Title: Post-translational modification of FOXP1 in the developing brain

Authors: *N. USUI, D. J. ARAUJO, M. CO, M. HARPER, G. KONOPKA;
Dept. of Neurosci., Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: Mutations in the gene encoding the transcription factor forkhead box P1 (*FOXP1*) result in brain developmental abnormalities and developmental disorders such as autism spectrum disorders (ASD) and intellectual disability (ID). However, the molecular mechanisms regulating FOXP1 function during human brain development and how disruption to these functions leads to developmental disorders are largely unknown. Our previous work has demonstrated that sumoylation of the related transcription factor FOXP2 is an important post-translational modification that regulates FOXP2 function and ultimately affects cerebellar development and related behaviors. We therefore assessed whether sumoylation of FOXP1 might similarly regulate its function in the brain. Here, we demonstrate that FOXP1 is sumoylated during brain development, and this modification peaks during embryonic brain development, at the time points relevant to genetic pathways implicated in ASD. The site of FOXP1 sumoylation at K636 is evolutionally conserved from mouse to human. We demonstrate that SUMO-1/2 and PIAS2/3 are the SUMO proteins and E3 SUMO ligases carrying out sumoylation of FOXP1. We further show a requirement for sumoylation of FOXP1 in neuronal development, in particular during embryonic brain development. Together, these data highlight one of the molecular mechanisms regulating the role of an ASD-relevant gene, *FOXP1*, during brain development.

Title: Counterbalanced neurogenesis after cortical devascularization. a functional interpretation of local circuits

Authors: L. V. VARGAS-SATURNO, Jr[1], *C. A. AYALA-GROSSO[2];
[1]Ctr. of Exptl. Med., IVIC, Caracas, Venezuela, Bolivarian Republic of; [2]Unidad de Terapia Celular, Caracas, Venezuela, Bolivarian Republic of

Abstract: Constitutive neurogenesis occurring in the subgranular (SGZ) and subventricular (SVZ) zones of the brain contribute to the turnover of neurons in circuits of hippocampus and olfactory bulb. Adaptive neurogenic response may occur as a result of intrinsic signals generated by cell components of the niche and, or, as a consequence of extrinsic signalling that include changes in blood supply or neurotransmission. Alteration of cerebral blood flow by ischemia or brain trauma may induce proliferation in neurogenic areas. We asked whether cortical devascularisation in an established animal model of cortical cholinergic denervation may induce a functional a response in neurogenic niches. C57BL/6L male mice of 25g, under deep anesthesia induced by ketamine, xylacine (75/7.5 mg/Kg in saline solution) after intra peritoneal administration, were craneotomized at 1 mm caudal from fronto-parietal suture and 1 mm medial lateral from midline to generate a window of 4 by 4 mm side. Lesion consists of removal of meninge and surface vasculature; control (sham) animals suffered craniotomy but not removal of meninges and blood vessels. After surgery, BrdU (50 mg/Kg), every 2 h, three doses during 48h period were administered to sham and lesioned animals. Animals were intracardially perfused with 4% p-formaldehyde at 1, 4, 7 and 10 days post surgery. Free floating sagital brain sections were analyzed under immunohistochemistry protocols. BrdU+ proliferative cells or coexpression with neuronal/glial progenitors phenotypic markers were counted to determine subpopulation of cells in the neurogenic niche. We established a significant increase of BrdU+ cells at 4 days postsurgery in the ipsilateral and contralateral SVZ and rostral migratory stream (RMS) in lesioned animals with respect to control. We determined a significant increase of BrdU+/Nestin+ and BrdU+/DCX+ in the contralateral SVZ and RMS with respect to ipsilateral neurogenic

hemisphere. We detected BrdU+/DCX+ in the lesioned cortex. No BrdU=/DCX+ cells were determined in the contralateral cortex. Counterbalanced neurogenesis may be explained by dysfunctional local circuits and projections of cholinergic and glutamatergic corticofugal efferents. In summary, dysbalanced cholinergic and glutamatergic neurotransmission was concurrent with proliferation and potentially migration of neural progenitors from SVZ and RMS to injured hemisphere.

Title: SNX27 deletion causes hydrocephalus through impaired ependymal cell differentiation and ciliogenesis

Authors: *X. WANG[1], Y. ZHOU[1], I.-C. TSENG[2], T. HUANG[2], Y. ZHAO[2], H. LUO[1], X. ZHANG[1], G. BU[1], W. HONG[3], H. XU[2];

Abstract: Ependymal cells line the cerebral ventricle epithelium and regulate cerebrospinal fluid (CSF) production and circulation. Although apical cilia in ependymal cells play a key role in the development of hydrocephalus, the underlying genetic factors and molecular mechanisms remain largely unknown. SNX27 regulates endosome-plasma membrane receptor trafficking to maintain

proper brain function, and modulates γ-secretase cleavage of APP and Notch. Here, we find that *Snx27*-deficient mice exhibit a marked reduction in ependymal cell and cilia density, abnormal cortical development, and severe postnatal hydrocephalus. SNX27 deficiency results in increased differentiation of radial glial cells into premature neurons and decreased production of ependymal cells. Inhibition of Notch intracellular domain (NICD) signaling using γ-secretase inhibitors reversed ependymal cells/cilia loss and dilation of lateral ventricles in *Snx27*-deficient mice, supporting the notion that Notch activity negatively regulates ependymal cell differentiation and ciliogenesis. Our study suggests that SNX27 is essential for ependymal cell differentiation and ciliogenesis, causing defective CSF flow and hydrocephalus.

Abstract: The size of neural stem cell (NSC) pool at birth determines the starting point of adult neurogenesis. Aberrant neurogenesis is associated with major mental illness, in which *ULK4* is proposed as a rare risk factor. Little is known about factors regulating the NSC pool, or function of the ULK4. Here we show that *Ulk4*$^{tm1a/tm1a}$ mice display a dramatically reduced NSC pool at

birth. Ulk4 is found to express in a cell cycle-dependent manner and peaked in G2/M phases, and targeted disruption of the *Ulk4* perturbs mid-neurogenesis and significantly reduces cerebral cortex in postnatal mice. Pathway analyses of dysregulated genes in *Ulk4*$^{tm1a/tm1a}$ mice reveal Ulk4 as a key regulator of cell cycle and NSC proliferation, partially through regulation of the Wnt signaling. In addition we have identified hemizygous deletion of *ULK4* gene in 1.2/1000 patients with pleiotropic symptoms including severe language delay and learning difficulties. *ULK4*, therefore, may significantly contribute to neurodevelopmental, neuropsychiatric and neurodegenerative disorders.

Abstract: The human cerebral cortex, the seat of our most highly developed cognitive functions and the largest structure of our brain, depends for its normal development and ultimate size on a precisely controlled balance between self-renewal and differentiation of diverse **neural progenitor cells** (**NPC**). The canonical NPC type of the mammalian cortex is the **radial glial cell (RGC)** with its distinct morphology: a cell body integrated into the neuroepithelium at the ventricular surface, and a long radial process that guides migrating neurons into the developing cortical plate. In addition to producing neurons directly, RGC also generate **intermediate progenitors (IP)** and **outer radial glia (ORG)**. The mechanisms that balance the self-renewal and differentiation of each of these NPC subtypes remain relatively unknown, motivating us to apply single-cell RNA-sequencing to these cells to examine in finer detail **the molecular time-course and lineage relationships of mammalian neurogenesis.** From these data, we identified **PPP1R17**, whose species- and progenitor subtype-specific expression is regulated by an enhancer derived from a primate lineage-specific insertion of an L1 repeat element. PPP1R17 is an inhibitory regulatory subunit of the phosphatase complex, and regulates the balance of proliferation and self-renewal in part through downstream modulation of canonical growth factor signaling pathways.

Title: Integrin linked kinase (ILK) deletion disrupts oligodendrocyte development by altering cell cycle

Authors: *R. HUSSAIN, W. B. MACKLIN;
Dept. of Cell and Developmental Biol., Univ. of Colorado Sch. of Med., Aurora, CO

Abstract: During development, neural precursor cells establish lineage-specific differentiation of glia and neurons by sensing environmental cues through membrane bound receptors and intracellular signaling pathways. This is a series of highly orchestrated events involving active communication between the extracellular environment, cytoplasmic mediators and finally nuclear effectors. Integrin linked kinase (ILK) is a crucial partner in signaling between the extracellular environment and the nucleus. It acts as a serine/threonine kinase as well as a scaffolding molecule. Through its scaffolding function, it interacts with numerous proteins and its kinase activity is involved in phosphorylating protein kinase B (AKT) and glycogen synthase kinase (GSK-3β). The current studies demonstrate that deletion of ILK in early neural precursors severely alters the normal commitment to oligodendrocyte precursor cells (OPCs). We found a significant decrease in the number of OPCs and mature oligodendrocytes throughout postnatal development in Olig1-Cre $^{+/-}$ X ILK $^{fl/fl}$ mice. These changes were accompanied by a marked decrease in phosphorylation of AKT at Ser473 and S6RP at Ser 235/236 and Ser 240/244. The number of myelinated axons was reduced at P30 in corpus callosum and spinal cord, likely because of reduced numbers of oligodendrocytes. Myelin thickness in spinal cord was unchanged, but it was thinner in corpus callosum. Intriguingly, we found a decrease in key proteins involved in cell cycle regulation; Cyclin D1/D3 and cyclin dependent kinase 2/4 (cdc2/cdc4) by western blot and immunohistochemistry along with upregulation of the inhibitory signaling protein p27 Kip1. In conclusion, ILK deletion impairs the developmental profile and proliferation potential of OPCs by interfering with cell cycle, but in general in cells that generate myelin, the myelin is relatively normal. This suggests that ILK has a greater impact on OPC proliferation than on myelination per se. Supported by the National Multiple Sclerosis Society.

Title: Sustained genomic abnormalities in embryonic neural progenitor cells (NPCs) may underlie cellular pathologies of Lysophosphatidic Acid induced congenital hydrocephalus in mice.

Authors: *W. S. MCDONALD, Y. YUNG, N. STODDARD, M. LEE, J. CHUN;
The Scripps Res. Inst., La Jolla, CA

Abstract: Post-hemorrhagic hydrocephalus (PHH) is a common neurological disorder afflicting newborns and children characterized by increased head size, cortical thinning, ventricular cerebrospinal fluid (CSF) accumulation and is frequently comorbid with other neural malformations and disorders such as cranial deformity, brain tissue loss, psychiatric and cognitive impairments. There are no curative therapies, with major treatments limited to palliative, surgical approaches that utilize shunts to remove excess CSF. Although the etiology of PHH isn't fully characterized, we identified the involvement of lysophosphatidic acid (LPA), a bioactive and blood-borne lysophospholipid, through its cognate G protein-coupled receptor LPA_1, in PHH pathogenesis (Yung et al., 2011). Our LPA-induced model of PHH recapitulates many pathological features of hemorrhagic injury mechanism identified in clinical hydrocephalus cases including cortical cell loss or dysfunction, NPC lineage alterations (including ependymal cell loss), ciliary dysfunction and/or loss, choroid plexus dysfunction and intracranial fluid imbalances. The existence of genomic mosaicism in normal brain through aneuploidies suggested a link between LPA exposure and genomic alterations, in view of an identified 8-16% of congenital hydrocephalus cases associated with aneuploidy, which predict a higher risk of poor clinical outcomes as well as other neurological disorders (*i.e.,* schizophrenia, and Down syndrome). To determine the effects of fetal exposure to LPA on NPC genomic abnormalities, E13.5 mouse embryos received varied dosing of intraventricular LPA, followed by DNA content analyses by flow cytometry and cytogenetics approaches in embryonic cortices from E14.5 to P0. Our results show that within 24 hours of LPA exposure, acute changes in chromosomal content are observed in cortical progenitor cells. Maintained genomic NPC aberrations were also observed at later ages. The results suggest that LPA exposure at critical periods during embryonic development alters survival, fate and functions of NPCs and neurons, which may promote CNS pathologies associated with hydrocephalus.

Title: Novel subcortical heterotopia caused by loss of basal complex protein, Lgl1, through dysregulated cell proliferation and polarity

Authors: *A. SIMMONS[1], R. PARK[1], A. PELUZZO[1], S.-H. CHO[1], V. VASIOUKHIN[2], S. KIM[1];
[1]Shriners Hosp. Pediatric Res. Center, Dept. of Anat. and Cell Bio, Temple Univ. Lewis Katz Sch. of Med., Philadelphia, PA; [2]Div. of Human Biol., Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract: Lethal giant larvae (Lgl1), a known tumor suppressor, has been shown to have a critical role in cell polarity maintenance and has been proposed to function upstream of cell growth regulation pathways. Due to early neonatal lethality, the role of Lgl1 in cortical development and beyond has not been explored. Here we demonstrate that conditional loss of Lgl1 in the developing cortical neuroepithelium results in severe disruption of cell polarity and the generation of an ectopic proliferating zone, ultimately leading to a novel subcortical heterotopia model with hydrocephalus. The heterotopic cortex forms as a result of hyperproliferation of cortical progenitors and significant disruption to tissue integrity. Loss of Lgl1 increases the apical progenitor pool by reducing cell cycle length with no change to S-phase length. The severely compromised ventricular lining results in rosette formation and a displaced apical membrane serving as a platform for bidirectional growth. Furthermore, the rosettes and ectopic ventricular lining are concentrated with apical protein Pals1, suggesting its function in proliferation at the ectopic locations. Remarkably, concurrent loss of Lgl1 and Pals1 results in removal of ectopic proliferation but partial restoration of cortical tissue in the decorticated *Pals1* CKO through accelerated cell proliferation. This finding provides unique insight on the interplay between polarity complex proteins in regulation of cortical progenitor proliferation. Thus, our study identifies Lgl1 as a new subcortical heterotopia causing gene by uncovering its role in cell cycle length regulation in combination with its well-established cell polarity function.

Title: Kruppel-like factor 5 maintains neural precursor cells undifferentiated in the developing brain

Authors: *T. FUCHIGAMI[1], Y. HAYASHI[2], A. KURODA[2], T. AZAMI[3], M. EMA[3], S. HITOSHI[2];
[2]Integrative Physiol., [3]Res. Ctr. for Animal Life Sci., [1]Shiga Univ. of Med. Sci., Ohtsu City/Shiga Prefecture, Japan

Abstract: Kruppel-like factor (Klf) family proteins are DNA-binding transcriptional factors, which share highly conserved sequences and redundant functions, for instances, in the regulation of cell cycle, cell differentiation and tissue organization. Among Klf family, Klf5 is indispensable for the blastocyst implantation, segregation into three germ layers and formation of cardiovascular system and optic vesicles. Klf5 shares overlapping function with Klf4, one of the Yamanaka factors, and it not only helps maintain the pluripotency of ES cells but also enhances reprogramming somatic cells to generate iPS cells. Although these precedence studies suggest the broad roles of Klf5 in the organogenesis, its roles in the central nervous system has not been investigated despite of its expression in the developing brain. We have investigated roles of Klf5 in the proliferation and maintenance of neural precursor cells (NPCs) in the developing cortex. Overexpression of Klf5 by *in utero* electroporation promoted the proliferation of the apical progenitors, whereas shRNA-mediated knockdown of *Klf5* showed little effects, possibly due to the redundant functions by other Klf family proteins. Indeed, the knockdown of *Klf2*, *Klf4* and *Klf*5 resulted in the significant reduction of the apical progenitor proliferation and in the impaired migration of NPCs. Furthermore, the self-renewal of NPCs was also reduced in the developing brain of NPCs-specific *Klf5* conditional knockout mice. Our data suggest that Klf5, together with Klf2 and Klf4, plays important roles in the neural development.

Title: Aristaless related homeobox (Arx) interacts with β-catenin, Bcl9, and p300 to regulates canonical wnt signaling

Authors: I.-T. CHO, Y. LIM, *J. A. GOLDEN, G. CHO;
Dept. of Pathology and Lab. Med., Brigham and Women's Hosp., Boston, MA

Abstract: Mutations in the Aristaless Related Homeobox (ARX) gene are associated with a spectrum of structural (lissencephaly) and functional (epilepsy and intellectual disabilities) neurodevelopmental disorders. How mutations in this single transcription factor can give rise such a broad range of phenotypes remains poorly understood. We have hypothesized that ARX regulates unique target genes through distinct interactions with specific transcription factors/cofactors in different cell type. To identify ARX interacting proteins, we used an unbiased proteomics approach and unexpectedly identified several components of the Wnt pathway including Ctnnb1 (β-catenin), BCL9 and LRRFIP2 expressed highly in cortical progenitor cells. The following studies revealed ARX positively regulates Wnt signaling and that the C-terminal domain of ARX interacts with the armadillo repeats in β-catenin to promote Wnt signaling. In addition, BCL9 and P300 cooperate with ARX to modulate Wnt signaling. These data provide new insight into how ARX can uniquely regulate cortical progenitor cell population and links two well-defined networks (ARX and Wnt) that had not previously been associated with each other.

Title: Essential role of KIF20A/MKLP2 in regulation of neural progenitors symmetric versus asymmetric division in the developing brain

Authors: *A. GENG[1], R. QIU[2], Q. LU[2];
[1]Developmental & stem cell Bio, [2]Developmental & Stem Cell Bio, Beckman Res. Inst. City of Hope, Duarte, CA

Abstract: The balanced production of progenitors and neurons is critical to embryonic neocortical development, but the governing mechanisms are not well understood, particularly with respect to the role of the cell division machinery, which is expected to control the mode (symmetric self-renewal versus asymmetric differentiation) of progenitor cell divisions. In this study, we investigated the functions of KIF20A/MKLP2, a mitotic kinesin important for ordered progression of cytokinesis, during cerebral cortical development. We show that KIF20A binds to RGS3 and facilitates its translocation into the intercellular bridge, where RGS3 and Gα subunit

coordinate in cell fate regulation. KIF20A is symmetrically expressed by daughter cells in self-renewal and asymmetrically expressed in daughter progenitors during differentiation. Inhibition of KIF20A function blocks the action of Ephrin-B/RGSsignaling and leads to early neuronal differentiation. Genetic knockout of Kif20a caused a loss of progenitors and neurons and resulted in thinner cortex and ventriculomegaly. Interestingly, loss-of-function of KIF20A induced early cell cycle exit and precocious neuronal differentiation without causing substantial apoptosis in mutant progenitor cells, and led to severe impairment in the production of cortical neurons. Collectively, the mitotic kinesin KIF20A/MKLP2 regulates symmetric versus asymmetric cell divisions in the embryonic cerebral cortex in coordination with the regulator of G protein signaling (RGS)-mediated Ephrin-B pathway. Our study demonstrates a crucial role of KIF20A in balancing self-renewal and differentiation during brain development and reveals a potential link of cytokinesis control to regulation of cell fate determination.

Title: The function of hominoid specific gene tbc1d3 on cortical folding

Authors: ***Q. HOU**, X. JU, Z.-G. LUO;
Lab. of Synaptic Signaling, Institude of Neurosci., Shanghai city, China

Abstract: It is generally assumed that the expansion of the mammalian neocortex during evolution correlates with the increase in intelligence, but it was unknown whether induction of cortical folding in animals with lissencephalic cortex could enhance cortical functions. We found that expression of the hominoid-specific gene *TBC1D3* in ventricular cortical progenitors of mice via *in utero* electroporation disrupted ventricular adherens junctions and caused delamination of radial glia, leading to an increased number of self-renewing basal progenitors with typical morphology of outer radial glia (oRG), which are most abundant in primates. Furthermore, localized oRG proliferation, resulting from either *in utero* electroporation or transgenic expression of TBC1D3, was often found to underlie cortical regions exhibiting folding. Notably, the transgenic mice showed more rapid motor learning during rotarod training. Thus, we have identified a hominoid gene that regulates the cortical expansion and folding via elevating oRG proliferation, and demonstrated that cortical expansion and folding could cause enhanced cognitive function.

Title: Role of cdk inhibitor $p57^{kip2}$ in regulating the fate of embryonic neural progenitor cells

Authors: *Y. HARADA, S. FURUTACHI, D. KAWAGUCHI, Y. GOTOH;
Univ. of Tokyo, Tokyo, Japan

Abstract: Adult neural stem cells (aNSCs) generate neurons that modify cognitive functions such as learning and memory. Our previous studies demonstrate that slowly-dividing neural progenitor cells (NPCs) exist in the embryonic ganglionic eminences and that a fraction of this population is destined to become aNSCs located in the subependymal zone (Furutachi et al., Nat. Neurosci. 2015). We found that these slowly-dividing cells highly express the CDK inhibitor $p57^{kip2}$ (p57) and that p57 is essential for quiescence of aNSC and these slowly-dividing embryonic NPCs. However, it remains unclear whether p57 influences the characteristics of aNSCs and these NPCs other than quiescence. In this study, we found that ectopic overexpression of p57 in the embryonic mouse neocortex led not only to cell cycle arrest but also to maintenance of the undifferentiated state of NPCs. This function of p57 appears to require the CDK domain. Moreover, our results suggested that high level expression of p57 results in the activation of Notch signaling. We are now examining the downstream targets and upstream regulators of p57 in the slowly-dividing embryonic NPCs.

Title: Characterization of function and regulation of Plzf in the P19 cell model of neurogenesis

Authors: *H.-C. LIN[1], Y.-H. LEE[4], P.-C. PAO[1], W.-C. CHANG[1,2], Y.-C. LEE[3,2];
[1]Grad. Inst. of Med. Sciences, Col. of Med., [2]Ctr. for Neurotrauma and Neuroregeneration, [3]Ph.D. Program for Neural Regenerative Medicine, Col. of Med. Sci. and Technol., Taipei Med. Univ., Taipei, Taiwan; [4]Dept. of Pharmacology, Col. of Med., Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: Promyelocytic leukemia zinc finger (*Plzf*), a *kruppel*-like zinc finger gene, is a transcriptional regulator and plays a role in maintenance of stem cells of various lineages, such as hematopoietic stem cells and spermatogonial stem cells. Previous studies showed that Plzf expressed in spatially restricted and temporally dynamic patterns in the central nervous system. Studies also revealed that Plzf has a function in maintenance of neural progenitors and inhibition of neurogenesis. In Drosophila, Plzf expression is regulated by Notch signaling, but the detailed mechanism is not clear. P19 embryonal carcinoma cell is a useful model for investigating the molecular mechanisms of neurogenesis. In our preliminary data, we found that Plzf was dramatically induced at the early stage of neuronal differentiation and diminished at the late stage. The temporal expression of Plzf during neuronal differentiation in P19 cells is similar to the pattern of expression observed in brain development. Using promoter activity assay, we found that E2F family, which is important for neural stem cell self-renewal and embryonic development, may activate *Plzf* gene promoter activity. We also found that BrdU incorporation was decreased in the *Plzf* knockdown cells, indicating that Plzf can regulate the neural stem cell-like properties in P19 cells. Further study such as site-directed mutagenesis, ChIP analysis will be used to examine the role of E2F family in P*lzf* gene regulation.

Title: Feed Forward Cytokine signalling in glioblastoma pathogenesis

Authors: *A. JAHANI-ASL[1], M. RUDNICKI[2], A. BONNI[3];
[1]McGill Univ., Montreal, QC, Canada; [2]Ottawa Hosp. Res. Inst., Ottawa, ON, Canada;

Abstract: EGFRvIII/STAT3 signaling plays a significant role in glioblastoma pathogenesis. Here, we identify the cytokine receptor OSMR as a direct target gene of the transcription factor STAT3 in mouse astrocytes and human brain tumor stem cells (BTSCs). Strikingly, we find that OSMR functions as an essential co-receptor for EGFRvIII. OSMR forms a physical complex with EGFRvIII and depletion of OSMR impairs EGFRvIII/STAT3 signaling. Conversely, pharmacological inhibition of EGFRvIII phosphorylation inhibits the EGFRvIII/OSMR interaction and activation of STAT3. EGFRvIII/OSMR signaling in tumors operates constitutively, whereas EGFR/OSMR signaling in non-tumor cells is synergistically activated by the ligands EGF and OSM. Finally, knockdown of OSMR strongly suppresses cell proliferation and tumor growth of murine glioblastoma cells and human BTSC xenografts in mice and prolongs lifespan of these mice. Our findings identify OSMR as a critical regulator of glioblastoma tumor growth that orchestrates a feed forward signaling mechanism with EGFRvIII and STAT3 to drive tumorigenesis.

Title: Sphingosine-1-phosphate receptor 1 expression in cerebellum regulates Sphingosine-1 Phosphate release and is a mediator of cerebellar granule cell progenitor proliferation and migration

Authors: C. DUMAN, *J. ALFONSO;
Clin. Neurobio., DKFZ, Heidelberg, Germany

Abstract: Sphingosine-1 phosphate (S1P) is a structurally simple lipid molecule that results in several diverse and potent cellular responses such as proliferation, migration and cell death via five G protein coupled receptors, S1P1-5. We previously identified S1P1 signaling as a critical mediator of neuroblast migration through RMS and into the olfactory bulb during the switch

from tangential to radial migration. Here we investigated the role of S1P1 signaling in early postnatal cerebellar development; an excellent model for neuronal progenitor development and subsequent circuit formation. In the first 2.5 weeks of age, mice continue to develop their cerebellum and house granule cell progenitors (GCPs) in the transient outermost layer of the cerebellar cortex, external granule layer (EGL). These progenitors, after rounds of symmetric division, become post-mitotic and first migrate tangentially along EGL. Tangentially migrating cells later switch to radial migration and using Bergmann glia as scaffold, they migrate through molecular layer (ML) to find their end position of differentiation in the inner granule layer (IGL). We found that S1P1 is strongly expressed in Bergmann glia but not expressed in the GCPs, or the Purkinje neurons. Using CNS specific Nestin-CRE x $S1P1^{flx/flx}$ conditional knock out mouse, BrdU pulse labeling together with acute slice imaging, we studied the proliferation and migration dynamics of GCPs. We found that lack of S1P1 in cerebellum results in significantly increased proliferation of GCPs in EGL at the age P10 and alter migration dynamics into the IGL at subsequent time points *in vivo*. Finally, we observed that in conditional S1P1 knockout mice cerebellum S1P producing enzyme sphingosine kinase 2 (SPHK2) levels are significantly increased. Our data indicate that the S1P1 signaling is potentially playing an indirect role in proliferation of GCPs through increased S1P levels in the cerebellum.

Title: MSCs promote axonal outgrowth via neuronal tPA and synergistically with astrocytic tPA

Authors: *J. QIAN[1], M. CHOPP[1,2], X. SHANG[1], Z. LIU[1];
[1]Henry Ford Hosp., Detroit, MI; [2]Oakland Univ., Rochester, MI

Abstract: We reported that exogenous administration of mesenchymal stromal cells (MSCs) after experimental stroke enhances neurological recovery, that MSCs increase tPA expression in astrocytes both in vivo and in vitro, and intranasal administration of tPA promotes neurological

recovery post stroke in animals. Here, using a microfluidics chamber, we tested the hypothesis that MSCs increase axonal outgrowth directly via neuronal tPA and indirectly via stimulating tPA expression in astrocytes. Primary murine neurons and astrocytes were isolated from WT and tPA-KO cortices of day 17-18 mouse embryos. Mouse MSCs (WT) were purchased from Cognate Inc. Neurons (WT or tPA-KO) were seeded in soma side of Xona microfluidics chambers. Three days later, astrocytes (WT or tPA-KO) and/or MSCs were seeded and cultured in the axonal side of the chambers. To test the effect of MSCs and astrocytes on hypoxic axons, a separate group of microfluidics (same neuronal and astrocyte/MSC conditions as above) were subjected to oxygen deprivation for 2 hours on the 4th day after neuron seeding. At day 6, all cells were stained by anti-Tuj-1 antibody for axon quantification. In a third group, primary neurons, astrocytes and/or MSCs were co-cultured for 3 days to quantify tPA by Western blot. In the microfluidic chamber, WT axons grew faster than tPA-KO axons (n=10-11, $P<0.05$). MSCs promoted WT axonal outgrowth alone (n=8-11, $P<0.05$) and synergistically with WT astrocytes (n=8-10, $P<0.05$) at both normoxia and oxygen deprivation conditions. The synergistic effect was inhibited by the ERK inhibitor, U0126 at 50uM (n=9-10, $P<0.05$). However, MSCs exerted no effect on tPA-KO axonal outgrowth after the same treatments (n=10-12, $P>0.05$). Western blot showed that co-culture of MSCs with WT-astrocytes enhanced tPA expression in astrocytes. We conclude that MSCs promote axonal outgrowth via neuronal tPA and synergistically with astrocytic tPA, suggesting tPA mediates MSC treatment-induced restorative neurite growth which may contribute to neurological recovery after stroke.

Title: Functional role of ribosome recycling during brain development

Authors: *M. TERREY[1,4], I. DOTU[5], J. H. CHUANG[6], S. L. ACKERMAN[2,4,3];
[1]UCSD, LA Jolla, CA; [2]Cell and Mol. Med., [3]Div. of Biol. Sci., UCSD, La Jolla, CA; [4]Howard Hughes Med. Inst., Chevy Chase, MD; [5]Res. Programme on Biomed. Informatics, Pompeu Fabra Univ., Barecelona, Spain; [6]The Jackson Lab. for Genomic Med., Farmington, CT

Abstract: Gene expression is controlled on multiple levels including transcription, mRNA degradation, protein translation, and degradation. However, gene expression regulated at the level of translation may be affected by mRNA secondary structure, mRNA stability, tRNA concentration, ribosome loading, the interaction between the ribosome and nascent polypeptide, and ribosome recycling. Generally, initiation is thought to be the main regulatory step of translation. However, it has become apparent that translation elongation is also highly regulated to eliminate translational pauses or stalls of ribosomes that may impair protein folding and translation. Ribosomes may stall on mRNAs containing a premature stop codon, cleaved, damaged or structured mRNAs, or as a result of polypeptides that form stable interactions, limited availability of tRNAs, or nutrition stress. Stalled ribosomes need to be recovered for further rounds of translation to limit their energetically costly replacement. While little is known about the components and function of the ribosome recycling pathways in higher eukaryotes, we have previously shown that *Gtpbp2* resolves stalled ribosomes in coding sequences due to tRNA deficiency and thereby, prevents neurodegeneration in mice. GTPBP2 is structurally similar to the mammalian ribosome rescue factor *Hbs1l* that in yeast has been shown to recycle ribosomes that proceed beyond the canonical stop codon. Here we show, the loss of *Hbs1l* is embryonic lethal in mice and its conditional deletion in the developing brain results in developmental defects. However, unlike *Gtpbp2*, loss of *Hbs1l* in post-mitotic neurons does not result in overt phenotypic abnormalities. Despite the structural similarity and cellular co-expression of GTPBP2 and HBS1L, our findings suggest that mammalian ribosome rescue factors may not be functionally redundant and may be necessary during different stages of brain development.

Title: Innate overexpression of BDNF improves taste dysfunction following chemotherapy

Authors: C. A. NOSRAT[1], L. PALACIOS[2], K. H. VU[2], S. A. KEZIAN[2], B. S. HENSON[1], *I. VUKMANOVIC NOSRAT[1];

Abstract: Basal-cell carcinoma (BCC) is the most common type of cancer of the skin. BCC is associated with mutations in the Hedgehog (Hh) signaling pathway. Genes encoding patched homologue 1 (PTCH1) and smoothened homologue (SMO) are affected. Vismodegib is an approved treatment for advanced BCC and selectively inhibits SMO. It also affects the proliferation and differentiation of taste cells by decreasing the number of taste progenitor cells, leading to a reduction of taste receptor cells. About 55% of patients being treated report dysgeusia. Taste-related adverse events might explain why many patients discontinue taking the drug. This study seeks to find a method to mitigate the negative side effects of vismodegib. We used novel transgenic mouse lines in which an alpha-gustducin promoter drives the overexpression of BDNF in taste buds (Gust-BDNF). BDNF is the most potent neurotrophic factor in the taste system and these mice have denser gustatory innervation, increased number of taste cells, and enlarged taste buds. We first studied if Gust-BDNF mice were able to detect tastants at lower concentrations compared to wild type mice. Furthermore, we evaluated if vismodegib administration affected the taste system in Gust-BDNF mice compared to wild type mice, and to what extent, in order to study if the taste-related side effects would be counteracted by innate overexpression of BDNF in Gust-BDNF mice. Circumvallate epithelia were laser microdissected, total RNA was extracted and real-time PCR was performed. Automated two-bottle choice test was used to evaluate taste preference and avoidance in mice. Additionally, vimodegib was administered orally for 10 weeks and evaluated for taste preference. Our data show that untreated Gust-BDNF mice showed a significant upregulation of sweet and bitter taste receptor genes, as well as some olfactory receptor genes compared to wild type mice. Gust-BDNF mice showed preference for sweet and aversion to bitter tastants at much lower concentrations compared to wild type mice. Most importantly, Gust-BDNF mice were able to detect sucrose after 10 weeks of vismodegib treatment, while wild type mice were not. We propose that BDNF, directly or indirectly, is able to counteract taste disturbances following vismodegib treatment.

Title: Valproic acid inhibits cortical precursor HDACs and rapidly upregulates cyclin E1 mRNA in embryonic rat cerebral cortex development.

Authors: *R. J. CONNACHER, X. ZHOU, E. DICICCO-BLOOM;
Neurosci. and Cell Biol., Rutgers Robert Wood Johnson Med. Sch., Piscataway, NJ

Abstract: Valproic acid (VPA) is a neurotherapeutic drug commonly used to treat epilepsy, migraine, and depression. However, VPA exposure during fetal development induces brain malformations, and increases autism risk. Although mechanisms are undefined, evidence suggests VPA modulates epigenetic processes. In previous studies using embryonic day 14.5 (E14.5) and E16.5 cerebral cortical precursors in vitro and in vivo, we have shown VPA stimulates DNA synthesis, cell division, and increases cell numbers, producing enlarged brains by P21. This stimulation corresponds with rapid increases in G1 cyclin proteins D3 and E and levels of acetylated histone 3, consistent with proposed VPA inhibition of histone deacetylases (HDAC). We hypothesize that the proliferation effects of VPA are due to changes in G1-S cyclin levels, which may be a direct result of VPA mediated HDAC inhibition. To define mechanisms we now characterize expression of HDACs in E14.5, E16.5, E19.5 and adult cerebral cortex using RT-PCR. HDAC members of classes I, II, IV, and Sirtuin 1 (class III) are expressed widely during development yet exhibit region- and time specific patterns. Because HDAC 1 and 2 regulate both cell cycle and differentiation, and class I HDAC proteins are primarily targeted by VPA, we assayed levels in cortical cultures: While both were highly expressed, HDAC 1 localized to nucleus and cytoplasm, while HDAC 2 was solely nuclear. After establishing key HDACs are present in cortical precursors, we next determined whether VPA can directly inhibit HDAC activity in E14.5 rat cortical precursors. At a dose that stimulated mitogenesis, VPA inhibited enzymatic activity by 24%, whereas a higher VPA dose that did not stimulate DNA synthesis, inhibited HDAC activity by 42%, suggesting a delicate balance of diverse HDAC targets are involved with stimulatory actions. To begin defining processes underlying rapid increases in DNA synthesis, we examined G1-S phase regulator cyclin E1 mRNA in vitro. VPA elicited increases in mRNA levels by 1.7 fold at 2h, 1.8 at 4h and 1.9 at 8h. Considering that our prior studies showed rapid increases of cyclin E protein by 4 hours, it follows that VPA may directly regulate this gene's expression through epigenetic mechanisms. In sum, VPA can inhibit HDACs in developing cerebral cortex, which in turn may directly target cyclin E1 gene

expression, an issue we will explore by ChIP analysis. Identification of this epigenetic role for VPA on cell cycle progression during cortical neurogenesis may provide insights into its teratogenic effects and possible contributions to autism.

Title: Common and unique roles of ASD candidate genes in cortical interneuron development: Increasing evidence for parvalbumin expressing interneurons.

Authors: *D. VOGT[1], K. K. CHO[2], S. E. ROBINSON[2], V. SOHAL[3], J. L. R. RUBENSTEIN[2]; [1]Dept. of Psychiatry, Univ. of California San Francisco, San Francisco, CA; [2]UCSF, San Francisco, CA; [3]UCSF, SanFrancisco, CA

Abstract: There are now multiple genes that are known to contribute to Autism spectrum disorder (ASD) risk. However, the functions of these genes during brain development are largely unknown. Moreover, how human ASD mutations in these genes disrupt brain function is also not understood. One hypothesis proposes that some forms of ASD are caused by an imbalance in brain excitation and inhibition, and that pallial GABAergic interneurons may have a pivotal role in this process. Thus, investigating ASD gene and allele functions in cortical inhibitory interneurons is an ideal experimental system. To this end, I will present work primarily examining the role of key ASD genes that regulate overlapping cell signaling pathways, in particular RAS/MAPK and AKT/mTor signaling. One of these genes, *NF1*, is an inhibitor of RAS signaling and is predicted to also inhibit mTor signaling. Thus, *NF1* dysfunction could potentially generate phenotypes shared with *PTEN* and *TSC1&2,* other syndromic ASD genes. However, deletion of *NF1* in cortical interneuron progenitors led to phenotypes not shared with *PTEN or TSC1* loss of function mice, suggesting unique roles for RAS/MAPK signaling during

development and in ASD. Interestingly, one common phenotype was observed, altered numbers and properties of interneurons that expressed PV. Further analyses revealed that alterations in PV+ interneurons is a common cell autonomous phenotype in another mouse model of ASD, including *CNTNAP2*. These data demonstrate that both unique and complimentary phenotypes are present in multiple models of ASD. Finally, these data could hint that therapies aimed at the PV+ interneuron population may have particular importance for ASD.

Title: Transcriptome profiles of neuronal activity-induced proliferating neural progenitor cells and newly-differentiated immature neurons in optic tectum of xenopus laevis

Authors: *L.-C. HUANG[1], K. VAN KEUREN-JENSEN[2], H. CLINE[1];
[1]Dorris Neurosci. Ctr., The Scripps Res. Inst., La Jolla, CA; [2]Translational Genomics Res. Inst., Phoenix, AZ

Abstract: Neuronal activity-induced neurogenesis has been suggested to play a critical role in maintaining neural circuit functions in adult hippocampus and olfactory bulb. Many factors, of which expression is activity-dependent, are required for neural progenitor cell proliferation, and survival and integration of new-born neurons (Ma et al., 2009). However, the mechanisms governing this neuronal activity-induced neurogenesis during development are largely unknown. Here we utilize RNA-seq to profile the transcriptomes of neuronal activity-induced proliferating neural progenitor cells and newly-differentiated immature neurons from optic tectum of Xenopus laevis in order to provide some insights into the potential mechanisms. Different visual experience protocols bias the fate of neural progenitor cells in the optic tectum towards proliferation or differentiation (Sharma and Cline, 2010; Bestman et al., 2015). Neural progenitor cells and newly-differentiated neurons were isolated using fluorescence-activated cell sorting from Sox2+ neural progenitor cells of animals reared in dark and enhanced visual stimulation for

24 hours, respectively, based on the turboGFP expression driven by Sox2 enhancer. Using RNA-seq, 1,130 differentially expressed transcripts were identified between these two cell types. Gene Ontology analysis using DAVID / PANTHER clusters the differentially expressed transcripts into categories of catalytic activity, transcription factor, receptor-mediated signaling and structural protein. This provides the potential functional roles of these transcripts in neurogenesis. The protein-protein interaction network analysis using STRING and Cytoscape identified the potential key players in neurogenesis based on their connectivity within the protein network. These most connected genes are likely to modulate the expression of many other transcripts. In addition, using ENCODE database, we identified a transcriptional network which may regulate the expression of differentially expressed transcripts in the Sox2+ neural progenitor cells and their neuronal progeny during neural development. This study provides an overview on the transcripts that are differentially expressed between neuronal activity-induced progenitor cells and newly-differentiated neurons, and a series of datamining and bioinformatic analyses reveal an overview of their potential roles in neurogenesis.

Title: TGF-beta signaling suppresses the formation of Muller glia derived progenitor cells in the avian retina

Authors: *L. J. TODD, N. MENDONCA, I. PALAZZO, N. SQUIRES, A. FISCHER;
The Ohio State Univ., Columbus, OH

Abstract: Müller glia are the major type of support cell in the vertebrate retina and are the only retinal glia type derived from neuroepthelial stem cells. In response to retinal injury or growth factor treatment, Müller glia can give rise to proliferating neurogenic progenitors with the ability to produce new neurons. The ability of Müller glia-derived progenitor cells (MGPCs) to regenerate neurons is robust in lower vertebrates, but is diminished birds and mammals. Therefore, understanding the mechanisms that orchestrate the ability of Müller glia to transition into MGPCs is imperative to harnessing the regenerative capacity of the retina. A network of signaling pathways underlying MGPC formation is beginning to be uncovered. TGFβ signaling

has been implicated as a negative regulator of MGPC formation in the zebrafish and the juvenile rodent retina (Lenkowski, et al. 2013; Close, et al. 2005). This study investigates whether TGFβ/SMAD-signaling influences the formation of MGPCs in the chick retina *in vivo*. We observed that SMAD2, a readout of TGFβ signaling, is specifically expressed in Müller glia and its nuclear localization is dynamically regulated following NMDA damage, when MGPCs are known to form. We found that intraocular injections of recombinant TGFβ2 ligand inhibited the formation of proliferating MGPCs after retinal damage. By comparison, inhibition of TGFβ signaling at the level of TGFβ receptor and the SMAD3 transcription factor significantly increased numbers of proliferating MGPCs in NMDA damaged retinas. Furthermore, we find that inhibition of SMAD3 in combination with FGF2 treatment leads to significant increase in the number of proliferating MGPCs compared to numbers seen in retinas treated with FGF2 alone. Lastly, evidence is provided that TGFβ signaling is coordinated with MAPK and mTOR signaling, and cross-talk between the pathways may influence the formation of proliferating MGPCs. We conclude that TGFβ/SMAD signaling plays a negative regulatory role during the formation of proliferating MGPCs in the *in vivo* chick retina.

Title: Nutrient-restrictions causes reversible neuronal G2 arrest in the Xenopus visual system.

Authors: *C. R. MCKEOWN, A. C. GAMBRILL, E. M. FITCHETT, C. K. THOMPSON, H. T. CLINE;
Mol. and Cell. Neurosci., The Scripps Res. Inst., La Jolla, CA

Abstract: Access to nutrients is critical for normal brain development, yet the impact of nutrient restriction on brain development and the consequences of nutrient restriction and availability on circuit formation and behavior remain largely unknown. Here we examine the effects of nutrient restriction and availability on neurogenesis in Xenopus laevis tadpoles. We are specifically interested in understanding the nutrient- responsive molecular and cellular mechanisms required for neural progenitor cell proliferation, as well as neuronal differentiation and circuit integration in the developing Xenopus visual system. Nutrient restriction (NR) beginning after yolk depletion results in a reversible block in neural progenitor cell (NPC) proliferation and a developmental stasis of tadpoles, from which animals recover if food is provided within with ~8 days of NR. In contrast to NR, nutrient enrichment (NE) significantly increases NPC proliferation in the optic tectum. Upon re- introduction to food after NR, neural progenitors initiate proliferation within 16hrs, rescuing cell proliferation rates as well as optic tectum size, comparable to non- NR counterparts. By continually labeling proliferating cells with BrdU for 24hrs concurrent with the re- introduction of food, followed by phospho- histone H3 immunofluorescence, we find that after a period of NR the nutrient- induced proliferating cells directly enter M- phase. These data suggest that NR causes a G2 arrest and that NE recruits these arrested progenitors to re- enter the cell cycle upon re- exposure to food. Consistent with this observation, we find that cellular levels of the G1/S-transition marker phospho-cdc2 are down-regulated upon NR and elevated with the reintroduction of nutrients. Furthermore, we show that in NE animals, phospho-cdc2 is apically localized in progenitors on the ventricular surface of the tectum. This localization is lost upon NR and restored just 12hrs after re-introduction to food. Using immunofluorescence and Western blotting, we determined that the mTOR inhibitor, Rapamycin, inhibits NE- induced proliferation, indicating that nutrient-induced proliferation requires mTOR signaling. Using electrophysiological assays, we find that NR decreased the intrinsic excitability of optic tectal neurons and impaired integration of newly generated neurons into the tectal circuit. These studies indicate that nutrient availability plays a key role in regulating neuronal proliferation, differentiation, and circuit connectivity in the developing tadpole visual system, specifically by recruiting quiescent progenitor cells to escape G2 arrest and re-enter the cell cycle.

Title: Neural stem cell responses to chronic stress are autonomously sustained and sexually dimorphic

Authors: M. NAVARRO-SOBRINO[1], A. BURGOS[2], A. GARCIA-GARCIA[1], E. LEONARDO[1], *A. DRANOVSKY[1];
[1]Psychiatry, Columbia Univ. / NYSPI, New York, NY; [2]Neurosci., Columbia Univ., New York, NY

Abstract: Adult stem cells are crucial for tissue homeostasis. In the adult hippocampus, neural stem cells (NSCs) appear to proliferate in response to stressful experiences. However, the functional capacity of accumulating cells and their impact on hippocampal structure and function remain unknown. We used multicolor fluorescent reporter mice to prospectively identify NSCs vs progenitors and purify them from the adult hippocampus. In vitro, social isolation increased the autonomous proliferative capacity of NSCs and the resulting cells exhibited increased potential for neurogenesis. In vivo, NSCs stockpiled during impoverished conditions were recruited for enhanced neurogenesis when conditions improved. Remarkably, these experience-dependent changes in NSC function occurred in male, but not in female mice. Together, our results indicate a sexually dimorphic, cell intrinsic mechanism by which resident NSCs contribute to normal tissue homeostasis and experience-induced brain plasticity. We suggest that NSCs present an avenue for investigating mechanisms underlying sex differences in stress resilience.

Abstract: The aldehyde dehydrogenase (ALDH) protein family is highly enriched in astrocytes and ALDHs are widely used as astrocyte-specific markers. Loss of function mutations in ALDH family members are known to cause a variety of human brain disorders. In particular, ALDH7A1 mutations cause pyridoxine-dependent epilepsy (PDE), a disease characterized by neonatal seizures and cognitive impairments. The seizures can be treated by large dietary intake of vitamin B6 (B6), but cognitive impairments persist. The leading hypothesis in the field is that seizures are caused by a functional B6 deficiency created by metabolic blockage of the lysine degradation pathway. How B6 deficiency causes seizures and the source of the untreated cognitive deficits remain open questions. This study attempts to address these two questions in parallel.

We hypothesize that B6 deficiency causes seizures due to reduced cofactor availability for production of neurotransmitters such as GABA. B6 may also directly act as an antioxidant. We generated *Aldh7a1*$^{-/-}$ mice and found metabolic blockage of the lysine degradation pathway and increased oxidative stress in prefrontal cortex (PFC). Similar to PDE patients, *Aldh7a1*$^{-/-}$ mice display reduced seizure threshold and deficits in higher brain function, but we did not detect any sign of spontaneous seizure activity by EEG. We found changes in GABAergic signaling and the intrinsic excitability of layer V PFC neurons, which may underlie the observed change in seizure threshold. We are investigating whether B6 treatment can rescue the deficits in seizure threshold and oxidative stress in *Aldh7a1*$^{-/-}$ mice.

We hypothesize that the persistence of cognitive deficits in B6-treated PDE patients is due to the continued dysfunction of ALDH7A1 in astrocytes. In other tissues, ALDH7A1 is needed for production of osmolytes, regulation of NAD+/NADH redox ratio, and degradation of reactive aldehydes. ALDH7A1 immunostaining is highly specific for astrocytes and we found that *Aldh7a1*$^{-/-}$ mice have an altered NAD$^+$/NADH ratio and higher ROS levels in astrocytes. To investigate the effects of astrocyte-specific deletion of *Aldh7a1* in the absence of systemic B6 deficiency, we are using *Emx1-Cre*$^+$ x *Aldh7a1*$^{F/F}$ mice for behavioral assays and *GLAST-CreER*$^+$ x *Aldh7a1*$^{F/F}$ mice for cellular assays. Intriguingly, we have also observed decreased ALDH7A1 expression in biopsied neural tissue from patients with schizophrenia and in PFC tissue of animals treated with phencyclidine, suggesting that decreased expression of ALDH7A1 may contribute to deficits in higher brain function in psychiatric disorders.

Title: Genetic approaches for achieving astrocyte specific transgene expression

Authors: *J. DUNPHY, T. PAPOUIN, M. TOLMAN, K. FLICK, P. G. HAYDON; Neurosci., Tufts Univ., Boston, MA

Abstract: Over the last 10 years, several molecular genetic techniques have been used to study the role of gliotransmission in the brain, including a mouse model that attenuates gliotransmitter release by expressing the cytoplasmic domain of VAMP2 in astrocytes (dnSNARE). Recently the cell-type specificity of the GFAP promoter and the conditional tetracycline responsive system has been called into question, and with it, a myriad of independently-verified astrocytic functions that have been discovered using dnSNARE mice. In this mouse line, the 2 kilobase human GFAP promoter drives expression of the tetracycline transactivator (tTA) in astrocytes. Since tTA is only permitted to interact with the tetracycline operator (tetOff) when doxycycline is removed from the diet, dnSNARE and the EGFP reporter expression is conditional.
To assess the validity of the claim of widespread transgene expression in neurons, we performed quantitative immunohistochemistry in dnSNARE mice and single-gene controls, both on and off doxycycline. Immunolabeling and colocalization analysis through 40μm thick z-stacks taken at 1μm intervals from dnSNARE mice revealed no single EGFP+ neuron among the 5,887 NeuN+ cells that were counted. Rather, 100% of the 1,636 EGFP+ cells that were counted had a distinct bushy morphology and co-localized with GFAP and DAPI, indicating that they were astrocytes.
Other cell-type specific molecular genetic approaches have been used to assess gliotransmission, including alternative promoters, and other conditional (such as cre/loxP) or region specific (virus-mediated) expression systems. We found that adeno-associated viruses (AAVs) that paired an abbreviated version (0.7 kilobase) of the GFAP promoter with the AAV5 serotype were effective in transducing astrocytes with the EGFP reporter. All of the 1271 EGFP+ cells counted colocalized with the GFAP marker. On the other hand, neuronal specificity was achieved by pairing the human Synapsin promoter (hSyn) with an AAV9 serotype virus. 99.15% of EGFP+ cells were neurons, with the remaining cells having microglial morphology (and not colocalizing with GFAP).
Several different approaches can be used in tandem to ensure that experimental results are

interpreted correctly. In this study, we evaluated many approaches that are currently being used to achieve astrocyte-specificity.

Title: Astrocyte-neuron involvement in oxytocinergic modifications of pain and anxiety.

Authors: J. WAHIS[1], S. GOYON[1], M. ELIAVA[2], V. GRINEVICH[2], P. POISBEAU[3], *A. CHARLET[1];

Abstract: Oxytocin (OT) is a hypothalamic hormone and neuropeptide well known for its numerous roles in social interaction, anxiety and pain modulation, among others. Particularly, OT can modulate the local circuitry of the central amygdala (CeA) in order to decrease the fear response and promote analgesia. Here, we study the action of OT on the calcium dynamics of astrocytes and the relevance of the astrocyte-neuron interaction to the OT neuromodulatory effect in the CeA. Through calcium imaging and patch clamp experiments on acute slices of rat amygdala, we characterize the response of astrocytes and neurons upon specific activation of OT-receptor, decipher the intracellular mechanisms involved and identify putative gliotransmitter(s) of the OT message. Finally, through a neuropathic pain model, we test the relevance of those mechanisms on pain threshold and anxiety levels. Taken together, our results provide new insights into the mechanisms underlying the OT action in the CeA and its role in pain and anxiety processing.

Title: Neuronal extracellular vesicles modify astrocyte lysosome function, promote trophic factor production and inhibit secretion of pro-inflammatory factors.

Authors: *E. R. HUTCHISON[1], E. EITAN[1], C. SUIRE[1], K. MAROSI[1], R. SPANGLER[1], Z. LIAO[2], K. W. WITWER[2], M. P. MATTSON[1];

Abstract: Astrocytes support many aspects of neuronal physiology, from basic cellular metabolism and neurotransmitter uptake to more complex actions such as synaptic pruning. Under pathological conditions, including injury or age-related neurodegenerative diseases such as Alzheimer's, astrocytes take on a reactive phenotype in which they migrate to pathological sites and acquire a pro-inflammatory status. Extracellular vesicles (EVs) are a population of circulating vesicles containing protein, RNA and DNA. EVs have been shown to deliver functional proteins, mRNA and ncRNAs, such as microRNAs, into recipient cells and thus confer altered cellular function. Neuronal excitation has previously been found to increase EV release from neurons and recent work from our lab has demonstrated that EVs can mediate the intercellular spread of pathology through the delivery of toxic proteins such as Aβ. Here we examine the functional effects of cortical neuron EVs on cultured astrocytes and demonstrate that these EVs suppress lysosome function in recipient astrocytes. mRNA profiling experiments revealed that astrocytes respond to neuronal EVs by increasing transcripts of trophic factors such as BDNF and decreasing mRNA levels of pro-inflammatory cytokines such as IL1β and TNFα. These findings were confirmed at the protein level using ELISA assays for TNFα and IL6. To identify the mechanism behind this phenotypic shift, we are performing both miRNA profiling and RNASeq analysis on neuronal EVs and investigating the relationship between these EV-enriched RNA species and neuronal activity, aging-related stressors including inflammation, DNA damage and lysosomal stress. We are currently examining the role of this novel form of neuron-astrocyte interaction in the context of neurodegeneration and Alzheimer's disease.

Title: Release of glutamate and ATP induced by optogenetic activation of astrocytes

Authors: W. SHEN, L. NIKOLIC, C. MEUNIER, *E. AUDINAT;
Inserm U1128, Univ. Paris Descartes, Paris, France

Abstract: Astrocytes can modulate synaptic transmission and neuronal excitability through the release of gliotransmitters, such as glutamate, D-serine or ATP. However, the mechanisms and conditions leading to the release of gliotransmitters are still highly debated. We therefore used a transgenic approach allowing optogenetic activation of astrocytes to study gliotransmission in the hippocampus. We crossed Cx30-cre-ERT2 (kindly provided by Frank W Pfrieger) and Floxed-ChR2-EYFP mice (Ai32; Jackson lab) to induce the selective expression of ChR2 in astrocytes. We confirmed by immunocytochemistry that EYFP was specifically expressed in the vast majority of hippocampal and cortical astrocytes. In acute hippocampal slices, we also confirmed that blue light stimulations induced in astrocytes direct membrane currents resembling those of ChR2-induced currents in other cell types. Using two-photon imaging, we observed that low intensity light pulses of more than one second reliably triggered calcium responses in EYP positive astrocytes. These calcium responses were largely inhibited in thapsigargin-treated slices, indicating the involvement of intracellular calcium stores. We then recorded principal neurons of

CA1 and of dentate gyrus regions to analyze the neuronal consequences of ChR2 activation in astrocytes. Light pulses of more than 1 second reliably induced a sequence of depolarizing-hyperpolarizing responses that were not blocked by TTX (1 μM). The hyperpolarizing current was abolished by the adenosine A1 receptor antagonist DCPCX (200 nM), suggesting a release of ATP or adenosine by astrocytes. The depolarizing component was fully blocked by antagonists of NMDARs (50 μM D-AP5, 40 μM MK-801, 50 μM 7Cl-KYN) but not of AMPA-KAR receptors (10-20 μM NBQX). This component was potentiated by the blocker of glutamate transporters TBOA (100 μM) but was not affected by application of glycine or D-serine, which in our conditions failed also to induce any change in the baseline membrane current. Pharmacological manipulations further indicated that light-induced NMDAR-mediated responses were due to the activation of GluN2B-containing extra-synaptic NMDARs by a low concentration of glutamate. Remarkably, light-induced calcium responses in astrocytes and NMDAR-mediated currents in neurons were largely inhibited by PPADS (100 μM), a broad spectrum antagonist of P2 receptors and by MRS 2179, a selective antagonist of P2Y1 receptors, the predominant P2 receptors expressed in astrocytes. Overall, these results validate the use of ChR2 to trigger gliotransmission and indicate that astrocyte glutamate release is tightly controlled by P2Y1 signaling.

Title: Loss of sigma-1 receptor chaperone promotes astrocytosis and enhances Nrf2 antioxidant defense

Authors: *S.-Y. A. TSAI[1], T.-Y. WENG[2], J. CIESIELSKI[1], T.-P. SU[1];
[1]NIDA/NIH, Baltimore, MD; [2]Academia Sinica, TAIPEI, Taiwan

Abstract: The sigma-1 receptor (Sig-1R) is an endoplasmic reticulum chaperone protein abundantly expressed both in neurons and glia and has been implicated in many neurodegenerative and psychiatric diseases. Here we used Sig-1R KO mice to examine CNS expression profiles of astrocytes and ubiquitinated proteins, which are common hallmarks of many CNS pathologies. Our results showed that Sig-1R KO neurons display increased glial

fibrillary acidic protein (GFAP) expression in primary cortical neuron culture and in the whole brain of fetuses and aged mice with concomitantly increased accumulations of ubquitinated proteins. Immunofluorescence data further supported the observation of astrogliosis in neuron-glia culture. Under proteasome and autophagy inhibitor treatments, the pronounced ubiquitinated proteins were further increased in Sig-1R KO cortical neurons compared with WT, indicating that the Sig-1R plays regulatory roles in both protein degradation systems and its pivotal role in protein quality control. Sig-1R deficiency has been associated with increased oxidative stress. Here, we also found that a transcription Nrf2 (nuclear factor erythroid 2-related factor 2), which functions to overcome the stress condition, was enhanced in the Sig-1R KO neurons, especially when the culture condition was antioxidant deprived. The Nrf2 also exhibited longer stability in the Sig-1R KO neurons. Mutation or deficiency of Sig-1Rs has been observed in neurodegenerative models, and this study indicates the critical roles for the Sig-1R in the maintenance of CNS homeostasis and strongly supports the idea that functional complementation signaling pathways are triggered in the Sig-1R KO pathology. (Supported by the IRP/NIDA/NIH/DHHS).

