± 3.40; $p<0.05$, $d = 0.49$). In addition, athletes with a history of concussion had a significantly higher score on the total mood disturbance scale of the POMS (17.81 ± 24.11) relative to controls (5.82 ± 16.94; $p<0.05$, d =

0.58). Further, the anger subscale is also significantly higher for the concussed athletes(8.30 ± 6.37) relative to controls (4.05 ± 3.77; $p<0.05$, $d = 0.81$). Bivariate correlations failed to reveal a relation between number of injuries and scores on either the BDI-II or POMS ($p's \geq 0.20$). Thus, a single concussion may be sufficient to cause small, yet persistent, alterations in psycho-affective functioning.

Title: Disruptions to white matter microstructure of the default mode network in pediatric traumatic brain injury

Authors: *V. G. BABOYAN[1,2,3], A. MEZHER[1], E. L. DENNIS[1], M. DAIANU[1], Y. JIN[1], T. BABIKIAN[2], C. GIZA[3], R. F. ASARNOW[2], P. M. THOMPSON[1];

Abstract: Traumatic Brain Injury (TBI) has been shown to disrupt Intrinsic Connectivity Networks (ICNs) in studies examining the Default Mode Network (DMN). This disruption may interfere in switching between task-dependent and task-independent networks, leading to various neurocognitive deficits. Reduced connectivity in the DMN may even cause or be driven by structural changes in white matter (WM) tracts connecting DMN hubs. Here we tested thickness measures in the cingulate gyrus - the underlying *cortical* structure of the DMN - and microstructural changes in the cingulum bundle - the underlying *subcortical* structure of the DMN. Neuropsychological tests, T1-weighted MRI scans, and high angular resolution diffusion

weighted imaging (HARDI) were obtained from 24 chronic (13-19 months post-injury) TBI participants (mean age: 15.65±3) and 26 healthy controls (mean age: 16.79±2.8). Principal Components Analysis (PCA) was used to generate a single performance index based on tests from several cognitive domains that are sensitive to brain injury. Multi-atlas based fiber clustering was performed on whole-brain tractography to extract 4 fibers (bilateral cingulum and their parahippocampal components), for which we extracted measures of WM integrity - FA (fractional anisotropy) and MD (mean diffusivity). We computed cortical thickness for 4 subdivisions of the cingulate gyrus (rostral and caudal anterior, posterior, and isthmus) along with the precuneus and parahippocampal gyri using FreeSurfer v5.3. To test for group differences in the microstructural integrity of the cingulum and separately, thickness measures across gyri, we ran a random effects regression, covarying for age, sex, and scanning site. We also tested relationships between DMN structure and cognitive function. Significant group differences were found in mean MD measures across all 4 fibers examined (FDR critical P= $p<0.05$, FDR corrected) - most pronounced in the left cingulum ($p<0.01$, corrected), with TBI participants having greater mean MD. Cortical thickness measures were not significantly different between groups and no relationships were found between gray/WM measures and the performance indices. Consistent with past findings, mean diffusivity of DMN WM was a sensitive biomarker of structural abnormalities in TBI. Understanding the structural and functional dynamics of the brain's ICN's in TBI may inform clinical decision making if therapies could target specific brain networks. Future work examining tract-wise WM microstructure of the cingulum and commissural fibers as well as vertex-wise gray matter volume will help evaluate their contributions to DMN function.

Title: Processing of complex, real-world information as awareness fades under sedation

Authors: *L. NACI, E. HOULDIN, R. CUSACK, M. ARANGO, C. HARLE, A. M. OWEN; Brain and Mind Inst., Western Univ., London, ON, Canada

Abstract: Anesthesia provides a controlled manipulation for abolishing consciousness in a reliable manner in healthy individuals. When combined with functional neuroimaging, it provides a unique approach for studying the brain mechanism of consciousness and how they go awry when consciousness is lost. The majority of anesthesia studies have used a stimulus- and task-free paradigm, known as the resting state, to investigate changes in neural activity as the brain transitions from the wakeful to the anesthesia-induced unconscious state. However, these studies cannot address the question of how processing of external information that evolves over time is affected by sedation. For the first time, we investigate the cognitive response to complex naturalistic stimuli in states of incremental sedation, from awake, to mild, and to deep sedation, a state characterized by lack of behavioral responsivity. We used a novel paradigm that presented a rich, auditory narrative to participants (N=17) in the functional Magnetic Resonance Imaging (fMRI) scanner. The level of propofol sedation was assessed with the Ramsay clinical scale (Ramsay 1974). Assessments of Ramsay 1, 3, or 5 determined awake, mild, or deep sedation, respectively. Perception and higher-order cognition were investigated by modeling the fMRI response with Statistical Parametric Mapping. Independent Component Analysis further characterized brain networks. In the awake state, we found robust responses in brain networks involved in sound processing, language, visual imagery, and executive function ($p<0.05$, FEW cor). In mild sedation, the sound processing and language networks were preserved, but the visual imagery and executive function networks were abolished. In deep sedation, the sound network was preserved, whereas the language network showed weak residual activity. No activity was observed in the visual and executive function networks. These results suggest a dose-dependent effect of sedation on some, but not all aspects of the brain response to complex naturalistic information. Moreover, they suggest hierarchical impairment of cognition in the unconscious state, with incremental impairment from sound to language processing, and a complete loss of visual imagery and executive function. By contrast to resting state studies, which suggest present albeit diminished activity across different brain networks, these data paint a more nuanced picture of loss and preservation of brain function in the unconscious state.

Title: Restoration of thalamo-cortical connectivity after severe brain injury: recovery consciousness or passage of time?

Authors: *M. M. MONTI;
UCLA, Los Angeles, CA

Abstract: What mechanisms underlie the loss and recovery of consciousness after severe brain injury? Conceived as a network-level impairment, thalamo-frontal connectivity is generally believed to be a central aspect for the maintenance (and restoration) of consciousness after severe brain injury. Indeed, in a landmark case report, it has been shown that thalamo-frontal connectivity appeared to be restored in concomitance with the return of awareness (Laureys et al., 2000). Yet, to date, the well accepted notion of the parallel restoration of thalamo-cortical functional connectivity and awareness after severe brain injury rests mainly on that single case report. We thus followed prospectively 11 patients surviving severe traumatic brain injury and acquired functional resting state data within the first week of insult and at six-months post-trauma. Data were acquired on a 3T Siemens TimTrio system, and included structural T1-weighted (MPRAGE) as well as T2*-weighted data. The blood oxygenation level dependent (BOLD) signal was measured, at both the acute and chronic timepoints, with a "resting-state" design. Data were preprocessed according to established procedures, including anatomical registration, slice time correction, motion correction, nuisance signal regression, temporal filtering ans smoothing (8mm FWHM). A seed based analysis, employing bilateral thalamus as the seed mask, was performed independently for each session (for each subject) and then entered in a paired-samples group analysis. At the group level, the variance was modeled employing a mixed-model approach, and statistical maps were thresholded using a cluster correction of $Z > 2.3$ and $p < 0.05$ (corrected). The results show that, as compared to the acute timepoint, greater thalamo-frontal connectivity was present across all patients -- replicating the original case report. However, contrary to the original report, the increase in thalamo-cortical connectivity was observed regardless of the change in consciousness state of the patient. Indeed, the degree of connectivity restoration in patients who recovered consciousness was comparable to that observed in patients who were already (minimally) conscious during the acute scan and remained so through the chronic scan. These findings suggest that while thalamo-cortical connectivity does return with time -- as shown in the original finding -- it might not necessarily be connected to the return of consciousness. Sci., New York, NY

Abstract: Background: Resting state acquisitions are by definition appropriate to assess non-communicating subjects. We here evaluated the clinical relevance of systems-level resting state fMRI in patients with disorders of consciousness with the aim to promote single-patient diagnostics. Methods: Seventy three patients in minimally conscious state (MCS), vegetative state/unresponsive wakefulness syndrome (VS/UWS) and coma were scanned in 3 different centers. The main analysis was performed on the dataset coming from one centre (Liège, 51 patients; 26 MCS, 19 VS/UWS, 6 coma; 16 traumatic, 32 non-traumatic, 3 mixed; 35 patients assessed >1 month post-insult) for whom the clinical diagnosis with the Coma Recovery Scale-Revised (CRS-R) was congruent with positron emission tomography scanning. Using a multiple-seed correlation approach, group-level functional connectivity was investigated for the default mode, frontoparietal, salience, auditory, sensorimotor and visual networks. Between-group inferential statistics and machine learning were used to identify each network's capacity to discriminate between patients in MCS and VS/UWS. Data from 22 patients independently scanned in two other centres (Salzburg: 10 MCS, 5 VS/UWS; New York: 5 MCS, 1 VS/UWS, 1 emerged from MCS) were used to validate the classification with the indetified features. Results:

CRS-R total scores correlated with key regions of each network reflecting their involvement in consciousness-related processes. Although all networks had a high discriminative capacity (>80%) for separating patients in MCS and VS/UWS, the auditory network was ranked the most highly. Specifically, bilateral auditory and visual cortices of the auditory network were more functionally connected in patients in MCS compared to VS/UWS. Connectivity values in these three regions discriminated congruently 20 out of 22 independently assessed patients. Conclusions: These findings highlight the significance of preserved multisensory integration and top-down processing in minimal consciousness which are seemingly supported by auditory-visual crossmodal connectivity, and promote the clinical utility of the resting paradigm for single-patient diagnostics.

Title: Default mode network anticorrelations are associated with better clinical outcome in patients with disorders of consciousness

Authors: *S. GABRIELI;
MIT, Cambridge, MA

Abstract: Introduction: Resting state functional connectivity (rs-fcMRI) reveals intrinsic, spontaneous networks that elucidate the functional organization of the human brain. These resting state networks offer insight into residual brain function in patients with disorders of consciousness (DOC), such as minimally conscious state (MCS) and vegetative state/unresponsive wakefulness syndrome (VS/UWS). During rest, the BOLD signal fluctuations in regions of the default mode network (DMN) strongly correlate with each other, whereas they are anticorrelated (negatively correlated) to regions such as the dorsolateral prefrontal cortex (DLPFC) in the “task positive network”(TPN). The DMN is thought to be engaged in “internal awareness” whereas the TPN is engaged in “external awareness” and the magnitude of the DMN/TPN anticorrelations may reflect an ability to toggle between internal and external modes of processing. Here we examined the DMN rs-fcMRI in 71 participants: 27 Control, 22 MCS and 22 VS/UWS participants. We hypothesized that the DMN positive correlations would remain in

patients with DOC while the anticorrelations would be selectively extinguished. Methods: 10-minute resting-state fMRI scans were collected and analyses were performed using a seed-driven approach in Conn, (http://www.nitrc.org/projects/conn). Group statistics were performed on the Fisher transformed correlation maps. Clinical outcome of the patients was measured with Glasgow Outcome Scale-Extended (GOSE). DMN rs-fcMRI was correlated with GOSE. Results: Controls had robust DMN correlations/anticorrelations. Both patient groups had significant positive DMN correlations however DMN anticorrelations were statistically eliminated. However, variation of DMN-DLPFC rs-fcMRI predicted clinical outcome such that more negative correlations were associated with better outcome. Although on average, the DMN-DLPFC antircorrelations were not significantly different from zero for both patient groups, the individual differences significantly related to clinical outcome both within and across groups. Conclusions: Patient heterogeneity of intrinsic functional networks may provide useful neuromarkers for clinical outcome.

Title: Neocortical dynamics of ongoing EEG reflects mesocircuit integrity in acute anoxic brain injury after cardiac arrest

Authors: *P. B. FORGACS[1,2], H.-P. FREY[3], E. MEYERS[3], A. G. VELAZQUEZ[3], S. THOMPSON[3], S. PARK[3], S. AGARWAL[3], M. C. FALO[3], M. SCHMIDT[3], N. D. SCHIFF[1,2], J. CLAASSEN[3];
[1]BMRI - Dept. of Neurol., Weill Cornell Med. Col., New York, NY; [2]The Rockefeller Univ., New York, NY; [3]Dept. of Neurology, Div. of Critical Care, Columbia Univ. Med. Ctr., New York, NY

Abstract: Functional changes of the anterior forebrain mesocircuit (AFM) (Schiff, 2010) measured in EEG and PET have been correlated with spontaneous recovery of consciousness (Forgacs et al. 2014, Fridman et al. 2014) and with observed effects of therapeutic interventions in patients with chronic brain injuries (Schiff et al. 2007, Williams et al. 2013). The AFM model

predicts graded transitions in neocortical dynamics as measured by the EEG based on the degree of functional or structural deafferentation of the corticothalamic system (Drover et al. 2011, Schiff, Nauvel and Victor, 2014). The goal of this study was to assess EEG markers of AFM integrity and correlate them with short-term recovery of consciousness in patients in the Intensive Care Unit (ICU) as determined by daily standardized behavioral exam (Coma Recovery Scale - Revised [CRS-R]) and clinical outcome at hospital discharge (Cerebral Performance Categories Scale [CPC]). EEGs of 54 patients in ICUs after cardiac arrest were analyzed using multi-taper method. Frequency spectra were categorized using a coarse-grained 4 point scale based on the AFM model (Schiff et al. 2014). All EEG analyses were performed blinded to all clinical variables. 36 (66.6%) patients could be classified into our pre-defined categories on at least one day of EEG analysis and had a known CPC. The non-classified patients included: 3 with unknown CPC, 4 with status epilepticus, 8 with other spectral features, 3 with technical problems limiting analysis. We did not find significant differences in age, time to return of spontaneous circulation, CRS-R and CPC between the two sub-cohorts. In the 36 classified patients, the level of AFM integrity correlated with behavioral exam (CRS-R). Importantly, Fisher's exact test revealed significant correlation ($p=0.0011$) between AFM markers and clinical outcome. These results demonstrate that neocortical dynamic features are linked to the degree of corticothalamic deafferentation as predicted by the AFM model and may provide new insights into cellular and network level mechanisms involved in short-term recovery of consciousness in the acute stages of severe anoxic brain injury. These results suggest the possible use of these measures to track recovery and the effects of neuroprotective or other specific restorative therapeutic interventions employed in very early stages of brain injury.

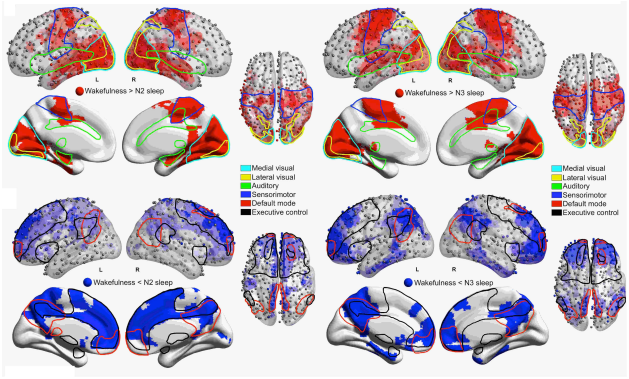
Title: Dynamics, connectivity and anatomical-functional coupling during loss of consciousness in deep sleep

Authors: *E. TAGLIAZUCCHI[1], N. CROSSLEY[3], E. BULLMORE[4], H. LAUFS[2]; [2]Neurol. Department,, [1]Univ. of Kiel, Kiel, Germany; [3]Inst. for Biol. and Med. Engin., Pontificia Univ. Catolica de Chile, Santiago de Chile, Chile; [4]Dept. of Psychiatry, Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Daily, we experience deep sleep as a state of reversible loss of consciousness. Why is brain activity during sleep not associated with conscious awareness, and which mechanisms allow the re-emergence of wakefulness? In response, we derive three fundamental principles of deep sleep from electrophysiology-combined functional neuroimaging data: 1) In contrast to wakefulness, activity in frontoparietal regions exhibits random, uncorrelated dynamics; 2) Large-scale functional connectivity changes in this set of regions - compared to wakefulness - represent a localised departure from the underlying constraints imposed by anatomical connectivity; 3) A simple model unfolding over the network of anatomical connections can accommodate both observations above, provided that a change in the threshold for activity propagation occurs. Our results highlight network-specific, diminished complexity of spatiotemporal dynamics as a correlate of loss of consciousness. They also suggest that deep sleep actively disrupts default patterns of functional connectivity in associative cortices, which are essential for the conscious access of information, and that anatomical connectivity acts as an anchor for the restoration of frontoparietal functionality upon awakening. This last observation may be the key for the understanding of conditions characterized by an irreversible loss of consciousness like coma or the vegetative state.



System-specific changes of anatomical-functional coupling during deep sleep.
Red: Regions where increased coupling was observed.
Blue: regions where decreased coupling was observed.

Title: Multimodal TMS/EEG, FDG-PET and active fMRI assessments in patients with disorders of consciousness and locked-in syndrome

Authors: *O. BODART[1,2], S. WANNEZ[1,2], A. THIBAUT[1,2], J. ANNEN[1,2], A. G. CASALI[3], S. CASAROTTO[4], O. GOSSERIES[2,5], M. ROSANOVA[4], M. MASSIMINI[4], S. LAUREYS[1,2]; [1]Neurol., CHU Sart Tilman, Liege, Belgium; [2]Cyclotron Res. Ctr., University of Liege, Belgium; [3]Fac. of Med. Clinics Hosp., Univ. of Sao Paulo, Sao Paulo, Brazil; [4]Dept. of Biomed. and Clin. Sci. 'Luigi Sacco', Univ. of Milano, Milano, Italy; [5]Dept. of Psychiatry, Univ. of Wisconsin, Madison, WI

Abstract: Introduction: Both transcranial magnetic stimulation coupled to electroencephalography (TMS/EEG), positron emission tomography (PET) of cerebral metabolism, and active fMRI paradigms may identify signs of residual cognition in severely brain damaged patients. However the clinical feasibility and diagnostic accuracy of the combination of all three techniques in patients with disorders of consciousness (DOC) have never been assessed. Methods: 52 patients with severe brain damage leading to a period of coma were studied by standardised behavioural assessments (coma recovery scale revised - CRS-R), TMS/EEG (perturbational complexity index - PCI - calculated as in Casali et al 2013), FDG-PET (regional changes in metabolism assessed as in Stender et al 2014) and active functional MRI - fMRI - performed as in Monti et al 2010. 15 unresponsive wakefulness syndrome/vegetative state, 26 minimally conscious state - MCS, 7 exit-MCS and 4 locked-in syndrome - LIS - participated. Results: Eight patients were behaviourally unambiguously unresponsive but had indirect signs of consciousness detected by TMS/EEG (5), PET (7), both TMS/EEG and PET (4) or active fMRI (1). All studied patients who emerged from MCS and all patients with LIS showed high TMS/EEG PCI values and relatively preserved cerebral metabolism. Clinical feasibility is shown in figure 1. The sensitivity to MCS of TMS/EEG was 91.7%, of FDG-PET 100%, and of active fMRI 33.3%, while the congruence with the CRS-R was 74%, 79%, and 40%, respectively. Conclusion: TMS/EEG permits the detection of covert consciousness in patients with chronic DOC with a similar accuracy but slightly lower feasibility than FDG-PET. Both TMS/EEG and FDG-PET seem more feasible and accurate as compared to active fMRI examinations in this challenging patient population.

Title: Differentiating consciousness from unconsciousness in non-rapid eye movement sleep using transcranial magnetic stimulation and high-density EEG

Authors: *O. GOSSERIES[1], J. O. NIEMINEN[2,1], M. MASSIMINI[3], M. BOLY[1], F. SICLARI[4,1], B. R. POSTLE[1], G. TONONI[1];

Abstract: Introduction: Combined transcranial magnetic stimulation and electroencephalography (TMS-EEG) allows for directly and non-invasively perturbing the brain and measuring the subsequent cortical response. Previous TMS-EEG studies have shown clear-cut differences between conscious and unconscious states. However, these studies did not investigate if TMS-EEG was sensitive to variations in the level of consciousness within the same physiological state, for example, non-rapid eye movement (NREM) sleep. Previously, it has been shown that subjects awakened from NREM sleep throughout the night report having conscious dream-like experiences in about 50% of the time. We here hypothesize that TMS-EEG responses differ depending on the presence or absence of a conscious experience in NREM sleep. Methods: Five healthy participants underwent TMS-EEG during NREM sleep (5 nights per subject). Brain activity was measured using a 60-channel TMS-compatible EEG amplifier and single-pulse TMS was applied to the superior parietal cortex. After each TMS session, subjects were awakened to ask for a dream report. Preprocessing analyses included bad-trials rejection and filtering the data (1.5 to 45 Hz). TMS-evoked potential were then averaged over the last 15 seconds before the awakenings and the phase locking factor was computed to compare between conscious and non-conscious conditions. Results: Our results reveal increased bistability when subjects do not report any conscious experience during sleep, as compared to when they do. Specifically, at

around 150-200 ms after TMS, the negative peak amplitude of the TMS-evoked response is larger, which probably reflects a downstate. Phase locking factor is of longer duration when subjects report conscious experiences as compared to when they do not. Conclusion: Our findings suggest that variations in the level of consciousness within the same physiological state - NREM sleep - are predicted by changes in the bistability of cortical networks revealed by TMS-EEG responses. This study shows that TMS-EEG is able to differentiate between conscious and unconscious states within the same physiological state.

Title: Characterization of synaptic dopaminergic deficits in post-traumatic brain injury (TBI) minimally conscious states

Authors: *E. A. FRIDMAN[1], J. R. OSBORNE[3], D. P. MOZLEY[2], N. D. SCHIFF[1]; [1]Brain and Mind Res. Inst., [2]Radiology, Weill Cornell Med. Col., New York, NY; [3]Radiology, Mem. Sloan Kettering Cancer Ctr., New York, NY

Abstract: Pharmacological stimulation can markedly improve some minimally conscious states (MCS) following severe TBI, restoring goal-directed behaviors. Previously we have shown that down-regulation of anterior forebrain function grades with level of consciousness (Fridman et al. 2014, PNAS). These findings may reflect both loss of long-range glutamatergic neurons and dopaminergic projection neurons in MCS. No prior studies have provided direct measurements of presynaptic and postsynaptic dopamine deficits of the mesolimbic and mesothalamic pathways in MCS. Here, we assessed the availability of dopamine D2-like receptors (D2LR) at rest and following dopamine reuptake blockade with dextroamphetamine (to test presynaptic level) in 10 normal volunteers (NV) and 4 MCS subjects, utilizing [11C]raclopride-PET. We manually defined substructures of the anterior forebrain mesocircuit in high-resolution MRI: the striatum was divided into 3 functional subparts: ventral striatum (VST), associative striatum (AST) and sensorimotor striatum (SMST); globus pallidus (GP) was a single structure; and, the central thalamus (c-TH). We analyzed the signal using the kinetic SRTM2 with cerebellum as reference tissue to extract binding potential nondisplaceable (BPnd) from ROIs. The mean BPnd at rest and mean delta % change (Δ BPnd) between pre- and post-AMPH were calculated and

analyzed using ANOVA (BPnd and Δ BPnd as dependent variables and group as independent variables in each ROI). Results at baseline showed that BPnd obtained from MCS and NV did not significantly differ in VST, AST, SMST and GP while significant differences were observed in c-TH and GP [c-TH: NV= .58 ± 0.1, MCS= 0.38 ± 0.1; F= 15.5, p = <0.001; GP: NV= 1.41 ± 0.1, MCS= 1.93 ± 0.3; F= 6.2, p = <0.02]. Following administration of dextroamphetamine the pattern of response of the presynaptic dopaminergic neurons showed a clear stimulus-response deficit in MCS patients compared to NV: mean Δ BPnd of MCS were significantly reduced in VST, SMST and c-TH [VST: NV= -22.8 ± 3.1, MCS= -7.6 ± 7.0; F= 5.2, p = <0.05; SMST: NV= -23.3 ± 2.5, MCS= -11.3 ± 1.1; F= 9.4, p= <0.01; c-TH: NV= -13.6 ± 2.6, MCS= 2 ± 6.7; F= 7.3, p = <0.05]. We suggest: 1) that the relative "normal-high" BPnd of MCS at baseline represents a partial presynaptic dopamine depletion; 2) that lower BPnd in c-TH of MCS patients reflects direct postsynaptic damage; 3) that the stimulus-response deficit observed in VST, SMST and c-TH reflects a presynaptic neuronal deficit in the synthesis and release of dopamine. This deficit may reflect partial loss of background presynaptic dopamine neuron activity in post-traumatic MCS that contributes to anterior forebrain down-regulation.

Abstract: Objective Each year in the United States, over two million traumatic brain injuries are diagnosed. This number is likely much greater if it were to include undiagnosed TBIs, as well as more mild forms of TBI. What is needed is an objective way to assess brain injury through the use of a test that is rapid and is based in an easily obtainable biological specimen. To work towards that goal, we studied college-aged football players using a combination of in-helmet monitoring and biospecimen based RNA biomarker profiling. Methods Urine samples were collected from Arizona State University Football players weekly within 24 hours following the completion of a game. Control urine samples were collected from a group of non-contact athletes of similar age as well as from every enrolled player prior to their first full contact practice. Head impacts were measured using the Riddell SRS at every contact practice and game. This system quantitatively measures every impact in real time. Extracellular RNA was isolated from urine with the NORGEN Total RNA Purification Maxi Kit. 2ng of total RNA was reverse transcribed with the Clontech SMARTer Universal Low Input RNA kit, and sequencing libraries were prepared with the Clontech Low Input Library Prep kit. This kit analyzes the whole RNA transcriptome. Libraries were sequenced on the Illumina HiSeq2500 with paired-end 83bp runs. Gene counts were computed and normalized with DESeq2. Classification of samples into case and control groups was performed using a Random Forest approach. Linear regression was used to identify genes that correlate with hit frequency and magnitude. Results From an average urine specimen, we generated 39 million reads and identified 41 thousand transcripts. Using linear regression, 29 genes were identified that significantly correlated with total number of hits sustained. 27 genes were identified that significantly correlated the magnitude of hits sustained. Using a Random Forest algorithm we classified cases and controls for highest magnitude hits and highest frequency hits. 25 genes with the highest information gain were selected for classification. Using these genes we correctly classified 100% of the highest frequency hit samples from baseline samples, and 81% of the highest magnitude hits from baseline samples. Conclusions This is an early attempt to assess brain injury by quantitative transcriptome analysis. Accurate, unbiased diagnosis of TBI is critical to the safety of athletes and others experiencing brain injury. These data suggest that extracellular RNA expression changes following head impacts can be detected in peripheral biofluids and may serve as biomarkers of TBI.

Title: Very low birth weight and preterm birth: Impacts on subcortical volumes and white matter tracts by middle childhood

Authors: *K. SRIPADA, A. E. SØLSNES, H. F. ØSTGÅRD, S. AANES, G. C. LØHAUGEN, K. J. BJULAND, L. EIKENES, A. HÅBERG, L. M. RIMOL, J. SKRANES;
Norwegian Univ. of Sci. and Technol., Trondheim, Norway

Abstract: Preterm birth is a worldwide problem, affecting 15 million newborns each year and burdening many survivors with lifelong physical, cognitive, and psychological challenges. Individuals born preterm with very low birth weight (VLBW: birth weight ≤1500 grams) are at an increased risk of perinatal brain injury and neurodevelopmental and cognitive problems. Cerebral white matter injury and neuronal and axonal abnormalities are considered the dominant neuropathologies in preterm-born infants and are believed to underlie many of these cognitive deficits. We investigated group differences in subcortical brain structure volumes and white matter tract properties between VLBW children and controls, as well as possible relationships between brain structure and IQ scores, birth weight, and gestational age. METHODS: 103 term-born children participating in the Norwegian Mother and Child Cohort Study and 37 VLBW children born between 2001 and 2007 underwent 1.5 T MRI and age-appropriate cognitive testing with Wechsler tests (mean age=8 years). We used FreeSurfer software version 5.3.0 to extract volumes of subcortical structures and diffusion tensor imaging (DTI) for assessment of white matter. We used the general linear model for between-group analyses of subcortical volumes and partial correlations for morphometric data and IQ scores, controlling morphometry analyses for age at scan, sex, and estimated total intracranial volume. RESULTS: Compared to controls, the VLBW group had reduced volumes of thalamus, right globus pallidus, right hippocampus, cortical white matter and brain stem, while the ventricular system was enlarged compared with controls. Uncorrected IQ scores were significantly lower ($p<0.001$) in the VLBW group (mean=98.6; SD 9.7) than in controls (mean=108.1; SD 13.6). Among all participants, IQ score correlated with volumes in cortical white matter, both thalami, right hippocampus, and right ventral DC; only in right hippocampus among controls; no correlations in VLBW group. A smaller number of subcortical volumes correlated ($p<0.05$) to birth weight and gestational age. DTI analysis showed group differences in mean diffusivity and axial diffusivity in major longitudinal association fibers; we did not find differences in fractional anisotropy.

DISCUSSION: Volumes of several subcortical structures and properties of white matter tracts in both hemispheres are associated with very low birth weight and preterm birth. These persistent structural differences may be due to perinatal brain injury or secondary postnatal events and likely influence cognitive, behavioral, and mental health as children enter adolescence and later life.

Title: Oculometric assessment of traumatic brain injury

Authors: *D. B. LISTON[1,2], L. R. WONG[1,2], L. S. STONE[1];
[1]NASA Ames Res. Ctr., Moffett Field, CA; [2]San Jose State Univ., San Jose, CA

Abstract: Diffuse tissue damage from impact or blast TBI degrades information processing throughout the brain. As precise oculomotor behavior depends on an extensive network of cortical and subcortical visuomotor brain areas, eye movements have long been known to be useful in the clinical assessment of brain pathology (e.g., Diefendorf & Dodge, 1908). To this end, we developed a 15-minute test that yields ten metrics of the oculomotor tracking response to visual motion, quantifying movement initiation, steady-state tracking, direction tuning, and speed tuning, and have collected a baseline database of “normal” human responses from 41 subjects (Liston & Stone, 2014). Methods. Subjects (N=30) with a clinically-diagnosed impact TBI in their past provided a numerical self-assessment of the current state of their impairment on a scale from 1 to 10 (with 1 defined as "back to the way I was prior to my injury" and 10 defined as "completely disabled"). They then ran our oculometric assessment test consisting of 180 trials of Rashbass (1961) step-ramp motion. The speed, direction, onset-timing, and initial location of target motion were randomized to promote uniform distribution of attention across space, time, and direction and to discourage predictive movements. We then processed their eye-movement responses to compute the ten test metrics. Finally, we measured the average pattern of oculomotor impairments associated in our TBI population (i.e., the TBI vector) and used this to quantify the severity of each individual’s impairment as a single scalar value (i.e., the “impairment index” or projection onto the TBI vector). Results. Our TBI subjects’ self-reported

severity values ranged from 1 to 7 (median: 3). Comparing them to our published control population, we observed significant impairments in: latency, acceleration, gain, catch-up saccade amplitude, proportion of smooth movement, and speed responsiveness (all p0.05). The ability of our test to discriminate TBI from control subjects increased as a function of self-reported severity (Pearson's R, $p<0.05$), ranging from an ROC area of ~0.6 for subjects subjectively reporting no residual impairment to an ROC area >0.90 for subjects reporting residual impairment of 5-7. Conclusion. Our 15-minute clinical test delivers ten metrics that quantitatively characterize several aspects of dynamic visual function and can detect mild impairments of neural function associated with TBI. Our method also quantifies the severity of an individual's impairment. We conclude that oculomotor tests could be used to screen for signs of TBI, quantify the extent of functional impairment, and monitor the time course of recovery.

Title: Lack of volumetric differences in brain regions of former athletes with multiple concussions

Authors: D. TERRY[1], M. FERRARA[3], *L. S. MILLER[2];
[1]Psychology, [2]Univ. of Georgia, Athens, GA; [3]Univ. of New Hampshire, Durham, NH

Abstract: Recent reports suggest that people with a history of head trauma, even of the form of a concussion, may experience brain atrophy in regions sensitive to head injury, as well as memory deficits, later in life. Other studies have failed to find these alterations. We aimed to investigate whether these volumetric differences are evident many years after multiple concussions occurred

and how these volumes are related to cognition. Two groups of community-dwelling males currently ages 40-65 who played high school football, but not college or professional sports, were recruited. The experimental group included 21 participants reporting a history of two or more concussions in the context of high school football participation on an empirically validated semi-structured interview (median=3; range=2-15). The control group included 20 similar participants who denied any concussive events. Participants underwent memory testing (California Verbal Learning Test-II, the Logical Memory subtest of the WMS-IV), completed a self-report index of current concussive symptomatology, and underwent structural MRI brain scanning. High-resolution T1-weighted images were analyzed using the Freesurfer software package, which produced automated volumetric results. A priori regions of interest (ROIs) were based on previous studies and included total intracranial volume (ICV), total gray matter, total white matter, bilateral anterior cingulate cortex, and bilateral hippocampi. ROIs were corrected for head size using a normalization method that takes ICV into account. The two groups were well matched on age, education, estimated premorbid IQ, and current concussive symptomatology. In the concussed group, 29.0% of the concussions were associated with loss of consciousness and 29.0% were associated with professional medical attention. Repeated measures ANOVAs failed to reveal volumetric group differences across the ROIs, main effects of hemisphere, or interactions despite a sample size larger than in previous studies with positive findings. Further, there were no differences on any memory indices across groups. Bivariate correlations between normalized hippocampal volume, memory indices, and number of concussions were non-significant in this sample. These data suggest that multiple sports-related concussions in the context of high school football may not be associated with measurable brain atrophy or worse memory later in life. This finding may suggest that the severity of injury and chronicity of sport exposure may be especially important when measuring long-term neuroanatomical and neuropsychological differences.

Title: Disruption to the dopaminergic system following traumatic brain injury

Authors: *P. O. JENKINS[1], S. DE SIMONI[1], J. J. FLEMINGER[1], A. E. JOLLY[1], J. H. COLE[1], D. TOWEY[2], D. J. SHARP[1];
[1]Computational, Cognitive and Clin. Neuroimaging Lab., Imperial Col., London, United Kingdom; [2]Radiological Sci. Unit, Imperial Col. Healthcare NHS Trust, London, United Kingdom

Abstract: *Background.* Cognitive impairments are a common cause of disability following traumatic brain injury (TBI). One potential cause is disruption of the neuromodulatory systems (e.g. dopamine), which are known to modulate cognitive functioning. Previous studies have identified dopaminergic dysfunction following TBI. It is unclear whether this dysfunction is related to damage to the dopaminergic nuclei in the substantia nigra or their ascending projections in the nigrostriatal tract. *Objectives.* To investigate: 1) whether TBI reduces striatal dopamine transporter (DAT) levels; 2) whether TBI causes structural changes to the nigrostriatal ascending pathways and/or atrophy of the substantia nigra or striatum; 3) whether there is a relationship between atrophy of the substantia nigra, structural changes to the nigrostriatal tract and DAT levels in the striatum. *Methods.* 19 subjects who had suffered a TBI at least 6 months previously and had persistent cognitive problems were compared with 10 healthy controls. All subjects underwent an ioflupane (^{123}I) single-photon emission computed tomography (SPECT) scan and magnetic resonance imaging (MRI) including diffusion tensor imaging. DAT levels were measured from the SPECT scan in the striatum, and voxel-based morphometry methods were used to calculate substantia nigra and striatal volumes. A nigrostriatal tract mask created from 100 participants from the Human Connectome Project was used to calculate mean fractional anisotropy measures. *Results.* Patients showed reduced striatal DAT levels and also demonstrated reduced fractional anisotropy in the nigrostriatal tract and reduced substantia nigra and striatal volumes. There was no significant correlation between DAT levels and either fractional anisotropy in the nigrostriatal tract or substantia nigra volumes. *Conclusions.* A proportion of patients who have suffered a TBI and have persisting cognitive problems have reduced DAT levels implying a disruption to their dopaminergic systems. We found no evidence for a clear relationship between damage to the ascending nigrostriatal tracts or substantia nigra and DAT levels. As the dopaminergic system is known to modulate certain cognitive functions, those patients with evidence of damage to their dopaminergic system may benefit from dopaminergic therapies.

Title: White matter disruption in the cingulum relates to apathy following traumatic brain injury

Authors: *N. GORGORAPTIS, A. JOLLY, P. O. JENKINS, C. FEENEY, G. SCOTT, J. H. COLE, S. DE SIMONI, D. J. SHARP;
Imperial Col. London, London, United Kingdom

Abstract: Apathy refers to a set of behaviours including reduced motivation, disinterest and lack of initiative. It is common following traumatic brain injury (TBI) and it has a detrimental impact on functional recovery, autonomy and response to rehabilitation. Diffuse axonal injury, leading to disruption of white matter pathways, is a common effect of TBI. Such white matter damage can be quantified using diffusion tensor imaging (DTI), and it relates to disruption of functional connectivity and to cognitive impairment following TBI. However white matter disruption in TBI has not been examined in relation to apathy. We used tract-based spatial statistics (TBSS) to examine microstructural white matter changes relating to apathy following TBI. Apathy was quantified using the Lille Apathy Rating Scale (LARS) and the apathy subscore of the Frontal Systems Behaviour Scale (FrSBe-A). 41 TBI patients [5 female, median age: 44 years (range: 20-65)] and 14 healthy participants [3 female, median age: 44 years (range: 21-61)] were studied. Apathy scores were significantly higher in patients than in controls. Higher apathy scores, as quantified by the caregiver-based version of the LARS, relate to lower fractional anisotropy (FA) values in the cingulate bundle in TBI patients, based on our TBSS analysis. No relationship was found between self-reported measures of (self-reported version of LARS and FrSBe-A) and changes in white matter microstructure. Using a voxelwise approach, we demonstrated that changes to the white matter structure of the cingulum relate to caregiver-reported apathy following TBI. This result is in keeping with DTI studies in other neurological conditions, such as Alzheimer's disease, as well as focal lesion mapping results from penetrating TBI, linking apathy with cingulum bundle disruption. Assessment of cingulum bundle integrity may have a role as a surrogate marker of apathy with potential use for patient stratification in future interventional studies.

Title: Subcortical atrophy and EEG in disorders of consciousness

Authors: *E. S. LUTKENHOFF[1], C. SCHNAKERS[2], P. VESPA[2], M. MONTI[3];
[1]Psychology-Clinical, [2]Neurosurg., [3]Psychology, UCLA, Los Angeles, CA

Abstract: In this work, we employ conventional T1-weighted magnetic resonance imaging (MRI) and electroencephalography (EEG) in a sample of patients with disorders of consciousness (DOC) in an effort to bridge the gap between clinical assessments of consciousness and underlying brain damage. The sample included 19 patients who survived severe brain injury and developed a disorder of consciousness without developing epilepsy or showing signs of seizure activity. To assess local brain atrophy on the basis of T1-weighted MR images, we employed a technique referred to as "shape (or vertex) analysis," available in FMRIB Software Library (FSL). The analysis included 3 preprocessing steps: (1) data were brain-extracted, using optiBET, (2) subcortical structures of interest were segmented, on an individual basis, and reconstructed into 3-dimensional vertex meshes and each segmentation was visually inspected, (3) to account for the effect of head size variability across individuals, we calculated each subject’s total normalized brain volume using SIENAX and included this measure as a covariate in all analyses. Segmentation and mesh construction were performed on all of the following brain regions, separately for each hemisphere: thalamus, caudate nucleus, putamen, globus pallidus, hippocampus, and brainstem. The EEG data was separated into spectra according to frequency bandwidths: delta (< 4 Hz), theta (4-8 Hz), and alpha (8-15 Hz). Then the mean and variance of the spectra over 24 hours were used in the analyses. Since the frequency bandwidths and demographics were collinear, a PCA factor analysis was used to separate the factors of interest across demographics, spectra averages, and spectra variances. The demographic information (post-injury day, days between MRI and EEG sessions, age, gender, and sedation level) was separated into 3 factors. The average spectra factors were comprised of alpha as one component and delta+theta as the second component. The spectra variance factors were also comprised of two components: delta variance and theta variance while alpha variance washed out. All the factors were included in a randomise (FSL) model, a nonparametric permutation test, to measure the correlation of the factors with subcortical atrophy. Initial findings indicate strong correlations between the average alpha factor and the theta variance factor and atrophy in various subcortical structures previously implicated in impairments of consciousness after severe brain injury.

Title: The role of the thalamus during propofol-induced loss of consciousness: New evidence from resting-state fMRI using dynamic causal modeling

Authors: *J. S. CRONE[1], E. LUTKENHOFF[2], B. BIO[2], S. LAUREYS[3], M. MONTI[2]; [1]UCLA, Los Angeles, ; [2]UCLA, Los Angeles, CA; [3]Univ. of Liege, Liege, Belgium

Abstract: Understanding the neural mechanisms of consciousness has been a focus of neuroscience in the last decades. Despite the fact that the mystery is far from being solved, the neural complexity of conscious experience has been related to network connectivity of distinct brain regions comprising areas within the medial frontal and posterior cortex as well as basal ganglia and thalamus. Especially thalamo-cortical connectivity has been considered to play a critical role in impaired consciousness. In this study, we have investigated the effects of propofol induced loss of consciousness on the effective network interaction between medial frontal cortex, posterior cingulate, globus pallidus, striatum and thalamus using spectral dynamic causal modeling (DCM) for resting state fMRI. 18 volunteers underwent 4 fMRI scans with different levels of consciousness (wakefulness; mild sedation; loss of consciousness; recovery). DCM was performed with the following steps: (1) extraction of fMRI time series from each subject using individual anatomically defined masks and individual coordinates obtained from independent component analysis; (2) specification and estimation of the model space with 7 plausible models; (3) implementation of Bayesian model selection routine (BMS) to identify the best model for each condition; (4) implementation of BMS between conditions to find significant differences. The results show significant differences in the “best” model between sedation and loss of consciousness (Fig. 1A). Remarkably, the efferent and afferent connectivity of the thalamus is not effected by loss of consciousness as has been proposed. Instead, the effective connectivity strength from the globus pallidus towards the ventral posterior cingulate is significantly reduced during loss of consciousness compared to sedation and recovery (Fig. 1B). This study demonstrates that - rather than connectivity of the thalamus - the driving influence of the globus pallidus on the ventral posterior cingulate cortex plays a crucial role in propofol induced loss of consciousness.

Title: Signatures of awareness in the resting-state brain activity dynamics. An EEG/fMRI study of similarities and differences between wakefulness, anesthesia and disorders of consciousness

Authors: ***J. D. SITT**[1,2], G. DECO[3], P. BARTTFELD[1], A. TAUSTE[3], F. RAIMONDO[4], L. NACCACHE[2], S. DEHAENE[1];
[1]Inserm-Cea Cognitive Neuroimaging Unit, Gif/Yvette Cedex, France; [2]Inst. du cerveau et de la moelle épinière, Paris, France; [3]Univ. Pompeu Fabra, Barcelona, Spain; [4]Facultad de ciencias exactas y naturales. Dept. de computacion, Univ. of Buenos Aires, Buenos Aires, Argentina

Abstract: At rest, the brain is traversed by spontaneous functional connectivity patterns. Two hypotheses have been proposed for their origins: they may reflect a continuous stream of ongoing cognitive processes as well as random fluctuations shaped by a fixed anatomical connectivity matrix. In this presentation I will show that both sources contribute to the shaping of resting-state networks, yet the level of consciousness modulates the respective contributions. Using a quantification of the distinct dynamical patterns of functional connectivity, extracted from the resting state functional MRI and EEG, I will show that wakefulness is characterized by a sequential exploration of a rich repertoire of functional configurations. These dynamical states are often dissimilar to the underlying anatomical connectivity structure, and comprising positive and negative correlations among brain regions. Conversely, under anesthesia the more frequent functional connectivity patterns inherit the structure of anatomical connectivity, exhibit fewer small-world properties, and lack negative correlations. This is also the case for the disorders of consciousness (DOC) - a set of pathological conditions like the vegetative state (VS) or the minimally conscious state (MCS) – where patients dynamically fluctuate between low and high efficiency information integration states (Fig 1A) but the rate of occurrence of the high efficiency state parametrically increases with the clinical level of consciousness (Fig 1B). These results reconcile theories of consciousness with observations of long-range correlation in the unconscious brain and show that a rich functional dynamics might constitute a signature of consciousness, with potential clinical implications for the detection of awareness in anesthesia and brain-lesioned patients. Figure caption. (A) Connectivity states maps extracted from EEG resting state recordings of DOC patients and normal controls. (B) Modulation of the dynamical

states rate of occurrence by the clinical state of the subjects (VS, MCS, CS -confusional- and H – healthy-)

Title: Characterizing the effect of chemotherapy on the developing brain and associated cognitive functions

Authors: *E. VAN DER PLAS[1], S. ITO[2], R. SCHACHAR[3], B. J. NIEMAN[4];
[1]Dept. of Psychiatry, The Hosp. For Sick Children, Toronto, ON, Canada; [2]Physiol. & Exptl. Med., The Hosp. for Sick Chidren, To, ON, Canada; [3]Psychiatry Res., The Hosp. for Sick Chidren, Toronto, ON, Canada; [4]The Mouse Imaging Ctr., Toronto, ON, Canada

Abstract: Over 90% of children with acute lymphoblastic leukemia (ALL) will be cured of their illness. Unfortunately, the chemotherapy treatment necessary to eradicate leukemia is also associated with long-term side effects. Between 40 - 60% of ALL survivors experience impairments in executive functions, including attention and working memory. These impairments are thought to be related to chemotherapy-induced alternations in brain development; however, there is limited literature exploring the relationship between brain morphology and cognitive impairments in ALL survivors. We sought to determine whether chemotherapy exposure alters brain structure and associated cognitive functions. ALL survivors (n=21) and age- and sex-matched controls (n=18) between 8 - 18 years old underwent 3T structural MRI (data collection ongoing). T1-weighted anatomical scans were processed using the CIVET pipeline. We performed volumetric measurements of gray matter and white matter,

and performed measurements of cortical thickness, surface area and volume. Attention and working memory abilities were assessed with the Stop Signal Task (SST) and the N-Back Task. The SST measures the ability to cancel an ongoing response (response inhibition), which is a sensitive parameter of attention. The N-Back presents participants with a sequence of stimuli that need to be remembered, capturing working memory. Linear regression models with age and group as explanatory variables were performed to explore the impact of chemotherapy on brain morphology and cognitive function. Frontal white matter volume was significantly reduced in ALL survivors relative to controls (FDR-corrected p-value, $q < 0.1$). Cortical surface volume deficits in ALL survivors were evident in the temporal lobes and the occipital lobes ($p < 0.01$). Relative to controls, ALL survivors showed impairments in response inhibition ($t = -2.82$, $p < 0.01$) and working memory ($t= 3.43$, $p < 0.01$). Deficits in response inhibition were significantly correlated with reduced white matter volume in the frontal lobes and the temporal lobes (average $r = 0.34$, $p < 0.05$). Working memory performance correlated significantly with cortical surface volume in the inferior orbitofrontal cortices and superior regions of the temporal poles (average $r = 0.42$, $p < 0.05$). Chemotherapy is neurotoxic to the developing brain and resulting changes in brain morphology may explain some of the cognitive impairments commonly observed in ALL survivors. Identification of these links will help reveal the pathophysiology of chemotherapy-induced brain damage, which will ultimately lead to remedies and prevention.

Title: The return-to-play recovery time for female concussion sufferers at a military academy

Authors: *C. J. D'LAURO[1], B. R. JOHNSON[2], E. WILLSON[2], J. JACKSON[2], D. ALLRED[2], G. MCGINTY[2], D. CAMPBELL[2];
[1]US Air Force Acad., Monument, CO; [2]US Air Force Acad., USAF Academy, CO

Abstract: Concussions have become a topic of popular interest as well as an important public health issue over the past decade. While women's interest in sport and integration into the

military have both steadily increased, the amount of research dedicated to female concussion and recovery time still lags behind that of men. In particular, the heavy focus on contact sports and the military, both heavily male endeavors, continues to influence the proportion of research addressing concussions in female athletes. Some studies have shown greater susceptibility to concussion in women or more severe immediate post-impact symptoms, but data on the full time course of recovery is lacking. The United State Air Force Academy (USAFA) provides a unique data collection environment for studying concussions: healthcare is on-site and free, physical education and training is mandatory, cadets must be medically excused to miss a class, and they must be medically cleared to return to class or sports following a concussion. In total, these regulations produce a concussion-susceptible and highly-compliant population that is much more frequently assessed than typical athletes recovering from sports-related concussions. The USAFA return-to-play protocol is based on the Zurich 2012 Consensus Statement on Concussions and on US Department of Defense protocols. Before cadets can be fully returned to sport, they must be symptom-free, pass a medical exam, and exhibit a normal computerized neurocognitive assessment (i.e. ImPACT). The sports medicine personnel at the USAFA Concussion Clinic began detailed tracking of concussion causes and recovery times beginning in Fall 2012 and continuing to the present. During the time period analyzed, clinic staff recorded 245 concussions with complete recovery data. Women comprise 23% of the cadet population and produced 64 (26.1%) of these concussions. All concussions were regressed on full return-to-play time with sex entered as a between-subjects factor. Women took significantly more time (m=42.3 days ±31.3) to complete return-to-play than men (m=28.4 days±24.7), $F(1,243)=12.88$, $p<.001$. Other studies have shown sex-based differences in concussion symptoms, but this study is the first to comprehensively track and compare male and female concussions and demonstrate a lengthier RTP for women.

Title: Adult myelin stimulates neurite outgrowth from neural progenitor cells

Authors: *G. H. POPLAWSKI[1], R. LIE[1], P. LU[2], C. GEOFFROY[1], R. KAWAGUCHI[3], G. COPPOLA[3], B. ZHENG[1], M. TUSZYNSKI[1,2];
[1]Neurosci., Univ. California SD, La Jolla, CA; [2]VAMC, San Diego, CA; [3]Neurol., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Adult central nervous system white matter inhibits axon outgrowth from adult neurons. However, grafts of multipotent neural progenitor cells exhibit extensive axonal elongation through adult white matter, suggesting either that early stage neurons are not inhibited by adult white matter, or are actually stimulated by white matter. To address these possibilities, we cultured multipotent neural progenitor cells from E14 rat spinal cords on crude adult myelin extracts and compared findings to adult DRG cultures. Whereas adult DRG neurons exhibited the predicted 60% reduction in neurite outgrowth on myelin compared to laminin substrates ($p < 0.001$), neuronal progenitor cell (NPC) cultures exhibited a significant 86% increase in neurite length compared to cells cultured in the absence of myelin ($p < 0.001$). While adult neurite growth inhibition is mediated in part by interactions with Nogo receptors, we found no change in neurite outgrowth when neural progenitor cells were plated on Nogo-deficient myelin, suggesting that the inhibitory and stimulatory pathways of myelin may be mediated by distinct molecules. In contrast, another class of neurite outgrowth inhibiting molecules, chondroitin sulfate proteoglycans, significantly inhibited neurite outgrowth from NPCs ($p < 0.01$). Neurite outgrowth stimulation from NPCs on myelin declined in cells isolated from embryonic day 16, suggesting that growth pathways are differentially regulated as maturation proceeds. We are currently investigating differences in the transcriptome of neural progenitors cultured on myelin-containing vs. myelin-free substrates to identify specific molecular species enhancing neurite-outgrowth of NPCs on myelin. Collectively, these findings indicate that at least a portion of the ability of multipotent neural progenitor cell grafts to extend very long axons on adult myelin may result from facilitation of growth on this substrate. Insight into mechanisms underlying this effect may generate novel strategies for promoting adult axonal regeneration through myelin.

Title: Caudal projection patterns of neural stem cells grafted to sites of spinal cord injury

Authors: *W. GOMES-LEAL, SR[1,2], S. ANIL[1,3], Y. WANG[1], D. WU[1], M. TUSZYNSKI[1], P. LU[1];
[1]Univ. of California (UCSD), San Diego, CA; [2].Institute of Biol. Sciences. Federal Univ. of Para, Belem, Brazil; [3]Neuroprosthetics and Brain Mind Inst., Lausanne, Switzerland

Abstract: Previously we reported that neural stem cells (NSCs) transplanted to sites of spinal cord injury (SCI) differentiate into multiple neural cell types, including neurons, and extend large numbers of axons over very long distances (Lu Cell 2012; Neuron 2014). Here we sought to determine the origin of axons within grafts that emerge and extend caudally into the host spinal cord: do caudally projecting axons arise from all levels of the graft and give rise to monosynaptic relays across lesion sites, or do they primarily arise from cells located only in the caudal sections of grafts, and therefore more likely give rise to polysynaptic relays across lesion sites? Rat embryonic day14 spinal cord derived-multipotent neural progenitor cells (NPCs) expressing GFP were implanted into C5 lateral hemisection lesions. 3 weeks later, the retrograde tracer fluorogold (FG) was injected 3mm caudal to the lesion/graft site, and animals were perfused 3 days later. Histological examination indicated that the greater proportion (~55%) of retrogradely labeled NPC neurons were located within 600μm of the caudal graft/host interface; the remaining 45% of retrogradely labeled NPCs were located at all rostral-caudal levels of the grafts. In a second experiment, rat embryonic day 14 NPCs were grafted into C5 lateral hemisection lesion sites, but only 1% of all grafted cells were labeled for GFP prior to implantation. This allowed examination of projection patterns of individual grafted neurons to caudal aspects of the host spinal cord. 3-dimensional analysis of these results is underway. Preliminary analysis indicates that NPC-derived axons extending caudal to the lesion site are most likely to originate from neurons located in caudal aspects of the graft; however, some neurons present at more rostral levels of the graft also project caudal to the lesion site. Thus, relays across the lesion most likely represent a mix of monosynaptic and polysynaptic projections; additional studies are in progress.

Title: Expression of the CSPG receptor, LAR, after spinal cord transection in the lamprey

Authors: *W. RODEMER[1], G. ZHANG[1], J. HU[1], M. SELZER[1,2];
[1]Shriners Hosp. Pediatric Res. Ctr., [2]Neurol., Temple Univ. Sch. of Med., Philadelphia, PA

Abstract: Traumatic spinal cord injury (SCI) results in devastating long-term neurological and musculoskeletal impairments arising from the failure of axon regeneration within the central nervous system. The chondroitin sulfate proteoglycans (CSPGs) are potent, extracellular inhibitors of regeneration that appear to create a sustained chemical barrier to regrowth through multiple mechanisms, some of which are mediated by members of the receptor protein tyrosine phosphatase family, including PTPσ and LAR. The anatomical complexity and extremely high barrier to regeneration set by the mammalian spinal cord make analysis of potential therapeutic strategies difficult. For this reason, we have used the larval sea lamprey as an experimental model. The lamprey recovers functionally following complete spinal cord transection. Individually identified large reticulospinal (RS) neurons regenerate their axons with varying but predictable probabilities, despite the presence of extracellular inhibitory molecules, including the CSPGs, as well as their receptors, PTPσ and LAR. Lamprey neurons that are “bad regenerators” also undergo a very delayed form of cell death, which is preceded by caspase activation and TUNEL positivity, suggesting that they die of apoptosis. Previous reports by this lab have demonstrated that PTPσ mRNA is expressed selectively in “bad” regenerating neurons and precedes caspase-activation induced by SCI. The present study examines LAR expression in the larval lamprey via *in situ* hybridization using a custom, antisense riboprobe targeting the region of mRNA encoding the extracellular Fibronectin III domain of the LAR protein. Similarly to PTPσ, LAR transcripts are preferentially expressed in “bad” regenerating RS neurons in the uninjured animal. However, the inverse correlation between mRNA expression and regeneration is stronger with PTPσ than LAR. Following complete spinal cord transection, the number of LAR mRNA-positive RS neurons increases, peaking at 7 weeks post-transection and returning to baseline after 10 weeks. Results from this study will guide future experiments to more directly address the role of CSPG receptors in inhibiting regeneration and promoting retrograde cell-death after SCI.