Title: Role of astrocytes in defining functional compartments in the chewing central pattern generator

Authors: *D. RYCZKO, D. VERDIER, A. KOLTA;
Groupe de Recherche sur le Systeme Nerveux Central, Dept. of Neurosci., Univ. Montreal, Montreal, QC, Canada

Abstract: Rhythmic motor activities such as walking, breathing or chewing are generated by specialized neural networks called Central Pattern Generators (CPG). Recent work from our lab shows that astrocytes and their protein S100ß are responsible for neuronal rhythmogenesis in the trigeminal main sensory nucleus (NVsnpr) thought to be part of the chewing CPG (Morquette et al. Nat Neurosci 18:844-54). S100ß, a calcium (Ca^{2+}) binding protein, decreases the extracellular Ca^{2+} concentration, and by doing so, activates a persistent sodium current in NVsnpr neurons,

causing a switch from a tonic to a rhythmic firing mode. It is unclear whether astrocytic coupling is involved in these effects. Morquette et al. showed that intracellular dialysis of an astrocyte with the Ca^{2+} chelator BAPTA prevented rhythmic bursting in the adjacent neuron, but only after prolonged periods of time, indicating that diffusion of BAPTA in the astrocytic syncytium was necessary to prevent neuronal bursting. Thus, we hypothesized that astrocytic syncytia could define functional compartments within which activity of adjacent neurons is synchronised when astrocytes are activated. Such units could be recruited by distinct sets of sensory inputs to the CPG, in order to generate different motor patterns. We tested part of this hypothesis by visualizing such functional units using brainstem slices of mice expressing a Ca^{2+} indicator (GCaMP6f) under the neuronal promoter Thy1. We mapped the Ca^{2+} responses of NVsnpr neurons to different sensory inputs which send their axons in two distinct tracts that can be stimulated separately. We show that each set of inputs can activate a different population of neurons. Using double patch-clamp recordings, we show that neurons located within a spatially restricted domain fire synchronously following sensory stimulation, while neurons slightly further apart are not synchronised by sensory stimulation. Next, we will examine whether syncytium deactivation disrupts their synchrony. This will allow us to determine the role of astrocytic syncytia in synchronizing neurons that are functionally linked by their sensory inputs.

Title: Hepatic encephalopathy is associated with impaired hemichannel mediated release of lactate in the cerebral cortex

Authors: *A. HADJIHAMBI[1], P. S. HOSFORD[2], F. DE CHIARA[1], A. HABTESION[1], A. KARAGIANNIS[2], R. JALAN[1], A. V. GOURINE[2];
[1]Liver and digestive health, [2]Neuroscience, Physiol. & Pharmacol., UCL, London, United Kingdom

Abstract: Background and Aims: Astrocytes, the most numerous glial cell, are hypothesized to play an important role in the pathological mechanisms underlying hepatic encephalopathy (HE), although the clinical manifestations are mainly neuronal. Astrocytes are extensively connected

by gap junctions formed of connexins, which may also exist as functional hemichannels allowing the exchange of molecules between the cytoplasm and the extracellular milieu. The astrocyte-neuron lactate shuttle hypothesis is a contested yet valuable concept suggesting that neuronal activity is fuelled (at least in part) by lactate provided by neighboring astrocyte. In pathological conditions, including HE, significant changes in astroglial anatomy and function are known to occur which could impair the astrocyte-neuron communication. In this study, we investigated changes in the hemichannel function and lactate release in the cerebral cortex and the role of ammonia in animal (rat) models of HE (bile duct ligation [BDL] and hyperammonemia) and the effect of ammonia lowering treatment, ornithine phenylacetate (OP). Methods: Microelectrode biosensors were used for real-time measurements of lactate release by cortical slices prepared from the brains of SHAM-operated (n=18), SHAM + high ammonia diet (HA, n=16), BDL (n=18) and BDL animals treated with OP (0.3g/kg) (BDL+OP, n=14). Fluorescent dye loading in cortical slices was also performed. The involvement of hemichannels was tested using blockers, carbenoxolone and 5-Nitro-2-(3-phenylpropylamino)benzoic Acid. Results: Both HA diet and BDL resulted in high plasma ammonia concentrations, which were reduced by OP treatment. Biosensor recordings showed a significant reduction ($p<0.05$) in both tonic and hypoxia induced lactate release in the cortical slices of HA and BDL rats, which recovered with OP treatment. Cortical dye loading indicated a decrease in hemichannel-mediated loading ($p<0.05$) in BDL animals. Conclusions: The results of the present study suggest that HE is associated with significant changes in the hemichannel functionality in the CNS under normal and hypoxic conditions, with ammonia playing a key role. These changes are hypothesized to contribute to the development of an altered neurochemical phenotype and HE pathogenesis.

Title: Astrocytes modulates hyperosmolality-induced behavior and hormonal release

Authors: *F. M. VECHIATO[1], R. COLETTI[1], J. B. M. DE LIMA[1], F. LUCIO-OLIVEIRA[2], S. G. RUGINSK[3], L. L. K. ELIAS[1], J. ANTUNES-RODRIGUES[1];
[1]Univ. of São Paulo/ Sch. of Med. of Rib, Ribeirao Preto, Brazil; [2]Southern Minas Federal Inst., Muzambinho, Brazil; [3]Alfenas Federal Univ., Alfenas, Brazil

Abstract: Astrocytes have been identified as the synapse third element, suggesting they are involved in neuronal modulation. During chronic dehydration, hypothalamic magnocellular neurons are activated to synthetize and release vasopressin (AVP) and oxytocin (OT) to neurohypophysis (NH). In this condition, astrocytes morphofunctional changes were also observed suggesting their participation in hydromineral homeostasis; however, the astrocytic role still remains little studied. Objectives: To evaluate astrocytes participation in behavioral and hormonal responses in 48-h water-deprived animals (48hWD), and in hormone release of hypothalamic and neurohypophyseal explants in response to hyperosmolarity. Methods: Male Wistar rats were used (250-300g). In *in vivo* protocols, animals were submitted to 48hWD and injected with fluorocitrate (FCA, 1 nmol/4 μL, icv), a glial metabolism inhibitor. After 2 hours, water intake and corticosterone, AVP and OT release were evaluated. In *in vitro* protocols, medial basal hypothalami (MBH) and NH were pre-incubated in KRBG (Krebs-Ringer bicarbonate buffer, 280 mOsm/Kg H_2O), containing or not FCA (6.6, 26.4 or 105.6 μM) for 90 min. The medium was replaced by KRBG medium (280 or 340 mOsm/Kg H_2O, the latter with mannitol or NaCl), containing or not FCA for 30 min. The medium was collected and AVP, OT and atrial natriurect peptide (ANP) secretion was measured. Results: 48hWD increased water intake ($F_{7,196} = 9.2$; $p < .0001$), which was enhanced by FCA ($F_{7,196} = 6.0$; $p < .0001$). There was an increase of corticosterone ($F_{1,34} = 34.1$; $p < .0001$), AVP ($F_{1,38} = 209.3$; $p < .0001$) and OT ($F_{1,33} = 55.9$; $p < .0001$) release in 48hWD animals; nevertheless, FCA reduced hormonal release of every evaluated hormone, respectively ($F_{1,34} = 5.8$; $p < .05$), ($F_{1,38} = 8.2$; $p < .01$) and ($F1,33 = 11.3$; $p < .01$). Incubation with FCA in basal conditions did not change hormone release in MBH and NH. Mannitol-induced hyperosmolality increased AVP, OT and ANP release in both MBH ($t_{52} = 5.6$; $p < .0001$), ($t_{55} = 8.5$; $p < .0001$), ($t_{52} = 20.2$; $p < .0001$) and NH ($t_{45} = 7.5$; $p < .0001$), ($t_{51} = 7.2$; $p < .0001$). In hyperosmolality, FCA, independently of tested concentration, reduced AVP ($F_{3,58} = 9.7$; $p < .0001$), OT ($F_{3,63} = 9.7$; $p < .0001$) and ANP ($F_{3,64} = 46.7$; $p < .0001$) release by MBH, and AVP ($F_{3,58} = 20.36$; $p < .0001$) and OT ($F_{3,64} = 22.9$; $p < .0001$) release by NH. Similar hormonal findings were obtained when hyperosmolality was induced by NaCl followed or not by incubation with FCA in MBH and NH. Conclusion: Astrocytes play a role in hyperosmolality-induced hormonal and behavioral regulation. Their metabolic integrity is crucial for neuronal homeostatic regulation.

Title: Impact of aquaporin-4 deletion on cortical spreading depression in awake mice

Authors: *R. ENGER[1], D. B. DUKEFOSS[1], W. TANG[1], K. H. PETTERSEN[1], D. M. BJØRNSTAD[1], P. J. HELM[1], V. JENSEN[1], R. SPRENGEL[2], K. VERVAEKE[1], O. P. OTTERSEN[1], E. A. NAGELHUS[1];
[1]Univ. of Oslo, Oslo, Norway; [2]Max Planck Inst. for Med. Res., Heidelberg, Germany

Abstract: Cortical spreading depression (CSD) is a phenomenon that gravely disrupts the ion homeostasis mechanisms on which normal brain function so critically depends. Demonstrating the sequence of events triggered by CSD holds the potential of providing new insight in the pathophysiology of a range of neurological disorders as well as the physiological processes underlying normal brain function. Here, we have studied the sequential progression of CSD in awake head-fixed mice by two-photon microscopy. We have compared wildtype mice, and mice with targeted deletion of aquaporin-4 (AQP4) or the inositol 1,4,5-triphosphate receptor type 2 (IP3R2). By use of a novel combination of genetically encoded sensors that permits an unprecedented temporal and spatial resolution we show that CSD leads to brisk Ca^{2+} signals in astrocytes and that the duration of these Ca^{2+} signals is shortened after deletion of AQP4 but not after deletion of IP3R2. The decrease of the astrocytic, AQP4 dependent Ca^{2+} signals coincides in time and space with a decrease in the duration of extracellular glutamate overflow. Our results suggest that in CSD, the glutamate accumulation in the extracellular space is extended through AQP4 dependent glutamate release from astrocytes. The present data point to a salient glial contribution to CSD and identifies AQP4 as a new target for therapy.

Title: Neuronal exosomal mir-124 upregulates astrocytic GLT1 by suppressing GLT1 mrna-binding micrornas

Authors: *J. M. YELICK, S. SEO, E. BROWN, Y. YANG;
Tufts Univ., Boston, MA

Abstract: Neuron to astrocyte signaling is essential for functional tripartite synapses in the mammalian central nervous system. Emerging evidence has shown that microRNAs are sorted into exosomes, delivered to the extracellular space, and internalized by other cells as an important mechanism of intercellular communication. Previous studies in our lab have shown that neuronal cultures secrete exosomes which contain multiple microRNAs, particularly microRNA-124 (miR-124). We further found that these exosomes significantly up-regulate glutamate transporter GLT1 protein expression in miR-124-dependent manner. In this current study we found that upon injecting fluorescently labeled microRNAs into the mouse sciatic nerve, miR-124 is specifically and actively transported into astrocytes from spinal motor neurons, as compared to c. elegans miR-709 control. In addition, we observed widespread expression of eGFP-tagged CD63, a surface marker on exosomes in our newly developed cre-dependent CD63-eGFP exosome reporter mice, indicating the presence of cell-type specific exosomes in an intact central nervous system.
To identify microRNAs that directly inhibit GLT1 expression, we bioinformatically analyzed microRNAs that were predicted to bind to the 3' untranslated region (UTR) of GLT1 mRNA. We also examined expression level of these microRNAs in cultured cortical astrocytes and astrocytes isolated from the BAC ALDH1L1-eGFP reporter mouse line using AffymetrixTM microRNA array and qRT-PCR. We further found that several of these microRNAs significantly decrease protein expression of GLT1 in cultured astrocytes. Interestingly, these microRNAs are also down-regulated by transferred miR-124, which also suppresses the inhibitory effect of these microRNAs on GLT1 expression. Together, our results have identified new microRNAs that are involved in GLT1 expression regulation, as well as characterized a novel exosome-mediated communication pathway from neurons to astrocytes *in vivo*.

Abstract: **Background:** Major Depressive Disorder (MDD) is a common medical impairment associated with a huge economic problem in the public health. Recently, astrocytic abnormality has been related to MDD. Astrocytes are likely to have an important role in modulating the excitatory glutamatergic synapses in the hippocampus, which is one of the core brain regions of depression. Ketamine is known as a novel glutamatergic antidepressant drug, with a rapid (within hours) effect, therefore, it is important to unravel rapid effect of ketamine on the alteration in the hippocampal vasculature and astroglial plasticity. In this context, we examined the morphological alteration of astrocytes and microvessels in the hippocampus of genetic rat model of depression.
Methods: Adult male Flinders Sensitive Line (a highly validated genetic animal model of depression) and Flinders Resistant Line rats as control group received a single injection of ketamine (15 mg/kg) or saline intraperitoneally one day before transcardial perfusion. Assessment of depressive-like behavior of animals was performed with the forced swim test (FST) was 30 minutes before perfusion-fixation. Investigation of morphological alteration of hippocampal astrocytes was done on glial fibrillary acid protein (GFAP) stained sections of hippocampus. Quantitative measurement of hippocampal microvasculature was done by applying global spatial sampling method.
Results: The FST showed significant rapid antidepressant like effect of ketamine in FSL rats one day after treatment by showing remarkable reduction in immobility time in comparison with FSL-vehicle group ($p<0.05$). In the hippocampus the size of the astrocytes enhanced significantly in the subregions (CA1.stratum radiatum and molecular layer of DG) ($p<0.05$). Moreover, the

analysis of the astrocytes branches complexity indicated significant positive rapid effect of ketamine on the astrocytic arborization in both FSL and FRL rats one day after injection. In addition to the morphological changes of astrocytes, ketamine had a rapid protective effect on the vascular structure of hippocampus by significant increasing in the total length of microvessels one day after treatment in FSL rats ($p<0.05$).
Conclusion: These data suggest that morphological changes of astrocytes and microvessels in the hippocampus are associated with the rapid antidepressant effect of ketamine and astroglial changes as well as vascular alteration of hippocampus respond rapidly to a single dose of ketamine injection.

Title: Structure-activity relationship study of lactate derivatives and their ability to evoke norepinephrine release in locus coeruleus

Authors: *V. MOSIENKO, D. JANE, S. KASPAROV, A. G. TESCHEMACHER;
Univ. of Bristol, Bristol, United Kingdom

Abstract: Astrocytes serve as main source of L-lactate (LL) which they synthetize through the glycolytic pathway from glucose or stored glycogen. According to the 'lactate shuttle' hypothesis, LL released by astrocytes is taken up by the neurons where it is used as a metabolic substrate. In addition, there is a large body of evidence supporting the hypothesis that LL has a signalling role in the brain. Previously, we demonstrated that bath application of LL or optogenetic stimulation of astrocytes excite noradrenergic neurons and stimulate norepinephrine (NE) release in locus coeruleus (LC) *in vitro*. These effects of LL were concentration-dependent, did not require its import into neurons, and were blocked by D-lactate (DL) and inhibitors of cAMP-dependent signalling. Altogether, our data pointed to the existence of a yet unknown excitatory G-protein coupled receptor (GPCR) for LL. To characterise the pharmacological

profile of this potential GPCR we performed structure-activity studies with LL derivatives while monitoring NE release. We tested compounds in which the potential active moieties of LL were systematically replaced by different functional residues. NE release *in vitro* was monitored using cell-based neurotransmitter fluorescent engineered reporter cells (CNiFERs) which express α1 adrenoceptors and TN-XXL, a FRET-based recombinant $[Ca^{2+}]i$ indicator (Muller et al., 2014). When seeded on organotypic brain slices containing the LC region, fluctuation of NE release upon stimulation by LL and its analogues could be detected by a rise in $[Ca^{2+}]i$ in the CNiFERs. We found that α-hydroxyisobutyric acid was equipotent to LL, and its effect was blocked by DL. However, neither (S)-(+)-mandelic acid nor (L)-(-)-phenyllactic acid were able to evoke NA release. This suggests, that the methyl group alpha to the carboxylic acid group of LL might participate in the interaction with the putative LL receptor. (-)-Methyl-L-lactate was without effect, while 2-hydroxy-2-propanesulfonic acid had a similar action to LL, and this effect was blocked by DL. These data suggest that the carboxyl group has to be in ionized form in order to interact with the receptor, however it can be mimicked by a sulfonic acid. L-Alanine, L- or D-serine did not evoke NE release, while (S)-(-)-2-methoxypropionic acid had a similar effect to LL, which was blocked by DL. These data suggest that the hydroxyl group in LL acts as a hydrogen bond acceptor but hydrogen bond donation is not necessary, and that an amino group cannot substitute for the hydroxyl group. These experiments will help to devise the molecular nature of the putative LL receptor and identify molecular determinants needed for LL binding to it.

Title: Human astrocyte complexity and function recapitulates in a novel three dimensional neuron coculture system

Authors: *R. KRENCIK[1], K. SEO[1], J. VAN ASPEREN[1], M. E. WARD[3], D. H. ROWITCH[2], E. M. ULLIAN[1];
[1]Ophthalmology, [2]Pediatrics, Univ. of California - San Francisco, San Francisco, CA; [3]Natl. Inst. of Neurolog. Disorders and Stroke, Bethesda, MD

Abstract: There is an essential need for an improved *in vitro* model of the complex human brain environment. To overcome this barrier, we have optimized a three dimensional organoid coculture system consisting of induced pluripotent stem cell (iPSC)-derived astroglial and neuronal subtypes genetically engineered for inducible expression of transcription factors. This system addresses the fact that human astrocytes have unique and complex characteristics that are not recapitulated in non-human cellular models or two dimensional cultures. We are using this system to ask several questions such as 1) what cell-cell interactions are necessary to induce structurally complex human astrocytes, 2) what intrinsic mechanisms are at play that give human astrocytes their unique characteristics and 3) what conserved and unique functional characteristics are present in human astrocytes. Recently, we have used iPSC approaches as a model for human astrocytes to comprehend this cellular complexity in normal development and in the context of neuropathology, and we now utilize this improved system for more in depth studies of astrocyte function and dysfunction in disease. Finally, to determine functional diversity of human astrocyte subtypes involved in providing signals to neurons, we used this system to obtain gene expression signatures of human astroglial progenitors regionally patterned *in vitro* and are investigating how this diversity supports regionally-matched neurons. By harmonizing human neurons with a more appropriate experimental environment, we have begun to identify critical signals that human astrocytes contribute towards human neuron circuit homeostasis in development and disease.

Title: Characterization of glia calcium signaling in the regulation of neuronal excitability

Authors: *Y. V. ZHANG, J. T. LITTLETON;
Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: Alterations in neuronal excitability can lead to severe neurological disorders like epilepsy. Studies in recent years have begun to reveal the essential role of glia in modulating the function of neural circuits. Previous work in our lab identified Zydeco (Zyd), a cortex glial potassium-dependent sodium calcium exchanger (NCKX), as a critical regulator of acute neural excitability in *Drosophila*. Mutations in *zyd* predispose flies to temperature-sensitive seizures and result in neuronal hyperexcitability at elevated temperatures. Meanwhile, near-membrane microdomain calcium transients found in wildtype cortex glia are abolished in *zyd* mutants, which instead show elevated intracellular glial calcium levels. These observations suggest a calcium-dependent cortex glia-to-neuron signaling cascade acutely regulates neuroexcitability in the *Drosophila* CNS. Characterizing this signaling cascade will greatly contribute to our understanding of how glia and neurons work in concert to maintain normal function of the nervous system. To further define this pathway, we performed an RNAi screen to knock down candidate genes in the *zyd* background using the pan-glial repo-Gal4 driver. Interestingly, we identified many seizure suppressors from the screen that were required in astrocyte-like glia instead of cortex glia, where the Zyd protein acts. This unexpected observation indicates that astrocyte-like glia function to propagate seizure-like activity that arises from a primary defect in cortex glial function. As such, both cortex glia and astrocyte-like glia play critical roles in regulating neuronal excitability in response to seizure-inducing signals arising from elevated calcium within cortex glia. We will present current progress in these studies in an effort to identify the mechanisms that distinct glia subtypes use to regulate neuronal function and excitability.

Title: Role of soluble adenylate cyclase in reactive astrocytes

Authors: *E. G. CAMERON[1], J. GALVAO[1], C. R. DOUGLAS[2], R. LODHAVIA[2], J. L. GOLDBERG[1];
[1]Ophthalmology, Stanford Univ., Palo Alto, CA; [2]UCSD, San Diego, CA

Abstract: In response to CNS injury or degeneration, astrocytes undergo a process referred to as reactive astrogliosis that leads to changes in tissue architecture and function. Cyclic-AMP (cAMP) has been demonstrated to play a significant role in regulating astrocyte physiology including glutamate uptake, glucose metabolism, differentiation and cytoskeletal remodeling. The extent to which cAMP signaling in astrocytes contributes to such features of reactive astrogliosis *in vivo*, however, remains a promising area of study. In mammals, cAMP is synthesized by a family of transmembrane adenylyl cyclases (tmACs) and by a bicarbonate- and calcium-sensitive soluble AC (sAC). In contrast to tmACs, sAC is insensitive to G-proteins and localizes in the cytoplasm and sub-cellular compartments. sAC promotes proliferation in cancer cells and recently was found to be a critical regulator of transendothelial migration. Moreover, sAC is highly expressed in astrocytes and underlies a key metabolic pathway that shuttles lactate to neurons in response to electrical activity or aglycemic conditions. Reactive astrocytes rapidly proliferate to form a glial scar that sequesters damaged tissue and may promote axon regeneration. Does sAC regulate proliferation and migration in astrocytes during reactive astrogliosis and scar formation? Is sAC-mediated metabolic coupling between astrocytes and neurons stimulated or inhibited by CNS injury? Here, we report that sAC is a key regulator of astrocyte migration and proliferation *in vitro* and characterize the effect of sAC KO on astrocyte reactivity and neuronal survival, *in vivo*. Using an *in vitro* scratch assay, we found that pharmacological inhibition of sAC (with KH7 and 2-HE) suppresses astrocyte proliferation and migration in a concentration-dependent manner. siRNA-mediated knockdown of sAC also inhibited astrocyte migration and reduced proliferation, supporting the hypothesis that these processes are regulated by sAC. Finally, we report our preliminary findings on the effect of sAC knockout on astrocyte reactivity and RGC survival and regeneration after optic nerve crush (ONC) injury in an inducible GFAP-CreERT/sAC$^{fl/fl}$ mouse model. Together these data point towards a critical role for sAC in the glial reaction to CNS injury.

Title: Endometriosis-like lesions on peripheral tissues in the mouse induces subtle changes in spinal cord glial reactivity

Authors: *K. DODDS[1], E. A. H. BECKETT[1], S. F. EVANS[2,3], M. R. HUTCHINSON[1,4]; [1]Physiol., [2]Pharmacol., Univ. of Adelaide, Adelaide, Australia; [3]Pelvic Pain SA, Norwood, Australia; [4]ARC Ctr. for Nanoscale Biophotonics, Adelaide, Australia

Abstract: Background: Endometriosis is a female-specific chronic inflammatory condition that often manifests with severe pelvic pain. Recent studies have implicated glia and their interactions with the central nervous system ("neuro-immune communication") in facilitating persistent pain development. This has not yet been studied in the context of endometriosis. Thus, we sought to develop a minimally-invasive mouse model of disease to investigate whether peripheral endometriosis lesions can induce central spinal glial adaptations. Methods: Endometriosis (ENDO) was induced in 8-14 week-old wild-type C57BL/6 or Balb/C mice by intraperitoneal injection of syngeneic donor endometrium (15-40mg) from either the proestrus (high estrogen) or estrus (low estrogen) phase of the estrous cycle. Toll-like receptor 4 knock-out (*TLR4*$^{-/-}$) mice were also induced with endometriosis using only the permutation of 40mg proestrus donor tissue. After three weeks development, the spinal cord was removed from recipient mice and dissected into segments spanning T13-S1. Spinal sections were then processed via fluorescent immunohistochemistry for glial fibrillary acidic protein (GFAP; astrocytes) and CD11b (microglia), and images analyzed using Image J software. Results: Endometriosis-like lesions were successfully established; the extent and location of disease dependent on mouse strain, estrogen status and amount of donor material injected. Preliminary analysis of animals from robust disease conditions (proestrus 40mg tissue) indicates an increased variance in the area occupied by GFAP-immunoreactivity in the T13-L5 dorsal horn of C57BL/6 ENDO mice compared to saline-injected controls (n = 5 per group). In contrast, GFAP-immunoreactivity in Balb/C ENDO mice with endometriosis remains unchanged at this stage (n = 2 per group). Immunostaining results for CD11b in wild-type animals and all spinal glia in *TLR4*$^{-/-}$ mice will additionally be discussed. Discussion: The model described here has successfully recapitulated endometriosis-like disease in the mouse, and allowed for analysis of glial reactivity in the spinal cord. Our early data suggests that there are strain differences in the development of disease. In

addition, the altered glial reactivity observed in C57BL/6 ENDO mice may play an important role in facilitating pain development attributed to endometriotic disease.

Title: Measurement of H+ fluxes from culture rat and mouse astrocytes using self-referencing H+ selective microelectrodes

Authors: *J.-I. CHOI[1], C. GOEKE[2], M. GUIZZETTI[2], R. P. MALCHOW[3];

Abstract: pH regulation in the brain is important and even small changes in intracellular or extracellular pH influence the functions of numerous enzymes and ion channels. Activities such as extracellular glutamate removal process done by glial cells are associated with change in extracellular levels of H+, which can by itself have a potent modulatory effect on neuronal excitability and synaptic transmitter release. In the present study, we have used self-referencing H+-selective microelectrodes to examine standing levels of extracellular H+ from quiescent cortical astrocytes cultured from rats and mice and have also examined changes in the level of extracellular H+ that occur upon addition of the different neurotransmitters. Cultured astrocytes recorded in a 24 mM bicarbonate-based saline solution or1 mM HEPES buffered solution exhibit a standing acidic flux. The standing flux observed in the 1 mM HEPES condition remained when all of the extracellular sodium was replaced with choline. Application of glutamate induced a transient extracellular alkalinization, consistent with its transport into the glial cells. Application of adenosine triphosphate (ATP) induced a pronounced extracellular acidification. These results are the first to show extracellular H+ levels adjacent to isolated glial cells using self-referencing electrodes and suggest the possibility that changes in extracellular H+ by glial cells in response to the release of different neurotransmitters may play a role in modulation of activity within the nervous system. This study was funded in part by National Science Foundation Grant 0924372.

Abstract: The clonal architecture of the brain is critical to understand the mechanisms involved in the specification of neural cell types as well as to understand which aspects of the brain function emanate from its organization. We have recently showed the clonal relationship of astrocytes location in different layers of the olfactory bulb and within the rostral migratory stream (RMS), concluding that a laminar specificity of astrocyte origin and morphology may underlie different functional demands (García-Marques and López-Mascaraque, 2016). We have also revealed the clonal organization of NG2 cell progeny in the olfactory bulb derived from pallial progenitors targeted by *in utero* electroporation at E14 (García-Marques et al., 2014). However, there is some controversy related to the origin and dispersion of the olfactory bulb oligodendrocytes and NG2-glia (also named OPCs), because of their spatial and temporal progenitor locations. To unravel the origin, fate and diversity of those glial populations we performed a clonal cell analysis from single progenitors. To this end, we used the StarTrack method, based on the combinatorial expression of 12 fluorescent reporters under regulation of specific promoters (NG2, GFAP and ubiquitous) to target olfactory bulb embryonic progenitors located into the more rostral part of the ventricular surface at different developmental time-points. This method produces inheritable marks that enable the long-term *in vivo* tracing of glial progenitor lineages and their progeny. Next, we will perform a detailed clonal analysis to elaborate a map of the laminar distribution and heterogeneity of adult glial cells in the olfactory bulb, based on their ontogenic origin.

Title: Calcium response of satellite glial cells to axonal injury

Authors: *B. POLAT[1], E. N. EKMEKCIOGLU[1], T. AKGUL CAGLAR[1], K. BAYAT[2], G. OZTURK[1];
[1]Regenerative and Restorative Med. Res. Ctr. (REMER), Istanbul Medipol Univ., Istanbul, Turkey; [2]Electrical and Electronics Engin. Dept., Marmara Univ., Istanbul, Turkey

Abstract: Glial cells are known to play key physiological and pharmacological roles in maintenance of the nervous system and the characteristic response of its peripheric and central counterparts to injury. The main type of glia in sensory ganglia is the satellite glial cells (SGCs). SGCs surround individual neurons and are coupled by gap junctions. They show morphological and physiological difference from other glial types but very little research is done on this particular type of cells. Satellite glial cells are known to sense and response to nerve injury and contribute to survival and plasticity of the ganglia neurons. In this study, we observed that the SGCs respond to axonal injury of nearby neurons in terms of elevated Calcium levels.
For this purpose, dorsal root ganglia (DRGs) were dissociated and cultured on laminin coated surfaces. At 48 hours in vitro, just as the SGCs begin to migrate away from neurons, the cell population was loaded with high affinity calcium indicator and imaging was performed under physiological conditions (488nm) We utilized, a precise femtosecond laser induced single cell axotomy injury model. The experiments were repeated in presence of a chemical gap junction blocker and in absence of Calcium. Neurons with and without neighbouring SGCs were chosen for axotomy.
As expected, neurons showed increased fluorescence intensity when axotomised. Unexpectedly, SGCs responded to the injury of neigbouring neuron in terms of a burst of elevated calcium levels. We observed that the neurons with SGCs shown less Calcium increase and this increase dissipated sooner than the standalone neurons. In presence gap junction blocker, aforementioned calcium increase in satellite glial cells was decreased. Same experimental procedure was conducted in a Ca free environment and all calcium activity was absent.
These results briefly show that neighboring SGCs respond to neural injury by means of elevated calcium levels and this interrelation may be regulated via gap-junction coupling. The external calcium is used for this buffering system. We argue that this pattern of Calcium elevation in SGCs may be crucial for maintaining in-ganglia homoestasis as part of an injury response mechanism.

Title: The effect of induced hyperglycemia on the dorsal root ganglia and sensory nerves in zebrafish

Authors: *H. ENNERFELT, J. CLARK;
Biol. Dept., Salisbury Univ., Salisbury, MD

Abstract: Diabetic peripheral neuropathy (DPN) is characterized by disrupted sensory signaling, the cost of which is rising sharply as the prevalence of diabetes mellitus increases exponentially. Patients with DPN often present with sensory system abnormalities that range from pain to loss of sensation. Although prevalent in diabetic humans, the molecular mechanisms behind DPN are unclear due to experimental limitations. Zebrafish are well suited for vertebrate research due to their similar physiology to humans, fecundity, and transparency that allows for direct visualization of fluorescent genes. Zebrafish have been used to study diabetic conditions such as retinopathy, nephropathy, and delayed wound healing. However, less is known about the health of peripheral nerves of hyperglycemic zebrafish. Therefore, in this study zebrafish are being used to study the effects of hyperglycemia on peripheral nerves hypothesized to be associated with DPN. To assure us that hyperglycemia is indeed being induced in the zebrafish, expression of the gene encoding insulin (*ins*) is examined using rt-qPCR. Using an established protocol to induce the zebrafish into a hyperglycemic state, we then examine the sensory neurons in the dorsal root ganglia (DRG). Following the induction of hyperglycemia in the zebrafish, our results suggest a number of sensory neurons migrate away from the DRG. In addition, there is apparent axonal defasciculation and blebbing in response to this metabolic change. Characterizing the response of peripheral nerve components in a hyperglycemic state may allow us to extend our work to determine the molecular mechanisms responsible for the breakdown of this important structure.

Title: Glutamate dependent translational control in cultured bergman glia cells

Authors: R. TIBURCIO-FELIX[1], S. ZINKER-RUZAL[2], M. FLORES-MÉNDEZ[2], *E. SUAREZ[3], A. ORTEGA[4];
[1]Genet., Cinvestav, Ciudad de Mexico, Mexico; [2]Genet., [4]Toxicology, [3]Cinvestav, Ciudad DE Mexico, Mexico

Abstract: GLUTAMATE-DEPENDENT TRANSLATIONAL CONTROL IN CULTURED BERGMAN GLIA CELLS
The amino acid L-glutamate (Glu) is considered to be the major mediator of excitatory signals in the Central Nervous System and is probably involved in most aspects of normal brain function including cognition, memory and learning. It also plays a major role in the development, including synapse induction and elimination, cell migration, differentiation and death. Most neurons, and even glial cells express glutamate receptors in their plasma membrane. Previously, we showed that Glu decreases [^{35}S]-Met incorporation into newly synthetized polypeptides in chick cerebellum cultured Bergmann glia cells (BGC) treated with 1 mM Glu for 15 min. After 30 min, [^{35}S]-Met incorporation has a slow recovery and after 2 h reaches normal levels. Furthermore, Glu responses are mediated by AMPA receptor activation, causing MAPK and mTOR signaling pathways activation. Accodingly, the rpS6 (ribosomal protein S6) is phosphorylated causing an increasing in translation. One important enzyme for Glu recycling is Glutamine (Gln) synthetase (GS) due to its ability to transform Glu to Glutamine as part of the so called *Glu/Gln shuttle*. In order to clarify the transient Glu effect on protein synthesis, we decided to isolate ribosomal fractions from control or Glu treated cells. To this end, a ribosomal profile was prepared by spinning the cell extracts through a continuous 15-50% sucrose gradient. The 40S, 60S, 80S and the polysomal fractions were isolated and the protein of each fraction was analyzed *via* western blots with anti rpS6 and anti p-rpS6 abs. An increase in rpS6 phosphorylation was detected in the 80S and polysomal fraction of Glu-treated cells for 15 and 30 min. We also detected a 15 min decrease of GS mRNA of GS in Glu treated cells but an increase after 30 min Glu.
These results favor the notion of a critical involvement of Glu signaling in the regulation of the

glial protein *repertoire* through the selective translation of specific mRNAs. A role of rpS6 phosphorylation is also suggested.

Title: Breast milk induced microchimerism in the brain

Authors: *M. S. AYDIN[1], E. EKMEKCIOGLU[2], E. VATANDASLAR[2], G. OZTURK[3], E. ERDOGAN[4], T. MUDOK[3];
[1]Fac. of Medicine, Dept. Histology and Embryology, Bezmialem Vakif Univ., Istanbul, Turkey; [2]Grad. Sch. of Hlth. Sci., [3]Intl. Sch. of Med., Istanbul Medipol Univ., Istanbul, Turkey; [4]Sch. of Med., Selcuk Univ., Konya, Turkey

Abstract: Microchimerism is the presence of cells of an individual in another genetically different host without inducing an immune response. It most commonly occurs between the mother and the offspring during pregnancy. Fetal cells cause fetal cell microchimerism by entering the maternal circulation through the placenta during the pregnancy while the passage of maternal cells to offspring is called maternal microchimerism. Transfer of maternal cells to the offspring through breast milk is also possible and this is defined as breast milk induced maternal microchimerism.
In this study, we aim to identify the cells that pass from mother to the central nervous system of the offspring during breastfeeding and characterize phenotypic features and the differentiation patterns of these.
The basic experimental paradigm of the study was to let green fluorescent protein expressing (GFP+) transgenic female mice breastfeed wildtype pups and to track GFP+ cells mainly in their nervous tissue. Immunohistochemistry, flow cytometry and PCR techniques were used to this end.
We detected GFP+ chimeric cells of the foster mother in the brain as well as in many other

organs of the pups at postnatal 7th day. We also demonstrated that many of these cells differentiate into glial cells.
The maternal microchimerism through breastmilk is a novel concept and it may have significant implications in the normal functioning and pathological processes of the nervous system.

Title: Gene expression changes during brain regeneration in adult zebrafish

Authors: *K. PALSAMY, J. PARENT;
Neurology, Univ. of Michigan Med. Ctr., Ann Arbor, MI

Abstract: In the mammalian brain, neural stem cells and neurogenesis persist into adulthood mainly in the subependymal zone-olfactory bulb pathway and hippocampal formation. Adult neurogenesis is proposed to play an important role in learning and memory, but it also offers the potential for replacing injured or diseased brain tissues through regeneration by neural stem cells. Despite the persistence of neurogenesis, mammals have limited brain regenerative capacity. Zebrafish, however, display robust regeneration in many different brain regions and can make mature, functional neurons after injury. We use adult zebrafish to explore the molecular networks induced by traumatic brain injury and quinolinic acid (QA)-induced neurotoxicity. We performed RNA sequencing on telencephalic tissue collected 24 or 48 hours after brain injury, with or without QA lesioning, and identified many interesting candidate genes involved in various biological processes. Our gene ontology and pathway analysis study confirms upregulation of immune response, tissue regeneration, wound healing, cell migration, angiogenesis processes, and Jak-Stat, interleukins, inflammatory-induced chemokines and cytokines, notch, and B cell and T cell activation pathways respectively. Based upon expression level changes and their known roles in neuroprotection or stem cell function, we selected a few candidate genes to explore for their potential involvement in brain regeneration. We first confirmed the RNAseq expression changes of the candidates after injury using real-time RT-PCR. Work is ongoing to examine cellular expression changes by in situ hybridization, and to

generate loss-of-function models to examine how alterations in the candidate genes influence brain injury and the regenerative process. We are also using the QA excitotoxicity model in mouse striatal lesioning with the goal of comparing gene expression changes with the zebrafish model. Our eventual aim is to shed light on mechanisms underlying the limited regenerative capacity of the mouse brain with the goal of improving brain repair.

Title: Hdac5 upregulation in retinal ganglion cells promotes optic nerve regeneration

Authors: *D. W. PITATHOMAS[1], Y. OH[2], V. CAVALLI[2];
[1]Neurosci., Washington university, Saint Louis, MO; [2]Washington university, St louis, MO

Abstract: Injuries in the optic nerve caused by ischemic optic neuropathy or glaucoma are followed by retinal ganglion cell (RGC) axon degeneration and cell death, and result in permanent visual function loss. In contrast, sensory neurons in dorsal root ganglion (DRG) are able to regenerate their axon following injury. This is partly due to their ability to activate an intrinsic pro-regenerative response. We have previously demonstrated a role for histone deacetylase 5 (HDAC5) in DRG axon regeneration. After sciatic nerve injury, HDAC5 leaves the nucleus to allow for the expression of pro-regenerative genes, and accumulates at the axon tip, to deacetylate tubulin. Both steps are important to stimulate axon regeneration. Here, we studied the role HDAC5 in RGC response to injury. We found that, in contrast to DRG neurons, HDAC5 is localized exclusively in the RGC cytoplasm and is insensitive to the canonical signaling pathways that regulate its nuclear localization in DRG neurons and other cell types. This rules out a major epigenetic role for HDAC5 in RGCs and rather suggests that HDAC5 plays a role in the cytoplasm. Similar to what we observed in injured sciatic nerve, optic nerve

injury led to a decrease in acetylated tubulin levels at the injury site. However, HDAC5 did not accumulate in injured optic nerve. We then tested whether increasing the levels of HDAC5 in RGC axons would improve axon regeneration. We expressed a cytoplasmic HDAC5 mutant, which localized to RGC axons, and observed that the number of regenerating axons beyond the optic nerve injury site doubled compared to control. We are currently testing whether HDAC5 has specific interacting partners and deacetylation targets in the axon that contribute to stimulate axon regeneration. These results suggest that increasing HDAC5 levels in the optic nerve can be exploited to promote axon regeneration

Title: Muscarinic M_3 receptor signaling inhibits differentiation and myelin repair by mouse and human oligodendrocyte progenitors.

Authors: ***J. J. POLANCO**, R. R. WELLIVER, Z. M. KHAKU, M. A. O'BARA, F. J. SIM; Pharmacol. & Toxicology, Univ. At Buffalo, Buffalo, NY

Abstract: Recent studies have identified anti-muscarinic drugs as potent modulators of oligodendrocyte differentiation and myelination, however the precise muscarinic receptor subtype signaling have not determined. Based on the high relative expression of muscarinic acetylcholine receptor subtype 3 (M_3R) in human oligodendrocyte progenitor cells (OPCs) and functional pharmacological analysis in rodent OPCs, we hypothesized that M_3R signaling acts to inhibit OPC differentiation. In this study, we investigated the role of M_3R in both rodent and human OPCs. In human primary PDGFRα/CD140a$^+$ OPCs, lentiviral shRNAi knockdown of M_3R increased O4$^+$ oligodendrocyte differentiation and myelin protein expression (MBP) mRNA *in-vitro*, relative to scrambled controls. Importantly, M_3R-knockdown in human OPCs increased oligodendrocyte differentiation and MBP$^+$ myelin following transplantation into hypomyelinated

shiverer/*rag2* mice at 12 weeks after engraftment. Next, to study the role of M_3R in myelin repair, we conditionally deleted M_3R in $NG2^+$ OPC using Ng2-CreER:$M3R^{fl/fl}$ mice and induced demyelination in adult mouse spinal cord by injection of lysolecithin. M_3R deletion in adult OPCs resulted in significantly increased oligodendrocyte density as determined by both *Plp1 in-situ* hybridization and CC1 immunostaining. The rate and number of recruited OPCs was similar in tamoxifen and oil-injected control animals, indicating that the effect of M_3R deletion was primarily on induced differentiation. These results indicate that M_3R signaling is a species-conserved inhibitor of OPC and oligodendrocyte differentiation that may be specifically targeted to improve both endogenous and transplant-mediated myelin repair.

Title: Shh signaling mediates complete retina regeneration through the activation of stem/progenitor cells located in the ciliary margin.

Authors: J. DI NAPOLI[1], C. OLMOS CARREÑO[1], L. FIORE[1], M. MEDORI[1], L. R. TERUEL[1], V. SANCHEZ[1], K. DEL RIO-TSONIS[2], *G. E. SCICOLONE[1];

Abstract: Retina regeneration in the embryonic chick can occur through two distinct pathways: 1) by retinal pigmented epithelium (RPE) transdifferentiation or 2) by the activation of stem/progenitor cells located in the ciliary margin (CM).
In chicks, retina regeneration is only possible during the fourth day of development (E4) and when it is stimulated by growth factors. Fibroblast growth factor 2 (FGF2) stimulates transdifferentiation and activation of stem/progenitor cells from the CM, whereas sonic hedgehog (Shh) induces activation of stem/progenitor cells from the CM.
RPE transdifferentiation produces an inverted retina without RPE, whereas regeneration from the

CM produces a normally oriented and laminated retina. Obtaining this last form of regeneration is the goal of any regenerative strategy.
The central aim of this work was to evaluate which treatment presented the highest efficacy to produce a complete retina along all its tangential extension. The Shh pathway and its analog activator SAG were evaluated for their potential to induce complete retina regeneration from the stem/progenitor cells of the CM.
After retinal removal at E4, we tested different treatments to evaluate retinal regeneration: FGF2 and RCAS-Shh or SAG alone or in combination with FGF2 were added to induce retinal regeneration.
We showed that the activation of the canonical Shh pathway induced by SAG produced the highest efficacy of complete retinal regeneration through the activation of stem/progenitor cells of the CM (100% of embryos) *in vivo.* We also showed that the retinal ganglion cells from this regenerated retina have positional information, as they expressed the Eph/ephrin system in a gradient similar to the retinas during development.
These results increase the probability of obtaining an efferent system that establishes a topographic order of connections in the tectum.
Retina stem/progenitor cells exist in other species, including humans. Thus, our findings provide insights on how retinal stem cells can be activated for possible regenerative therapies.

Title: Combinatorial transcription factor treatments to promote axon outgrowth in CNS neurons

Authors: *I. VENKATESH, M. SIMPSON, B. CALLIF, Z. WANG, M. BLACKMORE; Dept. of Biomed. Sci., Marquette Univ., Milwaukee, WI

Abstract: Developing neurons and peripheral neurons show a robust ability to regenerate axons following nerve injury. This is in part due to their intrinsic capacity to successfully re-activate

transcriptional networks supportive of re-growth. In contrast, injured mature CNS neurons fail to induce appropriate regeneration-associated genes (RAGs) resulting in abortive growth. We and others have shown that forced expression of transcription factors (TFs) can promote axon outgrowth in response to CNS injury, highlighting a promising strategy for therapeutic intervention. To build on this success, there is a need to identify molecular manipulations to enhance the efficacy of pro-regenerative TFs. An emerging idea in regeneration research is that regeneration depends on networks of interacting transcription factors, and that co-expression of multiple factors may be necessary to fully restore regenerative potential. We are taking a two-pronged strategy to test this idea. First, because AP-1 factors have been widely implicated in axon growth and are known to work interactively, we systematically over-expressed combinations of AP1 factors JUN, ATF3 and FOS in assays of neurite outgrowth in postnatal CNS neurons. Consistent with previous results, overexpression of JUN reliably increased neurite lengths. Interestingly, unlike recent results in peripheral neurons, we observed no synergistic effects of AP1 factor co-expression on neurite outgrowth. Immunohistochemistry indicated that even as cortical neurons extend neurites, basal levels of AP1 factors including JUN and ATF3 are highly variable and undetectable in many cells. Consistent with this, CRISPR-based knockdown of JUN minimally affected neurite outgrowth. These data hint at differences in the transcriptional regulation of axon growth in CNS neurons compared to DRG neurons. In ongoing work, we are taking a systems biology based approach to map the transcriptional landscape as CNS neurons age, to identify genome-wide changes in transcriptional networks that could underlie the age-related decline in CNS neuronal regenerative capacity. Future experiments will validate predicted networks through combinatorial overexpression and knockdown of hub TFs in assays of neurite outgrowth. Overall this research is expected to identify novel transcriptional regulatory codes that can be manipulated to increase axon regeneration following CNS injury.

Title: Remyelination and the Gut Microbiome

Authors: *C. MCMURRAN[1], O. ZIDON[1], Y. DOMBROWSKI[2], D. C. FITZGERALD[2], R. J. M. FRANKLIN[1];
[1]Wellcome Trust-MRC Cambridge Stem Cell Inst., Cambridge, United Kingdom; [2]Sch. of Medicine, Dent. and Biomed. Sci., Belfast, United Kingdom

Abstract: Across a range of tissues and species, regenerative processes are intimately linked to the innate immune system, which is in turn influenced by microbes in the gut.
After demyelination, the restoration of myelin sheaths depends upon infiltrating macrophages and their CNS-resident counterparts, microglia, which phagocytose debris and secrete growth factors. The normal functions of these innate immune cells depend on a healthy microbiome. Our hypothesis ties these two concepts together, and asks whether the gut microbiome can influence the efficiency of remyelination.
We have used a model in which mice are treated with high-dose antibiotics to deplete gut microbes, before stereotactic injection of lysolecithin to cause demyelination. Antibiotic treatment causes a depletion in oligodendrocyte progenitor cell differentiation in response to this. Future work will make use of germ-free mice to investigate whether this effect is mediated by the gut microbiome.

Title: Neural anatomical and synaptic changes observed following CNS injury that underlie functional plasticity displayed in a regenerating annelid model system.

Authors: *V. G. MARTINEZ ACOSTA;
Biol., Univ. of the Incarnate Word, San Antonio, TX

Abstract: Recent studies in the regenerating model system, *Lumbriculus variegatus*, suggest functional recovery following nerve injury may be mediated by the release of inhibition on synaptic connections that are already in existence along the body axis and that increasing

neuronal activity further stabilizes the dominant connection in an anterior-posterior specific manner (Lybrand and Zoran, 2012). To further develop this hypothesis, this study characterizes changes in neural architecture occurring at the synaptic level that would allow for rapid adjustments in motor function during regeneration. Transmission electron micrographs of regenerating and non-regenerating worm fragments are compared. Similar to architecture identified in other oligochaete worms (Jamieson, 1981; Zoran et al., 1988), giant fiber collaterals protrude through the myelin-like sheathing of the giant axons. Collaterals of the medial giant fiber in both anterior and posterior body segments contained clusters of small translucent synaptic vesicles, which were localized to the lateral edges of the protruding processes. These synaptic vesicle clusters likely represent interneuronal synaptic outputs to escape motor reflex pathways (Drewes, 1984). Intermediate giant fibers (IGFs), which are unmyelinated, are located in bundles just below the larger giant fiber axons within neuropile. Extensive chemical synaptic contacts were observed terminating onto the IGFs. These synaptic terminals were associated with plasma membrane thickenings, reminiscent of pre- and postsynaptic densities, and contained predominately small translucent vesicles, along with some dense core vesicles. Confocal analysis of regenerating and non-regenerating worms also revealed the presence of extensive serotonergic fibers within the neuropile. Peripheral neurons, which extend out into the musculature around the segment are also positively labeled with antibodies for serotonin. Using both TEM and confocal micrographs of wound blastemal and regenerating tissue, we will construct a more detailed map of the neuroanatomical changes that occur along the sensory-interneuronal and interneuronal to motor boundaries.

Title: Semaphorins limit axon regeneration after spinal cord injury

Authors: *Y. UENO, M. UENO, J. NIEHAUS, Q. R. LU, Y. YOSHIDA;
Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH

Abstract: Axon regeneration is limited in the central nervous system, which hinders reconstruction of functional circuit and recovery after spinal cord injury (SCI). Although multiple extrinsic molecules have been identified to inhibit axon regeneration, roles of semaphorin
family, one of major classes of repulsive axon guidance molecule, have not been thoroughly explored yet. We first found that expressions of a series of semaphorins (Sema3d, 4c, 4d, 5a, and 6d) were increased in $Olig2^{+}$ cells after SCI. Genetic deletion of
semaphorin ligands (Sema5a, 6d) or their receptors (Neuropilin1, PlexinA1) enhanced regeneration or reduced dieback of descending corticospinal and raphespinal axons. Chromatin immunoprecipitation sequencing (ChIP-seq) revealed that the basic-helix-loop-helix (bHLH) transcription factor Olig2 and Brg1, an ATP dependent chromatin remodeling enzyme, bound to enhancer regions of these semaphorin genes, suggesting that they are the key transcription regulators creating inhibitory environment. Our results highlight a novel molecular system inhibiting axon regeneration.

Abstract: Identifying molecular regulators of optic nerve degeneration and regeneration in response to injury and disease remains a critical step in preventing loss of vision and stimulating regeneration. In glaucoma, the leading cause of irreversible blindness worldwide, global proteome changes have been observed but not quantified with high temporal resolution. Here we undertook to understand how RGCs respond to axon injuries such as those that occur after optic nerve crush (ONC) or in response to elevated intraocular pressure, specifically examining protein synthesis and transport down their axons in the optic nerve. In particular, we hypothesize that identifying proteins that are newly translated in the retina after injury will allow us to dissect the proteomic response to pathologies. We used intravitreal injections of the non-canonical amino acid azidohomoalanine (AHA), which is incorporated in place of methionine during protein synthesis, and NHS-biotin, which binds to available lysine side-groups, combined with a novel quantitative mass spectrometry pipeline based on the DiDBiT protocol to detect biotinylated proteins (Schiapparelli et al, 2014, McClatchy et al, 2015) after optic nerve crush (ONC) in adult rats. We identified ~300 proteins from RGC axons whose transport down the optic nerve decreased after ONC, and ~30 whose transport increased, out of 500 RGC-tagged proteins detected in the optic nerve 12 hours following axon injury. We identified ~30 retinal proteins whose synthesis significantly increased within 27 hours after ONC out of ~400 quantifiable retinal proteins synthesized in the 27 hour window overall. Extending this methodology to glaucomatous injury will allow us to identify and quantify differentially translated and transported proteins in RGCs in the context of specific disease models, a key step in developing mechanistically-guided approaches to novel treatments.

Title: Influence of altered DNA methylation on axon growth capacity following preconditioning peripheral nerve injury

Authors: *H. SHIN[1], K. KIM[2], M. KWON[3], B. KIM[1];
[1]Ajou University, Med. Sch., Suwon, Korea, Republic of; [2]Samsung Advanced Inst. for Hlth. Sci. and Technol., Seoul, Korea, Republic of; [3]Yale university, New haven, CT

Abstract: Although mature CNS neurons do not spontaneously regenerate injured axons, conditioning injury (CI) to the peripheral branches of DRG sensory neurons can robustly upregulate regeneration-associated genes (RAGs) and thereby enhance central axon regeneration after lesions in the spinal cord. The mechanism by which CI regulates transcriptional activation of RAGs has not been fully understood. The present study sought to determine potential influence of DNA methylation changes on the transcriptional activation of RAGs in the CI-induced regeneration model. Methylated DNA immunoprecipiation (MeDIP) was performed using DNA samples from L4-6 DRGs followed by next generation sequencing. The MeDIP-seq revealed that approximately 2000 genes were hypermethylated and a similar number of genes were demethylated after CI. However, the extent of changes in the level of DNA methylation was not correlated with gene expression levels measured by RNA-seq in most genes, including the RAGs. Interestingly, pharmacological inhibition (5-aza-2'-deoxycytidine, 5-aza) or activation (S-Adenosyl methionine, SAM) of DNA methylation significantly decreased neurite outgrowth potentials in preconditioned DRG sensory neurons. To examine effects of pharmacological perturbation of DNA methylation on RAG expression, we performed a PCR array customized for 44 RAGs reported in literature. We found that both 5-aza and SAM treatment led to robust upregulation of Socs3 and Serpine1 genes accompanied by downregulation of well-known growth promoting genes such as Gap-43 and Sprr1a. These findings suggest that alteration of global DNA methylation does have influence on enhanced axon growth potentials by preconditioning injury. However, these effects do not seem to be mediated by direct regulation of transcriptional activity of RAGs.

Title: Rewiring of sympathetic circuitry and immune suppression after spinal cord injury

Authors: ***M. UENO**[1,2], Y. UENO-NAKAMURA[1], J. NIEHAUS[1,2], P. G. POPOVICH[3], Y. YOSHIDA[1];
[1]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [2]Japan Sci. and Technol. Agency (JST), Kawaguchi, Japan; [3]The Ohio State Univ. Med. Ctr., Columbus, OH

Abstract: Spinal cord injury (SCI) at high spinal levels often causes systemic immune suppression, which renders patients more susceptible to infection. However, the underlying mechanism remains unknown. Previous study showed that exaggerated activation of autonomic reflexes suppresses immune function, which concomitantly occurs with autonomic dysreflexia. Here we investigate the neuronal substrates responsible for immune suppression. We first examine the autonomic circuits connecting to the spleen, a major immune organ, using a trans-synaptic retrograde tracer. We find that abnormal sympathetic circuits develop below the lesion, which increase excitatory spinal interneurons involved in the circuit. Chemogenetic silencing of these spinal interneurons blocks immune suppression. These data highlight a novel neurogenic mechanism of immune suppression, and provide potential therapeutic methods to treat immune deficiency frequently seen in SCI patients.

Title: Regeneration after zebrafish traumatic brain injury is dependent upon microglia

Authors: *J. Y. CHEN[1,2], K. SKAGGS[4], Y. QADEER[1], D. GOLDMAN[3], J. M. PARENT[1,2]; [1]Neurol., [2]Neurosci. Grad. Program, [3]Biol. Chem., Univ. of Michigan, Ann Arbor, MI; [4]Biol., Univ. of Findlay, Findlay, OH

Abstract: Unlike mammals, adult zebrafish are capable of virtually full restoration of damaged brain tissues after injury. This repair is characterized by the lack of glial scar formation and the ability of adult-born neurons to establish long-distance projections to the contralateral hemisphere. The remarkable regenerative capacity of zebrafish allows for exploration of the cell types and molecular pathways necessary for effective regeneration. Brain injury induces a widespread neuroinflammatory response that recruits activated microglia to damaged regions. This is followed by proliferation of telencephalic ventricular zone (VZ) radial glia, whose neural progenitor cell progeny migrate to areas of injury and give rise to new neurons - a process that is complete in roughly 21 days post lesion (dpl). We generated a right telencephalic stab lesion in adult zebrafish using a 30-gauge Hamilton syringe. To determine the role of microglia in the injury response, we ablated these cells by injecting liposomal clodronate at the time of stab lesioning. EdU pulse labeling and immunohistochemistry staining showed that clodronate significantly decreases post-injury microglia and cellular proliferation in the parenchyma, but has no effect on proliferation in the VZ where glutamine synthetase positive radial glia reside. Remarkably, we found that the loss of microglia after injury was associated with a significant decrease in regenerative potential; clodronate-treated animals displayed persistent tissue damage even at 90 dpl when compared to controls, suggesting that microglial signaling plays a key role in the regenerative process. In separate experiments, we performed RNAseq to examine a brain injury model, quinolinic acid (QA)-induced excitotoxic lesioning, with even more robust regeneration than stab wound alone. Comparing injured, with and without QA, and uninjured brains allowed us to identify stab lesion-induced altered expression of many genes, a subset of which were further upregulated in response to QA injury. We have chosen candidates known to be secreted by microglia for further analysis. These findings highlight a microglial-dependent repair mechanism in the zebrafish brain that may provide strategies for promoting mammalian brain repair.

Title: Metabolic regenerative inhibitory signaling after nerve and spinal injury

Authors: *G. KONG[1], L. ZHOU[1], I. PALMISANO[2], E. MCLACHLAN[2], R. PUTTAGUNTA[1], S. DI GIOVANNI[2];
[1]Neuroregeneration and Repair, Hertie Inst. For Clin. Brain Res., Tuebingen, Germany; [2]Med., Imperial Col. London, London, United Kingdom

Abstract: While axonal regeneration and partial functional recovery in the injured peripheral nervous system (PNS) occur, axonal regeneration fails in the central nervous system (CNS) such as after a spinal cord injury (SCI), strongly contributing to unsuccessful functional recovery. Lack of regeneration in the spinal cord can be partially enhanced by an injury to the peripheral branch (conditioning lesion) or by overexpression in DRG neurons of selected regeneration-associated genes. We hypothesize that key retrograde signaling following peripheral but not central axonal injury regulates pathways that control the regenerative phenotype. Therefore, we believe that the combined investigation of protein as well as gene expression changes in the "DRG-axonal signaling unit" after central versus peripheral nerve injury is critical to identify crucial regenerative pathways. We performed combined RNAseq from DRG and proteomics from sciatic axoplasm in mice following an equidistant sciatic or spinal cord axotomy to investigate differential molecular responses in the "DRG-axonal signaling unit". Integrated bioinformatics analysis of the RNAseq and proteomics data followed by axonal injury experimental approaches identified key regulatory metabolic mechanisms that are currently investigated to enhance axonal regeneration and recovery after spinal injury.