Title: Role of CXCR4 in mediating axon sprouting after intrathecal infusion of CXCL12 in a mouse model of spinal cord injury

Authors: *F. TUNDO[1,2,3], V. ESTRADA[1], A. STAHR[3], A. HESKAMP[2], M. HENDRICKS[1], A. HALLENBERGER[3], A. ANDREADAKI[2], C. VON GALL[3], D. FISCHER[2], H. W. MÜLLER[1]; [1]Mol Neurobiol Lab, Neurology, Heinrich Heine Univ., Düsseldorf, Germany; [2]Div. of Exptl. Neurology, Neurology, Heinrich Heine Univ., Düsseldorf, Germany; [3]Inst. of Anat. II, Heinrich Heine Univ., Düsseldorf, Germany

Abstract: Background: Regeneration of injured axons is impaired in the central nervous system (CNS). The chemotactic cytokine stromal cell-derived factor-1 (SDF-1/CXCL12) is disinhibitory towards CNS myelin and plays a key role during development of the nervous system. Recent studies revealed that CXCL12 enhances sprouting of dorsal corticospinal tract (dCST) axons rostral to the lesion in a rat model of spinal cord injury (SCI) (Opatz et al., 2009). CXCL12 reportedly interacts with two G protein-coupled receptors, CXCR4 and CXCR7. However, which receptor(s) is involved in the sprouting effect is still unknown. Using a mouse model and murine primary DRG cultures, we are investigating the functional role of CXCR4 in mediating the axon growth promoting and disinhibitory effects of CXCL12 after its intrathecal infusion. As this method is rarely used in mice due to the very thin dura mater and the narrow epidural space, we had to establish an intrathecal application (epidural catheterization) method for the treatment of thoracic SCI in this species. Methods: CXCR4 floxed mice were cross-bred with ROSA reporter mice (CXCR4flox/flox/Rosa/-). Stereotaxic injection of adeno-associated virus serotype 2 expressing Cre recombinase into the layer V of the sensorimotor cortex leads to the generation of a conditional knockout of CXCR4 in the transduced pyramidal neurons projecting into the CST which, at the same time, expresses the reporter gene red fluorescent protein. After a dorsal spinal cord hemisection CXCL12 was intrathecally infused via an osmotic minipump. The CXCL12-induced rostral sprouting of dCST axons was investigated. To analyze the catheter fixation and the delivery via the osmotic minipump, and to rule out catheter-induced compression, minipumps were filled with Evans Blue. Trichrome staining was chosen to visualize connective tissue in spinal cord slices. Results: Strong Evans Blue staining at the lesion site confirmed the local distribution as well as stable epidural catheter fixation over seven days, whereas trichrome staining revealed no catheter-induced spinal cord compression. CXCR4 was expressed in

pyramidal neurons of the somatosensory motor cortex and in dCST axons. Upon Cre transduction CXCR4 immunoreactivity in pyramidal neurons as well as in dCST axons disappeared. Rostral sprouting of dCST axons was quantified after SCI. Conclusions: The ROSA reporter mouse was suitable to visualize the lack of CXCR4 expression after conditional gene knockout. We will discuss the sprouting of dCST axons in a mouse model of SCI after intrathecal CXCL12 infusion and the functional role of CXCR4 in promoting CXCL12 induced axon growth.

Title: Temperature sensitive injectable hydrogel bridges cystic cavities and supports functional recovery following contusive spinal cord injury

Authors: *H. A. LE;
Ajou Univ., Suwon, Korea, Republic of

Abstract: Cavity formation after spinal cord injury (SCI) is one of the major obstacles for axonal regeneration. Implanting artificial scaffolds into the cavity has been considered as a promising strategy, yet successful bridging with scaffolding biomaterials has not been convincingly demonstrated in clinically relevant contusive SCI model. Unpredictable and irregular geometry of cystic cavities formed in this model would necessitate the use of injectable hydrogel for this purpose. In the present study, we injected temperature sensitive poly(phosphazene) hydrogel, with a sol-gel transition behavior at 37°C, into the lesion epicenter in contusive rat SCI model at 1 week after injury. The hydrogel injection almost completely prevented cavity formation. In animals with the hydrogel injection, the lesion epicenter was replaced by fibronectin-enriched ECM by 4 weeks after the injection. Co-localization of FN and collagen-1α1 suggested that the majority of the newly formed ECM originates from perivascular fibroblasts. Intense activation of CD45+ macrophages indicated that the blood born macrophages were involved in the generation of new matrix. The fibronectin positive ECM was surrounded by GFAP positive glial scars with an interface laden with chondroitin sulfate proteoglycans (CSPG). Interestingly, zymography showed upregulation of MMP-9 activity in animals with the hydrogel

injection, and MMP-9 was highly expressed at the center of the fibronectin enriched ECM. The cellular source for the MMP-9 immunoreactivity was CD11b positive macrophages. Animals with hydrogel injection showed improvement in coordinated locomotion as evidenced by BBB test and Catwalk analysis. The improvement in locomotor function was accompanied by better preservation of myelinated white matter around the lesion epicenter. Our study establishes a proof of principle that the temperature-sensitive hydrogel can be used as a cavity-bridging therapy for contusive SCI. Considering the facility of hydrogel in a sol state incorporating various drugs and cells, this approach can also be utilized as a versatile platform for multifaceted combinatorial therapy.

Title: Protein synthetic machinery and mrna in regenerating tips of spinal cord axons in lamprey

Authors: *L.-Q. JIN[1], C. R. PENNISE[1], W. RODEMER[1], K. S. JAHN[2], M. E. SELZER[1]; [1]Shriners Hosp. Pediatric Res. Ctr., Temple Univ. Sch. of Med., Philadelphia, PA; [2]The Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Protein synthesis and mRNAs have been seen in growth cones of neurons *in vitro* and in regenerating peripheral nerve, but evidence for this is lacking in mammalian CNS. Based on work in the lamprey, we postulate that regeneration in the CNS does not involve conventional growth cones, so we asked whether regeneration in CNS axons involves local protein synthesis in the axon tips. Spinal cord axons were backlabeled by fluorescent tracers applied to a fresh transection. Two to three weeks later, the cords were re-exposed and the growth status (growing, static or retracting) of axons in the proximal stump determined over a 3hr interval. Then the axon tips were studied by one of two methods: 1) *In situ* hybridization for total mRNA (oligo(dT)) or individual transcripts, focusing on cytoskeletal proteins; or 2) microaspiration of axon tip cytosol followed by PCR amplification of mRNAs. Of 39 axon tips in 41 animals 14 tips were growing forward, 15 were static, and 10 were retracting. mRNAs were detected in axon tips but not in uninjured control axons. mRNAs were more abundant in regenerating than in static or retracting tips. Axoplasms were pooled from 6 growing and 6 static tips, and mRNAs were amplified by PCR. The cDNA products were used as templates for target-specific PCR. Lamprey NFL and β-tubulin mRNAs were abundant in growing tips, less so in static tips. β-actin and NF95 transcripts

were scarce in growing tips and not detected in static tips. NF180, NF132, and vimentin were not detected in the growing tips. EM showed polyribosomes, and in one tip, rough endoplasmic reticulum, in the distal-most regions of axon tips. Immunohistochemistry showed riboprotein S6 in a distribution similar to that of ribosomes. The results suggest that local proteins synthesis may participate in the mechanism of axon regeneration in the CNS.

Title: Blood-spinal cord barrier disruption after contusive spinal cord injury (SCI) rapidly recovers following intravenous infusion of bone marrow mesenchymal stem cells (MSCs) or MSC-derived exosomes

Authors: *K. L. LANKFORD[1], T. MATSUSHITA[1,2], E. J. ARROYO[1], P. W. ASKENASE[3], J. D. KOCSIS[1];
[1]Dept of Neurol., Ctr. For Neurosci. & Regen. Res., Yale Univ. Sch. of Med., West Haven, CT; [2]Dept. of Neural Regenerative Med., Sapporo Med. Univ., Sapporo, Japan; [3]Dept. of Immunol., Yale Univ., New Haven, CT

Abstract: Traumatic spinal cord injury (SCI) damages the blood spinal cord barrier (BSCB) and allows immune cells and toxic molecules to infiltrate into the cord, contributing to the neuronal loss, axon severing, and demyelination that can lead to paralysis. Intravenous infusion of mesenchymal stem cells (MSCs) can reduce the severity of experimental spinal cord injury (SCI), but the mechanisms are not fully understood. In this study, adult male Sprague Dawley rats were subjected to a moderate contusive spinal cord injury (SCI) at the T9 level, i.v. infused with $1x10^6$ rat MSCs or media one week post-SCI, and assessed for functional recovery, BSCB permeability, or distribution of transplanted MSCs. Alternatively, a small number of rats were infused with exosomes isolated from MSC-conditioned media. Locomotor function was assessed using the Basso-Beattie-Bresnahan (B-B-B) rating scale. Spatial and temporal changes in BSCB

integrity were assessed by i.v. infusions of Evans blue (EvB) with *ex vivo* optical imaging and spectrophotometric quantitation of EvB leakage into the parenchyma. Distribution of DiR-labeled GFP-expressing MSCs was assessed by *in vivo* and *ex vivo* imaging of organs and fluorescence microscopy of frozen sections. The results showed that contusive SCI resulted in diffuse and persistent BSCB leakage but that post-SCI BSCB leakage in was reduced in MSC transplanted rats. Furthermore, locomotor function in contused rats was improved beginning 1 week post-MSC infusion. However, i.v infused MSCs were not detected within the spinal cord at any time point, but instead appeared to traffic transiently to the lungs. Our preliminary data also showed that exosomes isolated from MSC conditioned media also reduced BSCB permeability and improved locomotor functioning 1 week post-infusion. Taken together, this data indicated that infusions of either MSCs or MSC-derived exosomes one week after contusive SCI were effective in reducing BSCB permeability and improved functional recovery and suggest that the therapeutic effects of MSCs on SCI may be mediated by MSC-derived exosomes.

Title: Neuroprotection and immunomodulation by mesenchymal stem cell and fibrin sealant treatment following intraspinal axotomy

Authors: *A. B. SPEJO[1], G. B. CHIAROTTO[1], R. S. FERREIRA JR[2], B. BARRAVIERA[2], A. L. R. OLIVEIRA[1];
[1]Univ. of Campinas, Campinas, Brazil; [2]UNESP, Botucatu, Brazil

Abstract: Despite great efforts, treatment of spinal cord lesion is vastly inefficient, resulting in poor outcome. In this sense, new repair procedures are needed. We have recently demonstrated that the use of fibrin sealant (FS) for reimplantation of avulsed ventral roots improves motor recovery. The use of mesenchymal stem cells (MSC), that secrete neurotrophic and angiogenic factors, enhances survival and decreases glial reaction. Thus, the present study investigated the inflammatory environment, neuronal survival and synaptic preservation following intraspinal axotomy (IA) and treatment with FS and/or MSC. In this way, female Lewis rats were subjected to intraspinal section of the ventral funiculus, that axotomizes motoneurons within the central nervous system. The lesion was either untreated or stabilized with FS. In addition, the

combination of MSC and/or FS was evaluated. RT-qPCR, one week after injury demonstrated in the groups that received FS, coupled or not with MSC, increased mRNA levels of TNFα (50%), IL-4 (450%), IL-10 (600%) and IL-13 (100%), indicating a predominantly anti-inflammatory microenvironment acutely after lesion. IL-6 expression was similar in all groups. In the acute phase post lesion, BDNF (brain derived neurotrophic factor) mRNA levels were unchanged, and VEGF mRNA (vascular endothelial growth factor) was downregulated (-100%) in all lesioned groups. Hematoxylin/Eosin staining demonstrated strong cell infiltrate, with predominance of putative M2 macrophages (Iba1/arginase-1 positive). Two weeks after injury, neuronal survival was calculated in Nissl stained sections, revealing enhanced motoneuron preservation after treatment with MSC and/or FS. Such rescued neurons, which were evidenced by GAP-43 immunolabeling, presented significant preservation of pre-synaptic inputs, positive to synaptophysin. Synaptic circuit preservation, in the MSC treated groups, was coupled with decreased astrogliosis, which has been previously shown to actively contribute to the detachment of synapses from the motoneuron surface. Overall, the present results indicate that the combination of MSC and FS therapy results in neuroprotection. Importantly, FS modulates local inflammatory response towards a predominantly anti-inflammatory profile, thus contributing to a more efficient recovery of homeostasis.

Title: Exercise induced changes in inflammation along the sensory neuroaxis after unilateral cervical spinal cord injury

Authors: D. QUIROS-MOLINA[1], S. CHHAYA[1], J. R. BETHEA[2], J. D. HOULE[1], *M. R. DETLOFF[1];
[1]Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Biol., Drexel Univ., Philadelphia, PA

Abstract: Microglia and macrophages are activated by immune and neuronal cytokines and may play a critical role in the onset and modulation of chronic neuropathic pain after spinal cord injury (SCI). Exercise is widely used in the clinical SCI population, and we have previously

shown that early administration of exercise prevents neuropathic pain development after experimental SCI. Here, we determined whether the exercise-induced reduction in pain correlates with a change in the post-injury inflammatory response throughout the spinal cord and brain as well as systemically. Sprague-Dawley rats received a moderate unilateral C5 spinal cord contusion and were separated into SCI and SCI+Exercise groups. Starting at 5 days post injury (dpi), SCI+Exercise group was exercised on automated running wheels for 20 minutes/day, 5 days/week for 4 weeks. Tactile allodynia was assessed weekly using von Frey monofilaments and mechanical conflict avoidance operant testing assessed cognition of nociceptive tactile stimuli. Blood was collected, and serum separated weekly. At 31 dpi, rats were sacrificed and cervical spinal cord and dorsal root ganglia, the ventroposterolateral nucleus of the thalamus and somatosensory cortex were dissected. Serum and tissue homogenates were probed for pro- and anti-inflammtory cytokines including CCL2, TNFa, IL-12, IL-4 and IL-10 and 22 others via multiplex ELISA (Eve Technologies). A subset of tissue will be processed for immunohistochemical markers of the microglial/macrophage response (Iba-1, ED-1, Arginase-1, CD206). By examining the inflammatory response in the brain, spinal cord, and DRG we will better understand possible mechanisms for the onset of neuropathic pain and for the efficacy of exercise. Detection of changes in systemic inflammatory response after SCI and/or exercise over time will identify potential biomarkers or predictors of pain development that could be directly translated to clinical SCI. These biomarkers would also inform on potential pharmacologic targets, as well as the effectiveness of the exercise possibly leading to refinement of the rehabilitation protocol.

Title: The acute inflammatory response after spinal cord injury and its role in the development of spinal cord injury-induced chronic neuropathic pain

Authors: *S. CHHAYA[1], D. QUIROS-MOLINA[1], J. R. BETHEA[2], J. D. HOULE[1], M. R. DETLOFF[1];

[1]Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Biol., Drexel Univ., Philadelphia, PA

Abstract: Neuropathic pain that develops in a majority of patients with spinal cord injury (SCI) is often refractory to treatment. Early after SCI, nociceptive processing by primary sensory neurons in the dorsal root ganglion (DRG) is altered and pain afferent fibres in the dorsal horn of the spinal cord exhibit robust aberrant collateral sprouting. Studies from our lab showed that exercise beginning early after SCI prevented the onset of neuropathic pain; however exercise initiated once pain is established had no effect, demonstrating that the early time window post-SCI is critical in the development of pain. Acutely after SCI, there is a robust intraspinal inflammatory response at and distal to the lesion. Cytokines and chemokines activate, recruit and polarize microglia and macrophages in the spinal cord and DRG into a pro-inflammatory (M1) phenotype. The upregulation of inflammatory mediators influences neuronal plasticity and may alter nociceptive processing of DRG neurons, contributing to the development of chronic pain. Thus, we assessed the acute inflammatory microenvironment in the dorsal horn of the cervical spinal cord and associated DRGs for levels of macrophage attractant CCL2, pro-inflammatory cytokines TNF-α, IL-1β, IL-6, IL-12 relative to levels of anti-inflammatory cytokines such as IL-4 and IL-10, and how they correlate with 1) the development of SCI-induced neuropathic pain and 2) effects of rehabilitative exercise. Female Sprague Dawley rats received a C5 hemilaminectomy or a moderate, unilateral C5 spinal cord contusion (n=6/group). A subset of rats were exercised 20 minutes/day 5 days/week using a forced exercise wheel walking system beginning at 5 dpi through to 17 dpi. Rats were assessed for the development of neuropathic pain using von Frey and Hargreaves' tests pre-operatively and weekly after SCI. Serum was collected at 1 hour, 24 hours, 3, 5, 7, 14 and 17 days to assess circulating markers and systemic inflammation. Subsets of rats were sacrificed at each of these time points and cervical spinal cord and DRGs were processed for ELISA. Preliminary data show elevated levels of chemokines such as CCL2 one day post-injury in the dorsal horn of the spinal cord, DRGs and serum that remain elevated above baseline beyond 14 days, which marks the onset of neuropathic pain. Identification of mediators involved in the maladaptive pro-inflammatory response and their pathway of activation may provide potential therapeutic targets to contain this aberrant immune response and resultant pain co-morbidity after SCI, as they may modulate nociceptors in the DRG as well as affect higher order pain-inhibitory pathways in the spinal cord resulting in chronic pain.

Title: Initial limb unloading after spinal cord injury alters glutamatergic synaptic plasticity associated with impaired functional recovery

Authors: *K. MORIOKA[1,2], T. TAZOE[2,3], J. HUIE[1], C. F. GUANDIQUE[1], M. XIAOKUI[1], J. HAEFELI[1], J. A. SACRAMENTO[1], J. T. TRUONG[1], S. TANAKA[4], J. C. BRESNAHAN[1], M. S. BEATTIE[1], T. OGATA[2], A. R. FERGUSON[1];

Abstract: Sensory inputs from the lower extremities modulate neural circuits controlling gait. Loading-related sensory inputs are essential for functional recovery after spinal cord injury (SCI). Identifying relevant loading conditions and therapeutic time-windows for locomotor training will lead to advances in neurorehabilitation. Here we investigate the impact of initial limb unloading after SCI using adult female SD rats subjected to mild contusive injury (T9; 50 kdyn IH). Three days following injury, subjects were randomized to two experimental groups: 1) hindlimb unloading (HU) by tail suspension for 2 weeks followed by normal-loading for 6 weeks, or 2) normal-loading control for 8 weeks. Assessments included: 1) BBB and kinematic gait analysis; 2) electrophysiological H-reflex testing; 3) biomolecular and robotic confocal microscopy for plasticity-related changes in spinal motoneurons. Results demonstrated HU reduced coordinated forelimb-hindlimb stepping by kinematics and impaired long-term locomotor recovery (BBB = 12 for HU vs 17 for normal-loading controls). H-reflex testing of the plantaris muscle at 8 weeks showed frequency dependent H-reflex suppression was diminished in HU compared to controls, indicating motoneuron hyperexcitability. Furthermore, acute HU drove a chronic increase in glutamate AMPA receptors in post-synaptic membranes of spinal motoneurons as measured in biochemical and confocal microscopic studies, suggesting that HU induced maladaptive plasticity in the spinal cord. Our findings also suggest that initial limb unloading after SCI can induce maladaptive plasticity that persists, undermining long term

recovery, and supporting the need for early rehabilitation to reverse maladaptive plasticity after SCI.

Title: A mechanical microconnector to improve regeneration after spinal cord injury: characterization of the therapeutic effect by tracing studies

Authors: *J. KREBBERS[1], N. BRAZDA[1], V. ESTRADA[1], C. VOSS[2,3], V. T. RIBAS[4], K. SEIDE[3], H. K. TRIEU[2], P. LINGOR[4], H. W. MÜLLER[1];

Abstract: Traumatic injuries of the central nervous system (CNS) lead to irreversible damage and prolonged functional deficits. As a result of spinal cord injury (SCI), supraspinal neuronal connections are interrupted, thus intentional movement and sensory perception are permanently impaired. In contrast to the peripheral nervous system, neurons in the CNS are hardly able to regenerate. In this study the previously described mechanical microconnector system (mMS) [Brazda et al. (2013) Biomaterials 34 10056-10064] was further characterized for its potential to support supraspinal reconnectivity using anterograde and retrograde tract tracing methods in the adult rat after complete midthoracic spinal cord transection. Briefly, the mMS is a device for re-adaptation of separated spinal cord stumps after complete transection and is made out of polymethylmethacrylate (PMMA) with honey comb structured holes. As described earlier, the two spinal cord stumps are sucked into the mMS by applying negative pressure and remain in place after removal of the vacuum. Rats with complete midthoracic SCI and mMS implantation show improved locomotor function compared to injured control animals without mMS. Moreover increased axonal outgrowth, angiogenesis, and the invasion of Schwann cells, which myelinated regenerating axons, was seen [Estrada et al. (2012) SfN Abstract 123.03]. In this study, supraspinal reconnectivity following mMS implantation was further investigated and three putative mechanisms were tested: (1) Regeneration of supraspinal axon tracts, especially the corticospinal tract (CST), (2) regeneration of interneurons through the mMS, and (3) formation of additional synapses of CST axons on interneurons rostral and caudal to the lesion, establishing a novel interneuronal bridge passing through the mMS. To test these hypotheses tracing studies and synapse stainings were performed. To trace the CST, an adeno-associated virus (AAV) construct coding for red fluorescent protein (dsred) was used. Descending tracts and interneurons regenerating beyond the lesion site into caudal healthy tissue were traced by using the retrograde tracer fluorogold. These morphological investigations could reveal important mechanisms for the previously observed functional benefits of the mMS, which is currently fabricated using bioabsorbable materials. Those techniques can be used to investigate reasonable combinations of the mMS with other already approved neuroregenerative therapies, such as chondroitinase ABC to degrade axon growth inhibitors or the application of small electric fields (through gold-coated mMS) to enhance and guide axonal outgrowth.

Title: clinical trials of stem cell therapy for spinal cord injury in south korea

Authors: *J. JUNG[1], S. Y. KIM[2], J. K. HYUN[1,2,3];
[1]Dept. of Nanobiomedical Sci. & BK21 PLUS NBM Res. Ctr. for Regenerative Med., [2]Deptartment of Rehabil. Medicine, Col. of Med., [3]Inst. of Tissue Regeneration Engin. (ITREN), Dankook Univ., Cheonan, Korea, Republic of

Abstract: There is no fundamental treatment to recover spinal cord injured (SCI) patients in the clinical setting, and various therapeutic strategies are developing to regenerate damaged spinal cord and make a hope for SCI patients. Since almost a decade ago, many clinical trials of stem cell transplantation (SCT) had been performed in many countries, albeit SCT is not yet approved as one of the treatment options of SCI in the clinical field. Herein we performed the survey for clinicians and SCI patients about SCT via multiple centers and individuals in South Korea, and also performed physical examination to stem cell-received SCI patients. We classified the subjects to four separated groups; non SCT-received SCI patients, SCT-received SCI patients, non SCT-performed clinicians, and SCT-performed clinicians. Expectation of moderate-to-complete functional improvement following SCT was the greatest in SCT-received patients (70%) than non SCT groups (27.4% for patients and 43.5% for clinicians). All participants worried about complications following SCT, and agreed with necessity of active rehabilitation program even after SCT. Among twenty SCT-received patients, stem cell types for transplantation were bone marrow mesenchymal stem cell (MSC) (65%), adipose MSC (25%), and unknown (10%). SCT were performed via intralesional (60%), intravenous (28%), and unknown (12%). Number of times to SCT was shown as once (35%), twice (10%), and more than 3 times (55%). Functional improvement following SCT was not obvious in SCT-received patients. About 15% of them felt some improvements following SCT, however physical examination revealed that neurological level of injury was not changed (60%) in most cases, but 20% cases showed even worsening. The proportion of bladder dysfunctions including frequency and incontinence was not different between non SCT-received and SCT-received patients. Some of SCT-received patients suffered from side effects following SCT, and neuropathic pain was obvious following SCT than non SCT-received patients (95% versus 63.1%). In conclusion, recognition to stem cell therapy was the same in all clinicians and SCI patients, and the greatest expectation group in stem cell therapy was SCT-received patients. Nevertheless we could not find the obvious neurological nor functional improvements in SCT-received patients while the neuropathic pain was increased following SCT.

Title: Lack of effect of anti-integrin treatment in contusion models of rat spinal cord injury

Authors: N. M. GEREMIA[1], T. HRYCIW[1], F. BAO[1], F. STREIJGER[2], E. OKON[2], J. H. T. LEE[2], B. K. KWON[2], L. C. WEAVER[1], *A. BROWN[1], G. A. DEKABAN[1];
[1]Biotherapeutics Res., Robarts Res. Inst., London, ON, Canada; [2]ICORD, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Neurological outcomes of rats and mice after clip compression spinal cord injury (SCI) are improved by acute treatment with a monoclonal antibody against an integrin expressed by neutrophils and monocyte/macrophages. However, the limited effects of this anti-integrin treatment reported by others suggest that severity and type of lesion may play an important role in the success of the treatment. For a comparison to the published efficacy of this treatment after clip compression SCI, we tested it in a moderately severe contusion models of SCI at the 8th (T8) and 12th (T12) thoracic spinal segments of rats. Dwell time and force in these contusion SCI models were adjusted to produce an injury severity comparable to that of our 35g clip compression SCI with respect to open field locomotor scores and tissue myeloperoxidase levels. Whereas the anti-integrin treatment lowered acute myeloperoxidase levels and improved locomotor recovery in the clip compression injury, no improvements in these measures were observed in the T8 and T12 contusion SCI models. Similarly the anti-integrin treatment did not improve neurological outcomes in a cervical hemi-contusion model of SCI. This suggests that the beneficial effect of the anti-integrin treatment depends on the type and severity of spinal cord injury being addressed.

Title: The role of fibronectin in BMSC survival and repair potential after spinal cord injury

Authors: *A. E. HAGGERTY[1], M. OUDEGA[2];
[1]The Miami Project to Cure Paralysis, [2]Univ. of Miami, Miami, FL

Abstract: Spinal cord injury (SCI) results in continuous loss of nervous tissue and poor functional recovery, which has devastating consequences for those that suffer damage to their spinal cord. Stem cell transplantation presents a unique opportunity for SCI treatment in part because the stem cells continuously secrete various growth factors that could halt secondary tissue loss and potentially induce regeneration/repair of damaged axons across the injury site. Adult mesenchymal stem cells exist in a variety of niches throughout the body, including bone marrow. These cells (best known as bone marrow stromal cells; BMSCs)) have previously been shown to improve tissue sparing (survival of healthy tissue) and, albeit to a limited degree, functional recovery when transplanted into rodent spinal cord following a contusive SCI. However, cell survival after transplantation is poor and we (and others) have previously shown that by two weeks post-transplantation the majority of the cells have died. BMSCs are susceptible to anoikis, or programmed death due to lack of adherence to a substrate, and this could be at least in part responsible for their poor survival after transplantation. Therefore,in order to address this problem we have studied whether fibronectin, an extracellular matrix protein that is important in attachment and anchoring of cells, when used as a transplant matrix would support BMSC survival. Fibronectin does not spontaneously polymerize in solution, which could potentially limiting cell binding motif availability. Others have shown that when fibronectin is mixed with the III-C fragment, it can be induced to self-polymerize in solution and when transplanted into the injured spinal cord, which does not lead to additional damage or side-effects. In order to maximize available binding motifs, we have considered multiple concentration and combinations of Fn and FnIII-C fragment to optimize BMSC survival *in vitro* and *in vivo* using an adult rat model of contusive SCI. By optimizing the transplant matrix for cell adhesion, we can decrease anoikis-driven apoptosis and enhance the repair potential of a BMSC transplant for treatment of SCI. A portion of this work was conducted at The University of Pittsburgh.

Title: Task-specific training-based rehabilitation improves bladder outcomes following human spinal cord injury

Authors: *C. HUBSCHER[1,2], A. HERRITY[2,3], L. MONTGOMERY[1,2], A. WILLHITE[2,3,4], C. ANGELI[2,3,4], S. HARKEMA[2,3,4];
[1]Dept Anatom. Sci. & Neuro, Univ. Louisville Sch. Med., Louisville, KY; [2]Kentucky Spinal Cord Injury Res. Ctr., Louisville, KY; [3]Frazier Rehab Inst., Louisville, KY; [4]Dept Neurolog. Surgery, Univ. of Louisville Sch. Med., Louisville, KY

Abstract: One of the major secondary challenges impacting overall health and quality of life following spinal cord injury (SCI) is the development of lower urinary tract dysfunction. Urological complications include bladder overactivity, uncoordinated contractions between the muscles of the bladder wall and bladder outlet, decreased bladder compliance and loss of continence. As a result, the ability to properly store and expel urine in a coordinated and timely manner becomes compromised. In an effort to ameliorate bladder outcomes post-SCI, management approaches include various catheterization techniques, pharmacological, surgical and electrical stimulation interventions. In addition, our previous study in a clinically relevant rodent contusion model indicates that rehabilitative methods introduced after SCI such as locomotor training (LT) positively influence micturition parameters (Ward P.J. et al., 2014. J Neurotrauma, 31: 819-833). Given the overlap of neural networks controlling bladder and locomotor function in the lumbosacral spinal cord, an interaction between these circuitries may be expected. We hypothesized that a vesico-somatic relationship is influenced by LT to improve bladder integrity and overall function. In this study, subjects who sustained a SCI (AIS: A or B) received 80 daily sessions of LT on a treadmill using body-weight support (one hour per session) or LT plus stand (weight bearing without stepping) training (one hour of each per day, separated by at least 3 hours). Urodynamic assessments were performed at pre-and post-training time points. Cystometry measurements demonstrated increases in bladder capacity and voiding efficiency post-training in the step and step/stand trained participants. These results suggest that an appropriate level of repetitive sensory information, in this instance, generated through task-specific stepping and/or loading provided to the spinal cord, appears to influence the neural circuitry controlling micturition. Experiments in progress include the impact of training-based rehabilitation without loading, using arm-crank exercise, and the effects of activity-dependent

plasticity induced by stand and step training on bladder outcomes in SCI subjects receiving epidural stimulation.

Title: Electroacupuncture combined with bone marrow mesenchymal stem cells transplantation attenuates inflammatory response and reactive astrogliosis in the transected spinal cord of rats

Authors: ***Y. DING**[1], R.-Y. ZHANG[2], Y.-S. ZENG[3];
[1]Zhongshan Sch. of Medicine, Sun Yat-Sen Universi, Guangdong, China; [2]Dept. of Histology and Embryology, Zhongshan Sch. of Medicine, Sun Yat-sen Univ., Guangzhou, China; [3]Zhongshan Sch. of Medicine, Sun Yat-sen Univ., Guangzhou, China

Abstract: It is known that the glial scar resulting from spinal cord injury (SCI) impedes axonal regeneration. Our previous study reported that Governor Vessel electroacupuncture (EA¬) combined with bone marrow mesenchymal stem cells (MSCs) treatment downregulated the expression of glial fibrillary acidic protein (GFAP) and chondroitin sulfate proteoglycans (CSPGs) after SCI. However, little is known about the mechanism of EA combined with MSCs downregulating GFAP and CSPGs expression. The present study investigated whether EA combined with MSCs (EA+MSCs) treatment could inhibit inflammatory response, and further attenuate the glial scar following SCI. The results showed that EA+MSCs treatment could decrease activation of microglia/macrophage, mRNA and protein expression of proinflammatory factors (TNF-α and IL-1β), and increase mRNA and protein expression of anti-inflammatory factor (IL-10) in injured spinal cords. Moreover, EA+MSCs treatment remarkably reduced reactive astrogliosis and accumulation of CSPGs after SCI. In addition, *in vitro* study demonstrated that TNF-α and IL-1β could increase astrocyte proliferation and mRNA transcription of GFAP and CSPGs. Therefore, the results of present study indicate that EA+MSCs treatment can inhibit inflammatory response, further attenuate the reactive astrogliosis and CSPGs deposition, and eventually inhibit glial scar formation following SCI. EA combined with MSCs treatment may be a potential therapeutic strategy for clinical treatment SCI.

Title: Automated robot system for high-throughput training, testing, and analysing skilled reaching performance in rodents before and after CNS injury

Authors: *K. K. FENRICH[1,2], A. TORRES-ESPIN[1,2], J. FORERO[1,2], Z. MAY[1,2], D. J. BENNETT[2,3], K. FOUAD[1,2];

Abstract: The single pellet grasping (SPG) task is a skilled forelimb motor task commonly used to evaluate fine motor control in rodent models of CNS injury and disease. The task requires animals to obtain food pellets located on a presentation shelf beyond a slit at the front of an SPG task enclosure. The major down side of training and testing animals in this highly detailed task is that it is very labour intensive - to the point where students and/or technicians can go crazy and attempt a lab mutiny! To reduce the incidence of lab mutiny, we developed an automated SPG training protocol using an Automated Pellet Presentation (APP) robot system. This system allows animals to train ad libitum 24 hours a day, 7 days a week, and improves grasping success rates while reducing researcher time and outcome variability compared to manually trained animals. Here we show that the APP system can be used to rehabilitate reaching and grasping movements in rats with cervical spinal cord injuries that impair forelimb function. Additionally, we describe an updated version of the APP system (APP 2.0) that allows automatic quantification of the SPG task and animal identification. Each APP 2.0 system is attached to a home cage for full-time ad libitum training and testing, which greatly reduces animal handling and variability in task performance associated with repeated handling. Moreover, to identify animals each system is equipped with a radio frequency identification (RFID) module that can read transponder tags implanted into each rat prior to the start of training. Furthermore, the APP 2.0 system is equipped with optical sensors to track attempts and evaluate each attempt as a pass or fail. Preliminary testing shows that naïve rats can be trained using the updated system, and the system can accurately identify animals as they performed the task and correctly categorized attempts as a pass or fail. Importantly, along with improved task performance and reduced

outcome variability compared to manual training, the APP 2.0 system reduced researcher time commitments to less than 5 min/week/rat (manual training usually requires ~100 min/week/rat). Concomitant with our testing of the APP 2.0 system for rats, we are developing a reduced version for mice. Taken together, the updated APP system facilitates the training and testing of forelimb function in rodent models and can be simultaneously be used for rehabilitative training, a process needed to evaluate clinically relevant treatments.

Abstract: Current preclinical researches on locomotor function after spinal cord injury (SCI) are mostly studied using rodent models. In terms of clinical trial, we have considered to test its compatibility in a newly established non-human SCI primate model of common marmosets. In the current study, we developed research toolkits for locomotion of marmoset including spinal contusion measure, a weight-support bipedal locomotion system, and a custom-made beam. Common marmosets (N = 2) received contusive SCI by a modified New York University (NYU) device (2.0 mm in diameter) by dropping the weight (10 or 20 g) from a height of 50 mm onto the dura mater at the T11 level. Manual bladder expression was carried out twice a day until voiding reflexes were reestablished. In addition, we tested bipedal locomotion on the treadmill with the body weight support in both the intact (N = 7) and SCI marmosets (N = 2). During bipedal locomotion, the reflective markers on the joints of marmosets were tracked by the motion capture system, and kinematics of the hindlimb movements was analyzed. The marmosets had little or no hindlimb movements until 3 weeks postoperative and then demonstrated a progressive recovery of the movements in next 2-3 weeks postoperative. In 8 weeks postoperative, a 20 g SCI model showed sweeping with hindlimbs during walking without

weight support, while 10 g SCI model showed frequent weight supported plantar stepping. Functional recovery of locomotion reached a plateau in both marmosets in 8-10 weeks postoperative. In a 20 g SCI model, luxol fast blue and cresyl violet staining showed 24 % of the spinal cord tissues were spared (bilateral anterior funiculus, 13 %; unilateral funiculus, 11 %) at the lesion site. In the both SCI models, the occasional hindlimb stepping was observed on the treadmill with the body weight support in 10 weeks postoperative. On the kinematics analysis, the maximum height of MTP joint position and length of time for swing phase were changed as compared to the intact of the same marmosets. Despite of gradual recovery of the hindlimb movements after SCI, the marmosets of the 20 g SCI model did not recover stepping movement with weight support even in 10 weeks postoperative. Previous studies showed that, remarkably small number of axons (a minimal amount 10%) could induce considerable recovery of stepping function in rats (Basso et al., Exp Neurol. 1996), but not in macaque monkeys (Eidelberg et al., Brain 1981). In marmosets, the recovery process of locomotor function after SCI was more similar to macaque monkeys than rats. This suggests primates may need more supraspinal inputs for stepping movements than rodents.

Title: Programmed freeze/thaw method dramatically improved cell viability of ips cell-derived neural stem cells for clinical application in spinal cord injury

Authors: ***Y. NISHIYAMA**[1], A. IWANAMI[1], J. KOHYAMA[2], G. ITAKURA[1], Y. KOBAYASHI[1], S. NISHIMURA[1], H. IWAI[1], M. MATSUMOTO[1], H. OKANO[2], M. NAKAMURA[1];

Abstract: Background: Recently, we have reported the effectiveness of transplanting human iPS cell-derived neural stem cells (iPS-NSCs) for subacute spinal cord injury (SCI) in mice as well as common marmosets. Because it takes 6 months to establish iPS-NSCs derived from patient's own somatic cells, at present, it is impossible to perform auto-graft of iPS-NSCs within an optimal therapeutic time window for SCI. To extend our results into clinical application, allogeneic transplantation is a realizable goal. However, there are still some concerns to overcome, such as iPS-NSCs storage and supply. It is especially critical to determine whether

freezing and thawing affects the viability and characters of cells since viability was extremely low when iPS-NSCs were cryopreserved in freezing container. **Purpose:** The purpose of this study is to improve the viability and assess the effects of cryopreservation on the characters of iPS-NSCs. **Materials and methods:** 201B7 iPS-NSCs, which are considered safe and non-tumorigenic as reported previously, were used in the present study. The iPS-NSCs were cryopreserved in STEM-CELLBANKER® by slow freezing method. We evaluated the cell viability to determine the timing of freezing (3 or 6 days after the last passage), the number of frozen cells (2 or 5 million/ml) and freezing method (programmed freezer or freezing container). Then proliferation, differentiation assays and microarray were performed under appropriate conditions in terms of cell viability. **Results:** The cell viability was highest when the iPS-NSCs were frozen on 6 days after the last passage at the concentration of 2 million cells/ml. Compared to the freezing container, the programmed freezer significantly increased the cell survival. Differentiation assay revealed that frozen-thawed (FT) cells dominantly differentiated into Tuj-1-positive neurons as same as non-frozen (NF) cells. There were no significant differences in proliferation and differentiation ability between FT and NF cells. Principal component analysis and hierarchical clustering revealed that the gene expression profile of FT cells was similar to NF cells. **Conclusion:** Towards clinical application of cell transplantation for SCI, cryopreservation of iPS-NSCs is essential in terms of cell viability. In this study, we succeeded in improving the viability of the iPS-NSCs by the programmed freezer. Furthermore, FT cells showed similar proliferation, differentiation ability as well as gene expression profile to NF cells, suggesting that our programmed freeze/thaw method would be useful for clinical application of cell therapy in SCI.

Title: Transplantation of human iPS cell-derived oligodendrocyte precursor cells enriched neural stem/progenitor cells in chronic and subacute spinal cord injury

Authors: *S. KAWABATA[1], A. IWANAMI[2], J. KOHYAMA[3], M. TAKANO[2], Y. NUMASAWA[4], G. ITAKURA[2], Y. KOBAYASHI[2], S. SHIBATA[3], H. OKANO[3], M. MATSUMOTO[2], M. NAKAMURA[2];

Abstract: Background: We have reported that there are limits to functional recovery by transplantation of neural stem/progenitor cells (NS/PCs) for chronic SCI. It was partly because of inadequate remyelination of surviving axons by transplanted cells. It is well known that remyelination of demyelinated axons could be a viable target in transplantation therapy for chronic SCI. Since human iPS cell-derived oligodendrocyte precursor cells (hiPSC-OPCs) enriched NS/PCs have potentials to differentiate into mature oligodendrocytes, these cells might be effective for the chronic SCI by remyelinating demyelinated axons in the injured spinal cord. In this study, we verified the effectiveness of transplanted hiPS-OPC enriched NS/PCs for mouse chronic SCI, then compared with the subacute transplantation. Methods: hiPSC-OPCs enriched NS/PCs were induced from pre-evaluated safe iPS cell line, and cytokine antibody array experiments were performed. Contusive SCI was induced in immunodeficiency mice and these cells were transplanted into the injured spinal cord 9 or 45 days after SCI (subacute and chronic transplantation group). Instead of cells, PBS was injected in each vehicle control group. For histological analyses, mice were intracardially perfused 12 weeks after transplantation. Locomotive motor functions were periodically assessed. Results: Cytokine antibody array analysis revealed that much more trophic factors were secreted from hiPSC-OPCs enriched NS/PCs than hiPSC-NS/PCs. Many grafted cells differentiated into MBP positive mature oligodendrocytes in both transplantation groups. Nodes of Ranvier were observed in the transplanted cells derived myelin sheathes. Furthermore transplanted cells promoted axonal growth and contributed to the synapse formation between grafted cells derived neurons and host neurons. Therefore there were many NF-H+ neuronal fibers in the both transplanted groups whereas a few NF-H+ axons were observed in the control group. The subacute transplantation group demonstrated significantly larger myelinated areas compared to control group, whereas myelinated areas did not significantly differ between the chronic transplantation group and chronic control group. Moreover, no significant motor function recovery was observed in the chronic transplantation group, compared to PBS group. Conclusion: The effectiveness of hiPSC-OPC enriched NS/PCs transplantation for chronic SCI was restricted compared to the transplantation for subacute SCI. Combination therapy of transplantation with debridement of glial scar formation or rehabilitation may be critical to achieve functional recovery for chronic SCI.

Abstract: Unsuccessful axonal regeneration in adult mammals following spinal cord transection is mainly attributed to the physical gap created between the two cord stumps, the glial scar formation, and the low intrinsic regenerating capacity of injured central nervous system (CNS) neurons. Schwann cells (SCs) can provide a permissive bridge for axonal regeneration across the lesion site. However, the reactive astrocytes surrounding the grafted SCs limit their integration into the host environment and therefore weaken the graft's efficiency. The segregation between grafted SCs and host astrocytes prevents regenerated axons inside the graft from growing back into the host cord, which is necessary for functional reconnection of neuronal circuit. We previously demonstrated that glial cell line-derived neurotrophic factor (GDNF) could modify interactions between SCs and astrocytes. In this study, we constructed an axonal growth permissive pathway following a thoracic spinal transection at T11 by transplanting SCs overexpressing GDNF (SCs-GDNF) into the lesion gap as well as into the caudal spinal cord. GDNF significantly improved the graft-host interface by promoting integration between SCs and

host astrocytes resulting in the migration of host astrocytes into the SCs-GDNF territory. The glial response within the caudal graft area was significantly attenuated. The astrocytes inside the grafted area were elongated with slim processes and bipolar orientation accompanied with dramatically reduced expression of glial fibrillary acidic protein. Remarkable number of descending propriospinal axons and supraspinal axons expressing serotonin and tyrosine hydroxylase regenerated across the lesion gap and grew back to the caudal spinal cord, which were otherwise hard to be seen in control groups. The regenerated axons were remyelinated and formed synapse with host neurons in the caudal spinal cord. The locomotor function in the group receiving SCs-GDNF-constructed growth-promoting pathway was also improved.

Title: Neurotrophin-3 normalises spinal reflexes after central nervous system injury

Authors: *C. KATHE[1], T. H. HUTSON[3], S. B. MCMAHON[2], L. D. F. MOON[2]; [2]Wolfson CARD, [1]King's Col. London, London, United Kingdom; [3]Ctr. for Restorative Neurosci., Imperial Col. London, London, United Kingdom

Abstract: Neurotrophin-3 (NT3) promotes the survival and neurite extension of specific neuronal populations including Ia proprioceptive fibers. We are investigating the mechanism by which NT3 modulates spinal reflexes mediated via this neuronal population and motor neurons *in vivo*. Firstly, we evaluated retrograde trafficking of NT-3 towards the spinal cord following AAV-NT3 overexpression in forelimb muscles. We have detected increased levels of NT3 protein in dorsal root ganglia connecting to the treated muscle groups. We are currently investigating transcriptional and post-translational changes of downstream molecules of its receptor trkC in dorsal root ganglia. Secondly, we use electrophysiology to functionally test the effects of NT3 overexpression in the muscle on the modulation of spinal reflexes involving proprioceptors and motor neurons. Rodents, like humans, develop spasticity after spinal cord

injury or stroke, caused by the hyper-excitability of the spinal reflex pathway. Thus, we developed an animal model, which allows for repeated electrophysiological assessment of this monosynaptic reflex. More specifically, we recorded the H-reflex from the abductor digiti quinti, a forepaw muscle, in rats every two weeks up to 10 weeks after a bilateral pyramidotomy. Rats were treated 24 hours post-injury by injection of an AAV-NT3 (or AAV-EGFP as a control treatment) into the forelimb flexor muscles on one side. Naive animals show a frequency-dependent depression of the H-wave at higher stimulation frequencies. After injury, this effect is reduced. However, neurotrophin-3 treated animals recover to baseline levels 6 weeks post-injury. Furthermore, rats treated with neurotrophin-3 have normalized polysynaptic reflexes and recover some motor function in their forelimbs whereas the control treated animals do not. Due to the profound effects observed after spinal cord injury following NT3 treatment, our data shows that spinal reflexes can be positively modulated after CNS injury with intramuscular neurotrophin-3 treatment.

Title: Optogenetic evaluation of functional synaptic reconnection by corticospinal tract axons in the injured spinal cord

Authors: *N. JAYAPRAKASH, B. HOEYNCK, N. KRUEGER, Z. WANG, M. BLACKMORE;
Marquette Univ., Milwaukee, WI

Abstract: Spinal cord injury results in partial or complete loss of neural communication across the site of injury. To restore function, axons must extend into denervated territory, and, critically, must form functional synapses with appropriate targets. We have previously shown that forced overexpression of transcription factors KLF7 or Sox11 promotes axon regeneration in corticospinal tract (CST) neurons, but that behavioral outcomes are modest or even negative. It is therefore unclear whether the newly sprouted axons are able to form functional synapses, or alternatively, whether functional synapses are formed in a mistargeted fashion. Here we use an optogenetic strategy to assess the ability of Sox11-stimulated axons to form functional synapses.

A pyramidotomy was performed in adult mice to deprive the left side of the spinal cord of CST input, and the right CST was treated with AAV-Sox11 or EBFP control, along with viral channelrhodopsin (rAAV9/CamKII-ChR2-EYFP). As we have shown previously, Sox11 treatment caused robust midline crossing of CST axons into the previously denervated left spinal cord. We then paired optogenetic stimulation of newly sprouted CST axon terminals in the left spinal cord with extracellular recordings of post-synaptic spinal neurons. We observed clear post-synaptic responses driven by optogenetic activation of Sox11-treated axons, demonstrating the ability to form functional synapses with target cells. Further, the use of multiunit electrodes enabled mapping of the pattern of spinal activity following light stimulation in different regions of the spinal cord. The presence of functional synapses without significant behavioral benefit suggests that new connections may be mistargeted, motivating ongoing experiments that incorporate rehabilitative training to refine the newly formed synapses. Overall these data illustrate the utility of an optogenetic approach to monitor and optimize functional reconnection by newly sprouted axons in the injured spinal cord.

Title: Combinatorial testing of transcriptional modification and chondroitinase treatment to promote axon regeneration and functional recovery after spinal cord injury

Authors: ***Z. WANG**, K. WINSOR, E. BALLE, P. POWERS, N. KRUEGER, M. BLACKMORE;
Dept. of Biomed. Sci., Marquette Univ., Milwaukee, WI

Abstract: Axon regeneration in the central nervous system (CNS) is prevented by extracellular inhibitory cues, as well as a failure on the part of many injured CNS neurons to activate transcriptional programs needed to sustain axon growth. We have previously identified two transcription factors, KLF7 and Sox11, which enhance regenerative axon growth when overexpressed in adult corticospinal tract (CST) neurons. Here we explore the hypothesis that combining these transcriptional interventions with chondroitinase, an enzyme that degrades growth-inhibitory chondroitin sulfate proteoglycans, may lead to additional gains in axon

regeneration and/or behavioral recovery. We created a lentiviral vector to drive expression of chondroitinase in host cells (Lenti-Chase) and confirmed that Lenti-Chase injections caused CSPG degradation in the injured spinal cord using immunohistochemistry with 2B6, and anti-CSPG stub antibody. In one set of experiments, a thoracic crush experiment was performed in adult mice, and CST neuronal cell bodies were treated with transcriptional active KLF7 (AAV8-VP16-KLF7) while Lenti-Chase was delivered to the site of spinal injury. Compared to control viral treatments, KLF7-treated axons showed enhanced proximity to the proximal side of the injury, an effect that appeared to be elevated in the presence of Lenti-Chase. In contrast to previous results using partial spinal injury, however, KLF7-stimulated axons were not observed to regenerate distal to the complete crush injury. In a second experiment, animals were challenged with a cervical hemisection, and AAV-Sox11 treatment of CST cell bodies was combined with spinal lenti-Chase. Consistent with our previous results, Sox11 significantly enhanced CST axon growth distal to the injury site. Growth was not further increased by application of Lenti-Chase. Animals did, however, show a trend toward behavioral improvement when Sox11 and Chondroitinase were combined. Replicating this finding, and further combining these treatments with rehabilitative training, are areas of ongoing research

Title: Mesoporous silica-supported lipid bilayer nanoparticles target gene transfer to motoneurons

Authors: *M. A. GONZALEZ[1,2], A. MUNIZ[4], J. BRINKER[4], G. C. SIECK[2,3], C. B. MANTILLA[2,3];
[2]Physiol. and Biomed. Engin., [3]Anesthesiol., [1]Mayo Clin., Rochester, MN; [4]Chem. Engin., Univ. of New Mexico, Albuquerque, NM

Abstract: The potential for treating neurological diseases using gene therapy is vast but underachieved. At present there are no effective non-viral vectors that specifically target motoneurons. Nanoparticles are novel drug delivery systems with exceptional therapeutic potential. We hypothesized that mesoporous silica nanoparticles (MSNPs) can be engineered to specifically target motoneurons delivering various cargos and thus be useful for gene therapy. We used MSNPs coated with a lipid bilayer (protocells) which exhibit advantageous fusion characteristics including 1) increased surface area with larger loading capacity, 2) stability and 3)

improved biocompatibility. Fluorescently labeled protocells (130 nm in diameter) were loaded with GFP plasmid to evaluate transfection efficiency in cultured motoneurons *in vitro*. Protocells showed efficient motoneuron uptake quantified by measurement of intracellular protocell fluorescent intensity. Quantitative assessment of confocal images for co-localization of fluorescently labeled protocells and lysosomes revealed that protocells can escape endo-lysosomal degradation. Biocompatibility was determined by lack of cytotoxicity and unimpaired proliferation. Transfection of motoneuron-like NSC-34 cells was evident by ~20% of motoneurons expressing GFP. In conclusion, protocells are a promising, customizable non-viral approach for targeting and delivering genes to motoneurons *in vivo*.

Title: Evaluation of immunological response in human iPS cell-derived neural stem cells using mixed lymphocyte reaction focusing HLA matching

Authors: *M. OZAKI[1,2], A. IWANAMI[1], J. KOHYAMA[2], G. ITAKURA[1], H. IWAI[1], M. MATSUMOTO[1], M. NAKAMURA[1], H. OKANO[2];
[1]Dept. of Orthopaedic Surgery, Keio Univ., Shinjuku-Ku Tokyo, Japan; [2]Dept. of Physiology, Keio Univ., Shinjuku-Ku Tokyo, Japan

Abstract: Background Recent studies demonstrated the effectiveness of transplantation of human induced pluripotent stem cell-derived neural stem cells (hiPSC-NSCs) for rodent as well as non-human primate spinal cord injury (SCI) model. Although human leukocyte antigen (HLA) matched allogeneic transplantation would be a realistic goal of first-in-human trial in taking advantage of iPS bank in Japan, the significance of HLA matching in hiPSC-NSCs transplantation for SCI has not been evaluated in detail. The purpose of this study is to determine the importance of HLA matching in allogeneic hiPSC-NSCs transplantation using mixed lymphocyte reaction (MLR). **Materials and Methods** Integration-free human iPS clone-derived NSCs were used in this study. Human peripheral blood mononuclear cells (PBMCs) which were purified from blood of healthy volunteers were co-cultured with irradiated HLA-mismatched hiPSC-NSCs and proliferative lymphocyte response was quantitatively measured by incorporation of ^{3}H-thymidine. As a control, human PBMCs were co-cultured with HLA-mismatched human fetal NSCs at the same time. Effects of passage number of hiPSC-NSCs on immune response were also evaluated. Then, PBMCs from same person who donated iPS cells

were co-cultured with autologous hiPSC-NSCs and autologous lymphocyte response to hiPSC-NSCs was compared with allogeneic lymphocyte response. **Results** The proliferation of lymphocytes co-cultured with HLA-mismatched allogeneic hiPSC-NSCs was significantly enhanced under the optimal condition. In allogeneic condition, proliferation of lymphocytes co-cultured with hiPSC-NSCs was similar to that of lymphocytes co-cultured with human fetal NSCs. Passages of hiPSC-NSCs less than 8 times did not affect the proliferation of allogeneic lymphocytes. Furthermore, the proliferation of lymphocytes stimulated by HLA-mismatched allogeneic hiPSC-NSCs significantly enhanced compared to that of lymphocytes co-cultured with autologous hiPSC-NSCs. **Conclusions** This study demonstrated that optimized MLR could predict immune responses in HLA-mismatched allogeneic hiPSC-NSCs transplantation. A higher response was observed in allogeneic MLR compared to autologous MLR, suggesting immune rejection was relieved by HLA matching in hiPSC-NSCs transplantation for SCI patients.

Title: 14-3-3 proteins targeted to promote axon regeneration

Authors: *A. KAPLAN[1], A. KRONER[1], S. LEONG[1], C. MADWAR[1], S. BANERJEE[2], I. RAMBALDI[1], N. BISSON[2], J. ANTEL[1], S. DAVID[1], A. FOURNIER[1];

Abstract: Spinal cord injury (SCI) results in the damage and disconnection of long axonal tracts. The inability of severed axons to regenerate is responsible for sustained paralysis and loss of sensation in SCI patients. An important strategy to approach this unmet need is to develop drugs that promote regenerative axon growth. We have identified 14-3-3 proteins, a family of phospho-serine/threonine-binding cytosolic adaptor proteins, as important mediators of axon regeneration. Overexpression of 14-3-3 isoforms enhances axon regeneration in an *in vitro* cortical neuron scratch assay. Moreover, we have identified a compound that stimulates axon regeneration through a putative mechanism of stabilization of 14-3-3 protein-protein interactions (PPIs).

Treatment of rat cortical neurons and human fetal neurons with the 14-3-3 stabilizer compound enhances neurite outgrowth in a dose-dependent manner, indicating a conservation of activity from rodent to man. The 14-3-3 stabilizer compound is known to bind to a pocket created by the interface between the 14-3-3 binding groove and certain client proteins, forming a tri-partite complex that enhances the stability of the PPI. PPI stabilization is a unique concept in drug design that, unlike PPI inhibition, does not necessitate competition with a natural ligand for target binding. Current efforts are focused on elucidating the mechanism-of-action of the 14-3-3 stabilizer compound and testing its efficacy in stimulating corticospinal tract regeneration after dorsal hemisection SCI in mice. Compounds that stabilize 14-3-3 PPIs may be valuable neuroregenerative agents for use in SCI and other conditions characterized by axonal damage.

Title: Dynamin inhibitors and their effect on endocytosis of surface functionalized nanospheres

Authors: ***S. SEBASTIAN**[1], R. AMMASSAM VEETTIL[1], D. HYNDS[1], T. MCALLISTER[2], S. GHOSH[2];

Abstract: Surface functionalized nanospheres (SFNPs) have the potential to target therapeutics to different subcellular destinations in damaged neurons. These SFNPs are entering the cells either through receptor mediated endocytosis or through adsorptive mediated endocytosis. Dynamin is a large GTPase involved in the fission of endocytic vesicles from plasma membrane in many pathways. The well known clathrin mediated endocytosis, caveolae mediated endocytosis, RhoA dependent endocytosis and some forms of macropynocytosis require dynamin for vesicle fission. We demonstrated that -COOH and -NH2 surface functionalized nanospheres can be endocytosed through caveolae and clathrin mediated mechanisms in B35

neuroblastoma cells and PC12 pheochromocytoma cells. Dynamin inhibitors can be used to block dynamin-dependent endocytic pathways to confirm whether SFNPs employ these pathways to enter the cells. In the present study, we treated B35 cells with dynamin inhibitors and tested their effect on endocytosis of SFNPs. Dynamin inhibitors can rapidly and reversibly block dynamin by targeting its specific domains. We tested the dynamin lipid binding (PH) domain targeting inhibitors MiTMAB and OcTMAb as well as GTPase allosteric site (GAS) domain targeting inhibitors dynoles and iminodyns. In future, we will be testing dynamin inhibitors in PC12 cells and rat cortical neurons to assess the mechanisms of endocytosis employed by SFNPs.

Title: Poly(ADP-ribose) polymerase 1 is a novel target to promote axonal regeneration

Authors: *C. BROCHIER[1,2], D. WILLIS[1,2], B. LANGLEY[1,2];
[1]Burke/Cornell Med. Res. Inst., White Plains, NY; [2]Weill Cornell Med. Col., New York, NY

Abstract: Therapeutic options for the restoration of neurological functions following acute axonal injury such as spinal cord injury are severely limited. In addition to limiting neuronal loss, effective treatments face the challenge of restoring axonal growth within an injury environment where inhibitory molecules from damaged myelin and activated astrocytes act as molecular and physical barriers. Overcoming these barriers to permit axon growth is critical for the development of any spinal cord injury repair strategy. Here, we identify Poly (ADP-ribose) polymerase 1 (PARP1) as a novel and critical mediator of multiple growth-inhibitory signals. We show that exposure of neurons to growth-limiting molecules such as myelin-associated glycoprotein and chondroitin sulfate proteoglycans activates PARP1, resulting in the accumulation of poly(ADP-ribose) (PAR) in the cell body and axon, and limited axonal growth. Accordingly, we find that pharmacological inhibition or genetic loss of PARP1 markedly facilitates axon regeneration over non-permissive substrates. Together, our findings provide critical novel insights into the molecular mechanisms of axon growth inhibition and identify PARP1 as an effective target to promote axon regeneration.

Title: Alterations in Regulator of G-protein Signaling 4 (RGS4) in schizophrenia

Authors: *S. KIMOTO[1,2], J. R. GLAUSIER[2], K. N. FISH[2], D. W. VOLK[2], H. H. BAZMI[2], D. ARION[2], D. DATTA[2], D. A. LEWIS[2,3];

Abstract: NMDA receptor (NMDAR) hypofunction in the dorsolateral prefrontal cortex (DLPFC) has been implicated in the pathology of schizophrenia. Accumulating evidence suggests that NMDAR hypofunction may reflect dysregulation of NMDAR signaling. NMDAR activity can be negatively regulated by signaling of some G-protein coupled receptors (GPCRs), and the ability of these GPCRs to regulate NMDAR signaling is dependent upon Regulator of G-protein Signaling 4 (RGS4). Because RGS4 activity reduces GPCR signaling, lower levels of RGS4 enhance the ability of GPCRs to reduce NMDAR activity. RGS4 expression levels have been reported to be lower in the DLPFC in schizophrenia, suggesting a possible mechanism that could contribute to NMDAR hypofunction. To further investigate this relationship, we quantified the laminar- and cell-type specific changes in RGS4 mRNA and protein levels in the DLPFC. To investigate the possible molecular mechanisms underlying altered RGS4 expression, we quantified levels of small non-coding RNAs, known as microRNAs (miRs), which regulate RGS4 mRNA after transcription. RGS4 mRNA and protein levels were positively correlated in all subjects examined, and both were significantly lower in schizophrenia subjects relative to healthy comparison subjects. The RGS4 mRNA deficit in schizophrenia was present in DLPFC pyramidal neurons in layers 3 and 5. In contrast, levels of miR16 were significantly higher in the DLPFC of schizophrenia subjects, and higher miR16 levels predicted lower RGS4 mRNA levels. The present findings provide convergent evidence of lower RGS4 expression in schizophrenia that may result from increased expression of miR16. Lower RGS4 is predicted to augment the ability of GPCRs to decrease NMDAR signaling in DLPFC pyramidal cells in schizophrenia.

Title: Signals recorded from the eye reveal disease states, including schizophrenia

Authors: ***R. F. MILLER**[1], A. MACDONALD, III[2], D. C. MILLER[3], M. S. LEE[4], C. G. SUMMERS[4], T. NETOFF[5], S. AMERI[2], T. TAKARA[4], D. C. MILLER[4], P. MOGHIMI[5]; [1]Neurosci., Dept. of Neuroscience, Univ. of Minnesota, Minneapolis, MN; [2]Dept. of Psychology, [3]Neurosci., [4]Dept. of Ophthalmology and Visual Neurosciences, [5]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: We have used signals recorded from the eye, with conventional, non-invasive, ERG techniques to determine if patients diagnosed with schizophrenia (SZ) have differences when compared to a control group. Patients with SZ and demographically-similar controls were screened for diagnostic criteria and ophthalmologic contraindications before undergoing electroretinography (ERG). Our findings have revealed that signals from the eye have significant differences between the controls and the SZ population. Initially, we emphasized the response to patterns (pERG) and the Photopic Negative Response (PhNR) because they represent activity of retinal ganglion cells where NMDA receptors are prominently represented. We were surprised, however to find differences in almost every measurement we carried out with the exception of the Scotopic ERG. We found differences in most of the ERG recordings, including the photopic

ERG, the flicker response (30 Hz), and the oscillatory potentials. The main difference in these responses was a delay in the SZ population such that the peak was delayed by less than 1 ms, yet this difference is valid below the .02 ($p = < .02$). The flicker response amplitude is decreased in SZ patients, with a delay in the peak response. The most interesting differences were found in the pERG and the PhNR; recordings of the pERG reveal significant differences in the amplitude and peak delay with SZ patients showing reduced amplitude and a slower rise time to the stimulus. The PhNR reveals an absence of the PhNR especially to increased light stimulation (5 and 7 cd.s/M2). To determine if the pERG can be used to identify SZ patients and distinguish them from controls, we used a machine learning algorithm. Stimulus response waveforms were reduced to 6 dimensional features using principle component analysis. The principle components were used to train a support vector machine (SVM) using a subset of the SZ patients and controls. Then, the SVM was used to predict patients from controls in patients not used for the training. In this pilot sample, SVM was able to classify patients using the pERG with 75% accuracy ($p<0.01$). Combining the PhNR with the pERG should improve the accuracy of our prediction. Perceptual abnormalities in schizophrenia have often been interpreted as the result of dysfunctions in occipital cortex, however the present findings raise the possibility of degraded inputs even at the earliest levels of perception. In addition, PhNR and pERG signals may track with cortical abnormalities in NMDA receptor function and therefore serve to understand heterogeneity in patients' predispositions, course and treatment.

Title: Computer model of endocannabinoid effects in CA3

Authors: *M. A. SHERIF[1,3,4,8], P. SKOSNIK[1,3], M. HAJÓS[2], W. LYTTON[5,6,7,9]; [1]Psychiatry, [2]Comparative Med., Yale Univ., New Haven, CT; [3]Psychiatry, VA Connecticut Healthcare Syst., West Haven, CT; [4]Grad. program in biomedical engineering, [5]Neurol., [6]Physiol. & Pharmacol., [7]Biomed. Engin., SUNY Downstate Med. Ctr., Brooklyn, NY; [8]Ain Shams Univ. Inst. of Psychiatry, Cairo, Egypt; [9]Neurol., Kings County Hosp. Ctr., Brooklyn, NY

Abstract: Schizophrenia (SCZ) involves disturbances in neural function at different spatial and temporal scales. Theta (5-10 Hz) and gamma (30-100 Hz) oscillations have been shown to be abnormal in SCZ. In healthy volunteers, delta-9-tetrahydrocannabinol (THC), a cannabinoid-1 receptor (CB1R) partial agonist, induces symptoms similar to those reported in SCZ. CB1R agonism has been used to model some aspects of SCZ-related neural dysfunction in animals. Previous work has shown that CB1R agonism decreases theta (5-10 Hz), slow gamma (30-50 Hz), and fast gamma (60-90 Hz) power in CA3 region in rats. These converging data provide the impetus for developing a computer model of the CA3 region incorporating glutamatergic, GABAergic and endocannabinoid systems to investigate how CB1R agonism might explain the oscillatory changes that may in part underlie the various symptom domains of SCZ. The current model consisted of 2000 pyramidal cells, 100 parvalbumin-positive basket cells (PV cells), 100 cholecystokinin-positive basket cells (CCK cells) and 100 Oriens lacunosum Moleculare (OLM cells). Connectivity was based on the available literature and our previously published models. CB1R effects were implemented by varying GABA transmission at the synapses from CCK to pyramidal cells, as well as varying glutamatergic transmission at recurrent pyramidal connections. Experimentally, LFPs from CA3 region of 5 rats anaesthetized by intraperitoneal injection of chloral hydrate were obtained at baseline for model validation. Frequency bands within LFP signals were used to compare theta and low gamma oscillations with LFPs from the computer model. Model neurons were tuned to produce 8.3 ms membrane time constant for PV cells, 25 ms for CCK cells. In response to a depolarizing current of 100 pA, PV cells spiked at rate of 60 Hz, while CCK cells spiked at rate of 28 Hz. In response to a depolarizing current of 300 pA, PV cells spiked at rate of 132 Hz, while CCK cells spiked at rate of 52 Hz. In the LFPs from the model, emergent theta oscillations were seen at a frequency of 6 Hz, while slow gamma (high beta) oscillations were observed at 30 Hz, in agreement with rat controls from our experiments. These oscillation frequencies emerged from the much slower firing of pyramidal cell due to network interactions. Multiscale computer modeling is one suitable way to integrate findings from various modalities to reach a mechanistic understanding of the role the different elements play in the etiology and pathophysiology of brain disease. Such an understanding in SCZ can suggest potential treatments which would not be likely to be found through random ligand assessment.

Title: Antipsychotic drugs, social interaction behavior and AMPA receptor RNA editing in mice

Authors: *E. NWABUISI-HEATH[1], E. DONG[2], A. GUIDOTTI[2], M. SODHI[3];
[1]Dept. of Pharm. Practice, [2]Dept. of Psychiatry, [3]Departments of Pharm. Practice and Psychiatry, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Glutamate receptors have been implicated in the pathophysiology of stress-related psychiatric disorders, including schizophrenia. The non-NMDA ionotropic receptors are modified by a process known as adenosine to inosine (A to I) RNA editing which has been shown to influence the alternative splicing, trafficking and function of these receptors. We have investigated the role of glutamate receptor RNA editing in adult mice subjected to prenatal restraint stress (PRS). C57BL6 male mice subjected to PRS and non-stressed (NS) controls were administered with clozapine (5mg/kg), haloperidol (1mg/kg) or saline (vehicle) at postnatal day 70 via repeated subcutaneous injections twice daily for 5 days. PRS mice exhibited reduced social interaction behavior. Clozapine administration reversed the deficit in social interaction behavior in PRS mice, and significantly increased hippocampal GRIA2 flop RNA editing in PRS mice. In contrast, haloperidol administration did not reverse deficits in social interaction behavior, but increased GRIA2 flop RNA editing in the hippocampus of PRS mice. NS mice administered with clozapine had lower levels of GRIA2 flop RNA editing in the hippocampus, while haloperidol was associated with lower levels of GRIA2 flip RNA editing in the prefrontal cortex. Analyses of the RNA editing enzymes, ADAR1, 2 and 3, revealed significantly lower ADAR3 mRNA levels in NS mice administered with clozapine ($F_{1,8}=12.4$, $p<0.01$) in the hippocampus, while higher ADAR3 mRNA levels were detected in the PRS mice administered with clozapine in the hippocampus ($F_{1,8}=11.7$, $p<0.01$), relative to vehicle controls. We are testing RNA editing of GRIA3, GRIA4, GRIK1 and GRIK2 to determine whether PRS and antipsychotic drugs alter glutamate receptor RNA editing in a generalized manner or if these effects are specific to GRIA2. Our results indicate that GRIA2 RNA editing in the hippocampus is associated with social interaction behavior and antipsychotic drug treatment. GRIA2 RNA editing is predicted to result in altered trafficking and reduced channel conductance of AMPA receptors, which is considered to be important for synaptic plasticity, learning and memory. Therefore RNA editing of GRIA2 may be a novel target for the development of psychotropic drugs.

Title: Acoustic startle response in patients with bipolar disorder and schizophrenia

Authors: *J. L. FRESCHL[1], A. MANIAR[2], A. SHAH[2], J. V. PATTERSON[3];
[1]Univ. of California, Irvine, Fairfield, CA; [2]Univ. of California, Irvine, Irvine, CA; [3]Psychiatry, Univ. of California, Irvine Med. Ctr., Orange, CA

Abstract: The overlapping symptoms found in bipolar I disorder (BPI), schizophrenia paranoid type, and schizoaffective disorder (SczA) can make the diagnoses difficult to differentiate. This may lead to ineffective treatments. The goal of this study was to investigate a possible biomarker derived from an electrooculogram called the acoustic startle response. Both sensorimotor gating of the acoustic startle response, measured using prepulse inhibition (PPI), as well as startle habituation, have been found to differ in patients with BPI or schizophrenia and control subjects. PPI describes the phenomenon in which a weaker, prepulse stimulus inhibits the subject's startle response to a stronger stimulus. Impaired PPI levels correspond to abnormalities in the inhibitory processing system. Startle habituation occurs when the acoustic startle response is diminished to trials at the end compared to the beginning of the trial sequence. Previous studies have investigated PPI and habituation in psychiatric disorders, however most lack analysis of specific subgroups within these disorders. The current study investigated differences between disorders as well as their subgroups to provide evidence regarding the specificity of these acoustic startle measures as biomarkers. There were seven different conditions to measure startle habituation and prepulse inhibition: Two conditions were used to measure percent startle habituation: (1) Startle Alone (white noise burst 115dB, 40ms tone duration) was presented six times in succession at the beginning of the sequence, and compared to (2) Startle Alone presented six times at the end of the sequence. Five different conditions were used to measure PPI: (3) Prepulse tone (78dB, 20ms duration) preceding Startle Alone by 60ms; (4) Prepulse tone (86dB, 20ms) preceding Startle Alone by 60ms; (5) Prepulse tone (78dB, 20ms) preceding Startle Alone by 120ms; and (6) Prepulse tone (86dB, 20ms) preceding Startle Alone by 120ms; used with (7) Startle Alone, randomly presented with the PPI trials to calculate percent PPI. Subjects' ocular motor response to each Startle Alone stimulus was measured. Using repeated measures analysis of variance (Group x Condition), for all the groups, there were significant differences among stimulus conditions for PPI and startle habituation. PPI showed significant differences between the groups; PPI latency was longest for the SczA group. PPI also showed differences between subgroups within SczA, with SczA BP type showing the least PPI. The results indicate that the use of PPI may provide an objective measure to help differentiate psychiatric disorders.

Title: Perineuronal net deficits in the polyi:c model of schizophrenia

Authors: *J. W. PAYLOR[1], B. LINS[2], Q. GREBA[2], N. MOEN[1], J. HOWLAND[2], I. WINSHIP[1];
[1]Neurosci., Univ. of Alberta, Edmonton, AB, Canada; [2]Physiol., Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Schizophrenia (SCZ) is a psychiatric disorder that, despite a high prevalence (1% population worldwide) and burden of disease (1% global burden of disease), has a poorly understood etiology. While symptoms of SCZ typically manifest during adolescence and early adulthood, there is a substantial body of research linking prenatal events (e.g. early infection) to one's risk for developing SCZ. Human post-mortem analyses have suggested perineuronal nets (PNNs) as a potential biomarker for SCZ, as PNNs are deficient in a number of disease-specific regions of SCZ patients. PNNs, which surround parvalbumin positive (PV) inhibitory interneurons, typically mature during late adolescence and early adulthood when SCZ symptoms often first present. As such, we sought to examine whether a developmental PNN deficit is present in a maternal immune activation model of SCZ in rats. Long-Evans rat dams were treated at gestational day 15 with polyriboinosinic-polyribocytidilic acid (PolyI:C) to induce a strong maternal immune response. The litters were carried to birth and offspring allowed to develop to post-natal days 7 (PND7), 21, 35, and 90. We used immunohistochemistry to assess PNNs, staining with the lectin *Wisteria Floribunda Agglutinin,* and examined their integrity using epifluorescent and confocal microscopy across a number of brain regions: frontal association cortex, prelimbic cortex, reticular thalamic nucleus, primary auditory cortex, amygdala, and dorsal and ventral hippocampus. Additionally, we stained for microglia (anti-IBA1) and PV interneurons (anti-PV) to assess immune activation and PV assess neuronal integrity respectively. Our results indicate that PNNs are not present in postnatal day 7 rats but are significantly upregulated by PND21 and reach a mature state by PND35. From PND21 on, we found that PolyI:C treated offspring have widespread deficits in PNN development in the frontal lobe, temporal lobe, and thalamus. While we did not observe parallel deficits in PV interneurons in the adult stage, we did observe a deficit of these interneurons in the reticular thalamic nucleus at early developmental time points (PND7 & 21). PNNs are critical structures in the regulation of neuroplasticity and along with PV interneurons are crucial to critical windows of heightened plasticity during development. A deficit in PNNs could lead to a permanent pathological upregulation of structural plasticity into adulthood, as well as PV interneuron and cortical inhibitory network dysfunction. Our results not only further validate the PolyI:C model as an

effective model of SCZ, but provide a platform in which the role of PNNs in SCZ pathology can be further examined.

Title: PsychENCODE: cis-regulatory epigenome mapping in schizophrenia

Authors: ***M. KUNDAKOVIC**[1], Y. JIANG[1], V. POTHULA[1], L. BROWN[1], E. ZHAROVSKY[1], A. DINCER[1], R. JACOBOV[1], I. MAGRO[1], D. KAVANAGH[1,2], M. FROMER[1,2], M. PETERS[3], S. SIEBERTS[3], J. S. JOHNSON[1,2], P. SKLAR[1,2], S. AKBARIAN[1]; [1]Friedman Brain Institute, Dept. of Psychiatry, Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Dept. of Genet. and Genomic Sci., Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Sage Bionetworks, Seattle, WA

Abstract: The majority of genetic risk factors for psychiatric disorders reside in non-coding regions of the human genome which have largely unknown functions. Recently, the Encyclopedia of DNA Elements (ENCODE) project has characterized functionally relevant parts of the human genome in multiple cell lines and peripheral tissues, showing that gene regulatory regions are often cell- and tissue-specific. This led to the launch of an NIMH-funded PsychENCODE consortium aiming to identify non-coding functional genomic elements relevant to neurodevelopment and mental disorders. The goal of our PsychENCODE project is to construct detailed maps for multiple active (H3K4me1/me3, H3K27ac, and H3K36me3) and repressive (H3K27me3) chromatin modifications in human neurons and glia, and to subsequently assess the relationship of two of these marks (H3K4me3 and H3K27ac) to genetic risk factors for schizophrenia (SCZ) in the Common Mind Consortium cohort of 338 SCZ cases and 315 controls. We focus on post-mortem brain tissue including the prefrontal cortex and anterior cingulate cortex as the most likely sites of pathological changes related to SCZ. As the cellular milieu of the human brain is complex, our project includes epigenomic profiling of neurons and glia using FACS-based separation of neuronal and non-neuronal nuclei followed by ChIP-seq. To be able to perform cell-type specific epigenomic profiling in a large-scale study in an efficient and timely fashion, we have developed a very rigorous pipeline for the quality control of our data. Here, we will provide a detailed step-by-step procedure of all quality control steps

that include: control of the FACS-sorted material; testing of the efficiency of the micrococcal nuclease digestion; quality control of histone antibodies; quality control of ChIP DNA and ChIP-seq libraries as well as quality control of the sequencing data using a bioinformatics pipeline. We will show our first set of the ChIP-seq data that confirm and emphasize the importance of performing cell-type specific epigenomic profiling in the brain. Our H3K4me3 and H3K27ac ChIP-seq data from control brain specimens show sharper resolution when compared to the data derived from the whole cortical homogenates as well as consistent differences between neuronal and non-neuronal chromatin across different subjects and genomic regions. As the final step of this project, we intend to integrate the epigenomic profiles with DNA variation and RNA sequencing profiles from the same brain specimens. The findings of this project will provide an extraordinary opportunity to improve our understanding of gene regulation in the brain and schizophrenia-relevant pathology.

Title: Schizophrenia susceptibility gene dysbindin maintains prefrontal function

Authors: *W. ZHANG, K. M. DALY, B. LIANG, L. ZHANG, Y. LI, D.-T. LIN;
Intramural Res. Program, Natl. Inst. On Drug Abuse, Baltimore, MD

Abstract: Schizophrenia is a chronic brain disorder that affects ~ 1% of general population. Genetic studies have identified substantial numbers of susceptibility genes, however the pathophysiology of schizophrenia is still unclear and current pharmacological treatments offered limited success, especially for improving negative and cognitive symptoms. Unraveling pathological mechanisms of schizophrenia is critical for developing effective therapeutic strategies. Dysbindin (DTNBP1) is one of the earliest identified susceptibility genes. Genetic variations of Dysbindin have been well replicated as genetic risks associated with schizophrenia, and reduced dysbindin expression has been found common in brain areas of schizophrenia patients. To illustrate the mechanism of Dysbindin on brain function, we injected AAV1-Cre-eGFP virus into the prefrontal cortex (PFC) of Dysbindin conditional knockout mice, a well-

established brain region for its involvement in cognition and schizophrenia. We found that Cre virus injection led to loss of Dysbindin expression in neurons of PFC. We then analyzed synaptic transmissions and behavior of mice injected with virus. We found that loss of Dysbindin significantly shifted excitation/inhibition balance toward hyperexcitation in PFC compared with that of wild-type mice. Deletion of Dysbindin in PFC also disrupted behavior of those mice. These results showed the important role of Dysbindin in synaptic activities and functions of PFC.

Title: An investigation of synapse deficits in 22q11.2 Schizophrenia using patient induced stem cell derived neurons

Authors: *E. DEBOER;
Psychiatry, Children's Hosptial of Philadelphia, Philadelphia, PA

Abstract: A growing body of research has demonstrated that schizophrenia (SZ) is a neurodevelopmental disorder characterized by deficiencies in cortical connectivity and signaling, where post-mortem studies of SZ patients have uncovered reductions in cortical synaptic spine density and callosal white matter that astroglia are critical to synapse formation and the fidelity of the cortical network connectivity deficits observed in SZ is a virtually unexplored. Historically, there have been several great challenges to investigating connectivity in schizophrenia. First, there is extreme heterogeneity in the causal background genetics between patients of schizophrenia, as demonstrated recently nature of psychotic disorders to human, mouse models of psychotic disorders are limited in scope not only from an evolutionary perspective, but also because they typically represent a single, rare genetic risk factor of many hundreds. Finally, given the nature of schizophrenia, patient tissue samples are rare and typically represent a lifetime's worth of pharmaceutical and other confounds which complicate experimental control. The most common genetic correlate to SZ is the 22q11.2 deletion syndrome (22qdel), in which 20-30% of those affected develop SZ by adulthood; an incidence rate 20x greater than that of the general population. We have combined the use of induced pluripotent stem cells (iPSCs) from this patient population together with a previously published protocol for the rapid generation of forebrain neurons to conduct a robust, reductive analysis of synaptic and signaling deficits in 22qdel neurons.

Title: P200 activity patterns in bipolar, schizoaffective, and paranoid schizophrenia patients in response to gaps-in-noise

Authors: *R. B. BATINO[1], C. VILLEGAS[2], S. MONDAL[2];
[1]Univ. of California, Irvine Med. Ctr., Anaheim, CA; [2]Univ. of California, Irvine Med. Ctr., Orange, CA

Abstract: The overlap of bipolar I disorder (BPI) and two types of schziophrenia—paranoid schizophrenia (SczP) and schizoaffective disorder (SczA)—both genetically and clinically made it difficult to uniquely distinguish the three types of disorders. Identifying biomarkers or endophenotypes that distinguish these disorders more objectively than the clinical criteria defined in the DSM-V would aid in better understanding both the neurological and genetic underpinnings of the disorders. Temporal processing has been studied in psychiatric disorders, especially schizophrenia, showing that patients have temporal resolution deficits. This study focused on abnormal auditory temporal processing as a possible biomarker in BPI, SczP, and SczA. The main goal was to compare the brain response activity patterns in participants with BPI, SczA, and SczP to controls and to each other using a Gaps-in-Noise (GIN) paradigm. The GIN test is used to analyze auditory temporal processing by assessing subjects' ability to detect silent gaps in continuous white noise. Almost no studies have been done on whether there are differences between psychiatric groups using GIN testing to detect temporal processing deficits. In particular, event-related brain potentials (ERP) following the GIN can be used to reflect temporal resolution. One of the ERP components that reflect auditory temporal processing in the gap detection test is the P200. More studies are needed to clarify the significance of the P200 in healthy populations, schizophrenia, and BPI. However, P200 appears to be relevant to the study of schizophrenia, given that it has been linked to deficits in stimulus processing. This study evaluated ERP component P200 in BPI, SczA, SczP, and control patents in response to length of silent gaps in continuous noise (50, 20, 10, 5, and 2 ms). Specifically, there was a statistically significant interaction between gap length and diagnosis ($F= 2.77$, $p<.001$). To highlight, it was found that the larger the gap length, the larger the difference in peak-peak to amplitudes between

the four groups studied. There were significant differences between patient groups at 50, 20, and 10 ms silent gaps but not at 5 and 2 ms gaps. All groups showed significant effects of event type for latency. Differences between patient subgroups were also observed with the BPI manic and SAD Bipolar type subgroups showing the smallest amplitudes, again increasing as gap length increased. We can conclude that there is potential to use GIN testing as a better way to understand temporal processing in psychiatric disorders and to investigate its potential as a biomarker.

Title: Cortico-limbic circuit dysfunction in NMDA receptor hypofunction model of schizophrenia

Authors: *A. RAVIKRISHNAN, S. C. GUPTA, B. HILLMAN, S. M. DRAVID; Pharmacol., Creighton Univ., Omaha, NE

Abstract: Schizophrenia (SZ) is a neurodevelopmental disorder that occurs in approximately 1% of the population worldwide. Previous studies have demonstrated that pharmacological inhibition of NMDA receptors leads to schizophrenia-like phenotypes, and that genetic suppression of NMDAR function in inhibitory neurons of the cortico-limbic region enhances the likelihood of disease development and progression. Our previous behavioral analysis indicates that GluN2C knockout exhibits several behavioral phenotypes observed in schizophrenia including a deficit in prepulse inhibition. In addition lower GluN2C subunit expression is reported in cortex and thalamus of schizophrenia patients suggesting GluN2C knockout model exhibits both face and construct validity for schizophrenia. GluN2C subunit is enriched in the parvalbumin (PV) interneurons in the medial prefrontal cortex (mPFC) and reticular thalamus (nRT) that drive gamma oscillations which are thought to govern cognitive function and social behavior affected in schizophrenia. We observed a reduction in parvalbumin expression in the mPFC and reticular thalamus in GluN2C KO mice. Further electrophysiology and biochemical analysis demonstrated a reduction in excitatory tone as indicated by a reduction in mEPSC frequency in the mPFC which corroborated with a reduction in dendritic spine density. A contrasting increase in inhibitory tone on pyramidal neurons in the mPFC as indicated by an increase in mIPSC and perisomatic GAD67 puncta on pyramidal cells was observed. Overall, while some of our observations in the GluN2C KO mice parallel those seen in schizophrenic subjects, there also appear to be inconsistencies, particularly the shift towards greater inhibition, instead of cortical

overexcitation. We hypothesize that these changes represent early synaptic abnormalities during the progression of schizophrenia-like state. Ongoing studies are evaluating the developmental changes in cortical and thalamic E/I imbalance in the NMDA receptor hypofuncton model.

Title: Human neuropsychiatric disease modeling using conditional deletion reveals synaptic transmission defects caused by heterozygous mutations in Neurexin-1

Authors: *C. PAK[1], T. DANKO[1], Y. ZHANG[1], J. AOTO[1], G. ANDERSON[1], S. MAXEINER[2], F. YI[1], M. WERNIG[1], T. SUDHOF[1];

Abstract: Heterozygous mutations of the *NRXN1* gene, which encodes the presynaptic cell-adhesion molecule neurexin-1, are repeatedly associated with autism and schizophrenia. However, diverse clinical presentations of *NRXN1* mutations in patients raise the question whether heterozygous *NRXN1* mutations alone directly impair synaptic function in human neurons. To address this question under conditions that precisely control for genetic background effects, we generated human embryonic stem (ES) cells with two different heterozygous conditional *NRXN1* mutations, and differentiated them into homogenous excitatory neurons using direct differentiation protocol. Upon analyzing two different types of isogenic control and *NRXN1*-mutant neurons derived from targeted ES cells, we found striking synaptic phenotypes associated with these mutations. Both heterozygous *NRXN1* mutations selectively impaired neurotransmitter release without changing neuronal differentiation or synapse formation. Our results show that unexpectedly, heterozygous inactivation of *NRXN1* directly impairs synaptic function in human neurons, and suggest novel avenues to selectively study the effects of disease-associated mutations independent of genetic background.

Title: Understanding the neurobiology of early-onset schizophrenia using whole-brain computational modelling: a connectomics approach

Authors: *H. M. FERNANDES[1,2], J. CABRAL[1], T. V. HARTEVELT[1], T. CROW[3,1], A. C. JAMES[3,1], G. DECO[4,5], M. L. KRINGELBACK[1,2];

Pompeu Fabra, Barcelona, Spain; [5]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Abstract: Early-onset schizophrenia is a severely disabling illness which is currently not well understood in terms of its underlying neurobiology. However, emerging evidence suggests that schizophrenia is strongly linked to disrupted cortical connectivity. Yet, it remains unclear how to link between this structural connectivity with the altered network topology in the large-scale resting-state functional connectivity (rsFC) in schizophrenia. Whole-brain computational modelling has proved to be a robust and valuable tool to simulate and predict the underlying network dynamics that arise spontaneously from intrinsic brain processes. Such models have successfully reproduced many details of the empirical neuroimaging data (rs-fMRI and rs-MEG). We compared the structural connectivity of a group of 20 adolescent patients with early-onset schizophrenia with a group of 20 age and gender-matched healthy controls, having constructed the structural connectomes using probabilistic tractography on diffusion tensor imaging data. We used a whole-brain computational model of spontaneous large-scale brain activity to characterize the dynamical shifts from the optimal healthy regime and explore the role of the structural connectivity in the large-scale dynamics of the brains of patients and healthy controls. Complex network analysis was used to characterize the different properties of the SC network dynamics for the two groups. We found significant changes in the structural connectivity in core brain areas associated with cognitive and emotional processing. The computational modelling revealed that the brain operates with lower global coupling strength, which shifts the dynamics from the optimal healthy regime to a point where functional networks appear subtly randomized and less small-world when compared to healthy participants.

Title: Altered gene expression of proinflammatory cytokines and their membrane-bound receptors in the lymphocytes of schizophrenia patients

Authors: *H. ZHANG, H. S. RIZAVI, X. REN, G. N. PANDEY;
Univ. Illinois at Chicago, Chicago, IL

Abstract: Abnormalities of the immune function have been observed to be associated with the pathophysiology of schizophrenia. The abnormalities of the immune function in SZ are based on both direct and indirect evidence. For example, the administration of cytokines such as interferon (IFN) to rats causes a constellation of symptoms known as "sickness behavior" that includes cognitive changes, slowed cognitive speed, diminished social interactions and reduced locomotor activity and executive functions. That inflammatory processes are also involved in SZ are based on the observation that proinflammatory cytokines, which are released from the immune cells as a result of inflammation or stress, are abnormal in the serum of patients with SZ. Whereas proinflammatory cytokines and their soluble receptors are studied in SZ, the membrane-bound receptors, which are involved in mediating the biological and functions effects of cytokines have not been studied in the blood of SZ patients. To examine if SZ is also associated with the abnormal gene expression of cytokines and their membrane-bound receptors, we studied mRNA expression of proinflammatory cytokines and their receptors in lymphocytes of SZ patients and normal control (NC) subjects. We determined the protein and mRNA expression of proinflammatory cytokines and mRNA expression of their receptors in lymphocytes from 30 SZ patients and 30 drug-free NC subjects. The subjects were diagnosed according to DSM-IV criteria. Protein levels of cytokines were determined by ELISA, and mRNA levels in lymphocytes were determined by the qPCR method. We found that the mRNA levels of IL-6, TNF-α, IL-1R1, TNFR1, and TNFR2, but not IL-1β, IL-1R2, IL-1RA, IL-6R, or GP130 were significantly increased in lymphocytes of SZ patients compared with NC subjects. We also found that the protein expression of IL-6 and TNF-α, but not IL-1β, was also significantly increased in SZ patients compared with NC subjects. These studies suggest that in addition to the reported abnormalities of proinflammatory cytokines and their soluble receptors in the plasma of SZ patients, an abnormal gene expression of these cytokines and their membrane-bound receptors may be involved in the pathogenesis of SZ.

Title: Brain volume changes following chronic antipsychotic treatment in animal models: MRI and histological study

Authors: *E. GUMA[1], J. ROCCHETTI[1], G. A. DEVENYI[2], J. LERCH[3], G. DAL BO[1], A. MATHIEU[2], B. COURCOT[2], M. M. CHAKRAVARTY[2], B. GIROS[1];
[1]Douglas Res. Ctr. - McGill Univ., Verdun, QC, Canada; [2]Brain Imaging Ctr. - Douglas Res. Ctr., Montreal, QC, Canada; [3]Mouse Imaging Ctr. Hosp. for Sick Children, Toronto, ON, Canada

Abstract: Over the past few decades, Magnetic Resonance Imagine (MRI) studies have shown that schizophrenic patients have specific brain abnormalities. However, these patients are generally treated with antipsychotic drugs (APD), making it difficult to determine whether the changes in brain structure are due to the pathology, to the effects of the medication, or to a combination of both. In order to address this confound further, we used animal models to longitudinally investigate the effects of APD on regional and global brain volume using chronically treated D3 dopamine receptor (D3R) knock out (D3KO), and D2 dopamine receptor (D2R) knock out (D2KO) mice with typical –haloperidol (HAL 1mg/kg/day) – or atypical – clozapine (CLZ 5mg/kg/day). Studying the effect of a typical and atypical AP medication on the brain volume in D2KO and D3KO mice allows us to further investigate if any observed neuroanatomical remodeling observed is the result of interactions with D2-like receptors, highly targeted by typical AP medication, or whether these changes involve alternate pathways. Animals were scanned using a Bruker 7T small animal MRI scanner before starting treatments, and then at 3, 6, and 9 weeks, generating T2/T1-weighted images with 140 μm isotropic voxels. The Multiple Automatically Generated Templates (MAGeT) brain algorithm was used to automatically segment the volumes of 62 regions of interest per hemisphere. We found treatment by genotype interaction in the left hippocampus of D2KO mice ($p<0.03$), a genotype effects in the striatum and globus pallidus of D2KO ($p<0.0001$) and D3KO ($p<0.05$) mice, as well as the basal forebrain for D2KO ($p<0.001$) and D3KO ($p<0.001$) mice. Voxel-wise deformation-based analysis confirmed that D2KO mice have a strikingly larger striatum compared to WT, following 9 weeks of HAL treatment, both D2KO and WT mice showed increases in striatal size (after 1% FDR correction). D3KO mice tend to have larger striatums than WT; following HAL treatment, both had reductions in the basal forebrain (after 5% FDR correction). To further understand the cellular basis of these volume changes, analysis of NeuN+ neuronal populations, Iba1+ microglia, and GFAP+ astrocytes was performed in the prefrontal cortex (PFC), striatum and

hippocampus of all the scanned animals to assess for cell density measures. Preliminary analysis shows a decrease in astrocyte density following APD treatment in the WT but not D3KO mice. In conclusion, this study helps to elucidate the region-specific structural effects of antipsychotics on mouse brain and the pathways implicated in these changes, which could allow for improvements in the design of treatments for psychotic disorders.

Title: Adolescent stress induced white matter changes revealed by diffusion mri in disc1 transgenic mice

Authors: *C. LIU, Y. LI, T. JIANG;
Queensland Brain Inst., ST LUCIA, Australia

Abstract: Environmental stress can exert long-lasting influences on brain maturation, but responses to stress also depend on genetic make-ups. Here, we utilised a recently described transgenic mouse model that combined genetic (a putative dominant-negative DISC1 under expression control of the prion protein promoter) and environmental (adolescent social isolation) factors (Niwa et al., 2013). Since DISC1 is a risk gene for various mental illnesses that are associated with white matter abnormalities, we mainly investigated the association between white matter impairments and behavioural abnormalities in the model by diffusion MRI and histological approaches. Four groups of mice were involved in this study, including group-housed wild types, group-housed DISC1 mice, social-isolated wild types, and social-isolated DISC1 mice. The social isolation began at P35 and lasted for three weeks. Compared with group-housed mice, social-isolated DISC1 mice showed significant behaviour abnormalities, including hyper-locomotion activities, and deficits in spatial working memory and fear conditioning. Based on high-resolution diffusion MRI, we observed a significant difference in

the mean diffusivity of the left fimbria across groups, which was significantly correlated with locomotion activities and fear conditioning. Targeting the left fimbria, we quantified the densities of total cells (DAPI+), oligodendrocyte lineage cells (OLIG2+), and mature oligodendrocytes (CC1+), as well as intensity of myelin (MBP+). Social-isolated mice had significantly higher densities of oligodendrocytes than group-housed mice. Importantly, the higher density of oligodendrocytes in the left fimbria was associated with the lower mean diffusivity of diffusion MRI, supporting the assumption that the diffusion of water molecules was hindered within abnormal white matter structures. Considering that hippocampus/fimbria plays a key role in the negative regulation of hypothalamic-pituitary-adrenal (HPA) axis, our findings support a possible mechanism in which structural impairment of the fimbria may impact the HPA axis and glucocorticoids following influences of genetic and environmental factors.

Title: Human mutant DISC1 induced expansion of the hindbrain oligodendrocytes progenitors to the forebrain during early development - relevance to schizophrenia

Authors: *P. L. KATSEL[1], P. FAM[2], W. TAN[3], S. RUDCHENKO[4], M. PLETNIKOV[5], V. HAROUTUNIAN[6];
[1]Dept Psych, Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]JJ Peters VA Med. Ctr., Bronx, NY; [3]Mount Sinai Med. Ctr., New York, NY; [4]Weill Med. Col. of Cornell Univ., New York, NY; [5]Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [6]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Strong evidence corroborates involvement of oligodendrocyte (OLG) dysfunction in the pathophysiology of schizophrenia (SZ). We previously showed that the forebrain-restricted expression of mutant human DISC1 (hDISC1) exerts a significant influence on oligodendrogenesis during early development evidenced by premature OLG differentiation and increased proliferation of their progenitors in forebrain regions. Concurrent reduction of OLG progenitor markers in hindbrain regions during fetal stage suggested expansion of hindbrain glial progenitors into the forebrain of hDISC1 mice. We tested this hypothesis by examining gene and protein expression of the molecular determinants of hindbrain OLG development (EGR2 and Nkx2-2) in samples from forebrain and hindbrain regions at E15 and P0 hDISC1 mice.

Additionally, in a postmortem study the gene expression of hindbrain OLG markers were measured by qPCR in the superior temporal cortex of persons with SZ (N=61) and compared to those of neuropsychiatrically normal controls (N=59). We found forebrain-restricted upregulation of gene and protein levels of the OLG hindbrain markers (EGR2 and Nkx2-2) at E15. Mutant hDISC1 and endogenous DISC1 are colocalized with Nkx2-2 and EGR2 in OLG progenitor cells. Proximity ligation assay between endogenous DISC1 and Nkx2-2 determined that these proteins interact with each other. Expression of mutant hDISC1 showed reduced interactions between DISC1 and Nkx2-2, which was associated with increased proliferation and differentiation of OLGs. These data suggest suppressive function of endogenous DISC1 for differentiation of Nkx2-2 positive OLG progenitors during early development. In parallel to animal study, several markers of hindbrain OLGs (PRX, LAMA1 and MPZ) were significantly upregulated in superior temporal cortex of persons with SZ. Our findings suggest a suppressive role of DISC1 in hindbrain OLG development, while expression of mutant hDISC1 interfered with endogenous DISC1 suppressive function and leads to expansion of Nkx2-2 positive OLG progenitors responsible for developmental positioning of OLG identity cells along the rostrocaudal axis and thus affecting cortical organization of the brain. Given the critical role of DISC1 in migration of neuronal and glial progenitors during brain development, our results provide new clues for the developmental mechanisms contributing to oligodendrocyte dysfunction in SZ.

Title: Impulsive or indecisive: Impairments of decision making in a cortical circuit model of disrupted excitation-inhibition balance associated with schizophrenia

Authors: *J. D. MURRAY[1], T. BORDUQUI[1], J. HALLAK[2], A. ROQUE[3], X.-J. WANG[1]; [1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]Neurosci. and Behaviour Dept., [3]Dept. of Physics, Univ. of São Paulo, São Paulo, Brazil

Abstract: There is an increasing recognition that, ultimately, behavioral disorders associated with mental illness need to be understood in terms of impairments of basic neural computations and their underlying circuit causes. However, rigorous studies to test this perspective are scarce.

In this study, using a biophysically-based model of an association cortical microcircuit (Wang, Neuron 2002), we investigated how circuit abnormalities may lead to impaired time integration underlying multiple cognitive deficits. Disruption in the balance between excitation and inhibition (E/I balance) in cortex is a leading hypothesis for pathophysiologies of neuropsychiatric disorders such as schizophrenia. Disorders such as schizophrenia are also associated with cognitive deficits, including impaired decision making. However, it is poorly understood how disruptions of E/I balance at the synaptic level propagate upward to the behavioral level leading to deficits in cognitive processes such as decision making. To link these levels of analysis, we studied the effects of synaptic disruption of E/I balance on neural activity and decision-making behavior in a cortical microcircuit model. In particular, we tested the effects of hypofunction of NMDA receptors at two key sites: on inhibitory interneurons (thereby elevating E/I ratio via disinhibition), versus on excitatory pyramidal neurons (thereby reducing E/I ratio). We found that disruptions to E/I balance in either direction can lead to impaired decision making performance as assessed by psychometric curves. Nonetheless, these two regimes make dissociable predictions that can be tested with fine-grained analyses of the time course of evidence accumulation. In the regime of elevated E/I ratio, behavior can be characterized as impulsive. In this regime, evidence early in time is weighted much more than evidence late in time, compared to a control circuit. In contrast, in the regime of reduced E/I ratio, behavior can be characterized as indecisive. In this regime, the circuit exhibits weakened evidence integration and reduced competition between options. This is consistent with a crucial role of NMDA receptors in slow integration. These regimes are further distinguished from the scenario of impaired upstream coding of sensory evidence. Our findings characterize a role of E/I balance in cognitive functions supported by cortical circuits. The model makes specific predictions for behavior and neural activity that can be tested in humans or animals under pharmacological manipulation or in disease states. We propose important features of task design for sensitive probing of altered evidence accumulation in decision making.

Title: Targeting hippocampal dysfunction improves cognition in a schizophrenia model

Authors: Y. SHAO, *M. KOH, M. GALLAGHER;
Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD

Abstract: Recent clinical studies using neuroimaging and preclinical models of schizophrenia indicate that aberrant hippocampal excitability may contribute to cognitive impairment and augment psychotic symptoms due to disinhibition of dopaminergic neurons. Thus treatment with compounds targeting hippocampal overactivity to normalize this condition might improve hippocampal-dependent memory and reduce dopamine hyperactivation via functional pathways connecting the hippocampus and ventral tegmental area. Here, we tested this therapeutic approach to assess both cognitive impairment and a potential benefit on the positive symptoms of schizophrenia associated with dopamine dysregulation. In a well-established ketamine model, rats were tested with the antiepileptic medication, levetiracetam (LEV), which mediates its effect via synaptic vesicle glycoprotein 2A (SV2A) that prime vesicles for activity-dependent transmitter release. For preparation of the preclinical model of schizophrenia, we injected male Long-Evans rats at 2-mo of age with ketamine, a non-competitive NMDA receptor antagonist (30 mg/kg; twice a day), or vehicle saline for two weeks, and behaviorally tested them at adulthood (4-6 mo-old). Rats were tested for hippocampal-dependent spatial memory in an eight-arm radial maze task using an extended delay to assess retention. Ketamine-exposed rats committed more memory errors than control rats at a 3-hr delay between study and test phases. When treated with varying doses of LEV, ketamine-exposed rats showed a dose-dependent memory improvement with significantly fewer errors at 10 mg/kg compared with vehicle. Rats were also tested for amphetamine-induced locomotor hyperactivity, a standard assay used to assess the efficacy of antipsychotics to attenuate positive symptoms in preclinical models of schizophrenia. Amphetamine (0.5 mg/kg), a dopamine agonist, was given with or without LEV (10 mg/kg) treatment in independent assessments on different days. When comparing LEV treatment to vehicle, ketamine-exposed rats showed an attenuation of the increased locomotor activity induced by amphetamine. In contrast, control rats that had not received ketamine exposure showed no effect of LEV administration on their response to the amphetamine challenge. Together, these findings indicate that LEV may be useful for normalizing hippocampal activity in schizophrenia-related cognitive dysfunction, as well as moderating a positive symptom of schizophrenia due to dopaminergic dysfunction.

Title: Measuring the efficacy of therapy in chronic stroke, active and passive range-of-motion do not reflect improvements in upper-limb motor-function

Authors: *P. A. MCNULTY[1,2], T. TRINH[1,2], P. LEE[1], G. LIN[1], A. G. THOMPSON-BUTEL[1], C. T. SHINER[1], S. G. FAUX[3,2];
[1]Neurosci. Res. Australia, Randwick, Australia; [2]UNSW Australia, Sydney, Australia; [3]St Vincent's Hosp., Sydney, Australia

Abstract: Quantification of upper-limb motor-function is important to identify the status of functional ability after stroke, measure the efficacy of rehabilitation interventions, and provide motivation for stroke survivors to continue therapeutic activities. Range-of-motion is commonly used as an outcome measure in clinical trials. Active and passive range-of-motion were measured as part of a suite of upper-limb assessments for i) a randomised controlled trial of a dose-matched 14-day program of Wii-based Movement Therapy (WMT) or modified-constraint therapy (mCIMT) (n=42); and ii) with additional kinematic data that were quantified using wireless electrogoniometry from 12 stroke survivors during early (day 2) and late (day 14) WMT. Functional assessments included the Wolf Motor Function Test-timed tasks (WMFT-tt), upper-limb motor Fugl-Meyer Assessment (FMA), and Motor Activity Log Quality of Movement scale (MALQOM). There was no clear pattern of change for either active or passive range-of-motion in the randomised controlled trial data after the WMT or mCIMT group, and no difference between groups. Motor-function improved on the WMFT-tt ($p<0.001$), FMA ($p<0.001$) and MALQOM ($p<0.001$) with no differences between groups. For the kinematic study there was no change in either active or passive range-of-motion after WMT, whereas improvements were seen for the WMFT-tt ($p=0.02$), FMA ($p=0.004$) and MALQOM ($p<0.001$). Significant changes were seen for shoulder but not elbow excursion, and peak acceleration and deceleration were faster for all movements. There were no correlations between active or passive range-of-motion and kinematics (joint excursion, velocity, acceleration or deceleration), game performance, WMFT timed-tasks or FMA scores. Significant correlations were found only for active range-of-motion and MALQOM but only at the shoulder: flexion ($r2=0.17$, $p=0.04$); extension ($r2=0.37$, $p=0.002$); and abduction ($r2=0.50$, $p<0.001$). The results of these two studies suggest that neither active nor passive range-of-motion are sufficient outcome measures in chronic stroke. Kinematic data provide greater resolution but participants experiences were better reflected in MALQOM scores which suggested significantly improved independence in activities of daily living.

Title: A constrained motor connectome can predict function of fine motor tasks of the non-paretic hand after stroke

Authors: *S. PETERS, K. P. WADDEN, J. L. NEVA, L. A. BOYD;
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Objective: The nonparetic hand may compensate for reduced motor function of the paretic arm after a unilateral stroke. Animal models of stroke have shown that white matter damage distant from the lesion may impact function. Thus, structural reorganization of both hemispheres after a stroke may contribute to the resulting altered function of both paretic and nonparetic hands. The purpose of this study was to examine whether motor function of the nonparetic hand could be predicted from a constrained motor connectome (CMC). Methods: Participants underwent diffusion imaging scanning at a 3T MRI research centre. A previously published bilateral sensorimotor network mask, created from a functional MRI connectivity analysis that demonstrated a connected motor network in healthy participants during motor performance, was used to extract CMC information (Wadden 2015). This functional motor network was shown to correlate with paretic hand performance post-stroke. To quantify motor performance for this study, the Wolf Motor Function (WMF) and Fugl-Meyer (FM) upper extremity tests were assessed. For the WMF, movement time to complete 15 items with the paretic and nonparetic arms was determined. A task rate was calculated as 60seconds/performance time (s) with a score of '0' given if a participant was unable to perform the task. The WMF was also divided into fine (WMF-f) and gross (WMF-g) motor tasks with separate task rates calculated. Pearson's correlations were computed for the WMF, WMF-f, and WMF-g, with diffusion measures (apparent diffusion coefficient (ADC), fractional anisotrophy (FA)). A regression followed for the non-paretic WMF-f with age, post-stroke duration (PSD), and ADC as predictors. Results: Twenty-six participants (age 66.2±11.8 years, PSD 62.0±57.5 months) were scanned. On average, participants were moderately impaired (FM 48.0±16.8). The nonparetic WMF-f was correlated with ADC ($r=-0.41$, $p=0.04$), and not with FA ($r=0.27$, $p=0.18$). No additional correlations were found. Multiple hierarchical regression analysis revealed that lower ADC within the CMC predicted faster fine motor task rates of the nonparetic hand ($r2=0.36$, $p=0.05$) and accounted for an additional 12% of the variance after age/PSD. Conclusions: A CMC can predict nonparetic fine motor hand performance after stroke. The diffusion metric ADC, characterized motor performance better than FA, consistent with other

work (Boespflug 2014). Application of this connectome to the post-stroke brain, may provide a comprehensive whole-brain biomarker for post-stroke sensorimotor function, and lends support to the theory that both hemispheres participate in reorganization after stroke.

Title: Increased interhemispheric coherence during transcallosal inhibition assessment in chronic stroke: a preliminary TMS-EEG investigation

Authors: ***M. R. BORICH**[1], L. A. WHEATON[2], B. LAKHANI[3], S. M. BRODIE[3], L. A. BOYD[3];

Abstract: Introduction: Reorganization and remodeling of motor network connections contributes to recovery of arm function after stroke. Changes in effective network connectivity in humans after stroke can be studied using concurrent transcranial magnetic stimulation (TMS)-electroencephalography (EEG). The primary objective of this study was to use imaginary coherence (IC) analysis of TMS-evoked EEG responses to directly characterize interhemispheric interactions between the primary motor cortices (M1s) in individuals with stroke. Methods: Ten participants with chronic ischemic stroke in the right (n=5) or left (n=5) hemisphere and four matched controls were tested. Standard TMS procedures were conducted bilaterally. Transcallosal inhibition (TCI) was evaluated by delivering single suprathreshold (150% resting motor threshold) TMS pulses over M1 while performing an ipsilateral grip force contraction (50% maximum). Suprathreshold TMS pulses were also delivered at rest. 64-channel EEG recordings were collected concurrently during TMS assessments. All standard data pre-processing steps were performed in EEGLAB. Epochs were extracted for each participant and concatenated within each group for IC analysis. Post-TMS (0-300ms) IC values between electrodes overlying M1 (C3, C4) bilaterally were calculated within the beta frequency band (15-30Hz) as the primary dependent measure of interhemispheric IC. Secondary analyses subdivided the stroke group based on lesion hemisphere. Level of physical impairment was evaluated using the upper extremity portion of the Fugl-Meyer (FM) Assessment. Results: Individuals with

chronic stroke showed greater TMS-evoked interhemispheric IC compared to controls (p=.017) during TCI assessment. No differences were seen during the rest condition. Greater interhemispheric beta IC during TCI was observed in participants with lesions in the right hemisphere regardless of stimulation site (p=.002). Qualitatively, participants with lesions in the left hemisphere exhibited greater arm impairment (median FM score: 16) compared to individuals with right hemispheric lesions (median FM score: 57). Discussion: Preliminary findings suggest increased interhemispheric interactions between M1s during an active motor state are present in chronic stroke that may be behaviorally relevant to persisting disability.

Title: A preliminary examination of electrical impedance myography in stroke

Authors: *H. SHIN, X. LI, S. LI, P. ZHOU;
Physical Med. & Rehabil., UT Hlth. Sci. Ctr. at Houston, Houston, TX

Abstract: Electrical Impedance Myography (EIM) was used to assess changes in muscle architecture and composition after a stroke. Eight subjects who suffered from chronic hemiparetic impairments (ages 47-70 years) participated in the study. The EIM was measured bilaterally from the biceps brachii muscles using high-frequency, low-intensity alternating current. Three major EIM parameters, resistance, reactance and phase angles, were calculated from the recorded voltage, representing tissue resistivity, membrane permittivity and membrane oscillation properties of the muscle, respectively. Electrical anisotropy of the muscle was also examined as the ratio between transverse and longitudinal impedance parameters. Comparison of muscle impedance variables between the paretic and contralateral side disclosed a pronounced decrease of values in muscle reactance and phase angle on the paretic biceps at 50 kHz frequency. The muscle tissue resistance, however, did not show significant difference between the two sides. Results from muscle anisotropy estimation indicated a lower value of the resistive anisotropy on the paretic biceps compared with the contralateral side. Such observance may reflect muscle structural changes induced by loss of muscle fibers and fat infiltration or quality changes of cell membranes post stroke.

Title: Imbalance between frontal and parietal cortex during choice reaction task in patient with spatial neglect

Authors: *Y. TAKAMURA[1,2], S. OHMATSU[1,2], M. IMANISHI[2], M. OSAKA[2], T. TOMINAGA[2], S. MORIOKA[3], N. KAWASHIMA[4];

Inst. Natl. Rehabil. Ctr. for Persons with Disabilities, Saitama, Japan

Abstract: Introduction Dorsal and ventral attention network is well known as distinct attentional processes such as top-down controlled attentional selection and the detection of unexpected stimuli, respectively. In this study, we attempted to clarify the relationship between two attention systems in patients with unilateral spatial neglect (USN) based on the results of electroencephalographic (EEG) recordings during choice reaction task. Method 21 patients with right hemisphere lesion participated in this study. The patients were divided into two subgroups based on the score of the behavioral inattention test (BIT) : spatial neglect: (USN, n=13), and non- USN right hemisphere damage group (RHD, n=8). Participants seated at the chair in front of eye tracker mounted PC display (Tobii TX60 Tobii inc., Sweden) and asked to perform eye pursuit-based choice reaction task. The task consists of 150 trials of eye pursuit motion toward a one of five randomly flashed circular objects after .5 second of auditory cue those are horizontally located on the display. In order to discuss neural mechanisms underlying behavioral results, EEG (19ch) was recorded during the task. We mainly focused on phase synchronization in the frontal and parietal lobes at before and after auditory cue. Result and discussion Our results clearly demonstrated that most of patients in USN group showed leftward gaze shift before the onset of eye movement. This phenomenon might reflect a compensatory strategy to overcome neglect symptom. While USN group showed strong synchronization in frontal lobe between before and after beep alert, RHD group contrastingly showed strong synchronization in parietal lobe. Interestingly, an extent of imbalance of phase synchronization between frontal-parietal lobes was clearly significantly correlated with the extent of leftward gaze shift in USN group, suggesting that those who could not activate bottom-up attention due to stroke tended to show greater frontal activity. Our result gives one of insight with regard to the compensational strategy if the bottom-up attention was disrupted due to brain damage.