Title: Epigenetic and miRNA-mediated silencing of Oct4 prevents Müller glia injury-induced dedifferentiation in mammals.

Authors: *B. ESTRADA LEYVA, L. REYES-AGUIRRE, M. LAMAS;
Farmacobiología, Ctr. De Investigación Y De Estudios Avanzados De, Ciudad DE Mexico, Mexico

Abstract: Müller glia (MG), a unique glial type located in the vertebrate retina, responds to damage by becoming reactive and starting a gliosis process, or by dedifferentiating and replacing dead neurons. This regenerative capability is restricted to teleost fish and chick embryo but is notoriously absent in mammals. We have previously reported that MG *in vitro* exhibits a partial dedifferentiation after treatments with subtoxic concentrations of glutamate, but ultimately fails to fully acquire a progenitor phenotype. We have also shown that excytotoxic injury induces a transient expression of Oct4, usually found in pluripotent cells. The rapid silencing of this gene, which becomes undetectable at 24 hours post injury (hpi) suggest the presence of kinetic barriers restricting MG to its glial phenotype. These barriers are still poorly understood, but might be comprised of epigenetic mechanisms, like DNA methylation, or miRNAs-mediated translational repression. In this study, we evaluated miRNA levels in both intact and injured mice retina, and identified a significant increase in miR-145 at 24 hpi localised in MG after magnetic associated cell sorting (MACS). We also characterised the methylation profile of Oct4 and the expression levels of DNA methyltransferases (DNMTs), finding a significant increase of Dnmt3b at 24 hpi. Oct4 silencing was reverted by the injection of the DNMT-inhibitor SGI-1027, as well as by transfection of a miR-145 antagomir. These findings prove that Oct4 is silenced by a recurrent mechanism, which locks MG into its glial phenotype, preventing a successful regeneration.

Title: Retinal Zn^{2+} elevation after optic nerve injury suppresses retinal ganglion cell survival and axon regeneration: upstream mechanisms involve GLT-1 mediated glutamate efflux, NMDA receptor activation, and NO generation

Authors: *Y. LI[1,2], L. ANDEREGGEN[1], K. YUKI[1], P. A. ROSENBERG[1], L. I. BENOWITZ[1]; [1]Boston Children's Hosp. and Harvard Med. Sch., Boston, MA; [2]State Key Lab. of Ophthalmology, Zhongshan Ophthalmic Center, Sun Yat-sen Univ., Guangzhou, China

Abstract: Zinc is essential for many cellular functions but also contributes to neuronal death in hypoxic-ischemic injury and other disorders. Shortly after injury to the optic nerve (nerve crush, NC), free zinc (Zn^{2+}) increases rapidly in amacrine cell terminals within the inner plexiform layer (IPL) of the retina, whereas levels within RGCs increase more slowly. Chelating Zn^{2+} leads to enduring survival of many RGCs and extensive axon regeneration [Li et al., *SfN Abstracts* 399.19 (2014); 568.02 (2015)]. Here we explored the mechanisms underlying presynaptic Zn^{2+} accumulation. Zn^{2+} can be liberated from metallothioneins (MTs) by nitric oxide (NO), and deletion of *nos1* (which encodes NO synthase-1, NOS1) prevented both the early Zn^{2+} signal in the IPL and the delayed signal in RGCs post-NC. Zn^{2+} accumulation was likewise suppressed by intraocular injection of the NO scavenger PTIO or the NOS1 inhibitor L-NPA. NOS1 is a Ca^{2+}/calmodulin dependent enzyme, and one route through which Ca^{2+} can enter cells to activate NOS1 is via NMDA receptors. The NMDA receptor antagonist MK801 fully prevented Zn^{2+} elevation in the IPL. In the spinal cord, nerve injury causes axon depolarization and reversal of glutamate transport (Li, Stys, *Neuroscience* 107: 675-83, 2001), resulting in non-vesicular

glutamate efflux. Supporting a role for glutamate transporter-mediated extracellular glutamate accumulation, both TBOA (1 mM), a general inhibitor of glutamate transporters, and dihydrokainate (DHK, 1 mM), a selective inhibitor of GLT-1, suppressed Zn^{2+} elevation in the IPL. The NO donor DETA-NONOate restored Zn^{2+} elevation in the presence of either MK801 or TBOA, confirming that glutamate transporter reversal and NMDA receptor activation are upstream of NO-induced Zn^{2+} accumulation. Together with our previous findings, these results support a model in which optic nerve injury leads to glutamate efflux by reversal of GLT-1 mediated transport, NMDA receptor activation, NO generation via NOS1, Zn^{2+} liberation from MTs, ZnT-3-dependent loading of Zn^{2+} into synaptic vesicles of amacrine cells, and delayed accumulation of Zn^{2+} in RGCs, where it critically suppresses RGC survival and optic nerve regeneration.

Abstract: Clarification of the gene regulatory mechanisms that contribute to regenerative failure after nerve injury remains critical for the design of molecules that promote regeneration and recovery after nerve and spinal damage. While we are beginning to learn how epigenetic mechanisms control the regenerative phenotype, here, after a pharmacological screening, we identified HDAC3 as a novel central epigenetic brake to axonal regeneration. HDAC3 activity is elevated when axonal regeneration is restricted but it is reduced when regeneration occurs. Accordingly, pharmacological and genetic HDAC3 inhibition promotes axonal regeneration both in the peripheral and central nervous system in the spinal cord. Mechanistically, only regenerative peripheral injury and calcium-dependent activation of PP4 dephosphorylate HDAC3 impairing its activity, acetylating histones and the regenerative gene expression programme, as shown by ChIP and RNA-seq. Together, we propose HDAC3-dependent signalling as a brake to axonal regeneration, whose inhibition represents a novel option to foster nerve regeneration and neurological recovery.

Title: *In vivo* study of the dopaminergic neuron regeneration in amphibian model of Parkinson's disease

Authors: *J. ZAREBA-PASLAWSKA, A. SIMON, M. KIRKHAM;
Dept. of Cell and Mol. Biol., Karolinska Inst., Stockholm, Sweden

Abstract: The tremendous development in human health care and increase in quality of life has almost duplicated the human life expectancy, compare to the turn of 19th and 20th century. It has a great influence on the increased number of people suffering from age related diseases, where the most common motor neurodegenerative disease is Parkinson’s disease (PD). The preferential loss of dopaminergic (DAergic) neurons in *substantia nigra* is a key hallmark of PD. Unfortunately, despite extensive studies, PD remains an incurable disorder with unknown origin. Both, motor and non–motor symptoms are debilitating for PD patients and contribute to the decrease of their life quality and expectancy.
The successful clinical experiments using human fetal tissue grafting for PD patients has proven

the concept of applying the cell replacement therapy in PD. However, mainly ethical and practical considerations hampered usage and development of this strategy. Nevertheless, the number of studies demonstrated that the cell replacement therapy based on stem cells provides the most promising results to obtain a fully functional repair of nigrostriatal DAergic neurons. By taking step forward and recruiting brain endogenous (resident) neural stem and progenitor cells (NSPCs) into regeneration process we might significantly improve, or to some extend even replace, current stem cells therapies. The key translational gap for endogenous NSPCs strategies is our scarce knowledge about naturally occurring process of DAergic neurons regeneration.
In our studies we aim to identify molecular and/or chemical markers characteristic for DAergic neurons regeneration *in vivo*. We take the advantages of the regeneration features of anuran amphibians (frogs), which possesses remarkable ability to regenerate neuronal structures as tadpoles (larval stage), which diminishes after metamorphosis in adulthood. This phenomenon is giving us the opportunity to compare regenerative and non-regenerative phase in one organism what greatly facilitate entire analysis process.
Our validation plan includes studying process of DAergic neurons regeneration in anuran amphibians (frogs) after DAergic neurons ablation. The experiment includes monitoring of proliferation response through BrdU incorporation and immuno-labeling for the cell cycle markers. Furthermore, glial cells support requirement, in principle microglia are also analyzed. We believe that by studying naturally occurring DAergic neurons regeneration we will identify key factors involved in driving and/or inhibiting this process which can be further translate to mammalians model of PD and ultimately to patients as a treatment strategy.

Title: Identification of regenerative processes in spinal cord injury using transcriptomic data in a developmental study

Authors: *B. J. WHEATON[1], P. UMALE[2], J. SENA[2], A. SUNDARARAJAN[2], F. SCHILKEY[2], R. D. MILLER[1];
[1]Univ. of New Mexico, Albuquerque, NM; [2]Natl. Ctr. for Genome Resources, Santa Fe, NM

Abstract: Spinal cord injury (SCI) typically results in little axon regrowth and permanent loss of function after injury in adult mammals. However, spontaneous axon regeneration is possible in some species (such as the lamprey) and at certain stages of development in mammals. The biology underlying such responses is poorly understood but, given the lack of success attained by single factor treatments to date, it is likely that it involves complex interactions of genes and cells-types.

To study this phenomenon, we applied an RNA-sequencing approach to identify the gene expression profile of regenerating and non-regenerating mammalian spinal cords using the marsupial Grey short-tailed opossum (*Monodelphis domestica*). In this model predictable axon regeneration and functional recovery follows injuries made very early in development, but not following injuries made later.

Spinal cords of regenerating and non-regenerating opossums were severed, allowed to recover for 1–7 days and collected for RNA studies or histology. RNA-seq (Illumina Hi-Seq) reads were mapped to the opossum genome (MonDom5), quantified before differential expression (DE) analysis was performed. RNA sequencing allows for identification of multiple factors involved in the response to injury. However, in whole cord homogenates such as this, determining patterns in the identified genes can be challenging. Here we present our analyses using gene ontology (GO) analysis, association of DE genes with single cell-type transcriptomic datasets, and histology.

GO analysis revealed over-expression of genes involved with immune function following injuries at both ages. This involved enrichment of macrophage activation and blood coagulation genes in regenerating cords, but a much wider variety of gene classes in non-regenerating cords, including complement activation, cell adhesion and cell communication.

When the DE genes were associated with cell type data (from published single cell datasets) SCI transcriptomes suggest a complex cellular response. Regenerating animals demonstrate a rapid microglial response (eg. *C1qA*, *IL1b*, *CSF1*) accompanied by a quickly resolving astrocytic response (*Herc6*, *Tagln*, *Aqp1*) and a delayed oligodendrocyte response (*Ermn*, *Mag*, *Mog*). This is in contrast with non-regenerating animals where a rapid oligodendrocyte response and a sustained astroglial response predominate, suggesting that temporal differences in injury progression exist.

The opossum represents a unique mammalian model for the study of axon regeneration in the absence of any external manipulations and could therefore lead to the identification of intrinsic factors underlying regeneration.

Title: Regulation of mammalian axon regeneration by Lin28/let-7 pathway

Authors: *X. WANG[1,2], P. A. HALL[1,2], C. D. KATCHIS[1,2], C. LIU[3], F. ZHOU[1,2];

Abstract: Recent studies have revealed that the diminished intrinsic axon growth ability of neurons in the mature mammalian CNS, controlled by coordinated regulation of gene expression, is the major reason that they do not regenerate their axons after the injury. Epigenetic regulation is emerging to be a key cellular mechanism to control coordinated expression of gene networks, making it a potential mechanism for controlling the intrinsic axon growth ability of mature mammalian neurons. The highly conserved RNA-binding proteins Lin28a/b have been shown to be involved in variant biological processes including development, reprogramming, carcinogenesis, metabolism and tissue repair. Its role in axon regeneration, however, has never been studied. Here we report that the Lin28/let-7 axis plays an important role in regulation of axon regeneration. Specifically, we observed significant changes in expression levels of Lin28a/b and let-7a/b in mouse DRGs following sciatic nerve injury. Functionally, we found that manipulation of Lin28a/b or let-7s in DRG neurons significantly affected sensory axon regeneration both *in vitro* and *in vivo*. Our results demonstrated for the first time that Lin28 and let-7 pathways are essential for mammalian axon regeneration. We are currently investigating if manipulation of Lin28a/b and/or let-7s can promote axon regeneration in the central nervous system, and the molecular mechanisms by which these molecules regulate axon regeneration.

Title: Examining astrocytes' roles and mechanisms in regulating retinal axon regeneration and pathfinding

Authors: *M. RIBEIRO, B. J. YUNGHER, E. R. BRAY, K. K. PARK;
Dept. of Neurolog. Surgery, Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: Optic nerve injury is a hallmark feature of optic neuropathies including glaucoma, and is characterized by axon degeneration and retinal ganglion cell (RGC) death, resulting in visual impairment. Although no effective treatments are available, experimental manipulations of cellular signaling pathways by intravitreal delivery of trophic factors, such as brain-derived neurotrophic factor or ciliary neurotrophic factor and/or by targeted-deletion of certain genes, such as phosphatase and tensin homolog (*Pten*), have been shown to protect RGCs and promote axon regeneration in animal models subjected to acute axonal trauma through procedures such as optic nerve crush. Glial cells including astrocytes have biological properties that can influence neural connectivity, both structurally and functionally. Although the exact functions of astrocytes in the CNS have been controversial, some of the beneficial roles fulfilled by astrocytes include providing neurotrophic and mechanical support for the injured (and regenerating) axons. Using optic nerve crush injury, we characterize astrocytes' dual roles in i) releasing trophic factors, leading to activation of distinct signaling pathways, promoting neuronal survival and axon elongation, and ii) expressing adhesion proteins that provide physical support for the axons to extend from the optic nerve to the brain. Experimentally, we investigate the cellular sources of trophic factors in the injured optic nerve using fluorescence in situ hybridization and assess RGC axon regeneration in conditional knockout mice that delete *Stat3* or *N-cadherin* specifically in astrocytes. We report and discuss findings from these studies that are aimed at characterizing the roles of astrocytes and distinct genes in affecting RGC axon regeneration and navigation.

Title: Transcriptional profiling to discern differential retinal axon growth capacity

Authors: *E. BRAY, B. YUNGHER, K. THAKOR, M. RANDOLPH, M. DANZI, J. BIXBY, V. LEMMON, K. PARK;
Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: Optic neuropathies damage retinal ganglion cell (RGC) axons of the optic nerve, resulting in permanent visual deficits. Substantial progress has been made in our ability to promote axon regeneration following axonal injury, but regeneration remains limited to a small number of RGCs. RGCs are a heterogeneous population, with more than 30 described subtypes. Through the use of transgenic mouse lines it has been determined that an RGC's subtype may predict its regenerative capacity. The molecular mechanisms that regulate subtype dependent differences in regenerative capacity have just started to be identified. In this study we report RGCs with distinct subtype specific growth capacity. Using RNAseq we identified the transcriptional networks of regeneration competent and incompetent RGCs. These genes will serve as novel therapeutic targets to enhance the regeneration of all RGCs, a critical step towards restoring lost vision.

Abstract: The brain processes information, makes decisions, and mediates cognitive and motor outputs through the function of different types of connected neurons organized in complex arrangements. In addition, neurons in brain circuits are often intermingled with non-neuronal cells that provide physiological support. Dissecting the biochemical processes taking place in different individual cellular components of neuronal circuits in the intact animals is crucial for the understanding the biology the brain cells. Given the complex structure of most neuronal circuits, identification and characterization of cellular processes and molecular components of each cell type is extremely difficult with current methodologies. Our interests focus on identification and characterization of translation and transport of protein subpopulations in specific neuronal components from brain circuits. To reliably identify and analyze protein subpopulations according to their source (for instance, brain region, cell type and/or target area), and to obtain meaningful information about cellular processes in different components of neuronal circuits, we have developed and combined new strategies for *in-vivo* labeling, circuit tracing, and ultrastructural visualization of biotin-labeled proteins with a novel methodology for accurate identification of biotin-labeled proteins by mass spectrometry called DiDBiT (Schiapparelli et al 2014). Using these combined strategies, we were able to identify ~1000 proteins that were newly synthesized over a period of 24 hours in healthy rat retinas. In addition, we identified what we call the retina “Transportome”, specifically proteins from retinal ganglion cells (RGCs) that are transported to their major targets in brain visual areas. In detail, we detected more 500 axonally transported proteins in the optic nerve (ON) and ~250 proteins that reached either the lateral geniculate nucleus (LGN) or the superior colliculus (SC) in adult rats. The protein subpopulations detected in either LGN or SC represent in part the “Pre-synaptome” of this specific long range projection. These populations of proteins can also be visualized in axons and presynaptic terminals in ON, LGN and SC by light and electron microscopy. These experiments will allow us to compare populations of proteins transported from the retina to presynaptic terminals in different visual targets, for example the LGN and SC, and to characterize molecular components present in these different types of neuronal projections with a specificity never reported before.

Title: Neoblast specialization during regeneration of the planarian S. mediterranea nervous system.

Authors: *K. KRAVARIK, P. REDDIEN;
Biol. Department, HHMI, Whitehead Inst. for Biomed. Research, MIT, Cambridge, MA

Abstract: Planarians are well known for their ability to regenerate entire animals from small tissue fragments. Planarian regeneration requires a population of dividing cells called neoblasts that are distributed throughout the body. Historically, neoblasts have largely been considered a homogeneous population of stem cells capable of differentiating into all cell types. Most studies, however, involved analysis of neoblasts at the population rather than the single cell level, making it difficult to determine how heterogeneous this population is. Here, we use the planarian nervous system, comprised of hundreds of different cell types, to study how neoblasts specialize into specific cell fates. We recently showed that 41 transcription factors expressed in distinct regions of the nervous system are also enriched in subsets of neoblasts during regeneration, marking putative progenitor cell types. Together with previously known transcription factors required for additional neuronal cell types, we infer that these genes specify a diversity of neuronal lineages within neoblasts, and we hypothesize that there may be one or more multipotent neural progenitor populations within neobasts, from which known neural sub-types are specified.
To test this hypothesis, we isolated single cells in the G2/M phase from intact head-pieces and sequenced the mRNA of 188 individual cells. Analysis of these data indicate that there are several unexplored populations of neoblasts that express transcription factors and other genes associated with neural development, and mark distinct populations of differentiated neurons in

uninjured animals. We are currently exploring the requirements of these transcription factors during regeneration.

Title: Activating neuron-intrinsic growth pathways to promote dorsal root regeneration

Authors: ***M. MANIRE**[1,2], H. KIM[1,2], J. ZHAI[1,2], G. M. SMITH[1,2], J. ZHONG[3,4], Y.-J. SON[1,2]; [1]Shriners Hosp. Pediatric Res. Ctr., [2]Anat. and Cell Biol., Lewis Katz Sch. of Med. at Temple Univ., Philadelphia, PA; [3]Burke Med. Res. Inst., Weill Cornell Med. Col. of Cornell Univ., White Plains, NY; [4]Brain and Mind Res. Inst., Weill Cornell Med. Col. of Cornell Univ., New York, NY

Abstract: Primary sensory axons injured by dorsal root (DR) injuries fail to regenerate into the spinal cord, leading to permanent sensory loss. Re-entry is prevented at the dorsal root entry zone (DREZ), the CNS-PNS interface. There is no curative therapy for patients, and present approaches for overcoming this regeneration failure have had only limited success. We have previously shown that induced expression of constitutively active B-RAF (kaBRAF, V600E) enhanced the regeneration competence of injured DRG neurons of adult mice (O'Donovan et al., 2014). In the present study, we tested whether robust regeneration of DR axons across the DREZ can be achieved by activating B-RAF alone or in combination with deletion of myelin-associated inhibitors or neuron-intrinsic growth suppressors (PTEN or SOCS3). To this end, we used *LSL-kaBRAF: brn3a-CreER^{T2}* mice in which kaBRAF can be induced selectively in sensory neurons. We have also bred *LSL-kaBRAF: brn3a-CreER^{T2}* mice with tKO mice lacking Nogo, Mag and OMgp or mouse lines carrying floxed alleles of *PTEN* or *SOCS3*. Single, double, and triple conditional mice were subjected to either cervical (C5-T1) or lumbar (L4-L5) DR crush, and AAV2-GFP vectors were used to selectively label regenerating axons of large-diameter neurons. We compared the extent of regeneration at 3 weeks or 2 months after DR injury using conventional anatomical, functional and behavioral analyses. We found that although induction of kaBRAF alone enabled many axons to penetrate the DREZ, these axons did not continue to regenerate deep into the spinal cord. Supplementary deletion of myelin-inhibitors only modestly

increased kaBRAF-induced regeneration. Deletion of PTEN or SOCS3 alone or together did not promote DR regeneration. In marked contrast, simultaneous deletion of PTEN, but not of SOCS3, dramatically enhanced kaBRAF-induced regeneration enabling many more axons to penetrate the DREZ and to grow more deeply into the spinal cord. Currently, we are testing whether such synergistic activity of BRAF activation and PTEN inactivation prolongs intraspinal regeneration, resulting in robust and long-range functional regeneration after DR injury. Our study has the potential to provide novel insights into how to promote far more robust DR regeneration than has been obtained before and to determine whether such vigorous regeneration will lead to functional recovery of sensory function after spinal root injury.

Title: Activity-dependent molecular programs for optic nerve regeneration

Authors: *Q. WANG[1,2], E. NIE[1], S. T. CARMICHAEL[1];
[1]Neurol., [2]Ophthalmology, UCLA, Los Angeles, CA

Abstract: In the mammalian visual system, retinal ganglion cells (RGCs) are unable to regenerate their axonal projections to targets in the brain following traumatic or ischemic damage or in degenerative diseases such as glaucoma. Cumulative work by many in the field have shown that these RGC axons can be coaxed into regrowing following optic nerve axotomy by manipulating both extrinsic (e.g. oncomodulin) and intrinsic molecular pathways (e.g. PTEN, SOCS3); however, despite these efforts, RGC axons are still inefficient at growing past the optic chiasm and innervating their visual targets. The optic nerve retinal ganglion system provides an excellent model for the study of candidate molecular systems in axonal sprouting.
Neuronal activity and activity-dependent cues play a critical role in driving correct circuit formation during development. In other CNS injury models, such as stroke, increasing neuronal activity through forced limb overuse has been shown to promote the formation of new circuits associated with improved motor recovery. Whether activity-dependent mechanisms can similarly promote reformation of retinofugal pathways following injury remains unclear. Our lab has

previously generated an RNA-Seq dataset of genes differentially regulated in novel neuronal connections formed in the limb overuse stroke model (Nie E., SfN 2015, Poster 307.22/F4). Using an AAV-mediated approach for *in vivo* overexpression and knockout (via CRISPR/Cas9) of candidate genes in RGCs, we are determining whether manipulation of these genes can also promote retinal axon regeneration in a unilateral optic nerve crush model and whether these effects are comparable to or can be further enhanced by visual stimulation of regenerating RGCs. Analysis of this data is ongoing.

Title: The mechanosensitive ion channel piezo regulates axon regeneration

Authors: *Y. SONG[1,2], L. Y. JAN[2], Y. JAN[2];
[1]Dept. of Pathology and Lab. Med., Univ. of Pennsylvania and CHOP, Philadelphia, PA;
[2]Departments of Physiol. and Biochem., Univ. of California San Francisco, San Francisco, CA

Abstract: Differentiated neurons exhibit a limited ability of repair. Given the demonstrated effect of mechanical forces on neuronal outgrowth *in vitro*, it is important to identify mechanosensitive (MS) ion channels that regulate axon regeneration. Here we show that DmPiezo, a Ca^{2+}-permeable non-selective cation channel, functions as an intrinsic inhibitor to hamper axon regeneration in *Drosophila*. Axonal injury activates the Ca^{2+}-permeable DmPiezo channels, leading to activation of nitric oxide synthase and the downstream cGMP kinase Foraging/PKG to restrict axon regrowth. Loss of DmPiezo function enhances axon regeneration of class III dendritic arborization (da) sensory neurons *in vivo*. This mutant phenotype can be rescued by expression of mammalian Piezo channels, but not by a mutant deficient in channel activity, suggesting that the ability of Piezo to regulate axon regeneration is evolutionarily conserved. These findings implicate Piezo channels as an integrator in neuronal maintenance and a potential therapeutic target for treating nervous system trauma.

Title: The role of myelin and other factors involved in optic nerve regeneration in xenopus laevis

Authors: *D. M. ROSENTHAL, M. BRYSON, M. GERBO, B. MISHAGHI, A. WATSON, F. L. WATSON;
Washington and Lee Univ., Lexington, VA

Abstract: The South African-Clawed frog, *Xenopus laevis* retains the ability to regenerate its injured optic nerve into adulthood, whereas mammals lose this ability prior to birth. Here we explore whether the difference in the low number of myelinated retinal ganglion cell (RGC) axons in *Xenopus* (6-10%) compared to that in mammals (100%) contributes towards the regenerative capacity of amphibian optic nerves. We crush the optic nerves of post-metamorphic *Xenopus* using forceps and harvest their optic nerves at various time points post-surgery (up to 210 days). To measure axonal regrowth, we use frogs expressing GFP under regulatory control of an RGC-specific promoter as a marker to visualize RGCs as they extend into the optic tectum. The time course of fluorescence recovery shows complete loss of fluorescence by post-injury day 7, partial recovery can be seen by day 35 but full recovery does not occur until day 210. To determine whether the presence of myelin debris poses a barrier to regeneration, we immunostain longitudinal nerve sections with myelin basic protein, a marker for live, intact myelin. Preliminary results show differences in the rate of myelin removal between nerve segments distal and proximal to the crush site. Specifically, myelin expression is absent in distal longitudinal optic nerve sections by post-injury day 7 but not absent in the proximal nerve segment until post-injury day 11. No myelin is detectable in the optic nerve by post-injury day 210 indicating that regrowth of RGC axons occurs in unmyelinated axons and that subsequent remyelination occurs at a rate that extends past post-injury day 210. In addition, we assess the expression patterns of γ-synuclein, a protein preferentially expressed in large caliber RGCs and previously implicated in neurodegenerative diseases. Results from our RGC-specific RNASeq injury model screen and subsequent immunostaining of retinal sections shows γ-synuclein decreases unilaterally in the

crushed eye during the period of recovery from injury. Interestingly, analysis of longitudinal optic nerve sections shows protein expression of γ-synuclein decreases in RGC axons in both the operated nerve and the unoperated contralateral nerve, a staining pattern that suggests a more global response to injury and local axonal regulation.

Title: The matrix metalloproteinase (Mmp9) functions in Muller glia stem cells and photoreceptor progenitors during injury-induced photoreceptor regeneration in the zebrafish.

Authors: *N. J. SILVA[1], J. LI[3], D. HYDE[3], P. HITCHCOCK[2];
[1]Neurosci., [2]Ophthalmology and Visual Sci., Univ. of Michigan, Ann Arbor, MI; [3]Biol. Sci., Univ. of Notre Dame, Notre Dame, IN

Abstract: Injury and disease in the central nervous system (CNS) activates a multifaceted network of signaling molecules from dying neurons, surviving neurons, and non-neuronal cells. One such molecule belongs to the family of zinc-dependent endopeptidases known as matrix metalloproteinase 9 (Mmp9). Mmp9 is an inflammatory proteinase, which is modulated by various cytokines, such as Tnf-α, Il-1, and Il-8. Previous studies by Nelson et al., (2013) demonstrate that Tnf-α is produced by dying photoreceptors and required for Müller glia proliferation. We show that selective injury and death of photoreceptors induces the expression of genes encoding the inflammatory molecules, *tnf-α, tnf-β, nfκβ1, nfκβ2, mmp9*, and *il-8.* The expression of *mmp9* is predominately in Müller glia and neuronal progenitors. Importantly, Mmp9 is catalytically active during the proliferation and migration of the photoreceptor progenitors. Intravitreal injections of the pro-inflammatory cytokine, TNF-α is sufficient to

stimulate the expression of *mmp9* in uninjured retinas. Interestingly, anti-inflammatory treatment by dexamethasone decreases the expression of *tnf-α, tnf-β,* and *mmp9* and suppresses cell proliferation and regeneration of rod photoreceptors. Our results demonstrate a critical role for neuroinflammation and places *mmp9* with Tnf-α signaling during photoreceptor regeneration in the adult zebrafish retina.

Abstract: Demyelination (the loss of myelin) is seen in many common neurological diseases including multiple sclerosis. Although usually robust, where the regenerative response (remyelination) fails, chronic denudation of the axon leads to axonal loss and neurological impairment. There is therefore a need for therapies that enhance remyelination, and outcome measures to assess their efficacy. Currently there are no non-invasive methods for specifically assessing remyelination.
Here we present evidence of a novel non-invasive technique for imaging remyelination in the central nervous system using T1 weighted Magnetic Resonance Imaging and Magnetic Resonance Microscopy. Using a lentiviral system to infect progenitor cells, we are able to demonstrate T1 weighted contrast enhancement of cells expressing an organic anionic transporter channel (OATP), which takes up gadolinium contrast agent. We are able to control the expression of this transporter under myelination specific promoters, thus making contrast agent uptake specific to myelin synthesis by OPCs which have differentiated into myelinating oligodendrocytes. We demonstrate OATP expression in vitro, in ex vivo slice cultures and in vivo; showing expression in both endogenously infected cells, and in transplanted cells. By applying this technique to models of demyelination we aim to develop a non-invasive method for

imaging remyelination, applicable as an outcome measure, for both the development of transplant, and pharmacological therapies.

Title: Adult leech CNS regeneration at the single cell level: effects of electrical stimulation

Authors: *S. COHEN, O. SHEFI;
Bar Ilan Univ., Ramat Gan, Israel

Abstract: Central nervous systems (CNS) of adult mammals fail to regenerate following an injury. Invertebrates' CNS, on the other hand, can undergo substantial regeneration with significant functional recovery. Moreover, many invertebrates provide the opportunity to work with identified neurons based on their size, location and characteristic electrical activity pattern within the tissue. Thus, invertebrates serve as a useful model for exploring cell strategies and mechanisms underlying successful CNS regeneration at the single cell level. Electrical stimulation (ES) has been previously reported as a promoting factor of axonal regeneration in sensory and motor neurons. The effects have been demonstrated mostly in the PNS but there are also experimental evidence for such occurrence in the CNS. For example, low-frequency ES at 20 Hz for a short period was found to be as effective as continuous stimulation over 2 weeks. In this research we aim to study the influence of different ESs on the neuronal growth. We have examined the effects of brief ES (20Hz, 30min) on the regeneration strategy of the leech CNS at the single cell level over a period of 72 hours. We used an ex-vivo model of the leech ganglia chain. We followed the regeneration process of single cells and compared the regeneration strategy with and without the electrical stimulation. Our preliminary results demonstrated that the dynamics of regeneration and growth rate were affected by the ES. Moreover, regenerated neurons under ES tended to change their dendritic tree orientation, as compared to control neurons. The results suggest that ES may (1) contribute for the direction of the spatial orientation of the regenerative axons and (2) influence the normal regeneration time course by interfering in specific time points.

Title: Ablation of astrocytic ephrin-B1 impairs synaptogenesis, synapse function, and animal behavior

Authors: *A. Q. NGUYEN[1], J. KOEPPEN[1], M. GARCIA[1], S. HANNA[1], A. OBENAUS[2], I. ETHELL[1];
[1]Univ. of California, Riverside, Riverside, CA; [2]Loma Linda Univ., Loma Linda, CA

Abstract: Astrocytes interact with and ensheath neuronal synapses through fine processes which allow for regulation of synaptic function and aiding in the stabilization and maintenance of synapses. Contact of astrocytes to synapses can be facilitated by astrocytic ephrin-B1 to neuronal EphB receptors; ephrin-B1/EphB signaling pathways participate in cell-cell interactions which regulate various developmental processes, such as axon guidance, cell migration and proliferation, synaptogenesis, and dendritic spine formation. In our study, we show that during adulthood, astrocytic ephrin-B1 continues to play a role in synapse formation, function, and maintenance. Using a Cre/LoxP system; inducible loss of astrocytic ephrin-B1 was achieved by crossing homozygous floxed ephrin-B1 female mice with Cre-GFAP-ERT2 male mice and providing experimental mice with tamoxifen to induce ablation of astrocytic ephrin-B1 in adulthood. Morphologically, we found a significant increase in the number of excitatory synapses in the SR region of the CA1 hippocampus of knock-out astrocytic ephrin-B1 mice through immunostaining of presynaptic terminals with vGlut1 and through DiI labeling of dendritic spines. Functionally, however, we see reduced population spike responses as well as attenuation of long-term potentiation in the CA1 hippocampus of knockout animals following stimulation of Schaffer collaterals. Behaviorally, knockout animals displayed impaired social memory in a three-chamber social interactions test but improved contextual fear learning, indicated by increased freezing, in contextual fear conditioning test. Our studies suggest astrocytic ephrin-B1 may play a role in maintenance of synapses; ablation of astrocytic ephrin-B1 triggers synaptogenesis of non-functional synapses, resulting in attenuation of functional responses, but may allow increased contextual learning when provided enough training. Future studies will determine its role during various developmental stages of synapse development. *This work was supported by the NIH grant RO1MH067121.*

Title: Astrocytic ephrin-B1 and its role in injury-induced synapse remodeling in the adult hippocampus

Authors: *J. KOEPPEN[1], A. NGUYEN[1], M. GARCIA[1], S. HANNA[1], A. OBENAUS[2], I. ETHELL[1];
[1]Univ. of California Riverside, Riverside, CA; [2]Loma Linda Univ., Loma Linda, CA

Abstract: Astrocytes can facilitate brain repair after injury by protecting neurons from glutamate excitotoxicity and regulating the blood-brain barrier; however, the role of astrocytes in rewiring neuronal networks is not well understood. Several astrocyte-derived factors that are implicated in synapse formation and maintenance may also regulate synapse remodeling following brain injury. Our studies suggest a new role of astrocytic ephrin-B1 in synapse remodeling following traumatic brain injury (TBI). Trans-synaptic interactions between EphB receptor and its membrane-bound ligand ephrin-B play an important role in synapse formation and their disruption has been implicated in neurodegenerative diseases. We observed an increase in astrocytic ephrin-B1 a controlled cortical impact (CCI) model of TBI. The observed up-regulation coincides with a decrease in excitatory synapses within the Stratum Radiatum (SR) of the CA1 hippocampus. Ablation of astrocytic ephrin-B1 resulted in the recovery in the number of excitatory synapses by 7dpi not seen in WT mice. We propose that the up-regulation of ephrin-B1 levels in astrocytes surrounding the synapse may disrupt the trans-synaptic EphB/ephrin-B interactions resulting in synapse collapse. In addition to the effect of ephrin-B1 after TBI *in* vivo we also investigated how ephrin-B1 reverse signaling affects synapse elimination *in vitro*. Indeed we observed an increased association of excitatory synapses with astrocytes overexpressing ephrin-B1 in primary astrocyte-neuron co-cultures. Utilizing ephrin-B1 signal transduction null mutants we have examined how ephrin-B1 signaling affects synaptoneurosome engulfment in primary astrocytes. To determine the role of ephrin-B1 reverse signaling in astrocytes we investigated STAT3 activation. STAT3 activation has been observed in reactive astrocytes after injury and is implicated in reactive astrogliosis. We have observed an up-regulation in phosphorylated levels of STAT3 within the hippocampus at 3 dpi, which was suppressed by astrocyte-specific ablation of ephrin-B1 *in vivo*. Furthermore, we observed an increase in STAT3 activation *in vitro* following activation of ephrin-B1 in astrocytes. Our studies suggest that astrocytic ephrin-B1 may play an active role in injury-induced synapse remodeling

after injury through the activation of STAT3-mediated signaling in astrocytes. *This work was supported by the NIH grant RO1MH067121*.

Title: Vesicular and non-vesicular gliotransmission: synergy and role in synaptic plasticity in the neocortex

Authors: *Y. PANKRATOV;
Univ. of Warwick, Coventry, United Kingdom

Abstract: Communication between neuronal and glial cells is thought to be very important for many brain functions. Astroglial cells possess the SNARE-like Ca^{2+}-dependent machinery for vesicular release of "gliotransmitters" like D-serine, glutamate, and ATP. Acting via release of gliotransmitters, astrocytes can modulate synaptic strength. The mechanisms of gliotransmission remain uncertain with exocytosis being the most intriguing and debated pathway. Previously, we showed that SNARE-dependent exocytosis of gliotransnitters can be triggered by elevation of astroglial Ca^{2+} via direct UV-uncaging or via glia- specific receptors (PAR-1, CB1 or α1-adrenoreceptors). Our recent studies revealed three types of responses of pyramidal neurons to activation of astrocytes in the neocortical slices of wild-type, dn-SNARE and Best1 KO mice: (1) burst of spurious fast NMDAR-mediated currents (sFICs, decay time about 25-40 ms) which were sensitive to ifenprodil, in contrast to baseline synaptic mEPSCs; this burst of glia-driven GluN2B-mediated currents was eliminated by perfusion of astrocytes with light chain of Tetanus Toxin; also it was inhibited in the dn-SNARE mice; (2) TREK-1 channel-dependent GluN2B-mediated slow inward currents (SICs, decay time 100-1000 ms); and (3) very slow (decay >3-5 sec) Best1-dependent currents. The glia-induced sFICs and SICs made approximately equal contributions to overall glutamate release. Importantly, both sFICs and SICs were dramatically decreased in the Best1KO mice but were rescued by application of exogenous D-Serine suggesting that major role of astroglial Best1 channels in Ca^{2+}-dependent release of D-Serine. Combined, our results show that cortical astrocytes can release glutamatergic gliotransmitters by

combination of Ca^{2+} and SNARE-dependent exocytosis and non-vesicular mechanisms dependent on TREK-1 and Best1 channels. Our data show that synergetic action of astrocyte-derived ATP and glutamatergic gliotransmitters is essential for synaptic plasticity. In particular, LTP was impaired in the neocortex of dnSNARE mice but could be rescued by application of exogenous D-Serine or non-hydrolysable ATP analogs. Moreover, we observed the deficit in working memory of dn-SNARE mice; this is a first evidence of physiological relevance of glial exocytosis in vivo. Interestingly, environmental enrichment rescued the LTP and working memory in dnSNARE mice, most likely via up-regulation of non-vesicular Ca^{2+}-dependent release of d-Serine via Best1 channels. To conclude, our data strongly support the importance of synergy between vesicular and non-vesicular gliotransmission.

Title: Dopaminergic activity-dependent astrocytic glycogenolysis in exercising rat hippocampus

Authors: *T. MATSUI[1], I. TORRES-ALEMÁN[2], H. SOYA[1];
[1]Fac. of Hlth. and Sport Sci., Univ. of Tsukuba, Ibaraki, Japan; [2]Cajal Institute, CSIC, Madrid, Spain

Abstract: Hippocampal lactate produced by astrocytic glycogenolysis plays a critical role in memory functions as a neuronal energy source and/or a neuromodulator. Although noradrenaline and serotonin are mediators for astrocytic glycogenolysis in the cortex, it is still unknown whether astrocytic glycogenolysis depends on neuronal activity and what mediates it in the hippocampus. Since running exercise elicits speed-dependent neuronal activation corresponding with energy demand, particularly in the hippocampus, we investigated this issue using a

treadmill running model for rats. First, we exercised rats on a treadmill for 30 min at different speeds (mild: 10 m/min, moderate: 20 m/min, and hard: 30 m/min) and sacrificed the rats using high-power (10 kW) microwave irradiation to detect glycogen, lactate, and monoamine levels in the brain (the hippocampus, cortex, cerebellum, brainstem, and hypothalamus), immediately after exercise. Glycogen in the brain, except in the hypothalamus, decreased in a speed-dependent manner associated with increased brain lactate levels. In the hippocampus, decreased glycogen and increased lactate were associated with running-speed-dependent dopaminergic activation, but not noradrenergic or serotonergic activities. Next, in vivo microdialysis during speed-incremental exercise (0, 10, 20, and 30 m/min) revealed that levels of hippocampal extracellular dopamine, but not noradrenaline or serotonin, increased with running speed. Furthermore, in primary cultured astrocytes of the rat cortex and hippocampus, the challenges of, respectively, dopamine and dopamine D2 receptor agonist (not D1) induced dose-dependent glycogen decrease. Finally, a local injection of dopamine D2 receptor antagonist (not D1) prevented hippocampal glycogen decrease during the mild running exercise. Our results provide the first evidence for dopaminergic activity-dependent astrocytic glycogenolysis in the exercising hippocampus, suggesting a novel role of dopamine in exercise-enhanced memory functions.

Title: Astrocytic PKC- and PKA-dependent regulation of astrocyte glutamate uptake and effects on neuronal excitability

Authors: *I. M. HOLMAN[1], Y. KIM[2], J. TRUONG[2], L. YOUNG[2], T. A. FIACCO[2];
[1]Neurosci., [2]Cell Biol. and Neurosci., UC Riverside, Riverside, CA

Abstract: Uptake of synaptically released glutamate by astrocytes is essential for maintaining a healthy level of excitatory activity in the brain and for regulating spillover to adjacent synapses. It is known that during neuronal activity, astrocytic metabotropic glutamate receptors (mGluRs) and other G protein-coupled receptors (GPCRs) are activated. Previously, our lab demonstrated that astrocytic G_q GPCRs rapidly potentiate glutamate uptake in a protein kinase C (PKC) - dependent manner (Devaraju et al., J. Neurophysiol., 2013). Here, we extend these findings with new data demonstrating that the PKC activator (-)-Indolactam V dialyzed into single astrocytes in stratum radiatum of acute mouse hippocampal slices rapidly potentiates astrocyte glutamate

uptake. Whole-cell synaptically-evoked transporter currents double in amplitude by 30 minutes compared to control recordings using the inactive enantiomer (+)-Indolactam V. Furthermore, inhibition of intracellular astrocytic protein kinase A (PKA) suggests that PKA normally functions to diminish astrocyte glutamate uptake over a similar time course. Collectively, our findings suggest that astrocytic PKC is both necessary and sufficient for rapid potentiation of astrocyte glutamate uptake, while PKA acutely depresses astrocyte glutamate uptake. Experiments are now underway to determine the effects of this bidirectional modulation of astrocyte glutamate uptake on neuronal excitability. Specifically, we are focusing on how changes in astrocyte glutamate uptake affect activation of extrasynaptic NMDA receptors, which are located in close proximity to astrocyte processes and are therefore likely targets for changes in astrocyte glutamate uptake compared to synaptic receptors. Preliminary data suggest that rapid potentiation of astrocyte glutamate uptake diminishes the NMDA receptor-dependent tonic current recorded in CA1 pyramidal neurons. Experiments are now in progress to examine the effects of changes in astrocyte glutamate uptake on other measures of extrasynaptic NMDA receptor activity.

Title: Astrocytic modulation of neuronal signaling in Rett syndrome

Authors: *B. RAKELA[1], P. BREHM[2], G. MANDEL[3];
[1]Neurosci., Vollum Institute/ Oregon Hlth. and Sci. Univer, Portland, OR; [2]Vollum Institute/ Oregon Hlth. and Sci. Univ., Portland, OR; [3]Vollum Institute/ Oregon Hlth. and Sci. Univ., portland, OR

Abstract: Astrocyte-mediated events are important for maintaining neuronal homeostasis and proper synaptic transmission. Recently, astrocytes were implicated in the autism-like spectrum disorder Rett syndrome (RTT), where global mutations in the X-linked methyl DNA-binding

protein MeCP2 result in dysregulation of neuronal function. Using brain slices prepared from wildtype (WT) mouse barrel cortex (p7-p12), paired recordings between SR101-positive astrocytes and neurons show that astrocyte stimulation (depolarization or agonist application) leads to a potent activation of synaptic signaling in neighboring pyramidal neurons. These synaptic currents are GABAergic and excitatory, as determined by their gabazine sensitivity (20μM) and reversal potential identified by gramicidin perforated patch recordings. Interestingly, when these stimulations were repeated in male MeCP2 null mice, a mouse model for RTT, astrocyte-mediated activation of neuronal GABAergic signaling was completely abolished. To determine whether the defective astrocyte-mediated signaling in the MeCP2 null cortex was due to the neuron, the astrocyte, or both, I exploited female RTT mice bearing a MeCP2-GFP fusion gene, allowing discrimination between WT (GFP+) and Mecp2 null (GFP-) cells, this mosaicism allowed me to record from every combination of WT and mutant cells. I found that loss of GABAergic signaling in neurons occurred whenever a MeCP2-deficient astrocyte was stimulated, regardless of the status of MeCP2 expression in the neurons. These data suggest that in WT mice, astrocytes are capable of modulating neuronal signaling by contributing to the GABAergic tone in the cortex; this contribution is absent in Rett syndrome, which further implicates astrocytes in the dysregulation of neuronal processes seen in this disorder.

Title: Studying neuronal ATP dynamics *In vivo*

Authors: *L. HOESLI[1,2], A. S. SAAB[1,2], J. HIRRLINGER[3,4], B. WEBER[1,2];
[1]Pharmacol. and Toxicology, Univ. Zürich, Zuerich, Switzerland; [2]Neurosci. Ctr. Zurich, Univ. and ETH Zurich, Zurich, Switzerland; [3]Neurogenetics, Max-Planck Inst. for Exptl. Med., Göttingen, Germany; [4]Fac. of Med., Carl-Ludwig-Institute for Physiology, Universtiy of Leipzig, Leipzig, Germany

Abstract: Neuronal energy requirements depend to a large extent on electrical activity and the ATP demand of Na^+/K^+-ATPases. Astrocytes and oligodendrocytes are suggested to fuel neuronal ATP demands by providing lactate to neuronal compartments such as dendrites and axons. One important source of lactate may be glycogen, which has been described to be relevant for cognitive functions such as learning and memory. However, little is known about activity-

dependent neuronal ATP dynamics *in vivo* and how glycogen levels or lactate distribution impact neuronal ATP homeostasis. Here, we used a transgenic mouse model that expresses an ATP biosensor (genetically encoded FRET sensor) in neurons, which allows us to study cortical ATP levels *in vivo* using two-photon microscopy. To simultaneously monitor neuronal activity, the calcium sensor RCaMP was introduced by viral delivery. Interestingly, spontaneous neuronal activity was not accompanied by any ATP level changes. Even sensory stimulations like whisker or hind limb, which evoke cortical activity measured by calcium transients, did not affect neuronal ATP levels. However, local cortical stimulations with a microelectrode induced significant ATP level drops that were dependent on stimulus strength and intensity. Hence, neuronal ATP levels are quite stable and only drop upon high energy consuming stimulation paradigms. Whether and how the glial metabolic support machinery such as glycogen levels or lactate distribution may be critical in regulating the neuronal ATP homeostasis is currently under investigation.

Title: Optical activation of hippocampal astrocytes boost synaptic transmission in CA1 pyramidal neurons

Authors: *S. MEDEROS, A. HERNANDEZ-VIVANCO, G. PEREA;
Inst. Cajal, CSIC, Madrid, Spain

Abstract: Astrocytes play critical roles in homeostatic functions. In the last years, studies focused on neuron-astrocyte signaling have revealed crucial roles of astrocytes in neuronal activity and synaptic physiology (Araque, et al. 2014). To extend our knowledge of the properties and consequences of astrocyte signaling in brain function, new tools and experimental approaches need to be developed. Here, taking advantage of optogenetic tools we manipulated astrocyte activity and evaluated their consequences on neuronal physiology. The ectopic expression of channelrhodopsin-2 (ChR2, a light-activated ion channel protein) was targeted specifically to hippocampal astrocytes by viral transfection (Perea et al., 2014). By immunohistochemically analysis we found a restricted expression of ChR2 to astrocytes. Using electrophysiological techniques in hippocampal slices, we found that optical activation of astrocytes enhanced local excitatory synaptic transmission in CA1 hippocampal pyramidal

neurons. ChR2-stimulated astrocytes induced an increase of NMDA-mediated slow inward currents in pyramidal cells, indicating the ability of ChR2 to stimulate the release of glutamate from transfected hippocampal astrocytes. The pharmacological analysis indicated that astrocyte induced modulation of synaptic transmission was mediated by activation of glutamatergic receptors at neuronal membranes. Additionally, stimulation of ChR2-transfected astrocytes in IP3R2 knockout mice, which show down-regulated evoked astrocytic intracellular calcium signaling, revealed similar potentiation of synaptic transmission to wildtype mice. Neuronal activity to light stimulation was recorded in vector-transfected slices and no significant changes were observed. Then, optical activation of astrocytes stimulates glutamate release that controls the synaptic strength of pyramidal neurons influencing the operation of hippocampal circuits. Title: An imaging screen to identify astrocyte factors controlling neuronal maturation and synaptogenesis

Authors: *J. MCGANN, G. MANDEL;
Vollum Inst., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: While it is well established that neurons and astrocytes are in intimate contact during nervous system development, only recently have studies revealed that proper neuronal maturation and synaptogenesis is dependent on astrocyte-specific factors. Several factors have been identified that regulate this dependence, but thus far they are limited primarily to secreted molecules. Little is therefore known about contact-mediated mechanisms of signaling or the

factors involved in the coordinated regulation of these processes. To shed light on this critical area of neurobiology, we have designed and undertaken a high-throughput image-based shRNAi screen to identify genes required in astrocytes to support normal neuronal development. Our screen utilizes P0 mouse cortical astrocytes grown in culture in 96-well format and subjected to lentiviral shRNAi knockdown. Subsequently, untreated P0 neurons prepared from a mouse expressing TdTomato globally are introduced and allowed to mature. We then image dendritic and axonal outgrowth followed by fixation and staining for the synaptic proteins Homer and Synaptophysin, as well as a marker of astrocyte reactivity, Glial Fibrillary Acidic Protein. Finally, we analyze the images computationally, identifying numerous morphological and cellular phenotypes, including total neurite length, branch number and position, synaptic density, and synaptic maturity. Thus far, we have screened for consequences of knock down of two functional gene families, encoding cell adhesion molecules and cytokine/chemokine receptors. Our screen has identified dozens of genes with consistent and significant effects on both astrocyte and neuronal biology. Two representative candidates that have been confirmed in three independent analyses are Neurotensin receptor 2 (Ntsr2), mutants of which have abnormal gait and a decreased startle response, and Progestin and AdipoQ Receptor family member 8 (Paqr8), mutations of which are implicated in human epilepsy. The identification of contact-dependent non-cell-autonomous effects with this methodology is robust and is broadly applicable to studying other functional gene families, as well as neurons and astrocytes from different sources, including models of neurological disease.

Title: Astrocyte-neuron interactions in long-term plasticity: a computational study

Authors: T. MANNINEN[1], A. SAUDARGIENE[2], R. HAVELA[1], *M.-L. LINNE[1];
[1]Tampere Univ. Technol., Tampere, Finland; [2]Vytautas Magnus Univ., Kaunas, Lithuania

Abstract: One significant challenge in neuroscience is to identify the key cellular and molecular mechanisms involved in modulation of synaptic long-term plasticity (Hellgren Kotaleski and

Blackwell, Nat Rev Neurosci 2010). In addition to neuronal mechanisms, astrocytic calcium signaling pathways and gliotransmission have increasingly been implicated as key elements in modulation of short- and long-term plasticity, in a variety of cortical areas in vitro (see, e.g., Perea and Araque, Science 2007; De Pitta and Brunel, Neural Plasticity 2016). In this study, we sought to study the role of several experimentally established modulatory mechanisms of plasticity by computational means. Computational data driven modeling is one promising tool to study complex interactions and time courses of multiple events that cannot easily be assessed simultaneously in a wet-lab experiment. First, altogether more than 60 previously published models of astrocyte-neuron interactions were evaluated in detail (Manninen et al. 2016, in press). Second, distinct models for three cellular compartments were developed and validated: models of the pre- and postsynaptic terminals of the cortical neurons and a model for an adjacent cortical astrocyte process. Third, the full model was integrated and validated against cortical long-term plasticity data. In short, the model includes the well-established biophysical mechanisms for neuronal sodium and neuronal and astrocytic calcium excitability, as well as the signaling pathways putatively important in plasticity. Extensive simulations were then run using classical stimulation protocols for long-term plasticity as synaptic input. Our simulations show that changes in the temporal patterns of synaptic input can select for specific neuronal signaling pathways, such as the endocannabinoid signaling. This raises calcium levels in the astrocyte process, which has the potential to cause, in a concentration-dependent manner, release of the gliotransmitter glutamate from the astrocyte to further modulate the vesicle release in the presynaptic terminal. In summary, our simulations demonstrate that the interacting neuronal and astrocytic processes possess the molecular mechanisms to dynamically modulate the presynaptic terminal and, hence, the long-term plasticity. Our work provides one of the first models combining cellular excitability and physicochemical properties of astrocyte-neuron interactions for deciphering the dynamics and mechanisms involved in long-term plasticity. It can be used in future in silico and in vitro studies to address how neural networks learn to represent memories.

Title: Lrp4 in astrocytes modulates glutamatergic transmission

Authors: *X. SUN;
Augusta Univ., Augusta, GA

Abstract: Neurotransmission requires precise control of neurotransmitter release from axon terminals. This process is regulated by glial cells; however, underlying mechanisms are not fully understood. Here we report that glutamate release is impaired in mutant mice lacking low density lipoprotein receptor-related protein 4 (Lrp4), a protein critical for neuromuscular junction formation. Electrophysiological studies indicate compromised release probability in astrocyte-specific *Lrp4* knockout mice. *Lrp4* mutant astrocytes suppress glutamate transmission by enhancing the release of ATP, whose levels are elevated in the hippocampus of *Lrp4* mutant mice. Consequently, the mutant mice are impaired in locomotor activity and spatial memory and are resistant to seizure induction. These impairments could be ameliorated by adenosine A1 receptor antagonist. The results reveal a critical role of Lrp4, in response to agrin, in modulating astrocytic ATP release and synaptic transmission. Our study provides insight into the interaction between neurons and astrocytes for synaptic homeostasis and/or plasticity.

Title: Cholinergic transmission tunes astrocyte- dependent gating of the NMDA receptor co-agonist binding site

Authors: *T. PAPOUIN[1], J. DUNPHY[1], K. T. DINELEY[2], P. G. HAYDON[1];
[1]Neurosci., Tufts Univ., Boston, MA; [2]Neurol., Univ. of Texas, Galveston, TX

Abstract: It is firmly established that D-serine is an endogenous agonist controlling the glycine-binding site of synaptic N-methyl D-aspartate receptors (NMDARs). However, conditions and

stimuli that govern D-serine release have remained unidentified.
Using molecular genetics, behavior, amperometry, *in vitro* electrophysiology and optogenetics we demonstrate that D-serine availability fluctuates across the sleep wake-cycle in mouse hippocampus, from low extracellular concentrations in the light (sleep)-phase to higher levels in the dark (active)-phase. Correspondingly, the saturation of the NMDAR co-agonist site oscillates during the 24h period at CA3-CA1 synapses, reaching full saturation in the dark (active)-phase, and this is sufficient to impact behavioral performance in a hippocampal-dependent learning task. We found that D-serine oscillations 1) are caused by daily fluctuations in astrocytic vesicular release and 2) are driven by a sleep homeostasis/activity-dependent mechanism wherein wakefulness promotes and maintains elevated extracellular D-serine concentrations.
Abundant evidence points to a modulatory function of endogenous acetylcholine (ACh) on synaptic plasticity and NMDAR function in cortical regions. Interestingly, cholinergic neurons from the medial septum and diagonal band of Broca (MS-DBB) represent the only source of ACh in the hippocampus and their activity co-varies with sleep stages such that ACh release is the highest during wakefulness. We found that optogenetic stimulation of MS-DBB cholinergic fibers causes an increase in D-serine levels at CA3-CA1 synapses and that pharmacological manipulation of the α7nAChR directly modulates D-serine availability. In addition, cell-specific knock-out of α7nAChR in astrocytes, but not neurons, is sufficient to abolish daily D-serine oscillations.
Additionally we determined that *in vivo* administration of an α7nAChR partial agonist (EVP-6124), evaluated in a Phase III clinical trials for the treatment of schizophrenia, elevates D-serine levels. Together our data demonstrate the existence of a new pathway, of clinical relevance, through which wakefulness-dependent release of ACh from the MS-DBB dictates hippocampal D-serine availability and NMDAR activity via astrocytic α7nAChRs.

Title: Heterogeneity in the synaptogenic potential of cultured astrocytes from distinct brain regions

Authors: *A. S. BUOSI, I. C. P. MATIAS, A. B. ARAUJO, F. C. A. GOMES;
Inst. de Ciencias Biomedicas, Univ. Federal Do Rio De Janeiro, Rio de Janeiro, Brazil

Abstract: Astrocytes, the most abundant glial cells in the Central Nervous System (CNS), comprise a heterogeneous population of cells. It is well known that across brain regions, as well as within the same region, astrocytes differ in their morphology, developmental origin, gene expression profile, physiological properties, functions and response to injury and disease. Recently, they have been recognized as important regulators of synapse formation and maturation. However, it is not yet clear if there are differences in the synaptogenic potential of distinct subtypes of astrocytes. Objectives: to analyze the synaptogenic property of astrocytes from different regions of the CNS. Methods: cortical, hippocampal, midbrain and cerebellar neuronal cultures from Swiss mice between 14 to 16 embrionary ages (E14-16) were treated with astrocyte conditioned medium (ACM) prepared from astrocytes derived from newborn mice. Synapse formation was evaluated by immunocytochemistry for the synaptic proteins, Synaptophysin and PSD95. The expression profile of the synaptogenic molecules secreted by astrocytes from distinct brain regions was analyzed by q-PCR. Results: ACM from the four regions analyzed increased significantly the number of Synaptophysin/PSD95 puncta on neurons from the same and from different brain regions. Differences on astrocytic synaptogenic potential between the regions were observed according to the protein concentration in conditioned medium. Thus, cerebellar astrocytes have higher synaptogenic effects when ACM is less concentrated, suggesting that there is quantitative and qualitative differences in their protein content. Gene expression analysis of synaptogenic molecules classically secreted by astrocytes showed that glypicans 4 and 6, hevin and SPARC are molecules with notable variation of expression between astrocytes from different brain regions. Furthermore, the analysis of synaptogenic factors levels and its distribution on different astrocytes confirmed that variance. Conclusions: these findings highlight the heterogeneity of astrocytes and suggest that their synaptogenic potential may be different in each brain region, mainly due to distinct gene expression profiles. The protocol of this study was approved by the Committee for Animal Research of the Federal University of Rio de Janeiro.