Title: Mapping brain function at the bedside during acute stroke recovery using High-Density Diffuse Optical Tomography

Authors: ***K. M. BERGONZI**[1,2], A. T. EGGEBRECHT[3], A. K. FISHELL[4], J.-M. LEE[5], J. P. CULVER[3,2,6];

Abstract: Introduction: Ischemic stroke, the major stroke subtype, typically begins with the occlusion of an artery in the brain. During the first hours after onset, brain injury evolves rapidly. MRI and CT provide clinicians with snapshots of brain structural health, while behavior is quantified via the patient's NIH Stroke Scale (NIHSS). An imaging modality that continuously measures brain function at the bedside could provide more frequent assays to better understand the acute progression of stroke and potentially inform clinical decisions. We have developed a portable high-density DOT system (Fig. 1a) that can measure changes in cortical blood oxygenation at the bedside. Herein, we demonstrate that HD-DOT is sensitive to altered brain function brought about by ischemic stroke as measured in the first 72 hrs since last known normal. Methods: The HD-DOT system contains 48 sources, each with both 750nm and 850nm light for spectroscopy, and 34 detectors. The imaging cap covers sensory, motor and cognitive areas (Fig. 1b). A total of 32 patients have been scanned; 21 were excluded due to poor data quality. Functional data obtained includes up to 50 minutes of resting quietly. Scanning did not

interrupt standard clinical care. Functional connectivity (fcDOT) analysis was performed on the [HbO] data. The fc results were summarized by a within hemisphere similarity metric which, for given seed or group of seeds, calculates the spatial correlation between a subject of interest and a group map of healthy controls. Concurrent with the DOT scan, we acquired the NIH Stroke Scale as a behavioral metric of stroke-induced functional deficit. Results: The presence of an infarct appears to disrupt typical bilateral connectivity patterns (Fig. 1d,f,h). . Across a group of stroke subjects (n=11) all had statistically significant lower within hemisphere similarity scores ($p<0.001$). Conclusions: Functional imaging using High-Density fcDOT can differentiate between a healthy and injured hemisphere and may have the potential to serve as a continuous longitudinal surrogate to behavioral exams.

Title: EEG phase synchrony of sensorimotor area reflects limb functions after stroke

Authors: *T. KAWANO[1], N. HATTORI[1], Y. UNO[2], K. KITAJO[2], M. HATAKENAKA[1], H. YAGURA[1], H. FUJIMOTO[1], T. YOSIOKA[1], M. NAGASAKO[1], I. MIYAI[1];
[1]Neurorehabilitation Res. Inst., Morinomiya Hosp., Osaka, Japan; [2]Rhythm-based Brain Information Processing Unit, RIKEN BSI-Toyota Collaboration Ctr. (BTCC), Riken Brain Sci. Inst., Saitma, Japan

Abstract: Objective: Focal brain lesions due to stroke can cause remote effects on neural networks. We previously reported a significant relationship between interhemispheric phase synchrony index (IHPS) and the Functional Independence Measure (FIM), a standard clinical scale for activity of daily living (ADL). The aim of this study is to investigate the association between the Phase Synchrony index (PSI) of a single electrode pair C3-C4, placed near the sensorimotor area symmetrically, and the motor scores of the Fugl-Meyer Assessment (FMA), a standard clinical scale for motor impairment after stroke. Methods: Forty-three patients with postacute supratentrial ischemic stroke (mean age 66.0 ± 13.7 years, 10 women, average duration was 40.6 ± 16.5 days after onset) admitted for inpatient rehabilitation were enrolled. After 2.5 minute measurement of eye-closed EEG, noisy epochs were eliminated by automatic processing.

The PSI of four frequency bands (alpha (α) (8-12Hz), beta (β)1 (13-18Hz), β2 (19−30Hz), and gamma (γ) (31-45Hz)) were computed, and correlations of the PSIs with the upper- and lower-limb motor scores of the FMA were investigated. In addition, EEG and the FMA scores were measured at discharge as well as on admission with average interval of 96.0±51.1 days in 19 subjects and index for the improvement in the upper-limb FMA scores (FMA index) and the increase in the PSI (PSI ratio) were calculated to evaluate longitudinal changes. For the statistical analysis, Spearman's correlation coefficient ρ was used with Bonferroni correction. Results: The PSI significantly correlated with upper and lower FMA scores in the β2 band ($\rho = 0.43$, $p = 0.0045$ and $\rho = 0.44$, $p = 0.0030$, respectively) and in the γ band ($\rho = 0.45$, $p = 0.0023$ and $\rho = 0.44$, $p = 0.0031$, respectively). No significant correlation was observed with the PSIs of adjacent electrode pairs (F3-F4 and P3-P4). In the longitudinal analysis, both the upper- and lower-limb FMA scores significantly improved at discharge. The upper-limb FMA indices and the PSI ratios significantly correlated only in the γ band ($\rho = 0.60$, $p = 0.0069$) Conclusion: The PSI near the sensorimotor area significantly correlated with the FMA scores representing upper and lower limb motor functions in a frequency-specific manner. In addition, the improvement of upper limb function significantly correlated with the increase of the PSI in the γ band in the relevant area. Thus, C3-C4 PSI can be a useful biomarker for the assessment of motor impairment after ischemic stroke.

Title: Correspondence of breath-hold and resting-state vascular reactivity measures in stroke patients

Authors: *R. V. RAUT, V. A. NAIR, C. LA, V. PRABHAKARAN;
Univ. of Wisconsin-Madison, Madison, WI

Abstract: Due to its vascular nature, stroke can lead to considerable changes in cerebrovascular reactivity (CVR) that could confound fMRI data. Measures of CVR may be of great utility in stroke patients for evaluating CVR and predicting regions of neurovascular uncoupling, as well as scaling task-fMRI data - which is dependent on intact neurovascular coupling - to increase its validity; however, they have thus far seen little use in the stroke population. Resting-state fluctuation amplitude (RSFA) is uniquely free of task-related confounds and may be best-suited for these purposes, though its correspondence with well-validated CVR measures has only been assessed in healthy populations, and in just a handful of studies (e.g., Kannurpatti & Biswal, 2008). We aimed to confirm voxel-wise agreement of RSFA and breath-hold CVR mapping in both young (N = 23, mean = 22 years) and old (N = 22, mean = 59 years) healthy subjects, and to determine this correspondence in acute stroke patients (N = 22, mean = 59 years). All participants completed a 10-minute resting-state and a 3-minute, 20-second-interval breath-holding scan. High average RSFA to breath-hold correlations ($r > .70$, $p < .01$) were observed for all three groups, with no significant between-group differences. This is the first study to assess the validity of RSFA in a clinical population. Our findings suggest that RSFA, which can be obtained from a short resting-state scan, may be a viable alternative to breath-hold CVR mapping and could be useful for the evaluation of CVR and task-fMRI scaling in stroke patients.

Title: Prolactin alteration after repetitive transcranial magnetic stimulation

Authors: *B. KEPPLINGER[1], B. SEDLNITZKY-SEMLER[2], C. KRONSTEINER[2], H. BARAN[2];
[1]Karl Landsteiner Res. Institute, Mauer, Mauer-Amstetten, Austria; [2]Karl Landsteiner Res. Inst. Mauer, Mauer-Amstetten, Austria

Abstract: Background: Repetitive transcranial magnetic stimulation (rTMS), a non-invasive brain stimulation technique has been suggested to be effective for the treatment of stroke patients. This study was designed to evaluate clinical outcome, EEG and changes of clinical markers prolactin and creatine-phosphokinase (CK). rTMS was performed using a Magstim Rapid 2 stimulator with a frequency up to 100 Hz. Coil position was determined by Brainsight Navigator®. The treatment was performed with a total number of ten sessions per patient, each with a train of 1000 stimuli. Intensity ranged at 80 % of resting motor threshold. The therapeutic effects were measured by NIHSS, Barthel-index and Ashworth scale. Prolactin is secreted from the pituitary gland in response to eating, mating, estrogen treatment, ovulation and nursing. Prolactin and CK level raise following epileptic seizures therefore, measurement of prolactin and CK are used as indicators for safe application of rTMS. Methods: Stroke patients with an age between 52-70 years (2F/11M) and an age between 71-89 years (4F/17M), 6 months after stroke were involved in the study. EEG and blood sampling were performed before, after the 5th and after the 10th stimulation session. Serum was coded to make the investigation anonymous and the study was carried out according to the ethical regulations of Lower Austria. Prolactin and CK were determined by Cobas 6000, Roche Diagnostics using Electro-chemiluminescence immunoassay (ECLIA) and UV-Spectrophotometric method, respectively. The one-way ANOVA and Student's t test was applied. Results: Stroke patients reported positive response after rTMS application. Prolactin and CK levels in the serum of stroke patients were in normal range, however we could observe a decrease of prolactin levels in female's patients with progressed age, while in males prolactin levels was increased. After rTMS treatment prolactin levels in male stroke patients were affected moderately, while in female stroke patients prolactin levels were changed significantly in the serum. In serum of female stroke patients younger than 70 years, prolactin levels were reduced significantly after 10th rTMS application (55 %, P = 0.0260) comparing with concentration before the 1st rTMS. CK concentration was not changed in stroke patients after rTMS. Conclusion: A significant enhancement of motor performance and a reduction of spasticity could be observed after rTMS. Positive clinical response in stroke patients, particularly in women could be due to prolactin changes in the periphery and probably also in the CNS after rTMS. Revealed data strongly suggest an advantage of rTMS also in patients with Parkinson symptoms.

Title: Proportional resolution of upper limb impairment after stroke depends on corticomotor integrity

Authors: *C. M. STINEAR[1], W. D. BYBLOW[1], A. BARBER[1], M. A. PETOE[2], S. J. ACKERLEY[1];
[1]Univ. of Auckland, Auckland, New Zealand; [2]Bionics Inst., Melbourne, Australia

Abstract: Recovery of motor function reaches a plateau within the first 3-6 months after stroke. Within this time patients also exhibit a resolution of upper limb impairment that is about 70% of the maximum possible, termed the "70% rule". A caveat is that the rule is upheld only for patients without severe initial impairment, but the boundary score has been difficult to identify a priori. Our aim was to determine if classifying patients based on functional and structural integrity of the corticomotor pathway would yield more accurate predictions about who will fit the rule. Using transcranial magnetic stimulation and MRI we tested the hypothesis that patients with a functional corticomotor pathway would fit the 70% rule, whereas those without would not. Resolution of upper limb impairment was examined in 93 patients in two cohorts. The first cohort of 48 patients received 4 weeks of standardised upper limb therapy. The Fugl-Meyer upper extremity assessment, motor evoked potentials and motor threshold in the paretic extensor carpi radialis, and fractional anisotropy asymmetry index between the posterior limbs of the internal capsule were determined. Initial impairment score, the presence of motor evoked potential and fractional anisotropy asymmetry were the only predictors of impairment change, indicating a key role for corticomotor tract function in recovery. For patients with motor evoked potentials at 5 days, initial impairment was the sole predictor of impairment change (impairment change = 0.45 × initial impairment, adjusted r2 = 0.88; 0.64 × initial impairment, adjusted r2 = 0.88; 0.70 × initial impairment, adjusted r2 = 0.95, at 6, 12 and 26 weeks respectively). The 70% rule was upheld for patients with motor evoked potentials irrespective of their initial impairment. The neural mechanisms underlying the rule are not known. The present study indicated that ipsilesional resting motor threshold decreased to a similar extent and time course to the upper limb impairment resolution. Another cohort (45 patients, all with motor evoked potentials at 5 days) was similarly examined in a rehabilitation setting. This cohort had a lower upper limb therapy dose than the previous cohort ($p < 0.001$). By 12 weeks impairment change was 0.68 × initial impairment (adjusted r2 = 0.92) and was insensitive to upper limb therapy dose ($p = 0.55$). These findings indicate that proportional resolution of impairment may occur within the ipsilesional corticomotor pathway, and may be insensitive to conventional upper limb physical therapy.

Abstract: During stroke recovery, excitatory neurons in the peri-infarct cortex undergo structural re-arrangements, at both the level of dendritic branches and spines. In contrast, very little is known about how stroke affects the morphology of cortical interneurons. This knowledge gap should be addressed because most interneurons release GABA and regulate cortical excitability, which is profoundly disrupted after stroke. Interneurons expressing vasoactive intestinal peptide (VIP) specialize in inhibiting other classes of inhibitory cortical neurons, such as those expressing parvalbumin (PV) and somatostatin (SOM). We utilized longitudinal *in vivo* two photon imaging and Cre-dependent transgenic mouse lines to investigate how stroke alters the growth and stability of dendritic arbors, spines and axons of VIP cortical interneurons. Our data shows that like their pyramidal neuron counterparts, VIP neurons in the peri-infarct cortex lose a significant number of dendritic spines in the first week after stroke. The initial loss of spines was followed by a protracted period of dendritic spine instability. The dendritic arbors of these neurons were stable before stroke, but showed a significant and balanced increase in branch tip extensions and retractions (>5μm in length) for up to 3 weeks after stroke. Stroke also increased the turnover ratio of peri-infarct en passant and terminal axonal boutons in a spatially restricted manner. Thus, afferent and efferent connectivity of VIP interneurons becomes highly unstable after stroke which may permit excessive inhibitory drive (from downstream PV and SOM interneurons) in the recovering cortex. The functional consequences of stroke related changes in VIP interneuron connectivity are currently being explored.

Title: Dorsal damage - ventral compensation: structural reorganization of left superior temporal and bilateral fusiform gyri induced by perinatal infarct in occipito-parietal cortex

Authors: *S. BAE[1], M. SCHAER[1,2], M. BEIDELMAN[1], T. EVANS[1], M. ZEINEH[3], C. BATTISTA[1], V. MENON[1];

Abstract: Brain lesion studies provide insights to the functional specificity of the focal region of injury and the compensatory neural mechanisms that may occur in lesion patients. However, little is known about the neurodevelopmental trajectory of such case studies when compared to gender and age matched longitudinal control samples. Here we report a longitudinal case of a female at age 9 and 10 with a perinatal infarct in the left occipito-parietal cortex, leading to aberrant cortical development of dorsal Brodmann area 19. In the absence of any neurological or psychiatric disorders, or learning disabilities, our goal was to identify compensatory mechanisms at the neuroanatomical level. We examined cortical morphometry using surfaced-based measures such as cortical thickness, local volume, and gyrification using FreeSurfer and computed the rate of change between the two time points. We then compared these measures at each vertex to the ones obtained from a longitudinal control group of females (n=19, age at Time 1 *M*= 8.5, *SD*=0.57 and Time 2 *M*= 9.5, *SD*=0.60) to obtain z-scores at each vertex, following previous approach suggested for automatic identification of focal dysplasia (Thesen et al., 2011). A cognitive profile was also compared against the same group of controls utilizing standardized measures of IQ (WASI) math and reading (WIAT-III & WJ-III). As expected, all cortical metrics above captured the localization of the lesion at baseline (z-score<-2). Further decreases in cortical thickness was observed in the left superior temporal gyrus (STG). Increased volume and area were identified in bilateral lingual/fusiform gyrus, right anterior temporal pole and left inferior temporal gyrus (z-score>2). Increased gyrification was found in the left inferior temporal gyrus. Patterns of thickness and volume changes were similar over a one year period, including less cortical thickness and volume decreases in the left superior temporal sulcus, supramarginal gyrus, bilateral dorsomedial prefrontal cortex, and right lingual gyrus (z-score<-2). This was accompanied by a fairly typical behavioral profile with the exception of superior nonverbal intelligence scores on standardized cognitive measures relative to controls, indicating potential compensatory mechanisms. Our study demonstrates the feasibility of automated extraction of cortical lesion, along with the delineation of associated compensatory changes from a longitudinal perspective. Results from the surface-based morphometry analysis suggest that

damage to the dorsal stream leads to structural reorganization within the ventral stream that may be associated with nonverbal visuospatial processing.

Title: Lesion location is associated with kinaesthetic impairment post-stroke

Authors: ***J. M. KENZIE**[1], J. A. SEMRAU[1], S. E. FINDLATER[1], J. A. DESAI[1], A. Y. YU[1], T. M. HERTER[2], M. D. HILL[1], S. H. SCOTT[3], S. P. DUKELOW[1];
[1]The Univ. of Calgary, Calgary, AB, Canada; [2]Univ. of South Carolina, Columbia, SC; [3]Queen's Univ., Kingston, ON, Canada

Abstract: Objective: Kinaesthesia, our sense of limb movement, is impaired in over 60% of individuals after stroke. Kinaesthetic impairments correlate with decreased motor recovery and decreased functional independence post-stroke. However, these impairments often are not identified clinically due to a lack of sensitive and reliable measurement techniques. Methods: To evaluate kinaesthesia, we used a mirror matching task of the upper limbs on a KINARM robotic exoskeleton. During this task passive movements of the stroke affected arm were made by the robot and subjects used their unaffected arm to mirror match the movements. We recorded measures of movement direction, speed, amplitude and response time to the passive movement. Subjects also underwent brain MRI or CT imaging within 10 days post-stroke (mean = 2 ± 2 days) to identify the location of lesion. Voxel-based Lesion Symptom Mapping (VLSM) and statistical region of interest (sROI) analyses were used to compare lesion location with kinaesthetic performance. Results: A total of 136 subjects (93 M, 43 F) were assessed within 30 days post-stroke (mean = 9 ± 6 days). Compared to healthy controls, 64.7% of subjects had impairments in movement direction perception, 31.6% in movement speed, 44.1% in movement amplitude, and 41.9% in response time. VLSM and sROI analyses identified discrete lesion locations associated with these different aspects of impaired kinaesthesia. Impaired perception of speed and direction of movement were significantly associated with lesions to primary somatosensory cortex, supramarginal gyrus, and the superior parietal lobule. Impaired perception of speed was also significantly associated with lesions to the middle frontal gyrus. Conversely,

impaired perception of arm path length was significantly associated with lesions to the caudate head, anterior striatum, and internal capsule. Increased response latency was significantly associated with lesions to the insula, subcortical white matter, superior temporal lobe, inferior and middle frontal lobes, and parietal lobe. Performance on all but one kinaesthetic measure was significantly correlated with clinical measures of functional independence and motor ability. Conclusions: These data suggest that different cortical and subcortical areas are required for processing different aspects of kinaesthesia. In addition, we provide further evidence for the importance of intact kinaesthesia in functional independence post-stroke.

Title: Lesion Symptom Mapping of brain regions involved in action selection and specification during Trail Making

Authors: *S. TRYON[1,2], O. SPEAD[2], A. MIDDLETON[2], B. MAREBWA[2,6], C. RORDEN[3,4], J. FRIDRIKSSON[5,4], S. FRITZ[2], T. HERTER[2];

Abstract: Introduction: Approximately one million Americans live with chronic post-stroke disabilities including limitations performing activities of daily living. Many daily activities, such as driving, involve continuous interactions between perceptual, cognitive and motor systems. Performance of these activities inherently involves neural networks that are broadly distributed across cortical and subcortical brain regions. A recent theoretical framework, the affordance competition hypothesis, proposes that action selection (choosing among alternative actions) is mediated by prefrontal-basal ganglia networks and action specification (planning spatial and temporal aspects of movements) is mediated by parietofrontal networks. Mapping patterns of brain damage to chronic behavioral impairments following stroke may improve our ability to identify and select rehabilitation interventions that minimize long-term disability. Here we use

Lesion Symptom Mapping (LSM) to identify brain regions that mediate performance of the Trail Making Test (TMT), a neuropsychological assessment that is predictive of post-stroke performance on driving tests. Methods: High-resolution anatomical neuroimaging was collected from 48 stroke survivors between 37 and 80 years of age. Subjects used a robotic device (KINARM Endpoint Lab, BKIN Technologies, Kingston, Canada) to perform two TMT tasks with their less affected hand. In the numeric task (TMT-A), subjects connected numbers (1, 2, ⋯ 25) and in the alphanumeric task (TMT-B) they connected numbers and letters (1, A, 2, B, ⋯ 13) in the shortest possible time. LSM was performed using the nii_stat tools in SPM12 (http://www.nitrc.org/projects/niistat), which mapped impairments in TMT-A and TMT-B to lesioned brain regions of the Johns Hopkins University (JHU) atlas. Results: Robotic measures of impairments on TMT-A were correlated with lesions of the precentral gyrus, postcentral gyrus, and middle frontal gyrus. Additional impairments observed in TMT-B were associated with lesions of the middle frontal gyrus and basal ganglia. Conclusions: These findings provide evidence that the parietofrontal and prefrontal-basal ganglia networks mediate action selection and specification during the TMT. They also suggest that neuroimaging may be used to provide prognostic information that can improve stroke outcomes through better optimization of rehabilitation interventions.

Title: Ischemic versus Hemorrhagic Stroke: Differences in motor recovery rates

Authors: *S. E. FINDLATER[1], J. A. SEMRAU[2], J. M. KENZIE[2], A. Y. YU[2], R. T. MOORE[2], T. M. HERTER[3], S. H. SCOTT[4], S. P. DUKELOW[2];
[1]Clin. Neurosciences, [2]Univ. of Calgary, Calgary, AB, Canada; [3]Univ. of South Carolina, Columbia, SC; [4]Queen's Univ., Kingston, ON, Canada

Abstract: Stroke is a leading cause of disability that typically requires lengthy rehabilitation. Emerging evidence indicates that stroke subtypes have differing recovery patterns. Rehabilitation

outcome studies indicate that patients with hemorrhagic stroke show greater initial impairment, but greater improvement at discharge compared to those with ischemic stroke. These findings are based on broad clinical measures such as the Functional Independence Measure or the Rankin Scale. However, these measures do not directly relate to impairments targeted with rehabilitation interventions. This study aims to determine whether motor recovery profiles differ between ischemic and hemorrhagic stroke. Using a robotic exoskeleton, motor function was assessed using a standard 8-target center-out reaching task. Subjects (N = 115; 96 ischemic, 19 hemorrhagic) were assessed at 1, 6, 12, and 26 weeks post-stroke. Motor performance was quantified according to performance on several spatial (e.g. direction error) and temporal (e.g. movement time) parameters. Determination of task and parameter impairment was based on healthy control normative ranges. Statistical Region of Interest analyses were used to compare motor performance with stroke lesion location. Preliminary results suggest that ischemic (IS) and hemorrhagic (HS) strokes demonstrate significantly different motor performance across the course of recovery. At 1-week post-stroke, IS subjects had significantly better motor performance than HS subjects on four parameters of the reaching task (movement time; initial direction error; number of speed peaks; and max speed, unpaired t-tests, $p < 0.05$). At 26-weeks post-stroke, IS subjects performed significantly better on all four motor parameters ($p < 0.05$). This trend persisted when we considered overall task performance across all parameters. At 1-week post-stroke, 24% of IS subjects demonstrated normal performance. In contrast, no subjects in the HS group performed normally at 1-week post-stroke. At 26-weeks post-stroke, 64% of the ischemic sample performed within normal limits, compared to 32% in the hemorrhagic group. Thalamic lesions were present in 63% of those with hemorrhagic stroke who demonstrated poor performance at 26 weeks. Preliminary analyses suggest that ischemic and hemorrhagic strokes may have significantly different motor recovery profiles. Subjects with hemorrhagic stroke were more impaired initially and at 26 weeks post-stroke compared to those with ischemic stroke. Additionally, thalamic hemorrhages may negatively impact motor recovery. These findings may provide prognostic information to guide rehabilitation practitioners.

Title: Neuroanatomical correlates of visually guided reaching after stroke

Authors: J. E. TAPPER[1], S. E. FINDLATER[1], J. M. KENZIE[1], M. M. WANG[1], J. A. DESAI[1], A. Y. X. YU[1], T. M. HERTER[3], S. H. SCOTT[4], *S. P. DUKELOW[2];

Abstract: Upper limb dysfunction occurs in many individuals after acute stroke. Understanding the neurological impairments that result from a given stroke lesion is fundamental to the development of targeted rehabilitation interventions to improve functional outcomes after stroke. This study invokes robotic technology and neuroimaging based voxel-wise lesion statistical analysis to investigate these structure-function relationships. We hypothesized that neuroanatomical correlates exist for performance deficits on visually guided reaching after stroke. We studied 141 subjects after acute stroke. Stroke lesions were identified on MR brain images (T2 FLAIR, DWI/ADC) or CT images at 2-10 days post stroke. Brain images were transformed to MNI stereotaxic coordinates for comparison across individuals. Movement of the stroke-affected arm during a visually guided reaching task was measured with the KINARM exoskeleton within 4 weeks of stroke. Nine behavioral variables were derived from the movement data (posture speed, reaction time, initial direction error, initial distance ratio, speed maxima count, min-max speed difference, movement time, path length ratio, maximum speed) and transformed to age and sex matched z-scores. Principal components were calculated from those z-scores. Voxel-based lesion symptom mapping was used to identify brain regions for which the presence of a lesion correlated with a performance deficit on the 9 behavioral variables and the 9 principal components. Statistical analysis was performed within voxels lesioned in >10% of subjects using t-tests with false discovery rate correction. Brain regions damaged by stroke in >10% of subjects were located primarily within the middle cerebral artery territory (80% of subjects) affecting large regions of the insular, parietal and temporal lobes (96% insula), white matter tracts (81% external/extreme capsule), and basal ganglia (75% putamen). Neuroanatomical correlates of reaction time, initial distance ratio, and speed maxima count were identified primarily within the insula, rolandic operculum and supramarginal gyrus (up to 56%). Neuroanatomical correlates of initial direction error, movement time, and maximum speed were identified within the superior corona radiata (up to 20%). Neuroanatomical correlates of the 1st principal component were found within white matter tracts (superior corona radiata 39%, superior longitudinal fasciculus 19% and external/extreme capsule 17%) and cortical regions (rolandic operculum 33%, supramarginal gyrus 22%, insula 25%). In conclusion, neuroanatomical correlates exist for performance deficits in visually guided reaching after stroke.

Title: Preservation of parietal area 5 is associated with improved motor recovery and functional connectivity following MCA stroke in non-human primates

Authors: *J. Y. NASHED[1], J. Z. WANG[1], C. HERNANDEZ-CASTILLO[3], J. GALLIVAN[1], J. FERNANDEZ-RUIZ[4], D. J. COOK[1,2];

Veracruzana,, Veracruz, Mexico; [4]Dept. de Fisiologia, Facultad de Medicina, Univ. Nacional Autonoma de Mexico, Mexico City, Mexico

Abstract: Stroke is a leading cause of death and disability worldwide. There is high variability in degree and rate of recovery following stroke. No single determinant of stroke recovery has been identified; however, stroke volume, anatomical location and patient demographics and comorbidities are likely contributors. We hypothesize that preservation of cortical areas that support functional remapping after stroke may enhance recovery. Parietal Area 5 (PA5), an integrator of sensorimotor information related to reaching and grasp, is at the edge of the ischemic penumbra and inconsistently infarcted following MCA occlusion (MCAO) in the cynomolgus macaque. We hypothesize that preservation of PA5 following MCAO is associated with improved post-stroke recovery and increased connectivity following MCAO. To test this hypothesis we utilized a non-human primate model of stroke. Fourteen cynomolgus macaques underwent transient 90-minute MCAO. Perfusion, Diffusion and T2-MRI images were obtained following MCAO occlusion and at 48h and 30d. Total stroke volume and regional stroke volumes in premotor (PM), primary sensory cortex (S1), primary motor cortex (M1), all Parietal regions including Parietal Area 5 (PA5) and White Matter were quantified. Neurobehavioural outcomes were evaluated using the Non-Human Primate Stroke Scale (NHPSS). Animals were dichotomized into good(NHPSS<9, n=7) and poor recovery (NHPSS≥9, n=7) by 30d NHPSS score. Comparisons between the good and poor recovery groups showed no difference in penumbra(PWI-DWI) and stroke core volume at baseline and no difference in total stroke volume at 48h and 30 days (both P>0.05). PA5 stroke volume was equivalent at 48h, but significantly decreased at 30 days (4.1mL vs.5.2mL, P=0.02) in the good versus bad recovery

group. Functional connectivity maps generated 30 days post-stroke confirmed stronger connections between contra- and ipsilateral M1, S1, and PA5 nodes in animals with good recovery. These data suggest that PA5 plays a key role in motor recovery following MCA stroke. Future mechanistic research focused on PA5-dependent motor recovery may lead to novel neurorestorative and/or neuromodulatory therapies.

Title: Quantifying motor recovery of the ipsilesional arm after stroke

Authors: ***J. A. SEMRAU**[1], T. M. HERTER[3], S. H. SCOTT[4], S. P. DUKELOW[2]; [1]Clin. Neurosciences, [2]Univ. of Calgary, Calgary, AB, Canada; [3]Univ. of South Carolina, Columbia, SC; [4]Queen's Univ., Kingston, ON, Canada

Abstract: After stroke, functional recovery is thought to be highly dependent on the motor abilities of the stroke-affected arm. However, recent studies have suggested that there may be prolonged ipsilesional motor deficits related to stroke that commonly go unrecognized and untreated. Recent work in our lab has used robotics to quantify sensorimotor behaviour after stroke. Here we aimed to determine the frequency and recovery patterns of ipsilesional motor deficits over the first 6 months post-stroke. One hundred sixteen subjects with first time, unilateral stroke performed a visually guided reaching task (N = 64 Left-affected (LA), N = 52 Right-affected (RA)) with both the affected and unaffected arms at four timepoints post-stroke (1, 6, 12 and 26 weeks). For the task, subjects sat in the robotic exoskeleton with their arms supported against gravity. Subjects viewed their fingertip as a one cm diameter white cursor, and were instructed to hold at a center target and move to a peripheral target as quickly and accurately as possible when it appeared. Subjects made 10 reaches to each of 8 targets (80 movements total) in pseudorandom order. We evaluated spatial and temporal aspects of movement (9 parameters total) and made comparisons to a healthy control reference range. Based on control performance, overall task failure was considered to be impaired performance

on 3 or more parameters. At one week post-stroke, we found that 34% of subjects (N = 40 total, N = 27 (LA), N = 13 (RA)) had significantly impaired motor function in the ipsilesional arm and 80% (N = 93 total, N = 51 (LA), N = 42 (RA)) had significantly impaired motor function in the contralesional arm. Fifty-three percent of subjects with ipsilesional deficits still had significantly impaired motor function of the contralesional arm at 26 weeks post-stroke. In comparison by 6 weeks post-stroke, the number of subjects with ipsilesional deficits dropped to 15% (N = 17). By 26 weeks post-stroke, the number of subjects with ipsilesional deficits was only 3% (N = 3). Our results suggest that while damage to either hemisphere may result in ipsilesional motor deficits, recovery of the ipsilesional arm occurs at a faster rate than that of the contralateral arm.

Title: Visuomotor learning is attenuated by impairments of visual search following stroke

Authors: *T. M. HERTER[1], K. FUSS[1], T. SINGH[1], C. PERRY[1], K. GOINS[1], B. MAREBWA[1,3], J. FRIDRIKSSON[2], S. FRITZ[1];
[1]Dept. of Exercise Sci., [2]Dept. of Communication Sci. and Disorders, Univ. of South Carolina, Columbia, SC; [3]Dept. of Psychology and Cognitive Sci., Univ. of Trento, Trento, Italy

Abstract: Visual search is used to gather visual information by actively scanning the visual environment with eye movements and peripheral vision. Visual search improves with practice and efficient visual search is linked with expertise in motor skills, suggesting that improvements in visual search may contribute to visuomotor learning. Impairments of visual search are seen in many stroke survivors, including many without spatial neglect. We predict that stroke survivors with impairments of visual search may experience poor motor outcomes. Here we examine the extent to which post-stroke impairments of visual search attenuate visuomotor learning.
Methods: Eight stroke survivors (38-81 years old) practiced a bimanual visuomotor task (Object

Hit and Avoid Task) using an upper-limb robotic device (KINARM Endpoint Lab, BKIN Technologies, Kingston, Canada). In this task, objects (eight distinct geometric shapes) moved towards the subjects who used virtual paddles attached to each hand to hit away two objects (Targets; n = 200), and avoid hitting the other six objects (Distractors; n = 100). Subjects completed six repetitions of the task once a week for six weeks. Object shape, location, and speed were randomly varied to ensure that every task repetition was distinct. Eye and hand movements were recorded to investigate the influence of visual search on task performance. Results: Four subjects (Selective Hitters) demonstrated improvements in task performance, reflecting increases in targets hit and distractors avoided. The other four subjects (Nonselective Hitters) showed increases in targets hit but decreases in distractors avoided, resulting in negligible improvements in task performance. Differences between Selective and Nonselective Hitters were linked to differential changes in several measures of visual search and eye-hand coordination. Measures of limb-motor control did not explain differences between Selective and Nonselective Hitters. Conclusions: These results provide evidence that impairments of visual search may contribute to poor motor outcomes following stroke. Interventions designed to improve visual search may enhance motor outcomes following stroke.

Title: Cell survival and regeneration in the ischemic core following focal cerebral ischemia in mice

Authors: *M. Q. JIANG[1], W. CAO[2], Z. Z. WEI[2], X. GU[2], L. WEI[2], S. YU[2], S. YU[2]; [1]Neurosci., [2]Anesthesiol., Emory Univ., Atlanta, GA

Abstract: Cerebral ischemia typically induces an ischemic core in the supplying territory of the occluded artery. The conventional definition of the ischemic core is that of “a volume of tissue with which all cells (neuronal and glial), blood vessels (arteries, veins and capillaries) and nerve fibers (myelinated and non-myelinated) have undergone necrosis” (Nedergaard M, 1988). So far,

research efforts have been heavily concentrated on the peri-infarct region due to the current consent that cells in the penumbra are savable. On the other hand, the fate and mechanisms of neuronal and vascular cells inside the core are largely unknown except the common belief that cells inside the core all die due to severe ischemia. In the present investigation, we tested the hypothesis that, inside the ischemic core, some neuronal and vascular cells could survive the initial ischemic insult and regenerative niches could exist many days after stroke. Adult male mice were subjected to focal cerebral ischemia. The ischemic insult uniformly reduced the local cerebral blood flow (LCBF) by about 90%. Massive cell death and a significant infarction were cultivated in the ischemic cortex 1-3 days later. Nevertheless, significant levels of trophic/growth factors BDNF and VEGF remained in the core tissue, some NeuN-positive and Glut-1/College IV-positive cells still resided inside the core 7-14 days post stroke. Using electron microscopy 7 days after stroke, we observed some surviving cells with neuronal features including a large nucleus with an intact plasma membrane and numerous cellular organelles in the cytoplasm. Some neuronal cells still maintained synaptic contacts between cells, composed of intact synapses with pre- and post-synaptic features such as presynaptic vesicles and a postsynaptic density (PSD). Myelinated axons were also identified in the core region. Many vessel like structures composed endothelial cells and astrocytes/pericytes that resembled the neurovascular unit existed in the core. *In vivo* and cultured cells from the ischemic core tissue also revealed regenerative activities several days after stroke. These data suggest that the ischemic core remains an actively regulated brain region with residual but viable neuronal and vascular cells acutely and chronically after stroke. The work advocates that the ischemic core should be an important target for neuroprotective as well as regenerative stroke therapies.

Title: Microstructural properties of a constrained motor connectome in individuals with stroke predicts motor learning

Authors: *K. P. WADDEN[1], S. PETERS[2], L. BOYD[2];
[1]Dept. of Physical Therapy, [2]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: INTRODUCTION Diffusion tensor imaging (DTI) is a reliable method to quantify white matter microstructural properties in the chronic stage following stroke (Mang et al. 2014). The aim of this study was to utilize a multimodal neuroimaging approach to study the underlying white matter properties of a previously identified functionally connected motor network (Wadden et al. 2015). This approach generated data characterizing a constrained motor connectome of white matter structures that was then used to predict change in motor performance when skilled motor practice was paired with *continuous theta burst stimulation* (cTBS) stimulation over the contralesional sensorimotor. METHODS Thirty-six individuals in the chronic phase of stroke were recruited. Participants were randomized to one of two stimulation groups: contralesional sensorimotor (SM1c; 25), or sham (11). DTI was collected on individuals with stroke as well as seventeen healthy controls. Over a 5-day intervention, motor practice of a serial tracking task (STT) followed contralesional cTBS. A movement time change score was calculated to quantify improvements in the STT. A bilateral sensorimotor network mask was created from a prior fMRI connectivity analysis (Wadden et al. 2015) that demonstrated a connected motor network during motor learning. The clusters within the network were used as seed regions to create a constrained motor connectome. Fractional anisotropy (FA) was extracted and was used as a measure of white matter properties. RESULTS Constrained motor connectome FA was significantly reduced in the stroke compared to the healthy group ($F = 24.95$, $p < 0.001$). In the SM1c group, in a linear regression model, motor network FA significantly accounted for 32.4% of the variance in change in motor performance ($p = 0.011$), however, this relationship did not exist in the sham group ($p > 0.05$). CONCLUSION Combining fMRI and DTI may provide a neurophysiological method, known as a constrained connectome, to determine the microstructural properties of an isolated network of regions to predict motor performance following stroke. Similar to the blood oxygenated response (Wadden et al. 2015), the diffusivity of the water molecules along the fiber tracts within this motor network was significantly different between healthy individuals and individuals after stroke. Interestingly, our results demonstrate that dysfunction in the underlying constrained motor connectome following stroke is an important variable in predicting response to cTBS stimulation over the contralesional sensorimotor cortex. Title: Metabolic pattern in capsular infarct model: ssm/pca and fdg-micropet based approach

Authors: *D. KIM[1], H.-I. KIM[2], S. JUN[1];
[2]Dept. of Med. Syst. Engin., [1]Gwangju Inst. of Sci. and Technol., Gwangju, Korea, Republic of

Abstract: Objective: The voxel-wise stat which has been used widely has a limitation in analyzing static PET data due to a large inner-group and small inter-group variance of PET data. As alternative of this problem, scaled subprofile method with principal component analysis (SSM/PCA) which is a multivariate method to classify two groups and obtains representative pattern of group could be an answer. The method has been successfully applied in neurodegenerative disease (Parkinson's and Alzheimer's disease). The objective of this study is to verify SSM/PCA in stroke study. For this, we performed microFDG-PET scanning of capsular infarct model then investigated the effect of stroke as natural recovery using SSM/PCA method. Methods: The forty sprary-dawley rats were used for this experiment then divided into four groups determining whether performing the surgery destructing internal capsule, behavioral task, or returning their motor skill: moderately recovered group (MRG, n=10), poorly recovered group (PRG, n=10), sham-operated group (SOG, n=10). All rats received microFDG-PET scanning before surgery (baseline scan), after 7, 14, and 21 days. The static PET scanning was performed during 25 minutes. After reconstruction, each PET data were normalized and co-registrated on histological template. Based on this, we applied SSM/PCA method Results: The obtained pattern of each group (the pattern of 7, 14, and 21 days compared with baseline for each group) well separated the baseline group ($p < 4.7x10-3$). In analysis of MRG data with time, the pattern showed deactivation of ipsi-lesional motor cortex, sensory cortex, and thalamus which is comparable with the previous study using voxel-wise stat (Figure 1). However, the activation of cingulate cortex, retrosplenial cortex was not seen in the previous result. The other groups showed similar result with voxel-wise analysis. However, there were certain differences. Conclusion: We showed SSM/PCA method could be used in micro FDG-PET analysis of capsular infarct model and it is suitable for obtaining a representative pattern of specific group.

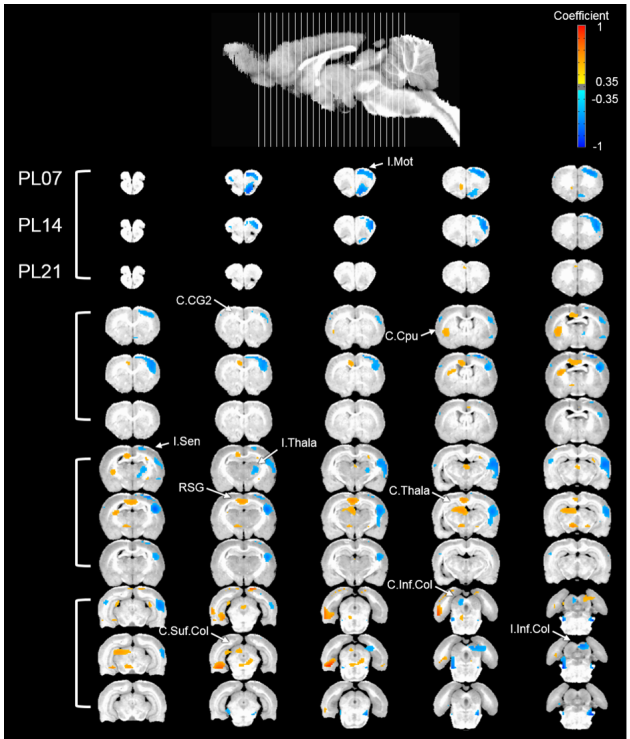

Figure 1. time-dependent metabolic pattern of MRG were depicted on the histological template. On the top, histological template with slice line. According to the line coronal view was shown. Positive value represents increase activity in post stroke and negative value represents decrease activity in post stroke. MRG, moderately recovered group; Mot, motor cortex; CG, cingulate gyrus; Cpu, caudate putamen; Sen, sensory cortex; Thala, thalamus; RSG, retrosplenial granular cortex; Inf.Col, inferior colliculus; Suf.Col, superior colliculus; PL, postlesion.

Title: Differential sympto-diagnostic features of ischemic stroke, and tools for the measurement of tPA outcome

Authors: M. J. CHAVES[1], E. S. FULMER[2], T. J. COCHRAN[1], D. BLACKHURST[3], S. STERNBERG[3], R. LEACOCK[3], *T. I. NATHANIEL[1];
[1]Biomed. Sci., Univ. of South Carolina Sch. of Med. At Greenville, Greenville, SC; [2]Univ. of South Carolina Sch. of Med., Greenville, SC; [3]Greenville Hlth. Syst., Greenville, SC

Abstract: This study focuses on the differential symptoms, clinical course, and outcomes of ischemic stroke following treatments with tPA. Data were obtained from Greenville Health

System's stroke registry on patients presenting with ischemic stroke between January 1st, 2010 and June 30th, 2013. Patients with initial NIH stroke scale > 25 or who were ineligible for tPA were excluded. Patients were grouped according to the presenting symptoms including weakness, aphasia, and/or altered level of consciousness. Three levels of recovery were assessed for 505 patients following treatment with tPA. Patient's original ambulatory status was "completely recovered" (patient returned to his/her pre-stroke baseline), patient's original ambulatory status was "partially recovered" (but patient did not return to baseline), patient's original ambulatory status "was not recovered". 167 (33%) were administered tPA, while 338 (67%) did not receive tPA. Most patients with altered level of consciousness (with or without weakness) did not show improvement when administered with tPA as compared to the untreated patients. However, patients with weakness (with or without aphasia or with all 3 symptoms combined) showed improvement when compared to the control group. The current study indicates that there are differential symptoms and clinical features that, in addition to the initial examination, may help in understanding cortical ischemic stroke. These clinical features may be important for both diagnostic and therapeutic approaches to acute stroke.

Title: Employing patient's individual characteristics to derive personalized brain stimulation therapies

Authors: *V. SANKARASUBRAMANIAN[1], N. VARNERIN[1], D. CUNNINGHAM[1], K. POTTER-BAKER[1], K. SAKAIE[1], A. CONFORTO[2], A. MACHADO[1], E. PLOW[1]; [1]Cleveland Clin., Cleveland, OH; [2]Sao Paulo Univ., Sao Paulo, Brazil

Abstract: Background: Non-invasive brain stimulation is one of the most well studied advances in stroke rehabilitation. The classical approach focuses on facilitating adaptive plasticity of the damaged hemisphere, particularly the primary motor cortex (M1). However, the promise of stimulation becomes inconsistent when studies include patients with serious damage and disability. In such cases, pathways from M1 are damaged frequently. And, instead, plasticity of alternate substrates in both damaged and intact hemispheres can contribute to recovery. But, how

does one identify which substrate to stimulate to precisely affect recovery? **Objective:** Since individual substrates offering plasticity vary with damage and disability, we premise outcomes of stimulating these substrates will similarly vary across the range of damage and disability. Comparing their variances will help derive patient-specific substrates for most consistent brain stimulation therapies. **Methods:** In a repeated measures crossover design, patients with chronic stroke ranging from mild to severe upper limb impairment received stimulation to facilitate damaged M1 and other damaged and intact substrates, besides sham. Patient characteristics including baseline disability and damage were quantified using scores of impairment and corticospinal integrity. Outcomes were indexed as change in functional reaching ability, and individual expressions of plasticity measured using transcranial magnetic stimulation. **Results:** Stimulation rather than sham modulated plasticity and outcomes of paretic upper limb. As predicted, outcomes and plasticity of stimulating different substrates varied differently with baseline impairment and damage. While outcomes of stimulating damaged M1 were robust in patients with mild impairment ($r=0.64$), the more seriously impaired best responded to stimulation of intact motor cortices ($r=-0.812$) with cut-offs at mild-to-moderate damage and disability. **Significance:** Our findings are consistent with the hypothesis that outcomes of stimulating different substrates vary differently with individual characteristics. The diametrically opposite relationships witnessed between outcomes of stimulating M1 and other substrates could help identify intersection or cut-offs along the range of damage and disability. Cut-offs can stratify patients in which range will benefit from stimulating damaged M1 vs. other substrates for precisely maximizing rehabilitative recovery.

Title: Assessment of post-stroke white matter change with HARDI track density imaging

Authors: *A. U. TURKEN[1], N. F. DRONKERS[1,2];
[1]Res. Service, Veterans Affairs Northern California Hlth. Care S, Martinez, CA; [2]Neurol. Dept, UC Davis Med. Sch., University of California, Davis, CA

Abstract: Accurate characterization of white matter integrity is critical for the diagnosis and treatment neurological patients who have suffered stroke. Here, we employed high angular resolution diffusion imaging (HARDI) and streamline tractography to visualize brain white matter pathways in chronic stroke, and track density imaging (TDI) to quantify their structural integrity. The study group included 38 stroke patients with unilateral injury (left or right hemisphere) in middle cerebral artery (MCA) territory. In order to ensure that the acute effects of infarction (edema and mass effects) had stabilized, MRI scanning was performed in the chronic stage (> 6 months). The study group also included 40 healthy controls. High-resolution anatomical images (T1w, T2w, FLAIR) and high angular resolution diffusion imaging data (b = 2000 s/mm2, 64 directions) were acquired on a 3T Siemens Verio scanner. The patient participants also underwent comprehensive neuropsychological assessments to characterize their cognitive abilities, and to correlate stroke-related behavioral deficits with white matter integrity as assessed with TDI. To ensure accurate anatomical registration, the anatomical scans were transformed to MNI152 space with a modified version of SPM8's unified segmentation normalization technique (Crinion et al., 2007) and an age-specific healthy brain template. Diffusion MRI data were pre-processed with FSL's EDDY function for movement and distortion correction. MRTrix was used for HARDI processing (Tournier et al., 2012). Fiber orientation distribution (FOD) functions were estimated at each voxel with constrained spherical deconvolution (CSD). Probabilistic streamline tractography, (iFOD2 algorithm), was used to generate 10 million streamlines (10-200 mm long) in each brain. TDI maps were generated for each dataset with MRTrix, quantifying fiber track density and mean fiber track length at each voxel (Calamante et al., 2010; Pannek et al., 2011). A trained expert manually delineated brain lesions on each stroke patient's structural scans for comparison with the HARDI TDI analysis of stroke-related white matter change. We observed that TDI can detect subtle changes in white matter integrity even in brain regions outside the lesion sites, and that TDI can also provide information on surviving white matter within lesioned areas. Finally, we found that damage to white matter regions that are characterized by high fiber track density in the healthy control group, such as the extreme/external capsule and postero-lateral temporal lobe white matter (Turken & Dronkers, 2011) predicted severe behavioral deficits in the patient group.

Med., Berlin, Germany

Abstract: Hand motor recovery prognosis in stroke patients is crucial to develop a realistic individual rehabilitation program. The aim of the work was to compare predictive role of corticospinal tract integrity based on diffusion tensor imaging and functional state of both affected and unaffected (UH) motor cortex based on navigated TMS (nTMS) assessment including nTMS mapping considering relationship between extrinsic and intrinsic hand muscle`s cortical representations. Total of 30 patients with the only chronic supratentorial ischemic stroke and various severity of hand paresis were enrolled (12 females,50,0±8,0 y.o.). Ten healthy volunteers (36,6±15,2 y.o.) underwent nTMS study. A software for multi-muscle nTMS mapping for automatic calculation of areas, volumes, overlaps and centers of gravities was developed. A significant difference between group of unfavorable outcome versus other groups based on fractional anisotropy (FA) in internal capsule and cerebral peduncle let to consider it FA an easy available clinical measurement for hand motor prognosis. Significantly higher disinhibition in the UH in well recovered and normal SICI in poorly recovered patients was demonstrated. For ICF in UH no significant difference between groups of motor outcome was found, at the same significant negative correlation between ICF and percentage of muscles cortical maps overlap was shown.

Title: Tracking changes in passive muscle stiffness after acute hemispheric stroke

Authors: ***A. LAI**[1,2], X. HU[2], N. SURESH[2], W. RYMER[2];
[2]Physiol., [1]Northwestern Univ., Chicago, IL

Abstract: Following stroke, skeletal muscles often resist lengthening. Such abnormal resistance to lengthening may be explained in part by an increase in passive muscle stiffness. However, the cellular and molecular mechanisms responsible for increased muscle stiffness are unclear. This is partially due to lack of data in the acute phase of stroke; without such knowledge, it is not possible to determine if proposed mechanisms of impairment follow a time course that is

consistent with scientific observations. Thus, the objective of this study was to track the changes of muscle stiffness in the acute stage of recovery. For three stroke survivors, we estimated muscle stiffness by measuring the velocity of shear wave propagation. To evaluate the relative changes in the two sides (paretic - contralateral), we calculated the difference in shear wave velocity (SWV) on each side in each of the 6 locations, and expressed the change as a percent of the contralateral SWV. Preliminary results suggest that over a period of 2-3 months, the shear wave velocity on the paretic side increases relative to the contralateral side, culminating in large differences in the chronic stage. This may be indicative of slow changes in the properties intrinsic to the muscle, such as the type and spatial distribution of collagen content, the amount of fat infiltration within fibers, the number of serial sarcomeres, and potentially sarcomere resting length.

Title: Brain sensorimotor structural network difference between two hemispheres in chronic stroke

Authors: ***B. KIM**[1], Y. OH[1,2], R. M. LEAHY[3,4], J. P. HALDAR[3,4], N. SCHWEIGHOFER[1,2], C. J. WINSTEIN[1];
[1]Div. of Biokinesiology and Physical Therapy, [2]Neurosci. Grad. Program, [3]Ming Hsieh Dept. of Electrical Engin., [4]Brain and Creativity Inst., USC, Los Angeles, CA

Abstract: Brain network among sensorimotor areas in both hemispheres is affected by hemispheric stroke. Brain structural network analysis was introduced to identify adaptive changes across the brain network after cerebral stroke, and to understand the relationship between changes in the network and motor behavior. This study aims to determine whether brain sensorimotor structural network analysis can be used to investigate the relationship between brain sensorimotor networks and motor behavior. This study is part of a longitudinal Phase-I clinical trial of rehabilitation in chronic stroke (ClinicalTrials.gov ID: NCT 01749358). Individuals with mild to moderate motor impairment after stroke participated (N=24, average chronicity= 3.04 years). Structural brain images (T1-weighted MRI and DTI) were acquired. Imaging data were processed using BrainSuite14a (http://brainsuite.org/). A total of twenty four cortical or subcortical sensorimotor areas (Twelve areas in each hemisphere) were chosen to

construct a structural connectivity network. Fractional anisotropy (FA) of the pathway (tractography between each pair of regions of interest [ROIs]) was calculated and a 24 X 24 FA matrix generated. We applied a threshold, optimized for each patient, to produce an undirected weighted graph and a binary adjacency matrix. Communicability between each pair of ROIs was calculated. Wolf Motor Function Test (WMFT) and Motor Activity Log (MAL) were performed to assess motor performance and the amount of the paretic arm use, respectively. For each ROI, the mean communicability was calculated, and a Wilcoxon signed-rank test was performed to compare the mean communicability between the homologous ROIs in the two hemispheres. Finally, Pearson correlation analysis was used to determine if there is a relationship between the brain sensorimotor network (communicability asymmetric index of each ROI and motor behavior (WMFT, MAL). The significance level was 0.05, and Bonferroni correction was applied for the Pearson correlation (alpha = 0.05/24 = 0.002). There was significantly lower communicability in ipsilesional superior parietal gyrus, caudate nucleus, putamen, and globus pallidus compared to communicability metrics of these same ROIs in contralesional hemisphere. However, any communicability metric was not significantly correlated with WMFT Time score or MAL score. These results show the potential use of sensorimotor tracts FA metrics to capture the brain sensorimotor structural network difference between two hemispheres in chronic stroke, although the asymmetry in communicability between hemispheres was not associated with the level of motor deficits.

Title: Optogenetic stimulation of cerebellar dentate nucleus reduces pCREB expression in the contralesional motor cortex after stroke

Authors: *M. Y. CHENG, S. ISHIZAKA, A. M. SHAH, E. H. WANG, A. R. BAUTISTA, G. SUN, G. K. STEINBERG;
Neurosurg., Stanford Univ., Stanford, CA

Abstract: Functional recovery after stroke has been observed in both human and animal studies. Post-stroke brain stimulations are promising neurorestorative techniques as they allow direct manipulation of the target area's excitability. Recently we have demonstrated that optogenetic

neuronal stimulation of the contralesional cerebellar dentate nucleus (cLCN) post-stroke promotes persistent recovery. In this study we investigate the effects of repeated cLCN stimulation on brain activation patterns during stroke recovery. In particular we examined phosphorylation of CREB (pCREB) as an indicator of neuronal activation and excitability. We hypothesize that stimulation of cLCN will cause a widespread change of excitability, as it sends excitatory outputs to multiple motor, premotor and sensory areas. Thy-1-ChR2-YFP line-18 transgenic male mice were used. Mice underwent stereotaxic surgery to implant a fiber cannula in cLCN, followed by an intraluminal middle cerebral artery suture occlusion. Three groups of mice were used: control non-stimulated stroke mice, short stim stimulated stroke mice (day5-14 post-stroke) and long stim stimulated stroke mice (day5-28 post-stroke). Sensorimotor behavior tests (rotating beam tests) were used to assess their recovery at day 0, 4, 7, 10, 14, 21 and 28 post-stroke. Animals were sacrificed at day29 and brains were processed for immunohistochemistry with antibodies targeting pCREB and CREB. Our data showed that cLCN stimulated stroke mice recovered quickly, with significant improvement in distance traveled as early as day7 ($p<0.05$), and faster speed at day14 post-stroke ($p<0.001$). The effect of stimulation was persistent, as stimulated stroke mice continued to recover after day14 without further stimulations and maintained similar functional performance at day21. Analysis of pCREB activation showed that cLCN stimulation activates the dentatothalamocortical pathway. Interestingly, cLCN stimulated stroke mice exhibited reduced pCREB expression in the contralesional hemisphere, most prominently in motor and sensory cortices. Our data suggest that cLCN stimulations post-stroke can promote persistent functional recovery, and stimulation leads to a reduced pCREB activation. Current studies examine the mechanisms of cLCN-induced recovery, including the contribution of pCREB and its signaling pathways.