Title: The flavonoid hesperidin modulates synapse formation and the synaptogenic potential of astrocytes

Authors: *I. MATIAS[1], L. DINIZ[2], A. BUOSI[2], G. NEVES[2], J. STIPURSKY[2], F. C. A. GOMES[2];
[1]Inst. of Biomed. Sci., Federal Univ. of Rio De Janeiro, Rio de Janeiro, Brazil; [2]Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: The Central Nervous System (CNS) is target for several neurodegenerative diseases characterized by neuronal death, synaptic and glial dysfunctions. Currently, new drugs have been studied as therapeutic alternatives for modulating cognitive processes in physiological and pathological conditions, and, among them, flavonoids have been noted for their remarkable pleiotropic actions. However, little is known about the mechanisms of these compounds on neuronal and glial physiology and their impact on learning and memory. Here we investigated the actions of the flavonoid hesperidin on synapse formation in vitro and in vivo, as well as the role of astrocytes as mediators of hesperidin's actions. **Methods:** Cortical neurons and astrocytes cultures were prepared from 14-15 embryonic days and 1-2 post-natal days Swiss mice, respectively. The neuronal cultures were treated with hesperidin (5 uM) for 24 hours or astrocyte conditioned medium (ACM) for 3 hours, and analyzed for synapses formation. Signaling and secretion of TGF-β1, a synaptogenic astrocyte derived-molecule (Diniz et al., 2012; Diniz et al., 2014), were analyzed in astrocyte cultures treated by hesperidin. Moreover, we evaluated if TGF-β1 secretion by astrocytes was involved in synapse formation induced by the ACM. **Results:** Hesperidin increased by 40% the number of synapses between cortical neurons. This event was followed by a 75% decrease in neuronal death and 85% increase in the pre-synaptic activity, as observed by immunocytochemistry and FM1-43 assay. ACM increased the number of synapses by 130%, whereas ACM from astrocytes treated by hesperidin increased by 250%, showing that hesperidin enhances the synaptogenic potential of astrocytes in vitro. Neutralization of TGF-β1 activity in the ACM significantly reduced its synaptogenic potential, suggesting that hesperidin's actions were dependent on TGF-β1 secretion by astrocytes. Preliminary in vivo results showed that hesperidin also modulated the number and levels of synaptic proteins in adult Swiss mice. **Conclusion:** Our data indicate a new function for hesperidin on synapse formation, and suggest a new mechanism of action of this compound in synaptogenesis, through the control of soluble factors production by astrocytes. The protocol of this study was approved by the

Committee for Animal Research of the Federal University of Rio de Janeiro. **Support:** CNPq, CAPES, FAPERJ, Ministério da Saúde.

Title: Impairment of astroglia calcium activation by ethanol and consequences for local circuit activity

Authors: L. YE, M. ORYNBAYEV, *M. PAUKERT;
Physiol., UT Hlth. Sci. Ctr. at San Antonio, San Antonio, TX

Abstract: Among the most prominent acute neurological consequences of ethanol exposure are impaired motor coordination (ataxia) as well as impaired attention and memory. Noradrenergic signaling, originated by locus coeruleus neurons, plays important roles in attentional shifts, optimization of brain circuit activity to the behavioral context, and in gating synaptic plasticity. Ethanol can reduce locus coeruleus activity; however, the functional consequences at the cellular and circuit level are not well understood. To overcome this obstacle, we employed a linear treadmill in combination with in vivo two-photon calcium imaging on mice expressing the genetically encoded calcium indicator GCaMP3 in cerebellar Bergmann glia and cortical astrocytes. Our previous experiments have revealed that locomotion leads to norepinephrine-dependent simultaneous calcium activation of Bergmann glia in the cerebellum and astrocytes in primary visual cortex. Here, we found that locomotion-induced calcium elevations in Bergmann glia as well as primary visual cortex astrocytes are reversibly and dose-dependently inhibited by ethanol exposure. Acutely enhancing norepinephrine release was sufficient to completely reverse this effect of ethanol suggesting that suppression of norepinephrine release might be the underlying mechanism by which ethanol inhibits behavioral state-dependent astroglia calcium activation. We investigated the consequences of ethanol impairment of astroglia calcium activation for calcium dynamics in local neurons. We recorded locomotion-induced calcium

elevations in Purkinje cells, the principal neurons of the cerebellar cortex, using transgenic mice expressing a variant of the genetically encoded calcium indicator GCaMP6. Locomotion induced a slow calcium elevation in Purkinje cells with an onset ~2 s following the onset of locomotion and lasting for 5-10 s, similar to corresponding calcium elevations in Bergmann glia. Prolonged Purkinje cell calcium elevations were inhibited by ethanol exposure and could be recovered by acutely enhancing norepinephrine release, suggesting the recruitment of a similar signaling pathway, or a hierarchical relationship between astroglia and neurons. We were able to distinguish between these two possible mechanisms using inositol triphosphate receptor type 2 knockout mice, in which the locomotion-induced global calcium activation of Bergmann glia was absent. Our findings provide a cellular and circuit mechanism that may contribute to impairments of attention by acute ethanol exposure.

Title: Amyloid-β Oligomers directly target astrocytes and impair their neuroprotective actions on synapses: prevention by astrocyte-derived tgf-β1

Authors: *L. P. DINIZ[1], V. TORETELLI[1], I. MATIAS[2], J. MORGADO[2], A. ARAÚJO[2], H. MELO[3], G. DA SILVA[3], S. FERREIRA[3], F. DE FELICE[3], F. C. A. GOMES[2];
[1]Inst. of Biomed. Sci., Federal Univ. of Rio De Janeiro, Rio DE Janeiro, Brazil; [2]Inst. of Biomed. Sci., Federal Univ. of Rio De Janeiro, Rio de Janeiro, Brazil; [3]Inst. de Biofísica Carlos Chagas Filho, Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: Alzheimer's disease (AD) is characterized by progressive decline of cognitive functions, mainly due to neuronal/synaptic dysfunction induced by amyloid-β peptide oligomers (AβOs). Although the effects of AβOs in neurons have been extensively studied, if and how

AβOs impact astrocytes remain largely unknown. Given the key role of astrocytes in synaptic formation and plasticity, we investigated the effect of AβOs on astrocytes and how it impacts synapse formation and function. Here, we show that murine hippocampal astrocytes are able to bind and internalize AβOs in vitro. Astrocyte conditioned medium (ACM) reduced AβOs binding to neurons, preventing AβO-induced synaptic loss. This "synaptic protection" ability of astrocytes was impaired by prior stimulation of astrocytes with AβOs. Also, protection provided by ACM was severely inhibited by blocking the signaling of TGF-β (Transforming growth factor-β), previously identified as a neuroprotective and synaptogenic factor secreted by astrocytes (Diniz et al., 2012; 2014). Intracerebroventricular injection of AβOs led to synaptic loss and memory deficit, followed by reduction in the levels of TGF-β1 in the hippocampus. Injection of TGF-β1 in the brain of these mice rescued synaptic/memory déficits caused by AβOs. Thus, we show that astrocytes and their soluble factors, particularly TGF-β1, can repress synaptic loss and AD progression. Further, we show that astrocytes are targets for AβOs, shedding light into a new mechanism underlying AβOs synaptotoxicity, indirect through glial cells. The protocol of this study was approved by the Committee for Animal Research of the Federal University of Rio de Janeiro.

Title: Characterization of neurite growth using permissive and inhibitory astrocyte cell lines

Authors: S. CHRISTIAN, M. SMITH, A. NEWSOM, T. REGETZ, V. LUMBERT, L. KRAUSE, A. RENDON, *D. R. COOK-SNYDER;
Neurosci. Program, Carthage Col., Kenosha, WI

Abstract: Central nervous system (CNS) injuries, including stroke and traumatic brain injury, are leading causes of disability and death worldwide in part due to the limited axon regeneration capacity of the CNS. Improved *in vitro* models, particularly those that are fast growing and readily modifiable by genetic and pharmacologic manipulations, are critical to further our understanding of the mechanisms inhibiting axon regeneration following CNS injury, and to develop high throughput screens for novel therapeutics. To address this need, our studies

characterize co-cultures of N2a neuroblastoma cells, which can differentiate and extend neurites, with two complementary CNS astrocyte cell lines: A7 cells, which are axon growth permissive, and Neu7 cells, which are axon growth inhibitory. Thus, we hypothesized that differentiated N2a neuroblastoma cells would show greater neurite growth in A7 co-cultures than Neu7 co-cultures. Our results suggest that serum starvation induces N2a differentiation in a dose- and time-dependent manner, and that differentiated N2a cells extend more and longer neurites when co-cultured with A7 cells than with Neu7 cells. Moreover, A7 and Neu7 exposure to a variety of stimuli, including potassium chloride and acidified media, produces hypertrophy and proliferation consistent with reactive astrocytosis, although neither cell line demonstrates upregulation of glial fibrillary acid protein. Continued characterization of N2a-A7 and N2a-Neu7 co-cultures and their potential for reactive astrocytosis may provide efficient and complementary models for rapid identification of mechanisms underlying axon regeneration following CNS injury.

Abstract: Astrocytes detect synaptic activity and regulate excitatory synaptic transmission through a variety of mechanisms including glutamate uptake and gliotransmitter release. The bidirectional communication between astrocytes and neurons takes place at the 'tripartite synapse', where astrocytic processes form intimate physical contacts with individual synapses. However, little is known about the influence of astrocytic coverage on individual synapses. A major obstacle to study these interactions has been the small size of the peri-synaptic astrocytic processes, which cannot be resolved by conventional fluorescence microscopy.
To overcome this problem, we combined live-cell STED microscopy of dendritic and astrocytic morphology with confocal Ca^{2+} imaging of astrocytes in living organotypic hippocampal slices. For this purpose, we used combinations of transgenic mouse lines (Ai6GFAP-ZsGreen for astrocytes, Thy1-YFP for neurons) and viral vectors (Sindbis-Citrine for neurons, AAV-GCaMP6s for astrocytes).
The super-resolution imaging approach revealed a reticular organization of astrocytic processes, which was characterized by bouton-like compartments strung together by a web of hyperfine connecting shafts. By co-labeling astrocytes and spines, we found that their physical association exhibited a wide spectrum of forms, from point-like contacts to nearly full coverage of the spine by the astrocyte. Notably, individual spines often were in contact with astrocytic compartments, suggesting that they form the glial element of the tripartite synapse. Confocal Ca^{2+} imaging showed that these astrocytic structures exhibited highly localized and uncorrelated Ca^{2+} transients during basal synaptic transmission, which often stayed restricted to the immediate proximity of a spine.
Together, our results reveal that tripartite synapses are highly individualistic structures, which exhibit unique spine-astrocyte morphological interactions and that astrocytic Ca^{2+} signals can be confined enough to affect only single synapses. These findings support the view that astrocytes can influence synaptic transmission with single spine specificity.

Inst., Seattle, WA

Abstract: The corpus callosum is the major axon tract that connects and integrates neural activity between the two cerebral hemispheres. However, ~1:4000 children are born with developmental absence of this tract, and the primary etiology of this condition remains unknown. Here, we demonstrate that midline crossing of callosal axons is dependent upon the prior remodeling and degradation of the intervening interhemispheric fissure during development. In mice and humans, this remodeling event is initiated by astroglia either side of the interhemispheric fissure, which intercalate with one another and degrade the intervening leptomeninges. Callosal axons then preferentially extend over these specialized astroglial cells as they cross the midline. We demonstrate that a key regulatory step in interhemispheric remodeling is the differentiation of these astroglia from radial glia, which is initiated by Fgf signaling to downstream Nfi transcription factors. Crucially, our findings from human neuroimaging studies reveal that developmental defects in interhemispheric remodeling are likely to be a primary etiology leading to human callosal agenesis.

Title: Astrocytes are necessary for synchronized bursting behavior of neuronal networks in culture

Authors: K. R. SANCHEZ[1], F. PERRY[1], M. A. HARRINGTON[1], *M. TEMBURNI[2];
[1]Biol. Sci., [2]Biol., Delaware State Univ., Dover, DE

Abstract: Synchronous oscillations are thought to be necessary for establishing functional neuronal networks for normal vertebrate brain development - however, the mechanisms of synchronization are not fully understood. Existing models of synchronous activity assume that it is a process intrinsic to neurons. Recently astrocytes, have been shown to participate in neuronal communication by releasing “gliotransmitters” like glutamate, and ATP. We hypothesize that astrocyte-neuron interactions are crucial for the development of synchronous activity seen in the developing vertebrate brain. We test this hypothesis by establishing pure and mixed (astrocyte and neuronal) cultures from the developing chicken brain (optic tectum) and recording neuronal activity using the multi-electrode array system, MED64 and Axion. Pure neuronal cultures were obtained by treating cultures with the mitotic inhibitor 5-fluorodeoxyuridine (FUdR) which kills mitotically active astrocytes but spares post-mitotic neurons. Neurons were kept alive in the absence of astrocytes by supplementing the culture medium with 50% astrocyte conditioned medium. Typically mixed cultures of astrocytes and neurons show random spiking activity in one week and synchronous activity in two weeks. Our initial results indicate that pure neuron only cultures show random spiking activity without synchronization even after two weeks thus clearly establishing a role for astrocytes in the development of synchronous activity. To insure the integrity of the neuronal structure in the absence of astrocytes Immunofluorescence (IF) microscopy was done. To further dissect the molecular pathways involved we are targeting three pathways within astrocytes that have been demonstrated to be crucial for communication with neurons - metabotropic glutamate receptor (mGluR). Activation of these G-protein coupled receptor by their respective neurotransmitters mobilizes intracellular calcium release leading to exocytosis of either glutamate. We are expressing dominant negative peptides designed to disrupt downstream signaling from these receptors and thereby calcium mobilization and exocytosis of gliotransmitters. Intracellular Ca^{++} release in astrocytes is monitored using GCaMPs.

Title: Dual-color calcium imaging of astrocytes and neurons in the ferret visual cortex

Authors: *V. KELLNER, J. SCHUMMERS;
Max Planck Florida Inst., Jupiter, FL

Abstract: The role of astrocytes as more than support cells in the brain has begun to emerge. Studies have shown that astrocytes respond to sensory stimuli in a manner that is not a mere reflection of neuronal activity. Specifically, astrocytes respond to visual stimuli in the ferret visual cortex with similar but sharper orientation tuning curves compared to nearby neurons. The interactions between astrocytes and neurons that shape network responses to physiological stimuli remain unclear. Few studies have measured astrocytic and neuronal activity simultaneously in the intact brain. Those that have, used bulk loading of calcium dye which labels the astrocyte cell body but not the thin processes. Recent work has determined that astrocyte processes can function independently of the cell body, which emphasizes the importance of measuring calcium activity in the processes as well. The recent development of genetically encoded calcium indicators (GECIs) has enabled the targeting of calcium in astrocytic processes and newly improved red-shifted GECIs enable the simultaneous imaging of astrocytes and neurons. Using this technology in the anesthetized ferret visual cortex, with its columnar functional organization, we are able to simultaneously measure visual responses in astrocytes and neurons. By varying parameters of the stimulus we are able to show that astrocytes integrate neuronal activity. We also show, using electroencephalography (EEG) to measure brain states, that astrocytes and neurons differ in their responses to visual stimuli during synchronized and desynchronized brain states. Imaging neuronal and astrocytic calcium signaling simultaneously will enable us to measure the transfer function between neurons and astrocytes on a trial-by-trial basis.

Title: Astrocytes regulate dendritic inhibition of pyramidal cells by somatostatin interneurons

Authors: *M. MATOS[1], I. RIEBE[1], C. REYNELL[1], J. VALLÉE[1], I. LAPLANTE[1], A. PANATIER[2], J.-C. LACAILLE[1], R. ROBITAILLE[1];
[1]Neurosciences, Univ. De Montréal, Montréal, QC, Canada; [2]Neurocentre Magendie, Univ. de Bordeaux, Bordeaux, France

Abstract: γ-aminobutyric acid (GABA) interneurons play crucial roles in the control of pyramidal neurons (PNs) and network activity. In addition, another level of regulation could be mediated by astrocytes, as they perform important roles in the regulation of excitatory synaptic networks. However, the interaction of astrocytes with GABAergic synaptic inhibition by interneurons remains ill defined. To address this question, we employed an optogenetic approach, with selective channelrhodopsin 2 (ChR2) expression in somatostatin-containing interneurons (SOM-INs), to specifically activate SOM-INs, while monitoring Ca^{2+} in astrocytes and recording inhibitory currents in PNs from CA1 hippocampal slices of SOM-ChR2/EYFP mice. Our data show that low-frequency (0.1 Hz) photostimulation of SOM-INs evokes inhibitory postsynaptic currents (eIPSCs) in PNs. They were potentiated by endogenous ATP-derived adenosine acting on adenosine A_1 receptors (A_1R), indicated by their decrease after bath-perfusion with A_1R selective antagonist DPCPX (100 nM) (decrease to 66.0 ± 3.1% of the baseline, $p< 0.01$). This was further mimicked by preventing ATP-to-adenosine catabolism with ectonucleotidase inhibitor AMP-CP (200 μM) (decrease to 50.0 ± 7.0% of the baseline, $p< 0.01$). To probe for a possible astrocytic calcium (Ca^{2+})-based mechanism for the adenosine acting on A_1R, as we previously showed (Serrano et al., 2006, J Neurosci. 26**:**5370), we examined the Ca^{2+} dynamics in astrocytes after stimulation of SOM-INs. Our data reveals that light-stimulation of SOM-INs induced Ca^{2+} transients (27.2 ± 2.6% mean ΔF/F, n=12) mainly mediated by astrocyte-specific GABA transporter type-3 (GAT-3) (54.0 % ± 6.0% ΔF, $p< 0.001$) as they were blocked by GAT-3 inhibitor (S)-SNAP-5114 (100 μM). Importantly, astrocyte Ca^{2+} chelation with

BAPTA (20 mM) led to a decrease on SOM-INs light-eIPSCS in PNs (decrease to 56.1 ± 6.2% of the baseline, $p< 0.001$), an effect occluded by previous treatment with (S)-SNAP-5114. This suggests that GAT-3 mediated a glial Ca^{2+}-dependent process leading to potentiation of eIPSCs on PNs. Finally, the inhibitory effect of A_1R antagonist DPCPX on eIPSCs was occluded by previous block of GAT-3. Overall, our results suggest that, in response to GABA released by SOM-INs, astrocytic GAT-3 triggered a Ca^{2+} signalling mechanism, leading to the release of ATP-derived adenosine which activated A_1Rs. This, in turn, potentiated SOM-INs synaptic inhibition in PNs. These data uncover a novel physiological interaction between a specific subpopulation of interneurons and astrocytes, involved in the regulation of dendritic inhibition of hippocampal pyramidal cells.

Title: Effects of GM1 on activation of signaling pathways in neurons and astrocytes, dependence of astrocyte-neuron interactions

Authors: *H. FIUMELLI[1], I. ALLAMAN[2], J.-L. MARTIN[3], P. J. MAGISTRETTI[1,2];
[1]Biol. and Envrn. Sci. & Engin. Div., King Abdullah Univ. of Sci. and Technol., Thuwal, Saudi Arabia; [2]Brain Mind Inst., Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland; [3]Ctr. for Psychiatric Neurosci., Lausanne Univ. Hosp., Prilly, Switzerland

Abstract: Preclinical and clinical studies have shown that treatment with the ganglioside GM1 is neuroprotective and restorative, relieving symptoms and slowing down disease progression in Parkinson's patients. Substantial evidence from *in vitro* experiments indicates that trophic actions of GM1 on various populations of central nervous system neurons resemble those of neurotrophic factors, suggesting that GM1 functions are mediated by similar molecular pathways. Testing this hypothesis on primary cultured cortical neurons, we did not detect changes in markers of the neurotrophin/tyrosine kinase receptor pathway following GM1 treatment (60 uM, up to 1h). However, in co-cultures of neurons and astrocytes (prepared on separate physical substrates and sharing the same culture media), we found that GM1 increased

TrkB and Erk1/2 phosphorylation levels and induced the expression of immediate early gene such as Arc, Egr1, and BDNF, suggesting that diffusible substances between astrocytes and neurons are important for GM1 actions. To gain insight into the long-term gene expression changes induced by GM1 in astrocytes and neurons, we analyzed the effects of GM1 treatment (60 uM, 24h) on the gene expression profile of co-cultured astrocytes and neurons, as well as of pure cultures of astrocytes and neurons, using whole transcriptome RNA-seq. Differential expression analysis, with a cutoff of fold change > 1.5 and FDR < 0.05, between control and GM1 treated cultures revealed that co-cultured cells display considerably higher numbers of differentially expressed genes than pure cultures. We identified 1717 and 801 genes modulated by GM1 in co-cultured neurons and astrocytes respectively, whereas only 78 and 291 genes were regulated in pure cultured neurons and astrocytes respectively. Interestingly, for each cell type, only few differentially expressed genes were in common between both culture configurations (astrocytes, 52; neurons, 42). We next subjected the differentially expressed gene sets to pathway and gene ontology analysis to highlight functional processes affected by GM1. We found that differentially expressed genes in co-cultured astrocytes were mapped to cell adhesion and recognition, immune response and cholesterol synthesis, while those in co-cultured neurons were associated with synaptic transmission, regulation of ionotropic signaling, behavior, cognition, extracellular matrix and inflammatory response. Altogether, these data indicate that the molecular and functional signals elicited by GM1 are highly dependent on interactions between astrocytes and neurons.

Abstract: Here we report that transduction of rat hippocampal neurons with constitutively active form of ras homolog enriched in the brain [Rheb(S16H)] using adeno-associated virus serotype 1 [AAV1-Rheb(S16H)] significantly increases the levels of cilliary neurotrophic factor (CNTF) and CNTF receptor α (CNTFRα) in astrocytes and neurons, respectively, even though the AAV1 transduction is limited within neurons. Neuronal brain-derived neurotrophic factor (BDNF) increased by AAV1-Rheb(S16H) transduction stimulated the production of CNTF in astrocytes, and CNTF and CNTFRα neutralization attenuated the Rheb(S16H)-induced neuroprotection against thrombin-induced neurotoxicity in the hippocampus. Moreover, neutralization and inhibition of tropomyocin receptor kinase B (TrkB), which is a specific receptor for BDNF, attenuated the production of CNTF in astrocytes *in vivo* and *in vitro*, resulting in inhibition of neuroprotective effects in the AAV1-Rheb(S16H)-transduced hippocampus. In the hippocampus of patients with Alzheimer's disease (AD), the protein levels of TrkB and CNTFRα were significantly increased compared with age-matched controls, even though the levels of BDNF and CNTF expression were significantly decreased or not altered, respectively, in the hippocampus of patients with AD, suggesting that there might be an endogenous neuroprotective system, exerting to protect hippocampal neurons against neurodegeneration. Thus, we conclude that viral vector transduction of neurons with Rheb(S16H) intensifies a beneficial construction of neuroprotective system through the heterotypic interactions between neurons and astrocytes, and the construction of neuroprotective system in the hippocampus may have therapeutic values against neurodegenerative diseases such as AD.

Title: Endogenous lactate reserves may fuel synaptic transmission via oxidative phosphorylation in hippocampal primary neurons

Authors: *C. SOBIESKI, N. WARIKOO, S. MENNERICK;
Dept of Psychiatry, Washington Univ. In St Louis, Saint Louis, MO

Abstract: Glucose is metabolized via glycolysis and oxidative phosphorylation to produce ATP required for neurotransmission. The contributions of glycolysis and oxidative phosphorylation in fueling synaptic function are unclear. In autaptic hippocampal primary cultures, we inhibited glycolysis with 2-deoxy-D-glucose (2DG) and oxidative phosphorylation with oligomycin (oligo). Although 2DG+oligo and oligo alone compromised sodium currents, indicating collapse of the somatic sodium gradient, only combined inhibition blocked evoked transmission, suggesting intact action potential propagation in the axons following inhibition of either glycolysis or oxidative phosphorylation alone. After combined inhibition, we were unable to evoke vesicle release by action potentials, direct depolarization of synaptic terminals (100 mM K^+), or by application of 0.5 mM sucrose, suggesting absence of docked, primed vesicles. Although 2DG or oligo did not affect basal synaptic activity, previous work suggests obstructing glycolysis or oxidative phosphorylation disrupts vesicle endocytosis during sustained stimulation. It remains unclear whether endocytosis is more sensitive to a loss of glycolysis or oxidative phosphorylation. Following inhibition of oxidative phosphorylation, PSCs failed to recover after vesicle depletion (30s of 90 mM K^+). PSCs recovered normally after blocking glycolysis. Sensitivity to oxidative phosphorylation may be consistent with the astrocyte-neuron lactate shuttle hypothesis, where local glutamate uptake by perisynaptic astrocytes fuels astrocytic glycolysis and lactate shuttling to neurons. To test astrocytes role in vesicle recovery, we employed microcultures containing (+) or lacking (-) astrocytes. Disrupting the lactate shuttle with either –astrocyte microcultures or acute application of alpha-cyano-4-hydroxycinnamic acid (4-CIN) did not affect EPSC recovery compared to +astrocyte controls. Furthermore, 16 hr

aglycemia failed to affect either +astrocyte or -astrocyte EPSC recovery following vesicle depletion. Trace lactate (0.31 mM) measured in aglycemic saline was likely important for sustaining transmission since blocking its transport via 4-CIN during aglycemia significantly increased neuronal death. Our results suggest that basal synaptic transmission is sustained by either glycolysis or by oxidative phosphorylation, but oxidative phosphorylation is required for vesicle recycling. Oxidative phosphorylation can be fueled by reserves derived from astrocytic glycolysis, but these results contradict the current view that local, immediately supplied lactate fuels synaptic transmission.

Title: The mediating effect of Lycium Barbarum Polysaccharides on retinal glial cells in a mouse model of acute ocular hypertension

Authors: *X. MI;
The First Hosp., Guang Dong, China

Abstract: Purpose: Acute ocular hypertension (AOH) could induce retinal damage through ischemia/reperfusion and mechanical injuries. The neuroprotective effect of *Lycium Barbarum* polysaccharides (LBP) has been discussed in our preliminary study. The purpose of this study is to investigate the effect of LBP on mediating retinal glial cells and recovering visual function.
Methods: AOH mouse model was induced in unilateral eye for one hour by introducing 90 mmHg ocular pressure. The animal was fed with LBP solution (1mg/kg) or PBS vehicle daily from 7 days before the AOH insult till sacrifice at day 4 post insult. The effects of LBP on retinal glial cells were examined by the glial cell number counting (for astrocytes and microglia) as well as the associated biomarker changes using S-100, GFAP, GS and AQP-4 as well as Iba-1. To investigate the visual function of mice, optokinetic test (OKT) and electroretinography (ERG) were performed.
Results: The neuroprotective effect of LBP was confirmed by number counting of retinal ganglion cells, which was as same as our previous report. Under the treatment of LBP, the recovery of animal's visual function was detected from the OKT and ERG data. After AOH

insult, increased number of astrocytes and microglia was observed. Together with increased expression of GFAP, GS and AQP-4, the morphological change of retinal astrocytes was also observed. After treatment with LBP, there was less increased number of astrocytes (lowering 43.5% when compared to PBS vehicle, $p<0.01$) and microglia (lowering 25.9% when compared to PBS vehicle, $p<0.01$), together with decreased expression of GFAP, GS, AQP-4 and APP when compared with the PBS vehicle treated retina.
Conclusion: The present study suggests the neuroprotective role of LBP is related to regulate the reactivity of retinal glial cells.

Title: Metabolic axon-glia interaction assessed by real-time imaging of ATP

Authors: *A. TREVISIOL[1], A. S. SAAB[2], U. WINKLER[3], J. HIRRLINGER[3], K. A. NAVE[1]; [1]Max Planck Inst. For Exptl. Med., Goettingen, Germany; [2]Inst. of Pharmacol. & Toxicology, Univ. of Zurich, Zurich, Switzerland; [3]Carl-Ludwig-Institute for Physiology, Fac. of Medicine, Univ. of Leipzig, Leipzig, Germany

Abstract: Myelin provides electrical insulation to axons in white matter but it also limits any possible access to extracellular metabolites to the Node of Ranvier. However, the hypothesis that oligodendrocytes and their associated myelin sheaths might function as a direct source and interface for metabolites delivery into the axons they engulf, has been supported by an increasing number of observations. We generated a mouse line that expresses in neurons a FRET-based sensor ($AT1.03^{YEMK}$; Imamura et al. 2009) for ATP, a central molecule in the cell's energy homeostasis. We developed a set-up that allowed us to control both axonal electrical activity in the optic nerve (ON, a CNS white matter tract) and the delivery of metabolites through a superfusion solution (aCSF) while imaging the ATP-sensor in axons by confocal microscopy. We challenged the ON by different combinations of high-frequency stimulation and low-

substrate condition to determine how axonal ATP fluctuations correlate with electrical activity measured as compound action potentials (CAP, classically used as neuronal energy-readout). Using this system we show that glia-derived monocarboxylates, i.e. lactate and pyruvate, are essential to maintain axonal energy balance. The temporal dynamics of ATP correlated well with the fast and reversible changes in CAP under conditions of sufficient glucose supply in the aCSF. However, when activity of monocarboxylate transporter (MCT) was thwarted in the myelin and in the glia compartment, we observed a larger decrease in axonal ATP, which surprisingly was not followed by a similar decrease in CAP, suggesting a more complex relationship of ATP and CAP than supposed previously.
We finally assessed the impact of a myelin impairment on the axonal energy status by crossbreeding our ATP-reporter mouse with *Plp1*-null mutants. The lack of Plp1, one of the most abundant protein within myelin, has been shown to cause axonal degeneration in adult mice, but the exact mechanism has never been clarified. We have found evidence that during high-frequency stimulation of *Plp1*-null ONs, axonal ATP metabolism is impaired in an early phase of the pathology. Our data suggests that impairment in the metabolic axon-glia interplay might be one of the first events during pathogenesis in white matter diseases.

Title: Active dendritic conductances regulate the impact of gliotransmission on rat hippocampal pyramidal neurons

Authors: *S. ASHHAD, R. NARAYANAN;
Indian Inst. of Sci., Bangalore, India

Abstract: Glial cells in the brain actively communicate with neurons through release of transmitter molecules that result in neuronal voltage deflections, thereby playing vital roles in

neuronal information processing. An important manifestation of this is the N-methyl-D-aspartate receptor (NMDAR)-dependent slow inward currents in neurons. Although a significant proportion of information processing in neurons is performed in their dendritic arborization, the intra-neuronal spatial dynamics of these events or the role of active dendrites in regulating their amplitude and spatial spread have remained unexplored. Here, we employed somatic and/or dendritic recordings from rat hippocampal pyramidal neurons and demonstrate that a majority of NMDAR-dependent spontaneous slow excitatory potentials (SEP) originate at dendritic locations and are significantly attenuated through their propagation across the neuronal arbor. We substantiated the astrocytic origin of SEPs through paired neuron-astrocyte recordings, where we found that specific infusion of inositol trisphosphate ($InsP_3$) into either distal or proximal astrocytes enhanced the amplitude and frequency of neuronal SEPs. Importantly, SEPs recorded after $InsP_3$-infusion into distal astrocytes exhibited significantly slower kinetics compared to those recorded after proximal infusion. Furthermore, employing neuron-specific infusion of pharmacological agents and morphologically realistic conductance-based computational models, we demonstrate that dendritically expressed hyperpolarization-activated cyclic-nucleotide-gated and transient potassium channels play critical roles in regulating the strength, kinetics and compartmentalization of neuronal SEPs. Finally, through the application of subtype-specific receptor blockers during paired neuron-astrocyte recordings, we provide evidence that GluN2B- and GluN2D-containing NMDARs predominantly mediate perisomatic and dendritic SEPs, respectively. Furthermore, in replicating experimentally observed somatodendritic SEP amplitudes in morphologically realistic conductance-based models, we arrived at a testable prediction that the density of extrasynaptic NMDARs should increase with dendritic distance from the soma. Our results add a significantly complex dimension to neuron-glia interactions by unveiling an important role for active dendrites in regulating the impact of gliotransmission, and suggest astrocytes as a source of dendritic plateau potentials that have been implicated in localized plasticity and place cell formation.

Title: Specific Hypolipidemia caused by VLDL degradation in Children with ASD

Authors: *H. MATSUZAKI[1], K. IWATA[1], K. NAKAMURA[2], M. TSUJII[3], N. MORI[4]; [1]Univ. of Fukui, Eiheiji-Cho, Yoshida-Gun, Japan; [2]Neuropsychiatry, Hirosaki Univ. Sch. of Med., Hirosaki, Japan; [3]Contemporary Sociology, Chukyo Univ., Toyota, Japan; [4]United Grad. Sch. of Child Develop., Osaka Univ., Suita, Japan

Abstract: Background: The neurobiological basis for autism remains poorly understood, but evidence is mounting in support of lipid metabolism playing a role in autism spectrum disorder (ASD). We have already revealed that Very Low Density Lipoprotein (VLDL) triglyceride was significantly decreased in children with ASD than those of normal control subjects (US PATENT #8518659). To elucidate the mechanism of VLDL down-regulation, it was necessary to clarify whether VLDL was reduced due to activation of the degradation or inhibition of its synthesis.
Objectives: In order to clarify the mechanism of VLDL down-regulation in ASD, we carried out measurements of free metabolite in plasma of children with ASD and examined correlation between VLDL triglyceride and the metabolites detected.
Methods: This study enrolled 30 children (6-11yrs old) with ASD recruited from the Asperger Society Japan and 30 age-matched healthy control subjects recruited by advertisement. Fasting human blood samples were collected by venipuncture in a sitting position with a tourniquet from all participants for both groups who are Japanese and drug-naïve. LC/CE-TOFMS measurement of free metabolite in the plasma was carried out using an Agilent LC System and CE Capillary Electrophoresis System (Agilent Technologies, Waldbronn, Germany). The size distribution of plasma lipoprotein particles was evaluated by high sensitivity lipoprotein profiling system with high-performance liquid chromatography (Skylight Biotech, Inc., Akita, Japan).
Results: By TOFMS analysis, a total of 258 metabolites were detected in the plasma of all set. Of these, 83 metabolites showed significantly different relative areas between the ASD children and the controls. The present study identified deviated plasma metabolite levels associated with oxidative stress and mitochondrial dysfunction in children with ASD. More, we found significant correlation between VLDL triglyceride decrease and 20 metabolites change including 12 free fatty acids, 3 free acylcarnitines, alanine, loganin, 2-hydroxybutyric acid, 3-hydroxybutyric acid and O-acetylcarnitine (ALCAR) in the ASD participants. Of these 20 metabolites, Alanine and Loganin were lower but the others were higher in the ASD participants than controls.
Conclusions: These results suggested that VLDL degradation may cause VLDL-specific hypolipidemia in children with ASD. This finding might be surrogate marker implicated in oxidative stress and mitochondrial dysfunction of ASD.

Title: Attention and neural response to simulated social interactions in ASD

Authors: *J. A. TRAPANI[1], A. J. NAPLES[2], M. J. ROLISON[2], J. H. FOSS-FEIG[2], J. C. MCPARTLAND[2];
[1]Child Study Ctr., Yale Univ., New Haven, CT; [2]Child Study Center, Yale Univ. Sch. of Med., New Haven, CT

Abstract: Atypical gaze, exhibited by difficulties with eye-contact and joint attention, is often an early sign of autism spectrum disorder (ASD) and research measuring event-related potentials (ERPs) with electrophysiology reveals atypical structural encoding of faces in ASD. Behaviorally, social differences in ASD are most pronounced during interactions, yet most existing experimental investigations of gaze processing use paradigms in which participants passively observe faces.
Using gaze contingent ERP, this study aimed to investigate attention to dynamic faces as measured by eye movements and neural response to eye-contact in children with ASD and typical development (TD). We also explored relationships among attentional and neural markers and clinical characteristics.
Participants were school-aged children with ASD (n=61) and TD (n=40) matched on age and IQ. ERPs were recorded using 128-channel sensor nets while eye movements were recorded concurrently with a remote eye-tracking system. In the current experimental paradigm, faces appear on screen and respond to participant gaze by either sharing or averting gaze. ERPs were time-locked to face movement; occipital N170 and central P300 were extracted for analyses.

An interaction between Condition and Group indicated the individuals with ASD had larger P100s to averted gaze while TD individuals had larger P100s to direct gaze [$F(1,79) = 4.68$, $p = .03$]. Across conditions, individuals with ASD had larger P100s to gaze [$F(1,79) = 7.79$, $p = .007$]. A main effect of Condition indicated that N170s to direct gaze were more negative than to averted gaze [$F(1,79) = 4.98$, $p = .028$]. A main effect of Group revealed that individuals with ASD looked less to the eyes of the face following gaze change [$F(1,99) = 27.95$, $p < .001$], and more to the bridge of nose (between eyes) following gaze change [$F(1,99) = 6.871$, $p = .01$]. In an interactive paradigm, direct gaze elicited greater face specific neural activity (N170) than averted gaze, suggesting reciprocal eye contact recruits greater face-specific brain activity than gaze aversion. Typically developing individuals showed larger P100s to reciprocal eye contact, while individuals with ASD exhibited larger P100s to averted gaze. This finding suggests typically developing individuals may prioritize social aspects of gaze (e.g., mutual eye-contact), whereas individuals with ASD may prioritize more directly functional aspects of gaze, such as directing attention. Increased attention to the eyes of the face correlated with better social function, suggesting that the ability to maintain reciprocal eye-contact in an interactive context is highly correlated with symptom presentation.

Title: Developing a passive viewing phenotypic measure of autistic traits

Authors: *O. E. PARSONS[1], R. BETHLEHEM[2], J. FREYBERG[2], O. SLUIJTERS[2], B. STONIER[2], S. BARON-COHEN[2];
[1]Dept. of Psychiatry, [2]Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Background Autism spectrum conditions (ASC) are associated with atypical face processing, reduced accuracy in face discrimination tasks and difficulties with recognizing emotional expression. Autistic traits and features of the autism phenotype are also expressed to a lesser extent in the general population. One current limitation of research in ASC is that the focus is skewed towards higher-functioning, verbal individuals due to pragmatic issues in testing

those lower on the spectrum.
Objectives The aim of this project was to develop a passive viewing paradigm sensitive to aspects of the ASC phenotype. We wanted to establish whether individual differences in neural responses during a face oddball task were correlated with characteristics associated with ASC in a typical population.
Method We used a fast serial visual presentation (FSVP) task to expose participants to a sequence of images. Stimuli were presented at a frequency of 6.0Hz, with faces being presented within this sequence at 1.2Hz. We used the steady state evoked potential (SSVEP) power at the social stimuli frequency relative to the baseline frequency as a measure of neural activation in response to faces. We recruited 37 typical participants who were asked to complete 3 questionnaire measures (Autism Quotient, Empathy Quotient and Systemising Quotient) associated with behavioural phenotypes in ASC as well as a behavioural measure of emotional recognition, the Reading the Mind in the Eyes Task (RMET).
Results Bayesian correlations between SSVEP response and the 3 questionnaire measures were not indicative of evidence of an association in either hemisphere. However, neither did the results provide strong evidence that scores on the questionnaires were truly independent from neural responses to faces. There was good evidence to suggest a true correlation between scores on the RMET and activation in the left fusiform gyrus.
DiscussionThe results reported here are the first to find an association between a behavioural measure and neural responses to faces using a FSVP paradigm. This approach has several advantages, particularly for working with a clinical population: It is a passive task, it only takes a few minutes to complete and the SSVEP provides a high signal-to-noise ratio. These results suggest a potential overlapping neural mechanism involved in both emotional processing and automatic face categorization. The implications of these results are discussed with reference to their potential application in ASC research.

Title: Cognitive and brain aging in autism spectrum disorder: executive functioning and frontal and temporal lobe differences

Authors: *B. B. BRADEN[1], C. J. SMITH[2], A. THOMPSON[1], T. K. GLASPY[1], E. WOOD[1], D. VATSA[1], L. C. BAXTER[1];
[1]Barrow Neurolog. Inst., Phoenix, AZ; [2]Southwest Autism Res. & Resource Ctr., Phoenix, AZ

Abstract: Introduction: The effects of aging in adults with autism spectrum disorder (ASD) are understudied, but of increasing importance in order to anticipate unique needs of this growing group of individuals. Executive functioning is particularly vulnerable in both high-functioning ASD and in normal aging. The current study combined neuroimaging and cognitive tasks to examine the relationship between cognition and brain measures in a late middle-aged ASD cohort and age-matched typically developing (TD) men. **Methods:** We evaluated 16 ASD and 17 age-matched TD individuals from ages 40 to 64. Participants completed a battery of neuropsychological tests and a functional MRI task assessing working memory (N-Back Task). Functionally connected network activity during the N-Back Task was assessed via independent component analysis. Structural connectivity was assessed via diffusion tensor imaging (fractional isotropy; FA) and gray matter volumes were assessed via T1-weighted images. **Results:** The participants were well matched according to age, IQ (83-131), and education (9-20 years). The ASD participants made more errors on an executive function task (Wisconsin Card Sorting Test; WCST) but performed similar to TD on tests of verbal learning and memory (Rey Auditory Verbal Learning Test), vocabulary (Wechsler Adult Intelligence Scale-III), and visual search (Group Embedded Figures Task). Functional connectivity analysis of the N-Back task showed decreased engagement of a network including the left inferior frontal lobe, bilateral hippocampi, amygdala, and striatum, and the thalamus in ASD participants compared to TD. Structurally, the ASD group had decreased white matter integrity (FA) bilaterally in the fimbria of the hippocampus and the genu of the corpus callosum (CC) and smaller bilateral hippocampi and right amygdala volumes. Furthermore, decreased CC integrity predicted increased executive function errors on the WCST in the ASD group. **Conclusion:** Results showed that older adults with ASD had weaknesses in executive functioning, less engagement of a working memory neural network, decreased fronto-temporal white matter integrity, and smaller limbic structures including the hippocampus. Reduced executive function performance correlated with differences in structural connectivity of the frontal lobe. The present cognitive and brain differences in older adults with ASD are concerning and overlap with changes that also occur during degenerative aging processes.

Title: Cerebellar differences associated with fine motor dysfunction in aging autism cohort

Authors: *B. R. DEATHERAGE[1], B. BRADEN[1], C. J. SMITH[2], M. K. MCBEATH[3], T. K. GLASPY[1], L. C. BAXTER[1];
[1]Neuroimaging, Barrow Neurolog. Inst., Phoenix, AZ; [2]Southwest Autism Resource & Res. Ctr., Phoenix, AZ; [3]Psychology, Arizona State Univ., Tempe, AZ

Abstract: Background: Gait disturbance, clumsiness, and other mild movement problems are often observed in autism spectrum disorder (ASD; Rinehart *et al.,* 2006). This study focused on brain changes that may indicate the neural basis for these motor symptoms that are common although not ubiquitous among ASD individuals. As the brain ages, these ASD-related symptoms may be exacerbated. Using magnetic resonance imaging (MRI), we examined cerebellar volumes and white matter integrity in a cross-sectional study comparing middle-aged adults with ASD and age-matched typically developing (TD) controls (n=33). We hypothesized that older adults with ASD would exhibit smaller cerebellar volumes along with decreased white matter integrity that would be related to fine motor dysfunction, as compared to their TD counterparts.
Methods: All images were collected using a Phillips 3T scanner. 3D T1 and diffusion tensor images were obtained to measure gray and white matter volume and white matter integrity. Freesurfer, a volumetric measurement software, was used to determine group cerebellar volume differences. In order to determine white-matter integrity with automated segmentation, we used Voxel-Based Morphometry. A finger oscillation (Finger Tapping) test was administered to determine if cerebellar differences predict fine motor performance.
Results: 16 ASD and 17 TD participants were matched according to age and similar for IQ and level of education. Smaller white matter volume and reduced integrity was found in the ASD group within the bilateral cortico-ponto-cerebellar white matter tracts as compared to TD. ASD individuals' finger tapping speed exhibited a trend of being slower compared to TDs. Cerebellar white matter predicted finger tap scores in the ASD participants. There were no differences

between ASD and TD participants for cerebellar cortical volume (gray matter).
Conclusion: A measure of cerebellar white matter correlated with reduced fine motor function in ASD subjects. Cerebellar atrophy, specifically in the white matter, may account for the prominence of fine motor dysfunction in older adults with ASD. Previous studies have found anatomical differences in younger ASD subjects (Courchesne *et al.,* 2011). This cross-sectional study extends findings to aging adults, with novel results that correlate cerebellar white matter with fine motor speed, suggesting cerebellar changes, especially in the white matter, are related to decreased motor functioning. Longitudinal assessments (every two years) are planned to determine whether older individuals with ASD show exacerbation in atrophy and fine motor change over time.

Ctr., Sacramento, CA

Abstract: Atypical responses to the sensory environment have long been known as a common feature of the Autism Spectrum Disorder ("ASD") phenotype and are part of DSM-5 criteria. For example, individuals with ASD judged auditory stimuli as uncomfortable at lower intensities as

compared to typically developing (TD) controls. The present study, part of a larger multi-disciplinary project to identify autism subphenotypes (The Autism Phenome Project) recorded 61-channel EEG auditory event-related potentials (ERPs) elicited by 50ms complex tones randomly presented at 50, 60, 70 or 80 dB to TD toddlers (n=24) and those diagnosed with ASD (n=36). The ASD diagnosis was confirmed based on ADOS, ADI-R, and expert clinical opinions using DSM-IV criteria. All children (age 2.5-4 years) were judged to have clinically normal hearing. Participants passively listen to ~1000 stimuli presented with a random inter-stimulus interval of 1 to 2 s while watching a quiet video of their choice. Group-averaged ERPs were computed at each intensity based on individual brain responses. Global Field Power (GFP), an estimate of electrocortical response strength, was calculated for the four intensities over the 600 ms post-stimulus epoch and compared with a 2 x 4 ANOVA with group as a between subjects factor and loudness a within subjects factor at each time point. Effects were considered significant if they remained at $p < .05$ for at least consecutive 11 time-points (here, 11 ms). Two time-windows showed a main effect of group (185-240ms and 530-555ms post-stimulus onset) with ASD children eliciting a higher averaged response in both time-windows. A main effect of loudness was found in two time-windows (60-110 ms and 136-542 ms post-stimulus onset) with 50 dB < 60 dB < 70 dB < 80 dB in both time-windows. A Group x Loudness interaction was found in two time-windows (45-60 ms and 240-315 ms post-stimulus). Over the 45-60 ms period, the TD group showed a linear increase of response strength with increased intensity, whereas children with ASD showed differences in response strength between soft (50 and 60dB) vs. loud (70 and 80dB) sounds. Over the 240-315 ms period, TD children again showed different response intensities depending on loudness whereas children with ASD showed similar response strength for all intensities. These data suggest that unusual responses to auditory stimuli shown in ASD children may result from atypical cortical processing at both early (< 150 ms) and late (> 150 ms) latencies. Next steps include exploration of the heterogeneity of these response differences within both groups in relation to demonstrated phenotypic differences.

Title: Many (but not all) DTI findings for ASD disappear with stringent motion matching

Authors: *S. K. SOLDERS[1], R. A. CARPER[2], R.-A. MÜLLER[2];
[1]Psychology/Biology, San Diego State Univ., San Diego, CA; [2]Psychology, Brain Develop. Imaging Laboratory, San Diego State Univ., San Diego, CA

Abstract: Background: Common findings in diffusion tensor imaging (DTI) studies of children and adolescents with autism spectrum disorder (ASD) include reduced fractional anisotropy (FA), and increased mean diffusivity (MD) and radial diffusivity (RD) of white matter tracts. But, recent findings suggest that group differences in head motion can produce similar effects (Koldewyn et al., 2014; Yendiki et al., 2013). Since few ASD studies control for such differences, previous results must be considered with caution. **Objective:** Determine whether group level motion matching alters DTI findings when comparing ASD and typically developing (TD) groups. **Method:** DTI was gathered from 57 ASD and 50 TD participants (7-18yrs). We compared 3 subsets at increasing levels of motion matching stringency: [A] full set; [B] after excluding scans with moderate image noise, slice-wise signal dropout, or shifts of head placement as identified visually; [C] highest stringency, after quantitative assessment to match groups on average inter-volume translation, rotation, proportion of slices with signal dropout, and signal dropout severity (Yendiki et al., 2013). At each stringency level, groups were compared on FA, MD, RD, and AD (axial diffusivity) using two analytic approaches: Tract-Based Spatial Statistics (TBSS) and probabilistic tractography (FSL) of bilateral association and commissural tracts. **Results:** TBSS: In set A, FA was significantly reduced in ASD compared to TD throughout much of the right hemisphere. In set B, this effect remained, but was less extensive. In the most stringent set C, no significant differences were found for FA, but effect sizes for some clusters (e.g., in right inferior fronto-occipital fasciculus [rIFOF]) *increased* with quality control and matching stringency. No significant group differences for MD, AD, or RD were seen in any set. Tractography: In set A, the ASD group had significantly reduced FA in bilateral inferior longitudinal fasciculi (bILF). In set B, this effect disappeared, but the ASD group had higher RD in bILF than the TD group. This effect remained in set C, where ASD participants also had higher MD than TD participants. **Conclusion:** Consistent with Koldewyn et al. (2014), our findings suggest that many previously reported DTI findings for ASD may have been artifacts of group differences in head motion. However, findings of effect sizes that increased with motion matching indicate that tract-specific anomalies (e.g., in bILF and rIFOF) probably exist in ASD. Overall, our results highlight the need for careful quality control and motion matching in comparisons between clinical and TD groups.

Title: The relationship of cortical GABA to corresponding gamma-band activity in autism: clinical and preclinical studies

Authors: *R. G. PORT[1], C. GAJEWSKI[2], S. J. SIEGEL[3], T. P. L. ROBERTS[4];
[1]Neurosci. Grad. Group, [3]Dept. of Psychiatry, [2]Univ. Of Pennsylvania, Philadelphia, PA; [4]Dept. of Radiology, Lurie Family Foundations MEG Imaging Ctr., Children's Hospital of Philadelphia, PA

Abstract: While there has been great progress researching Autism Spectrum Disorder (ASD), there is currently "no smoking gun" with regards to it's pathogenic origin. Increasingly it appears that multiple apparently separate, though ultimately converging, aberrant mechanisms lead to the constellation of behavioral phenotypes defining ASD. A leading hypothesis for one biological basis of ASD is neuronal imbalance in excitatory and inhibitory systems (E/I imbalance). A large body of research supports such imbalance, which span from bench to bedside (e.g. from ex-vivo immunohistochemistry to clinical neuroimaging-based spectroscopy). Additionally, the functional outcome of such E/I imbalance has been suggested by recent studies that observed significant coupling between regional GABAergic tone and local circuit electrophysiological functioning in typically developing (TD) adults. Such a relationship has not been demonstrated in the auditory system or in children, and it's relevance to ASD is undetermined. First, a clinical study (involving both MEGA-PRESS H^1 edited spectroscopy and magnetoencephalography) of

57 individuals (ranging from 6-42yrs old), suggested that while TD individuals demonstrate an association between Superior Temporal Gyrus GABA+/Cr and auditory-related cortical gamma-band coherence in childhood, individuals with ASD do not. Such improper development may result in the reduced auditory gamma-band coherence observed in the sub-population of adult with ASD. Second, a translational study tried to establish if such E/I imbalance was recapitulated in a murine mode relevant to ASD. Mice heterozygous for *Pcdh10* (and their WT littermates) underwent in-vivo electroencephalography as well as ex-vivo neurochemical measurement (using high performance liquid chromatography). The *Pcdh10* heterozygous mice demonstrated a specific reduction in gamma-band auditory steady state responses versus than WT littermates. Moreover, WT mice demonstrated a positive association of gamma-band activity and gamma-band coherence, which *Pcdh10* heterozygous mice failed to exhibit.

Title: Alterations in resting state electroencephalogram in young children with autism spectrum disorder as a result of behavioral interventions

Authors: *X. A. TRAN[1], S. S. JESTE[2];
[2]Univ. of California, Los Angeles: Ctr. for Autism Res. and Treatment, [1]UCLA, Los Angeles, CA

Abstract: In typically developing (TD) young children, gamma power measured at baseline correlates with later language ability (Benasich 2008). In children with autism spectrum disorders (ASD), theta power measured at baseline inversely correlates with nonverbal IQ (Jeste *in press*). We probed if behavioral intervention would cause a change in EEG power at theta and gamma frequencies. We asked if baseline EEG power at theta and gamma frequencies predicts improvement in language ability in children with ASD who underwent behavioral intervention. We hypothesized that higher gamma power and lower theta power measured prior to intervention would predict improvement in verbal IQ (VIQ) in children with ASD after intensive behavioral intervention.

Participants included 44 children with ASD (38.6% female; mean age 61.25 $\pm$ 9.01 months) and 16 TD controls (50% female; mean age 61.51 $\pm$ 9.78). The ASD cohort was recruited from an intensive, 10-week intervention program at UCLA. Baseline EEG was recorded while each subject watched a video of soap bubbles; data were processed per prior protocols (McEvoy 2015). For the ASD group, EEG was recorded prior to intervention (visit 1) and after intervention (visit 2). TD data were collected at same time points without intervention. Relative spectral power for theta (4-7 Hz) and gamma (31- 48 Hz) frequency bands was calculated using Welch's method, in 9 regions of interest (ROIs) across the scalp. We performed repeated measures ANOVA with 2 within-group comparisons (visit, ROI). Post hoc analysis using paired samples t-tests were performed for any significant main effects. We used linear regression to examine the relationship of theta and gamma power with VIQ.

There was a significant main effect of visit for the theta frequency band. Significant main effect of ROI was found at theta and gamma frequencies. In the ASD group, there was significant increase in relative theta power at left frontal, right central and right posterior ROIs. There was no change in relative gamma power between the 2 visits in the ASD cohort. Visit 1 relative theta and gamma power did not significantly predict change in VIQ.

After intervention, children with ASD showed an increase in theta power, which may reflect increased vigilance and attention while at rest. These results may be confounded by the medication taken by some children with ASD at the time of recording. Baseline theta and gamma power were not predictors of VIQ improvement in children with ASD, which conflicts with past findings in TD children. This may be explained by different patterns of theta and gamma activity between ASD and TD cohorts. In future analysis, we will compare baseline differences between ASD and TD children.

Title: Resting electroencephalogram signal complexity identifies patterns of atypical brain development

Authors: *J. FROHLICH, S. S. JESTE;
Univ. of California Los Angeles, Los Angeles, CA

Abstract: Biomarkers of atypical brain development may predict neurodevelopmental disorders such as autism spectrum disorder (ASD) in high-risk infants. Resting electroencephalogram (EEG) signal complexity has previously been used to classify infants 6 to 24 months of age according to ASD risk with high accuracy (Bosl et al, 2011) using multiscale entropy (MSE). However, developmental changes in EEG complexity from age 3 months remain uncharacterized, and it is unknown whether other measures of signal complexity are also useful for identifying neural patterns of ASD risk. Frequency variance (FV) is a measure of complexity that is sensitive to phase reset events and correlates with age in typically developing preschool age children (Frohlich et al, 2015). We examined changes in FV in high-risk infants with ≥ 1 sibling with ASD (n = 19) and low-risk infants with no siblings with ASD (n = 15) using a longitudinal study design at ages 3 and 9 months. Using methods described in Frohlich et al (2015), we calculated FV from beta-gamma (12-48 Hz) filtered resting EEG. Physiological artifacts were removed with independent component analysis (ICA) (Delorme and Makeig, 2004). Paired samples t-tests were performed between distributions of FV values from each of 124 EEG electrodes in high-density geodesic EEG nets (Electrical Geodesics, Inc) with multiple testing corrected with Benjamini-Hochberg False Discovery Rates (FDR). 44 electrodes--mostly occipital--in the high-risk group and no electrodes in the low-risk group showed significant decreases in FV from month 3 to month 9. Low-risk infants showed a trend of decreased FV less pronounced than high-risk infants. No electrodes in either group showed significant increases from month 3 to month 9. Signal complexity decreases in early infancy as a result of increased cortical synchronization. High-risk infants may show accelerated development to compensate for genetic alterations that confer ASD risk. Future work will relate trajectories of signal complexity to clinical outcomes in children at high risk for ASD.

Title: EEG measures of high frequency neural activity suggest variation in the balance of neural excitation and inhibition across autism spectrum disorder

Authors: *A. DICKINSON, I. M.REZAZADEH, C. DISTEFANO, S. SPURLING JESTE; UCLA, Los Angeles, CA

Abstract: The balance of neural excitation and inhibition (E/I) is often hypothesized to be disrupted in autism spectrum disorder (ASD). However, there are conflicting reports as to how this balance is altered. For instance, decreased levels of the excitatory neurotransmitter, glutamate (Robertson et al., 2015), and decreased levels of the inhibitory neurotransmitter, GABA (Rojas et al., 2014), have both been reported in ASD. Variability in E/I balance may inform the considerable clinical and behavioral heterogeneity seen in individuals with ASD. Here we investigate whether electroencephalography (EEG) measures of E/I balance, and their variability, may be used to discriminate clinically relevant sub-groups in a large sample of children with ASD.

Previous research has suggested that high frequency neural activity in both the beta (13-30Hz) and gamma (>30Hz) range can be used to indirectly study E/I balance. For instance, both higher peak gamma frequency (Edden et al., 2009), and higher peak beta power (Gaetz et al., 2011) have been reported to be associated with higher levels of the inhibitory neurotransmitter, GABA. In a clinically heterogeneous group of children with ASD (N=70) studied in the UCLA Center of Autism Research and Treatment, with IQ ranging from 16 - 132 and ages ranging from 12 months to 12 years, we measured both peak power and frequency in the beta and gamma frequency bands using EEG. High density EEG recordings were obtained during an eyes-open resting-state condition. Due to the inherent difficulty of measuring high frequency neural activity separately from the many non-neural artifacts occurring in the same frequency bands, EEG data were cleaned using independent component analysis. Sources of both beta and gamma activity were successfully identified in the signal following source localization (implemented through DIPFIT). Peak power and frequency in both the beta and gamma bands were extracted. Substantial variability was evident in all four metrics across the sample which will facilitate the use of methods such as the similarity network fusion algorithm and graph theory to construct networks of participants based on the EEG data. This will provide a comprehensive approach to explore physiologically meaningful sub-groups based on these metrics.

This work highlights that the contrasting reports of E/I balance in the ASD literature may be due to a focus on identifying a universal E/I imbalance at a group level. We put forward the suggestion that identifying heterogeneity through assays of E/I balance is crucial, as differences in E/I balance could potentially be used a biomarker to stratify individuals with ASD into clinically relevant subgroups.

Abstract: Visual statistical learning (VSL) refers to the detection of regularities within the visual environment (Bulf et al., 2011), and may be a precursor to later cognition and social communication (Romberg & Saffran, 2010). Studies have demonstrated reduced evidence of VSL in pre-school aged children with Autism Spectrum Disorder (ASD) using a novel electrophysiological (EEG) paradigm (Jeste et al., 2015). No studies have examined VSL in infants at risk for ASD.
We asked whether EEG signatures of VSL could be quantified at 3-months of age, and whether VSL distinguished high- and low-risk (HR, LR) infants (HR infants have an older sibling with ASD), and whether there was an association between VSL at 3-months and later cognitive function.
3-month-old infants (n=25, HR: n=12, LR: n=13) were exposed to a continuous stream of shapes based on a modified version of the Kirkham et al. (2002) VSL task. High density EEG was recorded and the event-related potential (ERP) of interest was the frontal Positive Slow Wave (PSW). A general linear model evaluated within-subject effects of region and condition and between-subject effects of group with respect to PSW mean amplitude. Learning was operationalized as differentiation between conditions. Whole group correlations between ERP markers of learning and cognitive skills at 6-months were also performed.
There was a significant group by condition interaction and a significant main effect of region. Post-hoc tests revealed greater mean amplitude within the middle region as compared to the right and left. Post-hoc tests revealed that HR infants significantly differentiated conditions, while LR infants did not. The absolute value PSW difference amplitudes correlated with 6-month visual reception and fine motor scores.
EEG correlates of VSL seem to differentiate HR from LR infants as early as 3-months of age, with HR infants displaying evidence of VSL. The relationship between VSL and non-verbal cognitive skill suggests that pattern learning is domain specific. Group differences in VSL

suggest that infants at risk for ASD may demonstrate strengths in processing visual patterns—a strength that may occur at the expense of later social communication skills.

Title: Stability of beta power in resting state EEG of children with Duplication 15q syndrome

Authors: *S. HUBERTY, J. FROHLICH, S. JESTE;
Ctr. for Autism Res. and Treatment, Univ. of California Los Angeles, Los Angeles, CA

Abstract: Duplication 15q11.2-q13.1 syndrome (Dup15q) is a rare genetic disorder featuring copy number variation of several genes on the q arm of chromosome 15. This region contains genes critical to brain development, including three GABAA receptor genes and ubiquitin ligase E3A (Ube3a). The disorder is characterized by global delay, hypotonia, intellectual disability (Battaglia, Parrini, & Tancredi, 2010), and an increased risk for epilepsy (Conant et al., 2014). Autism Spectrum Disorder (ASD) is highly comorbid with Dup15q syndrome, however children with Dup15q syndrome have more impaired motor skills and adaptive behavior compared with children with nonsyndromic ASD (Distefano et al., 2016). Recent cross sectional analyses in our lab indicate that children with Dup15q syndrome (*n=11)* show increased resting state beta1 (12 – 20 Hz) and beta2 (20 – 30Hz) power compared with an age and IQ matched nonsyndromic ASD cohort and an age matched typically developing cohort. However, given that beta power can be modulated by the cognitive and psychological state of the child, we asked whether this biomarker was stable across time. Stability of this signal would support the contention that this measure relates to underlying genetic mechanisms.
We quantified beta power in high spatial density, resting-state EEG recordings from four children with Dup15q syndrome at two visits, ranging 2-4 months apart. Genetic reports confirmed isodicentric duplications of chromosome 15q in all participants, three male (29, 44, and 56 months old), and one female (22 months old). EEGlab was used to bandpass filter the

EEG data from 1-50 Hz and to remove physiological artifacts using independent component analysis (ICA). We computed relative beta1 and beta2 power across 9 scalp regions of interest (ROIs) at each visit. A general linear model evaluated within-subjects effects of region and time on relative beta power.
Resting-state beta1 and beta2 power did not significantly differ between visits 1 and 2 in any of the 9 ROIs. We did not find a significant region by time interaction on beta1 or beta2 power. Beta power in children with Dup15q syndrome appears to be stable across multiple measurements. The stability of beta power over time reinforces the hypothesis it relates to the underlying genetic mechanisms of Dup15q syndrome and may be a biomarker for the syndrome. Over the next six months, we will continue to collect resting-state EEG at multiple time points on a larger cohort of children with Dup15q syndrome to confirm the stability of this biomarker.

Title: Assessment of cortical plasticity with continuous theta-burst stimulation in adults with autism spectrum disorders and neurotypical controls

Authors: *A. JANNATI[1], G. BLOCK[1], L. M. OBERMAN[2], A. ROTENBERG[3], A. PASCUAL-LEONE[1];
[1]BIDMC, Harvard Med. Sch., Boston, MA; [2]E.P. Bradley Hospital, Warren Alpert Med. School, Brown Univ., East Providence, RI; [3]Boston Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Objective: To evaluate the modulation of corticospinal excitability with continuous theta-burst stimulation (cTBS) as a possible physiologic phenotype for autism spectrum disorders (ASD).
Methods: Twenty-one neurotypical controls (NT; age 39.8 ± 12.3, 19 males, all right-handed) and 12 adults with ASD (age 36.9 ± 15.2, 10 males, 10 right-handed) underwent a cTBS protocol

consisting of bursts of three pulses of 50Hz stimulation at 80% of individual active motor threshold, repeated at 200ms intervals for 40 seconds (for a total of 600 pulses). Corticospinal excitability was assessed before and after cTBS by sets of 30 single pulses of neuronavigated transcranial magnetic stimulation (TMS) applied to the left primary motor cortex at 120% of individual resting motor threshold. TMS procedures were performed with a MagPro X100 stimulator, an MC-B70 Butterfly Coil (outer diameter 97mm), and Brainsight TMS navigation system, using a brain MRI template.

Peak-to-peak amplitudes of motor evoked potentials (MEPs) were recorded from the right first dorsal interosseous muscle with a PowerLab 4/25T data acquisition device and measured with LabChart 8 software. Percentage change in MEP amplitudes relative to baseline (%Δ) 5 to 60 minutes after cTBS (T5–T60) were calculated for ASD and NT groups. The change in MEP amplitude induced by cTBS is a metric of the mechanisms of cortical plasticity.

Results: Complete-linkage cluster analyses revealed two subpopulations within each group with distinct responses to cTBS. Within the NT group, 13 exhibited an inhibitory response to cTBS, while 8 showed a paradoxical excitatory response. Within the ASD group, 9 and 3 participants exhibited either inhibitory or facilitatory responses, respectively.

Comparing the ASD and NT subgroups with inhibitory responses revealed a maximal difference in MEP modulation at T40 that was statistically significant ($p = .036$). The numerical difference between average ASD and NT facilitatory responses was also the largest at T40 and showed a trend toward larger facilitation in the ASD subgroup ($p = .097$).

Within 21 participants who showed inhibitory responses across both groups, a logistic regression analysis of Group (ASD vs. NT) found a significant model [likelihood-ratio χ^2 (2) = 6.58, $p = .037$] with %Δ at T10 ($p = .087$) and %Δ at T40 ($p = .058$) as predictors.

Conclusions: Our results provide further insight into interindividual differences in the effects of cTBS on the primary motor cortex, indicate the existence of subpopulations with distinct patterns of response to cTBS within both ASD and NT groups, and support the utility of cortical plasticity measures by cTBS as a physiologic ASD biomarker.

Title: Interneuron dysfunction in syndromic autism

Authors: *T. TAKANO;
Shiga Univ. Med. Sci., Otsu, Japan

Abstract: Purpose: Autism is an extremely heterogeneous disorder, but its frequent co-occurrence with epilepsy leads to the speculation that there may be common mechanisms associated with these disorders. Inhibitory interneurons are considered to be the main cellular elements that control hyperexcitability in the brain, and interneuron dysfunction can cause pathological hyperexcitability linked to seizure susceptibility or epilepsy. Methods: This study presents some of the recent advances that support the relationship between interneuron dysfunction and cognitive impairment in human syndromic autism with particular reference to the pathophysiological findings of murine experimental models of autism.Results: Alterations to GABAergic circuits include a wide variety of neurobiological dysfunction and do not simply involve the loss or gain of any given type of inhibitory mechanism. The characteristics of interneuron dysfunction in each murine model of autism differ among each syndrome, and these diversities may be due to differences in the genetic backgrounds or some other currently unknown variances.Conclusion: Future studies should bring us a greater understanding of the involvement of different classes of GABAergic interneurons and allow us to define the relationship between the precise pathophysiological mechanisms and the corresponding clinical phenotypes in autism.

Title: Identifying novel biomarkers of social deficits in children with autism spectrum disorder

Authors: *O. OZTAN, L. P. JACKSON, R. A. LIBOVE, R. D. SUMIYOSHI, J. M. PHILLIPS, A. E. URBAN, J. P. GARNER, A. Y. HARDAN, K. J. PARKER;
Stanford Univ., Stanford, CA

Abstract: Autism spectrum disorder (ASD) is characterized by core social impairments, and is among the most devastating disorders of childhood, affecting 1 in 68 US children. Early and accurate diagnoses are difficult and there are no medications that effectively treat the social features of ASD. ASD is currently diagnosed using behavioral criteria because no biomarkers have been identified. Biomarkers improve our ability to make accurate diagnoses and provide biological targets for drug development and testing. Two promising biomarkers of ASD are the closely related neuropeptides oxytocin (OXT) and arginine vasopressin (AVP), which are critical for normal social functioning in animals and people. Experimentally-induced impairments in OXT and AVP neuropeptides and their receptors also produce social deficits in animal models with relevance to ASD. Our team is currently conducting OXT and AVP treatment trials in children with ASD. Treatment efficacy may be due to a patient's blood neuropeptide levels prior to treatment and the availability of OXT receptor (OXTR) and/or AVP_{v1a} receptor ($AVPR_{v1a}$) on which the drugs can effectively act to enhance social functioning. Despite the obvious need, no prior research has tested whether variation in expression of the OXTR and/or $AVPR_{v1a}$ genes has diagnostic and/or treatment implications in ASD. The aims of the present project therefore were: 1) to test whether expression of the OXTR and $AVPR_{v1a}$ genes differ between children with ASD and matched typically developing control children; and 2) to test whether OXTR and/or $AVPR_{v1a}$ gene expression predicts social functioning and disease symptoms or severity. Preliminary data showed that OXTR gene expression levels were lower in children with ASD compared to matched typically developing control children. Moreover, OXTR gene expression strongly predicted risk for ASD diagnosis and impaired social functioning in children with ASD. Findings

from this overarching research program may lead to the development of companion diagnostics and the first effective and personalized therapeutics to treat the social impairments of ASD.

Title: Limited somatosensory functional connectivity differences in youth with autism spectrum disorder

Authors: *B. CECHMANEK[1], H. JOHNSTON[2], C. LEBEL[1], S. BRAY[1];
[1]Radiology, Univ. of Calgary, Calgary, AB, Canada; [2]Werklund Sch. of Educ., Calgary, AB, Canada

Abstract: A majority of children and adolescents with autism spectrum disorder (ASD) experience tactile sensory sensitivities. These sensory sensitivities can have a negative impact on quality of life, and appear to be more pronounced in younger children and adolescents relative to adults. Functional connectivity differences, measured through resting-state functional MRI (rs-fMRI), may increase our understanding of the brain basis of these sensory sensitivities, and guide interventions or pharmacologic treatments. We examined whether youth with ASD have altered connectivity of somatosensory brain regions and if connectivity varies with age differently in ASD relative to typically developing (TD) controls. rs-fMRI data from 188 participants aged 8-15 years (67 ASD, 121 TD) from 5 sites in the Autism Brain Imaging Data Exchange database were analyzed using functional connectivity measures. Subjects included had >5 minutes of rs-fMRI data with <0.2 mm framewise displacement. TD and ASD groups did not differ in age (ASD=12.7(2.0), TD=12.2(2.3), P=0.11) or IQ (ASD=105.8(17.7), TD=109.5(11.8), P=0.13). Data underwent standard fMRI preprocessing steps, with additional bandpass filtering ($0.01<f<0.1$Hz) and nuisance regression (white matter, cerebrospinal fluid and motion signals). Eight functional-connectivity parcellated regions of interest (ROIs) along the somatosensory

strip were analyzed in a seed-to-voxel approach across the whole brain, as well within *a priori* networks: salience, limbic, sensory and cerebellar. At the second level, general linear models were used to estimate effects of diagnosis, age, and their interaction, while controlling for IQ, handedness, sex, imaging site, and eye status (open/closed). Significant over-connectivity in ASD was observed between a left lateral somatosensory seed and the left superior parietal lobule ($p=0.008$). An age-diagnosis interaction effect survived small volume correction in the salience network, between a right lateral somatosensory ROI and the dorsal anterior cingulate ($p=0.008$), demonstrating stable connectivity with age in TD, and increasing connectivity with age in ASD participants. No significant associations were found with symptom severity (Social Responsiveness Scores, Autism Diagnostic Observation Schedule). Despite previous findings of distributed connectivity differences in ASD, our study does not support robust differences related to the somatosensory network in youth with ASD, compared to TD. However, this study may be limited by a bias for youth with ASD who are high-functioning and able to stay still in the scanner environment.

Title: Typical emotional processing of special interest stimuli in adolescents with autism spectrum disorder (ASD)

Authors: *K. B. RIVARD[1], F. BURLES[1], M. SCHUETZE[1], I. CHO[1], S. VINETTE[2], F. CORTESE[1], A. PROTZNER[1], S. BRAY[1];
[1]Univ. of Calgary, Calgary, AB, Canada; [2]Med., Univ. of Toronto Mississauga, Mississauga, ON, Canada

Abstract: It has been suggested that the core symptoms of ASD, impaired social communication and restricted, repetitive patterns of interest or behaviors, may be related to atypical engagement of the brain's reward system (e.g., social motivation hypothesis). We investigated whether visual reinforcers, images depicting restricted interests, are processed abnormally in ASD, as a potential marker for reward system dysfunction. We collected electroencephalography (EEG) while 20 individuals with ASD (4 female) and 20 typically developing (TD) control participants (4

female), aged 14-20, performed a visual target detection task. Non-verbal IQ was not significantly different between groups (ASD mean = 104.9, range = 63-115; TD mean = 110.3, range = 86-150). The Autism Diagnostic Observation Schedule (ADOS-2) was administered to confirm ASD diagnosis. Each participant was presented with a set of images customized to include things that they liked and disliked (High- and Low-value images), as well as Neutral images from the International Affective Picture System (IAPS), Gabor patch stimuli and Target images, a picture of a zebra, to which they responded with a button press. In total there were 200 High-value, 200 Low-value, 200 Neutral, 200 Gabor and 100 Target image trials, with each image centrally presented for 500ms. Target detection accuracy and reaction time did not differ between groups. We evaluated differences in the late positive potential (LPP; 400-700ms post-stimulus), an event-related potential related to emotional processing, between valence conditions and diagnostic groups for High-, Low- and Neutral-valued images. Average amplitude between 400 and 700ms were calculated for central (Cz) and frontal (Fz) midline electrode sites. Repeated measures ANOVAs showed a significant effect of condition (High, Low and Neutral) for both Cz ($p=0.007$) and Fz ($p=0.05$). This effect was driven by a larger LPP during the High- and Low-value, relative to Neutral conditions. We did not, however, find a significant main effect of, or interaction with, diagnostic group. Our finding that TD and ASD individuals show a similar modulation of the LPP in response to High- and Low-interest visual stimuli suggests that distributed emotional processing of these stimuli is relatively intact in ASD. This further suggests that atypical affective responses may be specific to task context and type of stimuli, which could be explored in future studies. Understanding dysfunction of the reward system in ASD is critical as behavioral treatment approaches typically rely on reinforcement learning.

Abstract: Autism spectrum disorders (ASD) are characterized by deficits in social communication and restricted interests. Understanding the biological etiology of autism is critical for developing better diagnostic and treatment tools. Recently, studies using machine classification algorithms suggest that biological markers exist in this disorder and can be identified via magnetic resonance imaging (MRI). However, these models do not generalize to independent datasets, possibly because multiple etiologies may exist, i.e, distinct subgroups of individuals with ASD may have different underlying mechanisms. Classifiers, trained on behavioral data to identify discrete subpopulations in ASD, may assist in moving the field forward with this regard. In our study, we developed a random forest (RF) model to classify ASD (n = 68) from control (n = 65) subjects using accuracy and median reaction time (RT) measures from face identity, face affect, and vocal affect recognition tasks. RFs comprise many decision trees, where each tree divides groups of subjects into discrete subgroups using input variables. The RF was validated by measuring the classification accuracy of a random sample of 6 ASD participants and 6 controls removed from the training data. 1000 classifiers were trained to assess confidence intervals for accuracy. When compared to a null model, we found that the RF model was 71.6 percent accurate ($t(1998) = 38.7$, $p < 0.01$) with 73.3 ($t(1998) = 30.59$, $p < 0.01$) specificity and 69.9 ($t(1998) = 21.5$, $p < 0.01$) sensitivity. From the classifier, we can measure heterogeneity by measuring the proximity of each individual to another: the number of times two individuals end up in the same subgroup across all trees. Using a community detection algorithm on these proximity measures, we identified two subgroups of individuals with an ASD diagnosis. Relative to typical subjects, one group had very high performance in the visual face tasks but slow RTs, while the other group had worse performance in the visual face tasks but similar RTs. We examined whether the two subgroups showed differences within functional systems using resting state functional connectivity MRI. Chi-squared tests found a significantly greater number of between group differences ($p < 0.01$) within the cingulo-opercular, default, visual, and ventral attention systems. This finding hints at a potential approach to characterize heterogeneity in ASD, and under these conditions two subgroups of ASD children can be identified via performance on behavioral tasks. Importantly, these subgroups show differences in functional connectivity within multiple systems, highlighting potentially unique underlying etiologies.

Title: Atypical laterality in visual sensory activation during simple sensorimotor tasks in Autism Spectrum Disorders

Authors: *Y. TAKARAE[1], F. VIEIRA[2], W. SONG[1], C. SARON[3];
[1]Univ. of Texas Southwestern, Dallas, TX; [2]Univ. of San Francisco, San Francisco, CA; [3]Univ. of California, Davis, Davis, CA

Abstract: Impairments in sensorimotor control are frequently observed in autism spectrum disorders (ASD). We investigated neural correlates of sensorimotor dysfunction in ASD using 124-channel ERPs. The participants were 12 to 18 year old children,18 with ASD and 17 that were typically developing (TD). Participants performed, in alternating blocks, an antisaccade (ANTI) task that required looking away from a suddenly appearing peripheral target, or a prosaccade (PRO) task that required looking toward the peripheral target. The most notable group difference was a lateral activation at occipitoparietal sites starting approximately at 100 ms after stimulus onset. This occipitoparietal positivity reflected the contralateral organization in the visual system, with greater activity evoked by stimuli contralateral to the occipitoparietal electrodes. For the TD group, this activity was symmetric for left and right target conditions. The activation was first observed on the contralateral side, followed by activation on the ipsilateral side with slight delay, following patterns observed for lateral P1 responses in studies of TD adults (Di Russo et al., 2002). In the ASD group, while the general contra to ipsi shift was maintained, the occipitoparietal activation was less symmetric in both tasks, with overall greater activation at the contralateral occipitoparietal location with left targets than with right targets. Further, the ASD group had bilateral occipitoparietal activation without the clear contra to ipsi shift in the left target condition in the PRO task. Thus, the left occipitoparietal activation was reduced when contralateral to the target and enhanced, and of earlier onset, when ipsilateral to the target location. A contralateral frontal negativity preceding the occipitoparietal activation was also reduced in the ASD group compared to the TD group in both ANTI and PRO tasks. The negativity was also asymmetric in the ASD group with greater negativity in the left target than the right target condition. Thus, both occipitoparietal positivity and frontal negativity show asymmetry favoring right hemispheric activation in the ASD group. The findings are consistent with earlier studies demonstrating rightward cerebral asymmetry in ASD (Eyler et al., 2012; Floris et al., 2016). While most of those studies address asymmetry in language and motor

systems that are strongly lateralized, the current study suggest the atypical lateralization may also be observed with visual processes. The current findings additionally suggest this disorganization of early sensory processing may contribute to sensorimotor dysfunction in ASD.

Title: Altered p50 neuromagnetic evoked responses and neural synchrony related to auditory attention in Autism Spectrum Disorder

Authors: A.-M. FLORES[1], K. MCFARLANE[1], C. SWICK[1], T. ANDERSEN[1], K. RUSINIAK[1], I. KOVELMAN[2], S. BOWYER[3], *R. LAJINESS-O'NEILL[1];
[1]Eastern Michigan Univ., Ypsilanti, MI; [2]Univ. of Michigan, Ann Arbor, MI; [3]Henry Ford Hosp., Detroit, MI

Abstract: Atypical auditory attention (AA) may be evident at the P50 latency in Autism Spectrum Disorder (ASD), affecting higher-order domains like social/language functioning. This study examined relationships between evoked response (ERP), synchrony and AA.
11 ASD (Age: M = 8.8; SD= 0.9) and 10 neurotypical (NT) children (Age: M = 9.4; SD = 1.4) underwent magnetoencephalography at rest and during an oddball paradigm of plausible (S1) and implausible syllables (S2). P50 amplitudes (amp) and latencies were averaged. Gating was calculated as an amplitude difference score (S1-S2). Synchronization was quantified by coherence between cortical sites during resting state. Kendall Tau correlations were used to examine relationships of interest.
No group differences in amp, latency or gating. *ERP*: ASD: longer S2 latencies were related to lower AA (p=.03). NT: better gating was related to increased inhibition (p=.02). *Coherence:* ASD: higher right intrahemispheric occipito-parieto-temporo coherence was related to lower S1 amp (τ=-.56- -.72). Increased interhemispheric temporo-parietal coherence was related to longer S1 latencies (τ=.57-.63). Higher interhemispheric and right intrahemispheric coherence was related to lower S2 amp (τ=-.56- -.83). Lower angular, cuneus and temporal coherence was related to longer S2 latencies (τ=-.54- -.82). Higher right intrahemispheric long range coherence was related to poorer gating (τ=.67-.78). NT: higher intrahemispheric temporo-cingulo coherence

was related to lower S1 amp (τ=.51- .64). Increased temporo-occipito-fronto-cingulo coherence was related to longer S1 latencies (τ=.49-.67). Increased interhemispheric and right intrahemispheric fronto-parieto-occipito coherence was related to longer S2 latencies (τ=-.56- -.72). Decreased right intrahemispheric angular coherence was related to poorer gating (τ=-.60- -.96).
ASD: response to novel language was characterized by delayed responses associated with lower AA, increased coherence between reading-related regions predicting lower amps, and increased right long range connectivity associated with decreased response suppression. Increased connectivity associated with reading disorders was predictive of delayed/lower response to familiar language. *NT*: increased suppression of response to novel language was related to increased inhibition and increased coherence between reading related regions. Increased connectivity associated with reading was related to delayed responses to novel language. Results suggest aberrant connectivity in reading disorders is implicated in neural differences between ASD and NT processing of novel language.

Abstract: Autism spectrum disorder (ASD) is an early onset neurodevelopmental disorder, characterized by stereotyped or repetitive behavior and interests, social and communication deficits. ASD has also been linked to atypical memory processing, especially for the formation of restricted behavior and interests such as certain habits, and flexible remember and use of complex information. As DeLong wrote, “it is impossible to separate the study of memory from that of autism (DeLong,2003, p. 741). Understanding the brain basis of atypical memory processing in children with ASD will allow us to investigate influential neurobehavioral models of ASD and has the potential to provide new insight into the nature and etiology of the disorder.

We used resting state fMRI in conjunction with advanced analytic approaches to investigate functional integration and segregation of memory related brain networks in 45 children (aged 8-12 years old) with ASD and 45 matched neurotypical controls. A graph theory analysis of complex brain networks was implemented to parcellate the hippocampus based on resting state fMRI data. We identified three distinct clusters along the left and right hippocampal long axis, including the anterior, middle and posterior portions in TD children and children with ASD. Each portion shows distinct functional connectivity patterns with other regions on the whole brain level. Most importantly, when compared to TD children, children with ASD showed significantly weaker functional connectivity of the hippocampus with distributed brain regions in the primary visual cortex, the precuneus and thalamus, but significantly higher functional connectivity only with the right anterior caudate on the whole brain. Our study demonstrates that children with ASD show increased functional connectivity of the hippocampal memory system with brain systems important for visual sensory, default mode, and affective functions, but decreased connectivity with basal ganglia system important for the formation of procedural memory such as habits and rigid behavior. These findings provide important implications into the newly emerging view of autism as an early onset disorder of neural connectivity, thereby leading to atypical memory and cognitive development in late life for children with ASD.

Title: Cortical tau pathology in non-demented and demented individuals with down syndrome

Authors: ***S. E. PEREZ**[1], B. HE[2], M. N. SABBAGH[3], I. T. LOTT[4], E. DORAN[4], E. J. MUFSON[2];

Abstract: Down syndrome (DS), is a genetic disorder resulting from the triplication of chromosome 21, which carries the gene that encodes the amyloid precursor protein (APP) and is functionally characterized by intellectual disability. Brain tissue from individuals with DS displays an overexpression of APP as well as β-amyloid (Aβ) plaques and neurofibrillary tangles (NFTs), pathological hallmark lesions of Alzheimer's disease (AD). Brain amyloid plaques and NFTs appear between thirty and forty years of age and increases overtime in DS. Despite the fact that virtually all individuals with DS display AD lesions, most but not all individuals will develop AD dementia suggesting a disconnection between pathology and dementia related cognitive decline. Interestingly, of the two major AD lesions, NFTs are a better correlate of cognitive decline than amyloid plaques in AD. The main component of NFTs is the microtubule-associated protein tau that undergoes conformational and phosphorylational changes during the evolution of a tangle in the AD brain. Whether similar changes develop in non-demented compared to demented subjects with DS is unknown. Here, we examined the progression of NFT pathology in the frontal cortex in a total of 19 subjects with DS (n=7) and DSAD (n=12), ranging in age from 1-60 years. DS cases were confirmed either by blood karyotyping or in situ fluorescence hybridization for the detection of chromosome 21. Immunohistochemistry was used to detect the early tau phosphorylation (pS422 and AT8), conformational (Alz50 and MC-1) and the late tau marker (truncated TauC3) using free floating 40 micron thick frontal cortex sections. Semi-quantitation was used to estimate density of NFTs, neuropil threads (NTs) and amyloid plaques using antibodies against APP/Aβ (6E10), MOAB-2 (pan Aβ), Aβ42 and Aβ40 species. Findings revealed pS422 immunoreactive (-ir) NFTs and NTs were more abundant, followed by AT8, TauC3 and to a lesser extent MC-1 and Alz50-ir profiles in the frontal cortex of people with DSAD compared to DS. By contrast, Aβ pathology was comparable in the frontal cortex of DS and DSAD. The one year-old individual with DS did not display any tau or Aβ immunoreactivity. These data suggest that an increase in the early tau phosphorylation maker, pS422, plays a role in the onset of AD dementia in DS, rather than Aβ pathology.

Abstract: Down syndrome (DS) is caused by trisomy of chromosome 21, which contains the gene APP, encoding for the beta-amyloid (Aβ). In people with DS, the increased level of APP gene and the accumulation of Aβ are linked to the appearance of neuropathological markers of Alzheimer's disease-like (AD-like) characteristics, together with dementia. ACI-24, a liposomal vaccine containing human Aβ1-15 peptide, was developed for immunotherapy of AD patients. Immunization of APPxPS1 mice (AD mouse model) with ACI-24 led to a significant decrease of insoluble, plaque-related Aβ1-42 and Aβ1-40 and restoration of a cognitive memory. In addition, ACI-24 induced a T-cell independent antibody response, disabling a potentially harmful infiltration of antigen-specific T-cells in the brain. To address the efficacy of Aβ1-15 vaccine in vivo, a Ts65Dn DS mouse model was used, containing a trisomic portion of mouse chromosome 16 (homologous to human chromosome 21) with the murine gene for APP. Ts65Dn mice fail to develop neuritic Aβ plaques or neurofibrillary tangles, but demonstrate behavioral deficits in several memory tasks. The ACI-24 vaccine comprising the human Aβ1-15 amino acid sequence triggers a strong antibody response, which might be unable to recognize the murine Aβ sequence differing in three amino acids. In addition, we studied if the substitution from the human to the murine sequence would impact the antibody response due to the self-tolerance against the endogenous Aβ. To address these points, immunogenicity of vaccines containing human or murine Aβ1-15 (ACI-24 and DS-01, respectively) was tested in C57BL/6 mice. Both vaccines induced a strong antibody response against their respective antigen without cross-reactivity to the other sequence. Furthermore, the strong antibody response of DS-01 confirmed that it can break the tolerance against the endogenous mouse Aβ protein. 5 months-old Ts65Dn mice were immunized with the murine Aβ1-15 vaccine. Immunization resulted in robust anti-Aβ IgG titers, confirming the ability of the vaccine to break self-tolerance. Induced antibodies reacted with Aβ but not with APP. Immunization resulted in a trend to reduction of soluble Aβ levels in the brain. However, in vaccinated-Ts65Dn mice, the levels of Aβ were not different from those in vehicle- and vaccine-treated diploid (2N) mice. Importantly, vaccinated mice showed improved memory and a reduction in atrophy of cholinergic neurons compared to vehicle-treated mice, without any adverse effects. These data are the first evidence that an anti-Aβ immunotherapeutic approach may target plaque-free Aβ-related pathology, leading to the potential treatment of people with DS.

Title: Cerebral organoids and quantitative proteomics reveal molecular mechanisms in down syndrome

Authors: *T. D. MCCLURE-BEGLEY[1], C. C. EBMEIER[2], M. J. KLYMKOWSKY[2], K. E. BALL[2], W. M. OLD[3];

Abstract: To better understand the cellular and molecular processes associated with Down syndrome (DS) in the human central nervous system (CNS), we generated a model of early neuronal development using human induced pluripotent stem cells (IPSc) as a starting template. We obtained IPSc from an individual with Down syndrome and a line from an unrelated euploid individual. With some modifications to the method first described by Lancaster et al (Nature, 2013), we successfully generated human cerebral organoids from both cell lines and used them

for imaging experiments with whole-mount immunostaining and deep proteome profiling with label-free quantitation of over 8,500 proteins in each sample. Our imaging analysis shows neurons populating the outer edges of the tissue, with neuronal progenitors restricted to inner regions of the tissue; a cell type distribution of radial migration and differentiation similar to human cortex development. Our proteomics analysis shows many proteins changing in significant abundance due to Trisomy 21, with alterations in members of Wnt and Notch signaling pathways, catecholamine metabolism, axon guidance, and cell adhesion. A following experiment collected samples from each stage in organoid development: a.) IPSc growing in 2-dimensional standard maintenance culture, b.) embryoid bodies grown in suspension, 3.) neurospheres with fate-restricted neural progenitor populations and radial neuroectoderm, and 4.) organoids grown following embedding in extracellular matrix, cultured in suspension for 21 days and examined the effects of pharmacological inhibition of the protein kinase DYRK1A, located on the Down Syndrome Critical Region (DSCR). We observed changes in the proteome of drug treated organoids consistent with rescuing expression levels of several key signaling pathway members. These data are the first to interrogate cerebral organoids with proteomic approaches and targeted pharmacology in the study of complex genetic conditions with a spectrum of neurological phenotypes.

Title: Linguistic prediction in Down syndrome

Authors: J. RAMOS-SÁNCHEZ, J. B. BARRÓN-MARTÍNEZ, A. Q. ANGULO-CHAVIRA, D. R. CORTÉS-MONTER, *N. ARIAS-TREJO;
Facultad de Psicología, Lab. de Psicolingüística, UNAM, Mexico City, Mexico

Abstract: Previous literature has shown that adults and children are able to anticipate a referent when exposed to semantically informative verbs, articles and adjectives (Mani & Huettig, 2014; Mishra, Singh Pandey, & Huettig, 2012), given the relationship among words (e.g., eat-cake). However, currently there is no knowledge about the linguistic ability of prediction in people with Down syndrome (DS). Therefore, the present study aimed to identify if the relations of meaning stablished between verbs and nouns can allow people with DS to anticipate a referent.
Fifteen people with DS were evaluated (CA = 21, SD = 2.5 years, range = 18-25; MA = 6.7 years, SD = 1.8, range = 3.8-8.6 years). Participants performed a visual preference task by means of a Tobii eye-tracker X2-30. The task consisted of 10 trials with a duration of 6,000 ms each. Each trial involved the simultaneous display of two images on a screen (e. g., 'pencil'-'ball') and the auditory exposure to a sentence that contained - either a verb semantically related -RV- to one of the two images (e.g., 'I am going to write' related to 'pen') or an unrelated verb -NRV- ('I am going to see').
The total looking time was calculated for each of the images in a trial. Results showed that when exposed to a RV sentence (‘I am going to write’) participants looked proportionally more to the related target (‘pencil’) than to the non-related distracter (‘ball’) before the target was mentioned. In contrast, upon hearing the NRV sentence (‘I am going to see’) participants did not exhibit a preference for either image.
The findings of this study suggest that people with Down syndrome are able to obtain and use semantic information from verbs to predict a referent, which is an essential ability for the comprehension and establishment of predictions in oral speech.

Title: Isolation-induced ultrasonic vocalizations in the mouse model of Down syndrome Ts65Dn during pre-weaning postnatal development

Authors: *B. ZAMPIERI, M. W. JOHNSON, A. C. COSTA;
Dept. of Pediatrics, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS), the phenotypic consequence of trisomy 21, is the most prevalent chromosomal cause of intellectual disability. An area of particular concern in children with DS is speech and language development, which is generally delayed when compared with typically developing children. These include deficits in semantic, phonological, syntactic, and pragmatic components of speech production. The causal mechanisms underlying these deficits are still not well understood. Recently, there has been significant progress in the field of the development of speech production through isolation-induced ultrasonic vocalizations (USV) in mouse models of various neurodevelopmental disorders. Therefore, it is not unreasonable to expect that mouse modeling of this uniquely human phenotype could shed some light into speech and language development in DS. Here, we recorded USVs from five Ts65Dn mice and eighteen of their euploid littermates every other day from postnatal days 3 to 21 for 5 min inside a sound attenuating chamber (SonoTrack SMART Chamber, Metris). Data were recorded at 250 kHz using a Sonotrack system (Metris). Acoustical analysis was performed using Avisoft Bioacoustics SasLab Pro software (Version 5.2.09) and IGOR Pro 6 (WaveMetrics). Spectrograms were generated with a Fast Fourier Transform (FFT)-length of 512 and a Flat top window with 87.5% overlap using Avisoft whistle detection algorithm and post-processed in IGOR Pro. Each syllable was classified as one of nine waveform categories according to previous work by our group (Zampieri et al., 2014). In the present study, Ts65Dn pups showed no significant delay in the onset of USV emissions compared to wild-type control mice, contradicting the only study in the literature using a mouse model for DS (Holtzman et al., 1996). Additionally, there was no evidence of genotype differences in total number of calls, number of calls per day, amplitude, types of call, or call duration. However, a histogram of call counts versus call frequency (pitch) emitted by the mice revealed subtle, but significant genotype-dependent differences. Ts65Dn mice showed a clear bimodal distribution, with approximately equal peaks at 62 and 94 kHz, whereas control mice showed a primary peak at 62 kHz and a very weak peak around 86 kHz (about 16% of the primary peak). These results held across the types of calls and postnatal days. Consistent with our previous study in adult mice (Zampieri et al., 2014), Ts65Dn pup mice did not show overt vocalization phenotypes that can be easily and directly correlated to quantitative features of the speech and language impairments affecting individuals with DS.

Abstract: Individuals with Down syndrome (DS) exhibit Alzheimer's disease (AD) neuropathology by 40 years of age and are at greater risk of developing AD dementia later in life. Due to increases in lifespan of individuals with DS, the prevalence of AD dementia has increased but few treatments are available in part because co-morbidities of intellectual and functional disability in DS make a diagnosis of dementia difficult. Blood biomarkers quantifying pathogenic proteins elevated at the onset of AD neuropathology may be particularly valuable. A possible marker may be exosomes which are defined as cell-derived vesicles that are found in biological fluids. Exosomes are actively secreted from neurons, contain proteins of their neuronal source, and enter the blood from which they can be isolated. In the general population, AD has a preclinical phase with high blood neuronal exosome levels of neurotoxic proteins prior to onset of symptoms. We hypothesized that neuronal exosomes obtained from blood of individuals with DS also would have elevated levels of amyloid-beta (Aβ) peptides and phosphorylated-Tau (P-Tau) that could document a preclinical stage. We therefore quantified levels of neuropathological biomarkers in blood neuronal exosomes from individuals with DS, including those with and without clinical symptoms of dementia, and from age-matched controls. Quantitation revealed that neuronal exosome levels of Aβ1-42 and P-Tau were significantly elevated in individuals with DS compared to age-matched controls. These biomarker levels were significantly increased at an early age, and continued to increase in older individuals. P-S396-Tau levels were significantly elevated in participants with early symptomatic dementia or fully symptomatic dementia compared to adults with DS without dementia. No significant gender differences were

observed. These findings suggest that the early increases in Aβ1-42 and P-Tau in individuals with DS provide a basis for early intervention as better treatments become available.

Title: Tissue specific effects of EGCG on Dyrk1a activity and cognitive and skeletal phenotypes in a Down syndrome mouse model

Authors: *M. STRINGER[1], J. LACOMBE[2], R. J. ROPER[2], C. R. GOODLETT[3];
[2]Biol., [3]Psychology, [1]IUPUI, Indianapolis, IN

Abstract: Down syndrome (DS) is caused by three copies of human chromosome 21 (Hsa21) and results in phenotypes including intellectual disability and skeletal deficits. Ts65Dn mice, the most extensively studied DS model, have three copies of ~50% of the genes on Hsa21 and display many phenotypes associated with DS, including cognitive and skeletal deficits. *DYRK1A* is found in three copies in humans with Trisomy 21 and in Ts65Dn mice, and is involved in a number of critical pathways including CNS development and osteoclastogenesis. Epigallocatechin-3-gallate (EGCG), the main polyphenol in green tea, inhibits Dyrk1a activity. We have shown that a three-week EGCG treatment (~10mg/kg/day) during adolescence normalizes skeletal abnormalities in Ts65Dn mice, yet did not rescue deficits in the Morris water maze (MWM) spatial learning task or novel object recognition. A higher EGCG dose (50 mg/kg/day) failed to rescue skeletal abnormalities, or various motor and cognitive deficits. Therefore, we hypothesize that the effects of EGCG on various phenotypes are both dose and tissue-dependent. EGCG degrades in drinking water; thus, an oral gavage administration would control EGCG dosage. Furthermore, few studies have assessed EGCG's ability to inhibit Dyrk1a *in vivo,* or its inhibition in specific tissues. We tested whether a daily oral gavage administration of EGCG would inhibit Dyrk1a activity in specific tissues (cerebellum, hippocampus, cerebral cortex, femur). In addition, we anticipate that reductions in Dyrk1a activity in brain or bone tissue will correlate with improvements on behavioral and skeletal measures. Ts65Dn and euploid littermate mice were orally gavaged with 200mg/kg EGCG or PBS daily, beginning on postnatal day (PD) 42. Mice were tested on the Mulitvariate Concentric Square Field Maze (MCSF) task for two days. Mice then underwent three days of balance beam testing, followed by two days of rest. On PD57, mice were trained for eight days on the MWM. Mice were euthanized on PD65, and the cerebellum, hippocampus, cortex and femur were extracted. Proteins were isolated and subjected to a Dyrk1a activity assay. Preliminary data indicates that Ts65Dn exhibit behavioral deficits compared to euploid mice. Furthermore, we observed differential levels of Dyrk1a activity in various tissues. Ongoing analysis will focus on correlations between tissue-specific changes in Dyrk1a activity and behavioral and skeletal measures. The ability to correlate EGCG's inhibition on Dyrk1a activity in a specific tissue with a distinct phenotype may help identify more targeted pharmacotherapies for cognitive and skeletal deficits in individuals with DS.

Title: Infantile Spasms: Rescue of an animal model

Authors: ***K. JOSHI**[1], L. SHEN[2], A. MICHAELI[2], M. SALTER[2], J. H. EUBANKS[3], G. THIBAULT-MESSIER[2], S. HASHMI[2], M. A. CORTEZ[2], O. SNEAD, 3rd[2];
[1]Neurosci. and Mental Hlth., The Hosp. For Sick Children, Toronto, ON, Canada; [2]Hosp. for Sick Children, Toronto, ON, Canada; [3]Toronto Western Hosp., Toronto, ON, Canada

Abstract: Infantile spasms (IS) is a catastrophic childhood seizure disorder characterized by extension and/or flexor spasms with a characteristic EEG abnormality and impairment of cognition. Children with Down Syndrome (DS) are quite vulnerable to IS. Similarly, the Ts65Dn (Ts) mouse model of DS is exquisitely sensitive to an IS phenotype induced by γ-aminobutyric acid$_B$ receptor ($GABA_BR$) agonists. The Ts mouse contains the core genomic triplication of the DS critical region, which includes three copies of the *kcnj6* gene that encodes the $GABA_BR$-coupled G protein-coupled inward rectifying potassium channel subunit 2 [GIRK2] channel. We test the hypothesis that GIRK2 is necessary for the $GABA_BR$ agonist-induced IS phenotype in Ts. We assessed the effect of genetic knockdown of the GIRK2 channel in Ts brain upon the IS phenotype in Ts, and upon $GABA_BR$ currents in hippocampal neurons prepared from GIRK2-trisomic and GIRK2-disomic Ts mice. The reduction of the copy number of *kcnj6* in Ts mice rescued the $GABA_BR$ agonist-induced IS phenotype and normalized $GABA_BR$-mediated GIRK2 currents. The radial arm maze task showed no differences between Ts and wild type mice, but Ts mice showed impaired recognition memory when tested with the novel object recognition task. This impairment also was rescued in the GIRK2-disomic Ts mice. GIRK2 is necessary for the IS phenotype in the Ts mouse model of DS. Further experiments are needed to determine if GIRK2 is sufficient for the IS phenotype. These data suggest that GIRK2 antagonists may have therapeutic utility for the treatment of IS in patients with Down syndrome.

Title: Noninvasive high-resolution *In vivo* imaging of retinal morphology and vasculature alterations in the mouse model of Down syndrome using optical coherence tomography and angiography

Authors: A. C. COSTA[1], *D. B. VICTORINO[2];
[1]Pediatrics, Case Western Reserve Univ., Cleveland, OH; [2]Pediatrics, Case Western Reserve Univ., Cleveland Heights, OH

Abstract: Ophthalmic disorders are among the most prevalent comorbidities of Down syndrome (DS). Therefore, in trying to use mice to model the effects of trisomy 21 in persons with DS, it is essential that we understand how the visual system is affected in mouse models of DS. As we have argued in the past, poor understanding of how vision is affected in mouse models of DS and other neurodevelopmental disorders can lead to misinterpretation of data obtained through behavioral test that are highly dependent on the integrity of the visual system. Here, we used the Micron IV system (Phoenix Research Laboratories) to perform slit lamp examinations, image-guided Optical Coherence Tomography (OCT), and fluorescein angiography in the Ts65Dn mice, which is the most commonly used mouse model of DS. Cohorts of 38 Ts65Dn and 37 control mice were categorized into three different age groups (P17, P35, and adult mice - P41 to P102). For the OCT assessment, the thickness of inner, outer, and total retinal layers were obtained by measurements of four lateral distances from the optic nerve disc on both sides (100, 200, 300, and 400 μm). Our results did not show any evidence of congenital or age-related cataracts in either Ts65Dn or control mice in all age groups. Similarly, the numbers of retinal arteries and veins did not differ significantly between both genotypes. Using OCT, we found that the retina of the Ts65Dn mice shows a normal layered organization. However, quantitate analyses, revealed that the total thickness of the retina is significantly increased in the Ts65Dn compared to control mice in all four lateral distances for which this parameter was measured. This genotype-dependent increase in total retinal thickness was primarily due to the increased thickness of the inner retinal layer, which was significantly greater in the Ts65Dn compared to control mice in all three age groups investigated. In conclusion, our results indicate that the total

retinal thickness is increased in the Ts65Dn mouse, and that a genotype-dependent increase in the thickness of the inner part of the retina is the primary contributor to this phenomenon. The actual functional significance of this finding is still under investigation in our laboratory. Nevertheless, it is important to notice that these differences parallel published reports of OCT evaluation of retinal thickness in young persons with DS, which provides yet another validation of the Ts65Dn mouse as a powerful animal model of DS.

Title: High-density EEG assessment of mismatch negativity and 7T MRI whole-brain morphometric analysis of healthy adolescents and young adults with Down syndrome

Authors: *K. A. KOENIG[1], M. W. JOHNSON[2], M. R. STASKO[2], S.-H. OH[1], A. C. COSTA[2]; [1]Cleveland Clin., Cleveland, OH; [2]Div. of Pediatric Neurology, Dept. of Pediatrics, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS), the phenotypic consequence of trisomy 21, is the most prevalent genetically defined cause of intellectual disability. To date, no pharmacotherapy aimed at counteracting either the neurodevelopmental or the neurodegenerative component of this genetic disorder has been approved. However, recent preclinical and clinical work on the N-methyl-D-aspartate (NMDA) receptor antagonist memantine give some reason for optimism. The results described here are preliminary data on a small subset of participants of a current Phase II clinical trial on the efficacy, tolerability and safety of memantine on enhancing the cognitive abilities of adolescents and young adults with DS (NCT02304302 at http://www.clinicaltrials.gov). These results refer to a subcomponent of this study in which we investigate the usefulness of mismatch negativity (MMN) and high-resolution, whole-brain morphometric analysis (with emphasis on volumetric assessments of hippocampal subfields), as potential biomarkers of the severity of the cognitive disability in persons with DS as well as potential surrogate markers for the efficacy of memantine in persons with DS. We describe results from two male and two female subjects with DS, and two male and one female typically developing control subjects. A whole-brain anatomical MP2RAGE (0.75mm isotropic voxel

size) was acquired on a Siemens 7T Magnetom with SC72 gradient (Siemens Medical Solutions, Erlangen) using a 32-channel head coil (Nova Medical). The hippocampus was manually segmented according to the HarP protocol. Whole brain white matter, grey matter, and intracranial volume (ICV) was estimated using Freesurfer. MMN studies were acquired on an Electrical Geodesics EEG System 400 (Eugene, OR) 128-channel EEG at 1 kHz synchronized to a SmartEP AEP system (Intelligent Hearing Systems, Miami, FL) for the auditory stimulation. The MMN auditory stimulation used 100msec triangular waveforms at 440 and 557 Hz, with an 80% standard and 20% oddball paradigm with a total of approximately 300 oddball and 1200 standard stimuli per study. MMN analysis was performed using Igor Pro 6 (Wavemetrics, Lake Oswego, OR). Overall, the participants with DS appear to have a depressed MMN response compared to the control subjects. In addition, raw volumetric measures showed a decrease in subcortical grey matter, mean hippocampal, and total brain volumes in individuals with DS ($p < 0.05$), though only mean hippocampal volume remained significant after correction for ICV ($p = 0.031$). Future work will include segmentation of the hippocampus and techniques for optimizing the signal-to-noise ratio in the MMN analysis.

Title: Comparative study of brain development and perinatal behavior in three mouse models of Down syndrome

Authors: *N. M. AZIZ[1], J. L. OLMOS-SERRANO[1], F. GUEDJ[2], W. A. TYLER[1], J. W. GOODLIFFE[1], D. W. BIANCHI[2], T. F. HAYDAR[1];
[1]Boston Univ. Sch. of Med., Boston, MA; [2]Tufts Med. Ctr., Boston, MA

Abstract: Down syndrome (DS), a genetic condition leading to intellectual disability, is characterized by triplication of human chromosome 21. Major neuropathological hallmarks of DS are abnormal brain growth and reduced neurogenesis that manifest during fetal development

and continue throughout life. At birth, newborns with DS exhibit major motor and reflexive deficits and fail to meet typical developmental milestones. A major outstanding question is how DS-related prenatal and postnatal phenotypes are recapitulated in different mouse models. To begin answering this question, we directly compared differences in embryonic development and brain morphogenesis, postnatal neuronal and oligodendroglial populations, and neonatal behavior in three cytogenetically distinct mouse models of DS—Ts1Cje, Ts65Dn and Dp16/1Yey (Dp16). At E15.5, gross morphological and histological measurements indicate that Ts65Dn mice are the most profoundly affected with respect to somatic growth, brain size and pallial thickness compared to Ts1Cje and Dp16 embryos. Histological abnormalities extend to P15 at which time Ts65Dn mice exhibit a misallocation of excitatory cortical neurons, inhibitory cortical and hippocampal interneurons, and a block in oligodendrocyte maturation. Additionally, Ts65Dn and Ts1Cje mice show delayed acquisition of both early and late developmental milestones, while Dp16 mice only show late delays. Taken together, our data show differences in behavioral and brain developmental phenotypes in these three most widely used mouse models. These findings illustrate unique potential applications for each model when studying different aspects of brain development and function in DS. Importantly, this study will help inform future model selection for studies aimed at elucidating how observed neurodevelopmental abnormalities contribute to cognitive impairment and whether prenatal and/or postnatal therapeutic intervention could help improve intellectual disability and, therefore, quality of life of individuals with DS.

Title: Pharmacologically probing three modalities of CA1 hippocampal long-term potentiation in the Ts65Dn mouse model of Down syndrome

Authors: *J. J. SCOTT-MCKEAN[1], A. L. ROQUE[1], K. SUREWICZ[2], W. K. SUREWICZ[2], A. C. COSTA[1];
[1]Dept. of Pediatrics, [2]Dept. of Physiol. and Biophysics, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS), the result of trisomy 21, is the most common genetically defined cause of intellectual disability. The Ts65Dn is the most studied mouse model of DS. Long-term potentiation (LTP) has been the main form of synaptic plasticity assessed in these mice, with long-term depression (LTD) being investigated to a lesser degree. A survey of different modalities of LTP, coupled with the use of pharmacological agents with different mechanisms of action, all in the same study, has been lacking in the literature. Here, we probed three modalities of LTP in CA1 hippocampal slices from Ts65Dn mice and investigated the effects of memantine, picrotoxin, and soluble (membrane anchor-free) recombinant human prion protein (PrP). First, we studied memantine (1 μM) on either single high-frequency stimulation (HFS; 100 Hz for 1 s) induced LTP or theta burst stimulation (TBS; 4 trains of 5 pulses at 100 Hz, 200-ms inter-train interval) induced LTP in Ts65Dn and euploid control derived slices. In agreement with our previous work, we found no significant difference in HFS LTP between Ts65Dn and euploid control-derived slices, and detected a reduction in TBS LTP in Ts65Dn-derived slices. When used at the therapeutically relevant concentration of 1 μM, memantine did not alter the induction or maintenance of HFS LTP, and seems to rescue TBS LTP to control euploid levels in slices from Ts65Dn mice. Next, we studied LTP induced by four HFS (4xHFS), with 5-min inter-train intervals. We found decreased LTP in Ts65Dn compared with control euploid derived slices both at 60 and 180 min post-induction (the latter being known as late-phase or L-LTP). Then, we probed the effects of memantine (1, 3, and 10 μM) and picrotoxin (10 and 100 μM) on L-LTP. Memantine (1 μM) pretreatment did not inhibit L-LTP in either Ts65Dn or euploid control slices, whereas 10 μM of picrotoxin seems to rescue L-LTP to control levels while causing severe oscillations in postsynaptic potentials. At 10 μM, memantine inhibited 4xHFS in both euploid control and Ts65Dn-derived slices. Our research had recently shown that PrP blocks Aβ oligomer-induced inhibition of 4xHFS and that PrP rescues this inhibition in euploid slices. In Ts65Dn slices, which already shows a deficit in 4xHFS when compared to euploid controls, Aβ oligomers further depressed this modality of LTP. PrP rescued Aβ oligomer-induced inhibition 4xHFS in Ts65Dn slices, however, only to untreated levels, and PrP alone had no effect on Ts65Dn-derived slices. This research should bring us closer to understanding the mechanistic basis for previous electrophysiological and behavioral studies in this important mouse model of DS.

Title: Knockdown of overexpressed Down Syndrome Cell Adhesion Molecule results in the reversal of increased P21-Activated Kinase (PAK) activity in a neuronal model of Down Syndrome. Consequences on F/G actin ratio, cell process formation and extension.

Authors: R. PÉREZ-NUÑEZ[1], N. BARRAZA[1], J.-V. BARNIER[2], A. CÁRDENAS[3], *P. A. CAVIEDES[1];

Abstract: Down Syndrome (DS), or trisomy 21 in humans, results from the presence of an extra copy of autosome 21. The most striking finding is mental retardation. The CTb cell line, derived from the cerebral cortex of a trisomy 16 fetal mouse (Ts16), an animal model of DS, constitutes a permanent *in vitro* model to study DS-related cell pathophysiological phenomena. Using this cell model, and comparing with a cell line derived from the cerebral cortex of a normal animal, named CNh, multiple impairments in neuronal function have been studied, all linked to the overexpression of specific DS-related genes. One of such genes, which reportedly is involved in proliferation, maturation, synaptogenesis and neural development is *dscam*, which codes for the protein DSCAM (Down Syndrome Cell Adhesion Molecule), DSCAM recognizes netrin at the membrane level, which leads to a correct morphological development, through cellular signaling pathways involving the serine / threonine p21-activated kinases (PAK), acting on downstream effectors such as LIMK and cofilin, leading to reorganization of actin filaments. We have shown that CTb cells overexpress DSCAM by 40%, compared to CNh cells. Further, Sholl analysis has revealed that trisomic cells exhibit reduced process number and length compared to controls, and also an increased F/G actin ratio. We then evaluated the response of the PAK signaling pathway by stimulating DSCAM with its agonist, netrin. After stimulation, PAK, LIMK and cofilin exhibited increased phosphorylation (2 fold compared to basal, t_0) in the trisomic line, and for longer periods of time (10 minutes for PAK and LIMK, and up to 20 minutes for cofilin),

compared to CNh cells. In CTb cells, these effects were completely reversed in all components of the PAK pathway, after siRNA-induced *knockdown* of DSCAM to levels comparable to those of CNh cells. Our work confirms that PAK kinases are effectively deregulated in the trisomic condition of DS, due at least in part to DSCAM overexpression. Considering the existence of PAK inhibitors, this kinase could represent an interesting therapeutical target in DS.

Title: Age-related changes in cognitive abilities and related brain activity in Down syndrome

Authors: *C. M. STARTIN, S. HAMBURG, R. HITHERSAY, T. AL-JANABI, K. MOK, J. HARDY, M. DE HAAN, A. STRYDOM;
UCL, London, United Kingdom

Abstract: People with Down syndrome (DS) show large variability in their cognitive profiles. Some people have a mild intellectual disability (ID), while others a more severe ID. People with DS are also at an ultra-high risk of developing dementia, again with large individual differences; some people receive a dementia diagnosis in their 40s while others do not show cognitive decline in their 60s. The London Down Syndrome Consortium (LonDownS) is investigating factors influencing these differences across the lifespan. We have assessed over 300 adults (aged 16+ years) with DS. All adults were administered a cognitive battery, assessing both general abilities and specific aspects of cognition (mainly memory and executive function), and data was collected from informants regarding everyday adaptive abilities and relevant medical information. All participants also gave a blood or saliva sample for genetic analysis. A subgroup of participants underwent EEG assessments to investigate memory-related processes using event related potentials (ERPs) during auditory oddball and visual old-new paradigms. Cross-sectional

analyses revealed people with DS show decline in their early 40s for tasks requiring sustained attention. Other measures of cognition assessing general abilities, memory and executive function showed later changes, often in the early 50s. ERPs assessing memory processes showed earlier changes, with changes in amplitudes and latencies of relevant components starting in the late 30s. APOE4 genotype was associated with earlier onset of cognitive decline. Individuals who have recurrent infections showed poorer everyday abilities in young adulthood and cognitive decline at an earlier age. Our results describe changes in cognitive abilities across the lifespan in adults with DS. Changes in sustained attention occurred earlier than changes in general abilities, memory and executive function. Changes in memory-related ERPs were also seen earlier than changes in cognitive abilities. The presence of an APOE4 allele was associated with earlier cognitive decline, while presence of recurrent infections was associated with both poorer abilities in young adulthood and earlier decline in older adults.