Title: Deletion of the hemopexin or heme oxygenase-2 gene aggravates brain injury following stroma-free hemoglobin-induced intracerebral hemorrhage

Authors: ***B. MA**[1,2], J. DAY[1,2], E. TOLOSANO[4], S. DORE[1,2,3];
[1]Dept. of Anesthesiol., [2]Ctr. for Translational Res. in Neurodegenerative Dis., [3]Departments of

Neurology, Psychiatry, Pharmaceutics, and Neurosci., Univ. of Florida, Col. of Med., Gainesville, FL; [4]Departments of Mol. Biotech. and Hlth. Sci., Univ. of Torino, Torino, Italy

Abstract: The breakdown of hemoglobin released after intracerebral hemorrhage (ICH) causes brain injury. Hemopexin (HPX) has the highest binding affinity to heme, and heme oxygenase 2 (HO2) is the rate-limiting enzyme for the degradation of heme. Microglia are resident macrophages in the brain; however, the significance and role of HO2 and HPX on microglial clearance of hemoglobin after ICH still remain understudied. Intracerebral injection of stroma-free hemoglobin (SFHb) was used to induce ICH. HPX or HO2 knockout mice were injected with 10μL of SFHb in the striatum. After injection, behavioral/functional tests were performed along with anatomical analysis. Iron deposition and neuronal degeneration were shown by Perl's staining and Fluoro-Jade B staining, respectively. Immunohistochemistry with anti-Iba1 was used to demonstrate activation of microglial cells around the injured site. The study results showed that deleting HPX or HO2 aggravated SFHb-induced brain injury and revealed hemoglobin clearance by microglia after SFHb injection. Compared to wildtype littermates, larger lesion volumes were observed in HPX-/- and HO2-/- mice, which also bore more degenerating neurons in the perilesion area 24h post-injection. Fewer Iba1-positive microglial cells were detected at the peri-lesion area in HPX-/- and HO2-/- mice; which was associated with markedly increased iron-positive microglial cells. Moreover, the Iba1-positive microglial cells increased from 24 to 72h postinjection and were accompanied with improved neurologic deficits in HPX -/- and HO2-/- mice. These results suggested that activated microglial cells could engulf the extracellular SFHb and provide protective effects after ICH. We then treated primary microglial cells with SFHb. The results showed that microglial cells were activated to take up the extracellular SFHb. Moreover, we found that iron overload in microglia significantly reduced the Iba1 expression level and inhibited microglial phagocytosis. Together, this study reveals that microglial phagocytosis contributed to hemoglobin clearance after ICH, and that deleting HPX or HO2 will compromise this ability by reducing the Iba1 expression level induced by iron overload.

Title: Primacy coding of odor identity across concentrations

Authors: *C. WILSON[1], G. SERRANO[1], A. KOULAKOV[2], D. RINBERG[1];
[1]Neurosci., NYU Langone Med. Ctr., New York, NY; [2]Cold Spring Harbor Lab., Cold Spring Harbor Laboratory, NY

Abstract: The olfactory system supports identification of odorants regardless of concentration. This occurs despite the concentration driven variability of the input to the olfactory bulb from the nose. The mechanisms underlying the transformation of unstable sensory input into stable perceptual features is a fundamental question in sensory systems neuroscience. We proposed the Primacy Coding model for fast, concentration-invariant coding of olfactory stimuli. In this model, sensory neurons with the highest affinity for a given odorant encode identity across all perceptible concentrations. We hypothesize that this sensitive set can be determined using relative timing, with highly sensitive neurons responding earliest within the population regardless of concentration. One prediction of this model is that odor identification should be possible using information only from this early responding subpopulation. Through our optogenetic masking behavioral paradigm, we have identified that odor discrimination can be accomplished using sensory information arriving within the first 80 ms of inhalation. We hypothesize that information contained within this first 80 ms represents a primal set that supports odor identity. To test the stability of neural activity occurring within this time window, we recorded the mitral/tufted cell population response to odors across a range of concentrations.

Abstract: Circuits within the olfactory bulb transform the odor representations of the sensory periphery. The logic behind this transformation remains elusive, because a) it has been difficult to record from olfactory bulb neurons while knowing what their inputs are, and b) recordings should be done in awake animals as network dynamics change drastically with wakefulness. In order to understand this coding transformation, we have developed a technique to optogenetically identify and then record from olfactory bulb neurons that receive input from genetically-identified inputs in awake animals. Olfactory sensory neurons (OSNs) that express the same odorant receptor gene send axons that converge to form glomeruli, where they provide excitatory input to a small number of mitral/tufted (M/T) cells. The peripheral representation of incoming odors is modified in the M/T layer via an extensive inhibitory network before odor information is relayed to cortex. Using a gene-targeted mouse line that expresses Channelrhodopsin-2 in a genetically-defined subpopulation of OSNs -- cells that express a specific receptor (M72) -- we can identify the subpopulation of M/T cells that are functionally coupled to this same glomerulus. Light stimulation of the M72 glomerulus elicits a reliable, short latency response in these “M72” M/T cells. This technique gives us the opportunity to characterize how a specific subpopulation of “sister” M/T cells transforms their shared input. We recorded the activity of M72 M/T cells from awake, head-fixed, freely-breathing mice while we presented a range of odorants, for which the M72 OSN responses have been characterized. We found that, for most odors, there was a surprising amount of variability in responses among sister M/T cells, despite their common excitatory input. This response diversity was comparable to that seen across the greater population of M/T cells. However, a single odor stimulus -- the strongest known ligand of M72 OSNs -- provided an exception to this response heterogeneity, as it evoked a temporal pattern of firing that was highly consistent across M72 M/T cells. This response stereotypy was not seen in the larger M/T population. These data raise the possibility that response stereotypy and diversity within specific neural subpopulations could form a substrate for sensory coding within the olfactory bulb.

Title: Effects of odorant exposure on the M72 glomerular module

Authors: *A. LIU[1,2], N. N. URBAN[3,2,1];

Abstract: The mechanisms regulating organization and wiring patterns of olfactory bulb (OB) circuitry are largely unknown. Olfactory sensory neurons (OSNs) located in the olfactory epithelium project axons to the OB that coalesce into spherical structures called glomeruli. These glomeruli and their post-synaptic targets (including mitral and tufted projection neurons and periglomerular cells) form networks called glomerular modules, which comprise the basic odor-coding units of the OB. The identity of the odorant receptor expressed by OSNs plays a crucial role in reliable targeting of OSN axons to specific locations within the OB, as well as the stabilization of glomerular location during the early postnatal period. Odorant experience accelerates the maturation of glomerular targeting by OSN axons. In addition, early prenatal and postnatal odorant conditioning leads to enlargement of activated glomeruli and alters odorant preference. Our experiments investigate 1) the stability of anatomical and behavioral changes caused by early odorant conditioning, and 2) the organization of the glomerular module's post-synaptic targets following prenatal and early postnatal odorant conditioning. We focus on the development of one specific, genetically-identified glomerulus, the dorsolateral M72 glomerulus. We use an odorant conditioning paradigm involving food odorized with methylsalicylate, a specific M72 odorant ligand. Consistent with previously published work (Todrank et al, 2007), we show that early prenatal odorant experience causes a significant increase M72 glomerular volume (control vs. conditioned, 110367 ± 14920 μm3 vs. 189106 ± 10655 μm3, n=10, p=0.003). Concomitant behavioral changes are also observed, with conditioned mice demonstrating a preference for methysalicylate-scented food over control food. However, our data demonstrate that while the increase in glomerular volume persists well beyond the early postnatal odorant exposure period (glomeruli of conditioned mice weaned onto control vs. methylsalicylate-scented food sacrificed at P63, 248183 ± 20573 μm3 vs. 244611 ± 12167 μm3, n=16, p=0.8833, n.s.), the effect on odorant preference is transient and dependent on continued odorant exposure, suggesting that experience-dependent changes in glomerular volume are irreversible beyond an early critical period, while alternative circuit mechanisms underlie flexible experience-dependent behavioral changes. We are currently using *in vivo* dye electroporation to discover odorant exposure dependent changes to the organization of mitral and tufted cells associated with the M72 glomerular module.

Title: Ultrastructural analyses of mitral and external tufted cell dendrites in rat olfactory bulb glomeruli

Authors: *J. N. BOURNE, N. E. SCHOPPA;
Physiol. and Biophysics, Univ. of Colorado Anschutz Med. Campus, Aurora, CO

Abstract: Recent physiological studies in the olfactory bulb have provided surprising evidence that olfactory sensory neurons (OSNs) can signal to output mitral cells (MCs) through two parallel paths: a direct OSN-to-MC path and a multi-step path that is partly mediated by external tufted cells (eTCs; OSN-to-eTC-to-MC) and appears to be more dominant under a number of experimental conditions. To examine the morphological basis for these signaling mechanisms, we performed ultrastructural studies of the apical dendrites of MCs and eTCs in young rats (P9-14). MCs and eTCs (n = 2 for each) in bulb slices were filled with biocytin and the slices then fixed and incubated with an avidin-biotin complex and 3,3'-diaminobenzidine (DAB) to form an electron dense substrate within labeled cells. Three-dimensional analyses of DAB-labeled dendrites imaged on an electron microscope revealed that MCs have a significantly lower density of presumed OSN-synapses than eTCs (MCs: 0.32 + 0.06 syn/μm; eTCs: 0.59 + 0.12 syn/μm, $p<0.05$), although the densities of inhibitory dendrodendritic synapses were similar. OSN synapses on MCs, but not eTCs, also clustered on the 2 μm distal-most ends of the apical dendrites (MCs 2 μm: 0.71 + 0.19 syn/μm, MCs 4-8 μm: 0.22 + 0.08 syn/μm, $p<0.05$). Analysis of unlabeled dendrites within glomeruli indicated that some dendrites displayed both OSN synapses and gap junctions. In the gap junction-rich dendrites, which most likely reflected MCs (Gire et al., 2012), OSN synapses tended to cluster in distal regions (from distal end: 2-4 μm: 0.63 + 0.12 syn/μm, 6-10 μm: 0.14 + 0.05 syn/μm, $p<0.01$), but the gap junctions were evenly distributed (from distal end: 2-4 μm: 0.28 + 0.07 gj/μm, 6-10 μm: 0.28 + 0.05 gj/μm, n.s.). In addition, the gap junctions were positioned close to dendritic presynaptic release sites, suggesting a role in synchronizing signals in MC apical dendrites that result from dendritic glutamate release. Preliminary modeling of MCs provides evidence that an even distribution of gap junctions on the apical dendritic tuft can attenuate excitatory postsynaptic potentials originating in the distal apical dendrite by ~80%. Together, these data suggest that multiple mechanisms could favor a multi-step OSN-to-eTC-to-MC signaling over direct OSN-to-MC signaling, including a higher density of OSN synapses on eTCs versus MCs, a distal location for OSN synapses on MC dendrites, and more proximally-located gap junctions that could act to shunt direct OSN signals.

Abstract: Genetically encoded protein sensors can be used to optically monitor neural activity from distinct populations of neurons. The goal of the present study was to genetically target the voltage and calcium sensors ArcLight or GCaMP6f to mitral/tufted cells in the mouse olfactory bulb, and measure their population response to odorant presentation. Cre-dependent AAVs expressing either ArcLight or GCaMP6f were injected into Pcdh21-Cre transgenic mice, which resulted in expression restricted to mitral/tufted cells. Signals were measured using widefield epifluorescence imaging in anesthetized mice in response to odorants. We also measured the input to the bulb using calcium dye loaded in olfactory receptor neurons in order to compare input and output activity patterns with respect to response timing and concentration invariance.

Title: Olfactory bulb mitral cells exhibit distinct temporal response profiles during prolonged odor stimulation

Authors: *M. C. OGG, M. BENDAHMANE, M. L. FLETCHER;
Anat. and Neurobio., Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Mitral cells (MC), the primary output cells of the olfactory bulb (OB), receive olfactory sensory input via their apical dendrites in the glomerular layer and transmit odor information to multiple cortical regions. Processing by multiple interneuronal circuits within the OB can shape both the magnitude and time course of MC output responses. While an increasing number of studies have demonstrated that MC responses to brief odor stimulation show complex dynamics, comparatively little is known about how individual MC respond to prolonged odor input at timescales relevant to behavioral adaptation/habituation. To explore this question, we used *in vivo* widefield and two-photon calcium imaging and investigated the response profiles of mitral cells in the mouse OB before, during, and after a 30s odor presentation. We recorded activity of MC dendrites at the glomerular layer and MC soma at the MC layer. We found that glomerular responses tend to follow a stereotypical pattern of strong initial activity at odor onset followed by a decaying response. However, MC soma responses to the same odors exhibit a broad range of temporal patterns throughout and after the odor presentation. Using cluster analysis, we classified these soma response patterns into statistically significant response profiles. These profiles indicate that there are MCs that reflect the slow decay of the glomerular response pattern; that come on and go off rapidly; that maintain their response through the entire odor stimulation; and even some that initially do not respond very strongly but ramp up their activity as the odor presentation progresses. Since these response profiles seem to correspond to relevant odor events (e.g. odor onset, duration, odor offset) current work is underway exploring the consequences of these diverse patterns on OB odor coding. Ongoing experiments are also probing the mechanisms that underlie these varying temporal response patterns and their behavioral relevance in terms of odor perception and habituation.

Title: Parallel synaptic processing of afferent sensory information in the olfactory bulb

Authors: *C. E. VAAGA, G. L. WESTBROOK;
Vollum Inst., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: In order to understand how a circuit transforms afferent synaptic information, it is critical to appreciate the synaptic properties and firing patterns of principal neurons embedded within the circuit. In the olfactory bulb, primary afferents from the olfactory nerve converge on synapse-rich glomeruli, however, the connectivity and synaptic properties between primary afferents and the principal neuron subtypes remains controversial. Here we examined the responses of two principal neuron populations in the olfactory bulb, mitral cells and external tufted cells, to afferent stimulation of olfactory nerve axons. Using small-bore theta electrode stimulation, we selectively activated afferent inputs to a single glomerulus, which revealed that both principal neurons receive a fast, monosynaptic input from primary afferents. In paired whole-cell recordings at maximal stimulation intensity, the fast, monosynaptic peak EPSC was 4.1±1.68 (n=6 pairs) fold larger in external tufted cells. However, despite a smaller fast monosynaptic peak, the total charge transfer in mitral cells was much larger (5.1±0.92 fold larger (n=6 pairs)). The larger synaptic charge was the result of slow feedforward excitation specific to mitral cells, resulting from the dendritic release and subsequent spillover of glutamate. Importantly, the slower synaptic response in mitral cells led to repetitive action potential firing in mitral cells in response to brief afferent stimulation, compared to one or a few spikes in external tufted cells. The input-output (I/O) relationship, as measured in number of spikes, suggested a larger dynamic range for mitral cells such that they are likely more efficient at or near the threshold for odor detection. In contrast, the brief response of external tufted cells may be better suited for the tuning of inhibition within the circuit. Our results indicate that both principal neurons receive monosynaptic input from primary afferents; however, cell-type specific synaptic transformations endow these parallel input paths with discrete functions.

Title: Coordinated persistent granule cell and mitral/tufted cell structural plasticity in the olfactory bulb

Authors: *K. A. SAILOR[1], M. T. VALLEY[1], M. T. WIECHERT[1], G. J. SUN[2], W. ADAMS[3], C. DENNIS[3], H. RIECKE[3], G.-L. MING[2], H. SONG[2], P.-M. LLEDO[1];

Abstract: Throughout adulthood the mouse olfactory bulb is repopulated with new granule cell (GC) neurons. These GCs have been shown to exhibit enhanced structural plasticity during their growth and integration. It is unknown whether these dynamics are retained throughout the life of the GC, or whether this structural plasticity is unique to adult born GCs, or instead, is common to all olfactory bulb GCs. In this study, we tracked the dendritic and spine development of adult-born GCs using 2-photon *in vivo* imaging. Overall, adult born GC dendritic structure stabilized at one month. In contrast, adult born GC apical dendritic spine dynamics plateaued at two months, but maintained a highly dynamic, 20% daily turnover. We compared the spine dynamics of the adult born GCs with early post-natal day 14 born GCs and found matching spine turnover. To test whether the GC spine dynamics correlated with synapse turnover of their synaptic partners, mitral/tufted cells (MC), we labeled mitral/tufted cells with fluorescently labeled gephyrin, which marks the GABA receptor-containing post-synaptic sites that are synaptically opposed to GC spines. *In vivo* imaging of gephyrin puncta demonstrated similar dynamics to GC spines with 14% daily turnover. Using a computational model of GC-MC structural plasticity, we found that these dynamics enable the network to rapidly optimize its output in response to changes in the odor environment. Surprisingly, odor representations quickly settled into a steady state despite continued rapid remodeling of the circuit. GC to mitral/tufted cell synapses have so far been demonstrated to lack synaptic plasticity, therefore the olfactory bulb appears to be unique in the adult brain, where persistent structural dynamics may be its dominant form of plasticity.

Title: A hybrid coupled-oscillator network synchronizes gamma-band field oscillations in olfactory bulb slices

Authors: *S. T. PEACE[1], B. C. JOHNSON[2], A. C. MOLNAR[2], T. A. CLELAND[3]; [1]Neurobio. and Behavior, [2]Electrical and Computer Engin., [3]Psychology, Cornell Univ., Ithaca, NY

Abstract: In the rodent olfactory bulb (OB), coherent gamma oscillations (40-100 Hz) in the local field potential (LFP) are readily observed during active odor investigation, and have been attributed to reciprocal synaptic interactions between mitral and granule cells that synchronize neuronal activity across the OB. To investigate the mechanisms underlying this synchronous activity in the OB, we recorded from 300 μm thick OB slices taken from young adult (P28-P42) transgenic mice expressing channelrhodopsin-2 (ChR2) under the control of the olfactory marker protein (OMP) promoter, hence limiting ChR2 expression to olfactory sensory neuron (OSN) axonal arbors within OB glomeruli. To enable large area recordings across the OB slice, we used a 60-electrode planar microelectrode array (MEA; 200 μm pitch, 30 μm diameter, 30-50 kΩ impedance, 1.4 x 1.4 mm area) to record spike and local field activity. Metabotropic glutamate receptor agonists (ACPD or DHPG), the acetylcholine receptor agonist carbachol, or a brief 4 Hz blue light stimulus were used to induce long-lasting (>5 min) gamma oscillations (20-55 Hz in slice) that are coherent across ranges of up to 300 μm across the OB slice. The limited ranges of coherence are likely to be attributable to reductions in lateral dendritic connectivity arising from the slicing procedure itself; in support of this hypothesis, thicker slices exhibited larger pockets of coherence. Interestingly, the blockade of GABA(a) receptors in the OB slice (using BMI or gabazine) did not block induced gamma oscillations; rather, it reduced their frequency and limited the spatial extent of coherent regions to an area consistent with the field of a single glomerular column. We interpret these results as supportive of a hybrid coupled oscillator model of bulbar oscillogenesis, in which lateral GABAergic feedback via granule cells couples and synchronizes independent intracolumnar oscillators that rely on non-GABAergic coordination mechanisms (e.g., mitral cell subthreshold oscillations, electrical coupling).

Title: Functional characterization of calretinin-expressing periglomerular cells in the olfactory bulb

Authors: *N. BENITO, A. SANZ, D. DE SAINT JAN;
Inst. of Cell. and Integrative Neurosci., Strasbourg, France

Abstract: Periglomerular (PG) cells expressing calretinin (CR) form the largest population of interneurons in the glomerular layer of the olfactory bulb. Anatomical studies have shown that these cells establish dendro-dendritic synapses with mitral and tufted cells, the principal neurons of the bulb. However, their functional properties and their impact on principal neurons remain unknown. We have examined this question in a transgenic mouse expressing EGFP under the control of the CR promoter (Caputi et al., EJN 2009). In this mouse, only 63 ± 10.6 % of CR-immunopositive PG cells expressed EGFP (n=14 mice, 10 days to 7 month old). EGFP(+) cells filled with neurobiotin had beaded dendrites restricted to one glomerulus and apparently lacked an axon (n=6). Using patch-clamp recording in horizontal slices at different postnatal ages (P15-P60), we found that EGFP(+) PG cells receive fewer (1.8 ± 1.9 Hz) and smaller (13.9 ± 6.3 pA, n=18) spontaneous excitatory synaptic inputs than unlabeled PG cells (17.5 ± 8.9 Hz and 50 ± 23 pA, respectively, n=24). Their average polysynaptic response to the stimulation of the olfactory nerve was also smaller (33 ± 34 pA, n=17) than in other type 2 PG cells (424 ± 302 pA, n=31). In current-clamp experiments EGFP(+) PG cells responded to depolarizing current steps with a single and often small action potential (average amplitude 26 ± 20 mV, range 0-80 mV, n=62 cells). Consistent with this, EGFP(+) PG cells expressed smaller voltage-dependent sodium currents (0.4 ± 0.4 nA, n=28) compared with unlabeled PG cells (1.8 ± 1 nA n=12). Because these properties are reminiscent of those of postnatally generated immature neurons in the hippocampus or in the olfactory bulb, we tested the hypothesis that CR-EGFP(+) PG cells might be newborn neurons. However, only 6.2 ± 1.7 % of EGFP(+) cells colocalized with doublecortin, an immunohistochemical markers of immature neurons. Moreover, we used nestin-CreERT2 inducible transgenic mice crossed with Cre-dependent TdTomato reporter mice to study the lineage of nestin-expressing cells generated in the sub-ventricular zone. As expected, the olfactory bulb of mice sacrificed at P57 (i.e. 34 days after tamoxifen administration) contained a large number of postnatally born labeled cells in the granule cell layer and in the glomerular layer. However, only 22 ± 10 % of the Tdtomato-labeled PG cells expressed CR and doubled labeled PG cells represented only 6 ± 2 % of all CR-expressing cells (n=3 mice). Thus, although CR-EGFP(+) PG cells are poorly connected to the glomerular network only a small fraction might be immature newborn neurons.

Title: Functional mapping of circuits mediating inhibition of olfactory bulb periglomerular cells

Authors: ***A. SANZ DÍEZ**, N. BENITO, D. DE SAINT JAN;
INCI CNRS, Strasbourg, France

Abstract: The olfactory bulb (OB) is the first relay station in the brain for odor processing. It receives sensory afferents from olfactory sensory neurons (OSN). This information is transmitted to mitral and tufted cells, the principal output neurons of the bulb, within anatomical structures called glomeruli. Each glomerulus is surrounded by periglomerular (PG) cells that mediate intraglomerular inhibition. We recently characterized a specific PG cell subtype that mediates OSN-evoked intraglomerular inhibition of mitral and tufted cells (Najac et al. JNeurosci 2015). This PG cell subtype expresses EYFP in Kv3.1-EYFP transgenic mice represents 20-30% of all PG cells, is apparently axonless, projects its dendrites into a single glomerulus and receives input exclusively from mitral and tufted cells but not from the OSN defining it as a type 2 PG cell. EYFP(+) PG cells, like other PG cell subtypes, also receive inhibitory synaptic inputs (IPSCs) but the circuit mediating this inhibition is not known. We examined this question using whole-cell voltage-clamp patch-clamp recordings in horizontal OB slices from Kv3.1-EYFP transgenic mice. We found that stimulation of OSN producing excitatory postsynaptic currents (EPSC) in EYFP(+) PG cells (holding potential Vh = -75mV) did not evoke any IPSCs when the cells where clamped around the reversal potential for excitation (Vh = 0mV, n=14). In contrast, stimulation within distant (>200µm) glomeruli (n=13) or in the internal plexiform layer (n=5) produced a gabazine-sensitive monosynaptic IPSC (average amplitude 99.02 ± 83.38 pA; 20-80% rise time 0.73 ± 0.54 ms, decay time 19.08 ± 11.98 ms in the presence of NBQX and D-AP5) that were similar to those of spontaneous IPSCs (0.43 ± 0.14 ms and 20.23 ± 5.36 ms, respectively). These results suggested that inhibitory inputs onto EYFP(+) PG cells are not generated by the glomerular network but provided by deep short axon (dSA) cells with axons running within the glomerular layer. Interestingly, we found that 32% of the type 2 PG cells (n = 8/25) recorded in a transgenic mouse line expressing channelrhodopsin-2 (ChR2) under the control of the thy-1 promoter (Thy1-ChR2-YFP, Jackson Laboratory stock number 007612) responded with a monosynaptic IPSC to a short (1-10 ms) light (490 nm) stimulation (average amplitude 177.87 ± 207.01 pA (range 17-659 pA); rise-time 0.83 ± 0.29 ms and decay time 10.94 ± 6.44 ms, in the presence of NBQX and D-AP5). In contrast, light pulses did not evoke monosynaptic inhibition on type 1 PG cells (n = 4) nor on external tufted cells (n=7). Thus, this mouse line provides a valuable tool to map and evaluate the impact of the inhibitory circuits mediated by dSA cells in the olfactory bulb.

Title: Non-linear interactions between GABAergic inhibition and extrasynaptic glutamate gate output of olfactory bulb glomeruli

Authors: *J. D. ZAK, D. H. GIRE, N. E. SCHOPPA;
Physiol. & Biophysics, Univ. of Colorado, AMC, Aurora, CO

Abstract: Recent studies have implicated GABAergic periglomerular (PG) cells as an important contributor to odor-evoked suppression of spiking in olfactory bulb mitral cells (MCs; Fukunaga et al., 2014). To investigate the mechanisms of PG cell-mediated suppression, we measured inhibition (I) and excitation (E) in external tufted cells (eTCs) during patch-clamp recordings in olfactory bulb slices. eTCs are an intermediary cell between olfactory sensory neurons (OSNs) and MCs, and likely regulate MC activation based on the balance between PG cell-to-eTC inhibition and excitation. Using first a protocol in which inhibitory and excitatory currents in eTCs were elicited by electrical stimulation of OSNs, we found dramatic changes in the I/E balance as a function of stimulus intensity. Weak stimuli (Stimthresh = 1-10 μA) produced far more inhibition (I/E = 11.8 ± 2.7, n = 24, p = 0.001; I and E estimated from integrated charge at Vhold = 0 mV and -70 mV, respectively) while stronger stimuli produced more excitation (I/E = 0.51±0.10 at Stimthresh + 30 μA, n = 15, p < 0.0001). Thus, PG cell-mediated inhibition is dominant only when OSN inputs into a glomerulus are weak. We next considered that a potential contributor to the shifting I/E balance was the unusual extrasynaptic nature of recurrent excitation in a glomerulus (Gire et al., 2012). Accumulation of extrasynaptic glutamate could produce supralinear increases in recurrent excitation, making excitation relatively large with respect to inhibition under strong input conditions. Indeed, in pair-cell recordings, single spikes in eTCs produced very small glutamatergic currents in other eTCs and MCs (-35±4 pA*ms; n = 16), but currents rose supralinearly with increasing spike number (F = 3.5±1.1, n = 5, p = 0.022; where F = E due to N spikes/E due to one spike x N). In contrast, single spikes in eTCs produced large excitatory synaptic currents in PG cells (-196±24 pA*ms; n = 9), and excitation rose sublinearly (F = 0.53±0.02, n = 5, p = 0.0024). The shifting I/E balance in eTCs did not appear to reflect the intrinsic properties of PG cells versus eTCs/MCs, since PG cells and eTCs displayed similar threshold intensities at which OSN stimulation generated spikes during pair-cell

recordings (n = 10; p = 0.30). Taken together, our results suggest that non-linearities in GABAergic inhibition and extrasynaptic glutamate-mediated excitation contribute to condition-specific suppression of glomerular output.

Abstract: Characterizing the neural representation of chemical space is a formidable challenge in olfaction research. Unlike many other sensory systems, low-dimensional metrics for characterizing odors have remained elusive and it is unclear what features of chemical stimuli are represented by neurons. Here, we have endeavored to relate neural activity in the early olfactory system of mice to the physico-chemical properties of odorants. We imaged odor-evoked responses in identified tufted and mitral cells in awake mice using multiphoton microscopy. Although both mitral and tufted cells responded with diverse amplitudes and dynamics, mitral cells responses were on average sparser and less sensitive to changes in concentration of odorants compared to tufted cells. We characterized odorant features using a comprehensive set of 1,664 physico-chemical properties that has been extensively used previously. Similarity of physico-chemical features of odor pairs was a poor predictor of similarity of the corresponding neuronal representation by mitral or tufted cells. Dimension reduction revealed that ~22 dimensions could explain more than 90% of the variance in neural responses across the population, but fewer dimensions (~12) were necessary if neural activity was projected on to the space of physico-chemical properties. This suggests that factors other than the physico-chemical properties we considered, including non-sensory signals, are required to fully explain the neural responses. Responsive mitral and tufted cells were spatially dispersed, and cells within a local region were functionally heterogeneous with respect to odor identity and concentration. We used dimension reduction strategies to determine whether any odorant property is laid out in an orderly manner spatially and found only limited and variable dependence of mitral/tufted cell position on odorant characteristics. Our data indicate that novel descriptors are needed to link

chemical space to neuronal representations and that odor information leaves the bulb in a mosaic pattern, with substantial local diversity.

Title: Pharmacological rescue of altered neuronal circuits in a mouse model of X-linked intellectual disability

Authors: ***N. REDOLFI**[1], L. GALLA[1], A. MASET[1], E. SAVOIA[1], I. ZAMPARO[2], C. LODOVICHI[3];

Abstract: Oligophrenin1 (OPHN1) encodes a Rho GTPase-activating protein, that is involved in several developmental processes such as cell migration, axon outgrowth and dendrites formation. How these cellular events can affect neuronal wiring and information processing, leading to cognitive disabilities, remains to be investigated. To address these questions we exploited OPHN1 knockout (KO) mice to analyze circuit formation and function in the olfactory system (OS), where OPHN1 is highly expressed. The OS, one of the few neurogenic niches in the adult mammalian brain, allows a window into a continuous developmental process, in which cell migration, axon outgrowth and dendritic elaboration, that may be altered by mutation in OPHN1, can be thoroughly dissected. Using a cell division marker (Bromodeoxyuridine, BrdU), we found that the generation of new cells in the subventricular zone was not hampered in OPHN1 ko mice versus controls. However, 15 days post BrdU injection the number of newborn cells was significantly decreased in the olfactory bulb. To examine the morphology of the new granule cells (GCs), neuronal precursor were labelled in the SVZ with lentivirus expressing GFP. The morphology of the new GCs was analyzed in the olfactory bulb, 30 days after the SVZ injection. By analyzing the morphology of newborn GFP-labelled GCs, we found that the length and the branching of dendrites was similar in control and experimental animals. However the proportion of filopodia -like spines was significantly increased in OPHN1 ko versus controls. To assess whether the abnormalities in the number and morphology of new GCs could depend on overactivation of the ROCK/PKA signalling, OPHN1 ko and control mice were treated with the

kinase inhibitor fasudil. The treatment successfully rescued the abnormal number and morphology of the adult generated GCs in the olfactory bulb. Our results demonstrated a clear role of OPHN1 in the neurogenesis of the OS and offered a possible new therapeutical approach.

Title: Abnormal olfactory behavior and neural patterning in forebrain-specific Ctgf knockout mice

Authors: *H.-C. CHANG[1], L.-J. LEE[1,2,3];
[1]Grad. Inst. of Anat. and Cell Biol., [2]Grad. Inst. of Brain and Mind Sci., [3]Neurobio. and Cognitive Sci. Ctr., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Connective growth factor (CTGF) is a critical player in connective tissue development. However, in the nervous tissue, CTGF is expressed in some neural cells within distinct areas, such as the olfactory bulb. However, the function of CTGF in the olfactory bulb is far from fully understood. In this study, the role of CTGF in olfaction as well as the neural patterning in the olfactory bulbs was evaluated using forebrain specific Ctgf knockout (FbCtgf KO) mice. In mice, CTGF is expressed in the glomerular layers of the olfactory bulbs. In FbCtgf KO mice, the expression of Ctgf in the olfactory bulb was abolished, while the olfactory bulb was still present. The olfactory detection threshold, evaluated in buried food test, was equivalent between two genotypes. In the olfactory habituation/dishabituation test, wildtype and FbCtgf KO mice exhibited comparable sniffing time to nonsocial odors and homosexual odors, however, in FbCtgf KO mice, the sniffing time to heterosexual odors were increased in both sexes. On the other hand, the number of glomerular calretinin-positive cells was greater in FbCtgf KO mice than wildtype mice. However, the numbers of other juxtaglomerular neurons and glial cells were comparable between genotypes. Since olfactory behavior and olfactory bulb neural patterning are affected in adult forebrain-specific Ctgf knockout mice, our data suggest novel functions of CTGF in the structure and function of the olfactory system.

Title: Serotonergic modulation of olfactory bulb network dynamics

Authors: *M. LEWIS[1], S. T. PEACE[1], G. LI[2], T. A. CLELAND[2], C. LINSTER[1];
[1]Neurobio. and Behavior, [2]Psychology, Cornell Univ., Ithaca, NY

Abstract: The serotonergic dorsal and median raphe nuclei densely innervate the layers of the olfactory bulb, and serotonin (5-HT) has been shown to either excite or inhibit a number of olfactory bulb (OB) cell types (external tufted cells, juxtaglomerular cells, and mitral cells) through both through direct action and synaptic connections, respectively. With regard to animal behavior, 5-HT, within the OB, has been shown to be crucial in the formation of olfactory preference learning in neonatal rats. Within adult rats, we demonstrated that bilateral infusion of the 5-HT2 antagonist, cinanserin (6mM), into the OB, impaired behavior in both olfactory habituation and odor discrimination tasks (Lewis et al. in prep). While intracellular recording methods are crucial to the investigation of the effects of neuromodulators on intrinsic and synaptic properties of neurons, those methods do not allow for the observation and analysis of larger scale network activity in response to experimental manipulations. Here, utilizing a combined *in vitro* neurophysiological and biophysically-constrained modeling approach we are investigating the effects of 5-HT on OB network activity in olfactory bulb slices. To capture large-scale neurophysiological data, we recorded from 300 um thick OB slices taken from young adult (P28-P42) mice, using a 60-electrode planar microelectrode array (MEA; 200 um pitch, 30 um diameter, 30-50 kOhm impedance, 1.4 X 1.4 mm area) to record spike and local field activity under a variety of serotonergic conditions. This preparation revealed strong modulation of basal firing rates (both inhibition and excitation) and a highly robust induction of long-lasting (>1 min) gamma oscillations (OB slice: 20-55 Hz) in response to direct application of 200 uM 5-HT. These effects were blocked when OB slices were perfused with the 5-HT2R antagonist, cinanserin (20 uM) prior to 5-HT application. Current experiments are underway to both quantify these changes and to test lower doses of 5-HT which better mimic the physiological condition. Utilizing a biophysically-constrained network model developed in the NEURON simulation environment, we have begun to incorporate known effects of 5-HT from our and others' *in vitro* studies to better understand the effects of 5-HT on OB network activity.

Title: Behavioral modulation of corticalbulbar feedback and olfactory bulb output in a multisensory reversal learning paradigm

Authors: *P. GARCIA DA SILVA[1,2], B. REBOUILLAT[3,1], M. DAVIS[1], D. F. ALBEANU[1]; [1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Champalimaud Neurosci. Programme, Lisbon, Portugal; [3]Ecole Normale Supérieure de Cachan, Cachan, France

Abstract: To survive, animals need to dynamically alter neuronal sensory representations such as to facilitate efficient decoding of behaviorally relevant stimuli. Depending on context, the same sensory input may require distinct actions. Rodents rely on olfaction for survival and show remarkable ability to identify and discriminate odors of interest in complex environments. Despite significant research effort, to date little is known about how the olfactory system synthesizes odor identity and value from distributed input activity patterns of glomeruli on the olfactory bulb (OB) surface. Here, we combine multiphoton microscopy with multi-dimensional analysis of system dynamics to determine how feedforward signals at the level of mitral and tufted cells (M/T), the OB output channels, are mixed with descending feedback from the anterior piriform cortex (APC) to support olfactory behaviors in a context dependent manner. Towards this end, we devised a head-fixed two modality reversal "switching" task. Mice are asked to detect a target (go) sound and a distractor (no-go) odor and report by licking, or withholding response to a water delivery port. Using a sound instead of a second odor avoids overlap in the sensory activation patterns of the two stimuli, and helps disentangling population activity that reflects the outcome of the stimulus. Once the task is learned to >70% accuracy, the reward contingency is switched. The reversal is performed in a block-like fashion (35-45 trials per block) within each session, in the absence of a cue signal for switching epochs. Mice master the task within 10-15 days (~80% accuracy, 8 mice), perform an average of 5-8 switches (~ 400 trials) per a session and take ~10 trials to switch strategies - licking to new go cue independent of modality. The learned association is robust across days, and the same animal can learn multiple odor/sound pair associations (N=3 mice, >80% accuracy). We are currently monitoring M/T cells dynamics via two photon imaging of GCaMP6f signals (TBET-Cre x Ai95 mice) and corticalbulbar axonal terminals in mice injected with AAV-GCaMP5 in the APC. Preliminary results show that, at the population, level odor and sound responses cluster differently across different task conditions (hits vs. correct rejections vs. false alarms), supportive of top-down behavioral modulation of neuronal dynamics within the OB.

Title: Olfactory bulb plasticity during complex perceptual learning in mice

Authors: *J. FOREST, J. SACQUET, M. RICHARD, A. DIDIER, N. MANDAIRON;
Lyon Neurosci. Res. Ctr., Lyon Cedex 07, France

Abstract: Olfaction is critical in many behaviors, such as research for food, predator avoidance or reproduction. To accomplish these behaviors successfully, an animal must be able to discriminate very close olfactory stimuli with great accuracy. Discrimination performances can be modified by perceptual learning which is defined as an increase in discrimination capabilities of two perceptually close odorants after exposure to this pair of odorants. One of the key supporting structures of this learning is the olfactory bulb (OB) (Mandairon et al. 2008). Interestingly, in the OB, granule cells, a type of inhibitory interneurons, are the target of an important adult neurogenesis originating in the subventricular zone of the lateral ventricles. Previous work showed that adult-born neurons are required for perceptual learning in mice (Moreno et al. 2009). Until now, studies have analyzed behavioral performances and neurogenic correlates during simple olfactory perceptual learning, involving only one pair of odorants. However, in real life, animals are exposed to more complex olfactory environments. Thus, in this study, we investigated how the animal adapts its perceptive abilities when exposed to more odor pairs and examined the underlying neurogenic modulations. We showed that i) increasing the complexity of perceptual learning leads to the discrimination of more odor pairs, ii) perceptual learning increased adult-born cell density independently of the complexity of enrichment (using Brdu labelling of adult-born neurons), iii) increasing the complexity of perceptual learning enhances the functional recruitment of adult-born neurons (using zif268 expression), iv) increasing the complexity of perceptual learning increases structural plasticity of adult-born neurons (labelled by GFP-expressing lentivirus), and v) structural plasticity is specific of adult-born neurons since it is not observed in neurons born during ontogenesis (using lentivirus injection at P1). All together, these results showed that increasing complexity of perceptual learning increases structural plasticity of adult-born neurons (but not of neurons born during ontogenesis) as well as their involvement in processing the learned odorants. Enhancing the complexity of the task thus intensifies adult-born neuron plasticity resulting at the behavioral level in discrimination of a higher number of perceptually similar odorants.

Title: Learning-related changes in odour representations in mitral and tufted cells of the mouse olfactory bulb

Authors: ***R. JORDAN**[1,2], I. FUKUNAGA[1], M. KOLLO[1], A. T. SCHAEFER[1,2];
[1]Neurophysiol., Francis Crick Inst. Mill Hill Lab., London, United Kingdom; [2]Neuroscience, Physiology, Pharmacol., Univ. Col. London, London, United Kingdom

Abstract: The olfactory bulb (OB) consists of feedforward and recurrent circuitry driven by sensory input. However, a large number of inputs from higher centres raises the possibility that odour representation is shaped by contextual input. While contextual changes in OB activity have been reported, the origins of these changes remain unclear. To gain mechanistic insight, we performed intracellular whole cell recordings in the OB of head-fixed mice as they learned to perform a simple olfactory go/no-go discrimination task. Concurrently, odour sampling behaviour was measured via a pressure sensor. Mice were trained to rapidly learn discrimination between two novel odour mixtures, typically reaching criterion of 80% correct responses within 40 trials (~8 mins). We recorded from 18 presumptive mitral and tufted cells (pMTCs) during successful acquisition of this task. Recordings remained stable for 19±7mins (mean±sd) with a mean access resistance of 56±37MΩ. Each odour mixture comprised 3-6 distinct monomolecular odorants known to activate dorsal glomeruli. A large proportion of recorded cells were responsive to these odours, evoking firing rate (FR) changes in 28 of 36 cell-odour pairs. During learning, 8 of 36 cell-odour pairs showed a significant change in average FR response, with either increases for the rewarded odour (CS+; +4.0±4.2Hz, n=3) or decreases for the unrewarded odour (CS-; -10.2±4.1Hz, n=5). These altered responses may arise from top-down modulation of OB processing. However, OB activity is driven by the sniff rhythm. For the cells recorded in behaving animals here, 13 of 14 pMTCs displayed significant sniff coupling of Vm. Therefore, the learning related changes could also arise from altered input patterns to the OB via changes in sniffing behaviour. To evaluate whether changes in odour response may be partially due to altered sniffing, we quantified changes in sniffing frequency during odour stimuli that occurred

across learning. Sniffing frequency changed in various ways for both CS+ (+0.22±0.73Hz) and CS- (-0.02±0.55Hz). These changes showed a significant positive correlation with changes in FR and Vm responses to odours for the CS+ (FR: R2=0.60, p=0.01, Vm: R2=0.59, p=0.002), while no such correlation was observed for the CS- (FR: R2=0.22, p=0.17, Vm: R2=0.02, p=0.61). We conclude that learning results in changes in pMTC responses to odours. However, the accompanying changes in sniff frequency suggest that odour sampling behaviour cannot be excluded as an underlying explanation for altered odour FR responses.

Title: fMRI study of olfaction in the olfactory bulb and higher olfactory structures of rats

Authors: ***F. ZHAO**, X. WANG, H. ZARIWALA, J. M. USLANER, A. HOUGHTON, J. EVELHOCH, C. WINKELMANN;
Merck & Co., West Point, PA

Abstract: Olfactory pathways being rich in synaptic processing would be advantageous for study of *in vivo* pharmacodynamic drug responses. Translatable method such as fMRI has been used to study odor stimulation-induced hemodynamic responses in the olfactory bulb (OB) of rodents. However, fMRI measurements of olfactory processing in other higher olfactory regions (HOR) such as anterior olfactory nucleus, olfactory tubercle and piriform cortex in rodents have not been reported. Since olfactory processing in the HOR of rats has been measured by electrophysiology recording and ultrasound, we hypothesized that fMRI would likewise detect an olfactory processing in HOR. In this study, cerebral blood volume (CBV) fMRI with superparamagnetic iron oxide nanoparticles (USPIO) as contrast agent was used to study olfactory processing in rats. fMRI data were acquired in sixteen 0.75-mm coronal slices covering the OB and HOR. For each animal, either thirty or sixty consecutive fMRI measurements were made during a 3-h experimental session, with each measurement consisting of a baseline period, an odorant-stimulation period, and a recovery period. Two different stimulation paradigms with a stimulation period of 40-s or 80-s were used to study the olfactory responses in OB and HOR, respectively. Our data shows that odorant-induced CBV increases can be robustly observed in the OB and HOR of each individual animal. The olfactory adaptation, which is characterized by the attenuation of responses to continuous or repeated stimulations, has different characteristics in OB and HOR. For the adaptation during the continuous 40-s or 80-s odor exposures, the CBV responses in the OB were stable and did not show adaptation, but the CBV responses in the HOR

were state-dependent, with no adaptation during the initial stimulations, but significant adaptation during the latter stimulations. For the adaptation to the repeated stimuli, while it was observed in both OB and HOR, the responses in HOR adapt more significant than the responses in OB. These results support previous reports that HOR plays a more significant role than OB in olfactory habituation. The technical approach with simultaneous fMRI measurements of olfaction in OB and HOR presented in this study should enable more extensive fMRI studies of olfactory processing in rats.

Title: Top-down cortical modulation of olfactory processing

Authors: H. CHAE, *G. H. OTAZU, M. B. DAVIS, D. F. ALBEANU;
Cold Spring Harbor Lab., Cold Spring Harbor, NY

Abstract: The olfactory bulb (OB) projects in a distributed fashion to several brain areas including the piriform cortex (PC) and anterior olfactory nucleus (AON). These, in turn, send massive glutamatergic projections back into the bulb. To date, little is known about the dynamics and importance of these top-down feedback signals. We used multiphoton calcium imaging to monitor the activity (GCaMP5) of individual piriform cortex feedback axon boutons in the bulb of awake head-fixed mice. Responses of PC feedback boutons were sparse, odor specific and often outlasted stimulus duration by several seconds. Odor presentation either enhanced or suppressed their baseline activity. However, any given bouton responded with stereotypic polarity across multiple odors, preferring either enhancement or suppression. Pharmacological inactivation of PC increased odor responsiveness and pairwise similarity of mitral cells, but had little impact on tufted cells. We propose that PC feedback specifically acts on mitral cell representations to enable odor separation, while only mildly affecting tufted cell responses. We are currently comparing the effects of suppressing activity in the PC versus AON on the two output channels (mitral and tufted cells) of the bulb to understand the roles played by distinct

feedback signals on processing sensory input in the early olfactory circuits. To selectively suppress corticalbulbar feedback axons without disturbing the overall cortical activity, we are using optogenetic methods (JAWS) for local inactivation of the axonal terminals in the OB.

Title: Dynamics of spontaneous activity in the mouse piriform cortex *in vitro*

Authors: ***M. L. TANTIRIGAMA**, J. M. BEKKERS;
The Australian Natl. Univ., Canberra, Australia

Abstract: The mammalian brain remains highly active even in the absence of sensory input. In cortical regions, spontaneous activity carries important information about the network's baseline state. Piriform cortex (PC) is also known to exhibit spontaneous activity, but its origin and statistical properties are unknown. Here, we simultaneously measured the activity of up to 239 neurons in the PC of anesthetized mice that are freely breathing charcoal-filtered air. We used 2-photon microscopy and functional calcium imaging, employing the calcium indicator dye Cal-520. The main input layer (layer 2) of PC contains two distinct populations of glutamatergic neurons: semilunar (SL) cells in layer 2a and superficial pyramidal (SP) cells in layer 2b. We found the properties of spontaneous calcium transients to significantly differ between SL and SP cells in their kinetics (rise time constant: SL, 63 ± 2 ms; SP, 55 ± 1 ms, $p < 0.05$; decay time constant: SL, 372 ± 16 ms; SP, 467 ± 45 ms, $p < 0.05$, mean ± SEM, t-test, n = 4 mice). The frequency of spontaneous calcium transients was higher in SL cells than in SP cells (SL, 0.20 ± 0.02 Hz; SP, 0.13 ± 0.01 Hz, $p < 0.05$). Deconvolution of the calcium signal also estimated a higher spike rate in SL cells than SP cells (SL, 1.6 ± 0.1 Hz; SP, 0.9 ± 0.1 Hz, $p < 0.05$). For both cell types, the frequency distribution deviated from a Poisson distribution in most cases (SL: 80 %; SP: 60 %, both $p < 0.05$, Chisqr test), indicating a non-random temporal structure in the spontaneous events. Topical application of the NMDA channel blocker MK801 to the PC surface completely abolished spontaneous activity (n = 2 mice), indicating a strong dependence on NMDA receptor-driven excitatory transmission. To test whether spontaneous activity is driven by nasal air flow across the olfactory epithelium, we tracheotomized mice to bypass the airway and found that spontaneous activity was unchanged (spike rate, tracheotomized vs. intact, $p = 0.68$, n = 2 mice). We next tested whether spontaneous activity is driven by intrinsic activity in

the olfactory bulb (OB). Removal of the ipsilateral OB significantly reduced the occurrence of spontaneous activity in both layers of PC (spike rate, SL, 0.06 ± 0.04 Hz; SP, 0.07 ± 0.04 Hz, n = 2 mice), and removal of OBs in both hemispheres abolished all activity in the PC. To confirm the bulbar origin of this activity, we imaged up to 112 mitral/tufted (M/T) neurons in the OB. As expected, M/T cells exhibited spontaneous calcium transients at a rate of 0.12 ± 0.01 Hz (n = 2 mice). The findings suggest that computations in PC are superimposed on cell-type specific non-random spontaneous activity that emerges from the OB.

Title: Is the innervation of piriform by the olfactory bulb random?

Authors: *P. A. RHODES;
Evolved Machines, Mountain View, CA

Abstract: Odorant representation in the vertebrate piriform as well as its homolog, the insect Mushroom body, is sparse and widely distributed, and a number of studies (Jortner et al 2006; Stettler and Axel 2009) have concluded that the cortical representation is consistent with fully random innervation. However, the plausibility of random wiring has only been assessed with simplified mathematical realizations, and the results of self-organizing wiring processes have not often been considered. In order to examine whether random wiring is consistent with the observed reliability and sparsity observed in piriform cortex *in vivo* (Stettler and Axel 2009), the wiring between an array of axons representing mitral cell output and an array of branched cortical neurons, each receiving O(103-4) synapses as seen in most insect and all vertebrate systems, was self-organized during simulated sensory input. To model the self-organization of wiring gated by local events, initially random synapses were endowed with an initial stability value which incremented or decremented upon the conjunction or disjunction of presynaptic activity with postsynaptic dendritic and neuronal firing. The sign and magnitude of these adjustments were parameters that controlled the results of the wiring process. Axonal activation patterns were modeled as abstract sets of co-active mitral axon populations as might be associated with single glomeruli, with odorants represented by conjunctions of such subsets. With random wiring, the same sensory input was provided but the wiring reorganization processes were turned off. We found, robustly across sensory environments and other parameters of this system, that the initially random wiring produced odorant encodings that were either highly overlapping, or so fragile to input variation that just a few percent jitter in spike timing

resulted in the cortical representation of repeated presentation of a given odorant varying far more than the 80% repeatability observed (Stettler and Axel 2009). In contrast, if wiring self-organized at the single neuron level so that postsynaptic firing stabilized co-active inputs then the representation that emerged was both highly stable as well as sparse, as observed in cortical systems across phylogeny. The self-organization of wiring at the single neuron level comprised of frequently coactive mitral axons was entirely consistent with the fully distributed nature of the representation of a given odorant across the cortex. The predicted neuron-level convergence of axons emanating from a single or frequently correlated glomeruli in piriform will be straightforwardly assayed by its future connectomic reconstruction.

Title: Somatostatin interneurons in piriform cortex

Authors: *A. M. LARGE[1,2], A.-M. M. OSWALD[1,2];
[1]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [2]Ctr. for the Neural Basis of Cognition, Pittsburgh, PA

Abstract: Odor information is processed by the neural circuitry of the piriform cortex. Pyramidal cell responses to odor information are controlled by GABAergic inhibitory interneurons. Recent studies have characterized interneurons in piriform cortex (1) but little is known about the functions of distinct classes. Interneurons that express somatostatin (Sst) are a major class of interneurons that inhibit pyramidal cells. In this study, we analyzed the diversity and connectivity of Sst cells in APC using two transgenic mouse lines, GIN (2) and Sst-Cre (3). Previous studies have suggested that Sst interneurons can be divided into at least three classes based on their expression in distinct mouse lines: GIN, X94, and X98 (4). In contrast to many other sensory cortices, we find that APC has a dearth of GIN cells. Furthermore, using Sst-cre/lox-tdTomato mice, we find a greater proportion of fast-spiking (FS) interneurons consistent with X94 cells versus regular spiking (RS), X98-like cells. To study the targets of Sst cells, we selectively activated Sst interneurons in brain slices from Sst-cre/lox-ChR2 mice while recording inhibitory postsynaptic currents (IPSCs) in Sst(+) interneurons as well as Sst(-) interneurons and pyramidal cells in anterior piriform cortex (APC). We find that Sst cells target both types of FS cells (PV(+) and SSt(+)) as well as PCs. Moreover, the spatial profile of inhibition differs markedly between PC and interneuron cell classes. We are currently addressing the function role of Sst neurons in APC circuits and odor processing. 1) Suzuki and Bekkers (2010) Cerebral

Title: Encoding odors with ensembles of piriform cortex neurons in awake and anesthetized mice

Authors: K. A. BOLDING, *K. M. FRANKS;
Neurobio., Duke Univ., Durham, NC

Abstract: Previous studies have indicated that odors are encoded by ensembles of coordinately active neurons distributed across piriform cortex. However, the nature of these ensembles remains poorly understood. Moreover, earlier studies were performed exclusively under either awake or anesthetized conditions but it is not known how anesthesia affects cortical odor representations. We therefore recorded spontaneous and odor-evoked spiking activity from populations of piriform cortex neurons in awake, head-fixed mice. Mice were then anesthetized with ketmaine/xylazine (k/x) to generate multiple, simultaneously recorded sets of cell-odor pairs measured under both awake and anesthetized conditions. Spontaneous activity, which was higher and tonic when the mouse was awake, slowed and became strongly coupled to respiration under k/x. Despite these differences in spontaneous activity, odor responsiveness was similar in awake and anesthetized conditions: only a few cells responded to each odorant with significant increases in spiking (8% awake; 10% k/x; 1,260 cell-odor pairs), and lifetime and population sparseness were similar across conditions. Responsive cells fired in brief bursts shortly after inhalation onset, with responses being slower and slightly longer in k/x. Suppression was also observed and was more prevalent in awake compared to k/x conditions, occurred later in the sniff than activation, and typically persisted for the remainder of the sniff. Population odor responses were defined by spike counts for each cell during the first full sniff following odor onset. A linear classifier could accurately determine the odorant that evoked these responses when trained and tested on responses evoked within a condition, indicating that these ensembles do indeed encode odor identity. However, only ~1/3 of the neurons that responded to a given odor in one condition also responded to that odor in the other condition, and the classifier, while still well

above chance, performed significantly worse when trained and tested on responses from different conditions. However, cells that responded to an odor in both conditions typically responded earlier than cells that only responded in only that condition, suggesting that the temporal structure of an ensemble may also encode important information about odor identity. It also suggests that early-responding inputs may be preferentially driven by direct sensory information while inputs responding later in the sniff may be preferentially recruited by more state-dependent, intracortical activity. These studies therefore help define and provide mechanistic insight into the nature of cortical odor representations.

Title: Piriform outputs effect multi-stage normalization of cortical odor representations

Authors: *K. A. BOLDING, K. M. FRANKS;
Dept. of Neurobio., Duke Univ., Durham, NC

Abstract: Odor identity is thought to be encoded by ensembles of neurons in piriform cortex. Although activation of odorant receptors and olfactory bulb glomeruli scale steeply with odorant concentration, odors typically retain their perceptual identities over a large range of concentrations suggesting that olfactory information must be normalized within the bulb, within piriform cortex, or both. Previous *in vitro* electrophysiology and computational modeling studies have suggested that recurrent excitatory circuits in piriform cortex may play a major role in normalizing piriform output by recruiting strong and scaled feedback inhibition. We tested this prediction by unilaterally introducing AAVs that conditionally express tetanus toxin (TeLC) into piriform cortex of emx-1-cre mice. This strategy selectively *muted* piriform principal cells, which retained their feedforward excitatory and inhibitory inputs and could fire action potentials, but could no longer drive recurrent excitation or recruit feedback inhibition. We first recorded odor-evoked spiking to multiple odorants at different concentrations (0.03% - 1% vol./vol.) from populations of presumptive olfactory bulb mitral/tufted (M/T) cells and pirifrom cortex neurons from the uninfected hemisphere. Comparing spiking across the population at the highest and lowest concentrations, we found output increased by 75% in the bulb and 55% in piriform cortex. Some normalization of bulb output therefore occurs in piriform cortex. Analysis of

single-unit responses revealed that, while a few cells responded to higher odorant concentrations with increased firing, many other cells became increasingly suppressed. Odorants at low concentrations activated qualitatively similar ensembles in control and tetanus-infected cortices. However, increasing odorant concentration 30-fold produced a dramatic 212% increase in spiking in the muted cortex, with almost no suppression observed in single units. Principal neurons in piriform cortex therefore play a major role in normalizing their output. This normalization may occur through recruitment of cortical feedback inhibitory circuits, but TeLC will also mute piriform projections back to olfactory bulb, and these may normalize bulb output via disynaptic inhibition of M/T cells. We therefore also recorded M/T cell responses ipsilateral to the TeLC-expressing cortex and indeed found a 165% increase in spike output, indicating that some of the normalization seen in the piriform is due to suppression of bulb output. Taken together, these results demonstrate that piriform cortex neurons normalize their output at multiple stages in the olfactory pathway.

Title: State-dependent oscillatory coding and interactions between olfactory bulb and piriform cortex

Authors: *S. GAUTAM, S. CHAKRABORTY, W. L. SHEW;
Univ. of Arkansas, Fayetteville, AR

Abstract: How a neuron responds to sensory stimulation depends on the state of the network in which the neuron is embedded. The network state shifts depending on behavioral context; for example, learning, changes in attention, sleep, and anesthetic depth can result in very different ongoing network dynamics and different response to sensory input. In the olfactory system, such state-dependent coding of sensory information has been observed in olfactory bulb (OB) and, in separate studies, in piriform cortex. However, olfactory information is processed by cooperative interactions between OB and cortex and it remains unclear how changes in network state affect interactions between OB and cortex. Previous studies suggest that certain frequencies of oscillations (~10-40 Hz, in particular) mediate interactions between OB and cortex. Other studies highlight the fact that oscillations depend on network state. Indeed, changes in ongoing oscillations are often used to define changes in network state. Considered together, these

previous studies raise a basic question: how do changes in the state of the OB-cortex network impact the processing of olfactory sensory information? To address this question, we studied ongoing activity and odor-evoked activity using simultaneous dual microelectrode array recordings in OB and anterior piriform cortex (aPC) in urethane anesthetized rats. Two different odorants were administered by two different routes - either orthonasally or retronasally. As in previous studies, we observed prominent local field potential (LFP) oscillations at a few distinct frequencies during both ongoing and odor-evoked activity. Our primary finding is that the degree of oscillatory coordination between OB and aPC was dependent on both the stimulus type and the network state. For all stimuli and network states, odors evoked oscillations in both OB and aPC, but these oscillations were coordinated only when a shared frequency existed in both brain regions, typically in the 10-40 Hz range. The lower frequencies tended to be correlated with smaller phase lag than higher frequencies. Our findings demonstrate that olfactory information is relayed to cortex, no matter what the network state is - changes in network state do not gate sensory information. But, the interactions between OB and aPC vary dramatically depending on network state and stimulus type. Our results suggest that the olfactory system must cope with olfactory codes that change depending on network states.

Title: The olfactory cortex areas coordinately perform inhalation-exhalation switching between superficial- and deep-layer active states

Authors: *K. NARIKIYO[1], H. MANABE[2], K. MORI[3];
[1]Lab. for Neurobio. of Synapse, RIKEN Brain Sci. Inst., Saitama, Japan; [2]Dept. of Systems Neurosci., Doshisha Univ., Kyoto, Japan; [3]Dept. of Physiol., The Univ. of Tokyo, Tokyo, Japan

Abstract: Olfactory perception depends on discrete respiration cycles, each consisting of an inhalation and exhalation phase. The central olfactory system is engaged in online processing of external odor information during inhalation but is isolated from the external environment during

exhalation. Although sensory processing in the olfactory cortex during inhalation has been reported previously, the functional role of olfactory cortex activity during exhalation remains unclear. To investigate the activities of the olfactory cortex during exhalation, we recorded local field potentials and unit activities in the anterior olfactory nucleus and piriform cortex in a head-fixed conscious rat using a linear multi-channel electrode. Concurrently, we monitored the respiration. Local field potentials of the olfactory cortex showed respiration-paced slow oscillations. Current source density analysis revealed fast oscillatory current sinks superimposed on a slow current sink in the superficial layer (layer I) during the inhalation phase. Surprisingly, the deep layers (layers II and III) showed oscillatory current sinks and a slow current sink during the exhalation phase. Olfactory sensory deprivation by naris occlusion or bilateral olfactory bulbectomy did not eliminate the inhalation-coupled slow current sink in the superficial layer and neither did it eliminate the exhalation-coupled slow current sink; however, whereas inhalation-coupled fast oscillatory current sinks (gamma or beta oscillations) were diminished. Both the superficial and deep layer current sinks accompanied spike discharges of olfactory cortex neurons. Importantly, the exhalation-coupled neuronal firings persisted, even after bilateral olfactory sensory deprivation, thereby suggesting intrinsic generation. These results indicate that the olfactory cortex areas simultaneously perform inhalation-exhalation switching of the operation mode. The inhalation phase is the time-window for processing olfactory sensory input in the superficial layer circuits whereas the exhalation phase is the temporal framework for the internal generation and coordination of the deep layer circuit activity across different regions of the olfactory cortex.

Title: Spatial profiles of inhibition onto semilunar and pyramidal neurons in piriform cortex

Authors: N. W. VOGLER, A. M. LARGE, *A.-M. M. OSWALD;
Dept. of Neuroscience, Ctr. for the Neural Basis of Cognition, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Inhibition regulates neural activity throughout the cortex. While numerous studies have investigated the temporal relationship between excitation and inhibition in piriform cortex, little is known about the spatial recruitment of inhibition. In this study, we investigated the spatial profiles of inhibition onto semilunar cells (SL, n=16), L2 (n=14) and L3 (n=17) pyramidal cells (PC). For each excitatory cell, we recorded IPSCs in response to optical

activation of surrounding inhibitory interneurons in sagittal slices from vGAT-ChR2 mice using two protocols- 1) *Local*: focal (~70 μm) light spots directed a grid locations separated by 150 μm, and, 2) *Global:* full field illumination. We compared the local, global, laminar, and rostral-caudal recruitment of inhibition between the three excitatory cell classes. In response to local stimulation centered on the recorded neuron, SL cells and L2PCs received comparable inhibition that was significantly weaker than inhibition received by L3PCs. However, in response to global stimulation, a subset of L2PCs received more inhibition than simultaneously recorded nearby (<50 μm) SL cells. For each cell type we analyzed the laminar profiles of inhibition as a percentage of the total inhibition. We found that SL cells received significantly greater inhibition from L1 interneurons and significantly less from L3 compared to L2 or L3 PCs. In addition, L3 pyramidal cells received significantly greater inhibition from deep L3 interneurons than SL or L2PCs. Finally, we found that SL cells as a population do not receive biased inhibition along the rostral-caudal axis. In contrast, L2 and L3 pyramidal cells received significantly caudally biased inhibition. In all cases, significance at $p<0.05$ using paired and unpaired t-tests. Taken together these results suggest that inhibition increases from L2 cells to L3 cells as well as along the rostral caudal axis in PCs. Thus, SL, L2PCs and L3PCs have both overlapping and distinct laminar sources of inhibition that may be differentially recruited by afferent or recurrent circuit activation. Ongoing studies are directed at identifying the functional role of these spatial gradients of inhibition in odor processing.

Institute, Harvard Med. Sch., Boston, MA; [5]Brain Res. Institute, Univ. of Zurich, Zurich, Switzerland; [6]ETHZ, Zurich, Switzerland

Abstract: It is established that the lateral entorhinal cortex (LEC) supports different functions, including object recognition, novelty detection and odor processing. The LEC receives direct input from the olfactory bulb (OB) and other olfactory cortical areas and conveys this information to the hippocampus. This connectivity designates the LEC as crucial relay station for odor information processing and the formation of associative memories in the hippocampus. Whereas it has been shown that single cells in LEC superficial layers respond to odors, it is not known how this activity relates to specific cell types. We characterized the two major excitatory cell types, calbindin- and Reelin-positive neurons, as well as GABAergic interneurons in layer II LEC, using anatomical approaches and *in vivo* calcium imaging combined with patch-clamp recording. Odor stimulation induced calcium transients in layer II neurons with odor responsiveness differing in a cell-type specific fashion. Reelin-expressing feedforward neurons responded with higher selectivity to specific odors compared to calbindin-expressing putative feedback neurons and GABAergic neurons. Notably, at the population level the performance in odor discrimination was comparable for Reelin- and calbindin-positive neurons, but significantly lower for GABAergic neurons. Our results highlight the functional differences among defined neuronal subpopulations in the LEC.

Title: The encoding of stimulus valence and primary reinforcers in the olfactory tubercle

Authors: *M. A. GADZIOLA, K. A. TYLICKI, D. L. CHRISTIAN, D. W. WESSON; Neurosciences, Case Western Reserve Univ., Cleveland, OH

Abstract: Sensory information acquires meaning to adaptively guide behaviors. Despite odors mediating a number of vital behaviors, the components of the olfactory system responsible for assigning meaning to odors remain unclear. The olfactory tubercle (OT), a ventral striatum structure that receives monosynaptic input from the olfactory bulb, is uniquely positioned to encode reward and transform odor information into meaningful neural codes. In recordings from mice engaged in an odor discrimination task, we report that the firing rate of OT neurons robustly and flexibly encodes the valence of conditioned odors over identity, with rewarded odors evoking greater firing rates. This coding of rewarded odors occurs prior to behavioral decisions and represents subsequent behavioral responses. To further evaluate the OT as a substrate for motivational information processing, in a second experiment we investigated whether OT neurons respond to primary reinforcers. Mice were trained to lick a spout according to a fixed-ratio (FR-18) schedule for delivery of a liquid reward. Reward type and magnitude was randomized and included tap water, 2 mM saccharine, and 1 mM quinine solutions, delivered at 4, 8 or 12 μL volumes. Firing rates of OT neurons were modulated by both the licking behavior and reward delivery, with larger volume rewards evoking greater firing rates. Taken together, these results illustrate the profound capacity for the OT to encode both stimulus valence and primary reinforcers in manners likely essential for not only basic sensory coding but also motivated and affective behaviors.

Title: The olfactory thalamus: characterizing single-unit activity of the mediodorsal thalamic nucleus in behaving rat

Authors: *E. COURTIOL[1,2], D. A. WILSON[1,2];
[1]Emotional Brain Inst., Nathan Kline Inst. For Psychiatric Res., Orangeburg, NY; [2]Dept. of Child & Adolescent Psychiatry, New York Univ. Langone Med. Ctr., New York, NY

Abstract: The thalamus is a key crossroad structure in the brain and is recognized as a major contributor to sensory perception, attention, sleep and arousal and memory. For all senses except olfaction, the information from the sensory neurons necessarily passes through a thalamic

nucleus before reaching the primary sensory cortex. However, an olfactory thalamic nucleus exists: the mediodorsal thalamic nucleus (MDT) receives direct input from different olfactory structures including the piriform cortex (PCX), and in turn has bi-directional projections with the orbitofrontal cortex (OFC). Functionally, we have shown that, in urethane-anesthetized rats, MDT units respond to a wide variety of odorants and that odor stimuli induce a conjoint emergence of beta frequency oscillations in both the MDT and the PCX. Beyond this odor responsiveness, the precise role of the MDT in olfaction remains unclear. In fact, lesion studies in both humans and animal models suggest a role for the MDT in olfactory perception, odor discrimination, learning and attention. The MDT is a higher order thalamic nucleus and is involved in various cognitive processes such as spatial and working memories, instrumental decision-making and stimulus-reward association. Despite the unusual arrangement of the olfactory pathway, how are primary sensory and higher order cognitive functions interwoven in MDT activity? To investigate precisely the role of the MDT in olfactory processing, we recorded MDT single unit activity, using a multi-tetrode drive, in 8 rats performing a two alternative odor discrimination task. We observed that a subset of MDT units are odor selective. Intermingled with this sensory function, we also observed that the MDT presents specific temporal patterns of activity during the pre-sampling period and seems to encode the direction/goal location. Our results thus reveal the involvement and the complex role of the MDT in olfactory processing. Finally, the preliminary analyses of the field potentials and MDT spike-local field potentials in both PCX and OFC will help us to better understand the role of the MDT and the relationship between MDT, its olfactory input and output.

Title: Variability and adaptation of odor representations in the zebrafish homolog of olfactory cortex

Authors: G. A. JACOBSON, *R. W. FRIEDRICH;
Friedrich-Miescher-Institute For Biomed Res., Basel, Switzerland

Abstract: Odor-induced activity patterns arising from the vertebrate olfactory epithelium are initially processed in the olfactory bulb (OB), which subsequently transmits stable and decorrelated activity patterns to the olfactory cortex (OCx). We studied the dynamics of odor representations in the zebrafish homolog of olfactory cortex, area Dp, in response to repeated applications of the same odor, with the aim of analyzing the stability of odor representations. Population activity patterns were measured by 2-photon Ca2+ imaging in an ex-vivo preparation of the intact brain. Response patterns exhibited large trial-to-trial variability and marked adaptation, phenomena not observed in the OB output. To study whether synaptic plasticity mechanisms are involved in generating variable responses within OCx, we blocked NMDA receptors using APV (50 μM), which has minimal effects on OB output. In the presence of APV, odor responses were highly stable and exhibited no significant adaptation. Moreover, spontaneous activity of OCx neurons was suppressed. Two processes contributed to the variability of odor responses under control conditions. First, a small part of the variability is explained by a gradual change in the neuronal representation across trials, as correlations between pairs of response patterns decrease as a function of the separation between the trials. NMDA blockage may suppress plasticity mechanisms underlying this gradual change in representation. Second, we characterized neurons categorically as spontaneously active or silent. Spontaneously active neurons exhibited significantly higher variability in their responses, even when controlling for adaptation. This suggests that spontaneous activity in the OCx, suppressed in the presence of APV, interacts with the stable patterns arriving from the OB and contributes to response variability.

Abstract: The mushroom body (MB) of the *Drosophila* olfactory system is critical for olfactory learning and memory. Intrinsic neurons of the MB, Kenyon cells (KCs), receive olfactory inputs from projection neurons in the calyx, converge to form the pedunculus, and bifurcate to form the vertical and medial lobes. We used a second-generation high throughput transmission electron microscopy (EM) camera array (TEMCA2) to acquire a large-scale EM dataset of 863 serial thin (<50 nm) horizontal sections (z = ~34.5 μm, 4x4x40 nm/voxel) through the entire adult *Drosophila* brain, centered on the pedunculus of MB. After stitching and registration, the resulting image volume comprises 1.9 million 8-bit camera images consuming 12 TB of disk storage, and each section is 150,000 x 95,000 pixels (600 x 380 μm) in width and height. We used the web-based annotation tool CATMAID (Saalfeld et al. Bioinformatics 2009) to reconstruct a subset of neurons within the volume with skeleton tracing. We identified 32 KCs by their inputs from olfactory projection neurons in micro-glomeruli of the calyx (Butcher et al. J Comp Neurol 2012) and traced them to completion within the volume. Their relative locations, morphology, and trajectories in the pedunculus and γ-lobe match those of γ KCs in light microscopy data (Aso et al. eLife 2014). Our tracings reveal that γ KCs form small synapses with each other in pedunculus. Additional possible sites of synaptic interaction are observed in calyx and the γ1 lobe, often in proximity to synapses between the reconstructed KCs and a single postsynaptic MBON innervating γ1. In a parallel effort at Janelia using a FIB-SEM dataset, similar motifs have also been observed in the α-lobe of the mushroom body (Janelia Fly EM Project, unpublished data). Based on arbor structure, innervation area and γ KCs as a source of input, we identified the MBON as γ1-pedc>a/B (Aso et al. eLife 2014). A connectivity graph of 32 γ KCs that are fully reconstructed in the EM volume is revealed. After initial sampling of olfactory space by KCs in the mushroom body calyx, the synaptic interactions we observe between KCs in the pedunculus may allow channel mixing of olfactory information prior to arrival of olfactory information in the associational compartments of the MB.

Title: Plasticity-driven individualization of olfactory coding in mushroom body output neurons

Authors: ***T. HIGE**[1], Y. ASO[2], G. M. RUBIN[2], G. C. TURNER[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]HHMI, Janelia Res. Campus, Ashburn, VA

Abstract: Although all sensory circuits ascend to higher brain areas where stimuli are represented in sparse, stimulus-specific activity patterns, relatively little is known about sensory coding on the descending side of neural circuits, as a network converges. In insects, mushroom bodies (MBs) have been an important model system for studying sparse coding in the olfactory system, where this format is important for accurate memory formation. In *Drosophila*, the 2000 Kenyon cells (KCs) of the MB converge onto a population of only 35 MB output neurons (MBONs). Here we provide the first comprehensive view of olfactory representations at the fourth layer of the circuit, where we find a clear transition in the principles of sensory coding, and demonstrate their flexibility. We show that MBON tuning curves are highly correlated with one another. This is in sharp contrast to the process of progressive decorrelation of tuning in the earlier layers of the circuit. Instead, at the population level, odor representations are reformatted so that positive and negative correlations arise between representations of different odors. At the single-cell level, we show that uniquely identifiable MBONs display profoundly different tuning across different animals. Interestingly, tuning of the same neuron across the two hemispheres of each fly was nearly identical. These results show that individual-specific coordination of tuning arises at this level of the circuit. Furthermore, we find that this individualization is an active process that requires a learning-related gene, rutabaga. Ultimately, neural circuits have to map highly stimulus-specific information in sparse layers onto a limited number of different motor outputs, in a way that is flexible. The reformatting of sensory representations we observe in the MBON layer may mark the beginning of this sensory-motor transition in the olfactory system.

Abstract: Humans and monkeys can perceive multiple sounds simultaneously. However, it is still unknown how the mammalian auditory system parses free-field stimuli in order to create a 'menu' of sound streams for cortical attention processes to select from. This is a problem for the brain because in the free-field case, each sound stream generally arrives at both ears. Here, we use single-unit and multi-unit recordings in the primate inferior colliculus (IC) to investigate the encoding of scenes containing multiple sounds. A methodological challenge in interpreting neural responses to multiple stimuli is knowing which individual stimulus in the scene triggered each spike in the response; in other words, which individual stimulus is 'represented' by the neurons at each point in time. The auditory system including the IC offers a good setting to study this: spikes in the IC can phase lock to the sound that evoked them. We reasoned that it if phase locking is maintained in the presence of multiple sounds, we could use the frequency of phase locking to assign each spike in a response to the sound that evoked it: a frequency-tagging approach. . We presented auditory environments containing two simultaneous sounds to two passive rhesus monkey listeners. Sounds were always presented from separate locations and had different envelope frequencies (amplitude modulations, AM). We tested two scenarios: sounds that differed in carrier frequency (spectral content) vs. sounds that had the same carrier frequency. We found a robust relationship between the neuron's physiological frequency preferences in the single sound case and its phaselocking preference in the dual sound case. Thus, the auditory scene was parsed according to the same tonotopic gradient that was used for single sounds, creating a tonotopic 'menu' of the auditory scene. In the case when the sounds had the same spectral content, the IC used a different scheme: spatial location itself provided a means of sorting. Most neurons represented the sound contralateral to themselves, creating a spatial 'menu' of the scene. This spatial sorting cannot be explained by the spatial encoding of single-sounds, because the effect does not positively correlate with spatial tuning for single sounds, and furthermore, the dual-sound spatial tuning is significant at the population level even among the subpopulation of sites with minimal/no spatial tuning for single sounds. . Our results demonstrate that the IC is capable of parsing apart auditory scenes containing multiple sounds, and can change between different mechanisms depending on the cues available.

Title: The code biasing the owl's orienting behavior in situation of uncertainty

Authors: *F. CAZETTES[1], B. J. FISCHER[2], J. L. PENA[1];
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Mathematics, Seattle Univ., Seattle, WA

Abstract: How the brain, often a biased estimator, translates sensory information into adaptive behavioral responses is still a matter of debate. We study this question in the sound localization system of the barn owl. We have previously shown that neurons in the owl's midbrain map of auditory space are tuned to the most reliable auditory cue and that the degree to which a cue can be trusted is encoded in the shape of tuning curves. The next outstanding question is how the neural population is readout to capture cue reliability in the behavioral response. We tested the hypothesis that a population vector captures cue reliability and explains the biased orienting behavior of the owl in situation of uncertainty. We examined if a vector decoder can be computed by a population of neurons in the owl's midbrain tegmentum, which directly commands head orientation. We showed that convergence and normalization from the midbrain map leads to the emergence of a population vector in the tegmentum. We further demonstrated that manipulating the sensory input to modify specific response properties of the midbrain population can enhance or reduce the owl's behavioral bias in a manner predicted by the population vector and by the population response in the tegmentum. This is the first time a biased behavior has been explained at the encoding, decoding and behavioral levels.

Title: Amplitude modulation rate discrimination and cortical encoding in the awake-behaving gerbil

Authors: *G. VON TRAPP, M. N. SEMPLE, D. H. SANES;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Fluctuations in sound amplitude (AM) are an important component of animal communication signals. Here, we explore the relationship between perceptual sensitivity and auditory cortex neuron encoding of AM rate in gerbils. Freely-moving animals were tested on an AM rate discrimination task while recording telemetrically from an electrode array implanted in core auditory cortex. Animals received a water reward on correct responses to target stimuli ("Go" trials), and no reward on trials that did not contain the target ("Nogo" trials). We measured the sensitivity of auditory cortex neurons to identical stimulus sets during two behavioral conditions: (1) Discrimination of any "Go" token greater than 4 Hz (the "Nogo") or (2) discrimination of any "Go" token slower than 32 Hz (the "Nogo"). Neural responses were also measured when animals were not engaged in the task. Psychometric analysis of AM rate discrimination thresholds showed similar sensitivity for both behavioral conditions (JND was 0.98 (n=5) and 0.91 (n=7), respectively). The sensitivity of individual auditory cortex neurons to AM rate stimuli were quantified using metrics of both discharge rate and temporal pattern, and compared to the behavioral thresholds. Title: Activation of parvalbumin-positive interneurons enhances transient responses and changes tuning of offset responses in awake auditory cortex

Authors: *K. J. HILDEBRANDT[1], P. J. GANÇALVES[2], M. SAHANI[2], J. F. LINDEN[3];

Abstract: Alterations of cortical inhibition have been proposed to play a crucial role in modulation of cortical activity. While optogenetic manipulation of different functional groups of interneurons has become an important tool for studying the roles of different cells in sensory

processing, the timing of light relative to sensory stimulation is often a confounding factor, and the pattern of supra-threshold activation of inhibitory neurons may not be physiologically accurate. Here, we circumvent these limitations by using stable step-function opsin (SSFO), which can be rendered continuously active or inactive with short pulses of light. We expressed SSFO in parvalbumin-positive (PV+) interneurons in the primary auditory cortex of mice, and recorded both local field potentials (LFP) and spiking responses to tone pips of varying frequency in awake animals. Prolonged low-level activation of PV+ cells profoundly changed the dynamics of spike responses in several and diverse ways. While spontaneous activity and sustained responses to tones were mostly suppressed during PV+ activation, onset and offset responses where either enhanced or reduced less than spontaneous responses, thus increasing signal-to-noise ratio. Frequency tuning of offset responses changed, with best frequencies shifted downwards by as much as an octave. The tuning shift was much less pronounced in sustained and onset responses. PV+ activation also resulted in narrower frequency tuning of offset responses in the majority of recorded cells. Intriguingly, tuning broadened for a small fraction of units whose spontaneous activity increased during activation. Possibly, these units were PV+ cells directly activated by SSFO. Analysis of LFP data confirmed the contrary effect of PV+ activation on transient and sustained responses. Activation of SSFO caused a decrease of the power in the high-gamma range (50-150Hz) during spontaneous and sustained tone-response phases. Both onset and offset responses were boosted compared to control, and offset responses increased more than onset responses. Generally, SSFO activation increased power in the low-frequency range of the LFP (<50Hz) and decreased power in the high-frequency range (50-150Hz, high gamma). In summary, our experiments show that prolonged low-level activation of PV+ cells with SSFO increases the signal-to-noise ratio of transient responses to sound and changes tuning of offset responses. These results indicate that alterations of inhibition have a profound impact on cortical network dynamics.

Title: Cortical population nonlinearities reflect asymmetric auditory perception in mice

Authors: A. KEMPF[1], T. DENEUX[1], P. EMMANUEL[2], *B. BATHELLIER[1];
[1]UNIC, CNRS, Gif sur Yvette, France; [2]IRCAM, Paris, France

Abstract: Natural sounds display strong temporal variations of intensity, which are part of the features influencing perception and recognition of sounds. Strikingly, for example, humans perceive a tone that increases in intensity as louder than same tone with a decreasing intensity profile, although both sounds have the same energy and frequency content. The underlying neuronal mechanisms of this perceptual asymmetry are still elusive. To test if the direction of intensity variations is asymmetrically processed by the auditory system, we have measured the activity of large populations of neurons in the auditory cortex of awake mice using GCAMP6 two-photon calcium imaging. Pooling a large number of recordings together, we observed that the time integral of cortical population firing rate is much larger for sounds ramping-up than for sounds ramping-down. This asymmetry demonstrates that cortical population response is strongly non-linear. To test for perceptual consequences of this non-linearity, we performed behavioral experiments in which the saliency of a sound is measured through associative learning speed. We observed that increasing ramps are more rapidly associated to a correct behavior than decreasing ramps, showing that the asymmetry of cortical population responses reflects an asymmetry in perceived saliency. Moreover, finer analysis of cortical data indicate that ramps produce complex population activity sequences in which distinct patterns emerge depending on the direction of sound intensity variations. Based on simple population models, we show that the asymmetry of population firing rate and the complexity of activity sequences could be explained by competing populations of neurons encoding different aspects of the temporal profile (e.g. sound onset, offset). Beyond proposing a mechanism for a perceptual asymmetry that may emphasize approaching sound sources, our results suggest that non-linear interactions between temporal feature detectors could be one of the bases of sound recognition.

Title: Local sensory context modulates responses to complex sounds in multiple brain areas along the auditory pathway

Authors: *A. F. MEYER[1], J. F. LINDEN[2], M. SAHANI[1];
[1]Gatsby Computat. Neurosci. Unit, [2]Ear Inst. and Dept. Neuroscience, Physiol. & Pharmacol., Univ. Col. London, London, United Kingdom

Abstract: Neurons in the auditory system are sensitive not only to the spectro-temporal pattern of a sound but also to the context in which that pattern occurs. Spectro-temporal sensitivities of neurons have been extensively studied using the spectro-temporal receptive field (STRF), a linear model relating a sound to the evoked response. However, little is known about the context-dependence of these sensitivities during stimulation with complex sounds. We characterized neuronal responses using the context model [1], a previously proposed form of multilinear model [2] which simultaneously characterizes both a linear "principal receptive field" (PRF) and a "contextual gain field" (CGF). The CGF describes how local gain at a particular point in the PRF is modulated by local stimulus context. We fit the context model to spiking data recorded in inferior colliculus, auditory thalamus and primary auditory cortex of rodents, as well as publicly available data sets [3] from homologous auditory areas in birds, all recorded during presentations of complex but stationary broadband sounds. In every case, the context model provided a more accurate description of neuronal responses than did the linear STRF model, yielding an increase in cross-validated predictive power of about 20%. Local facilitation in CGFs varied, but all areas shared a common pattern of reduction in input gain by preceding sound energy within about an octave range -- an input-frequency-specific, divisive form of forward suppression. The temporal structure of this suppression varied, with latencies ranging from 5-15 ms in birds and up to 80 ms in rodents. Both latency and temporal extent increased from midbrain to forebrain. Using analytical results and simulations, we demonstrate that a cascaded context model can account for the increasing extent of contextual gain effects along the ascending auditory pathway. The results suggest that these nonlinear features of sensory neurons, which are not captured by linear STRFs, are transformed along the auditory pathway in a feed-forward manner. Further exploration of these mechanisms may help to elucidate the role of nonlinear integration in generating more complex sound representations in the auditory system. Title: Swarm intelligence meets the brain: estimating cellular parameters related to auditory processing in young and aged rats using particle swarm optimization

Authors: *B. S. COVENTRY[1], A. PARTHASARATHY[1], E. BARTLETT[1,2];
[1]Weldon Sch. of Biomed. Engin., [2]Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN

Abstract: Age-related hearing loss affects 29% of male and 23% of females over the age of 60 (Yamasoba et al, 2013) and is marked by deficits in processing speed (Wingfield et al, 1985) and difficulty with speech in complex listening environments (Frisina and Frisina, 1997). The inferior colliculus (IC) is a major auditory integrative center, receiving inputs from cochlear nuclei, the superior olivary complex and nuclei of the lateral lemniscus (Kelly & Caspary, 2005). How these inputs converge to generate complex frequency and temporal processes is not well understood. Moreover, while the synaptic and membrane properties that shape this processing have largely been examined in isolation, their interactions are poorly understood. In addition, age-related changes in GABAergic markers upset the delicate balance of excitation and inhibition in the IC (Caspary et al, 1999; Palombi and Caspary, 1996). Here we utilize a modified version of our previously published IC computational model (Rabang et al., 2012) to elucidate synaptic input parameters that fit individual recorded single unit responses in IC, using the NEURON programming environment under control of Python (Hines et al, 2009; Carnevale and Hines, 2005). To fit responses of the model to responses from single unit recordings of the rat IC, the model was modified to incorporate particle swarm optimization (PSO), an optimization method which models social networks of flocking birds or schooling fish to solve mathematical problems (Kennedy and Eberhart, 1999). We have recently developed a new PSO social network that mimics visual cortex winner-take-all coding (WTAPSO). WTAPSO has shown excellent performance in higher dimensional problem solving (Coventry & Bartlett, in prep) compared to other PSO algorithms. With computational models linked with WTAPSO, we will test whether age-related changes in frequency tuning can be explained by changes in synaptic parameters, such as GABAergic inhibition, consistent with what has been seen *in vivo*. Additionally, we will explore other synaptic mechanisms, such as those involved in onset and sustained responses and how they contribute to age-related processing deficits. WTAPSO can be applied widely to optimization problems such as those encountered in neuronal modeling.

Title: Representations of voice onset timing cues in the inferior colliculus of young and aged rats

Authors: *C. S. SOVERNS[1], A. PARTHASARATHY[2], E. L. BARTLETT[1,2];
[1]Biomed. Engin., [2]Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN

Abstract: Specific timing cues are important in addition to firing rate for speech recognition in the auditory pathway. Of particular interest are neural representations of complex sounds and sound attributes, such as the consonant-vowel transition, and how such patterns change with age. Here we have investigated specific firing patterns in response to a vocalization as voice onset time (VOT) was varied along the ba-pa spectrum. Extracellular recordings were made in the inferior colliculus (IC) of anesthetized young adult and aged male rats in response to the acoustic stimuli. Standard and novel analysis techniques were employed to extract specific features of the responses. Such features identify representation strategies likely to be used by IC neurons to communicate VOT-related information leading to perception of the respective consonant-vowel combination. The Victor-Purpura spike distance metric was utilized to contrast firing patterns across stimuli and units and to investigate potential degradation of repeatability with age. A recent fusion of wavelet decomposition and information theory was utilized for identification of time scales and temporal locations of characteristic features. With knowledge of such features we sought to construct distinct firing pattern templates for the stimuli, identify patterns of age-related degradation, and inform future efforts to restore perception in degraded cases. Rather than a global agreement or disagreement of response patterns across the population, we have found evidence for local clustering of neurons with distinct regions sharing similar response properties.

Title: Chronic calcium imaging of neuronal ensembles in the mouse auditory cortex

Authors: *D. F. ASCHAUER[1], J.-B. EPPLER[2], M. KASCHUBE[2], S. RUMPEL[1];
[1]FTN - Rumpel Lab., Johannes Gutenberg-University Mainz, Mainz, Germany; [2]FIAS, Johann Wolfgang Goethe Univ., Frankfurt, Germany

Abstract: We recently found that the activity of local neuronal ensembles of the auditory cortex encode broad sound categories into non-linear population response modes (Bathellier et al., Neuron 2012; 76, 435-449). The discrete responses of these ensembles generate a basis set of perceptual categories that can be used to drive behavioral decisions. Additionally, chronic *in vivo* imaging approaches have demonstrated that the structural correlate of the postsynaptic component of excitatory synapses, dendritic spines, are highly dynamic throughout the life time of an animal (Loewenstein et al., J. Neurosci. 2011; 31(26):9481-9488). The interplay between these two very distinct but inherently interconnected types of dynamics has been challenging to address. In particular, how do functional neuronal ensembles emerge in the context of dynamic connectivity? How is information (e.g. sensory perceptions) maintained in such constantly rewiring neural circuits? Classical neurophysiological approaches, like extracellular recordings of action potentials, have largely not been able to provide chronic observations of activity dynamics due to technical limitations. Towards this goal, we established a procedure to monitor the activity of local neuronal ensembles of the auditory cortex in response to sounds over prolonged periods of time in the awake animal. Using AAV-mediated neuronal expression of the genetically encoded calcium indicator GCaMP6m enabled measurements of a few hundred individual cells simultaneously. Alignment of neuronal populations within a recording session to compensate for movements of the animal and alignment across imaging sessions at a two day interval is controlled by the co-expression of the stable nuclear marker H2B:mCherry. We developed automated image analysis routines that allow compensation for movement and detection of frames that cannot be reliably aligned. We are currently analyzing this dataset to measure the stability of functional neuronal ensembles forming auditory representations over the period of several days to more than a week. This question is of fundamental interest given the volatility in structural connections between neurons of the neocortex.

Title: Modeling discrete cortical representations and their stability in the presence of synaptic turnover

Authors: ***J.-B. EPPLER**[1,2], D. ASCHAUER[3], S. RUMPEL[3], M. KASCHUBE[1,2];
[1]FIAS, Frankfurt, Germany; [2]Johann Wolfgang Goethe Univ., Frankfurt, Germany; [3]FTN - Rumpel lab, Johannes Gutenberg Univ., Mainz, Germany

Abstract: Synapses in the auditory cortex display prominent changes in size over a period of several days, even in the absences of any explicit learning paradigm (Loewenstein et al., J. Neurosci. 2011; 31(26):9481-9488). It is currently unclear to what extent this volatility in structural connections impacts the functional properties of cortical circuits. Here we address this issue by studying the robustness of responses to brief complex sounds in a circuit model of mouse auditory cortex. Population responses in this system were observed to typically cluster into one out of a small number of observed states (Bathellier et al., Neuron 2012; 76, 435-449), a property we aim to exploit here to reveal the stability of such near discrete representations under synaptic turnover. First, we propose a model class consisting of networks of firing-rate neurons, which robustly displays several key properties of population activity in the mouse auditory cortex, including a skewed distribution of activity across neurons and a clustering of broad sound categories into non-linear population responses. In a broad parameter regime where recurrent connections are sufficiently heterogeneous and the network is dominated by inhibition, different sounds modeled as temporally varying random inputs are grouped spontaneously into a small number of different activity clusters. The degree of clustering is largely independent of network size (after rescaling synaptic strengths appropriately). Second, we use this model to study systematically the impact of synaptic turnover on collective response properties. We change the strength in a subset of connections and monitor the amount of drifts this induces in the activity vectors themselves and in the cluster means. We also assess to what extent stimuli get re-mapped to different activity clusters under synaptic turnover. Predictions of our model are tested in parallel experiments employing chronic two-photon imaging of population activity in mouse auditory cortex.

Title: Prediction of neural population responses to complex acoustic stimuli

Authors: *D. LYZWA;
Dep. Nonlinear Dynamics Max Planck Inst. For Dynamics and Self-Organization, Göttingen, Germany

Abstract: Reliable prediction of neural responses to complex sounds in the midbrain is desirable and would have important medical applications. In this work, a generalized linear model for

responses from single neurons and groups of a few neurons is presented. It models responses from the midbrain of guinea pigs and covers the main auditory frequency range, and furthermore includes several values for amplitude modulation preferences. The model is derived from neural responses to a broad range of acoustic stimuli, including artificial sounds such as white noise, pure tones and clicks, as well as complex natural sounds like calls and songs. This generalized linear model is compared to previous findings which predict temporal spiking responses to acoustic stimuli based on a) specific frequency tuning of the neurons, b) biophysically detailed modeling, or c) based on first and second order spectrotemporal receptive fields. This model reliably predicts a range of complex natural sounds.

Title: Change in brain state leads to stimulus information degradation through the thalamocortical circuit

Authors: *J. BAMBER[1], S. SAKATA[2], J. HERRMANN[3];
[1]Inst. for Adaptive and Neural Computation, Edinburgh, United Kingdom; [2]Strathclyde Inst. of Pharm. and Biomed. Sci., Univ. of Strathclyde, Glasgow, United Kingdom; [3]Inst. of Perception, Action and Behaviour, Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Brain state is known to influence evoked activity in the cortex and is ultimately involved in sensory perception. For example, wakefulness is associated with a high degree of perception, whereas little sensory information is perceived during sleep. Quite how and where information degrades through cortical circuits remains unknown. Here we look at evoked spiking activity at the first stage of cortical processing using recordings from the auditory thalamus (MGB) and across layers in primary auditory cortex (A1) in rats. 5ms white noise was presented over a range of intensities in two distinct brain states: the inactivated state, characterised by

strong collective activity across units; and the activated state, characterised by desynchronised firing activity. The inactivated state is natural under urethane anaesthesia, whilst the activated state was induced through electrical stimulation of the nucleus basalis, a region known to be involved in neuromodulation of cortical dynamics. We find that multiunit spiking activity differs depending on recording location and brain state, and that A1 evoked activity consists of separate initial and secondary components. Initial A1 activity correlates strongly with MGB activity, and secondary A1 activity correlates strongly with initial A1 activity, demonstrating propagation of activity through the circuit. Using mutual information to quantify stimulus information in spike counts at the single unit level, we find that during the initial stage of activity the most significantly modulated units are found in MGB, thalamorecipient layer and upper infragranular layers. These locations also contain the most informative units and display significantly more stimulus information during the activated state. During secondary activity, we find that much fewer units are significantly modulated by stimulus than in the initial activity. These units are mostly found in upper infrangranular layers, where the most informative units are found. Again, stimulus information is significantly greater during the activated state. The secondary stage is less informative than the initial stage, but relative decrease in information between states is larger, suggesting an increased propensity for local information loss in the inactivated state in cortical circuits. In summary, our results suggest that information flows through this first stage of cortical sensory processing similarly between brain states, but that the inactivated state is associated with less informative input from the thalamus, worse stimulus intensity representation in A1, and increased degradation of information as activity propagates through cortical circuits.

Title: Quantifying temporal structure of auditory cortex multineuronal patterns

Authors: ***J. DECHERY**[1,2], J. N. MACLEAN[3,1];
[2]Committee on Computat. Neurosci., [3]Neurobio., [1]Univ. of Chicago, Chicago, IL

Abstract: The complexity of natural auditory stimuli is derived from the temporal features of one dimensional pressure fluctuations in atmospheric pressure. Multineuronal activity patterns in auditory neocortex, whether evoked by sound or arising spontaneously, can be similarly characterized by their temporal features. A fundamental step toward understanding the neural

representations of sound is a quantitative description of the dynamics of these multineuronal patterns. This is especially true in neocortex, where recurrent connectivity dominates and neurons must work in concert to encode behaviorally relevant stimulus features. Precision of spike timing is of particular interest, due to its potential for reliable information representation and its elusive mechanistic underpinnings. Here, we analyze temporal aspects of naturalistic network dynamics in A1 acute slices at the single cell, pairwise, and network level. Spiking activity is measured in populations as large as 1000 neurons with two photon calcium imaging. By comparing these recordings to simulated data that preserves firing rates but destroys pairwise temporal information, we statistically determine the temporal characteristics not driven solely by spike rate. We identified subsets of neurons that have very reliable and temporally structured activation patterns relative to both intrinsic and extrinsic reference points. At the pairwise level, highly correlated neurons acted as building blocks that together formed reliable sequences of propagating network activity. Finally, we explored the dynamics underlying an observation that spike-time variability increases throughout a multineuronal pattern. This analysis acts to both describe the dynamics of neocortical neurons solely driven by local connectivity, as well as to contribute to the conceptualization of networks as more than the sum of their components. Our results imply that activity in A1 can be described as sequences of reliable and structured multineuronal activity patterns. Characterizing the variance and stereotypy of activity propagating through A1 networks will be key to understanding how the underlying synaptic inputs drive spiking and how the networks themselves encode and transform auditory input.

Abstract: Electrical stimulation of the cochlear nerve via a cochlear implant (CI) is successful in restoring auditory sensation to individuals with profound hearing loss. However, many questions

remain unanswered regarding how the central auditory system processes the electrical stimulation. Understanding how the brain processes CI stimulation should help guide improvement of CI technology, but techniques for studying human cortical processing have low spatial resolution, and the extent to which non-primate or anesthetized animal models represent the human case is unclear. We therefore developed an alert non-human primate CI model in the common marmoset (Callithrix jacchus) by implanting a multi-channel electrode array in one cochlea while leaving the other cochlea acoustically intact. This preparation allows us to directly compare a cortical neuron's responses to acoustic and CI stimulation in the awake condition. We found that acute, episodic CI stimulation was less effective in activating primary auditory cortex (A1) neurons compared to acoustic stimulation. This may be explained by broader cochlear excitation areas caused by electric stimulation compared to acoustic stimuli, because many cortical neurons exhibit narrow frequency tuning and sideband inhibition. For neurons driven by both CI and acoustic stimuli, we characterized responses as a function of current level and sound intensity. A majority of these neurons showed monotonic responses to CI stimuli; less than 20% had non-monotonic responses. This compares to acoustic responses which had 40% non-monotonic responses. We observed that ~40% of non-monotonic CI-driven neurons showed monotonic responses to acoustic stimuli, while ~25% of monotonic CI-driven neurons showed non-monotonic responses to acoustic stimuli. This change of response pattern in the same neuron suggested that CI and acoustic stimuli evoked different neural circuits. Consistent with clinical psychophysical data from CI users, dynamic ranges of A1 cortical neuron responses to CI stimuli were much smaller than those to acoustic stimuli (3.4 dB vs 32 dB in our experiments). For a given A1 neuron, thresholds of CI and acoustic stimuli were positively correlated, but their dynamic ranges were not significantly correlated. Response latencies were also positively correlated between the two stimulation types. In addition, acoustic stimuli usually evoked greater firing rates than CI stimuli. These findings suggest that the coding mechanism for stimulus intensity differs between the stimulation modes, and that CI stimulation is less efficient in driving A1 neurons.

Title: Spectro-temporal dynamics of excitatory, suppressive, and inhibitory influences in the auditory nerve and ventral cochlear nucleus following sensorineural hearing loss

Authors: *M. G. HEINZ[1], K. S. HENRY[3], M. SAYLES[2,4];
[1]Speech, Language, Hearing Sci. and Biomed. Engin., [2]Speech, Language, Hearing Sci., Purdue Univ., West Lafayette, IN; [3]Dept. of Biomed. Engin., Univ. of Rochester, Rochester, NY; [4]Lab. of Auditory Neurophysiol., KU Leuven, Leuven, Belgium

Abstract: Nonlinear cochlear signal transduction, reflecting outer-hair-cell function, manifests as suppressive spectral interactions; e.g., decreased auditory-nerve-fiber (ANF) firing rate to one tone when a second, simultaneous tone is presented. For broadband sounds, there are multiple interactions between spectral components. These frequency-dependent nonlinearities are important for neural coding of speech. Outer-hair-cell damage in hearing-impaired mammals is associated with loss of nonlinearity, which auditory prostheses attempt to restore, e.g., with "multi-channel compression" algorithms. At the first stage of brain-stem processing, the ventral cochlear nucleus, many neurons receive frequency-tuned inhibitory input in addition to ANF excitatory input. Emerging evidence from evoked-potential studies suggests "central gain" changes following acoustic trauma; which may indicate altered inhibitory-excitatory balance in synaptic input to brain-stem nuclei, or changes in cochlear nonlinearity reflected in their ANF input. We used spike-triggered neural-characterization techniques to probe altered spectro-temporal dynamics of excitatory and suppressive/inhibitory influences on ANF and VCN-unit firing probability in anesthetized chinchillas following noise-induced hearing loss.Hearing-impaired (HI) animals had elevated single-unit excitatory thresholds (by ~20-40 dB), broadened frequency tuning, and reduced-magnitude distortion-product otoacoustic emissions; consistent with mixed inner- and outer-hair-cell pathology, and loss of nonlinearity. We characterized suppression (ANFs) and suppression/inhibition (VCN units) using second-order Wiener-kernel (h_2s) analyses of responses to broadband noise (ANFs: 92 NH, 148 HI; VCN units: 122 NH, 95 HI). Using singular-value decomposition, we factored h_2s into excitatory and suppressive/inhibitory sub-kernels, to quantify the relative strength and spectro-temporal characteristics of suppression/inhibition. Suppression strength was decreased in HI ANFs, which correlated with broadened frequency tuning. In the VCN, we recorded from all major unit types in NH and HI animals, with no difference in their relative distribution (χ^2, $p>0.05$). We found evidence for altered balance between suppressive/inhibitory and excitatory influences on VCN units following noise-induced hearing loss, consistent with recent evidence for central-gain change following acoustic trauma. These data help guide novel amplification strategies, particularly for complex listening situations (e.g., speech in noise), in which current hearing aids struggle to restore intelligibility.

Title: Single trial decoding of task-relevant variables in auditory and frontal cortex during sensorimotor decision-making

Authors: *M. INSANALLY[1], I. CARCEA[2], B. ALBANNA[3], R. FROEMKE[2];
[1]New York Univ., NY, NY; [2]New York University, Skirball Inst. for Biomolecular Med., NY, NY; [3]Fordham University, Dept. of Natural Sci., NY, NY

Abstract: Single-unit activity recorded from behaving animals can often have heterogeneous response profiles. A fraction of recorded cells typically exhibit trial-averaged responses with obvious task-related features, such as pure tone frequency tuning in the auditory cortex, or ramping activity in secondary motor areas. However, a substantial number of cells do not appear to fire in a task-related manner and require novel analytical methods. We analyzed single-units recorded from rats during a frequency recognition task in order to identify to what extent task variables are reflected in individual spike trains of every recorded neuron - independently or as part of small ensembles of cells. Adult rats were trained on a go/no-go frequency recognition task that required them to nosepoke to a single target tone for food reward and withhold from responding to multiple nontarget tones. Using multielectrode arrays we recorded from 59 single-units in the auditory cortex and 57 single-units in the frontal cortex (FR2). Spike trains were complex and highly variable from trial to trial. However, these single-trial responses are the only signals available to downstream neurons. Accordingly, we devised a novel unbiased spike-timing based algorithm for trial-by-trial decoding. Surprisingly, we found that frontal cortex is more informative about stimulus category than auditory cortex, and cells in auditory cortex can be informative about the upcoming behavioral choice. Furthermore, decoding improves when using ensembles of cells demonstrating that the approach is scalable. Our method reveals that responses from nominally non-responsive cells, which are often neglected, can contain a significant amount of information about task relevant variables.

Title: Encoding and decoding of amplitude modulated signals amongst populations in auditory core of awake squirrel monkeys

Authors: *M. J. RUNFELDT[1], B. J. MALONE[2];
[1]UCSF, Burlingame, CA; [2]Otolaryngology, Head and Neck surgery, UCSF, San Fransisco, CA

Abstract: Neurons in primary auditory cortex simultaneously encode information about multiple stimulus dimensions, including the envelope and fine structure of modulated signals. Individual neurons can exhibit carrier-bandwidth, carrier-frequency, and carrier level-specific modulation tuning, which can be expressed in the neuron's firing rate and/or the timing of spikes relative to the phase of the modulating waveform. It is unclear how the response properties of individual neurons shape the information available to downstream 'read-out' neurons that receive multiple simultaneous inputs. Using simultaneous multichannel recordings from awake squirrel monkey cortex, we analyzed the responses of local neural populations to sinusoidal amplitude modulation (4 to 512 Hz) applied to pure tone and noise carriers. We focus our analyses on how network- and stimulus-driven spiking correlations, temporal coherence, and diversity within single neuron tuning properties impact population decoding of signal modulation frequency. In a simple convergent model based on spike summation, pooling the activity of multiple neurons can either increase or decrease decoding performance depending on the interplay between spiking patterns among neurons comprising the encoding population. For example, pooling across neurons that fire at different phases with respect to the modulation envelope will limit the synchrony of the pooled response, and decrease information about the envelope carried by spike timing. Analyzing multi-unit activity, we found that increasing the number of simultaneously-recorded channels that contribute to a summed population response is detrimental to the decoding of modulation frequency on average. When intertrial correlations were removed by shuffling responses across trials, however, adding more channels almost always improved performance. We explore whether this reflects loss of information due to signal averaging and/or redundancy in local populations. Additionally, using single-unit activity from spike-sorted data, we identify optimal encoding populations and characterize the features that contribute to their performance.

Title: Differential effects of multiple anaesthetic regimes on spontaneous, sensory and multisensory recordings from guinea pig cortex

Authors: *O. WOOLNOUGH, J. I. BERGER, B. COOMBER, M. N. WALLACE, A. R. PALMER, C. J. SUMNER;
MRC Inst. of Hearing Res., Nottingham, United Kingdom

Abstract: Anaesthesia is widely used in *in vivo* studies of sensory neural processing. Previous studies of the effects of systemic general anaesthesia on neurons in the auditory cortex have shown significant changes to frequency tuning and responses to basic features within the stimulus such as onsets and offsets. Studies of this nature have typically used a single anaesthetic agent, comparing awake and anaesthetised states, and it remains unclear to what extent the choice of anaesthetic agent will affect basic response properties of neurons to sensory stimulation. EEG is a widely used technique in humans and as it is a relatively simple protocol to implement in animals could provide an important methodological bridge between species. However, the effects of anaesthesia on EEG are relatively poorly characterised in animals. Electrophysiological recordings were made with chronically implanted, extradural electrodes, positioned over auditory and visual cortices. Recordings were made both while awake and under a range of anaesthetic regimes including opiates, NMDA antagonists and GABA potentiators. Recordings of spontaneous oscillations replicate the results of previous human studies, showing a rapid increase in power of low-frequency (<10Hz) oscillations at loss of consciousness, most prominently in the visual regions, and suppression of high frequency activity - effects which appear mostly independent of anaesthetic regime. Responses to a range of basic sensory stimuli such as auditory clicks, visual flashes and sequences of adapting stimuli were also recorded. Unlike spontaneous activity, we observed substantive differences in processing of even basic sensory stimuli between anaesthetic regimes. For example, the cortical auditory evoked potential in response to a tone shows an early (~25ms) and late (~50ms) deflection. Under ketamine anaesthesia both potentials were suppressed, diazepam supressed the early potential but enhanced the later one and fentanyl and urethane both increased the size of the early potential but abolished the later one. We have also observed significant changes between anaesthetics in the time constants governing the onset and recovery from adaptation and, under all anaesthetic regimes tested, auditory responses in visual cortex were absent. In conclusion, we have demonstrated that anaesthesia has significant effects on systems level sensory processing and that the choice of anaesthetic used for recording can have grossly different effects on the response to even simple sensory stimuli.

Title: Neural dynamics for encoding stationary sound stimuli in the primary auditory cortex of marmoset monkeys

Authors: *W. SUN, D. L. BARBOUR;
Dept. of Biomed. Engin., Washington Univ. in St. Louis, Saint Louis, MO

Abstract: Neural systems usually respond to external stimuli with rich dynamics, even when the stimulus itself is stationary. In primary auditory cortex, responses to stationary sounds contain two dynamic components. The onset component occurs immediately following stimulus onset, which spreads across a wide range of neurons at high population activity level. As the stimulus proceeds, responses of many neurons fade away, leaving only a small subset of neurons firing sustainably throughout the stimulus duration. This sustained response is the second component. Previous studies showed higher response selectivity for sustained responses and proposed distinct functions for the two response components, where onset responses encode the occurrence of a sound onset and sustained responses convey stimulus-specific information. To quantitatively investigate sound encoding properties of the two components, we recorded neural spiking activities from the primary auditory cortex of awake marmoset monkeys in response to pure tones. Through population decoding methods, we found that both response components contained stimulus-specific information. Moreover, to achieve a particular decoding accuracy, the required window length for onset responses was shorter. Along the entire stimulus interval, analysis windows with the same number of spikes showed the same decoding accuracy. Thus, the higher-rate onset responses can perform encoding at a faster speed. Finally, we showed that the observed relationship between activity level and decoding speed can be explained by the inherent properties of Poisson neurons, in which higher rates result in more reliable rate estimation and thus a shorter encoding interval. In contrast to onset responses, sustained responses were more energy efficient with their lower spiking rates. Instead of uniformly lowering the activity level of each neuron, however, a large number of neuron responses faded away while only a small subset remained active. This sparseness potentially helps maintain the statistical power of the system in the sustained low activity level regime, and improves code orthogonality, thereby preserving encoding capacity for new stimuli. The trade off, however, is a slower encoding speed. This unified theory accounts for the existence of primary-like neuronal responses that can rapidly encode sensory changes in the environment when they occur while also efficiently maintain that representation in face of no additional stimulus changes. These complementary strategies arise out of constraints from behavior, neuronal biophysics and metabolic factors.

Title: Rapid estimation of neuronal frequency response area using Gaussian process regression

Authors: *X. D. SONG, W. SUN, D. L. BARBOUR;
Biomed. Engin., Washington Univ. In St. Louis, Saint Louis, MO

Abstract: Frequency response area (FRA), an auditory neuron's firing rate to tonal stimuli as a function of tone frequency and intensity, is a basic characterization that provides useful information about the neuron under investigation, such as the distribution of excitatory and inhibitory inputs. Traditionally, FRA is obtained by sampling the frequency/intensity plane in a grid fashion, then interpolating the measurements for a smoothed estimate. Due to the many frequency/intensity combinations, acquiring data for FRA is often time-consuming and risks loss of contact with the neuron or animal status change. We derived a procedure for rapid FRA estimation using Gaussian process (GP) regression, a Bayesian machine learning technique, to estimate the entire FRA function from a relatively small set of responses. Furthermore, these responses can be determined by a Bayesian active learning strategy to successively select stimuli informative to the FRA estimate, thereby speeding data acquisition. Neurons in primary auditory cortex of marmoset monkeys were tested with tones in a frequency/intensity grid. A GP with a two-dimensional squared exponential kernel was first conditioned on a random subset of these responses. The GP posterior was then used to predict firing rates and to quantify confidence of the prediction. Next, for the active sampling strategy, the frequency/intensity combination with the lowest prediction confidence was added to the conditioning subset. Derived FRA accuracy was assessed by comparison to 1) FRA estimation with all samples smoothed by a traditional method, 2) FRA estimation using GP regression with all samples, and 3) observed firing rates averaged over multiple trials. Efficacy of the active sampling method was evaluated by comparison to GP estimates derived from randomly selecting the same number of samples. FRA estimates produced by the GP were comparable to the smoothed and trial-averaged firing rates, and provided principled estimates of neural responses outside the range of collected data. As the number of data points used to condition the GP increased, the accuracy of the estimate also improved. Compared to the traditional grid search strategy, the Bayesian active learning sampling strategy demonstrated a more rapid increase in estimation accuracy as a function of size of the sample set, achieving the same level of accuracy with considerably fewer samples. These results demonstrate that GP regression can be used to build principled estimates of FRAs, and along with Bayesian active learning, can produce accurate FRA estimates with limited data, thus expediting the experimental process.