Title: Oromotor characterization of the Ts65Dn mouse model of Down syndrome

Authors: *T. J. GLASS[1], N. P. CONNOR[2];
[1]Surgery, Univ. of Wisconsin, Madison, WI; [2]Univ. of Wisconsin Madison, Madison, WI

Abstract: Down syndrome (DS) is often associated with oromotor impairment, which can impact vocal communication, feeding, and swallowing. Difficulties in feeding and swallowing in DS are complex and likely involve alterations in underlying muscle systems. Our prior work

found reduced levels of myosin heavy chain (MyHC) 2b in the digastric muscles of Ts65Dn mice, a commonly used model of DS. However, the biochemical composition of tongue muscles in this murine model of DS is not known. Because the tongue has an important role in bolus containment and transport during the swallow, this information is necessary for identification of putative mechanisms of swallowing impairment in DS. In this work, the Ts65Dn mouse model was used to address the hypothesis that myosin heavy chain isoform (MyHC) alterations in extrinsic tongue muscles contributes to deficits in feeding and swallowing. Videofluoroscopic swallowing and mastication assays were performed in 27 adult Ts65Dn mice and euploid controls ranging in age from 9 to 36 weeks of age (n = 7 male mice per genotype, and 6-7 female mice per genotype). Adult Ts65Dn collectively showed slower swallow rates and increased inter-swallow-intervals. MyHC isoform analysis was conducted of the genioglossus muscle (a tongue protrusor) and the styloglossus muscle (a tongue retrusor) across this age range. We found similar MyHC 2b levels in these muscles between genotypes. Collectively, these findings suggest that the adult Ts65Dn mouse model has utility for the study of functional feeding and swallowing differences in this syndrome. However, findings of typical MyHC isoform profiles of the GG and SG suggest that swallowing differences in adult Ts65Dn may not primarily involve biochemical alterations of extrinsic tongue muscles. Work is ongoing to increase sample sizes for discrete age points and to characterize the relationship between aging and swallow function in this model. Avenues for future study of altered swallowing in adult Ts65Dn include examination of the intrinsic tongue muscles and esophagus, both of which are implicated in altered feeding and swallowing in humans with DS.

Title: Inhibitory GABA mode in the CA1 region of adult Ts65Dn mice, a genetic model of Down syndrome

Authors: J. YU[1], F. MADAMBA[1], A. TYRTYSHNAIA[2], *A. M. KLESCHEVNIKOV[1];
[1]Neurosciences, Univ. of California San Diego, La Jolla, CA; [2]Sch. of Biomedicine, Far Eastern Federal Univ., Vladivostok, Russian Federation

Abstract: Down syndrome (DS) is a genetic disorder characterized by developmental delays and profound cognitive impairment in children and adults. Studies in mouse genetic models suggested that deficient cognition in DS is due, in part, to an increased efficiency of the GABAergic system that restricts synaptic plasticity. Recently this view was challenged by a study, in which an excitatory mode of GABA action was observed in the hippocampus of adult Ts65Dn mice, a genetic model of DS (Deidda et al., Nature Medicine, 2015). Because this study used mostly invasive electrophysiological techniques, the results could be affected by damage of neural tissue during the experiments. Here we re-examined the excitatory/inhibitory mode of GABA action in the CA1 region of hippocampal slices of 3-4 month old Ts65Dn mice using a 'non-invasive' approach - measurements of multi-unit activity (MUA) during bath application of the GABAa receptor agonist isoguvacine (10 μM, 90 s). We observed that applications of isoguvacine resulted in significant reduction of MUA frequencies in slices from both Ts65Dn and WT mice (Ts65Dn: 35.4 ± 10.2%, n = 8; WT: 42.4 ± 11.4%, n = 8; p = 0.63). This result suggests that the primary mode of GABA action in the Ts65Dn hippocampus is inhibitory.

Title: Increased GABA inhibition in the Dentate Gyrus in a mouse model of Down syndrome

Authors: *S. HANNAN[1], S. WATSON-SCALES[3], E. LANA-ELOLA[3], F. WISEMAN[2], E. M. C. FISHER[2], V. TYBULEWICZ[3], T. SMART[1];
[1]Neuroscience, Physiol. and Pharmacol., [2]Dept. of Neurodegenerative Dis., Univ. Col. London, London, United Kingdom; [3]Francis Crick Inst., London, United Kingdom

Abstract: Down syndrome (DS) is characterised by severe cognitive deficits that are considered to arise from dysfunctional GABA-mediated inhibition in the brain[1]. In the hippocampus, increased inhibition impairs the development of long-term potentiation[2] (LTP), a potential cellular correlate of learning and memory at the circuit level. Here we used the Dp1 Tyb mouse model that contains an extra copy of the region of mouse chromosome-16 that is syntenic with human chromosome-21 to study the nature of GABAergic inhibition in the dentate gyrus of the hippocampus, using whole-cell electrophysiology of adult (P100-135) animals.
Using acute brain slices, we observed that the frequency of spontaneous inhibitory postsynaptic currents (sIPSCs) in dentate granule cells is increased in trisomic animals compared to their disomic controls, without changing sIPSC amplitude. In addition, trisomic cells also exhibited increased levels of tonic inhibition. Overall, such findings are consistent with increased GABA-mediated inhibition in trisomic neurons.
In regard to granule cell excitability, there was no change in resting membrane potential between trisomic and disomic neurons. However, the threshold for spike firing was increased for trisomic cells in accord with the increased synaptic and tonic inhibition suppressing spike firing. These effects may contribute to the cognitive impairment observed in DS and the reduced level of LTP in DS mouse models.
By dye filling single granule cells, we also show that trisomic neurons undergo dendritic remodelling and from immunolabelling, we reveal that the number of parvalbumin positive interneurons is significantly increased in the dentate suggesting the mechanisms by which the increase of phasic frequency and tonic current is orchestrated.

Title: EEG in adults with Down syndrome: how resting-state characteristics relate to cognitive ability

Authors: *S. HAMBURG[1], C. M. STARTIN[1], M. DE HAAN[2], A. STRYDOM[1];
[1]Div. of Psychiatry, Univ. Col. London, London, United Kingdom; [2]Ctr. for Developmental Cognitive Neurosci., UCL Inst. of Child Hlth., London, United Kingdom

Abstract: Electroencephalography (EEG) characteristics, particularly alpha activity, have been associated with cognitive ability in the typically developing (TD) population. Atypicalities in the EEG of individuals with Down syndrome (DS) are common and include power, frequency, topographical and connectivity measures; 'slowing' of the EEG is commonly reported in DS. However, the relationship of these characteristics with cognitive ability in DS remain unclear. Exploring these relationships may be important for understanding brain development and maturation in DS, as well as for identifying potential EEG characteristics indicative of cognitive decline (biomarkers). We used 128-channel EEG in two resting state paradigms (eyes-open and eyes-closed; 5.5 min each) to explore individual differences in EEG characteristics and their relationship with cognitive ability in younger adults with DS (n=39; aged 16-35). Raw K-BIT 2 scores provided an estimate of general cognitive ability and memory was assessed using a seven object immediate recall test. We report that individual alpha peak frequency (iAPF) was significantly negatively correlated with both memory ability and general cognitive ability during the eyes-open paradigm. In conclusion it appears that slower alpha-band activity while eyes are open confers a cognitive benefit in younger adults with DS.

Title: Implications for chromosome 21-encoded miRNAs and MeCP2 in synaptic dysfunction in Down syndrome

Authors: *V. R. MIRABELLA, H. MCGOWAN, A. VILLEGAS, Z. PANG;
Neurosci. and Cell Biol., Child Hlth. Inst. of NJ, Rutgers-Rwjms, New Brunswick, NJ

Abstract: Trisomy 21 (T21) is characterized by a number of clinical hallmarks, including cognitive impairment and mild to moderate intellectual disability. Animal models have demonstrated synaptic aberrations, including altered synaptic density, impaired endocytosis and excessive inhibitory signaling. Additionally, human induced pluripotent stem (iPS) cell models have demonstrated reduced synaptic connectivity. The formation and maintenance of synaptic connections is paramount to central nervous system function and is highly regulated. Emerging evidence implicates non-coding RNAs, including microRNAs (miRNAs), in regulating synaptic function. For example, several miRNAs have been implicated in spinogenesis, dendritic arborization, and synaptogenesis. Thus, over- or under-expression of miRNAs may contribute to synaptic dysfunction in neurodevelopmental disorders. T21 results in increased gene dosage of several miRNAs encoded by human chromosome 21 (HSA21), and our preliminary evidence suggests that HSA21 miRNAs target methyl CpG binding protein 2 (MeCP2), the protein mutated in Rett syndrome. These data suggest that HSA21-encoded miRNAs may regulate neuronal maturation and synapse formation via MECP2. Utilizing innovative induced neuronal (iN) cell technologies, we are studying the effects of HSA21 miRNAs on synaptogenesis in human neurons derived from several isogenic T21 patient iPS cell lines. We discovered MeCP2 as a target of these miRNAs by a dual luciferase assay and have confirmed the overexpression of HSA21 miRNAs in T21 iNs. Our preliminary data suggest that reduced MeCP2 expression in these neurons is also reduced. Synaptic function in T21 iNs will be assessed by morphological and functional analyses, including electrophysiology and calcium imaging. Preliminary electrophysiological data suggest that T21 iNs are less synaptically active. By combining interdisciplinary analytical methodologies with the iN cell and iPS cell technologies to examine the functions of HSA21 miRNAs in the nervous system, we will test causal-effect relationship of HSA21 miRNAs and synaptic alterations in T21 human neurons. This study will broaden our knowledge of the biological functions of these important and versatile regulatory molecules and provide important insight into the mechanistic and molecular basis of synaptic dysfunction in T21.

Title: Microglial defects are present in the dp16 murine model of down syndrome.

Authors: *B. PINTO[1,2], L. PERLINI[1], L. CANCEDDA[1];
[1]NBT, IIT, Genova, Italy; [2]Neurosci., Scuola Normale Superiore, Pisa, Italy

Abstract: Down syndrome (DS) is a neurodevelopmental disorder caused by the presence of a supernumerary chromosome 21 (Chr21), and it represents the most frequent cause of genetic intellectual disability. Interestingly, some of the genes located on Chr21 are essential for the correct function of the immune system, and DS individuals often suffer from immunological disorders.
Microglia are the main immune cells of the brain and play important roles in its development. In particular, they are involved in neuronal progenitor phagocytosis and synaptic pruning, which are mechanisms essential for cognitive functions. However, it is not known whether microglial defects are involved in the development of cognitive deficits associated with DS.
Here, we investigated the presence of microglial alterations during brain development in a DS murine model (DP16). We found no difference in the density of microglial cells in the embryonic cortex of DP16 animals when compared to WT littermates. However, at postnatal day 1, we found an increased density of microglia that accumulated in the periventricular zone of the forebrain in DP16 mice. Interestingly, this increase was followed by a decreased microglia density that persisted into adulthood. Moreover, the distribution defects were accompanied by morphological alterations.
The accumulation of microglia in neurogenic locations of the developing DS brains together with microglial morphological alterations suggest a possible involvement of these cells in cerebral defects typical of trisomic brains. Thus, microglia may be a potential future target for early interventional therapies for the treatment of cognitive impairment in DS individuals.

Title: Memantine rescues delayed development of visual acuity in the Down syndrome mouse model Ts65Dn

Authors: D. B. VICTORINO, M. R. STASKO, J. J. SCOTT-MCKEAN, B. L. ZAMPIERI, *A. C. COSTA;
Div. of Pediatric Neurology, Dept. of Pediatrics, Case Western Reserve Univ., Cleveland, OH

Abstract: Down syndrome (DS) is the most common genetically defined cause of intellectual disability. This genetic disorder also affects the visual system in a variety of ways, which include high incidence of refractive errors, accommodative inaccuracy, amblyopia, strabismus, nystagmus, abnormal oculomotor and vestibular functions, decreased visual acuity, and decreased color and contrast sensitivities. In a previous study (Scott-McKean et al., IOVS 51: 3300- 3308, 2010), we demonstrated electrophysiologically that adult Ts65Dn mice (a murine model of DS) exhibit deficits in luminance threshold, spatial resolution, and contrast threshold, compared with euploid control mice. Here, we investigated visual thresholds of optokinetic tracking (OKT), a visual behavior that facilitates the relative stabilization of retinal images. Using the methods of Prusky el al. (IOVS 45:4611-4616, 2004), we quantified OKT thresholds of untrained, freely moving Ts65Dn and control euploid mice, daily, from eye opening (postnatal day 14; or p14) to 35 days of age, and then in longer intervals (5-10 days), until the animals were 60-day old. We found that Ts65Dn mice show a significant delay in the maturation of the visual system, which translated to detectable significant differences from p14 to p26. For example, whereas the mean spatial frequency sensitivity to a 100% contrast grating projected on a virtual cylinder for 14-day old euploid control mice was 0.20 c/deg, the mean value of this measure was 0.08 c/deg for Ts65Dn mice. Ts65Dn mice only achieved mean spatial frequency sensitivities of 0.20 c/deg at 16 days of age. At p35, the measured values of mean spatial frequency sensitivity reached mature levels at 0.46 and 0.44 c/deg for control euploid and Ts65Dn mice, respectively. The development of contrast sensitivity was also delayed in Ts65Dn mice. At 17 and 35 days of age, contrast sensitivity was 6% and 17% in Ts65Dn mice versus 9% and 26% in control mice, respectively. We tested the effect of a single dose of the NMDA-receptor antagonist memantine (5mg/kg i.p.) on Ts65Dn and control euploid mice at p17 and p35. Using this treatment, we found that memantine produces an enhancement of the mean spatial frequency sensitivity in Ts65Dn mice to control euploid levels, and does not have any significant effect in control euploid mice. We are currently attempting to replicate these behavioral-based findings with objective, *in vivo* electrophysiological experiments. Given that the observed delay in the maturation of the visual system in a mouse model of DS mimics the qualitative features of the same phenomenon seen in young persons with DS, this finding may have important therapeutic applications.

Title: Postnatal neuro-behavioral effects of prenatal ethanol exposure in a mouse model of FASD.

Authors: O. O. KOZANIAN, *K. J. HUFFMAN;
Psychology/Neuroscience, Univ. of California, Riverside, Riverside, CA

Abstract: Human ethanol consumption during pregnancy results in developmental abnormalities in offspring brain and behavior that often persist into adulthood. Fetal alcohol spectrum disorders (FASD) is an umbrella term that describes a wide range of adverse developmental conditions caused by prenatal ethanol exposure (PrEE). Children diagnosed with FASD exhibit a range of deleterious phenotypes including, but not limited to, growth retardation, facial dysmorphologies, neurological anomalies and cognitive-behavioral deficits. Given the cognitive and behavioral abnormalities present in children with FASD, the palette of PrEE-related developmental deficits in humans have led to hypotheses centering around neocortical dysfunction, a structure within the nervous system that is responsible for complex cognitive function, thought and behavior. Our laboratory was first to demonstrate the disruption of the network of intraneocortical connectivity within sensori-motor regions of neocortex in newborn PrEE mice. Specifically, disrupted targeting of ipsilateral intraneocortical connections and altered gene expression patterns were observed in newborn PrEE mice (El Shawa et al., 2013). The current study extends our laboratory's initial findings by examining whether PrEE-related phenotypes observed in newborns are maintained throughout 'childhood'. Here, we investigate whether aberrant INCs and altered gene expression patterns found in the PrEE newborn are transient or persist into pre-pubescence (P20). We also implement a battery of behavioral assays in order to correlate cortical development after PrEE with behavioral outcomes. Results indicate that PrEE-induced changes in newborn gene expression are maintained through pre-pubescence, while PrEE-induced ectopic cortical connectivity observed at P0 is rescued by P20. Although ectopic cortical connectivity is rescued by P20, pre-pubescent PrEE mice continue to show significant behavioral deficits including poor motor coordination and sensori-motor integration, as well as depression. Outcomes from this study will help identify long-term neurobiological and behavioral effects resulting from prenatal ethanol-exposure related brain dysfunction in humans with FASD.

Abstract: Fetal Alcohol Spectrum Disorder (FASD) is a developmental disease characterized by various behavioural problems and physical defects. FASD has been shown to affect all parts of the eye, from extra-ocular structures to the optic nerve [1]. The results of ERG studies in children suffering from FASD are similar to those carried out in aging populations [2-4]. Here, we directly compared these effects by testing Fetal Alcohol Exposure (FAE) in monkeys (*Chlorocebus sabaeus*) spanning a large age range, from 3 to 12 years old, as well as their matched controls. We measured ERGs in 78 monkeys, across 12 flash intensities in photopic conditions, and 14 flash intensities in scotopic conditions - after a period of dark adaptation. FAE and age both affected electroretinographic waves. More specifically, in photopic conditions amplitudes of a-waves and b-waves increased with age, and were higher in FAE than age matched controls. In scotopic conditions, the amplitude of the a-wave was affected by age, but the effect depended on the intensity of the flash. In contrast, the amplitude of the b-wave decreased with age in controls with little or no difference in the FAE sample, which overall had smaller b-wave amplitudes compared to controls. The differences in retinal responsiveness from these populations suggest a different maturation in the FAE population and should be followed up with anatomical explorations.

Title: Alterations in cognitive function in male and female rats in MAM rodent model of schizophrenia

Authors: *M. GHASEMZADEH, C. BOLDIG, K. BOLDIG, V. SCHLOEGEL, R. DIDOMINICIS, C. ALBRECHT, B. PAHLAVAN;

Abstract: Schizophrenia (SZ) is a neurodevelopmental mental disorder with devastating personal and family consequences. The MAM animal model (E17 gestational methylazoxymethanol acetate administration) is a neurodevelopmental model that displays many of the anatomical, neurochemical, and functional deficits associated with schizophrenia. We have examined the performance of MAM-treated animals (Sprague-Dawley rats) in several behavioral cognitive tasks to evaluate the extent and nature of the deficits in this model. Rats were bred on site and MAM (22 mg/kg, ip) or saline (1 ml/kg, ip) was administered on gestation day 17. Male and female offspring were housed 3-4 per cage and were provided with enrichment at all times. All animals were tested between 3-8 months of age. All efforts were made to eliminate all sources of stress in these animals during development and behavioral testing. Both male and female MAM-treated rats responded with higher locomotor activity to a novel environment. In an open field test, both male and female MAM-treated rats spent more time in the center of the arena compared to the saline-treated animals. In addition, both male and female MAM-treated animals spent more time on the open arm of an elevated plus maze compare to saline-treated rats. Surprisingly, while male MAM-treated rats engaged in higher levels of social interaction, female MAM-treated rats were not different from saline-treated animals. Both gender performed the same as the saline-treated rats in the novel object recognition task. The overall pattern of behaviors displayed by MAM animal model is suggestive of a decrease in behavioral inhibition.

Some aspects of the schizophrenia symptoms also suffer from the loss of behavioral inhibition. The data suggest that the MAM model may be useful in examining the neuronal basis of behavioral inhibition. Studies to further characterize these behavioral abnormalities and their developmental timeline are ongoing and results will be presented.

Title: Sevoflurane anesthesia causes apoptosis in the developing nonhuman primate brain

Authors: *C. IKONOMIDOU[1], K. CROSNO[2], V. ELAM[2], S. WOELFFER[2], H. SIMMONS[2], A. MEIJA[2], J. M. HAYES[2], S. FRENCH[2], K. BRUNNER[2], S. CAPUANO III[2], K. NOGUCHI[3], C. A. TURSKI[1];

Abstract: Anesthetics, sedatives and antiepileptics utilized in neonatal and pediatric medicine, can be harmful to the developing brain. They have been shown to cause widespread active cell death (apoptosis), impair synaptic maturation and plasticity and inhibit neurogenesis in the brains of rodents and nonhuman primates (NHP). Studies in rodents and in NHP have provided compelling evidence that early life exposure to these drugs also triggers behavioral toxicity (i.e., they cause long-term behavioral and cognitive deficits that persist when the animals mature). Furthermore, retrospective clinical studies raise serious concerns that exposure of human infants to these classes of drugs may lead to neurocognitive and behavioral disorders. Sevoflurane (SEVO) is becoming one of the most frequently used general anesthetics in pediatric medicine. In this study, we exposed neonatal rhesus macaque monkeys (n=2) to sevoflurane anesthesia over 5 hours according to current clinical standards in pediatric anesthesia. Brains were collected 3 hours later and examined immunohistochemically (activated caspase 3 immunohistochemistry) to analyze apoptotic neuronal and glial death. Sevoflurane anesthesia was well tolerated with

oxygen saturation, end tidal CO_2 and electrolyte levels remaining at optimal levels throughout the procedures. Brains of rhesus monkeys exposed to SEVO on postnatal days 2-6 displayed significant apoptosis in both the white and gray matter throughout the central nervous system. Areas predominantly affected included the visual, frontoparietal, cingulate and retrosplenial cortex, and the thalamus, globus pallidum and putamen. Within the white matter apoptosis was seen to affect the corpus callosum and diffusely the subcortical white matter. Approximately 50% of the dying cells were glia and 50% were neurons. Oligodendrocytes (OLs) engaged in myelinogenesis were selectively vulnerable. As expected, the apoptosis response to sevoflurane is very similar to the response to isoflurane, reported by Brambrink et al. (Ann Neurol 2012;72:525-535) in infant rhesus monkeys. Our findings indicate that exposure of the infant rhesus macaque to sevoflurane for 5 hours is sufficient to cause widespread apoptosis of neurons and OLs throughout the developing brain.

Title: Paternal aging-induced differential DNA methylation in sperm: possible transgenerational effects on gene expression and behavior in offspring

Authors: *R. KIMURA[1], K. YOSHIZAKI[1], T. KOIKE[2], R. YAMASHITA[3], K. KOIKE[1], T. KIKKAWA[1], H. INADA[1], Y. MATSUI[4], T. KONO[2], N. OSUMI[1];

Abstract: Recent studies suggested that advanced paternal age could be a risk for some psychiatric diseases like autism and schizophrenia, and how paternal aging affects their offspring's health is becoming a fundamental issue. In this study, we established a model to

examine the biological basis for how paternal aging affects specific traits in their offspring. First we confirmed behavioral abnormalities in offspring derived from old male mice. The offspring showed defects in isolation induced vocal communication and sensorimotor gating function, but their social communication and repetitive behavior were comparable to those derived from young male mice. Because several literatures have indicated age-associated DNA methylation changes in sperm as a possible risk for the health problem in offspring, comprehensive targeted DNA methylome analysis was carried out using young and old mice sperm. We found in old sperm 16 hypermethylated and 96 hypomethylated genome loci, in which several autism/schizophrenia related genes are included. Further analysis revealed that profiles of these differentially methylated regions (DMRs) were similarly observed among individual sperm samples. We also revealed conserved motives potentially bind to a transcriptional repressor within hypomethylated loci. These findings suggest that age-associated DNA methylation changes may cause deterioration of transcriptional regulation of target genes/loci during brain development. We are now investigating, in the offspring's brain, expression profiles of genes related with DMRs in old sperm.

Title: Sex-specific neuroinflammatory and sociability alterations in a mouse model of autism

Authors: *N. KAZLAUSKAS[1], M. CAMPOLONGO[2], C. ZAPPALA[2], A. DEPINO[2]; [1]Inst. For Physiology, Mol. Biol. and Ne, Argentina; [2]Inst. For Physiology, Mol. Biol. and Ne, Buenos Aires, Argentina

Abstract: Autism is a neurodevelopmental disorder characterized by decreased sociability, impaired communication and the presence of stereotyped or restrictive behaviors. These

symptoms typically appear during the first years of childhood and affect 1 in 100-200 children, with a 4:1 male:female ratio. Although many factors have been implicated in this disease, the exact underlying causes are still unclear. However, previous studies have shown a link between autism and neuroinflammation. VPA administration at GD12.5 produced decreased sociability in adult male mice, but not in females. Interestingly, we have found that adult female mice show increased micro and astroglial cell density in the cerebellum and an exacerbated peripheral inflammatory response upon a LPS challenge. However, these alterations are not present in males. We hypothesized that there is a developmental critical window in which maturation and consolidation of the neural systems responsible for autism symptoms typically occur. In order to define this temporal window, we characterized the peripheral and neuroinflammatory state of female mice from P7 to P42. We found glial alterations in the hippocampus and cerebellum of VPA mice at early ages (P21, P28 and P35). We then administered LPS during this period (P21 to P35) to further explore the direct effect of neuroinflammation on sociability in male and female mice. We found that eliciting postnatal inflammation produces distinct behavioral outcomes depending on sex.

Title: The metabolic effects of creatine loss in adult creatine transporter conditional knockout mice

Authors: *K. C. UDOBI, M. R. SKELTON;
Dept. of Pediatrics, Neurol. Div., Cincinnati Children's Res. Fndn., Cincinnati, OH

Abstract: Creatine (Cr) transporter (CrT) deficiency (CTD) is a leading cause of X-linked intellectual disability. CTD is characterized by a lack of brain Cr, severe intellectual disability and aphasia. We generated mice with exons 2-4 of *SLC6A8* flanked by *loxP* sites ($CrT^{flox/flox}$). Ubiquitous CrT knockout mice ($CrT^{-/y}$) and conditional knockout mice (cKO) generated from this line exhibit cognitive and metabolic deficits, mimicking the human disorder. While it is clear that Cr is essential for proper cognitive and metabolic function as evidence by cognitive deficits

present in $CrT^{-/y}$ mice, it is still unknown if these deficits result from an absence of Cr during development or the persistent absence of Cr. A better understanding of the role of Cr in cellular metabolism is essential for the development of treatments and treatment strategies for CTD. The purpose of this study is to determine if the lack of Cr leads to changes in whole body metabolism in adult CrT knockout mice. To better understand if the metabolic deficits in $CrT^{-/y}$ mice are due to developmental changes resulting from an absence of cellular Cr, the CrT was deleted in adult mice. $CrT^{flox/flox}$ mice were crossed with mice expressing a ubiquitous tamoxifen-inducible Cre recombinase to create a temporally mediated CrT knockout mouse (uKO). Recombination was initiated by tamoxifen administration from postnatal day 60-65. Brain CrT transcripts were undetectable 5 days following Cre recombinase induction. Following the induction of Cre recombinase activity, cKO mice exhibit a significant reduction in body weight compared to wildtype (WT) mice. Following validation of the knockout, cognitive and metabolic function were assessed based on deficits observed in the $CrT^{-/y}$ mice. In the visible platform testing, cKO mice show no significant difference in latency to the platform compared with controls. There were no differences between groups in latency and path length during the Morris Water Maze (MWM). No reference memory deficits were present. Control and cKO mice performed similarly in tasks of object recognition and fear memory. Oxygen consumption and carbon dioxide waste were measured for a 24 hour period using the Columbus Instruments Comprehensive Lab Animal Monitoring System (CLAMS). The adult uKO mice showed no observable differences in oxygen consumption and carbon dioxide waste compared to controls. The absence of cognitive and metabolic deficits in the adult uKO mice suggest that the deficits seen in the $CrT^{-/y}$ mice are likely due to a lack of Cr during critical points in development.

Title: The influence of the electrical stimulation of the raphe magnus on neuronal structure of the serotonergic system in rats

Authors: *K. K. PTASZEK, K. PLUCINSKA, G. JERZEMOWSKA, E. JURKOWLANIEC; Dept. of Animal and Human Physiol., Univ. of Gdansk, Fac. of Biol., Gdansk, Poland

Abstract: Serotonin (5-HT) is the endogenous amine present in the tissue of vertebrates, invertebrates and even the plants. In humans, 5-HT is located in the blood platelets, intestine cells and brain, mainly in the raphe nuclei and pineal gland. The serotonergic system develops earliest of the neurotransmitter systems and become the most expanded, linking together many regions in the brain. The influence of 5-HT on the organism is strictly connected with the interaction between this neurotransmitter and the specific serotonergic receptors.
Our previous study indicated that electrical stimulation of the raphe magnus (RMg) increased rats locomotor, anxious and reduced sociability. Now, we would like to verify the influence of the RMg stimulation on serotonergic neurons in different brain structures, especially those that are responsible for previously observed rats behaviors.
Male Wistar rats (3-months old) were implanted with electrodes into the RMg. After 10-day convalescence, 13-day electrical stimulation was performed with the stimulation current determined individually for each animal (60-140 μA). Rats were divided into stimulated (n=6) and non-stimulated (sham; n=7) groups. Every day, each animal had 25 stimulation trials (30-s stimulation followed by 20-s break). One hour after the last stimulation, rats were sacrificed, their brains were perfused with 0.9% saline followed by 4% paraformaldehyde (PFA). Next, brains were removed and stored in the PFA for 24 h, then for 48 h in 30% sucrose. After that the frozen brains were cut into 30 μm thick sections and collected slices were stained during immunofluorescence procedure, especially were incubated with primary antibody to 5-HT (*ab66047*, Abcam, UK) and probed with secondary antibody (*ab150129*, Abcam, UK). Images were taken by fluorescent microscope (*PrimoStar*, Carl Zeiss, Germany) and processed using the imaging software (*Axio Vision*).
Results were analyzed as total numbers of 5-HT positive cells per structure at magnification 100 × 10. The RMg stimulation increased number of 5-HT cells in hypothalamic nuclei: arcuate nucleus (77 vs. 56 in sham) and periventricular nucleus (65 vs. 0), motor cortex (63 vs. 36), reticulotegmental nucleus of the pons (16 vs. 12) and RMg (44 vs. 29). In turn, the number of 5-HT cells were decreased in supraoptic nucleus (31 vs. 41), reticular thalamic nucleus (9 vs. 22) and hippocampus (34 vs. 47).
Summarizing, the RMg stimulation affected the serotonergic projections either to the limbic structures or motor cortex. It can be assumed that hyperactivity of the serotonergic system may correlate with behaviors observed in different disorders, such as Autism Spectrum Disorder.

Title: GABA receptor involvement in sensorimotor gating in the rat model: an autoradiography study

Authors: E. T. CHOW[1], M. FAZAL[1], C. R. CLANCY[1], J. SKEFOS[1], E. D. LEVIN[2], *M. L. BAUMAN[1];
[1]Boston Univ. Sch. of Med., Dept. of Anat. and Neurobio., Boston, MA; [2]Dept. of Psychiatry and Behavioral Sci., Duke Univ. Med. Ctr., Durham, NC

Abstract: Sensorimotor gating relates to the process of filtering irrelevant external and internal stimuli, in order to modulate a motor response to salient stimuli. Sensorimotor gating can be gauged behaviorally by indexing prepulse inhibition (PPI), a measure of startle response suppression to a strong sensory stimulus (e.g., 110 dB acoustic pulse) when preceded by a weaker sensory stimulus (e.g., 68-77 dB acoustic pre-pulse). Abnormal sensorimotor gating has been implicated in many neurological disorders, including autism spectrum disorders, sensory processing disorders and schizophrenia. The neural circuitry underlying PPI is complex and has been shown to include dopaminergic, GABAergic, cholinergic and histaminergic systems. Our prior work in a rat model explored the role of cholinergic/histaminergic systems in PPI. We utilized the NMDA glutamate receptor antagonist, dizocilpine, to induce PPI impairment, and administration of the histamine H1 receptor antagonist, pyrilamine, to reverse this PPI impairment, as had been previously demonstrated. In this autoradiographic study, we extend these findings by investigating potential GABAergic involvement in the PPI disruption induced by treatment with dizocilpine, as well as PPI improvement induced by treatment with pyrilamine. We explore key brain regions that participate in the sensorimotor gating network, e.g., the basolateral amygdala (BLA), anterior cingulate cortex, insular cortex, hippocampus and striatum. Four treatment groups were studied, with 9 Sprague-Dawley rats per group. Control animals were administered saline, and treatment animals were administered either dizocilpine, pyrilamine, or the combination of dizocilpine and pyrilamine for 4 weeks. Specific binding of the GABA-A and GABA-B receptors was determined using [3H]Muscimol and [3H]CGP54626, respectively. Preliminary results found no differences in GABA-A/B receptor binding density between the PPI impaired treatment groups with and without pyrilamine in the BLA ($p=0.62$), although GABA-B receptor density was significantly decreased in dizocilpine-exposed groups in

the BLA (p=0.01). GABA-B receptors may thus play a mechanistic role in dizocilpine's effect on PPI in this model. Further studies are ongoing to explore additional brain regions and confirm the role of GABA in PPI impairment/recovery, which may aid in the development of treatments for disorders such as autism, where GABAergic abnormalities are widely reported.

Title: Inheritance of neocortical molecular layer heterotopia

Authors: *A. R. TOIA[1], J. CUOCO[1], A. JOSHI[1], J. AHSAN[1], G. TORRES[1], V. BOLIVAR[2], R. RAMOS[1];
[1]New York Inst. of Technol., Old Westbury, NY; [2]Biomed. Sci., State Univ. of New York at Albany, Albany, NY

Abstract: Neocortical molecular layer heterotopia (MLH) in mouse models, such as C57BL/6 inbred mice, contain diverse cellular and axonal constituents. First, diverse excitatory neurons are present in heterotopia, including neurons normally destined for deep (layers VI and V) and superficial layers (layers II and III) as well as layer IV. These data indicate that pyramidal neurons born throughout corticogenesis are found in MLH. Second, diverse GABAergic neurons are present in heterotopia including those born in distinct regions of the ganglion eminence. Third, all three types of glial cells are found in MLH including astrocytes, oligodendrocytes, and microglia; however, there is no evidence of reactive astrocytes or activated microglia. Finally, diverse projections to and from MLH are present including those from brainstem nuclei as well as intracortical and callosal connections.
The genetic mechanisms of MLH formation are poorly understood and the extent to which MLH are present in other inbred strains of mice is unclear. In the present report, a neuroanatomical survey was performed of the neocortex of 7 widely-used inbred mouse strains for the presence of MLH, including strains commonly used in the production of genetically-engineered mice. In order to understand the basic principles of inheritance of MLH in C57BL/6 mice, the presence of heterotopia was examined in 2 first filial generation (F1) hybrids, numerous different recombinant inbred strains, one consomic strain, and several genetically-engineered mouse lines. Our results indicate that MLH formation is a weakly penetrant trait which requires homozygosity

of one or more C57BL/6 alleles outside of chromosome 1. These data are relevant for understanding normal neocortical development and the mechanisms of cortical lamination. In light of the fact that C57BL/6 mice are the most popular strain used as animal models of neurological disorders, our results also have broad implications for the use of these mice in diverse studies as well as in the creation of knockout and transgenic mice.

Title: Magnetic resonance and diffusion tensor imaging of basal ganglia circuitry in an animal model of repetitive behavior

Authors: B. J. WILKES[1], L. M. COLÓN-PÉREZ[2], A. M. MUEHLMANN[2], M. FEBO[2], *M. H. LEWIS[2];
[1]Psychology, Univ. of Florida, Gainesville, FL; [2]Psychiatry, UF Col. of Med., Gainesville, FL

Abstract: Restricted, repetitive behavior is a prominent feature of a number of neurodevelopmental disorders and diagnostic for autism spectrum disorder (ASD). Our lab utilizes an inbred mouse strain (C58) that demonstrates robust repetitive motor behavior phenotype (vertical jumping, backward somersaulting). Previous histochemical work in our lab suggests that alterations in basal ganglia circuitry mediate the expression of this repetitive behavior. We previously found reduced cytochrome oxidase (CO) expression, a marker of cellular activity, and decreased dendritic spine density in the sub-thalamic nucleus (STN) in animals with high levels of repetitive behavior (Tanimura et al., 2011). Furthermore, animals that exhibit attenuated repetitive behavior following rearing in an enriched environment show increased CO and dendritic spine density in the globus pallidus (GP) and STN, compared to standard housed controls (Bechard et al., 2016). In order to further investigate the role of basal ganglia circuitry alterations in repetitive behavior, we performed *ex vivo* magnetic resonance imaging (MRI) on C58 mice and C57BL/6 controls. We used 3D FLASH gradient echo and 2D diffusion weighted spin echo scans to assess regional morphology and structural connectivity, respectively. Volumetric comparisons and probabilistic fiber tracking were performed for structures of the basal ganglia and the associated white matter tracts. Consistent with our hypothesis of indirect pathway dysfunction, we found significantly smaller volumes of the GP

and STN in C58 mice, as well as trends for lower fractional anisotropy and mean diffusivity in fiber tracts connecting the GP and STN. These findings are consistent with human neuroimaging findings indicating altered basal ganglia morphology that is correlated with repetitive behavior symptoms in ASD (Herbert et al., 2003; Hollander et al., 2005; Langen et al., 2009). These findings provide hypotheses that can be tested using diffusion tensor imaging investigations of intra basal ganglia connectivity in ASD and related neurodevelopmental disorders.

Title: Convulsive seizures from experimental focal cortical dysplasia occur independently of cell misplacement

Authors: *L. S. HSIEH[1], J. WEN[1], K. CLAYCOMB[2], Y. HUANG[2], F. HARRSCH[3], J. NAEGELE[3], F. HYDER[2], G. BUCHANAN[4], A. BORDEY[1];

Abstract: Focal cortical dysplasia (FCD), a local malformation of cortical development, is the most common cause of pharmacoresistant epilepsy associated with life-long neurocognitive impairments. It remains unclear whether neuronal misplacement is required for seizure activity.

Here we show that dyslamination and white matter heterotopia are not necessary for seizure generation in a murine model of type II FCDs. These experimental FCDs generated by increasing mTOR activity in layer 2/3 neurons of the medial prefrontal cortex are associated with tonic-clonic seizures and a normal survival rate. Preventing all FCD-related defects, including neuronal misplacement and dysmorphogenesis,with rapamycin treatments from birth eliminate seizures, but rapamycin withdrawal is followed by the recurrence of seizures. In addition, bypassing neuronal misplacement and heterotopia using inducible vectors ddo not prevent seizure occurrence. Collectively, data obtained using our new experimental FCD-associated epilepsy suggest that life-long treatment to reduce neuronal dysmorphogenesis is required to suppress seizures in individuals with FCD.

Title: Late adolescent shift from local to distributed monosynaptic inputs onto fronto-posterior cortical projection neurons.

Authors: *E. NABEL[1], M. DEMARS[2], S. LOPEZ[2], G. TACCHERI[2], H. KOIKE[2], H. MORISHITA[2];
[1]Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Visual attention, the cognitive ability that enhances the perception of selected stimuli, develops postnatally and is disrupted in neurodevelopmental disorders such as autism. A direct long-range projection from the anterior cingulate cortex (ACC) to primary visual cortex is a key circuit mediating “top-down” modulation of visual processing, which is a hallmark component of attention. However, little is known about this projection’s input sources, and if inputs undergo developmental modifications. In this study, an intersectional viral genetic technique was employed to map the monosynaptic inputs onto top-down cells in adolescence and adulthood. Whole brain maps of top-down inputs were generated, and regions of interest were further characterized by cell type. Cortical areas contributed the majority of monosynaptic inputs onto top-down cells. Local inputs from the ACC and secondary motor area comprise the large source; other major sources of cortical contributions include the retrosplenal, prelimbic, and infralimbic

cortex. Non-cortical regions provide distributed inputs from the basal forebrain, dorsal thalamus, and hypothalamus. Inputs from the basal forebrain, the major neuromodulatory source for this projection, comprise of approximately 80% cholinergic, 14% putative glutamatergic, and 6% inhibitory neurons. Comparison of the adult and adolescent whole brain maps revealed a larger number of inputs from local cortical regions during adolescence lost in adulthood. No age-related differences were observed in other cortical and non-cortical areas. This result suggests that local pruning during late adolescence causes a relative shift in input weight from local to distal brain regions between adolescence and adulthood. This cortical maturation may be required to establish effective top-down control of attention.

Title: Chemogenetic targeting of prefrontal parvalbumin interneurons affects social behavior in mice

Authors: *L. BICKS[1], H. KOIKE[1], C. MILLER[3], M. PENG[1], S. AKBARIAN[2], H. MORISHITA[2];
[2]psychiatry, [1]Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Marymount Manhattan Col., New York, NY

Abstract: Social processing is a domain that is commonly dysregulated in psychiatric disorders, and is poorly treated by available psychiatric medications. In humans and rodents, portions of the

evolutionarily conserved medial prefrontal cortex (mPFC) are part of a network that regulates social behavior. Many disorders with shared social processing deficits show impairments in inhibitory neurotransmission within the brain, particularly in the mPFC, suggesting a role for PFC inhibitory action in regulating social behavior. We investigated the role of prefrontal parvalbumin (PV) interneurons, a major class of cortical inhibitory neurons, in social behavior of adult mice by leveraging chemogenetic technologies. We selectively expressed hM4Di, an inhibitory DREADD (Designer Receptor Exclusively Activated by Designer Drugs), in PV interneurons in the mPFC. Acute selective suppression of mPFC PV interneurons decreased sociability in a 3-chamber test and disrupted social recognition in a habituation-dishabituation paradigm. Suppression of PV interneurons did not affect spatial working memory, olfactory discrimination, or anxiety-related behaviors, suggesting a specific effect of PV interneuron suppression on social behavior. These results demonstrate that PV interneuron activity in the mPFC is necessary for appropriate social behavior in mice.

Title: Minor spliceosome inactivation in the mouse pallium causes progenitor cell death and microcephaly

Authors: *A. OLTHOF[1], M. BAUMGARTNER[1], C. LEMOINE[1], S. AL SEESI[2], K. HYATT[1], N. STURROCK[1], N. NGUYEN[1], K. DRAKE[1], R. GOZ[1], J. LOTURCO[1], R. KANADIA[1]; [1]Physiol. and Neurobio., [2]Computer Sci. Engin., Univ. of Connecticut, Storrs, CT

Abstract: Microcephaly in microcephalic osteodysplastic primordial dwarfism type 1 (MOPD1) is linked to U4atac mutations. U4atac is a crucial component of the minor spliceosome, which is responsible for splicing of <0.5% of introns. This suggests that inactivation of the minor spliceosome can lead to loss of expression of minor intron-containing genes (MIGs). To test whether this is the underlying cause for the MOPD1 phenotype, we ablated the U11 snRNA,

another crucial component of the minor spliceosome, in the mouse dorsal telencephalon. Here we report that minor spliceosome inactivation in the developing neocortex resulted in microcephaly. We found that loss of U11 caused death of self-amplifying neural progenitor cells (NPCs) at E12, due to defects in mitosis. Intermediate progenitor cells (IPCs) were not produced in the U11 knockout mouse. In contrast, neuron-producing NPCs were unaffected, since U11-null neurons were produced and survived postnatally. RNAseq data revealed drastic downregulation of non-coding RNAs, specifically small nucleolar RNAs (snoRNAs) in the U11 knockout mouse. No transcriptional changes in MIGs were observed, except for *Spc24*, which is a MIG involved in kinetochore assembly. Since we disrupted the minor spliceosome activity, we tested for splicing efficiency. We found that loss of U11 caused defective minor intron splicing of MIGs, leading to minor intron retention. This could introduce premature stop codons and degradation of the transcript by the non-sense mediated decay (NMD) pathway. However, we observed that the MIG *Upf1,* an essential component for the NMD pathway, also has increased minor intron retention in the U11 knockout mouse. This might cause inactivation of the NMD pathway, explaining why the majority of the MIGs did not change in their net expression. In all, we show the underlying molecular and cellular defects caused by inactivation of the minor spliceosome in the developing mouse neocortex. These findings reveal a potential mechanism for the pathogenesis of MOPD1.

Title: Missense polymorphisms in the brain-derived neurotrophic factor binding region of nTRK2 in randomly selected pools of human trace DNA

Authors: *G. HEINRICH[1,2], I. YAO[3], A. J. KING[4];
[1]VA NCHCS, Martinez, CA; [2]Intrnl. Med., UC Davis, Sacramento, CA; [3]Biol. Sci., USC, Los Angeles, CA; [4]Reed Col., Portland, OR

Abstract: The NTRK2 gene encodes a high affinity transmembrane receptor for brain-derived neurotrophic factor (BDNF). Binding of BDNF to NTRK2 triggers numerous biological responses in multiple systems including nervous, immune and skeletal systems. The extracellular BDNF binding site of NTRK2 is known from mutation analysis, crystallography, and functional studies. The binding site is encoded by three conserved exons of the NTRK2 gene - coding exons 6, 7, and 8 spanning amino acids 196 - 386. Numerous single nucleotide polymorphisms have been identified in the NTRK2 gene, among them 199 missense SNPs in the coding region. So far only 1 SNP has been clearly associated with a phenotype, an A to G transition that changes the functionally critical tyr722 in the intracellular kinase domain into cys722. The remaining SNPs have not yet been associated with any phenotypes nor have their distributions in non-selected populations been determined. We focused on exons 6-10 because changes in these regions may affect binding of BDNF, intracellular signaling, and consequently downstream effector pathways during development, adulthood, and aging.
To identify known and new SNPs in anonymous phenotypically unselected populations we collected samples from commonly touched objects in our healthcare setting and extracted trace DNA using a kit from Norgen BioTek. The extracted DNA was then amplified using primer pairs that spanned each of the target exons. The experimental system was verified by nucleotide sequencing of DNA amplified from saliva of 12 anonymous volunteer subjects. Using this procedure, we successfully amplified NTRK2 exons from trace DNA obtained by saline rinses of door and cabinet handles, computer mice, and telephone touch pads. We are in the process of sequencing these samples and searching their sequences for SNPs. Future efforts will expand the sample collection to public objects, developing linear statistical analyses of nucleotide sequences from pooled DNA to identify potential SNPs, and functional in vitro and in silico studies of the effects of missense SNPs in exons 6-10 on BDNF binding and signaling.

Title: PAK1(p21-activated kinase 1) regulates GABAergic synaptic transmission via endocannabinoid signaling in mouse hippocampus

Authors: *S. XIA[1], Z. ZHOU[1], C. LEUNG[2,3], Y. ZHU[1], X. PAN[1], J. QI[1], M. MORENA[4], M. HILL[4], W. XIE[1], Z. JIA[2,3];

Abstract: Normal brain function, including learning and memory, requires balanced excitation and inhibition, but the mechanisms underlying such balance remain unclear. p21-activated kinases (PAKs) are a family of protein kinases known to play critical roles in neuronal development, synaptic regulation and behaviors. In addition, recent studies show that PAK inhibitors can rescue the neurobiological and behavioral deficits in the mouse models of a number of neurodevelopmental disorders including autism and schizophrenia. However, how PAKs impact synaptic function and mental dysfunction remains elusive. In this study, we have found that sustained kinase activity of PAK1, a major form of PAKs expressed in the brain, is indispensable for a proper excitation/inhibition ratio in the hippocampus and this function of PAK1 is mediated by affecting GABAergic synaptic transmission and the retrograde endocannabinoid signaling. These results suggest a novel process by which PAK1 regulates brain function. This study also provide potential therapeutic targets to treat related brain disorders.

Abstract: Glucagon-like peptide 1 (GLP-1) is a hormone synthesized in gut by L cells and in brain by Preproglucagon neurons. GLP-1 binds to a specific receptor with a ubiquitous localization and with multiples effects. It is known that GLP-1 secretion is induced by the presence of food bolus in gut and also an indirect activation on its secretion can be induced by neuroendocrine mechanisms. A significant increase in GLP-1 circulating levels has been observed in patients after ileal interposition surgery. A neuroprotective effect induced by GLP-1 has been reported in neurodegenerative alterations like Alzheimer and Parkinson disease. Our hypothesis is that after ileal interposition surgery GLP-1 levels will increase both in serum and cerebroventricularly. Ileal interposition surgery consists in the transposition of the ileal proximal segment at the level of the ligament of Treitz, in order to enhance the contact of food bolus with intestinal L cells. Male Wistar rats (350-400g) GLP-1 levels in serum and cerebroventricular fluid will be analyzed after three weeks of the ileal interposition surgery by enzyme-linked immunoassays. The aim of this work is to evaluate the degree of peripheral and cerebroventricular elevation of GLP-1 levels after Ileal interposition surgery.

Title: DEAF1 regulates expression of UBE2M

Authors: P. J. JENSIK[1], S. RAJAMANICKAM[1], L. A. ARBOGAST[1], *G. M. ROSE[2], M. W. COLLARD[1], J. I. HUGGENVIK[1], S. R. MCGEE[1];

[1]Southern Illinois Univ. Sch. of Med., Carbondale, IL; [2]Neurosci. Res. Ctr., Southern Illinois Univ., Carbondale, IL

Abstract: Deformed epidermal autoregulatory factor 1 (DEAF1) is a transcription factor that binds TTCG motifs and acts as either a transcriptional repressor or activator on target gene expression. Several mutations in the DNA binding domain of the *DEAF1* gene have been identified in individuals with moderate to severe intellectual disabilities. Mice with conditional knockout of *Deaf1* in the brain (NKO mice) have altered cognitive function indicating DEAF1 has conserved roles in learning and memory. The objective of this study was to identify DEAF1 target genes. RNA-sequencing, using RNA isolated from hippocampal tissue of NKO and WT mice, identified 348 genes that were differentially expressed in the hippocampus of NKO mice. Ubiquitin-Conjugating Enzyme E2M (UBE2M, also referred to as UBC12) acts as a NEDD8 conjugation enzyme and the expression of *Ube2m* was reduced 2-fold in the hippocampus of NKO mice compared to WT mice. Similar reductions in *Ube2m* expression were also observed in RNA isolated from frontal cortex and cerebellum tissue of NKO mice. In order to ascertain if *UBE2M* is a direct target of DEAF1 transcriptional regulation, the CRISPR-Cas9 system was used to generate a DEAF1 knockout (KO) human cell line. Compared to control lines, there was a similar 2-fold reduction in both *UBE2M* RNA expression and UBE2M protein levels in the DEAF1-KO cell lines. A conserved putative DEAF1 TTCG-containing DNA consensus sequence was identified in the mouse and human *UBE2M* promoter. Chromatin immunoprecipitations (ChIP) indicate DEAF1 is bound to the *UBE2M* promoter in mouse neuronal and human neuronal and kidney cell lines. DEAF1 interactions with the *UBE2M* promoter were not detected in the DEAF1-KO cell line demonstrating specificity of the DEAF1 antibody in ChIP analysis. A dsDNA probe encompassing the *Ube2m* promoter putative DEAF1 consensus sequence was generated and used in electrophoretic mobility shift assays to determine if DEAF1 can bind directly to this sequence. The influence of an identified human DEAF1 mutation p.Q264P and corresponding mouse p.Q265P mutation on DEAF1 interactions with this putative consensus sequence was also assessed. Both purified mouse and human DEAF1 proteins bound to the *Ube2m* promoter DEAF1 consensus sequence; however the human p.Q264P and mouse p.Q265P DEAF1 mutant proteins did not bind to the consensus sequence. Taken together, these data indicate that DEAF1 regulates *UBE2M* expression and changes in DEAF1 activity may have resultant effects on UBE2M levels and the neddylation pathway.

Title: Inositol hexakisphosphate kinase-1 physiologically associates with alpha actinin and regulates focal adhesion kinase activity

Authors: *C. FU, J. XU, A. M. SNOWMAN, S. H. SNYDER;
Neurosci., Johns Hopkins Univ. Dept. of Neurosci., Baltimore, MD

Abstract: Inositol hexakisphosphate kinase-1 (IP6K1), which generates inositol pyrophosphates, physiologically mediates numerous functions, such as insulin secretion and histone demethylation. IP6K1 deleted mice are small and males are sterile. Here, we report that IP6K1 physiologically associates with alpha-actinin, and localizes in the focal adhesion complex. IP6K1 deletion elicits a severe deficit of focal adhesion kinase (FAK) activity. IP6K1 deleted cells display substantial decreases of FAK phosphorylation, as well as impaired spreading and migration delay. Regulation of FAK by IP6K1 requires its kinase activity. Pharmacologic inhibition of IP6K by TNP recapitulates the phenotype of IP6K1 deletion. This study demonstrates that IP6K1 physiologically regulates focal adhesion kinase activity and cell migration via kinase dependent mechanisms.

Federal Fluminense, Rio de Janeiro, Brazil; [6]Inst. de Bioquimica Medica Leopoldo de Meis, Univ. Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: Hyperphenylalaninemia (HPA) is the hallmark of phenylketonuria (PKU), a genetic disorder caused by the deficiency of phenylalanine (Phe) hydroxylase. Brain injury is a clinical characteristic of PKU patients, although the pathophysiology of this damage is poorly understood. The aim of the present work was to investigate the brain-derived neurotrophic factor (BDNF) levels in brain of rats submitted to an experimental model of HPA. In this study, animals received a single subcutaneous administration of 0.9 % NaCl (control group) or 5.2 μmol/g Phe plus 0.9 μmol/g p-chlorophenylalanine (HPA group). One hour after the administration, the animals were euthanized by decapitation. The brain structures cerebral cortex, striatum and hippocampus were isolated and homogenized and BDNF levels, pro-BDNF, tropomyosin-related kinase B (TrkB) receptor and $p75^{NTR}$ relative messenger RNA levels, total and phosphorylated c-Jun N-terminal kinase (JNK), total and phosphorylated protein kinase C (PKC), tissue-type plasminogen activator (tPA) and p11 immunocontent were determined. It was observed that animals subjected to acute HPA presented decreased BDNF levels in cerebral cortex, hippocampus and striatum, while pro-BDNF mRNA levels were increased in striatum. Furthermore, phosphoPKC/PKC ratio was decreased in cerebral cortex and hippocampus of HPA group, probably due to the decrease of BDNF signaling. On the other hand, TrkB and $p75^{NTR}$ (BDNF and pro-BDNF receptors, respectively) mRNA expression, and tPA, p11 and phosphoJNK/JNK immunocontent were not altered by high Phe levels in any structure. Taken together, our results suggest that Phe induces alteration in BDNF homeostasis. Since this neurotrophic factor plays a fundamental role in brain development and plasticity, contributing to synaptogenesis, synaptic plasticity, cognitive functions and memory, it is tempting to speculate that BDNF alterations might contribute to the intellectual deficiency observed in PKU patients.

Title: Transcriptomic analysis of retinal pericytes exposed to high glucose and Notch signaling

Authors: *A. I. MACHUCA PARRA, J. D. LAM, L. A. KIM, J. F. ARBOLEDA-VELASQUEZ;
Ophthalmology, Schepens Eye Res. Inst., Boston, MA

Abstract: Notch signaling pathway is highly conserved and essential for controlling cell fate decision and tissue patterning during development. The Notch 3 receptor is mainly expressed in mural cells, which include pericytes and vascular smooth muscle cells. In humans, Notch 3 malfunction has been related to Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL). These patients develop arteriopathy, chronic ischemic degeneration of neurons and glia, vascular smooth muscle cell degeneration and the appearance of granular osmiophilic deposits in vessels. Diabetic Retinopathy (DR) is a progressive degeneration of the neurovascular unit in the retina and the leading cause of permanent vision loss worldwide. Interestingly, CADASIL and DR both share a key pathological feature: the progressive loss of mural cells, which causes the destabilization of the vasculature and endothelial dysfunction. Since little is known about the gene expression of pericytes in CADASIL and DR, we prepared co-cultures of bovine retinal pericytes (BRPs) and human embryonic kidney cells (HEK) expressing the Delta1-GFP receptor with normal (5 mM) and high glucose (20 mM). Delta1-GFP expression is controlled by a tetracycline inducible promoter in our cell line. For BRPs-HEK co-cultures, we tested four conditions including: normal glucose with Tetracycline (1 μg/ml) and without Tetracycline (controls) and high glucose with and without Tetracycline. BRPs were isolated after coculture by FACS followed by total RNA isolation and transcriptomic analysis using RNA sequencing. Data was analyzed using Partek Flow software. Whole transcriptomic profiles were constructed for all four conditions. Principal component analysis (PCA) of the transcriptomes demonstrated similar expression profiles for control samples (high glucose without Tetracycline) while the profiles of the high glucose with Tetracycline samples were broadly dispersed, indicating significance gene expression changes. High glucose with Notch activation was associated with significantly elevated Notch-related genes including PTP4A3 (54,794 fold increase, $p= 2.11x10^{-4}$), SMTN (32,475 fold increase, $p= 4.14x10^{-5}$), and BAD (13,219 fold increase, $p= 7.91x10^{-7}$). These findings suggest a relationship

between high glucose and Notch signaling. This approach will help to identify molecular targets and signature Notch genes related to pericyte function and survival in CADASIL and DR.

Title: Regulatory control of microglial phagocytosis in the developing rat cerebellum.

Authors: *M. PEREZ-POUCHOULEN, S. J. YU, M. M. MCCARTHY;
Dept. of Pharmacol., Univ. of Maryland, SOM, Baltimore, MD

Abstract: Microglia are the resident immune cells of the central nervous system and play important roles during normal development and under injury or infectious conditions in adulthood. We recently showed microglia are non-uniformly distributed in the developing rat cerebellum and execute phagocytosis in an age and region dependent manner. Such microglial phagocytosis peaks from PN17 to PN19 in the granular layer, a timeframe when proliferation of granule cells is still occurring. Furthermore, we showed that microglial phagocytic cups engulf dead cells. Based on this, we sought to determine whether cell death regulates the phagocytic activity of microglia. To this end, we first injected both the cell death inhibitor BMN673 and vehicle (1µl, i.c.v.) from PN4 to PN6, when the highest cell death occurs in the cerebellum, and counted pyknotic cells on PN7 vermis stained with cresyl violet to confirm the cell death inhibitor works. We found a significant decreased of 26.35% in pyknotic cells in the granular layer, but not, in the molecular layer in animals treated with BMN673 compared to control. This confirms that BMN673 reduces cell death in the developing cerebellum, but in a regionally specific-manner. Subsequently, we injected through the cisterna magna 1µl of the cell death inhibitor BMN673 (5nM/µl) from PN12 to PN16 in male and female rats, obtained the cerebellums and processed them for Iba1 immunohistochemistry. We quantified the number of phagocytic cups exhibited by microglia as well as microglial morphology in the cerebellar cortex at PN17 as we previously described (Perez-Pouchoulen et al. eNeuro, 2015). The cerebellums from animals treated with BMN673 showed a 16.5% significant reduction in overall microglia density compared to control. We also looked at the phagocytic cups per phagocytic microglia

and found that animals treated with BMN673 had a significant lower number of phagocytic cups per phagocytic microglia than control animals (1.08 versus 1.18, respectively). Thus, it appears that inhibition of cell death during the second postnatal week reduces microglial phagocytosis during the third postnatal week. There were no sex differences in the effects of BMN673 treatment. We conclude that the phagocytic activity of cerebellar microglia, which peaks at PN17, is very tightly regulated and coupled to naturally occurring cell death during the prior week of development. Title: Haploinsufficiency of the minor spliceosome-specific U11 snRNA in the mouse cortex results in enhanced motor performance.

Authors: *M. BAUMGARTNER[1], P. PERRINO[2], R. H. FITCH[2], R. N. KANADIA[1]; [1]Physiol. and Neurobio., [2]Psychological Sci., Univ. of Connecticut, Storrs, CT

Abstract: Eukaryotic gene expression requires splicing, the removal of introns from pre-mRNA transcripts, which is mediated by the spliceosome, a complex of small nuclear RNAs (snRNAs) and associated proteins. In most metazoans, there are two distinct spliceosomes: the major spliceosome, which removes the vast majority of introns (major introns), and the minor spliceosome, which splices <0.5% of introns (minor introns). Mutations that inactivate the minor spliceosome have been linked to the severe developmental disorder microcephalic osteodysplastic primordial dwarfism type 1 (MOPD1) and Roifman syndrome, which commonly presents with dwarfism, microcephaly, intellectual disability, and hypotonia. Together, these disorders underscore the importance of minor splicing in brain development and function. To verify the causal link between minor spliceosome disruption and microcephaly, we generated a conditional knockout (cKO) for *Rnu11*, which encodes the U11 snRNA, a crucial component of the minor spliceosome. *Emx1*-cre-mediated removal of *Rnu11* in the developing cortex resulted in severe microcephaly at birth, caused by embryonic loss of self-amplifying neural progenitor

cells (NPCs). However, neuron-producing NPCs were not affected by U11 loss, as U11-null neurons were produced and survived postnatally. Despite their postnatal survival, these neurons displayed severe axon projection defects at P0, which were not observed in wild-type or heterozygous mice. Behavioral analyses of adult wild-type, heterozygous, and mutant mice revealed significant motor deficits and anxiety in the mutant mice. Unexpectedly, we also found that heterozygous mice displayed significant enhancement on the rotarod test, relative to the wild-type mice. Together, our findings indicate that minor splicing is not only essential for neuron development and function, but that 50% loss of U11 significantly modulates the function of neurons involved in motor coordination.

Title: Selective sensory-motor connections determined by dendritic and axonal positioning

Authors: *N. BALASKAS, T. M. JESSELL, D. NG;
biochemistry and molecular biophysics, Columbia Univ., new york, NY

Abstract: The selectivity with which pre-synaptic axons form connections with their post-synaptic targets is thought to rely on complementary recognition molecules. The prominence of this view has recently been challenged by emerging evidence that the settling position of neuronal cell bodies is a critical determinant of connection selectivity. This positional perspective, however, leaves open the question of whether the pattern of neuronal dendrites and axonal projections also contributes to the specificity of connections. To address this issue we focused on spinal motor circuits, mapping the orientation of dendrites in different motor pools as well as the trajectory of sensory axons. We find that lumbar motor pools exhibit diverse dendritic orientations, ranging from simple crescent-like patterns to configurations with radial morphology. We provide genetic evidence that in FoxP1 mutants, in which motor neurons lack pool identities, the dendritic diversity of limb-innervating motor neurons reverts to a common bipolar pattern that resembles the organization of hypaxial motor neurons. These results imply that the ground-state assignment of motor neuron dendritic arbors is bipolar and that radial orientation represents the apex of a dendritic hierarchy. The axons of muscle-defined sensory

neurons also exhibit distinct angular trajectories *en route* to their recipient motor pools. Dendritic and axonal orientation accurately predicts the identity of target motor pools, as well as the asymmetric dendritic domain of sensory-motor synapses. These findings argue for a significant role for dendritic and axonal positional cues in defining the assembly of sensory-motor circuits, simplifying the task of recognition.

Title: Cortical activation and excitability in congenital hemiparesis.

Authors: M. LIXANDRAO[1], C. PRUDENTE[2], B. MUELLER[2], T. RICH[2], M. CHEN[2], *B. T. GILLICK[2];

Abstract: Background: Functional magnetic resonance imaging (fMRI) and transcranial magnetic stimulation (TMS) are non-invasive techniques that allow insights into the re-organization of the cortical motor system and resultant hand function after perinatal stroke.
Aims: To report cortical activation during paretic and non-paretic hand movements and excitability during TMS testing in children with perinatal hemiparesis.
Methods: Five children with perinatal stroke (3 male, age= 11.4±2.9 years) participated in MRI and TMS assessments. Structural T1-weighted images and functional T2-weighted images with blood oxygenation level dependent (BOLD) contrast were acquired. fMRI conditions included active movement and resting sessions with each hand. fMRI data processing and registration to individual T1 images were carried out using FSL (FMRIB's Software Library). Whole-brain

analysis was employed to contrast active blocks with baseline. Z statistic images were thresholded using clusters determined by Z greater than 2.3 and a (corrected) cluster significance threshold of p=0.05. TMS assessment included single-pulses delivered over the motor cortex using a Magstim 200 stimulator connected to a 70-mm figure of eight coil. The resting motor threshold (RMT) was determined for the first dorsal interosseos muscles to assess motor evoked potentials (MEP) responses.
Results: All children presented with a MEP response during TMS testing over the contralesional hemisphere (RMT= 56.4±11.1% maximal stimulator output (MSO)). During non-paretic hand movement, four children presented with significant contralesional activation in precentral gyrus. Three children presented with ipsilesional MEP response due to TMS (RMT= 66.6±11.1% MSO). During paretic hand movement, these three children presented with significant ipsilesional activation in precentral gyrus. In the two children who did not present with an ipsilesional MEP response, no significant activation was found in the ipsilesional precentral gyrus during paretic hand movement. However, these children presented with bilateral activation or ipsilateral activation in the occipital lobe during paretic hand movement.
Conclusion: The absence of ipsilesional precentral gyrus activation during paretic hand movements and the absence of ipsilesional MEP could be related to persistent or expanded ipsilateral corticospinal tract projections after perinatal stroke. Activity was also noted in occipital areas during paretic hand movement, potentially related to motor imagery, task planning or an alternative cortical pattern of reorganization.

Title: Developmental origins of inhibitory interneuron diversity in limb and thoracic motor circuits

Authors: *L. B. SWEENEY[1], J. B. BIKOFF[2], M. BAEK[3], M. I. GABITTO[2], S. BRENNER-MORTON[2], C. DIAZ[2], J. S. DASEN[3], T. M. JESSELL[2], C. R. KINTNER[1];

Abstract: Motor output varies along the rostrocaudal axis of the tetrapod spinal cord. At limb levels, a large number of motor pools are needed to control the alternation of flexor and extensor muscles and produce movement about a joint. At thoracic levels, a smaller number of pools supply muscle groups that support posture, inspiration and expiration. We have examined whether the difference in motor neuron and muscle number at limb and thoracic levels is associated with a similar distinction in interneuron diversity.
We used V1 spinal inhibitory interneurons as a means to explore interneuron diversity along the rostro-caudal axis of the mouse spinal cord. V1 interneurons regulate locomotor rhythm, and with V2b interneurons, control many aspects of flexor/extensor alternation. Differential expression of 19 cell type specific transcription factors divides the lumbar V1 population can into ~50 distinct subpopulations (Bikoff et al 2016, Gabitto et al 2016). These diverse V1 subpopulations fall into four major clades, with differential synaptic connectivity and electrophysiological properties, suggesting they define distinct microcircuits.
We have now examined the expression of these 19 transcription factors at thoracic levels, to define distinctions in V1 subset representation at thoracic and limb levels. Using a Bayesian framework to infer cell type identity, our analysis indicates that the four lumbar V1 clades and many of their subpopulations also exist at thoracic levels. This analysis also detects V1 interneuron subpopulations that are restricted to limb versus thoracic levels, and vice versa. The identification of such restricted V1 subpopulations provides an initial step in defining segment-specific spinal microcircuits.
The existence of rostro-caudally restricted V1 subpopulations led us to explore how V1 diversity is generated along an organism's rostrocaudal axis. Is V1 diversity influenced by cell-intrinsic transcriptional programs, cell-extrinsic cues from the surrounding cellular environment, or both? Using the transcription factors that define limb- and thoracic-specific V1 populations as markers, we find that limb- and thoracic-specific differences in V1 interneurons, like motor neurons, require the Hox gene, *HoxC9*. But in motor neuron deficient *Olig2* mutant mice, the rostrocaudal distribution of limb-specific V1s is largely unaffected, supporting a model in which early Hox patterning of the spinal cord specifies the rostro-caudal identity of V1 interneurons, independent of motor neurons. Future work aims to explore the connectivity and function of limb- and thoracic-specific V1 interneuron subpopulations.

Biophysics, Columbia Univ., New York, NY; [5]Dept. of Physiol., Emory Univ., Atlanta, GA

Abstract: Animals interact with the world through movement, transforming patterns of neural activity into the orderly contraction of muscles. The circuits directly responsible for movement reside in the spinal cord, where inhibitory interneurons play a crucial role in shaping patterned motor output. Yet the grain of identity of these inhibitory interneurons and the organizational logic through which they influence motor output have remained obscure.
We have used the genetic accessibility of mice to gain insight into the organization of inhibitory

circuits for limb motor control. We undertook a detailed analysis of transcriptional diversity within the V1 class of spinal inhibitory interneurons. This class represents the largest inhibitory population in the ventral spinal cord, and their elimination slows rhythmic locomotor output and perturbs flexor/extensor alternation. Our analysis identifies 19 transcription factors that fractionate the parental V1 population into highly diverse subsets[1]. Transcriptionally-defined V1 subsets exhibit distinct physiological signatures and highly structured spatial distributions, supporting the view that transcriptionally-defined subsets correspond to distinct cell types.
To define the extent of cell-type diversity within this inhibitory population, we developed a sparse Bayesian framework that uses transcription factor expression and positional information to derive a rigorous estimate of V1 interneuron diversity. Bayesian analysis infers the existence of ~50 candidate V1 cell types, each defined by 3-9 transcription factors, and more generally provides a means of delineating cell type heterogeneity in any mixed tissue[2].
Finally, we explored the connectivity of two subsets, $V1^{Sp8}$ and $V1^{R}$ (Renshaw) interneurons, with proprioceptive sensory neurons and motor neurons operating on hip, ankle, and foot muscles. Anatomical and electrophysiological analyses demonstrated that interneuron position appears to constrain patterns of input from proprioceptive sensory neurons and motor neurons, and thus determines microcircuit organization. Moreover, variant patterns of inhibitory circuitry operate on different hindlimb muscles, exemplified most clearly by the monosynaptic connectivity of hip but not ankle or foot sensory afferents onto $V1^{R}$ interneurons. Our findings reveal the existence of diverse V1 interneuron subtypes which form variant inhibitory microcircuits in response to biomechanical constraints operating on muscles controlling different limb joints.

Institu, Bron, France; [3]Claude Bernard University, Univ. of Lyon, Lyon, France; [4]Inst. of Neuroscience, Sch. of Medicine, Catholic Univ. of Louvain, Louvain, Belgium; [5]Dept. of Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA; [6]Pierre Wertheimer Hospital, Hospices Civils de Lyon, Lyon, France

Abstract: In adult non-human primates direct cortical control over motor output is largely mediated by contralateral projections to spinal motor centers, and only a minority of all corticospinal neurons (CSN) project ipsilateral (Galea and Darian-Smith, 1994). Both contralateral and ipsilateral CSN are restricted to motor, somatosensory, cingulate and insular regions, although compared to the contralateral projection the tangential distribution of ipsilateral projecting neurons is much reduced. In the newborn macaque the areal distribution of contra and ipsilateral CSN is marginally more widespread than that observed in the adult (Galea et al. 1995).

An ongoing study of the team concerns the developmental changes in the areal distribution of CSN during in utero development. By injecting the retrograde tracer fast blue at cervical levels of the spinal cord of cynomolgus monkeys at embyronic day (E) 95 and E105 we have shown that the retrogradely labeled CSN in the contralateral hemisphere are restricted to layer 5, and that there is a greater extent of cortical territory projecting to the contralateral spinal cord during development than in newborn and adult, including projections from prefrontal, occipital and temporal cortices.

Here we report the distribution of ipsilateral projections to the cervical spinal cord during development. Preliminary results show that CSN projecting ispilaterally (1) are restricted to layer 5, and (2) their distribution is similar to that of the contralateral CSN. Ongoing analysis aims to quantify these projections across regions in order to allow direct comparison of areal weights of ipsi- and contralateral projections.

Overall, our results indicate that the difference between ipsi- and contralateral CSN projections is quantitative, rather than qualitative. This is especially relevant to studies of human development. These studies suggest developmental motor disorders related to lesions of the motor cortex could be the consequence of a maintained exuberant ipsilateral projection from the non-lesioned hemisphere (Eyre 2007).

Title: Labeling Dbx1 neurons and glia in the preBötzinger complex based on the timing and dose of tamoxifen administration in inducible Dbx1 Cre-driver transgenic mice

Authors: *C. A. MARTIN, A. KOTTICK, C. A. DEL NEGRO;
Applied Sci., The Col. of William & Mary, Williamsburg, VA

Abstract: The brainstem preBötzinger Complex (preBötC) generates the rhythm that underlies inspiratory breathing movements in mammals, and its core rhythmogenic interneurons are derived from neural progenitors that express the embryonic transcription factor Dbx1. Elucidating the cellular mechanisms of respiratory rhythm generation depends on the ability to fluorescently tag and manipulate Dbx1-derived preBötC neurons (i.e., Dbx1 neurons). To that end we employ tamoxifen-inducible Dbx1 Cre-driver mice with Cre-dependent reporters to map neurons as well as glia formed by Dbx1-expressing precursors. The timing and dose of tamoxifen administration during embryonic development critically influences fusion protein expression in Dbx1-derived cells. To better understand preBötC development, and ultimately optimize Cre-dependent fusion protein expression in Dbx1 preBötC neurons specifically, we examined the relationship between the timing of tamoxifen administration and the pattern of labeled neurons and glia in the preBötC. We varied the timing of tamoxifen administration between E7.5 and E11.5 corresponding to the window of Dbx1 expression during embryonic development, and then performed passive clearing (CLARITY) and confocal imaging of the preBötC using medullary slices from juvenile mice. Immunohistochemistry and morphometric criteria were used to define populations of Dbx1-derived neurons (immunoreactive for NeuN) and Dbx1-derived astroglia (immunoreactive for Sox9). Experiments using human synapsin driven adeno-associated virus (AAV) in the preBötC aided the morphological identification of neurons in this region. Using an ImageJ cell counting function to quantify Dbx1 neuronal and glial populations with induced fluorescence at different time points we found that glia are formed at a constant rate from E7.5 through E11.5 while neuron formation peaks at E9.5. These data can be employed to plan breeding and tamoxifen administration strategies that optimize intersectional mouse genetic approaches that label and manipulate Dbx1-dervied neurons (or glia) and study their roles in the respiratory brainstem.

Title: Expression of a genetically-encoded fluorescent voltage sensor, ASAP1, in neurons of the embryonic chick spinal cord

Authors: A. FRASSATO[1], L. DEROSSETT[1], S. FROMHERZ[2], P. R. PATRYLO[3], *A. A. SHARP[4];
[1]John A. Logan Community Col., Carterville, IL; [2]Dept. of Biol., Saginaw Valley State Univ., Saginaw, MI; [3]Dept Physiol, [4]Dept Anat, Southern Illinois Univ. Sch. of Med., Carbondale, IL

Abstract: Understanding the interactions of large numbers of neurons within various circuits is a fundamental goal in neuroscience. However, obtaining membrane potential recordings from large numbers of neurons in freely behaving animals is challenging, especially for embryonic systems. Nonetheless, numerous approaches to record from large ensembles of neurons have been developed, but many of these approaches, e.g. large electrode arrays, are not amenable to embryonic systems due to the relatively small size and fragility of embryonic tissues. The new generation of fluorescent reporter molecules with increased temporal dynamics and greater fluorescence may now be ready to be applied to embryonic systems. The goal of this study was to adapt the recently developed genetically-encoded fluorescent voltage sensor Accelerated Sensor of Action Potentials 1 (ASAP1, St-Pierre et al. 2014) for use in chick embryos. The chick embryo has been one of the primary model organisms for studying vertebrate sensorimotor development. The similarity of chick developmental timing to that of humans along with its bipedal nature and development outside of the mother provides numerous experimental advantages over rodent models. Transposon systems can be used to establish stable expression of heterologous proteins via electroporation. It has been shown that the Piggybac system can be used to allow for channelrhodopsin-2 expression in chick embryos and that the relatively transparent nature of embryonic tissue allows for light stimulation of motor neurons in order to regulate motility in mid-stage chick embryos (Sharp and Fromherz, 2011). Therefore, it was hypothesized that a similar approach could be used to introduce ASAP1 and to allow for optical voltage recording from neurons in both freely moving embryos and reduced preparations. Standard molecular procedures were used to exchange the open reading frame for ASAP1 from pcDNA3.1/Puro-CAG-ASAP-1 (AddGene) with the channelrhodopsin-2 open reading frame in the plasmid pPB-ChIEF-Tom from the aforementioned study in order to create pPB-ASAP-1. In order to induce ASAP1 expression in neurons of the spinal cord, pPB-ASAP-1 was

electroporated into the neural tube of embryonic day (E) 3 embryos. Fluorescence from the GFP-component of ASAP1 could be detected in living embryos on E4 and was observed to persist until at least E10. Imaging of tissue sections indicate that ASAP1 is likely expressed in the plasma membrane of neuronal somata, dendrites and axons. Functional imaging and electrophysiological experiments are underway to determine the potential applications of this approach to advance our understanding of neural development.

Title: Analyzing ensemble activity in the developing zebrafish spinal cord

Authors: *Z. WEI, Y. WAN, P. KELLER, S. DRUCKMANN;
Janelia Res. Campus, Ashburn, VA

Abstract: Statistical analysis of the dynamics of ensembles of neurons is a question of long-standing interest in neuroscience. A central approach is the use of latent space methods where the detailed observed dynamics are assumed to have been generated by a phenomenological lower dimensional space where each of the dimensions corresponds to a mode of network activity. A major difficulty of these approaches is that they are underconstrained, i.e., there are many different descriptions of latent spaces that can capture a particular set of observed dynamics. Moreover, the ensemble activity may change over time on multiple different timescales. Here, we utilize a unique experimental paradigm, long timescale functional imaging in embryonic zebrafish spinal cord, to both inform specific biological questions and test the applicability of latent space models to describe complex ensemble dynamics over multiple timescales.
A hallmark of the developing zebrafish spinal cord is the emergence of patterned ensemble activity, but this dynamic process is only poorly understood. We analyze the underlying dynamic changes using cellular-resolution functional imaging data from multiple segments of the spinal network. We first compare neuronal correlations against time and observe that spinal cord neurons undergo a rapid transition from sporadic single-neuron activity at the early embryonic stage to ipsilaterally-correlated and contralaterally-anticorrelated activity late in development. In

order to probe the mechanism for such evolution, we develop a continuous-time factor analysis model that identifies sparse, yet anatomically-meaningful functional communities (FC) across time. With an infomax-like constraint on network structure, our model predicts that FCs are located exclusively ipsilaterally and reveals a seamlessly development of FCs as a function of time. Interestingly, we find that FCs first occur locally within small groups of neurons, and subsequently merge with other ipsilateral FCs through synchronization from anterior to posterior spinal cord, which finally forms a patterned network. At the single cell level, our model shows that within a FC, the activity of each neuron can be predicted from the others in the same FC. Our model can thus estimate the joining time of each cell to a FC, as its activity is essentially explained by others. Importantly, the joining time of cells shows an anterior to posterior gradient along the spinal cord. In summary, we show that latent space methods, appropriately tailored and complemented by specific analyses, can shed light on ensemble activity and its development over time in the embryonic zebrafish spinal cord.

Title: Information structure of proprioceptive feedback in infantile spontaneous movements

Authors: *H. KANAZAWA[1,2], Y. YAMADA[3], Y. KUNIYOSHI[1];
[1]The Univ. of Tokyo, Tokyo, Japan; [2]Res. Fellow of JSPS, Tokyo, Japan; [3]IBM Res. - Tokyo, Tokyo, Japan

Abstract: From early developmental phase, human infants exhibit complex and various types of spontaneous whole-body movements. Recent animal studies have shown that these spontaneous movements play an important role in early sensorimotor development. In addition, human studies have actively characterized infantile spontaneous movements in terms of limb trajectory and its coordination in order to deepen our understanding of how the spontaneous movements contribute to the sensorimotor development. Although motor output patterns have been well characterized,

little is known about the characteristics of sensory feedback evoked by spontaneous movements. In this study, we quantify proprioceptive feedback during infantile movements by combined use of experimental data of whole-body kinematics and a musculoskeletal body model of human infant. Specifically, we performed full-body motion capture of one infant (3-months-old) during spontaneous movements without external stimulation. We recorded three-dimensional positions of total 54 markers using 8 infrared cameras at 100 fps, and obtained joint angles for each frame. Combining these joint angles with an infantile musculoskeletal body model based on MRI/CT data, we estimated 88 muscle lengths of both legs during the spontaneous movements. We regarded the muscle lengths as proprioceptive signals, and investigated the characteristics of proprioceptive feedback. First, we calculated pair-wise correlations of muscle lengths between each two muscles. As a result, 39.5% of all possible pairs in the modeled muscles showed significant correlations during infantile spontaneous movements. Next, we categorized the muscles into 8 groups according to the level of the spinal cord from which they arise, and then compared the correlations of muscle length within and across the groups. Consequently, correlations within group were significantly higher than those across group (median correlation coefficients; 0.53 vs 0.22, $p < 0.001$, ranksum-test). By combined the measured kinematics and infantile musculoskeletal model, we quantified information structures of proprioceptive feedback in spontaneous movements of human infant. Our preliminary results indicate that infantile spontaneous movements can provide structured proprioceptive information reflecting spinal segments, although previous studied have reported less inter-limb correlations in motor patterns. Combined with analysis of motor outputs, our quantification of sensory feedback can help deepen our understanding of the relationship between spontaneous movements and sensorimotor development.

Title: Alteration of dendrite morphology and electric responsibility in the sensorymotor cortex on the developmental white matter injury model rat

Authors: *Y. UEDA[1], Y. BANDO[2], S. MISUMI[1], S. OGAWA[1], H. HIDA[1];
[1]Dept Neurophysiol & Brain Sci., Nagoya City Univ. Grad Sch. Med. Sci., Nagoya-Shi, Japan;
[2]Dept Funct Anat & Neurosci, Asahikawa Med. Univ., Asahikawa-shi, Japan

Abstract: Since the brain of preterm infant is vulnerable to hypoxia-ischemia (H-I), the preterm infant tends to contract the developmental white matter injury (DWMI), causing the neurodevelopmental deficits such as cerebral palsy, cognitive disorder, and attention deficit/ hyperactivity disorder. We previously reported a DWMI model by right common carotid artery occlusion followed by 6% hypoxia for 1 hour in postnatal day 3 (P3) rat. We found oligodendroglial but neuronal loss in this model, concomitant with mild hindlimb dysfunction with motor coordination deficit and the reduction in the hindlimb area of the sensorymotor cortex in adulthood (Misumi et al., Cell Transplant, 2016). However, it is unclear when these alterations starts and if the change of neuronal morphology contributes to these alterations. To answer these questions, we performed electrophysiological and histological experiments in our DWMI model rat. We first performed intracortical microstimulation (ICMS) at P35 to elucidate if the change of motor map has already started earlier than 10-week-old when we had already confirmed the change. Electric stimulation (duration, 200μsec; 30 bipolar pulses at 333Hz; 10μA-270μA) was given to the sensorymotor cortex (1.0-3.0 mm posterior and lateral from bregma) through glass-insulated tungsten electrode (Impedance, 750kΩ) and the response of muscle contraction was checked. The size of the hip-joint contracting portion tended to be smaller in the DWMI model. To elucidate this tendency to shrink the hip-joint portion in DWMI, we next focused dendritic morphology in the cortex as the number of neurons was kept in our model. We evaluated the motor cortex of which 1.0-3.0 mm posterior and lateral from bregma. The basal dendrites in the intermediate layer of the cortex were more developed in the ipsilateral H-I side. These data indicate that H-I insult at P3 causes the alterations of the dendritic formation and electrical responsiveness in the cortex, probably due to the change of sensory inputs and/or the trophic support from oligodendrocytes which development is disturbed in our DWMI model.

Title: Novel efferent pathways from the mouse substantia nigra

Authors: *E. SOTO, J. A. MENDEZ;
Univ. Autonoma De San Luis Potosi, San Luis Potosi, Mexico

Abstract: Substantia nigra (SN) plays a central role in motor control. Whereas the substantia nigra pars compacta (SNc) supplies the dorsal striatum with dopamine, the substantia nigra pars reticulata is the main output nucleus of the basal ganglia. In addition to Dopaminergic and GABAergic neurons, SN contains purely Glutamatergic neurons as well as Dopaminergic neurons that corelease GABA or Glutamate. The output connections of Dopaminergic neurons of the substantia nigra are very well known. However, despite local projection evidence, little is known of output projections of the Glutamatergic neurons. In order to gain insight into novel Glutamatergic projection pathways from the substantia nigra, we performed pressure injections of the anterograde tracer Dextran Alexa-Fluor 546 into the SNc of adult p90 mice. 10 days later, the fluorescent signal was detected within several brain areas including the dorsal striatum. To confirm some of the projections, the retrograde tracer FluoroGold was injected and the signal was recovered in the substantia nigra. Then the identity of the projecting neurons was assessed by multiplex single cell RT-PCR against Tyrosine Hydroxylase (TH), Glutamate Decarboxylase (GAD1) and the vesicular Glutamate Transporter type 2 (VGluT2). In addition to the expected Dopaminergic striatonigral and nigrocampal pathways, we identified Glutamatergic neurons that project their axons from the substantia nigra to the following nuclei: putamen caudate, globus pallidus and the CA1 region of the hippocampus. Also, we detected the presence of GABAergic neurons from the SNc projecting to the putamen caudate, globus pallidus, the CA1 region of the hippocampus and the parafasicular nucleus of the thalamus. Remarkably, neurons of the Glutamatergic/GABAergic double phenotype were found to project from the SNc to the globus pallidus. Our results contribute to a better understanding of the circuitry of the substantia nigra, a so called Dopaminergic nucleus.

Title: Where handedness starts: Gene expression asymmetries in human fetal spinal cord

Authors: *J. SCHMITZ, S. OCKLENBURG, O. GUNTURKUN;
Dept. of Biopsychology, Ruhr-University, Bochum, Germany

Abstract: Handedness is the strongest and most widely investigated form of motor asymmetries in humans, but little is known about its underlying molecular mechanisms. Since about 85% of embryos exhibit more right arm than left arm movements already 10 weeks after gestation, fetal cortical gene expression asymmetries have been suggested as underlying functional hemispheric asymmetries. However, the motor cortex is not yet functionally linked to the spinal cord at this developmental stage, which indicates that early motor asymmetries are likely controlled by the spinal cord. Human spinal cord was collected from fetal tissue at 10, 12, and 14 gestational weeks following induced pregnancy terminations. Cervical and anterior thoracal left and right segments were separated along the midline. Total RNA was extracted from each half of the spinal cord. Next generation sequencing revealed gene expression profiles and genes with significant expression differences were examined for functional gene ontology (GO) groups. We then targeted candidate genes that had previously been associated with development of hemispheric asymmetries. The number of genes showing significant expression asymmetries, measured as $\log_2$(fold change) of at least 1.5, critically varied with the developmental stage. By far the most asymmetrically expressed genes were found at week 10 with 3.3% being asymmetrically expressed between the left and right spinal cord. With 0.05%, asymmetry was reduced in week 12 and almost absent in week 14 (0.01%). Accordingly, the number of significant GO groups was the highest in week 10 (123) and reduced in week 12 (41). In week 14, no GO group reached statistical significance. Out of the candidate genes, *FOXP2* displayed a significant rightward asymmetry at week 12. *BDNF-AS* was significantly stronger expressed in the left spinal cord at week 10. The findings are discussed with regard to existing models on handedness ontogenesis. As motor asymmetries start by gestational week 10, we suggest this developmental stage as the critical period for handedness formation. Expression asymmetries in genes relevant for CNS development might provoke differential development of neuronal circuits in the right arm and hand, for example in terms of larger motoneuronal somata in segments innervating the right than the left arm, which causes more developed motor behavior. Spinal cord and motor cortex are functionally connected from week 17. By then, the well-established behavioral asymmetry might lead to asymmetries in use-dependent neuronal plasticity processes in the motor cortex, ultimately leading to the cortical correlates of handedness.

Title: Anatomic course and variation of femoral nerve in human fetuses

Authors: ***M. BUYUKMUMCU**[1], E. CIHAN[2], A. AYDIN KABAKCı[3], D. AKIN[1], S. GUNGORER[4];
[1]Meram Med. Fac., KONYA, Turkey; [2]DEHA Rehabil. Ctr., KONYA, Turkey; [3]Anat., Meram Med. Sch., KONYA, Turkey; [4]Educ. and Res. Hosp., KONYA, Turkey

Abstract: INTRODUCTION Femoral nerve is primary nerve innervating the anterior aspect of the thigh and the largest of the peripheral branches of the lumbar plexus. It emerges through the psoas major fibers, then passes underneath the inguinal ligament just lateral to the femoral artery as it enters the thigh. Variant origin, level of the divisions and branches measurements of the femoral nerve have a clinical important. The femoral nerve block is performed on the main trunk of the femoral nerve just below the inguinal ligament .The higher division of the femoral nerve in iliac fossa results in incomplete femoral nerve block. **MATERIAL AND METHODS** This study was performed on 30 fetuses (17 male and 13 female) with no gross anomalies from the fetus collection of Necmettin Erbakan University, Meram Medical Faculty Anatomy Department. We were used microdissection instruments, 0,01 mm precision digital caliper (stainless hardened), microsurgery microscope (Kaps Sam 62) and a camera (Canon D1000). We determined the course and variation of femoral nerve in human fetuses. Furthermore,we measured thickness and lenght of trunk and divisiones of the femoral nerve.The obtained data were evaluated by using SPSS 21.0 (Statistical Package for Social Sciences). Data were analyzed by both descriptive (mean value, standard deviation, maximum and minimum values, percentages) and quantitative statistical methods. Results were evaluated statistically in %95 confidence interval and differences were accepted significant if $p<0.01$. **RESULTS AND CONCLUSION** The localization of the division points femoral nerve divides into its branches were assessed under 3 categories as 1-above the inguinal ligament, 2- under the inguinal ligament, 3- at a level below the inguinal ligament. Femoral nerve divides into its branches above the inguinal ligament in 2 fetuses (6.7%), under the inguinal ligament in 17 fetuses (56.7%) and at a level below the inguinal ligament in 11 fetuses (36.7%). The right distance between femoral nerve and its dividing point was found 3.56±1.53 cm and 2.36±0.65 cm fort he left sides in males. These mesuraments wee determined 3.82±2.03 cm and 4.90±3.56 cm for females, respectively. When right and left parameters of all fetuses were compared, it was

observed that statistically difference was between thickness of anterior and posterior branches of femoral nerve and also distance between femoral artery and femoral nerve ($p<0.05$).

Title: Identification of the interactor of CLAC-P/Collagen type XXV in motor nerve innervation of skeletal muscles

Authors: ***H. MUNEZANE**[1], H. OIZUMI[1], T. YOSHIDA[2], T. WAKABAYASHI[1], T. IWATSUBO[1];
[1]Dept. of Neuropathology, Grad. Sch. of Med., The Univ. of Tokyo, Tokyo, Japan; [2]Dept. of Mol. Neurosci., Univ. of Toyama, Toyama, Japan

Abstract: CLAC-P/Collagen type XXV is a trans-membrane collagen, which was originally identified as a component of senile plaques in Alzheimer's disease brains. Collagen type XXV is classified as a member of membrane-associated collagens with interrupted triple helices(MACIT), together with type XIII, XVII, and XXIII collagens. To examine the *in vivo* function of collagen type XXV, we generated *Col25a1* knock-out (KO) mice, in which motor axons properly elongated toward the target muscle, but failed to arborize within the muscle. Failure in intramuscular innervation of motor axons led to severe and selective loss of motor neurons in the spinal cord. Further analysis revealed that collagen type XXV expressed in skeletal muscles is indispensable for the proper elongation and arborization of motor neurons in the target muscle. However, it remains to be solved how collagen type XXV controls motor innervation. In this study, we examined receptor protein tyrosine phosphatase (RPTP) σ and δ, whose knock-out phenotype resembles that of *Col25a1* KO mice, as a candidate of the interactor

of collagen type XXV in this context. To investigate whether the two molecules bind each other, we performed cell surface binding assay, where HEK293 cells expressing RPTP were incubated with secreted form of collagen type XXV. We found that the secreted collagen type XXV specifically bound to the surface of RPTP-expressing cells. Deletion mutant analysis of RPTP revealed that the immunoglobulin-like domain of RPTP was essential for the binding to collagen type XXV. Furthermore, we have developed a co-culture preparation of spinal cord explants and HEK293 cells expressing collagen type XXV, with which we are able to assess the interaction between motor axons and collagen type XXV. Data on the specific interaction between collagen type XXV and RPTPs on the motor nerve will be presented.

Title: Development of visuo-motor processing required to hit the fast ball over 150 km/h in baseball batting

Authors: *H. KOBAYASHI[1], M. SHINYA[1], H. OBATA[2], K. HAGIO[1], M. KUWATA[1], K. NAKAZAWA[1];
[1]Grad. Sch. of Arts and Sci., The Univ. of Tokyo, Meguro, Japan; [2]Kyushu Inst. of Technol., Fukuoka, Japan

Abstract: Baseball batting is a complex visuo-motor skill that requires a batter to produce a spatially and temporally accurate bat swing in as little as 400 ms, when a ball is pitched at 150 km/h. Although visuo-motor processing ability develops with age, it is unknown when a baseball batter acquires the specific visuo-motor ability to cope with the over 150 km/h fast ball. The present study aimed to verify development of the visuo-motor ability to deal with fast ball and whether reaction times would relate to the visuo-motor ability. We measured the time from the ball release to the moment of hit the ball (time to contact: TTC) during the official games in each generation (average level primary school: average level PS, top level primary school: top level PS, junior high school: JH, high school: HS and college: CL). We recorded the pitcher and batter in the same video picture with a high-speed camera (600 fps) to analyze TTC and the ball

velocity of each pitch with a radar gun. In reaction time tasks, 15 PS (age: 11.0 ± 0.6 years), 23 JH (age: 13.6 ± 0.5 years), 35 HS (age: 16.7 ± 0.4 years) and 53 CL (age: 20.6 ± 0.9 years) baseball players performed the button-press simple and Go/Nogo reaction time tasks. Participants were instructed to react as quickly as possible to the green LED (both tasks), but not to the red LED (Go/Nogo task). As we expected, average level PS pitchers were the lowest average ball velocity during the actual game than the pitchers in the other groups. Although the average TTC in the CL game was shortest among the groups (447.5 ± 31.2 ms), the top level PS (469.2 ± 46.6 ms) showed the shorter TTC than the average level PS (592.7 ± 57.2 ms), JH (549.2 ± 50.6 ms) and even HS (489.0 ± 37.5 ms). It was remarkable that the shortest TTC in the top level PS (410 ms) was comparable to that in the CL (400 ms). In reaction time tasks, mean simple reaction times of the PS group (216.3 ± 21.5 ms) were the significantly longer than the HS (182.9 ± 14.3 ms) and the CL (190.4 ± 24.5 ms) groups, but not different from the JH group (214.8 ± 29.3ms). Similarly, mean Go/Nogo reaction times of the PS group (293.8 ± 37.7 ms) were longest among the groups (JH: 270.0 ± 34.8 ms, HS: 237.7 ± 30.7 ms and CL: 239.1 ± 31.5 ms). The observed short TTC in the top PS players suggests that they have already obtained the visuo-motor processing required to hit the over 150 km/h ball in baseball batting. Together with the longer reaction time observed in PS players further imply that the neural mechanism underlying baseball batting is different from that underlying simple or choice reaction tasks. Overall, the present results strongly suggest that the neural function required to baseball batting develops rapidly before puberty.

Title: Transcription factor profiling of vestibulospinal neurons in mouse and chicken embryos reveals developmental subdivisions

Authors: *A. LUNDE[1], B. OKATY[2], S. DYMECKI[2], J. C. GLOVER[1];
[1]Univ. of Oslo, Oslo, Norway; [2]Dept. of Genet., Harvard Med. Sch., Boston, MA

Abstract: Vestibulospinal neurons are organized into discrete groups that project from the brainstem to either the ipsilateral or the contralateral side of the spinal cord, enabling animals ranging from agnathans to humans to maintain proper balance and posture. Our previous studies in the mouse and chicken have mapped the developmental origin of the ipsilateral lateral vestibulospinal tract group (LVST) to hindbrain segment (rhombomere) 4, and of the contralateral medial vestibulospinal tract group (cMVST) to rhombomeres 4 and 5.
To characterize differential expression patterns of post-mitotic transcription factors in the LVST and cMVST, we performed RNAseq analysis on manually sorted retrogradely labeled neurons in embryonic day (E) 13.5 mice, and embryonic day (d) 7.5 chickens. Control tissue from the medial parts of rhombomere 4 and 5 was also analyzed to exclude pan-neuronal and rhombomere-generic transcription factors. Highly differentially expressed transcription factors were further investigated by immunohistochemistry at E13.5-15.5 in the mouse, and d7.5-9 in the chicken. Serial sectioning and confocal microscopy was used to generate 3D models of the LVST and cMVST groups with superimposed immunolabeling to assess the transcription factor expression patterns within the groups.
RNAseq analysis revealed well over 100 significantly differentially expressed transcription factors in both mouse and chicken. Of the top 100 upregulated transcription factors in LVST versus cMVST, compiled separately for mouse and chicken, roughly 10% were shared between the two species. For cMVST versus LVST, roughly 15% were shared. Immunohistochemical analysis of select transcription factors revealed that they are expressed in characteristic spatial domains, indicating a developmental subdivision of both the LVST and the cMVST.
These data provide new information about the transcription factors that specify the two main vestibulospinal neuron groups, as well as a first step towards unraveling the molecular heterogeneity of each group.

Title: Sim1 transcription factor regulates the distinct neurogenesis profiles of spinal V3 INs and their subsequent functional separation

Authors: *D. A. DESKA-GAUTHIER, J. CHOPEK, Y. ZHANG;
Med. Neurosci., Dalhousie Univ., Halifax, NS, Canada

Abstract: V3 interneurons (INs) in the spinal cord are a major group of excitatory commissural INs that are essential in establishing a robust and balanced locomotor rhythm during walking. In the early embryonic mouse spinal cord, V3 INs arise from the most ventral progenitor domain (P3) as marked by the post-mitotic expression of the basic helix-loop-helix transcription factor, Sim1. Subsequently, V3 INs form both dorsal and lateral migratory streams establishing separate subpopulations by postnatal day (P) 0 with distinct laminar distributions, axon projection profiles and membrane properties. In order to better understand the developmental mechanisms underlying the formation of different V3 subpopulations we investigated their respective temporal neurogenesis profiles. V3 INs were visualized by the expression of Td-tomato fluorescent protein using a Sim1Cre;Rosa26TdTom mouse line. Distinct dorsa-ventral subpopulations in the higher lumbar region were further divided into ascending and descending groups via biotin-dextran-amine retrograde labeling. The birthdates of V3 INs at P0 were determined by preempted 5-Ethynyl-2′-deoxyuridine (EdU) pulses between embryonic day (E) 9.5 and E12.5, respectively. Dorsal V3 INs are born between E9.5 and E10.5 while ventral V3 INs are born later between E10.5 to E12.5. In addition, preliminary data also suggests the dorsal and early born ventral V3 INs are predominately ascending projecting cells while later born ventral V3 INs are descending. Furthermore, using a Sim1 complete knockout mouse model, we have observed a potential delayed exit of the mutant V3 INs from their progenitor state and therefore a shifted neurogenesis profile to later embryonic stages. Subsequently, dorsal and ventral V3 subpopulations are no longer physiologically distinguishable at P0 in the Sim1 mutant. These results suggest embryonic Sim1 expression establishes a patterned V3 neurogenesis profile and downstream functional separation of V3 subpopulations.

Abstract: In *in vitro* organotypic co-culture of the cerebral cortex and spinal cord, the corticospinal (CS) neurons make synapses upon spinal neurons but later exuberant synapses in the ventral spinal cord are eliminated. This type of the CS synapse elimination was shown to be dependent upon spinal GluN2B subunit-containing NMDA receptors. We previously suggested that monosynaptic connections between CS neurons and the motoneurons innervating the forearm muscles (forearm MNs) in juvenile rodents were subsequently eliminated during development *in vivo*. However, it is not known whether the CS-MN synapse elimination *in vivo* is dependent upon GluN2B or not. In this study, we tested this possibility *in vivo* using Grin2b-flox mice and a genetically modified rabies virus.

To delete GluN2B gene specifically in the forearm MNs, the neonates of Grin2b-flox mice received intramuscular injections of adeno-associated virus (AAV) encoding Cre recombinase, which retrogradely infect the forearm MNs. To examine the monosynaptic connectivity between CS neurons and the forearm MNs in those animals, we employed monosynaptic tracing with the recombinant rabies virus. Three proteins were introduced into the forearm MNs of Grin2b-flox mice through retrograde infection of adeno-associated viruses (AAVs) from the neuromuscular junctions at postnatal day 1 (P1): (1) TVA, which is a receptor for EnvA that is engineered to be expressed in the recombinant rabies virus (i.e. EnvA-psudotyped rabies virus), (2) rabies virus glycoprotein which is required for transsynaptic spread of the rabies virus, and (3) Cre recombinase to delete GluN2B gene. Cre-mediated Grin2b targeting was confirmed by whole cell recordings from the AAV-infected MNs in the spinal cord slices prepared at P9-P10. Next, EnvA-pseudotyped- and glycoprotein-deleted rabies virus was directly injected into the forearm MN pool in the spinal cord (C5 to Th1 segments) at P18. Histological examination was carried out at P26. Labeled neurons were found in the cervical cord and brainstem similarly to the wild type mice but no labeled cell was detected in the cerebral cortex. These results indicate that the corticomotoneuronal synapses were eliminated normally from the GluN2B-deleted MNs. Thus, it is unlikely that the GluN2B in the MN is indispensable for the corticomotoneuronal synapse elimination.

Title: Emergence of patterned activity in the developing zebrafish spinal cord

Authors: *Y. WAN, Z. WEI, S. DRUCKMANN, P. KELLER;
HHMI Janelia Res. Campus, Ashburn, VA

Abstract: Spontaneous, patterned neuronal activity has been closely linked to developmental mechanisms shaping the early nervous system and is suggested to play a key role in the fine-tuning of developing circuits. However, little is known about how patterned activity emerges *de novo* and what factors control this maturation process. Major limitations to this end have been (1) the lack of functional recordings at the whole-circuit level and throughout the period in which patterned activity emerges, and (2) the technical challenge of mapping the origin and roles of neurons participating in the functional maturation process back to neurogenesis, when neurons are first born. Here, we use Simultaneous Multi-view (SiMView) Light-sheet Microscopy to image the emergence of patterned activity in the developing spinal cord of embryonic zebrafish. We developed imaging assays and computational tools to record embryogenesis at the cellular level and systematically track cellular dynamics and lineage relationships in the developing spinal cord. By seamlessly transitioning from developmental imaging to high-speed volumetric functional imaging, we furthermore mapped calcium activity in all post-mitotic neurons for a large fraction of the developing spinal cord at a temporal resolution of 4 Hz. These data show that spinal cord neurons undergo a rapid transition from sporadic single-neuron activity to ipsi-laterally correlated and contra-laterally anti-correlated activity between 18 and 22 hours post fertilization. We developed a computational model to reconstruct the maturation process of this spinal cord circuit from our image data at the single-neuron level and characterize dynamic changes in functional connectivity as a function of time. We found that early functional communities are first established by spatially neighboring neurons, and neighboring communities subsequently merge by synchronization to form a patterned network. The time of recruitment of neurons to the spinal cord circuit follows, on average, a gradient from the anterior to the posterior spinal cord. Finally, we identified the cell types of active neurons using genetic markers and found that different types of neurons play different roles in circuit maturation. Ventral interneurons and motor neurons appear to serve as pioneers in the emergence of local functional communities, whereas dorsal commissural neurons may play a key role in establishing and maintaining the phase-locked state between left and right hemi-segments of the spinal cord.

Title: Sox14 is a definitive developmental marker for cerebellar nuclei neurons projecting to the inferior olive

Authors: H.-T. PREKOP[1], C. FERNANDES[1], L. ZAGORAIOU[2,3], T. M. JESSELL[3], *R. J. WINGATE[1], A. DELOGU[1];
[1]King's Col. London, London, United Kingdom; [2]BRFAA, Athens, Greece; [3]Columbia Univ., New York, NY

Abstract: The neuronal circuitry between the cerebellum and inferior olive (IO) is of crucial importance in motor function. However, the role of climbing fibre input from the IO is still under debate: The two main hypotheses associate the signal with motor learning by communicating error to drive synaptic plasticity, and with motor timing by phase-locking action potentials. The foundation of the latter hypothesis is the observation that neurons of the IO are characterised by intrinsic oscillatory properties and electrical coupling, which control synchronous firing of climbing fibres to excite and entrain large cohorts of Purkinje cells in an isochronic manner. Previous work has suggested that GABAergic nucleo-olivary afferents from the cerebellar nuclei modulate and determine the spatial distribution of electrotonic coupling within olivary populations, thereby creating a reciprocal firing loop between the two structures. Confirmation of this role has been hampered by the lack of an *in vivo* tool to target the nucleo-olivary neurons to assess the contribution of these cells in the circuitry. Our lab has defined Sox14 as a genetic marker for the nucleo-olivary neurons in the circuitry during development in mice. Using with a $Sox14^{GFP}$ knock-in mouse line, we identified cells expressing Sox14 in the nuclei of the cerebellum. Sox14 expression is initiated following the birth of these cells from E10.5-11.5 and is maintained until P21. Immunohistochemistry and *in situ* hybridization confirmed that these cells express both GABA and Gad1 mRNA consistent with an inhibitory neuronal identity. Using cre-dependent AAV viral tracing in $Sox14^{CRE}$ mice, we established that this genetically defined population specifically innervates the IO. Furthermore, we injected an AAV driving expression of diphtheria toxin A subunit to ablate cre-expressing cells and mCherry expression in all the infected cells (AAV-mCherry-flex-dtA). Following ablation of $Sox14^{+}$ cells, no other

cerebellar nuclei neurons, expressing mcherry, was observed to project to the inferior olive. Therefore, the cerebellar nucleo-olivary projection neurons are entirely derived from a Sox14 expressing inhibitory progenitor population. Preliminary behavioural assessment of mice in which Sox14 nuclear neurons have been specifically ablated suggest that targeted loss of nucleo-olivary neurons leads to deficits in motor learning.

Abstract: In the olfactory system, key aspects of brain development, such as neuron differentiation, and axon outgrowth occur robustly throughout life. The olfactory epithelium (OE) retains throughout adulthood the capacity for continuing neurogenesis, sustained by progenitor and stem cells. Maturing OE olfactory receptor neurons (ORN) send their axons into the subjacent lamina propria (LP), where they form odor-specific axon bundles and find their way to odor-specific olfactory glomeruli in the olfactory bulb (OB). Chondroitin sulfate proteoglycans (CSPGs), a main component of brain extracellular matrix (ECM), are suspected to play a key role in OE neuronal maturation and axon guidance. On going studies from our group indicate that CSPGs form ECM structures surrounding ORN axons accompanying them from the

OE through the OM and into odor-specific glomeruli in the (OB). This system is relevant to the pathophysiology of schizophrenia (SZ) and bipolar disorder (BD), neurodevelopmental disorders with significant olfactory identification deficits and CSPG abnormalities. The present in vitro study was designed to test the hypothesis that specialized cells within the OM, express and secrete CSPGs, in a differentiation stage-specific manner, and that this process may be altered in people with SZ. Stem cell lines were established using a protocol for isolating human nasal olfactory ectomesenchymal stem/progenitor cells. Starting with OM biopsies from control, SZ and BD subjects, primary cells were isolated, and spheres were generated to select for stem/progenitor cells and allowed to differentiate spontaneously. CSPGs were detected using immunocytochemistry and western blot with antibodies detecting distinct CSPGs and CS sulfation patterns. Our results show that OM stem/progenitor cells allowed to spontaneously differentiate in culture express and secrete CSPGs. This process was detected at early differentiation stages (day 1) and continued as cells matured, creating increasingly dense structures reminiscent of those observed in OM tissue. Differentiating cells were observed to align along these structures according clearly defined patterns. Preliminary results from comparison studies suggest that CSPGs labeled with the lectin *Wisteria Floribunda* agglutinin (WFA) and bearing the chondroitin sulfation pattern CS-6 may not be altered in SZ and BD subjects. Our results so far support the validity of this OM *in vitro* model for investigations on the role of CSPGs in axon guidance in the olfactory system. A disruption of this function in people with SZ or BD may result in miswiring of the connectivity between the OE and the OB, in turn contributing to olfactory deficits.

Title: Resting state functional connectivity relates to response inhibition in adolescents

Authors: *S. M. TASHJIAN, D. GOLDENBERG, A. GALVAN;
Psychology Dept., UCLA, Los Angeles, CA

Abstract: Human neuroimaging literature has identified functional networks in the brain active in the absence of external stimuli, or when the brain is at rest. These networks are present across a variety of states, including during task performance. The strength of the correlation of spontaneous activity between regions of these networks can be a valuable tool for understanding individual differences in cognitive and behavioral abilities, and resting-state functional connectivity (rsFC) methods can elucidate links between the developing brain's functional organization and task performance.

Response inhibition, or suppression of a prepotent response to external stimuli, develops throughout adolescence and is a central component of impulse control. In the go/no-go (GNG) task, a standard measure of response inhibition, a motor response has to be selectively inhibited depending on whether a "go" or "no-go" cue is displayed. Several studies indicate that adolescents can perform with adult-like competence on response inhibition tasks. However, the brain regions recruited during task performance have been found to differ such that adolescents show greater recruitment of the prefrontal cortex compared to adults. These findings suggest for adolescents to achieve adult-like performance they must engage cognitive control circuitry to a greater extent. However, the extent to which functional connectivity of cognitive control circuitry is related to adolescent inhibitory control abilities is not well established.

The goal of this study was to examine the relation between adolescent behavioral performance on the GNG task and the strength of rsFC in cognitive control circuitry. Data for 48 adolescents (M_{age} = 16) were analyzed. Seed-based correlation analysis revealed a significant negative correlation between false alarms (responding "go" when a "no-go" cue is presented) and rsFC, $r(48)$=-.32, p=.029. Adolescents with greater rsFC between the superior frontal gyrus and the anterior cingulate cortex (ACC), caudate, cerebellum, medial prefrontal cortex, and dorsolateral prefrontal cortex (Z = 2.3, $p < .05$) were better able to inhibit their prepotent responses on the GNG task. These data support a role of the prefrontal cortex in adolescent response inhibition. Prior work establishes the role of the ACC in error monitoring and the caudate in response inhibition. Importantly, this study extends our understanding of the link between the stability of coordination in this circuitry and individual differences in behavioral response inhibition in adolescents.

Title: Perinatal lead exposure and white matter microstructure in children

Authors: ***M. HORTON**[1], P. CURTIN[2], C. GENNINGS[2], V. WANG[3], E. PROAL[4], L. SCHNAAS[5], M. TÉLLEZ ROJO[4], E. ROLDAN-VALADEZ[6], F. CASTELLANOS[7], C. TANG[3], R. WHITE[8], R. WRIGHT[3];

(Ci3M), Mexico City, Mexico; [7]New York Univ., New York, NY; [8]Boston Univ., Boston, MA

Abstract: Background
Perinatal lead (Pb) exposure is associated with adverse cognitive and behavioral outcomes that may be mediated by altered brain structure and function. Childhood Pb exposure has been associated with persistent impacts on adult white matter microstructure. The objective of this study was to assess the impact of perinatal Pb exposure on white matter microstructure in children using diffusion tensor imaging (DTI).
Methods
This study took place in the ELEMENT cohort in Mexico City. We randomly selected 20 subjects at age 6 years for a magnetic resonance imaging (MRI) pilot study. DTI images were acquired with a 3T Philips Achieva scanner using gradient echo planar imaging. A voxel-wise statistical analysis for diffusivity measures, including fractional anisotropy (FA), was performed along major white matter tracts. All 20 subjects had blood biomarkers of Pb collected during 2nd and 3rd trimesters and at delivery (umbilical cord blood). We examined correlations between Pb biomarkers and FA values. To capture associations between perinatal Pb exposure and within-brain variability at different time points, we focused on mean FA and standard deviation (SD) of FA across 48 template regions of interest (ROIs); the latter metric captures bidirectional effects that may discretely increase or decrease FA values. Linear regression models examined the association of 2nd, 3rd-trimester and cord blood Pb levels, FA and SD of FA from the ROIs.
Results
Pb levels in 2nd trimester blood were positively correlated with increased global FA after controlling for multiple comparisons ($p < 0.05$). Higher cord blood Pb was associated with increased FA ($\beta = 0.010$, $p = 0.05$) and increased variability of FA ($\beta = 0.0014$, $p = 0.07$).
Discussion
These pilot data suggest changes in white matter microstructure associated with perinatal Pb exposure. Pathological alterations can decrease or increase FA, thus our pilot findings may be consistent with neurotoxic effects of perinatal Pb exposure.

Title: Heritability of the human connectome

Authors: *O. MIRANDA DOMINGUEZ[1], E. FECZKO[1], J. T. NIGG[2], D. A. FAIR[3]; [1]Behavioral Neurosci., [2]Behavioral Neurosci. & Psychiatry, [3]Behavioral Neurosci. & Psychiatry & Advanced Imaging Res. Ctr., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Understanding the degree to which variance in the human connectome is shared among relatives is of high interest to the field. With the recent development of methods to reliably characterize individuals using fMRI data (i.e., "connectotyping" or functional fingerprinting (Miranda-Domínguez et al., 2014)), we can now ask to what extent the connectotype is familial or, in the case of twins, heritable. Following a machine-learning framework, we analyzed data from two well-characterized samples of child and adult sibling. The work revealed that the connectotype or "functional fingerprint" of the brain is familial and preserved in youth and adulthood. First, we show that the functional fingerprint enables the identification of an individual, even after several years. These findings are important as they suggest that despite developmental changes in connectivity patterns with age, the essence of the connectotype accounts for more individual subject variability than the developmental change. Second we show the correspondence of the connectotype across family members is consistent

with heritability. Using a machine learning algorithm we are able to classify the connectomes of sibling pairs at a high rate (74%). Correspondence is strongest for monozygotic twins (86%), followed by dizgygotic twins (77%), non-twin siblings (71%), and last, unrelated pairs. This heritability appears to be driven by high-order systems including the fronto-parietal, dorsal-attention, ventral-attention, cingulo-opercular, and default systems. Understanding the link between individual and familial connectomes is critical to future work characterizing individual differences in brain function.

Title: High-resolution shape analysis reveals reciprocal patterns of subcortical alteration in 22q11.2 deletion and duplication carriers

Authors: *C. R. CHING[1,2], B. A. GUTMAN[2], D. SUN[3], R. K. JONAS[3], A. LIN[3], L. KUSHAN[3], P. M. THOMPSON[2,4], C. E. BEARDEN[3], T. ENIGMA 22Q11.2 WORKING GROUP[2];
[1]UCLA, Los Angeles, CA; [2]USC Imaging Genet. Ctr., Marina del Rey, CA; [3]Semel Inst. for Neurosci. and Human Behavior and Dept. of Psychiatry Univ. of California-Los Angeles, Los Angeles, CA; [4]Departments of Neurology, Psychiatry, Radiology, Engineering, Pediatrics and Ophthalmology, Marina del Rey, CA

Abstract: 22q11.2 deletion syndrome (22qDel) results from a microdeletion on chromosome 22 and causes a range of physical and neurodevelopmental anomalies. Sixty percent of 22qDel patients meet criteria for a developmental neuropsychiatric disorder and roughly 30% develop

schizophrenia (SCZ). Recent evidence suggests that a reciprocal microduplication at the 22q11 locus (22qDup) may be protective against SCZ. Neuroanatomic variation underlying these genomic alterations has not yet been investigated. Here, using the ENIGMA Shape Analysis Pipeline, we reveal complex subregional differences between 22qDel, 22qDup, and healthy controls (CN).

T1-weighted brain MRI scans (22qDel=57, 22qDup=15, CN=49) were processed to derive two shape metrics of local thickness and surface area: 1) Radial distance (thickness), and 2) the Jacobian determinant (Jacobian) or surface dilation to a template, were measured across thousands of homologous points for bilateral accumbens, amygdala, caudate, hippocampus, putamen, pallidum, and thalamus shape models. A multiple linear regression was fitted at each surface point to assess Jacobian and thickness differences between groups after adjusting for age, sex, scanner, and intracranial volume. All results were corrected for multiple comparisons using standard FDR correction.