Title: Neural signatures of predictive coding in cortical pitch processing

Authors: *W. SEDLEY[1], P. E. GANDER[2], S. KUMAR[1], H. OYA[2], H. KAWASAKI[2], M. A. HOWARD, III[2], T. D. GRIFFITHS[1];

Abstract: Accumulating evidence suggests that perception is not simply the consequence of serially processed input from sensory organs, but results from a weighted combination of this information with prior expectations based on a generative model of the environment. In predictive coding (1,2), prior expectations take the form of predictions, represented by their mean and precision (inverse variance), and sensory information in violation of these is called prediction error, which is related to surprise (the negative log probability of a sensory event occurring). Theoretical models based on cortical microarchitecture (3) propose that predictions are represented by local field potential oscillations in the beta band (~20 Hz), and prediction errors in the gamma band (> 40 Hz), though empirical evidence is limited and mainly relates to gamma band activity. In the present study of cortical pitch processing, we varied the fundamental frequency of an otherwise constant pitch stimulus in order to explicitly manipulate and dissociate prediction error, surprise, prediction mean and precision. Recordings were made from primary and non-primary auditory cortex (in Heschl's gyrus and superior temporal gyrus) from awake patients undergoing invasive monitoring for epilepsy localisation. We found that the amplitude of gamma correlated with surprise (rather than prediction error), beta with changes to prediction mean, and theta (~6 Hz) with precision of predictions. The findings relating to beta and gamma lend strong support to existing hypotheses, and for the first time demonstrate quantitative relationships between the relevant neuronal and computational processes. Theta oscillations are of fundamental importance to a wide range of cognitive and perceptual processes, and have been shown to have an organising and modulatory effect on higher-frequency oscillations. The present results suggest that one such role may be to encode the precision of predictions passed from higher centres, which could be achieved through dynamic modulation of higher frequency prediction and error signals. - 1.Rao, R. Title: Single and population neural discrimination of vocalizations in noise

Authors: ***R. NI**[1], D. A. BENDER[2], J. R. GAMBLE[1], D. L. BARBOUR[1];
[1]Dept. of Biomed. Engin., [2]Dept. of Biol., Washington Univ. in St. Louis, Saint Louis, MO

Abstract: Robust sensory perception is critical for prompt behavior responses. Vocal communication in particular requires reliable auditory processing for both human and animals to interact with conspecifics. The nature of robust neural representation of vocalizations is incompletely understood. Recent research has revealed the existence of background-invariant neurons in higher auditory areas of songbirds, as well as site-dependence of the effect of masker type upon high-level neural representation. Auditory cortex contributes to the processing of complex natural sounds in primates, but relatively little is known about the impact of different noises on cortical encoding of vocalizations. Here we investigate the influence of two kinds of noises on the single and population neural discrimination of vocalizations in a highly vocal primate, the common marmoset monkey (Callithrix jacchus). Single-unit activities in auditory cortex were recorded from alert adult marmoset monkeys while animals passively listened to the playback of natural and modified conspecific vocalizations. White Gaussian noise (WGN) and 4-vocalization babble noise were mixed with five natural marmoset vocalizations at eight different signal-to-noise ratios. To quantify the influence of noise on individual neuron responses, we implemented spike-train distance-based discrimination analysis and further derived a robustness index for each neuron. An intensity invariant index corresponding to each vocalization was also developed in a similar way. We further trained diverse classifiers on pooled population response to assess the robustness of population encoding. Over the 224 primary auditory cortex neurons studied, the robustness indices of individual neurons against two noises are poorly correlated, revealing only a weak positive relationship. No significant relationship was shown between single units' intensity invariance and noise robustness under both noise cases. With regard to

population coding, WGN leads to a lower detection threshold for the presence of target vocalizations than babble. Additionally, optimized subpopulation neurons outperformed the whole population for each of vocalization-noise pairs. Our results are consistent with our previous finding based upon correlation-based analysis and indicate individual neuron responses across different sound background are context-dependent in primate primary auditory cortex. The general influence of noise on cortical representation is revealed successfully by population coding and suggests that a variety of individual neuron responses is a prerequisite for robust coding across different conditions.

Title: Avalanche dynamics of population activity in the auditory cortex

Authors: D. WINKOWSKI[1], S. SESHADRI[2], D. PLENZ[2], *P. O. KANOLD[1];
[1]Biol., Univ. of Maryland, College Park, MD; [2]NIMH, Bethesda, MD

Abstract: The layered organization of cortex fundamentally organizes how information is processed in the brain. Sensory input enters layer 4 (L4) from which activity quickly spreads to superficial layers 2/3 (L2/3), deep layers 5/6 (L5/6) as well as to other cortical areas. In primary auditory cortex (A1), our recent *in vivo* 2-photon experiments revealed a homogeneous frequency (tonotopic) organization in L4, which is more heterogeneous in the next layer, L2/3. The organization of stimulus preference in L2/3 is currently not well understood, yet, numerous studies have shown that L2/3 incorporates ongoing cortical activity, usually in the form of reverberating activity from within or distant cortical regions, that reflect the state and behavioral context of the animal. A promising candidate dynamics are neuronal avalanches which emerge in L2/3 and provide a scale-invariant organization of activity patterns that correlate distant cortical sites in a highly selective manner, a prerequisite to form perceptual categories. Towards understanding the spatiotemporal properties of population activity in A1 and the functional relationship of neurons participating in neuronal avalanches we investigate the presence of neuronal avalanches in A1. We use *in vivo* 2-photon imaging of spontaneous and sound evoked activity of A1 in awake mice using GCaMP6. We deconvolve the signal from ROIs to derive the instantaneous neuronal firing rates. Non-zero firing rates from local clusters were calculated and the cluster size distributions were examined for power law behavior to identify avalanche

dynamics. We then compare avalanche dynamics of ongoing and evoked activity in different lamina in the anesthetized and awake state. Together our experiments characterize the spatiotemporal population activity in the auditory cortex.

Title: Determining the joint neural encoding of phonetic and speaker features with EEG

Authors: B. KHALIGHINEJAD, M. YANG, J. O'SULLIVAN, *N. MESGARANI; Columbia Univ., New York, NY

Abstract: Humans possess the ability to simultaneously and continually perceive speech and speaker information. This perceptual ability requires the extraction of linguistic features such as consonants and vowels from a complex acoustic signal, and the linking of these features to the speaker that uttered them. Recent invasive and non-invasive studies have shown an acoustic phonetic feature representation of speech in human auditory cortex. However, how speaker specific variability affects the representation of phonetic features remains unknown. Here, we addressed this question by analyzing scalp electroencephalography (EEG) data recorded from subjects who listened to continuous stories with alternating sentences read by a male and female speaker. To ensure the attentional engagement of the participants, they were required to answer questions regarding the content of the stories. The stories were segmented into time-aligned sequences of phonemes, and the neural responses to all instances of each phoneme were obtained. We then grouped these responses into phonetic feature categories and found that the neural responses to different phonetic categories (e.g., consonant-vowel, manner of articulation) were discriminable. In order to determine the dependence of such a phonetic representation on speaker specific characteristics, we compared the average responses to each individual phoneme spoken by each speaker. We used the pairwise Euclidian distance between phoneme pairs as a measure of dissimilarity. We found a varying degree of overlap between the phonetic feature representations of the two speakers. Furthermore, by performing similar analysis on the average

spectrograms of each phoneme, we found that the joint acoustic similarity of speaker and phonetic features determined the organization of the neural responses. These results suggest a joint encoding of speaker information and phonetic features, which is a fundamental step towards determining the neural basis of the ability to attend to a single speaker in multi-talker and noisy environments.

Title: Characterizing the dynamic representation of acoustic spectral regularity in humans

Authors: ***A. M. GIFFORD**, M. KAHANA, Y. COHEN;
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Auditory perception depends on the auditory system's ability to detect and segregate or group the spectrotemporal regularities in the acoustic environment. In particular, the pattern of spectral progression over time is widely thought to be a signal that the auditory system can use to group and segregate acoustic events into distinct sounds. However, it is currently unclear how the auditory system tracks and reflects changes in spectral regularity over time in an ongoing, dynamic stimulus. Moreover, much of the previous work on the brain's representation of spectral regularity focused either explicitly on the contributions of the core auditory fields or was conducted with techniques that have poor spatial localization (such as electroencephalography). As a result, little is known about the extent to which aspects of spectral-regularity representation are specific to either the core or higher-order auditory fields, or general to the auditory system as a whole. The goals of this study were (1) to test how the human auditory system reflects local spectral regularities on short time scales in ongoing acoustic-tone sequences with pseudo-random structure and (2) localize these representations in cortex. Because neural oscillatory activity influences the timing of neural spiking and correlates with deviations in spectrotemporal regularities, we examined the contribution of oscillatory activity to dynamic spectral regularity representation by measuring electrocorticographic activity in human epileptic patients. Subjects listened passively to sequences of alternating tone bursts of two frequencies presented in a pseudorandom order. We analyzed oscillatory activity as a function of temporally local configurations of tones within the overall sequences (e.g., subsets of tone triplets). We found

generally that, whereas analytic phase concentration was positively correlated with the degree of spectral regularity on local timescales, analytic amplitude was not. Additionally, we found that these phase-concentration effects were widespread across cortex, present not only in regions along the classical auditory pathways, but also other more multisensory regions. These findings support a role for oscillatory activity in dynamically tracking local spectral regularities and organizing the auditory scene.

Title: The encoding mechanism throughout the human auditory pathway

Authors: *Q. ZHANG[1], X. HU[2];
[1]Computer Sci. and Technol., [2]Tsinghua Univ., Beijing, China

Abstract: It is unclear that whether there is a consistent encoding mechanism throughout the human auditory pathway. In this paper, we used an unsupervised deep neural network, named sparse-HMAX, which is inspired by the V1 simple cell and complex cell to modulate the speech data. In the first layer of the network, the neurons decompose the speech in frequency domain, which is just like the cochlea neurons. In the next two layers, the neurons fired as IC neurons. They have similar receptive fields with corresponded acoustic features, such as harmonic stacks, onsets and terminations, and also more exotic structures as checkerboard patterns and spectral motion patterns. Then in the fifth layer, the neurons tend to represent the phonetic features such as plosive and nasal, which is very similar to the human auditory neurons. Finally, in the last layer of our network, the neurons can represent phonemes with population coding methods. Our results suggest that the sparse coding mechanism and the simple/complex cell pattern are widely used throughout the human auditory pathway.

Title: Geometric diversity of axons in afferent and efferent projections of the mouse visual cortex

Authors: P. RÉGNIER, I. MASSÉ, R. TREMBLAY-LALIBERTÉ, *D. BOIRE;
Anatomie, UQTR, Trois-Rivieres, QC, Canada

Abstract: The branching structure of axons shows the spatio-temporal distribution of information in the brain. In addition, the structure of the arborisation is relevant to computational properties that can take place at the axonal level. Diameter inhomogeneities such as bifurcations and varicosities can alter spatio-temporal propagation of action potentials along the branching tree. Specifically, abrupt changes in the diameter of axons as found at varicosities and differences in the diameter ratio of the mother and daughter branches at an axonal bifurcation could introduce delays in the transmission of action potentials (Goldstein & Rall, 1974). It has been suggested that the structural diversity of axon projections between cortical areas form a complex network of lines of communication with different geometrical and time computing properties (Innocenti, Vercelli, & Caminiti, 2014). This study compares the geometric structure of cortico-cortical axons to understand their underlying principles. This analysis helps evaluate if functional differences of intracortical connections are reflected in axon topology. MATERIALS AND METHODS: Iontophoretic micro-injections of high molecular weight biotinylated dextrans (10kDa) were made in the primary visual cortex (V1), somatosensory barrel field (S1BF) and auditory cortex (Au) of C57BL/6 mice. Three-dimensional reconstructions were performed to obtain complete arbors of axons for projections from V1 to the extrastriate visual areas LM and AL; for the intermodal projections from V1 to S1BF and S1BF to V1 and from Au to the lateral portion of V2 (V2L) and to V1. Analysis of axon diameter at branching points, segment lengths and density of varicosities were made with Neurolucida (Microbrightfield Bioscience). Geometric ratios of mother and daughter branches were calculated for every branching point. RESULTS: Reconstructed axons showed a significant diversity of branching structure, total length, density of varicosity, average diameter at origin point and values of geometric ratios. The diameter of mother branches showed little variation along the axon arbor. There was no relation between the position of branching points along the axon and the values of their geometric ratio. There seems to be a relation between mother branch diameters and the maximum possible value of their geometric ratios. This tendency seems to be common among all axons observed. CONCLUSION: There were significant differences in axonal morphology between the studied projections and also a significant diversity of geometric and possible computational properties of axonal arbors within each of these projections.

Title: The spatiotemporal distribution of synaptic inputs to simple cells of V1: challenging a classical model of receptive field structure

Authors: ***M. M. TAYLOR**, M. SEDIGH-SARVESTANI, L. E. VIGELAND, L. A. PALMER, D. CONTRERAS;
Neurosci., Perelman Sch. of Med., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Simple cells in layer 4 (L4) of primary visual cortex (V1) have receptive fields (RFs) composed of at least one elongated sub-region sensitive to either bright or dark contrast (Hubel & Wiesel, 1962). Adjacent sub-regions are sensitive to opposite contrasts, making these cells responsive to edges in the visual field. Extracellular observations of these cells' visual responses led to a push-pull model of RF organization: within a sub-region, one stimulus contrast increases firing rate (push), while the opposite contrast decreases firing rate (pull) (Palmer & Davis, 1981; Jones & Palmer, 1987). The mechanisms of push and pull were later interpreted as pure excitatory and inhibitory postsynaptic processes, respectively (Ferster 1988; Hirsch et al., 1998; Anderson et al., 2000). A synaptic push-pull theory in simple cells would entail opponent excitation and inhibition in response to opposite contrasts within a sub-region, leading to spatially segregated excitation and inhibition across sub-regions. Here, using intracellular recordings in cats *in vivo* from simple, regular spiking cells in V1 (Area 17) L4, we estimate the underlying synaptic structure of simple cell RFs. We use single or pairs of optimally oriented bars flashed in different positions within the RF. We record membrane potential (Vm) with various levels of current injection, and we calculate synaptic conductance and Vrev, from which we estimate excitatory and inhibitory conductances. Our results depart from key predictions of push-pull in at least two ways. First, we find that a stimulus that evokes an excitatory conductance also evokes a comparable inhibitory conductance. We find that this inhibition from excitatory stimuli is delayed relative to excitation. Second, while excitation is spatially segregated according to RF sub-region, we observe broad inhibition across the RF. We further show that delayed inhibition plays a functional role in reducing the "window of opportunity"

(Pinto et al., 2000) for synaptic inputs to trigger spikes, in effect increasing the precision of the cells' output, as we have proposed previously (Cardin et al., 2010), and as we and others have demonstrated in other sensory systems (Wilent & Contreras, 2005; Higley & Contreras, 2006; Wehr & Zador, 2003). Our results suggest not only that synaptic inhibition suppresses responses to non-preferred stimuli and thereby shapes the cell's RF; additionally, in response to excitatory drive from preferred stimuli, inhibition dynamically shapes the timing of a V1 simple cell's spiking output.

Title: The effect of callosal projections on stimulus responses of layer 2/3 neuronal populations in rodent visual cortex

Authors: *V. RAMACHANDRA, V. PAWLAK, J. N. D. KERR;
Behavior and Brain Organization, Res. Ctr. Caesar, Bonn, Germany

Abstract: In rats, left and right primary visual cortex (V1) are linked by strong, reciprocal and anatomically specific callosal projections which are most prominent in the binocular region. However, these interhemispheric projections' effect on visual responses remain poorly understood. We recorded spontaneous and stimulus-evoked population activity in layer 2/3 of anesthetized rat V1 while reversibly inactivating the contralateral region projecting to the imaged area. We first anatomically labeled the contralateral region projecting callosally to V1 with cholera-toxin based retrograde tracers, and functionally located it within the binocular region using intrinsic optical imaging. To reversibly inactivate this contralateral region, we expressed the light-activated proton pump archerhodopsin in neurons using adeno-associated virus. Using two-photon imaging of the calcium indicator Oregon green BAPTA-1, we measured population responses to drifting gratings (8 orientations in both directions) with and without inactivation of contralateral V1. Inactivating contralateral V1 reduced visual responses in a subpopulation of neurons, leading to a significant overall decrease in responsiveness, but did not change neurons' preferred orientations or reduce spontaneous activity. Responsiveness to stimulation was reduced for either eye, but was stronger for the ipsilateral eye. Thus callosal projections contribute significantly to stimulus responses of neurons in rat V1 while maintaining their targets' preferred stimuli.

Title: Neural circuits for the cortical control of the optokinetic reflex

Authors: ***B. LIU**[1], A. HUBERMAN[1], M. SCANZIANI[1,2];
[1]UCSD, La Jolla, CA; [2]HHMI, La Jolla, CA

Abstract: The cerebral cortex of mammals has the ability to control and modulate innate, reflexive behaviors mediated by subcortical structures. By adjusting these behaviors to the prevailing conditions or according to past experiences the cortex greatly expands the behavioral repertoire of mammals. One example of such cortical modulation is the impact of visual cortex on the optokinetic reflex (OKR), a compensatory eye movement that stabilizes retinal images during self-motion. The initial stages of the OKR are mediated by phylogenetically old subcortical brainstem nuclei of the accessory optic system (AOS). Here we study the cortical control of the OKR as a model system to understand the mechanisms enabling cortex to modulate innate behaviors. We optogenetically silenced the visual cortex of mice to evaluate the cortical contribution to the OKR and to the activity of AOS nuclei. We observed that cortical silencing moderately but significantly reduced the OKR gain by 10-30%, depending on visual stimulus parameters. Furthermore the reduction in OKR gain upon cortical silencing could be largely accounted for by the concomitant decrease in AOS activity without affecting the sensorimotor transformation function. We further demonstrate that layer V neurons in the visual cortex project to and form functional excitatory synapses onto AOS neurons, implying that the cortex can modulate AOS activity through this direct projection. Finally we discover that surgical disruption of the vestibulo-ocular reflex, another gaze stabilization mechanism, leads to a compensatory enhancement of OKR gain and that this enhancement is achieved, primarily if not exclusively, by the visual cortex increasing its contribution to AOS activity. Our results thus indicate that visual cortex, via its direct corticofugal projection, amplifies the activity in the AOS to modulate OKR behavior. This circuit enables visual cortex to compensate for disruptions in reflexive gaze stabilization mechanisms.

Title: Effect of running on surround suppression in inhibitory neurons of mouse visual cortex

Authors: *M. DIPOPPA[1], A. RANSON[2,1], M. KRUMIN[1], M. CARANDINI[1], K. D. HARRIS[1]; [1]Univ. Col. London, London, United Kingdom; [2]Cardiff Univ., Cardiff, United Kingdom

Abstract: The dynamics of cortical networks are shaped by functional connectivity between different classes of inhibitory interneurons. In the superficial layers of the mouse primary visual cortex (V1), interneurons expressing somatostatin (Sst) have been implicated in surround suppression of pyramidal neurons, in a model where they increase their activity with visual stimulus size (Adesnik et al., 2012). Interneurons expressing vasoactive intestinal peptide (Vip) are thought to disinhibit pyramidal cells during running, by inhibiting Sst interneurons (Fu et al., 2014). Also, running decreases surround suppression in pyramidal neurons, suggesting an interaction between the two effects (Ayaz et al., 2013). We asked how this interaction emerges from the local cortical circuit, and what is the role of the different interneuron classes. We used two-photon calcium imaging in V1 of multiple transgenic mouse lines to study how locomotion modulates neural activity and size tuning in Vip, Sst, parvalbumin-expressing (Pvalb), and unidentified (putatively mainly pyramidal) cells. Mice were head-fixed and free to run on an air-suspended ball while visual stimuli of different sizes were presented. To identify interneuron classes we generally expressed GCaMP6m in all neurons and tdTomato in a specific subclass. In control experiments we expressed GCaMP6m in only Sst neurons, to study their responses in the absence of out-of-focus fluorescence. In all cell classes visual responses increased during running. For Sst cells, this result is at odds with the disinhibitory model of modulation by running. Consistent with prior reports, Sst neurons did not typically show surround suppression during running - however, in the stationary condition, all cell types showed surround suppression. Finally, while pyramidal and Vip neurons increased their spontaneous activity during running, spontaneous activity of Pvalb and Sst neurons could show either a decrease or an increase. This last result may in part explain the discrepancy of different studies on effects of running in the Sst population (Polack et al., 2013; Fu et al., 2014). Using a mean field model of the recurrent cortical network, we show how the effects we observed can be produced by a running-induced rebalancing from recurrent to feedforward excitation – a canonical effect of

neuromodulators such as acetylcholine. We conclude that the reduction of surround suppression during running cannot be explained by the disinhibitory model. Instead, we suggest that it arises from more complex network dynamics, in which excitatory recurrent connectivity is controlled by neuromodulation.

Title: Functional properties of deep layer projection neurons in the primary visual cortex

Authors: ***G. LUR**, L. TANG, J. A. CARDIN, M. J. HIGLEY;
Neurobio., Yale Univ., New Haven, CT

Abstract: In the mammalian neocortex, pyramidal neurons (PNs) in layer 5 provide the principal source of efferent information to subcortical structures. Within layer 5, distinct pools of PNs can be identified based on their morphology, physiological properties, local connectivity, and subcortical projection patterns. However, most data regarding the properties of L5 PNs has been obtained from *in vitro* preparations. Whether these disparate characteristics translate into distinct functional roles (e.g., the ability to encode sensory information) *in vivo* is unclear. Here, we group L5 PNs in the mouse primary visual cortex based on their projections to either the superior colliculus, the dorsal striatum or the contralateral cortex. First, we show that these groups, identified by retrograde tracers, comprise largely non-overlapping populations. We further demonstrate that all three groups receive monosynaptic thalamic input from the lateral geniculate nucleus, suggesting they are well-suited to encode basic features of visual inputs. We then use *in vivo* video-rate calcium imaging of GCaMP6 in targeted subsets of L5 PNs to monitor their activity in response to visual stimulation. We find that visual response properties are highly heterogeneous across the different populations. Tuning for orientation and spatial frequency is broadest in cells projecting to the superior colliculus. Furthermore, responsiveness of superior colliculus-projecting neurons saturated at moderate contrast levels while other L5 PNs exhibited significantly broader dynamic range. Finally, we have characterized the synaptic inputs to each class of cells *in vivo*. We find that inputs to the apical tuft of single L5 PNs exhibit narrow orientation and spatial frequency tuning, consistent with receiving direct sensory-related

information. We also find evidence for both local and dendrite-wide spiking that suggests dendritic nonlinearities contribute to visual processing. In summary, our findings highlight substantial functional differences between distinct populations of L5 PNs in the mouse visual cortex. We suggest that superior colliculus-projecting cells are best described as “detectors”, while other populations may be more suited for discrimination. These results indicate that L5 consists of multiple parallel processing streams for routing specific features of sensory information to their target structures.

Title: Binocular organization of cortical maps for ON/OFF spatial phase and orientation in primary visual cortex

Authors: *J. KREMKOW[1,2], J. JIN[2], Y. WANG[2], J.-M. ALONSO[2];
[1]Inst. for Theoretical Biol., Humboldt Univ. of Berlin, Berlin, Germany; [2]State Univ. of New York, Col. of Optometry, New York, NY

Abstract: A hallmark of the primary visual cortex (V1) is the systematic mapping of different stimulus attributes such as eye input, orientation preference and ON/OFF spatial phase (Wang et al. 2015). We have recently showed that cortical maps for ON/OFF spatial phase are closely related to the geometry of cortical orientation maps in cat V1 (Kremkow et al. 2014). However, it is not fully understood in what extent the relation between these maps depend on eye input. To address this question we performed horizontal penetrations through the primary visual cortex in cat with 32-channel multielectrode arrays (inter-electrode separation: 100 microns) and studied the binocular organization of ON/OFF spatial phase and orientation/direction preference. To characterize the orientation map, we presented moving bars and calculated the orientation/direction preference as the angle that generated the maximum response. To characterize the ON/OFF spatial phase map, we measured the ON/OFF receptive fields (RF) with light and dark sparse noise. ON/OFF retinotopy was then characterized by the center-of-

mass of the ON/OFF receptive subfields and spatial phase by fitting a Gabor function to the ON-OFF receptive field. Our analysis shows that the cortical maps for orientation and direction are precisely matched across eyes: the mean difference in orientation preference was only 13 deg (n=1417 with orientation selectivity > 0.3) and the mean difference in direction preference was 17 deg (n= 550 with direction selectivity > 0.3). In contrast, the cortical map for ON/OFF spatial phase was more variable across eyes. In accordance with previous studies (DeAngelis et al. 1991), we found cortical sites that were precisely matched for spatial phase and cortical sites that were mismatched (median phase difference = 43 deg, n = 324). The diversity of binocular spatial phase was also reflected in the organization of binocular ON/OFF retinotopy. While on average ON/OFF retinotopy was well matched across eyes (mean distance between same sign receptive subfields = 0.27 RF diameters, n=648), we found also cortical sites with retinotopic distances larger than 0.5 RF diameters (n=94/648). Interestingly, our data also show that OFF retinotopy is less scattered than ON retinotopy across eyes (ON-ON distance / OFF-OFF distance = 1.5, n=324, $p<0.001$, Wilcoxon test), and moreover, that the ON-ON distance is more strongly correlated to spatial phase differences ($c=0.54$, $p<0.00001$) than the OFF-OFF distance ($c=0.3$, $p<0.001$). Our results suggest that ON/OFF spatial phase maps are, on average, well matched across eyes and that phase mismatches are more likely caused by binocular differences in ON retinotopy.

Title: Direction selectivity of thalamic excitation onto single neurons in mouse primary visual cortex

Authors: ***A. D. LIEN**[1], M. SCANZIANI[2];
[1]GIND, Gladstone Inst. of Neurolog. Dis., San Francisco, CA; [2]HHMI/University of California San Diego, San Diego, CA

Abstract: Primary visual cortex (V1) contains neurons that are selective for the direction of movement of visual stimuli, a feature thought to play a key role in representing the visual world for perception and behavior. Our understanding of the underlying neuronal circuit mechanism is incomplete. Sensory information reaches V1 neurons via excitatory synaptic input from the thalamus. Whether the thalamic excitation exhibits direction selectivity and how such selectivity

might arise remain open questions. We address these issues by isolating and recording thalamic excitation onto mouse L4 V1 neurons in response to visual stimuli consisting of drifting or static gratings using *in vivo* whole-cell recording and optogenetic silencing of intracortical excitation. In response to drifting gratings thalamic excitation fluctuates in amplitude at the temporal frequency of the grating (F1 modulation). We find that while the total excitatory charge (or average excitation) across the stimulus duration was similar regardless of stimulus direction the amplitude of the F1 modulation was selective for direction. That is, large amplitude fluctuations (strong F1 modulation) occurred in the preferred direction and small ones (weak F1 modulation) in the opposite. How can the temporal dynamics of thalamic excitation be so different in response to the same spatial pattern moving in opposite directions? We hypothesize that at certain spatial phases the drifting grating triggers thalamic excitation with a prolonged time course while at other phases the same grating triggers transient excitation. Thus, if the movement of a drifting grating occurs such that phases evoking prolonged excitation precede phases evoking transient excitation it will produce optimal temporal summation and strong F1 modulation. Movement in the opposite direction, i.e. transient phases before prolonged ones, will result in poor temporal summation and weak F1 modulation. Consistent with this hypothesis, in neurons with direction selective thalamic excitation, the time course of thalamic excitation in response to static gratings varies as a function of the spatial phase of the grating with certain phases producing a prolonged excitation and others producing a transient one. The preferred direction of thalamic excitation was well predicted by the relative spatial phase of the prolonged and transient responses. In conclusion, we find that direction selectivity is present in the thalamic excitation onto V1 neurons and that such direction selectivity is likely generated by an asymmetric distribution of the time course of thalamic excitation across the receptive field.

Title: Laminar processing of global visual contours in V1 and V2

Authors: R. CHEN[1], F. WANG[1], H. LIANG[2], *W. LI[1];
[1]Beijing Normal Univ., Beijing, China; [2]Drexel Univ., Philadelphia, PA

Abstract: Linking line segments into global contours is important for coherent visual perception. Increasing evidence indicates important roles of both feedforward and feedback connections in

contour integration, but the underlying intra- and inter-cortical circuitry is unclear. Using a pair of laminar electrodes (U-probes, Plexon Inc), each with 24 recoding contacts spaced 100 μm, we simultaneously recorded multiunit activities from different layers in monkey V1 and V2 at retinotopically matched locations. The monkeys were trained to detect visual contours formed by different number of collinear bars embedded in a background of randomly oriented bars. Referring to the known anatomical structures and using current source density analysis, we separated each cortical area into three laminae approximate to the supra-granular (SG), granular (G) and infra-granular (IG) layers. Cells showing responses correlated with contour length were defined as the contour cells. The distribution of contour cells across cortical layers were different. V1 contour cells were largely confined in the SG and IG layers, scarcely seen in the G layer, while in V2 the contour cells were mainly located in the SG, G and upper IG layers. The time course and the strength of contour-related signals also varied across layers. In V1 contour signals did not emerge until ~100 ms after stimulus onset for almost all contour cells, and the contour signals became progressively earlier and stronger towards the upper SG (~cortical layer I/II). In V2 a small proportion (~10%) of contour cells in the SG and G layers started to signal the global contour since their visual response onset (~50 ms after stimulus onset); the contour signals in the remaining cells were much delayed, similar to V1 contour cells, but the shortest latencies and maximal strengths of contour signals were seen in the lower SG layer of V2. The overall contour signals in V2 were much stronger than V1. The global contour induced a Mexican-hat response profile in both V1 and V2, facilitating neurons with receptive fields on the contour and suppressing those on the background. The facilitation preceded the suppression, and this difference systematically varied across layers. Conditional Granger causality analyses showed interdependence of contour signals across different layers in V1 and V2. Our results suggest that different cortical layers and areas play different roles in contour integration, and that the inter-laminar and inter-areal processes work synergistically to amplify the contour signals and suppress interfering image components.

Title: Two-photon imaging of neuronal populations in the primary visual cortex representation of the overhead visual field

Authors: ***S. RULLA**[1], B. NG[1], J. MACKE[2], D. WALLACE[1], J. SAWINSKI[1], J. KERR[1]; [1]Dept. Behavior and Brain Organization, [2]Res. Ctr. Caesar: A Max Planck Inst., Bonn, Germany

Abstract: Rodents have a large binocular field of view that extends from the snout to over the animals head. Recent experiments have shown that rodents have a strong, innate, evasive behavior evoked exclusively by stimuli presented above them. However, little is known about the functional properties of cortical neurons that represent the overhead visual field. Here we describe a method for allowing direct optical recording from populations of neurons representing the overhead visual field. Firstly, the conventional microscope objective has been replaced with a periscope coupled to a miniature objective to facilitate placement of a stimulus monitor above the rat's head. Secondly, we developed a method for presentation of visual stimuli on the OLED display of a tablet running the Android OS, and a camera-based method for calibrating the position of the stimulus display in relation to the animals head. Using this setup, we recorded in rats the activity of neurons in the representation of the overhead visual field of the primary visual cortex in response to a range of stimuli. Neurons were labeled with the calcium indicator OGB-1 with counterstaining of astrocytes using sulforhodamine 101. Stimuli were either an expanding or contracting looming dot, or a moving dot that moved at constant speed along multiple trajectories to cover all positions within the display. In both stimulus types, differing sets of foreground/background luminance were used. Preliminary results show that 19% of the neurons responded with clear and reproducible transients to the looming dot stimulus, and 30% were responsive to moving dot stimuli. The response profiles of neurons to different stimulus types and parameters were further analyzed in detail and compared between cortical areas and receptive field properties established for this cortical region.

Title: Cortical spread of correlations between orientation selectivity and orientation preference in primary visual cortex

Authors: ***J. JIN**[1], J. KREMKOW[1,2], Y. WANG[1], R. LASHGARI[1,3], J. ALONSO[1]; [1]SUNY-Optometry, New York, NY; [2]Inst. for Theoretical Biol., Humboldt Univ. of Berlin, Berlin, Germany; [3]Neurosci. and Neural Engin. Res. Lab., Iran Univ. of Sci. and Technol., Tehran, Iran, Islamic Republic of

Abstract: The primary visual cortex of carnivores and primates contains a systematic map of stimulus orientation. Within this map, the highest orientation selectivity is found at regions with the slowest orientation gradient and the lowest selectivity at regions with the fastest gradient. Although this relationship between orientation selectivity and orientation gradient appeared weak or inexistent in early studies, recent work demonstrates that it is robust (Nauhaus et al. 2008) and could play a potential role in cortical map development. To investigate how the relationship between orientation selectivity and orientation gradient varies with cortical distance and eye input, we performed horizontal penetrations through the primary visual cortex with 32-channel multielectrode arrays (inter-electrode separation: 100 microns). We selected recording sites that responded robustly to moving bars either when stimulated through the contralateral eye (n=3077) or the ipsilateral eye (n=1912) and then fitted a von Misses function to calculate orientation preference and orientation selectivity. The orientation preference was calculated as the angle that generated the maximum response and the orientation selectivity as the ratio between the responses to the preferred orientation and orthogonal orientation. For each possible pair of recordings, we calculated the average orientation selectivity and orientation gradient (difference between orientation preferences) and then measured the correlation between both as a function of cortical distance (from 100 to 2500 microns). This analysis demonstrate that orientation selectivity is negatively correlated with orientation gradient at distances of 100 microns ($r=-0.38$, $p<0.0001$ for contralateral eye and $r=-0.39$, $p<0.0001$ for ipsilateral eye), the correlation fully decays within 500 microns (e.g. $r=0.02$, $p=0.2$ for contralateral eye) and then becomes slightly positive ($r = 0.1$, $p < 0.0001$ at 600 microns) before returning to baseline. The functions relating cortical distance with the selectivity/gradient correlation were remarkably similar between eyes ($R^2 = 0.99$, slope = 1.03) and could be accurately described with a difference of Gaussian functions with standard deviations of 322.13/391.52 microns for contralateral eye ($R^2=0.97$) and 309.69/379.96 for the ipsilateral eye ($R^2=0.94$). These results demonstrate that the correlation between orientation selectivity and orientation gradient is a robust feature of cortical orientation maps, it is remarkably similar across the two eyes and has a cortical spread comparable to the size of a column for spatial phase in visual cortex (Kremkow et al., 2014; Wang et al., 2015).

Title: Cortical topography and cross-orientation interactions in visual cortex

Authors: *E. KOCH, J. JIN, M. JANSEN, C. PONS, J. ALONSO, Q. ZAIDI;
SUNY Col. Optometry, New York, NY

Abstract: The primary visual cortex of carnivores and primates is organized into functional maps for orientation preference that contain regions where the orientation is similar among neighboring neurons (iso-orientation domains) and regions where it is very different (pinwheel centers/ fractures). Within this cortical map, cross-orientation interactions are thought to be important for making a more efficient population code for orientation processing, but it is currently unknown if cross-orientation suppression varies across the different regions of the map. To address this question, we performed horizontal penetrations with multi-electrode arrays in the primary visual cortex of anesthetized cats, and sampled populations of neurons in different orientation domains (32-channel Neuronexus probe, 100 microns inter-electrode distance). Neurons were stimulated with a sequence of flashed (100 msec) sinusoidal gratings of 8 orientations, 8 contrasts, and 4 phases, and pairs of these gratings (plaids). We measured the semi-saturation constant (C50), orientation tuning bandwidth measured as half width at half height (HWHH), and local homogeneity index (LHI) at each site. The LHI gives a measure of the orientation gradient: closer to 0 in pinwheel centers/ fractures and closer to 1 in iso-orientation domains. A suppression index (SI) was calculated by subtracting the plaid response from the summed responses to the individual gratings, and normalizing by the maximum response. Recent studies indicate that cross-orientation suppression originates from contrast saturation in thalamic inputs. Consistent with these studies, we found a negative correlation between C50 and SI ($r=-0.58$, $p< 0.0001$, $n=150$). In addition, we found a positive correlation between LHI and SI ($r=0.39$, $p<0.0001$), implying that there is more suppression in iso-orientation domains than pinwheel centers. HWHH was correlated with LHI ($r=-0.33$, $p<.0001$) but not with C50 ($r=0.008$, $p=0.93$). LHI was also correlated with C50 ($r= -0.4$, $p<0.0001$) indicating that neurons located in iso-orientation domains generate responses that saturate more with luminance contrast than those located around pinwheel centers. A step-wise regression demonstrated that LHI had a significant effect on SI beyond that of C50 (combined $r=0.66$; LHI coefficient: 0.31, $p<0.001$). Existing models of cross-orientation suppression can predict the relation of C50 with SI and LHI but not the relation between SI and LHI. Therefore, we conclude that cortical topography for orientation preference significantly affects cross-orientation interactions in visual processing, a finding that may require rethinking existing models.

Title: Specificity in the spatial organization of receptive fields supporting multiple functional maps in tree shrew visual cortex

Authors: *K.-S. LEE[1,2], X. HUANG[1], D. FITZPATRICK[1];
[1]Max Planck Florida Inst., Jupiter, FL; [2]Integrative Biol. and Neurosci. Grad. Program, Florida Atlantic Univ., Boca Raton, FL

Abstract: *In vivo* 2-photon imaging of calcium sensors in visual cortex has provided a host of new insights into the fine scale columnar mapping of response properties like orientation, direction, and visual space. However, it remains unclear how the inputs supplied by the LGN are spatially arranged to generate these functional maps. Extracellular recording in carnivores have shown that nearby geniculate afferents in layer 4 exhibit spatially offset ON and OFF centers, which could provide the basis for the generation of orientation selectivity. In the tree shrew, the ON and OFF pathways remain segregated in layer 4, but converge for the first time in layer 2/3, where selectivity for orientation emerges. In this study we used 2-photon imaging of GCamP6s calcium fluorescent signals to map the receptive fields of neurons in layer 2/3 of tree shrew visual cortex with reverse correlation using sparse noise. We found a diverse array of receptive field properties in layer 2/3 including neurons with classic simple, complex and single sign receptive fields (either ON or OFF). The ON and OFF subfields in layer 2/3 were found to exhibit topologically distinct relationships with the maps of visual space and orientation preference. In most cases, the centers of OFF subfields for neurons in a given region of cortex were confined to a compact region of visual space and displayed a smooth retinotopic progression, while the centers of the ON subfields were distributed over a wider region of visual space and displayed less retinotopic precision. Consistent with the arrangement of ON and OFF subfields of simple cells in other species, the angle of displacement in visual space of the ON and OFF subfields for individual neurons could be used to predict the organization of the orientation map. Taken together, these results suggest that the differential arrangement of ON and OFF subfield centers by cortical circuits meets the conjoint constraints of mapping both visuotopy and orientation in a single population of neurons and in a fashion that preserves continuity for both stimulus features.

Title: Phase and structure selectivity depend on grating class in primary (V1) and secondary (V2) visual cortex

Authors: *P. DE LUNA, J. POIROT, R. KRETZ, G. RAINER;
Univ. of Fribourg, Switzerland, Fribourg, Switzerland

Abstract: Many studies have shown that neurons in early visual cortex are tuned for the structure, i.e. orientation and spatial frequency, of Cartesian gratings, and often exhibit activity modulations dependent on spatial phase. Here we systematically explored how neural responses in V1 and V2 of the tree shrew (species Tupaia belangeri) depend on structure and phase of gratings taken from the Cartesian, as well as hyperbolic and polar grating classes. We analyzed single neuron activity from 86 cells, as well as visual evoked potentials (VEPs). As expected, structure selectivity was greatest for Cartesian gratings for both neural signals, but unexpectedly, phase sensitivity was best revealed using hyperbolic gratings (3-way ANOVA, $p<0.01$). We observed a number of differences between V1 and V2: V2 neurons exhibited greater structure selectivity than V1 neurons for Cartesian gratings, whereas the reverse was true for the VEP (unpaired t-tests: $p<0.05$). At the same time, the VEP was more sensitive to phase in V1 than in V2. By presenting gratings at 1x, 2x and 4x the size of the minimum response field, we also investigated how contextual modulation affected neural responses. We observed that visual stimulation of the surround often resulted in an enhancement of the responses for single neurons and VEPs, with suppression occuring only rarely. Surround enhancements were more pronounced for Cartesian than other grating classes. Our findings support recent evidence about a functional organization of neurons according to phase, i.e. phase columns, in V1 but not V2. At the same time, phase sensitivity based on Cartesian grating responses may underestimate the actual sensitivity of visual cortical neurons to phase, which can be revealed by hyperbolic grating stimulation. We discuss our findings in regard to the extent to which they may reflect general principles of visual cortical function or species-specific adaptations that are characteristic of the tree shrew.

Title: Orientation- and direction- selective responses of GABAergic neurons in ferret visual cortex

Authors: *D. E. WILSON[1,2], G. B. SMITH[1], A. JACOB[1], T. WALKER[1], J. DIMIDSCHSTEIN[3], G. J. FISHELL[3], D. FITZPATRICK[1];

Abstract: The response properties of inhibitory neurons critically shape the function of the circuits in which they participate. Genetic tools in the rodent visual cortex have revealed that GABAergic inhibitory neurons show weak response selectivity across all subtypes, but it remains unclear whether these results generalize to other mammalian lineages. We used an adeno-associated viral construct to express GCaMP6f in GABAergic neurons in the ferret visual cortex. The orientation and direction selectivity of these neurons was assessed through *in vivo* two photon calcium imaging and inhibitory subtypes were identified using post hoc immunostaining. We find that the virus effectively labels inhibitory neurons with high specificity across multiple subtypes, including both somatostatin-positive and parvalbumin-positive interneurons. In contrast to the mouse visual cortex, we find that multiple subtypes of inhibitory neurons exhibit strongly selective responses for orientation and direction of motion in the ferret visual cortex. Neighboring inhibitory neurons share similar orientation and direction preferences and are organized into columnar maps, that are consistent with maps of population activity derived through intrinsic signal imaging. The degree of orientation and direction selectivity is similar to excitatory neurons and appears to vary based on location within the orientation map. These findings suggest that feature-selective inhibition plays a prominent role in shaping the response properties of cortical circuits that manifest columnar architecture.

Title: Self-organization of receptive fields and orientation maps in layer 2/3 of the primary visual cortex: Comparisons between cats and rodents

Authors: *M. MIYASHITA[1], N. WAKABAYASHI[2], S. TANAKA[3];
[1]Numazu Natl. Col. of Technol., Numazu, Shizuoka, Japan; [2]Toyohashi Univ. of Technol., Aichi, Japan; [3]The Univ. of Electro-Communications, Tokyo, Japan

Abstract: Spatial representation of preferred orientations is revealed to be salt-and-pepper-like in the rodent visual cortex, whereas that in the cat visual cortex exhibits an orderly map structure. Recently, our mathematical model of the activity-dependent self-organization of geniculocortical inputs has demonstrated that the connection probability of lateral excitations (p) determined which type of orientation representation is formed in layer 4; the salt-and-pepper-like representation emerges at lower probability p, whereas orderly maps appear at higher p. Irrespective of p values, almost all model layer 4 neurons were oriented and characterized by simple-cell response properties. In the present study, we extended the model by taking into account fast and slow decay time constants of postsynaptic currents of neurons in layer 2/3. In the framework of the cascade model, we performed computer simulations of self-organizing feedforward connections from layer 4 to layer 2/3 as well as from the lateral geniculate nucleus to layer 4 at different values of p. Simulations showed that average values of orientation selectivity indices of neurons in model layer 2/3 were higher than those in model layer 4. As in layer 4, orientation representation changed from orderly maps to salt-and-pepper-like structures when p became smaller than about 0.1. To classify model neurons into simple and complex cell

types, we calculated the ratio of F(2) to F(0) harmonics in responses to sinusoidal gratings drifting in the preferred direction for each neuron in model layer 2/3. The number of neurons classified into complex cells evidently decreased when orientation representation became salt-and-pepper-like. In the cascade model, the phase invariance of complex cells in layer 2/3 is achieved by the integration of feedforward inputs from layer 4 simple cells with similar preferred orientations over various spatial phases. In the cortex exhibiting salt-and-pepper-like orientation representation, it may be difficult to find sufficient phase variation of neurons with similar preferred orientations within a short distance to eliminate phase dependence. Thus, it is suggested that in layer 2/3 of the visual cortex, simple cells are abundant in rodents, whereas complex cells are rich in cats.

Title: Receptive fields mapped with natural and artificial stimuli in macaque monkey V1

Authors: ***H.-Y. WU**[1,2], Y.-C. HSU[2], C.-I. YEH[3];
[1]Dept. of Psychology, Natl. Taiwan Universi, Taipei, Taiwan; [2]Inst. of Neuroscience, Natl. Yang-Ming Univ., Taipei, Taiwan; [3]Dept. of Psychology, Natl. Taiwan University,, Taipei, Taiwan

Abstract: Our visual system has evolved to process natural stimuli that are very complex in both spatial and temporal aspects. However, properties of visual neurons in the primary visual cortex V1, the first cortical stage of visual processing, are primarily studied with artificial stimuli that have simple and well characterized properties (Felsen and Dan 2005; Rust and Movshon 2005). Few studies had used both artificial and natural stimuli to map V1 receptive fields (Ringach et al 2002; Sharpee et al 2006), but it remains unclear whether natural and artificial maps are comparable or not. We addressed this question by using both stimulus types to measure the receptive field of neurons in different layers of macaque monkey V1. The artificial stimulus is a binary white noise (m-sequence, 16x16 pixels, Reid et al 1997), and the natural stimulus is a movie (48x48 pixels) recorded from a camera attached to the head of the cat walking in

grassland and forest (Kayser et al 2003). In comparison with the m-sequence, the movie has lower spatial and temporal frequencies, and has more low-luminance pixels (lower than the mean luminance). The frequency power of the movie is higher along the vertical than the horizontal axis, so we also rotate the movie by 90 degrees to measured receptive fields of the same neurons. We used a multi-electrode matrix (8x8 array, 200 um spacing, Neuronexus) to simultaneously record from many neurons in different layers of V1. Receptive fields were calculated by reverse correlation. Preliminary results show that the receptive field size and the separation of different subareas tend to be larger for natural maps than for artificial maps. The change in the frequency power of the natural movies [from vertical dominated to horizontal dominated] also has an effect on receptive field properties. Overall, receptive fields of V1 neurons are not fixed and can vary with different stimulus ensembles.

Title: Impact of speed and contrast on response latency and spatial representations in primate area MT

Authors: *S. C.-Y. CHEN[1,2,3], J. W. MORLEY[4], S. G. SOLOMON[5];
[1]Ctr. for Perceptual Systems, Austin, TX; [2]ARC Ctr. of Excellence for Integrative Brain Function, Sydney, Australia; [3]Sch. of Med. Sci., Univ. of Sydney, Sydney, Australia; [4]Sch. of Med., Univ. of Western Sydney, Penrith, Australia; [5]Dept. of Exptl. Psychology, Univ. Col. London, London, United Kingdom

Abstract: The response latency of neurons in visual pathway depends on features of the visual stimulus, including its speed and contrast. Stimulus dependence of response latency may influence motion computations, which depend on the fine temporal structure of visual response, and thus contribute to speed-dependent biases in the perceived position of a moving object. To assess this we measured spiking activity in area MT of sufentanil-anaesthetised marmoset monkeys (n=4) using 10x10 planar electrode arrays. Response latency depended on the speed and contrast of a large field of moving white dots, in agreement with previous work. Latency decreased from 73 ms for speeds of 1 degree/s to 58 ms at 80 degrees/s; for dot fields moving at 20 degree/s, latency decreased by 20 ms when Weber contrast was increased from 22 to 100%. Regression analysis shows that response latency depends on speed, contrast and response

amplitude, but not motion direction. To determine if changes in response latency influence the representation of spatial position we analysed responses to a single white disk (contrast 22 or 100%), moving steadily at speeds ranging between 12.5 and 100 degrees/s. The spatial profile of receptive fields obtained at each speed and contrast could be brought into register by assuming a single fixed response latency. A Bayesian decoder trained on population response at the lowest speed was capable of predicting the position of the disk at higher speeds without bias. Similarly, a decoder trained on population response to a 100% contrast disk predicted the position of a 22% contrast disk without bias. We conclude that while speed and contrast can influence the latency of population response in area MT, they have little influence on its representation of the position of a single moving object.

Title: Response properties of neurons specialized in motion detection in extrastriate area 21a of the cat cortex

Authors: *H. ASLANYAN[1], A. KHACHATRYAN[2], D. KHACHVANKIAN[1], B. HARUTIUNIAN-KOZAK[1], A. GHAZARIAN[1];
[1]Inst. of Applied Problems of Physics of NAS, Yerevan, Armenia; [2]Dept. of Ophthalmology, SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: The neurophysiological mechanisms underlying central information processing in the cortical visually sensitive areas, including extrastriate area 21a, is still a fundamental problem in neuroscience. Since the pioneering studies of Hartline and Hubel and Wiesel the “receptive field” (RF) concept of a single visually sensitive neuron has become the most important substrate for the interpretation of mechanisms governing the perception of stationary and moving visual images. A concept was introduced, according to which the receptive field stationary structure, as a rule, predetermines the transformation and central processing of incoming visual information concerning the moving visual stimuli. Numerous subsequent studies have confirmed this concept, however earlier experiments from our group showed that certain discrepancies in this approach are evident. In our investigations of the neuronal mechanisms of visual information processing of moving visual images, we observed only a weak correlation, and in some cases, an almost complete absence of correlation between the RF stationary structure and the neuron response patterns to moving stimuli. In the present study we present further observations concerning a small group of neurons in extrastriate area 21a which did not react to the stationary

flashing light spot positioned in its RF, determined by the hand held stimuli, but responded strongly to the moving visual stimuli. We propose that there is a minority of neurons (5.2%) that lack responses to stationary visual stimuli yet reveal a strong ability to detect moving images by discriminating contrasts, sizes, directions and orientations of the motion of visual images. It is likely that these neurons participate in the central processing of visual information by acting as highly specialized motion-detectors. Our results allow us to suggest that a small group of neurons in central visual pathways while being unresponsive to stationary visual stimuli, with great probability are strictly specialized in motion detection, a result of modulatory influences of the activated adjacent neurons, having RFs overlaping with the RF of the neuron under investigation. It is likely that such interactions may be temporary events taking place during the time of moving image motion. Further investigations are needed to elucidate the nature and neurophysiological mechanisms underlying such specialized temporary influences in the central processing of visual information.

Title: Motion-direction tuning in the post-saccadic remapped response in macaque MT

Authors: *T. YAO[1,2], S. TREUE[1,3,2], S. KRISHNA[1];
[1]German Primate Ctr., Goettingen, Germany; [2]Fac. of Biol. and Psychology, Goettingen Univ., Goettingen, Germany; [3]Bernstein Ctr. for Computat. Neurosci., Goettingen, Germany

Abstract: In the neural phenomenon of perisaccadic remapping, neurons in several visual and attentional/oculomotor brain areas respond to stimuli that appear in their post-saccadic receptive fields (RFs) before the saccade occurs. A robust debate exists regarding its properties and potential function with one view emphasizing its role in keeping track of relevant locations across saccades (the “attentional pointer” hypothesis) while others additionally emphasize its role in transsaccadic feature integration and the perception of visual stability across saccades. A critical difference between these two views lies in whether the remapped response contains only information about stimulus location, but no information about features like orientation and motion direction (as the attentional pointer hypothesis predicts). We previously showed that

neurons in macaque MT show a remapped post-saccadic response that was greater for task-relevant stimuli, but was not tuned for stimulus motion direction. However, the neurons in our study, like those in all other prior studies of remapping, mostly had RF centers well away from the fovea. Visual experience in humans and macaques is predominantly influenced by foveal processing, and saccadic eye movements serve to bring interesting locations in the visual scene onto the fovea. Further, it is known that attention shifts towards the saccade target (ie. the future foveal stimulus) just prior to saccade execution. We therefore trained two monkeys to fixate and attend to a moving random dot pattern (RDP) in order to respond to a brief direction change with a manual response. In addition, during this period, the fixation point could disappear, serving as the cue for the monkey to make a saccade towards the RDP. The monkey had to continue to monitor the RDP and respond to the direction change when it occurred. While the monkeys performed this task, we recorded from neurons with foveal or parafoveal RFs in area MT. The RDP moved in one of four directions and was located well outside the neurons' RF before the saccade, until the saccade brought the RDP into the neurons' RF. Critically, on about half the trials, the RDP disappeared just before the saccade, so that the RDP never appeared within the neurons' RF. On these trials, our preliminary results indicate that the post-saccadic response of MT neurons differs depending on the motion direction of the RDP that occupied the spatial location of the post-saccadic RF (but before the saccade). This suggests that the role of remapping can extend beyond merely serving to remap the retinotopic position of attended locations across saccades to possibly playing a role in transsaccadic motion integration.

Title: Topographic maps of depth in human visual cortex

Authors: *D. BERMAN, N. J. FINLAYSON, J. D. GOLOMB;
Dept. of Psychology, The Ohio State Univ., Columbus, OH

Abstract: Depth is a frequently overlooked aspect in vision research, especially in humans, despite the fact that recognizing and perceiving depth cues are essential when it comes to appropriately interacting with our surroundings. Behavioral and physiological studies have provided a solid framework for understanding depth perception, but we have yet to establish the

precise neural organization of depth representation in human visual cortex. In order to advance our understanding of this question we mapped depth representations via fMRI using a phase-encoded stimulus that travels along the z-axis (depth), analogous to the standard 2D retinotopic mapping paradigm (wedges and rings; Engel et. al., 1994; Sereno et. al., 1995). Our stimulus was a large 2D patch that consisted of rapidly moving black and white dots. The stimulus traversed along 13 discrete depth planes either forwards or backwards (in alternating runs), completing a full cycle every 28 seconds. Subjects wore red/green anaglyph glasses while in the scanner so that they could perceive depth. Using a standard phase-encoded cross-correlation analysis, we found voxels selective for different depth planes in several intermediate and later visual areas. Depth representations appear to be organized into a large-scale map-like representation across visual areas V3d, V3A, V3B, and V7. Furthermore, this result was seen to have high within-subject reliability across multiple scanning sessions. Our findings provide critical insights regarding the neural correlates in which depth is represented, and we detail for the first time depth maps in human visual cortex.

Title: Evidence for neurochemical alterations in area MT following damage to V1 in monkeys

Authors: *O. HOPKINS[1], K. DING[1], J. FANG[3], H. RODMAN[2];
[1]NBB Program, [2]Psychology and NBB Program, Emory Univ., Atlanta, GA; [3]Med. Col. of Georgia, Augusta, GA

Abstract: Primates with damage to primary visual cortex (V1) show some recovery or sparing of visual function, in particular an ability to detect and discriminate moving stimuli. This ability is likely subserved by spared neural activity in motion-related cortical areas MT and MST. In humans, the residual vision is typically not conscious and has thus been referred to as 'blindsight'. However, the remaining visual activity in MT/MST is weaker than in intact animals, and the preserved motion-processing abilities are correspondingly abnormal. Here, we hypothesized that alterations in calbindin expression might be associated with these changes in MT function. Calbindin D-28K (Cal) is a calcium-binding protein that is both preferentially associated with inhibitory cell populations in cortex and with buffering of calcium transients that

impact cellular excitability throughout the brain. Moreover, earlier studies in cats (Huxlin & Pasternak, 2001, *J. Comp Neurol*.), showed that lesions of areas 17/18 produce decrements in expression of Cal in the supragranular layers of area PMLS, a proposed homolog of MT. To address the possibility of similar alterations in primates, we quantified Cal neuron populations in the supragranular layers of MT/MST in four *Macaca rhesus* with unilateral (left) lesions of central V1 in either adulthood (2 animals) or infancy (5-6 wks of age, 2 animals). After a survival period of 4-7 yrs, Cal immunoreactivity was revealed in 50 µ brain slices using the ABC method, DAB as the chromogen, and Giemsa counterstaining. Cal-immunoreactive cells were counted in six areas of 5-8 sections per hemisphere using the optical disector method and a counting frame of 120 by 80 µ. Using each lesioned case as its own control, we found significantly reduced densities of Cal neurons of layer III specifically in the foveal portion of MT (but not peripheral MT or MST) of the damaged hemisphere in two of the cases and a marginally significant difference in this same comparison in a third. Age at lesion was not a factor. The hemispheres did not differ in calbindin density in any region sampled in two intact control brains. However, comparison of blood vessel density between the hemispheres of the lesion cases indicated that alterations in vascularization may accompany the changes in Cal populations. It remains to be seen whether the changes in Cal density found reflect changes in expression or loss of specific Cal populations. The results contribute to our understanding of the suite of neurochemical, structural and connectional changes that accompany damage to V1 in a monkey model of 'blindsight'.

Abstract: Recent studies reveal that multiple cortical areas in non-human primates represent heading. However, little is known about the dynamics by which heading and choice are represented in neural activity. To disassociate the time-varying contributions of these signals to neural population activity, we trained macaque monkeys to report the direction of self-motion relative to straight ahead in either visual or vestibular heading discrimination tasks. Using electrophysiological techniques, we quantified the contributions of heading and choice to neural responses in two areas that exhibit multimodal (visual-vestibular) heading signals (dorsal medial superior temporal, MSTd; ventral intraparietal, VIP) and in an area (parieto-insular vestibular cortex, PIVC) with only vestibular activity. To separate heading- and choice-related components of each cell's response dynamics, we computed partial correlations between spike counts, heading, and choice, and then squared to calculate the accounted variance between neural activity and heading/choice. By averaging the squared partial correlation coefficients across all cells within an area, we could estimate population dynamics explained by heading and choice. Vestibular heading signals were similar in PIVC and MSTd, and slightly weaker in VIP. Choice-related activity was strongest in VIP, with MSTd showing the weakest choice activity. Similar observations were found for visual heading signals in VIP and MSTd. Targeted dimensionality reduction techniques were used to further examine how much variance in the population responses could be explained by the velocity and acceleration components, as well as choice. For vestibular signals, the time course of the targeted dimensions revealed that cell activities followed the dynamics of the velocity and acceleration components of the heading signals. The largest contribution of velocity signals was in MSTd, with weaker contributions in PIVC and VIP. Acceleration signals were strongest in PIVC and MSTd, and weakest in VIP. Corroborating the partial correlation analysis, choice-related activity was strongest in VIP and weakest in MSTd. Similar results for the visual condition were found except that the acceleration component was not observed in MSTd and VIP (PIVC does not show visual responses). We conclude that visual-vestibular signals are differentially represented across areas, with the strongest vestibular acceleration in PIVC, visual-vestibular components of velocity in MSTd and choice in VIP. Our dimensionality reduction analyses support this observation because the population activities of these areas occupy different regions of the state space.

Title: Contributions of visual and extra-retinal mechanisms to rotation-tolerant heading selectivity in macaque area MSTd

Authors: *A. D. DANZ[1,2], D. E. ANGELAKI[3], G. C. DEANGELIS[2,1];
[1]Dept. of Brain and Cognitive Sci., Univ. of Rochester, Rochester, NY; [2]Ctr. for Visual Sci., Rochester, NY; [3]Dept. of Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Optic flow provides a reliable cue for heading estimation when the eyes do not rotate relative to the scene. When the eyes rotate relative to the world, a global component of motion is added to the retinal flow field, thus confounding the relationship between optic flow and heading. To overcome this confound, the visual system could use extra-retinal (e.g., efference copy) signals to compensate for the effects of eye rotation on responses of heading-selective neurons. Alternatively, the visual system may have mechanisms to decompose the flow field into translational and rotational components based on the differential depth dependencies of these flow components. Previous neurophysiological studies have shown partial compensation for eye rotations in heading tuning curves of neurons in area MSTd. However, the relative contributions of visual and extra-retinal signals to this compensation remain unclear because these previous studies either used an improper visual control for eye rotation or did not include a visual control. In addition, it remains unclear whether visual mechanisms of compensation require rich depth structure in the scene. We measured the heading tuning of MSTd neurons while macaque monkeys actively pursued a moving target or maintained fixation while eye rotations were simulated visually. Depth cues were manipulated by presenting either a 3D cloud or a fronto-parallel (2D) plane of random dots on a visual display subtending 90x90° of visual angle. Heading was varied within the horizontal plane, spanning the full range of 360° in 45° intervals. Measuring full tuning curves allowed us to distinguish between tuning shifts, response gain changes, and bandwidth changes resulting from real or simulated eye rotation. Compensation for rotation was quantified using a novel analytical method (Sunkara et al. 2015, eLife) that extracts tuning shifts due to rotation while controlling for changes in response gain and expected changes in tuning bandwidth. Results to date show stronger rotation compensation of heading tuning with the 3D virtual environment than with the 2D scene structure, for both real and simulated eye rotations. In the 2D environment, real eye rotation results in greater compensation than simulated rotation. In all conditions, the extent of rotation compensation is greater than what is expected from rotation-intolerant neurons. These data suggest that both visual and non-visual mechanisms contribute to generating a neural representation of heading in area MSTd that is partially tolerant to eye rotations. We will compare our findings to recent results from the ventral intraparietal area (Sunkara et al. 2015).

Title: Contributions of visual and vestibular cues to rotation-tolerant heading perception

Authors: *A. SUNKARA[1], B. LI[1], G. C. DEANGELIS[2,3], D. E. ANGELAKI[1];
[1]Neurosci., Baylor college of medicine, Houston, TX; [2]Brain and Cognitive Sci., [3]Ctr. for visual science, Univ. of Rochester, Rochester, NY

Abstract: Navigating through the world requires estimating one's heading, i.e. egocentric translation direction (T), but optic flow cues to heading are confounded by eye or head rotations (R). Several sources provide information about T and R, including visual and vestibular cues, as well as efference copy (EC) signals. Most human psychophysical studies have examined the roles of EC and visual cues (optic flow) in estimating heading in the presence of R. Since optic flow patterns are a sum of T and R components, it is hypothesized that EC is used to estimate R, which is then subtracted from the optic flow (Royden et al., 1992; Royden, 1994). Theoretically, heading in the presence of R can also be calculated based on purely visual cues (Longuet-Higgins & Prazdny, 1980) or through multi-sensory integration of visual and vestibular cues. Importantly, T can be estimated without the need for a separate estimate of R by using motion parallax cues from optic flow or otolith signals from the vestibular system. Since previous studies did not use vestibular T signals, it is unclear how T is extracted from optic flow and how vestibular cues contribute to heading perception in the presence of R. To address these questions, we used a 2-alternative forced choice task in which subjects (n = 8) reported their perceived heading relative to straight ahead. First, we evaluated the role of visual cues by using 3D optic flow stimuli that simulated T and R. All subjects had heading biases that were significantly smaller than the bias expected (20°) for no rotation compensation. These results show that visual cues can be used to partially compensate for R (consistent with neuronal data; Sunkara et al., 2015). Next, we evaluated the role of vestibular cues in heading perception by adding vestibular T to optic flow using a motion platform. This significantly reduced heading biases compared to the visual-only condition, showing that the integration of visual and vestibular translation signals plays a key role in estimating heading. In contrast, when vestibular R was added to the visual stimuli using a yaw motor to passively rotate subjects, heading biases increased substantially. Furthermore, when both vestibular T and R were added, biases were significantly greater than when only vestibular T was added. These results contradict the prevailing hypothesis that an estimate of R is subtracted from optic flow, which would predict smaller biases in heading perception when more information about R is present (in the form of vestibular R cues). Hence,

our results support an alternative hypothesis that heading is derived directly through multisensory combination of visual and vestibular T signals, without first estimating R.

Title: Multisensory representation of self-motion in macaque area 7a

Authors: ***K. LAKSHMINARASIMHAN**[1], E. AVILA[1], G. C. DEANGELIS[2], D. E. ANGELAKI[1,3];
[1]Dept. of Neurosci., Baylor Col. of Med., Houston, TX; [2]Brain and Cognitive Sci., Univ. of Rochester, Rochester, NY; [3]Electrical & Computer Engin., Rice Univ., Houston, TX

Abstract: Area 7a of macaque posterior parietal cortex, which projects to the hippocampal formation, is believed to be critical for spatial perception (Andersen, 1989) and has previously been shown to contain neurons sensitive to the pattern of optic flow (Motter and Mountcastle, 1981; Steinmetz et al., 1987; Siegel and Read, 1997; Merchant et al., 2001). Whether the same neurons are also tuned to non-visual self-motion signals remains unknown. To test whether area 7a, like other parietal areas, is multisensory, we used visual, vestibular and multisensory heading stimuli to characterize the tuning of 7a neurons. We recorded from seventy-five single units in area 7a of a macaque monkey trained to passively view different patterns of optic flow while fixating at the center of the screen (visual condition). Different optic flow patterns depicted the movement of the animal along 8 different directions spanning 360° on the azimuth plane of a three-dimensional environment. A subset of sixty neurons was additionally recorded while the monkey was passively translated along the same directions by a motion platform (vestibular condition), as well as simultaneously subjected to both visual and vestibular stimulation (combined condition). Roughly half of the neurons (n=37/75) exhibited significant tuning ($p < 0.05$; ANOVA) to egocentric heading direction in the visual condition. The median strength of their tuning, as quantified using a standard direction discrimination index (DDI), was found to be 0.67±.2. A vast majority of the neurons also exhibited significant direction tuning ($p < 0.05$) under the vestibular (67%, n=40/60) and combined (70%, n=42/60) conditions and their DDIs were comparable to the visual condition (vestibular: DDI=0.6±.2; combined: DDI=0.65±.2). To our knowledge, these findings constitute the first evidence for a multisensory representation of

self-motion in area 7a. A comparison of the DDIs suggests that the precision of heading representation in area 7a is comparable across both modalities. This complements several anatomical studies (Andersen et al., 1990; Lewis and Van Essen, 2000) and supports the idea that heading representation in area 7a may be acquired from convergent inputs from other parietal areas.

Title: Perception of object motion during self-motion: multisensory contributions to flexible reference frame transformations

Authors: *R. SASAKI[1], D. E. ANGELAKI[3], G. C. DEANGELIS[2];
[1]Ctr. for Visual Sci., [2]Dept. of Brain and Cognitive Sci., Univ. of Rochester, Rochester, NY;
[3]Dept. of Neurosci., Baylor Col. of Med., Houston, TX

Abstract: When a moving observer views a moving object, the retinal image velocity of the object is the vector sum of two components: object motion in the world and self-motion. To estimate object motion in the world, one has to compensate for the effects of self-motion on the retinal image. Other times, we may need to judge how an object moves relative to our head/body, which does not require compensating for self-motion. The brain must therefore perform computations of object motion that flexibly incorporate self-motion signals based on task demands, and we hypothesize that vestibular signals regarding self-translation play an important role. Our goal was to develop a behavioral paradigm for macaques that can be used to study how neurons mediate this flexible computation of object motion. We trained two monkeys to report whether an object moves upward/rightward or upward/leftward by making a saccade to one of two choice targets. In the world-coordinate task, the monkey is required to judge whether the object moved to the left or right of vertical in the world; in the head-coordinate task, the animal reports left or right relative to the head. The two tasks are randomly interleaved, as cued by fixation point shape. In the absence of self-motion (Object only condition), the two task

conditions are equivalent. However, in the presence of lateral self-motion, the animal must compensate for self-motion to perform the world-centered task. Self-motion information was provided by background optic flow (Object+Visual condition) or by a combination of optic flow and translation of a motion platform (Object+Combined condition). Perceptual biases were measured by constructing psychometric functions that plot the proportion of 'rightward' choices as a function of object direction in world coordinates. If the animal compensates fully for self-motion in the world-coordinate task, psychometric functions for rightward and leftward self-motion should overlap. Monkeys successfully switched between performing the world- and head-coordinate tasks. In the world-coordinate task, perceptual biases are substantially greater in the Object+Visual condition than the Object+Combined condition, indicating that vestibular self-motion signals contribute to perception of object motion in the world. Performance was largely accurate in the head-coordinate task, indicating that self-motion signals can also be gated out of the computation of object motion. Our findings demonstrate that perception of object motion incorporates self-motion signals as dictated by task demands, and they set the stage for electrophysiology experiments to explore flexible neural representations of object motion.

Title: Decoding feature spaces in primate MT: An evaluation of multivariate pattern analysis methods

Authors: *T. A. CARLSON[1], E. GODDARD[1], H. HOGENDOORN[2], S. S. SOLOMON[3], S. G. SOLOMON[4];
[1]Macquarie Univ., Sydney, Australia; [2]Helmholtz Inst. Exptl. Psychology Div., Univ. Utrecht Utrecht, Utrecht, Netherlands; [3]Albert Einstein Col. of Med., New York, NY; [4]Dept. of Exptl. Psychology, Univ. Col. London, London, United Kingdom

Abstract: In recent years there have been substantial developments in the application of multivariate pattern analysis methods to neuroscience data, e.g. fMRI, EEG/MEG, and single unit recordings. Many of these developments have come from studies examining the brain's coding of visual objects, a model system in which the underlying coding principles are poorly understood. In contrast, the coding of visual motion in the brain is relatively well known. We

know the fundamental features of motion, i.e. direction and speed, and understand how these features of visual motion are coded in MT, the brain area most often associated with representing motion. In the present study, we leveraged our knowledge of visual motion to study the effectiveness of inferential and exploratory methods for analysing multivariate brain recordings. We analysed single unit activity in multielectrode recordings from area MT of sufentanil-anaesthetised marmoset monkeys. The visual stimuli were moving dot patterns varying in speed and direction (7 speeds x 12 directions), or moving grating patterns varying in spatial frequency (SF), temporal frequency (TF), and direction, (3 SF x 3 TF x 12 directions). For each dataset, we used a linear classifier to compute decoding performance from the recordings for all possible pairwise combinations of stimuli. We first applied representational similarity analysis (RSA; Kriegeskorte, 2008), an inferential model testing approach, and confirmed that speed, direction, SF and TF were represented in population response. We then explored the utility of multidimensional scaling (MDS), an exploratory method of "discovering" important feature dimensions in the neural code. MDS was capable of revealing speed and direction feature dimensions for moving dot patterns; for grating patterns, however, MDS conflated SF and TF, and gave no indication that motion direction was relevant. We then applied hierarchical cluster analysis, another exploratory method that assumes categorical structure and aims to recover the categorical divisions. Cluster analysis conflated the feature dimensions in both dot and grating datasets, and provided limited interpretative value. Our findings show that in a well characterised system (visual motion analysis in area MT), where critical stimulus features have been explicitly manipulated, that exploratory analyses have limited value in "discovering" the underlying coding principles used by the brain. Theory and explicit model testing provide better means to uncover the brain's neural code.

Title: Direction tuning of response variability in populations of MT neurons is different in awake versus anesthetized recordings

Authors: *J. LOMBARDO, M. MACELLAIO, B. LIU, L. C. OSBORNE, S. E. PALMER; Univ. of Chicago, Chicago, IL

Abstract: Populations of sensory neurons exhibit variable firing in response to repeated stimulus presentations. This trial-to-trial stochasticity arises from variability in transmitter release, differences in underlying network state, and uncontrolled sensory inputs. The structure of this variability directly affects the information coding capacity of the population as quantified by the Fisher information. Many models of neural responses assume a Poisson or gamma-Poisson distribution of spike counts. These models fit data well, with spike count variance being proportional to the underlying firing rate, and exhibit a Fano factor (FF) of 1 or greater. While we find our recordings from MT neurons in anesthetized macaques to be consistent with a gamma-Poisson model with a moderate amount of "extra" variance, we find lower levels of variability in recordings from alert macaques, (FF significantly less than 1), arising from shorter time scales of response autocorrelation in the alert state. The difference in FF in the alert and anesthetized states,, and the difference in spike count correlations over time, suggest that consciousness alters the reliability of cortical responses at the level of single neurons. We observed a significant tuning of variability with respect to the preferred motion direction in MT neurons in alert recordings, with FF decreasing for preferred stimuli. We observed the opposite tuning in anesthetized macaques, with FF increasing for preferred stimuli as firing rate increases. New models of stimulus-dependent variability in MT responses are needed to account for these data, and for testing theories of population coding capacity in MT.

Title: Synergistic coding of motion direction and speed in MT neurons in monkeys

Authors: *M. V. MACELLAIO, B. LIU, L. C. OSBORNE;
Neurobio. Dept., Univ. of Chicago, Chicago, IL

Abstract: Neurons often encode multiple features of sensory stimuli. For example, in the middle temporal cortical area (MT), many neurons are selective for visual motion and are tuned for both direction and speed. Using one neural population to represent multiple stimulus features presents a challenge to downstream circuits that need to recover information about multiple features, e.g. direction and speed. For example, smooth pursuit eye movements translate visual estimates of target direction and speed arising from a population of MT neurons to rotate the eye in order to cancel retinal image motion. We ask how the joint encoding of direction and speed in MT neurons affects the precision of internal motion estimates and how that in turn affects pursuit. While we cannot directly observe an internal estimate of direction or speed, we can use the eye movement as a loyal representation of internal sensory estimates because <10% of the variation in pursuit arises from motor processing. We use a combination of extracellular recording in area MT of alert monkeys and analysis of eye movement behavior to analyze information about motion direction and speed over time, both at the level of single neurons and at the behavioral output. We find that MT neurons encode motion parameters synergistically, i.e. they encode more information about direction and speed together than the sum of the information about each singly. Synergistic coding arises from nonlinearities in the cortical input-output functions.

Title: Navigation and decision in mouse parietal cortex

Authors: *M. KRUMIN, K. D. HARRIS, M. CARANDINI;
Univ. Col. London, London, United Kingdom

Abstract: Posterior parietal cortex (PPC) in primates is believed to be involved in cognitive operations such as coordinate transformations and decision making. In rat PPC, some

experiments revealed decision signals, but others revealed signals related to navigation. Does mouse PPC carry signals related to decision or to navigation, or a mixture of these and other signals? To investigate the role of PPC in mice, we developed a two-alternative forced choice task based on a virtual T-Maze. The initial corridor contains a grating, whose contrast and position (left wall or right wall) are varied randomly across trials. The mouse indicates the position of the grating by turning to that side at the end of the corridor, and receives a water reward for correct choices. Wrong choices are marked by a brief sound. Mice learned the task after 2-3 weeks of training. During the behavior we recorded neural activity in PPC and other areas of the visual cortex, using two-photon imaging of the calcium indicator GCaMP6f through a chronic window. A typical imaging session yielded the activity of several hundreds of neurons (predominantly from layer 2/3) within ~0.5x0.5 mm. The firing of PPC neurons was strongly modulated by the virtual position and heading of the mouse. We expressed these responses as a function of two variables: virtual position of the mouse along the main corridor (z, between 0 and 100 cm), and virtual head direction (θ, between -30 and 30 degrees). Many of the cells had localized 'place-heading fields' in these coordinates. Predicting calcium signals from just these two variables (and not from variables such as speed, stimulus position, or behavioral choice) gave a reasonable prediction of each neuron's activity. These place-heading fields could occur at any location in z-θ space, and indeed the neurons recorded in a single session typically tiled the T-maze . In some cells, the strength of the place-heading field was additionally modulated by the contrast and position of the visual grating (on left or right wall). However, the final choice made by the animal did not seem to affect the responses of PPC cells beyond what could be simply predicted from their place-heading field. These results indicate that mouse PPC is largely concerned with the use of visual information in spatial behavior, including navigation. Some PPC cells showed an interaction of visual information with spatial position, which resembles the interaction of visual stimulation with eye position observed in monkey PPC (Andersen et al, Science 1985). Perhaps PPC plays an analogous role in monkeys and mice, by converting visual information from one coordinate system to another.

Title: Bimodal-distributed saccadic reaction time of predictive and reactive saccades

Authors: *K. NI[1], Z. HAN[2], M. ZHANG[2];
[1]Inst. Of Neurosci., Chinese Acad. of Sci., Shanghai, China; [2]Beijing Normal Universisty, Beijing, China

Abstract: To boost the chances of survival in competition, animals especially primates have evolved with not only reactive responses, but also predictive responses to the environment. We find that saccadic reaction time (SRT) is bimodal-distributed when monkeys perform the memory-guided saccade task. The second modal of the SRT distribution should be from reactive saccades triggered by fixation point off, and the first modal is hypothesized to be from predictive saccades triggered by internal timing. To causally prove the relationship of the first modal and temporal prediction, we first lengthen the delay period to prove the sufficiency of temporal prediction to the first modal, and then randomize the delay period to prove the necessity. By comparing the differences between predictive and reactive saccades, this behavior paradigm can be used to study the neuronal mechanism of temporal prediction.

Title: Saccade trajectory curvature induced by planning of sequential saccades

Authors: *R. AZADI, R. M. MCPEEK;
Grad. Ctr. for Vision Research,SUNY Optometry, New York, NY

Abstract: Saccadic trajectory curvature can be modulated by different factors; for example, when a target is presented along with a distractor, saccades to the target show greater curvature in their trajectories than when the target is presented without a distractor. Here, we investigated the effect on saccade trajectory of the planning of a subsequent saccade. In this experiment, subjects were instructed to perform a sequence of two saccades, as quickly as possible, when a central fixation point disappeared. The first saccade was a vertically-directed movement to a visual target presented below the fixation point and the second saccade was either a leftward or rightward movement to one of two additional targets, flanking the first target. The direction of the second saccade was visually cued by a small oriented bar presented at the fixation point during the whole fixation period (1000±250ms). We also included a control condition, in which subjects were cued to only make a single vertical saccade but no second saccade. The three trial types (leftward, rightward and no second saccade) were randomly interleaved in the experiment.

Thus, in each trial, the peripheral visual stimuli were identical and the initial saccade was directed to the same location; only the direction of the second saccade differed. Across these three conditions, we did not find any significant differences in landing position or peak velocity of the initial saccade. But in agreement with earlier studies, when two sequential saccades were made, the latency of the initial saccade was slightly longer than when only a single movement was made. More importantly, the trajectory curvature of the initial saccade differed significantly among the three conditions: on average across all subjects, the vertical saccades in the control condition showed less curvature than when the same movement was followed by a second saccade. Moreover, when two sequential saccades were made, the initial saccade tended to curve away from the goal of the second saccade. These results indicate that planning of a subsequent saccade induces systematic saccade curvature even when the visual stimulus and initial saccade are kept constant. This is consistent with the idea that planning of a saccade sequence involves activation of a future saccade goal at a relatively low level in the oculomotor system (e.g., superior colliculus), where it can influence the execution of the current movement.

Title: The effects of visual target goal on the adaptation of saccades

Authors: *R. SOETEDJO;
Univ. of Washington, Seattle, WA

Abstract: The ability of saccades to recover following nerve palsy and extraocular muscle injuries suggests that the saccadic system has access to adaptation mechanisms that gradually correct persistent motor errors. In the laboratory, a more practical intrasaccadic-step paradigm is used to simulate saccade dysmetria and produce adaptation. Our understanding of the neuronal mechanisms underlying adaptation of saccades is based almost solely on data obtained from targeting (visually guided) saccades. Several studies show that adaptation of targeting saccades involves the cerebellar oculomotor vermis (OMV). The OMV receives mossy fiber projection from the nucleus reticularis tegmenti pontis that appears to relay desired saccade vector signal from the superior colliculus (SC). Recent studies of the SC indicate that SC activity may also encode target goal signal. How these two different signals from the SC affect saccade adaptation is unknown. Targeting saccade, a task used in most saccade adaptation studies, cannot

distinguish the effects of the two signals because its target goal and desired saccade vectors are congruent. Therefore, we employed double-step saccade task (DST) to dissociate the two vectors. In this task, two sequential saccades are made in the dark following two flashes of a small target spot in different locations on a tangent screen. The task allows us to vary the eccentricity of target goal while keeping the desired saccade vector of the second saccade constant, and vice versa. We tested whether saccade adaptation relies on the context of the desired saccade vector or target goal by measuring the transfer of adaptation of targeting saccades to the second saccades of DST, and vice versa. If adaptation of saccades modifies desired saccade vector signal, the two types of adaptation (targeting and second saccade of DST) would transfer to each other as long as their desired saccade vectors are identical. On the other hand, if adaptation modifies target goal, then the amount of transfer would be determined solely by the target goal vector irrespective of the desired saccade vectors. We show that transfer of adaptation of targeting saccades to the second saccades of DST is a function of how close the target goal of the second saccades to the adapted saccade target vector is. If the target goal of the second saccades and the adapted saccade target vector were dissociated, very limited or no transfer was observed even though the two saccades had identical desired saccade vectors. Our results suggest that adaptation of targeting saccades modifies the target goal, but not the desired saccade vector signal.

Title: Modulation of vigor during a temporal discounting task

Authors: *T. REPPERT[1], K. M. LEMPERT[2], P. W. GLIMCHER[2], R. SHADMEHR[1];
[1]Johns Hopkins Univ., Baltimore, MD; [2]New York Univ., New York, NY

Abstract: Value-based decision making is a complex process depending on factors such as socio-economic status, age, and impulsivity. Previous studies of value-based decision making have focused on explicit choices as the primary measure of preference. Given an individual's choices in a well-designed binary choice task pitting small, immediate rewards against large, delayed rewards, we can derive an accurate, precise measure of subjective valuation of rewards. Here, we present findings that suggest that movement vigor serves as an implicit measure of choice preference. Specifically, vigor of saccades made before the time of decision reflects the

subjective valuation of the rewards. Sixty subjects participated in a standard temporal discounting task with a series of choices between small, immediate monetary rewards and large, delayed rewards (e.g., "$10 today or $20 in 30 days"). The delay was held constant at 30 days, and we presented each subject with the same group of 60 distinct reward pairings, displayed in random order. Each reward pairing was presented twice, for a total of 120 trials, each lasting 16.5 sec. As the subjects made their decisions, we monitored their eye movements. We found that, before a decision was made, saccade vigor was higher to the reward which was eventually chosen. Moreover, vigor of saccades was modulated by the difference in subjective values of the reward offerings. In this manner, vigor served as an implicit measure of choice preference. We also found that vigor of saccades dropped significantly after a decision was made, corroborated by the fact that vigor decremented most steeply on trials in which subjects made relatively quick decisions. Thus vigor also encoded timing of decision, in a manner consistent with previously established behavioral measures of decision making, such as pupillometry. We present vigor of saccades as a novel tool to be leveraged to assess value-based decision making.

Title: On the role of intrinsic microsaccadic biases in influencing behavior in Posner cueing

Authors: ***X. TIAN**, Z. M. HAFED;
Werner Reichardt Ctr. for Integrative Neurosci., Physiol. of Active Vision, Tuebingen, Germany

Abstract: Microsaccades are modulated in systematic manners during Posner cueing. Immediately after spatial-cue onset, microsaccades are biased in the cue's direction, and they then flip to being opposite the cue. Microsaccade frequency is also modulated. We recently suggested that both direction and frequency modulations reflect a resetting of microsaccadic oscillatory rhythms by cue onset (Hafed & Ignashchenkova, J. Neurosci., 2013). Moreover, we also found that subsequent behavioral performance modulations observed in Posner cueing (e.g. increases or decreases in reaction time, RT, to the post-cue target) can be accounted for by the instantaneous phase at which post-cue targets appear (Tian & Hafed, Vision Sciences Society, 2014, 2015). That is, microsaccades occur in a repetitive manner, and are anti-correlated in direction relative to the previously executed microsaccade. If a target appears spatially-congruent with the current microsaccadic plan, performance is facilitated; if it appears incongruent, performance is impaired (as in inhibition-of-return). However, it remains unclear why on a given

trial, a cue may or may not influence microsaccades. According to the microsaccadic rhythmicity hypothesis, if a monkey has an intrinsic microsaccade direction bias (e.g. largely purely downward), then cue onset (e.g. either purely above or purely below fixation) would be more or less likely to occur congruent with the current microsaccadic plan. This would alter how a cue might influence microsaccades, and could potentially help explain asymmetries in final attentional performance (e.g. RT) as a function of visual field location. We ran two monkeys in a Posner cueing paradigm. In each trial, a cue/target (1 deg diameter white circle) appeared at 5 deg eccentricity, either horizontally or vertically. Cue-to-target onset asynchrony (CTOA) was random (between 32 ms and 1532 ms), and the post-cue target could appear either in the "same" or "opposite" cued location. We collected >4000 trials per monkey and measured RT to the target. In monkey P, intrinsic microsaccade bias was purely downward. In monkey N, the bias was more rightward. In both monkeys, cue onset opposite the microsaccade bias was more effective in driving early microsaccades towards its location. Subsequent microsaccadic direction oscillations reflected the intrinsic bias. These results suggest that the efficacy with which cues influence both microsaccades and final performance can depend on individual intrinsic biases in subliminal, fixational oculomotor activity. This has implications on our understanding of the neuronal bases for visual field asymmetries in attentional performance.

Title: Foveal attention amplifies a position-correcting mechanism during ocular pursuit

Authors: *S. J. HEINEN[1], E. POTAPCHUK[1], S. WATAMANIUK[2];
[1]Smith-Kettlewell Eye Res. Inst., San Francisco, CA; [2]Wright State Univ., Dayton, OH

Abstract: Previously we showed that more catch-up saccades occur during pursuit when the stimulus has a central target than when it does not, and that even more catch-up saccades occur when the central target is attended (Heinen et al., SfN 2013; 2014). Here we investigate the mechanism underlying these results. Since catch-up saccades are thought to be generated by a combination of retinal position and velocity errors (deBrouwer et al., 2002), we asked how the presence of a central pursuit target and attention interact with these factors. We first investigated the influence of a central target. Stimuli were either a single spot, four peripheral dots which formed a virtual diamond, or a 5-dot composite of these stimuli. Critically, all these stimuli are

symmetrical, and create identical magnitude position and velocity errors on the retina when they move. Therefore, they should generate identical numbers of catch-up saccades during pursuit. However, the four dot stimulus produced fewer saccades than the two stimuli with central elements for the same combinations of position and velocity error, indicating that these errors are not the only factors contributing to catch-up saccade generation, and that the presence of a foveal target is also a factor. Since attention shifts precede saccades (Peterson et al., 2004), and saccades correct position error, we wondered whether attention to the foveal target influenced the position mechanism during pursuit. We directed attention to and away from the fovea using a detection task in which either the central target or one of the peripheral ones briefly dimmed. Drawing attention to the central target increased saccade frequency, while drawing it away reduced it. Importantly, the relative contribution of position error to catch-up saccades was greater when the stimulus had a central target, and increased further when that target was attended. Conversely, removing the central target, or taking attention away from it, produced saccades driven mostly by velocity error. The results suggest that attention to a foveal target amplifies position error signals during pursuit, leading to more catch-up saccades.

Title: Inter-trial correlations in sequences of saccade endpoints: further reflections on fractal structure in motor control

Authors: *M. J. SHELHAMER[1], A. WONG[2], P. FEDERIGHI[3];
[1]Biomed Engineering/Otolaryngol, [2]Neurol., Johns Hopkins Univ. Sch. Med., Baltimore, MD;
[3]Univ. of Firenze, Florence, Italy

Abstract: This work continues our investigation into inter-trial correlations between consecutive saccades, made in response to periodically paced visual targets. There is significant variation in the performance of such saccades from one trial to the next, even if paced at a constant rate with two targets at fixed locations. Previously, we demonstrated that variations in the amplitudes of sequences of these saccades exhibit a fractal structure: the power spectrum of the sequence of amplitudes has a power-law form, reflecting a gradual power-law decay of the autocorrelation.

This in turn implies that performance information is stored from one trial to the next, enabling the programming of subsequent movements in a predictive (anticipatory) manner. We found that a larger magnitude of spectral slope is associated with faster saccade adaptation in a subsequent double-step task, suggesting that subjects who adapt faster are better able to utilize prior experience to modulate future behavior. Why the inter-trial correlations are power-law and not exponential remains a mystery. Here, we investigate similar properties in inter-trial correlations in the endpoints of sequences of predictive saccades. Subjects made sequences of predictive saccades, paced periodically between two fixed targets, along a horizontal or vertical axis. Variations in endpoints were examined for inter-trial correlations and fractal structure, along the axis of the targets and orthogonal to that direction. In the primary movement direction (aligned with the targets), there were little or no inter-trial correlations, as reflected in an approximately flat power spectrum (similar to white noise): slopes of the spectra in log-log coordinates were not significantly different from zero. In contrast, in the direction orthogonal to target motion, the endpoints did exhibit inter-trial correlations: slopes were 0.40±0.19 (H) and 0.33±0.21 (V). These results are different from those with saccade amplitudes, where scaling was significant in the direction of target motion. While saccade amplitudes are programmed neurally, the endpoints reflect movement error. Hence, uncorrelated errors along the direction of target motion suggest that the maximum amount of information has been extracted from previous movements for the programming of the next saccade: the sequence of residuals is white (uncorrelated). In the direction orthogonal to target motion there are remaining inter-trial correlations, suggesting that more information could have been extracted from this sequence. Thus, subjects control movement accuracy by utilizing previous performance information only along task-relevant directions.

Title: Short-term saccadic adaptation to intra-saccadic conjugate and disconjugate background shifts

Authors: *C. BUSETTINI[1], K. P. SCHULTZ[2];
[1]Vision Sci., [2]Ophthalmology, Univ. Alabama Birmingham, Birmingham, AL

Abstract: The double-step paradigm elicits short-term adaptive changes in saccadic gain. The subject is asked to respond to a first target shift with a (primary) saccade. During its execution, the target is shifted a second time, introducing an artificial landing error. In a previous report on macaques, using small targets in a dichoptic viewing, we studied the adaptive process elicited by introducing the same error in both eyes (conjugate error) and equal and opposite in both eyes (symmetric disparity error) after a conjugate primary saccade. At the start of the session the animal responded to conjugate errors with a corrective (secondary) saccade and to disparity errors with a smooth vergence response. Repeating this process gradually caused the saccadic system to alter the primary saccade to include the landing error. The evidence suggested that the mechanism involved in compensating the disparity error, by making the saccade asymmetric, has different properties than the mechanism compensating the conjugate error. These results indicated that saccadic adaptation is a binocular process and not a monocular mechanism where each eye recalibrates its gain independently from the other. To further explore this aspect, again in macaques, we modified the paradigm by adding to the target a large 40x40° b/w random-dots background. The dots were 2° in size with an approximate 50% density. The target (0.5°) is now used only to drive the primary saccade and it is extinguished at the same time that the background is shifted. Thus, the landing error is on the background only. There is no primary shift of the pattern. The primary steps were conjugate 10° rightward or leftward in a randomized sequence starting from center and the initial position of the background was randomized to eliminate local cues. The errors were +2° or -2° conjugate or 2° symmetric crossed or uncrossed disparity. Conjugate shifts of the background did not elicit saccadic adaptation, but only a robust, unspecific decrease in the gain of the primary saccade, suggesting that the disappearance of the small target prior to the end of the primary saccade put the saccadic system in a post-saccadic visual open-loop state which, as default, decreased the gain of the saccade. On the contrary, disparity errors elicited powerful disconjugate adaptation, with time constant similar or even faster than the one we observed with no background. We also tested anti-correlated backgrounds (one image the negative of the other). Our studies on short-latency vergence with anti-correlated patterns observed transient vergence responses in the opposite direction but also not giving depth perception. No disconjugate adaptation was observed.

Title: Camera-based calibration system for obtaining gaze vectors from freely moving rats in a screened arena

Authors: *M. E. SILVA PRIETO, K.-M. VOIT, D. S. GREENBERG, G. NOTARO, J. SAWINSKI, D. J. WALLACE, J. N. D. KERR;
Behavior and Brain Organization, Res. Ctr. Caesar: A Max Planck Inst., Bonn, Germany

Abstract: Detection and escape from predatory threats is an innate behavior in rats, even those bred in captivity. Escape responses that are potentially similar to those evoked by predators are observed when rats are exposed to specific overhead visual stimuli. We used this behavioral readout to measure what part of the overhead visual field rats respond to, prior to their escape response. With the recent advances in camera-based tracking techniques, we were able to record the eye movements during these escape responses. We achieved this, by implanting miniaturized head-mount cameras on freely moving rats, placed in an arena consisting of a base surrounded by side screens, and a screen located overhead. Simultaneously, we tracked the animal's position and head orientation with four overhead cameras. With this data, we could translate the gazing vectors into the static coordinate frame of the overhead camera setup. To relate these gazing vectors to the displayed stimuli, we used the same camera system that is also employed to track the animal's head position. However, some of the screens were out of view of the cameras - especially the overhead screen - and none of them emitted IR light, so were invisible to the tracking cameras. To address these problems, we equipped each screen with four IR LEDs, and used a calibration mirror, which also contained IR LEDS, so that all screens could be viewed by the tracking cameras. This allowed us to accurately relate the LED positions to pixel coordinates of the stimuli. We next extended the beam-path model of our software framework for camera tracking to take into account the mirror, including refraction in the glass layer above the reflective coating. We verified the accuracy of our mirror tracking framework by comparing the reconstructed 3D model of the screen setup with physical measurements of the real-world setup, both regarding distances between LEDs on a single screen and distances between two different screens. With the setup presented, we are able to determine the gazing vectors with respect to the stimuli positions on the screens for freely moving rats.

Title: Rat eye movements diminish visual field blind spots during free movement

Authors: *J. N. KERR, D. S. GREENBERG, J. SAWINSKI, Jr, D. J. WALLACE;
Behavior and Brain Organization, Res. Ctr. Caesar: A Max Planck Inst., Bonn, Germany

Abstract: Rats have a large visual field that extends vertically from below their snout, over the top of the head to almost 60 degrees beyond vertical behind their head. This large coverage is due, in part, to the eye optics, which have a large angle of acceptance (>180 degrees), and in part to the semi-lateral position of the two eyes optical axis, (~58 degrees from frontal plane and ~36 degrees above horizontal). When freely moving, rats exhibit large disconjugate eye movements that are strongly correlated with head rotations. As a consequence of the position of the eyes on the head and the large disconjugate eye movements observed, rats forgo constant binocular fusion. We suggested that one purpose of these eye movements is to reduce 'blind spots' which can involve either or both eyes thereby increasing the ability to detect overhead threats. Here, we examined the effects of eye movements on the coverage of visual space above the animals head during free movement to test whether blind-spots were reduced by eye-movements. We computed a probability map for coverage of visual space around the animal (n = 3 animals, 6 recording sessions, 92519 time points, range of head pitch 120º , range of roll 60º). Altogether, the area covered included 76.9% of all space above the horizon or 15868.6 square degrees. When this map was computed with the eyes fixed to their mean positions the total covered area above the horizon was reduced to 67.9% or 14011.8 square degrees, introducing additional blind spots of 1856.8 square degrees; this was especially obvious in the overhead region. Thus, when including all regions of visual space and all orientations of the head without distinction, the overall effect of eye movements is a reduction of blind spots above the horizon. We next examined whether there were particular head positions that eye movements had greatest effect in reduction of blind spots. By dividing head- and eye-tracking data into five equally sized segments based on head pitch (-90º to -63º , -63º to -36º , -36º to -º 9, -9º to 18º , and 18º to 45º) we computed the probability of visual space coverage as a function of elevation and azimuth, both including observed eye movements and with the eyes fixed to their mean positions. The greatest differences in coverage were seen in the two groups with most extreme head pitch. During periods of downward pitch of the head, eye movements always increased the average coverage of visual space above the horizon These measurements show that although the eye movements of the rat are disconjugate, one purpose they serve is to maintain a stable visual coverage above the horizon and to reduce blind spots in the visual field, especially overhead.

Title: Oculo-videography of eye movements in freely moving ferrets and tree shrews

Authors: *D. J. WALLACE[1], D. S. GREENBERG[1], J. SAWINSKI[1], R. CORLEW[2], D. FITZPATRICK[2], J. N. D. KERR[1];
[1]Dept. of Behavior and Brain Organization, Res. Ctr. Caesar: A Max Planck Inst., Bonn, Germany; [2]Dept. of Functional Architecture and Develop. of Cerebral Cortex, Max Planck Florida Inst. for Neurosci., Jupiter, FL

Abstract: Most cortical and subcortical regions processing visual information are organized in a retinotopic manner. Both the movements of the two eyes and how the movements of left and right eye are coordinated critically determine the visual information that the brain has to process. In humans and primates, the coordination of eye movements is such that both foveas are continuously directed towards the same visual target, and both fixation and ocular-alignment are tightly controlled. We recently showed that the coordination of eye movements in the rat is dominated by the vestibulo-ocular reflex (Wallace, Greenberg, Sawinski, Rulla, Notaro, and Kerr (2013) Nature. 498: 65-9). The vestibular-driven movements combined with the animals' laterally-pointing optical axis has the consequence that ocular-alignment is not continuously maintained. The continuously changing ocular-alignment has significant implication for binocular processing in the cortex. To investigate the extent to which the coordination of eye movements is dominated by the vestibulo-ocular reflex in other animal species we recorded eye movements in freely moving ferrets and tree shrews. Simultaneous recording of the movements of both left and right eyes were acquired using custom-built, miniature oculo-videography systems while the animals were exploring or pursuing objects in a large arena (2.6x1.3m for ferrets and 1.3x1.3m for tree shrews). Simultaneous tracking of the animals position and head orientation was conducted using a custom built overhead tracking system, consisting of 6 high-speed digital cameras. In freely moving ferrets, like in freely moving rats, there was a strong relationship between horizontal eye position (along the nasal-temporal axis) and the degree of head pitch. Strong nose-down head pitch results in marked temporal movement of both eyes, while nose-up pitch results in nasally directed movement of both eyes. During the temporal movements there was a strong misalignment of the optical axes, similar to that seen in rats. However, unlike rats, we did not observe a strong relationship between roll of the head and vertical eye position. Eye movements observed in freely moving tree shrews consisted mainly of very rapid, saccade-like conjugate movements, and neither correlations between head pitch and horizontal eye position nor head roll and vertical eye position were observed. Preliminary analysis indicates that alignment of the optical axes was continuously maintained. Each of the three species (ferret, tree shrew and rat) show distinct and different coordination of eye movement, with the implications for processing of binocular information being distinct for each species.

Title: Fixation eye movements of monkeys studied with bright and dark background

Authors: *O. SPIVAK[1], P. THIER[2], S. BARASH[3];
[1]Cognitive neurology, Hertie Inst. For Clin. Brain Res., Tuebingen, Germany; [2]Dept. of Cognitive Neurol., Hertie Inst. for Clin. Brain Res., Tuebingen, Germany; [3]Dept. of Neurobio., Weizmann Inst. of Sci., Rehovot, Israel

Abstract: Fixation eye movements may contribute to visual perception. However, the evidence supporting this assertion relates mostly to photopic vision. In photopic vision, saccades and fixation direct the fovea to interesting locations in the scene. In scotopic vision, the fovea is largely insensitive. Directing the fovea to interesting locations seems pointless; it is not clear what exactly the functions of saccades and fixation are in scotopic conditions. Interestingly, even if the (small) target is bright and only the background is dark, monkeys direct their eyes so that the fovea is above the target. This background-luminosity-contingent 'upshift' of gaze was described in several studies; we recently showed that the upshift continues for the entire duration of 2-s fixations. The aim of the present study is to test whether the upshift is accompanied by changes in fixation eye movements; that is, if fixation eye movements depend on background luminosity, and how this putative dependence relates to the upshift. The upshift is a gradual phenomenon; dim luminosities were previously shown to yield small upshifts, with upshift being larger the darker the background is. Here we test whether fixation movements change with background luminosity, similarly to the upshift. We test two possibilities: either the change is in individual movement parameters (such as microsaccade amplitude) or it reflects combinations of states, a bright-background state and a dark-background state. In the present study we have collected data from 3 monkeys. We used two tasks. In both tasks, the monkey fixates target dots appearing in 24 locations, arranged 3 concentric circles. Both tasks test fixations with and without a fixation spot. In both tasks there were blocks of trials with background being dark (0 cd/m2) or bright (6 cd/m2). One task explored intermediate background luminosities, which might mimic mesopic-like conditions. This task contained also blocks with background being one of three levels (0.1, 0.3, and 0.7 cd/m2). The second task tested the effect of dark adaptation. During dark-adapted testing, targets were dim, barely above threshold. In all other testing, targets were bright (44.6 cd/m2). Dark adaptation was obtained by waiting in the dark for 40 min. Altogether we now have more than 20000 fixation trials. At the time of writing this abstract, the data is being analyzed. Our hope is that the findings on fixation eye movements in different background luminosities will reflect on the visuomotor processes that occur in photopic, scotopic, and mesopic vision.

Abstract: Saccadic intrusions (SIs), predominantly horizontal saccades that interrupt accurate fixation, include square-wave jerks (SWJs; the most common type of SI), which consist of an initial saccade away from the fixation target followed, after a short delay, by a return saccade that brings the eye back onto target. SWJs are present in most human subjects, but are prominent by their increased frequency and size in certain parkinsonian disorders and in recessive, hereditary spinocerebellar ataxias. SWJs have been also documented in monkeys with tectal and cerebellar etiologies, but no studies to date have investigated the occurrence of SWJs in healthy nonhuman primates. Here we set out to determine the characteristics of SWJs in healthy rhesus macaques (Macaca mulatta) during attempted fixation of a small visual target. Our results indicate that SWJs are common in healthy nonhuman primates. We moreover found primate SWJs to share several characteristics with human SWJs, including the relationship between the size of a saccade and its likelihood to be part of a SWJ. One main discrepancy between monkey and human SWJs was that monkey SWJs tended to be more vertical than horizontal, whereas

human SWJs have a strong horizontal preference. Yet, our combined data indicate that primate and human SWJs play a similar role in fixation correction, suggesting that they share a comparable coupling mechanism at the oculomotor generation level. These findings constrain the potential brain areas and mechanisms underlying the generation of fixational saccades in human and nonhuman primates.

Abstract: Traditionally, the striolar region in the vestibular otolith endorgans in vertebrates has been defined by a lower hair cell density, the presence of complex calyces, smaller otoliths, and hair cells and calyces with a greater diameter (Lindeman 1969; Fernandez et al., 1988, 1990, 1995). Our laboratory used the marker, calretinin, to define the striolar region (Desai et al., 2005a,b) based upon the finding that calretinin labels pure calyx afferents (Desmadryl and Dechesne, 1992), a class of vestibular afferents with distinct physiological traits (Baird et al., 1988; Goldberg et al., 1990; Lysakowski et al., 1995). The Desai definition matched the earlier areal delineation, but was not based upon a clear definition of the reversal line, which was depicted running down the middle of the striolar region. Recent studies have determined that the line of polarity reversal (LPR) in the utricular macula is located lateral to this striolar region in mice (Li et al., 2008) and rats (Schweizer et al., 2009). Individual organs were dissected and their hair bundles were removed by gentle sonication. Hair-bundle polarization was determined by the kinocilium location, indicated by a hole in the cuticular plate, which was otherwise labeled by spectrin. We now have evidence for a finding similar to that in mice and rats in a third rodent species, Chinchilla laniger, from a different Rodentia suborder, Caviomorpha, albeit also lateral-eyed. The large majority (95%) of calyx afferents, as in previous studies, were located

medial to the LPR. The implications for sensory processing are profound. The results are of interest because utricular afferents originate to one side or the other of the LPR, separating the utricular macula into a medial and lateral extrastriola. According to Maklad et al. (2010), the medial extrastriola projects to the vestibular nuclei, while the lateral extrastriola projects to the cerebellum. If this is true, then the entire population of calyx afferents projects to the vestibular nuclei and none to the cerebellum.

Title: Whole-cell recordings from type II vestibular hair cells with basolateral processes in the mature mouse utricular macula

Authors: *A. GONZALEZ GARRIDO[1], J. S. STONE[2], R. A. EATOCK[1];

Abstract: The vestibular epithelia of amniotes have two hair cell types, type I and type II, contacted, respectively, by large calyceal afferent or more compact bouton terminals. Recently it was discovered that type II hair cells in mature mammalian vestibular epithelia can have extensive basal (sub-nuclear) cytoplasmic projections that contact supporting cells, neurons and even other hair cells (Golub et al., J Neurosci 32:15093, 2012; Pujol et al., J Comp Neurol 522:3141, 2014). To evaluate whether hair cells with basolateral processes are a distinct type II population, we are measuring their electrophysiological properties in semi-intact utricular epithelia from mature mice. Here we report whole-cell recordings from the lateral extrastriolar zone of epithelia from mice between 3 and 7 weeks of age (34 ± 2.9 postnatal days, n=13). The epithelia were bathed in L-15 culture medium at room temperature and recording pipettes contained conventional KCl-based solutions and fluorescent dye, either sulforhodamine 101 (n=11) or Lucifer Yellow (n=2). In 10 successful fills, 8 had either simple or branched processes similar to those described in Golub et al. (2012) and 2 had no cytoplasmic processes. In no case did we observe dye transfer from a recorded hair cell to any of its neighbors, consistent with the lack of evidence for gap junctions (Pujol et al. 2014). The electrophysiological properties in our sample resembled those provided in previous reports for younger mouse utricular type II hair cells. Input resistance was 1.0 ± 0.3 GΩ (mean ± SEM, n=13 cells), capacitance was 4.4 ± 0.5 pF

and resting potential was −64 ± 2 mV (junction potential corrected). In all cells, hyperpolarizing voltage steps evoked inward HCN currents and depolarizing steps evoked outward currents that activated positive to resting potential and showed some inactivation during 200 ms. For the outward currents, Boltzmann fits of the tail current activation curve yielded a midpoint of −30 ± 1.4 mV (n=13), a slope factor of 9 ± 1 mV and a maximum steady-state conductance of 21 ± 5 nS. The activation curve parameters are in good agreement with previous values reported for outward K+ currents in type II hair cells and clearly different from values for currents in type I hair cells, which activate more negatively. Voltage responses to current steps in current clamp experiments were also consistent with previous reports for type II cells: positive steps evoked a sharp initial peak and a strongly rectified response, and negative steps evoked a "nose" attributable to HCN current. These preliminary results suggest that hair cells with basolateral processes are typical type II hair cells rather than a distinctive sub-population.

Title: Modulatory actions of metabotropic glutamate receptors on spontaneous electrical activity of the vestibular afferents: an ontogenic study

Authors: R. VARELA[1], E. MONJARAZ[1], *F. GALINDO[1], J. CEBADA[2], A. FLORES[1]; [1]Inst. de Fisiología, Benemerita Univ. Autonoma De Puebla, Puebla, Mexico; [2]Facultad de Medicina, Benemérita Univ. Autónoma de Puebla, Puebla, Mexico

Abstract: Glutamate is one of the most important neurotransmitters in the inner ear, like many other transmitters, exerts its pleiotropic roles by means of multiple receptor proteins. Activation or changes in the expression of metabotropic glutamate receptors (mGluRs) have been related to a variety of important ontogenic events, such as neuronal migration and the formation of synaptic circuitry. The purpose of this work was to study the presence and physiological role of mGluRs during embryonic development of the chicken's vestibular organ (Gallus domesticus). We performed a multiunit extracellular recording from the posterior branch of the vestibular nerve in a preparation isolated from the chicken inner ear of 16, 19 and 21 embryonic days. 1S,

3R-ACPD, a mGluRI and mGluRII agonist (1µm-100µm; n=47) increases the basal discharge of vestibular afferents mainly at E19 and E21 in a dose-dependent way (131±5.6% and 207±1.25%, respectively at 100µm). L-AP4, specific agonist of the mGluRIII (0.1-100µm; n=53) also increased the vestibular afferent discharge, however, the main effect was on E16 (148.7±1.9% at 100µm). The presence of MCPG or MPPG, a mGluRII and mGluRIII antagonist, respectively (1µm-100µm), decreased significantly the spontaneous and agonist evoked electrical activity. Complementarily, RT-PCR experiments revealed the presence of the three receptor groups. mGluRI and mGluRII increases its presence at ages near of hatching while mGluRIII have the most important expression at early stage (E16). Our results suggest that mGluR could modulate the spontaneous activity of the vestibular afferent fibers at age-dependent way in the chicken embryo's inner ear.

Title: Histamine receptor 4 antagonist JNJ7777120 inhibits the sodium currents modulating the discharge of vestibular afferent neurons of the rat

Authors: ***R. VEGA**[1], E. SESEÑA[2], E. SALCEDA[1], E. SALINAS[1], E. SOTO[1];
[2]Sch. of Med., [1]Univ. Autonoma De Puebla, Puebla, Mexico

Abstract: The histaminergic drugs are some of the most commonly used in the treatment of vestibular disorders. Drugs JNJ7777120 and JNJ10191584 thought to be selective type 4 histamine receptor (H4R) were shown to potently inhibit action potential discharge of the vestibular afferent neurons (VAN) (Desmadryl et al., 2012). However, its mechanism of action on the VANs has not yet been determined, with this aim we studied the voltage dependent ionic currents modulated by JNJ7777120 and the participation of G-protein mediated signaling involved in the JNJ77777120 effect. The action of JNJ7777120 on the VAN ionic currents from the rat were studied using the current and voltage clamp technique. In voltage clamp experiments

JNJ7777120 decreased inward and outward current components, effect that remained in cells pretreated with *pertussis toxin* for 20 hours. The isolated voltage gated sodium current (I_{Na}) showed two components: a transient (I_{Nat}) and a persistent (I_{Nap}), the application of JNJ7777120 produced a concentration dependent inhibition of both components of the I_{Na} with an IC_{50} of 41 nM for the I_{Nat} and 16 nM for the I_{Nap}. The JNJ7777120 produced non-significant changes in both I_{Nat} and I_{Nap} current activation or inactivation parameters. The effects of JNJ7777120 remained even after the use of the G-protein blocker GDP--S and zero GTP in the pipette solution. The use of H4R agonists VUF4430 did not significantly modified the I_{Na}. In current clamp experiments JNJ7777120 decreased the action potential discharge produced by depolarizing current injection, and modified the action potential waveform decreasing the amplitude, the maximum depolarization rate, the maximum repolarization rate and increased the action potential duration. Our results show that JNJ7777120 inhibits the VAN electric activity through the inhibition of the I_{Nat}, I_{Nap}, through a mechanism independent of the H4R, and independent of G protein coupled receptors suggesting that JNJ7777120 directly interacts with the voltage gated sodium channels. Title: Spontaneous and driven activity of vestibular afferent calyces in the extrastriolar zone of the mouse utricle

Authors: ***O. LOPEZ**, V. LUMBRERAS, R. A. EATOCK;
Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Mammalian vestibular sensory epithelia have distinct concentric zones, which are called the striola (center) and extrastriola (surround) in the utricle and saccule. In the chinchilla utricle, primary afferents from the extrastriola have much more regular spike timing than afferents from the striola (Goldberg, Exp Brain Res 130:277, 2000). We are exploring the difference in spike timing in *ex vivo* preparations of the rodent saccule and utricle, which include the sensory epithelia and afferent nerve fibers. Most of the afferents form both calyceal