22qDel carriers displayed largely reduced shape metrics (local volume and surface area) compared to CN across all subcortical structures of interest. In contrast, 22qDup carriers showed largely increased volumes compared to 22qDel, and more subtle patterns of both increased and decreased shape measures compared to CN [Figure 1].

Our analysis identified complex patterns of increased and decreased local shape measures between groups, across many subcortical structures of interest. To our knowledge, this represents the first neuroimaging study of 22q11 gene dosage effects on brain structure, motivating future work to elucidate relationships between reciprocal genetic and anatomic variation at the 22q11 locus and neuropsychiatric phenotypes.

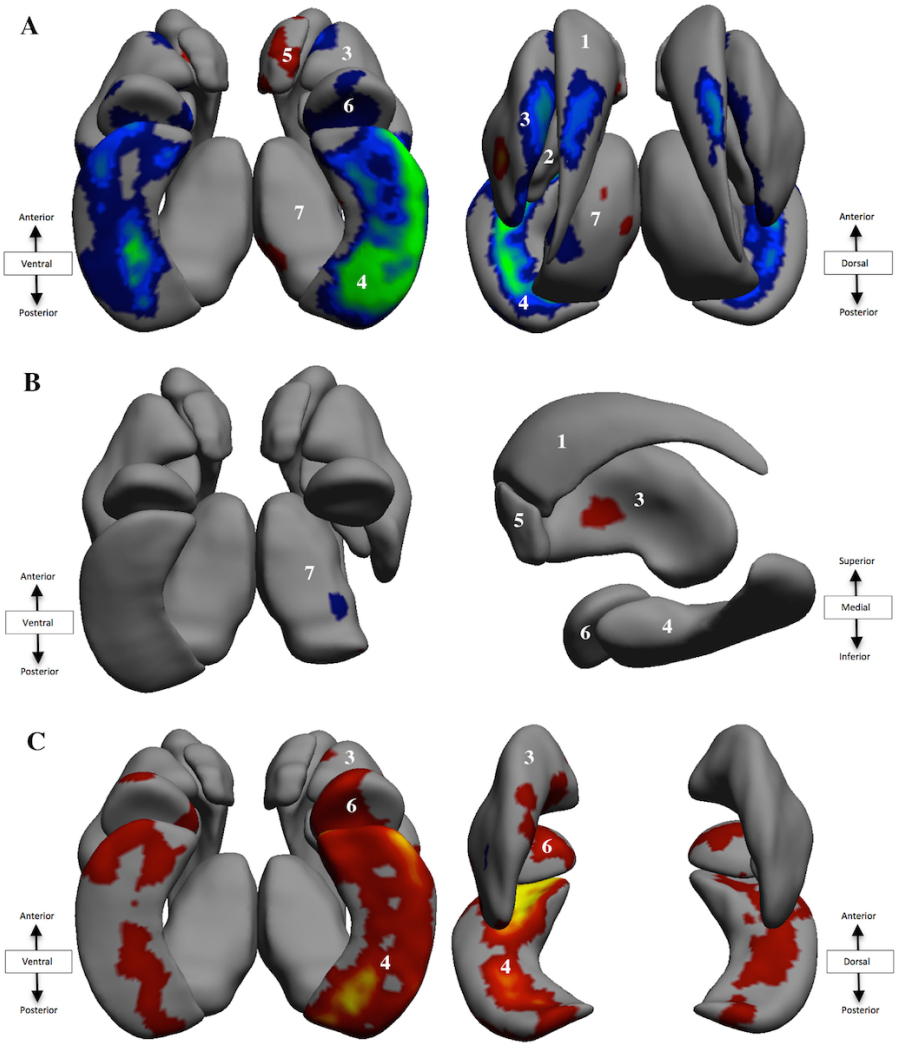

Figure 1. Maps showing β values plotted in significant regions after correction for multiple comparisons. **A. 22qDel vs. CN** Red/Yellow indicate positive β values or regions where 22qDel subjects have greater surface area/volume compared to CN. Blue/Green indicate negative β values or regions of reduced surface area/volume in 22qDel compared to CN. Left: ventral view; Right: dorsal view. **B. 22qDup vs. CN** Red/Yellow regions indicate greater surface area/volume in 22qDup subjects compared to CN. Blue/Green regions indicate reduced surface area/volume in 22qDup vs. controls. Left: ventral view (hippocampus removed; Right: medial view (thalamus and globus pallidus removed). **C. 22qDup vs. 22qDel** Red regions inidcate where 22qDup subjects have greater surface area/volume compared to 22qDel subjects. Title: Awareness of alcohol advertising and limbic-frontal activations during an emotional counting stroop task in adolescents

Authors: *K. VIACAVA[1], S. EL DAMATY[2], B. W. STEVENS[2], J. LEISER[2], E. J. ROSE[3], D. H. FISHBEIN[3], J. W. VANMETER[2];
[1]Georgetown Univ., Washington, DC; [2]Georgetown Univ., Washington, DC, DC; [3]The Pennsylvania State Univ., State College, PA

Abstract: Awareness of alcohol advertising is a proximal factor that may also increase risk in adolescents for engaging in drinking behaviors (McClure et al., 2013). Although it is argued that effects of repeated exposure to alcohol advertising are independent of awareness, there is still no consensus on this topic. Thus, the aim of this study was to investigate if and to what extent different levels of awareness of alcohol advertising might covary with attentional bias (AB) to alcohol-related cues in mediating potential exposure effects. Participants were recruited as part of the Adolescent Development Study (ADS, funded by NIAAA), a prospective longitudinal neuroimaging study of alcohol initiation and escalation. A subset of 70 adolescents enrolled in the ADS performed an Emotional Counting Stroop (ecStroop) task during fMRI. Thirty-one participants from this sample (mean age = 14.85 yrs; 17 females) completed both the Media Exposure Questionnaire (MEQ) and the Advertising Awareness Questionnaire (AAQ). We examined neuronal activations from the subjects that did not complete the questionnaires (N = 39) to obtain a bias-free set of region(s) of interest (ROIs) to use in a subsequent analysis to determine whether awareness to alcohol advertising mediates the relationship between exposure and AB. Results revealed that awareness of alcohol ads positively mediated the relationship between alcohol ad exposure and AB towards alcohol-related words ($F(2,30) = 7.03$, $p < .01$, $R^2 = .33$); as awareness to alcohol ads increased, so did the association between exposure and AB. The association between awareness and AB ($r = .53$; $p < .01$) was slightly stronger than the one between exposure and AB ($r = .48$; $p < .01$), which supports the heuristic marketing receptivity

model (McClure et al., 2013) (i.e., the influence of marketing on behavior may involve both distal (exposure) and proximal (awareness) factors). Awareness of alcohol ads mediated the regulation of superior temporal gyrus (STG) over affective responses toward alcohol ads ($F(2,19) = 6.99$, $p < .01$, $R^2 = .45$). There were positive correlations between affective responses to alcohol ads and the insula ($r = .50$, $p = .02$), mid-cingulate ($r = .69$, $p < .01$) and STG ($r = .47$, $p = .03$), implying that as receptivity to alcohol ads increases, greater neural effort was devoted to process the emotional content captured in alcohol advertising. Altogether, these results substantiate the idea that awareness of alcohol advertising is more proximal to behavior than exposure and that both might increase receptivity to alcohol consumption in adolescents.

Abstract: Human brain maturation during adolescence is characterized by complex changes that support behavioral flexibility and enhanced executive function. Recent work has demonstrated that functional brain modules become increasingly differentiated during youth, but it remains unclear whether structural brain networks undergo an analogous reconfiguration. Here, we evaluated the development of structural brain networks in a sample of 882 participants (ages 8-22 years) who received diffusion tensor imaging as part of the Philadelphia Neurodevelopmental Cohort. We hypothesized that structural brain networks would become increasingly modular with age, that such modular structure would support improvements in executive function, and that environmental adversity associated with low socioeconomic status (SES) would impact this process. Applying tractography methods and community detection procedures, we observed that structural brain networks become increasingly modular with age ($p < 0.0001$): within-module connectivity increased, whereas between-module connectivity decreased. Furthermore, as adolescence progressed, the community structure of structural networks became more similar to that found in adults. Increased network segregation was reflected on a regional level by widespread declines in the participation coefficient, which were especially prominent in regions within the default mode network. The only exception to this was the anterior prefrontal cortex, where conversely the participation coefficient increased with age. Notably, even when controlling for age, increased modular segregation was correlated with improved executive efficiency in a cognitive battery ($p < 0.0001$). In contrast, lower SES (as summarized by a previous factor analysis) was associated with impaired development of structural modules ($p < 0.0001$). These findings are buttressed by convergent results from supplementary analyses that used alternate edge measures (fractional anisotropy versus streamline connectivity), varied modularity resolution parameters, and use of an independent partition derived from functional brain networks. Taken together, these data delineate a developmental process whereby structural brain networks become increasingly segregated in order to support executive function, and emphasize that this process may be impacted by environmental adversity. This work provides an empirical basis for additional studies investigating how environmental factors may impact development of the brain's structural connectome and be associated with risk of neuropsychiatric symptoms.

Abstract: Adolescence, the transition from childhood to adulthood, is marked by steep changes in social and risky behaviors, as well as enhanced vulnerability to psychiatric disorders. Importantly, the effects of puberty on the ontogeny of brain organization remain unclear. Striatal intrinsic functional connectivity (iFC) using resting state fMRI was examined in 387 adolescents who participated in the IMAGEN Study. Data were collected from 5 sites across Europe. Data processing and analyses were conducted with Analysis of Functional NeuroImages (AFNI). Eighty participants were removed from the analysis due to excessive motion, leaving 307 adolescents (14.5 +/- 1.3 yo; 2.6 +/- 1.4 Puberty Development Score (PDS); 52% male). Multiple regression analyses were used to examine the effects and interactions of puberty, age, sex, and site on striatal iFC. Using a voxel-wise approach, puberty was negatively correlated with ventral striatum (VS) iFC to ventromedial prefrontal cortex (vmPFC), and with dorsal striatum (DS) iFC to thalamus and insula. As an initial interpretation, these negative correlations of puberty with striatal iFC to regions involved in attention, risk-taking behavior and value coding, suggest a role of pubertal maturation in the rise of risky behaviors and impulsive decision-making in adolescence.

Title: Developmental emergence of frontostriatal connectivity mediates flexible upregulation of cognitive control under high stakes

Authors: *C. INSEL, E. K. KASTMAN, S. F. SASSE, M. C. GARRAD, L. H. SOMERVILLE; Psychology, Harvard Univ., Cambridge, MA

Abstract: Development of frontostriatal circuit function is thought to result in unique integration of reward and cognitive control. In high stakes situations, adults often strategically improve cognitive control when performance matters. But it remains unclear whether adolescents can integrate frontostriatal systems to flexibly upregulate goal directed cognitive control. The aim of this study was to test whether adolescents could selectively enhance flexible cognitive control when high incentives were at stake. We examined whether the frontostriatal mechanisms subserving motivation-cognition interactions would exhibit a unique functional profile paralleling a developmental shift in performance. 88 participants aged 13-21 underwent fMRI during an incentivized go/no-go task with low and high stakes conditions. First, a high (+$1.00/-$0.50) or low (+$0.20/-$0.10) stakes cue was shown. Next, a series of go's (required response) and no-go's (required no response) were presented. There was a significant age by stakes interaction whereby adults improved during high stakes but adolescents did not. This effect was mediated by developmental changes in functional connectivity between the ventral striatum and vlPFC that was selectively enhanced during high stakes with age. This indicates that the ability to capitalize on stakes may be an especially late developing feature of goal directed behavior. The maturation of of frontostriatal connectivity may set the stage for successful goal directed cognitive control.

Title: Earlier alcohol use and lower neuropsychological performance in adolescents from public compared to private schools

Authors: *A. R. WILLHELM[1], K. R. VIACAVA[2], J. W. VANMETER[3], R. M. M. DE ALMEIDA[2];
[1]Porto Alegre, Brazil; [2]Inst. de Psicologia, Univ. Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Dept. of Neurol., Georgetown Univ., Washington, WA

Abstract: Adolescence and puberty are characterized by the development of physical, cognitive and emotional abilities that provide the necessary skills for autonomy later in life (Spear, 2000). However, this period is also marked by impulsive and risk-taking behaviors that may increase the initiation and escalation of alcohol and drugs use, setting the stage for addiction (Spear, 2013). The school's social environment might play a role in this process, as it impacts the onset of alcohol consumption (Koch & McGeary, 2005). Investigating the relationship between alcohol drinking in adolescence and type of school (public and private) is relevant given the accumulated findings of alcohol use on both cognitive skills (Renna, 2008) and academic achievement (Balsa, Giuliano, & French, 2011). Here we show a mediation model of age in the relationship between type of school and alcohol use in adolescence. Participants were 190 adolescents (10-16 years, mean age = 13.76, 112 females) selected from four public and two private schools located in Porto Alegre - RS, Southernmost Brazil. Neuropsychological measures, such as impulsivity (Barratt Impulsiveness Scale - BIS for youth), inhibitory control (Go/No-go Task), processing speed and attentional control (Five Digits Test), as well as IQ (Wechsler Abbreviated Scale of Intelligence - WASI) were assessed. Results revealed that approximately 60% of the sample had started drinking alcohol and 17% used illegal drugs. The proportion of individuals consuming alcohol increased with age such that 87% of adolescents between 15 and 16 years old had consumed alcohol. Age positively mediated the relationship between type of school and alcohol use, indicating that adolescents from public schools started drinking earlier than those from private schools ($p < .001$). In accordance with the adolescence neurodevelopmental model (Spear, 2013), we found a significant increase in neuropsychological performance as a function of age ($p < .01$). There were also significant differences in neuropsychological performance between types of school, particularly in impulsivity ($p < .05$) and inhibitory control ($p < .01$), such that better neuropsychological performance was found in students from private schools. In conclusion, adolescents from public schools initiated alcohol

use earlier and showed lower neuropsychological performance than same-aged peers from private schools.

Title: The family environment predicts children's fMRI-measured responses to emotional stimuli

Authors: *S. K. TOLIA[1], M. NOBILE[2], M. RE[2], P. PANDHER[1], K. RAMASESHAN[1], V. A. DIWADKAR[1], P. BRAMBILLA[3];
[1]Dept. of Psychiatry and Behavioral Neurosciences, Wayne State Univ., Detroit, MI; [2]Polo Bosisio Parini, Scientific Institute, IRCCS Eugenio Medea, Lecco, Italy; [3]Univ. of Udine, Udine, Italy

Abstract: Introduction
A child's familial environment affects behavioral measures of cognitive and emotional development, and is likely to exert effects on functional brain responses to emotional context. Yet these effects have not been characterized. Here, we examined the effects of intra-family care based on the Parental Bonding Instrument (PBI) (Parker et al., 1979) on fMRI responses while children attended to continuously presented emotional faces of varying valence. The study focused on attention to negatively or positively valence because each class evokes obligatory but distinct emotional demands.
Methods
36 consenting or assenting participants (mean age:15.0 yrs.) rated the intra-family environment using the PBI. We focused on the "care" (as opposed to the "overprotection") dimension, deriving a common care metric using ratings for both parents. fMRI data were collected (3T, Siemens) using a novel emotional continuous performance task (Soloff et al., 2015). We manipulated contextual attention to rapidly presented (1 s) negative or positive faces in an extended block of trials (30 s). Emotional context (+ve or –ve) defined whether a letter ("A" or "X") on a face was a target or distracter (an overlaid "X" was a target only if the facial emotion was consistent with the context). By gating the cognitive response to evaluated emotional context, we sought to induce obligatory emotion regulation. fMRI data were processed (SPM8) using typical methods. First level contrasts were created to identify relative differences in

activation (Negative ≠ Positive). Contrasts were forwarded to second level regression analysis: values from the PBI were employed as a single regressor of interest (p<.05, cluster level).

Results

PBI predicted *increased* fMRI responses to negatively valenced contexts across multiple regions associated with attention, interoception and affective control. These included the precuneus, inferior and superior parietal lobules, the angular gyrus, the superior and middle temporal gyrus, the insula and the dorso-lateral and orbitofrontal cortices.

Conclusion

Intra-family care is highly predictive of functional brain activity when children are attending to negatively valenced faces. The increased activation in regions associated with emotion regulation, face processing and control (Weibert et al., 2015) may reflect a normative effect of increased care within the family environment on the brain's regulatory emotional responses. These results have implications for understanding of familial influence on cognitive development and responses, and suggest that psycho-social factors may exert substantial effects on functional brain responses.

Title: Developing consistency in reaction time associated with stable individual differences in motor system microstructure - a longitudinal DTI study of children and adolescents

Authors: *K. S. MADSEN[1,2], T. L. JERNIGAN[3], C. REUTER[3], W. K. THOMPSON[4], W. F. C. BAARÉ[1];

[1]Danish Res. Ctr. for Magnetic Resonance, Copenhagen Univ. Hosp., Hvidovre, Denmark; [2]Metropolitan Univ. Col., Copenhagen, Denmark; [3]Ctr. for Human Develop., Univ. of California

San Diego, La Jolla, CA; [4]Inst. of Biol. Psychiatry, Mental Hlth. Ctr. Sct. Hans, Roskilde, Denmark

Abstract: The corticospinal tracts (CST) and striatum continue to develop throughout childhood and adolescence, and indices of their maturation can be obtained using diffusion tensor imaging (DTI), with mean diffusivity (MD) decreasing with age. We observed previously that faster and more consistent reaction times (RT) on a visuomotor task were associated with lower MD in the CST and striatum after controlling for age in 7-13 year old children. It is unknown whether these associations are mediated by individual differences in the phase of maturation of the CST and striatum in children of similar age, or by more stable individual differences in the architecture of the motor system. Here, we examined this question.

Eighty-eight healthy participants aged 7-19 years underwent longitudinal structural MRI, including DTI on a 3T scanner, (2-11 visits, 708 visits) and a 5-choice RT task (Fig. 1a). Mean RT and RT coefficient of variance (RTcv) were estimated. ROIs were made in the CST, caudate nuclei, and putamen. Mean ROI MD were then extracted bilaterally. Within-subject age-related changes in RT and ROI MD were estimated using generalized additive mixed models (GAMMs). Multivariate functional principal component analysis (mFPCA) of the mean RT, RTcv and ROI MD as a function of age was also conducted (Fig. 1b), allowing for correlation of component scores across measurement domains.

Significant age-related decreases were observed for mean RT and RTcv ($ps<10^{-11}$) as well as for MD in all ROIs ($ps<10^{-15}$). The results from the mFPCA are reported in Fig. 1b. The age-related changes in mean RT and RTcv were correlated with the maturational trajectories of CST MD, and for RTcv also to putamen MD (Fig. 1c). Further, individual differences in both RT performance and ROI MD appeared to be stable over time. Together this suggests that children with better RT performance have lower MD in the motor system, while children with poorer performance higher MD in the motor system, and that this relationship remains stable within the investigated age range in spite of superimposed biological changes associated with maturation.

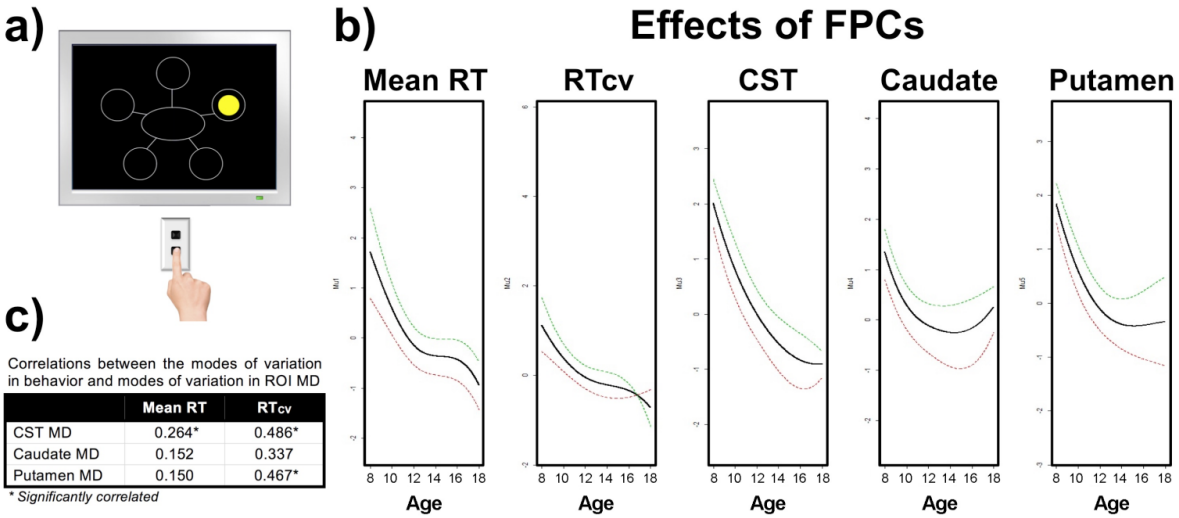

Figure 1. a) Set-up of the 5-choice reaction time (RT) task in CANTAB. Participants are instructed to press a button on a pad. After a random delay, a yellow dot appears in one of five circles. Participants must release the button as quickly as possible and touch the yellow dot. The button release time was used to estimate mean RT and RTcv. b) Results from the mFPCA of the behavioural performance and mean diffusivity (MD) of the ROIs as a function of age. From left to right, the plots display the mean fits (black lines) of the standardized mean RT, RTcv, corticospinal tract (CST) MD, caudate nuclei MD and putamen MD against age. The dashed green and red lines represent respectively the +1 and -1 standard deviation of the first principal component scores for each domain. c) Correlations between the principal component scores of the behavioral measures (mean RT and RTcv) and ROI MD (CST, caudate and putamen). An * indicates a significant relationship between two scores.

Title: Hippocampal shape analysis in typical development

Authors: *K. M. LYNCH, L. ZHAO, A. TOGA, K. CLARK;
Stevens Neuroimaging and Informatics Inst., USC, Los Angeles, CA

Abstract: Introduction: The hippocampus is a subcortical structure critical for learning and memory. While several studies have described hippocampal changes in typical aging, few studies have addressed the normal developmental trajectory of the structure in early childhood and adolescence. The purpose of this study is to examine the cross-sectional age-related changes and sex differences in hippocampal shape in a cohort of typically developing children.
Methods: In total, 770 subjects (3-21 years) were scanned through the Pediatric Imaging, Neurocognition, and Genetics (PING) multi-site project (11 +/- 4.9 years; 356 Female). Hippocampal volumes extracted from T1-weighted MRI images were converted to a triangulated mesh and registered to the average hippocampus surface using Metric Optimization for Computation Anatomy (MOCA). Hippocampal radial thickness measures were mapped onto the average surface using Laplace-Beltrami eigen-projections. Age-related changes in hippocampal shape were analyzed using linear mixed effects models and random field theory.
Results: Significant age-related changes (controlling for sex) and sex differences are shown in Figure 1. Specifically, the bilateral hippocampi exhibit the largest age-related changes between 3 and 7 years (corrected p=.0001). Additionally, sex differences were most pronounced during adolescence. A significant age*sex interaction in overall size was noted in the left hippocampus, with males exhibiting an increase in size with age while the structure remains stable in females (p=0.046).

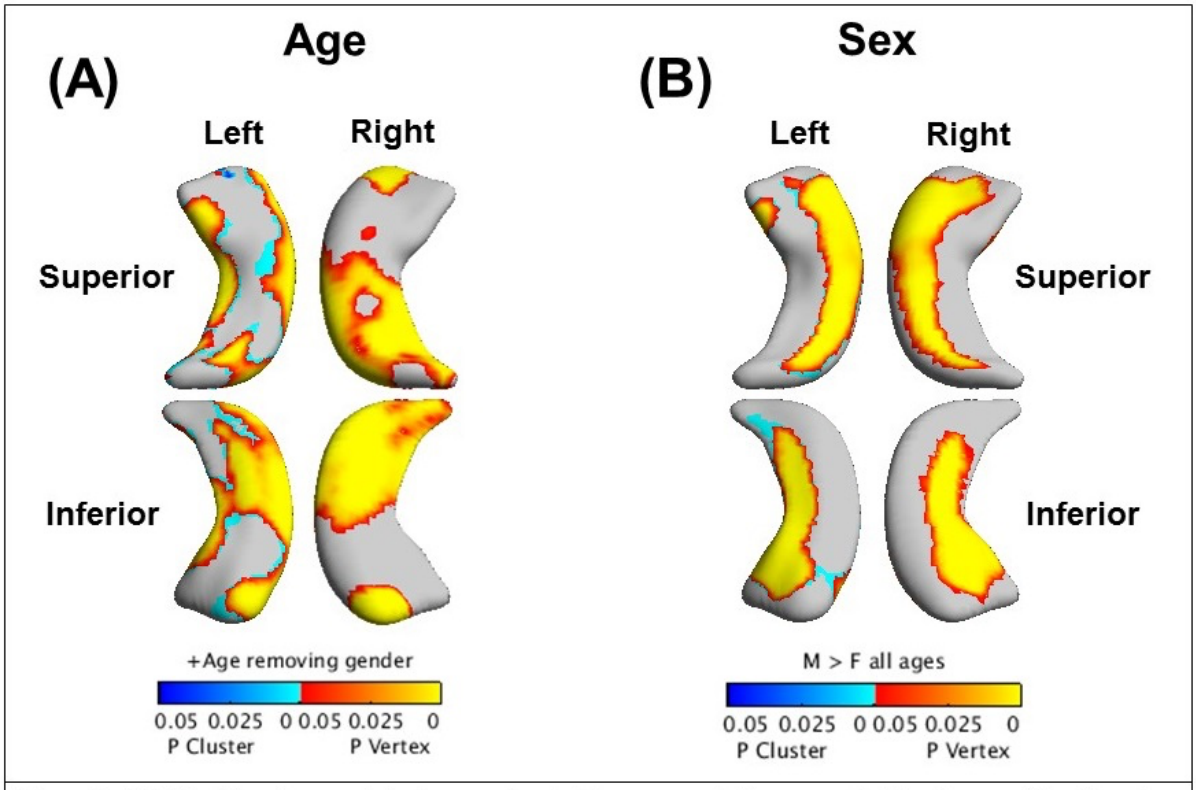

Figure 1: (A) Significant age-related expansion in hippocampal shape, controlling for sex. Significant regions include the CA1 and CA2-3 in the left hippocampus and hippocampal tail and posterior CA1 in the right hippocampus. (B) Significant sex differences in hippocampal shape among all ages. Note the bilateral expansion of CA1 and subiculum in males versus females.

Conclusion: Our results show that hippocampal shape changes significantly during childhood and adolescence, with the greatest changes occurring in before puberty. Meanwhile, sex differences in the hippocampus do not emerge until adolescence, suggesting that hippocampal shape may be under hormonal control. These results show that shape analysis is a powerful tool for detecting specific, regional developmental changes in the hippocampus.

Title: Adaptive adjustment in cognitive control over reward in adolescence

Authors: *J. Y. DAVIDOW[1], K. R. A. VAN DIJK[1,2], J. SNYDER[3], C. VIDAL[1], M. A. SHERIDAN[3], L. H. SOMERVILLE[1];
[1]Dept. of Psychology and Ctr. for Brain Sci., Harvard Univ., Cambridge, MA; [2]Athinoula A. Martinos Ctr. for Biomed. Imaging, Dept. of Radiology, Massachusetts Gen. Hosp., Charlestown, MA; [3]Dept. of Psychology and Neurosci., Univ. of North Carolina, Chapel Hill, NC

Abstract: Theories of the mechanisms underlying increases in risk-seeking behavior during adolescence suggest a dynamic interplay in the ability to exercise cognitive control for appetitive cues. Prior work has evaluated control for stimuli whose appetitive qualities are central to the stimulus itself, finding that adolescents can be impaired at exerting control over appetitive stimuli. A critical open question is whether adolescent control limitations persist for cues that were previously rewarding, but no longer signal reward. We tested whether a history of reward association is sufficient to perturb adolescents' cognitive control. Inhibitory cognitive control for cues with and without previous reward association was assessed with the Conditioned Appetitive Response Inhibition Task (CARIT) during fMRI. A final sample of 130 participants 8-26 years old performed the inhibitory control task containing two no-go cues, prior to which one cue underwent operant conditioning to form a reward association, while the other was never associated with reward. Behaviorally, we found an interaction between age and previous reward conditioning, such that beginning in early adolescence proportionally more errors were made to the previously rewarded stimulus. Adolescents recruited regions within the striatum less than children and adults when successfully withholding a response for the previously rewarded cue compared to the neutral cue, consistent with signals in primate midbrain at the omission of a cued reward, and adolescent fMRI studies showing reduced striatal signals to relatively smaller rewards. Thus, in the present study, though the intrusion of reward on cognitive control emerged during adolescence, this interference was attenuated in adolescents in the absence of continued reinforcement, whereas it persisted for adults. This suggests a potential adaptive mechanism in adolescence, whereby initial strong reward-related responses could be tempered by rapid adaptation.

Title: Association among sleep, neural circuitry, and pubertal hormones during adolescence: Implications for risky decision-making

Authors: *D. GOLDENBERG, S. M. TASHJIAN, A. GALVAN;
Psychology, UCLA, Los Angeles, CA

Abstract: Adolescence is characterized by dramatic increases in pubertal hormones, profound changes in sleep habits, and significant remodeling of motivational and regulatory neural systems. Separate lines of research have linked these neurobiological changes during adolescence with increased rates of risky decision-making. Importantly, emerging evidence suggests these neurobiological changes are intricately related to one another. Wake-sleep cycles likely change during adolescence in a manner that is hormone-dependent (Hagenauer & Lee, 2013) and poor sleep quality in adolescents is related to reduced functional connectivity between regulatory (e.g. DLPFC) and reward-related regions (e.g. ventral striatum, insula) during risky decision-making (Telzer et al., 2013). Given the potential link between these key neurobiological changes, the purpose of the current study was to examine the associations between sleep quality, pubertal hormone levels, and neural response during risky decision-making in a sample of adolescents. Fifty-five adolescents (ages 14-18 years; 52% female) provided salivary assays analyzed for pubertal hormone levels (testosterone, estradiol, and DHEA). Sleep quality and duration were assessed subjectively (self-report) and objectively (actigraphy measurements) over a two-week period. Participants underwent functional magnetic resonance imaging (fMRI) while performing a decision-making task designed to contain conditions of response inhibition and risky choice in pursuit of reward. This is important because poor sleep during adolescence likely impairs recruitment of regions involved in cognitive control (e.g. prefrontal cortex) in addition to eliciting increased neural response in reward-related regions (e.g. ventral striatum), both of which may result in greater risky behavior. A repeated-measures ANOVA revealed significant differences in mean reaction time by trial type [$F(2.85, 88.21)=34.16$, $p < .01$], suggesting differential processing by condition. Main effects during risky choice revealed significant activation in reward-related regions (e.g. ventral striatum) while cautious choice elicited

response in regulatory-regions (e.g. DLPFC). Both cautious choice and response inhibition elicited activation in the DLPFC, with a lesser extent of activation during inhibition. Only cautious choice elicited activation in the insula. Functional connectivity analyses will be conducted and correlated with measurements of sleep quality. Moderation analyses will assess the influence of pubertal hormones on the relationship between sleep and functional connectivity during risky decision-making.

Title: I want it now! The role of pubertal testosterone in impatience of adolescent boys

Authors: *C. LAUBE, R. LORENZ, W. VAN DEN BOS;
Max Planck Inst. For Human Develop., Berlin, Germany

Abstract: The onset of adolescence is associated with an increase in transgressive behaviors, from juvenile delinquency to substance use and unprotected sex, which are often attributed to increased impulsiveness. This increase is assumed to result from differential maturation of a subcortical affective brain network and a cortical control network. More recently it has been hypothesized that pubertal hormones may specifically modulate the function of the subcortical regions, and increasing reward seeking behavior. However, much is still unknown about how pubertal hormones impact brain and behavior. Here we focus on the role of testosterone in impulsiveness in adolescent males. In an behavioral study (*N*=72, ages 11-14) we found dissociable effects of age and pubertal testosterone on impatient behavior on an intertemporal choice task. That is, increased sensitivity to immediate rewards was specifically related to an increase in pubertal testosterone, whereas a general reduction of impatience was related to increased age. To gain further insight into these mechanisms, we designed a follow-up study in which we aim to investigate the different effects of age vs. pubertal testosterone on brain function and structure (*N* = 75, ages 10-15, and *N*=25, ages 20-30) on several delay discounting paradigms in and outside the MRI scanner. Preliminary results reveal that adolescents showed less activity in the insula in presence of immediate rewards compared to adults, and insula activity was also related to individual differences in pubertal status. We will discuss these results against the background of current neurodevelopmental models of adolescent brain development and will present specific effects related to testosterone. As a conclusion, our results highlight the

importance of studying pubertal development and emphasize the necessity to also integrate measures of pubertal development (and not exclusively age) when trying to understand adolescent impulsivity.

Univ., Portland, OR; [9]Psychology, Northwestern Univ., Evanston, IL; [10]Psychology, Yale Univ., New Haven, CT; [11]Brain Res. Institute, UCLA, Los Angeles, CA

Abstract: Adolescence marks a time of increased risky and impulsive behavior when the capacity for cognitive control is susceptible to socioemotional influences[1]. Adolescents are more risky in their choices when among peers[2] and more impulsive than adults to social cues[1,3]. Thus, social cues can trigger impulsive actions, overriding goal-directed behavior during adolescence. This adolescent specific effect in behavior is paralleled by greater activity in reward related circuitry[3-4]. Yet, when this capacity matures is still unclear. Moreover, studies examining the effects of incentives and peers typically examine these factors independently, although they rarely are in real-life.
The goal of the current study was to examine changes in the capacity for self control with age

under conditions that may better reflect real world situations for teens. We tested the impact of the perceived presence or absence of a peer when performing an impulse control task[5] that consisted of positive social cues under a state of excitement. A diverse sample of 171 participants ages 13 to 25 years were tested. We found that under excitement when detecting smiling faces in the presence of peers, adolescents showed diminished cognitive control relative to when alone, as indexed by d-prime $F(1, 66) = 9.19$, $p < .005$ and to other age groups $F(2, 163) = 4.62$, $p < .01$). This pattern of performance was paralleled by greater activity in the orbitofrontal cortex (MNI coordinates: x=6.5, y=36.5, z=-20.5, 44 voxels; $p < .02$, corrected) in teens relative to adults for the peer condition $F(2, 163) = 5.53$, $p = .005$.
These data suggest the combined "triple threat" to self control of peers, excitement and positive cues may lead to a greater anticipation of reward and increased impulsivity during adolescence but not in other age groups. This research has important implications for law and policy regarding diminished cognitive capacity during the adolescent years in emotionally charged situations.

Title: Resting-state functional connectivity can differentiate children and adults: An EEG study

Authors: S. KANG[1,2], D. KIM[2], *S.-H. JIN[3];
[1]Seoul Natl. Univ. Col. of Nursing, Seoul, Korea, Republic of; [2]Natl. Standard Reference Data Ctr. for Korean EEG, Seoul, Korea, Republic of; [3]Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Objective: To evaluate whether the support vector machine (SVM)-based group classifier based on electroencephalography (EEG) in the eyes-closed resting-state can distinguish children and adults. **Methods:** We compared resting-state functional connectivity between 150 children (age range = 8 to 11) and 123 adults (age range = 24 to 50). Imaginary coherence values between the 19 EEG electrodes were calculated. The most informative connectivity with statistical significance (Bonferroni corrected, $p < .00001$) across leave-one-out group comparisons were sorted in a descending manner and became candidate feature sets for support vector machine (SVM) learning to identify the optimal group classifier. **Results:** The optimal SVM group classifier with the top 8 ranked features in the alpha frequency band distinguished children and adults with a mean accuracy of 79.3% (sensitivity = 77.1%; specificity = 81.5%; positive predictive value = 81.1%; negative predictive value = 78.5%). Adults had enhance functional connectivity between frontal and parietal (Fz-P4, F4-P4) or central regions (Fp1-C4, Fp2-C4), between frontal regions (F7-F3, F7-Fz, Fp1-F8), and between central and parietal regions (Cz-P4). Interestingly, all functional connections composing the optimal SVM model were observed in the alpha frequency band among the conventional 4 frequency bands. **Conclusion:** We showed the potential of electrophysiological resting-state functional connectivity, which reflect differences of functional brain networks between children and adults mainly in the alpha frequency band, as a possible EEG biomarker that differentiates children and adults.

Title: Age associated differences in resting-state network topology predict differences in task-evoked activity

Authors: *M. Y. CHAN[1], F. ALHAZMI[1], N. K. SAVALIA[1], D. C. PARK[1,2], P. F. AGRES[1], G. S. WIG[1,2];
[1]Ctr. for Vital Longevity and Sch. of Behavioral and Brain Sci., Univ. of Texas at Dallas, Dallas, TX; [2]Dept. of Psychiatry, Univ. of Texas Southwestern Med. Ctr., Dallas, TX

Abstract: The organization and information processing of human brain areas can be examined using multiple features (e.g., resting-state and task-based connectivity, task-evoked activity, morphometry). It is hypothesized that individual differences in these features are related to one another. While a number of recent studies have described the spatial overlap between resting-state functional correlation (RSFC) network topology and task-evoked activity, it is unclear whether individual variations in a brain area's RSFC topology may inform its activity during task execution. To pursue this question, we analyzed RSFC patterns using graph theory to characterize the network topology of brain areas, and then examined how individual differences in RSFC topology were related to differences in task-evoked activity (blood-oxygen-level dependent; BOLD) collected from two independent tasks with differential stimulus and task processing demands (i.e., a visual classification task and a semantic categorization task).
Data from the Dallas Lifespan Brain Study were analyzed, first focusing on a sample of healthy young adults (N=64; 20-34y) to understand how the connectional topology of a given brain node (brain area) as defined by RSFC relates to its activity during task. We found that relative to other nodes of the same system, nodes with connections largely limited to other nodes of their own functional system (i.e., exhibiting a lower participation coefficient [PC]) elicited greater BOLD activity than nodes with many connections to nodes in other systems (i.e., higher PC). Importantly, individual differences in 'activation selectivity' were primarily observed in those functional systems under heavy processing demands during the corresponding task. We next examined healthy participants across the adult lifespan (N=238; 20-89y) in order to compare brain networks that exhibited age-related differences in resting-state functional topology (Chan et al., 2014). With advanced age, decreased distinctions were observed in node topology in terms of connections within and between systems. Furthermore, brain networks with less differentiated topology (i.e., older adults) exhibited decreased activation selectivity across nodes. Together, the results provided evidence that the functional topological properties observed at rest are important for describing the functional activity of brain areas during active tasks (or vice versa) across participants. In doing so, these results also provided a possible network-based explanation for previous reports of the 'dedifferentiation' in brain activity observed in aging.

Title: SLC7A10 - a novel candidate for human hyperekplexia

Authors: *C. VILLMANN[1], S. ATAK[1], R. J. HARVEY[2], P. DREHMANN[1];
[1]Univ. Wuerzburg, Wuerzburg, Germany; [2]UCL Sch. of Pharm., London, United Kingdom

Abstract: Human hyperekplexia (Startle disease) is a rare neuromotor disorder. Characteristic symptoms are enhanced startle responses following unexpected sensory or tactile stimuli. Several affected genes including the *GLRA1* as the most common gene, *GLRB*, *SLC6A5* as well as *ARHGEF9* and *GPHN* have been identified as the underlying causes for the observed pathology. Mutations in these genes can be assigned to about 20% of patients leaving the underlying pathology for 80% of patients diagnosed for startle disease unknown. We screened the genomic DNA from 50 hyperekplexia patients for mutations in Asc-1. The Asc-1 transporter is a plasma membrane antiporter with high affinity for neutral small amino acids such as glycine, L-serine, D-serine, alanine and cysteine. All 11 exons including flanking intronic sequences have been analyzed by sequencing. In our screening we discovered three exonic single nucleotide polymorphisms generating one missense mutation in exon 7 c.919G>A; G307R and two synonymous mutations c.1158G>A; T386T in exon 9 and c.1374G>T; T458T in exon 10. In addition, we detected several intronic nucleotide variations that might have an input on splicing or binding of enhancer/silencer elements. Furthermore, we detected 5'UTR and 3'UTR variations that may influence gene expression by changes in the translation efficiency, stability and transport of the mRNA. The missense mutation G307R was cloned into an expression vector for analysis of the transporter function in transfected cell lines. To do so, HEK293 cells were transfected with the mutated Asc-1 G307R together with h4F2hc. The latter represents an accessory subunit of the transporter required for transport of Asc-1 to the surface. Cells carrying both transporter subunits were incubated with [^{3}H]-glycine to determine uptake of labeled ligand in comparison to cells transfected with wild-type Asc-1. As a control, D-isoleucine incubation was used which is an inhibitor of Asc-1. The functional analysis of the mutated variant is under investigation. A previous knockout study of the Asc-1 (alanine-serine-cysteine) transporter in mice suggested Asc-1 as a novel gene for startle disease. Our data show that the human *SLC7A10* (Asc-1) indeed represents a novel candidate gene for human hyperekplexia.

Title: Ferroptosis and the molecular regulation of SLC7A11 in glioma

Authors: *R. A. UMANS[1], J. MARTIN[2], E. THOMPSON[2], H. SONTHEIMER[2];
[2]Ctr. for Glial Biol. in Health, Disease, and Cancer, [1]Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Ferroptosis, a non-apoptotic, iron-catalyzed cell death pathway, is mediated by reactive oxygen species and has been implicated in various forms of cancer. Ferroptosis studies have shown that the tumor suppressor gene, *p53*, negatively regulates the solute carrier *SLC7A11*. *SLC7A11* encodes the catalytic subunit for System XC, a cysteine/glutamate antiporter. *SLC7A11* is overexpressed in almost half of gliomas and is a marker of poor clinical prognosis. Coincidentally, *p53* is also mutated at a similar percentage in glioma. To date, ferroptosis has not been investigated in glioma but would further elucidate how high *SLC7A11* gliomas are more lethal *in vivo*. We hypothesize that *p53* negatively regulates *SLC7A11* in glioma and that high *SLC7A11* results in a higher concentration of antioxidant, protecting these cells from ferroptosis-induced oxidative cell death. To address this hypothesis, we have induced ferroptosis with the drug erastin in continuous and xenoline cultures with different *p53* and *SLC7A11* statuses. Additionally, we have performed biochemical assays for the roles of *p53* and *SLC7A11* in ferroptosis as well as chemically and genetically modulated the *p53* status in our cell lines. With these ferroptosis assays in vitro, we demonstrated sensitivity to ferroptosis in cell lines that have wild-type *p53* and lower *SLC7A11* expression status. Furthermore, wild-type *p53* cells can be protected from ferroptosis with a glutathione analog as well as conversely making mutant *p53* cells sensitive to ferroptosis by reactivating *p53*. Understanding the molecular regulation of *SLC7A11* in gliomagenesis would reveal potential therapeutic targets that may be protective for tumor progression. These therapies may also be used in conjunction with already approved *SLC7A11* inhibitors to more intently target the glioma cell population that promotes the bleak outcome in this CNS disease.

Title: Functional characterization of the mitochondrial na^{+}-ca^{2+} exchanger (nclx) in the peripheral nervous system using nclx knock-out mice

Authors: *J. RYSTED, Z. LIN, A. GNANASEKARAN, Y. USACHEV;
Pharmacol., Univ. of Iowa, Iowa City, IA

Abstract: In neurons, mitochondria efficiently buffer Ca^{2+} influx during excitation, and then release Ca^{2+} back into the cytosol, which helps shape $[Ca^{2+}]_i$ transients and regulates many Ca^{2+}-dependent neuronal functions such as excitability, neurotransmission, gene expression and neuronal survival. Past research has identified solute carrier from family 8 member B1 (SLC8B1, also known as NCLX) as the mitochondrial Na^{+}-Ca^{2+} exchanger. NCLX has been proposed to be one of the mechanisms involved in mitochondrial Ca^{2+} extrusion found in the inner mitochondrial membrane. However, the role of NCLX in neurons remains largely unknown. Using RT-PCR, we found that NCLX is expressed throughout the brain, and is also present in dorsal root ganglia (DRG) neurons. By simultaneously monitoring Ca^{2+} concentration in the cytosol ($[Ca^{2+}]_{cyt}$) and mitochondria ($[Ca^{2+}]_{mt}$) of cultured DRG neurons, we found that NCLX knockout (KO; Jackson Lab, C57BL/6J background) did not significantly alter the amplitude of depolarization-induced $[Ca^{2+}]_{cyt}$ or $[Ca^{2+}]_{mt}$ elevation as compared to WT animals. However, $[Ca^{2+}]_{cyt}$ and $[Ca^{2+}]_{mt}$ recovery to baseline in response to moderate and strong depolarization (30 mM, 50 mM KCl respectively, both for 30 s) was slowed by 2-3 fold, but not halted, in NCLX KO as compared to WT animals. In contrast, when $[Ca^{2+}]_{cyt}$ and $[Ca^{2+}]_{mt}$ elevations were elicited by trains of action potentials (5-8 Hz, 4-8 s) using extracellular field stimulation no significant difference was found between NCLX KO and WT DRG neurons in either recovery kinetics or amplitudes. In control experiments, we found that the pharmacological inhibitor of mitochondrial Na^{+}-Ca^{2+} exchanger, CGP37157 (3 and 10 μM) markedly slowed the recovery of $[Ca^{2+}]_{mt}$ to the baseline in both WT and NCLX KO. In addition, replacement of Na^{+} with Li^{+} did not significantly alter the ability of mitochondria to extrude Ca^{2+} from the mitochondrial matrix in DRG neurons. Collectively, our data suggest that NCLX contributes to Ca^{2+} extrusion from mitochondria in DRG neurons following large depolarization-induced $[Ca^{2+}]_i$ transients, but not

smaller ones evoked by electrical field stimulation. Our findings also point to the existence of additional, distinct from NCLX transporter(s) that mediate Ca^{2+} efflux from mitochondria in a CGP37157-sensitive manner in DRG neurons.

Title: Identification of a novel osmoregulatory membrane transporter in D. Melanogaster

Authors: *M. M. ERIKSSON[1], E. PERLAND[2], E. LEKHOLM[2], M. WILLIAMS[2], R. FREDRIKSSON[1];
[1]Pharmaceut. Biosci., [2]Neurosci., Uppsala Univ., Uppsala, Sweden

Abstract: Membrane bound transporters are vital for cell homeostasis since they translocate molecules over cellular membranes. Disturbances in membrane transporters are involved in several diseases and are therefore crucial to study; it is highly possible that knew drug targets will be discovered and causes of diseases identified among the so far unstudied transporters. We have identified a possible sugar transporter in *D.melanogaster* belonging to the major facilitatory superfamily Pfam clan, with homologues in rodent and humans. With the use of the UAS/Gal4 system, we visualize its expression in the malphigian tubuli, the flies' equivalent to our kidney, and hind gut, suggesting an involvement in osmoregulation. Ubiquitous knock down of the *CG4928* protein in fruit flies leads to a constantly increasing edema, which eventually kills the

flies. In the edema, there was approximately 40% increased sodium concentration, while the potassium concentrations were unaffected. Furthermore, flies lacking the CG4928 protein have decreased starvation resistance ($p>0.001$) as seen in a starvation test. By measuring the mRNA levels of *CG4928* in wild type flies, reduced expression was detected within 3-9h after food removal. Interestingly, the knock down flies have normal food intake, hence suggesting the phenotypical changes are due to metabolic disruption rather than food consumption. To understand what changes occur in the CG4928 knock down flies, RNA sequencing analysis was performed on knock down flies' vs controls, and it revealed changed expression of genes involved in sugar metabolism and sugar homeostasis. Hence it is plausible that CG4928 is a novel sugar transporter. This was elucidated further by studying the gene expression in flies raised on different diets.
We have identified a novel membrane bound transporter in fruit flies that is involved in osmoregulation over the malphigian tubule and the hind gut. Furthermore, we provide data claiming *CG4829* to be a novel sugar transporter.

Title: Characterization of solute carrier transporters in the brain

Authors: *S. BAGCHI, V. ARAPI, R. FREDRIKSSON;
Dept. of Pharmaceut. Biosciences, Mol. Neuropharm., Uppsala Univ., Uppsala, Sweden

Abstract: Glutamate is a key regulator in the brain and imbalance in the glutamine-glutamate cycle has been shown to cause numerous neuropsychiatric conditions, including anxiety, bipolar disorder and mood disorders. Drug targets within the glutamate system for neuropsychiatric diseases are currently lacking. We aim to functionally characterize transporters of solute carrier family 38, also named as sodium-coupled neutral amino acid transporters (SNATs) that are possibly involved in glutamine and glutamate transport during glutamine-glutamate cycle and can be potential drug targets. These transporters include 11 members that are expressed throughout the brain. SNAT6, one of the transporters within this family has already been reported to be exclusively expressed in the excitatory neurons and is localized at the synaptic membrane (Bagchi *et. al.* 2014, PLOS One). Due to its presence at the synaptic plasma membrane and clear interaction with SNARE (soluble N-ethylmaleimide-sensitive fusion protein attachment protein receptors) complex protein Snap25 and vesicular protein Synaptotagmin (Bagchi *et. al.* 2014, PLOS One), SNAT6 is a strong candidate for glutamine transport in the glutamine-glutamate cycle at the active zone where the synaptic vesicles are fusing to the synaptic membrane to release neurotransmitters at the synapses. We are using high-resolution Total internal reflection fluorescence (TIRF) microscopy and single molecule imaging to visualize SNAT6 in respect to secretory vesicles at the synaptic membrane. Our group is developing transgenic mice where SNAT6 is knocked out conditionally and we will then use material (brain tissue, spinal cord and other organs where transporters of interest are expressed as well as primary cell cultures from embryos) from them to confirm localization and specify further functions of these transporters with immuno-staining, Proximity Ligation Assay and uptake assays with quantum dot conjugated amino acids. This will enable us to put the puzzle pieces together and get a more complete picture of glutamine-glutamate system.

Politécnico Nacional-UPIBI, Ciudad de Mexico, Mexico; [5]Toxicology, Ctr. de Investigación y de Estudios Avanzados del IPN, México City, Mexico

Abstract: Mexico heads the first places with major number of persons sick with diabetes. National survey of Health and Nutrition reported that 20 percent of the diagnosed cases do not have access to any treatment, a 85.6 percent is treated by oral agents, whereas 6.2 percent do not use pharmacological therapy and that 13 percent uses insulin treatment or in combination. In Mexico, about 5000 species of plants have medicinal attributes. Ibervillea sonorae Greene belongs to Cucurbitaceae family and it is native to arid areas of northern of Mexico. Pharmacological studies showed that plant roots display hypoglycemic, antiinflammatory, antioxidant, antimicrobial and antifungal activities. A recent study conducted on human preadipocyte cells showed that aqueous root extracts from I. sonorae stimulate glucose uptake by a PI3K independent pathway. This evidence supports the antidiabetic properties attributed to I. sonorae root. This work, it is centered on the primary system of transport of glucose, on specific GLUT 1 and GLUT 3, due to the fact that its expression, regulation and activity play a basic role in the homeostasis neuronal. Roots of I. sonorae are washed with distilled water and dried at 40°C. The powder was extracted with 50 percent ethanol or water stirring occasionally. The extract was filtered and concentrated under reduced pressure on rotavapor and concentrated extract was spray-drying. To get of fractions of extracts of I. sonorae, five g of extract were separated by exclusion chromatography. One sought to determine the activity of watery and ethanol extracts of I. sonorae in the expression of the above mentioned carriers in an in vitro system using cells gliales of Bergmann (BGC) and neuronal granullar cells, for it technologies were used of western blot in solid phase and captures of glucose in cultures and hereby to evaluate the expression to level membranal. Glucose levels increase in capture assay and the GUT1 at maximum expression (572 percent at 4 hours). In case of the granullar cells, the same trends were observed in the capture and the expression of GLUT3 (371.22 percent at 4 h). The effect of fractions of I. sonorae showed a differential effect in the Glucose Transport in CBG. We conclude that the GLUT1 and GLUT3 expression and the glucose capture support a directly proportional relation under stimuli of I. sonorae to 0.1 percent w/v. The ethanolic extract promoted the capture of glucose in more than the acuose extract to the same concentration. I. sonorae promoted in major measure the carriers' expression of glucose in astrocytes that in neurons.

Title: Functional characterization of an amino acid transporter situated in the Golgi apparatus

Authors: *K. NORDENANKAR, F. LINDBERG, R. FREDRIKSSON;
Uppsala Univeristet, Mol. Neuropharm., Uppsala, Sweden

Abstract: Solute carriers (SLCs) are the largest class of membrane bound transporters proteins. Many of them are neuronal amino acid transporters with important functions in cellular processes, including role as transporters for amino acids between cells and for neurotransmitter cycling. The SLC38 family includes eleven members and are also called sodium-coupled neutral amino acid transporters (SNATs). Glutamine appears as a favored substrate for most of the members throughout the SNAT family. Glutamine is the most abundant amino acid in the human body and is involved in more physiological processes than any other amino acid such as providing ATP for intracellular protein turn over, nutrient transport through the plasma membrane, cell growth and migration as well as maintenance of cell integrity. Here we now report the functional characterization of the SNAT10 transporter by using gene targeting. We have produced a conditional knock out mouse for SNAT10, based on the 'knockout-first' design, a strategy that combines the advantages of both a reporter-tagged and a conditional mutation. By utilizing different behavioral paradigms, including rotarod, beam walking, elevated plus maze and marble burying test we are investigating the basal motor, cognitive and emotional behavior of the mice. We also characterized the localization of the protein, using immunohistochemistry on mice brain at different developmental stages and embryonic cell cultures.

Title: Potentiation of presynaptic glutamate release by pregnanolone sulfate: mechanisms and implications for neuroprotection

Authors: *T. SMEJKALOVA, D. CHUDA, L. VYKLICKY;
Inst. of Physiology, CAS, Praha, Czech Republic

Abstract: Tonic NMDAR activation by elevated extracellular glutamate mediates excitotoxicity, but phasic NMDAR activation by synaptically released glutamate can be neuroprotective. Thus, optimal neuroprotection may be achieved by blocking tonically but not synaptically activated NMDARs. Recently, we have shown that endogenous neurosteroid pregnanolone sulfate (PA-S) has better selectivity for inhibiting tonically over synaptically activated NMDARs than memantine, an NMDAR inhibitor with known neuroprotective effects. At the same time, PA-S, unlike memantine, potentiates presynaptic glutamate release. The mechanism of the presynaptic potentiation by PA-S, and the consequences of increased synaptic glutamate release for PA-S neuroprotection are unknown. To characterize the mechanism of the presynaptic potentiation by PA-S, we compared presynaptic effects of PA-S and a structurally similar neurosteroid pregnenolone sulfate (PE-S), which has been shown to increase mEPSC frequency in primary hippocampal cultures via a pertussis toxin (PTX)-sensitive mechanism. Our recordings of mEPSCs in hippocampal microisland cultures reveal a striking variability in the PE-S effect, not previously appreciated from recordings in mass cultures. PE-S (30 μM) increases mEPSC frequency in autaptic neurons 0- to 50-fold (average normalized mEPSC frequency in PE-S is 8.92 ± 5.49, $n = 9$; $p < 0.05$). As expected, pretreatment of cells with PTX (500 ng/ml for 24 h) blocks the PE-S effect (normalized mEPSC frequency in PE-S in PTX-treated cells is 1.35 ± 0.27, $n = 6$, $p = 0.16$). In contrast, PA-S (100 μM) consistently increases mEPSC frequency and this effect is insensitive to PTX (normalized mEPSC frequency in PA-S is 3.20 ± 0.42 in control cells, $n = 6$, $p < 0.05$; and 4.53 ± 1.11 in PTX-treated cells, $n = 4$, $p < 0.05$). We conclude that PA-S and PE-S potentiate glutamate release by different mechanisms. Increased synaptic glutamate release in PA-S may contribute to toxic glutamate buildup and thus reduce PA-S neuroprotective potential. We compared neuroprotection against *in-vitro* hypoxia by 200 μM PA-S vs.10 μM memantine; these concentrations cause similar tonic NMDAR inhibition, but memantine has no known presynaptic effect. Using primary hippocampal cultures stained with propidium iodide and Hoechst 33342, we find $37 \pm 4\%$ neuronal death after 3 h hypoxia, in

contrast to only 11 ± 4% neuronal death after hypoxia with 200 µM PA-S, and 15 ± 3% neuronal death after hypoxia with 10 µM memantine (n = 5, ANOVA $p < 0.05$). These results show no evidence of a toxic effect of the glutamate release potentiation by PA-S and confirm that neurosteroids are a promising class of NMDAR inhibitors with clinical potential.

Abstract: The detection of neurotransmitter release gives us a lot of knowledge about neuronal conditions and differentiations. In order to observe the spatio-temporal transmitter release in cerebellar cortex, we have developed the enzyme-linked photo- assay system for glutamate and GABA, with an immobilized specific enzyme on a quartz surface and the CMOS camera. Using this device, we have succeeded in visualizing region-specific transmitter releases in both the developing and juvenile cerebellar slices. However it has been unclear whether this system could apply the detection of the transmitter release from cultured cells, because background autofluorescence derived from mitochondria in individual cells might be more significant than the target fluorescence. In order to discriminate the target signal from background fluorescence, we proposed a new simple device for visualizing the neurotransmitter release. In this device, we irradiated the samples with two UV-LED lights aligned with different angles, and analyzed the data by using the independent component analysis (ICA). The mixture ratios of the target and background signals of two images derived from two UV lights, were different, so that the target signal could be separated by the ICA. Using this improved system, we observed the stimulation-evoked releases in developing cerebellar slices distinctly. So, we next investigated whether this

new system can detect glutamate release at single-cell level using cultured rat cerebellar granule cells, or the cells differentiated from rat neurosphere. Granule cells were derived from neonatal rat cerebellar external layer and cultured for a week in high K^+ conditioned medium. Cultured neural stem/progenitor cells derived from rat embryo were proliferated in a medium containing bFGF and differentiated by removing bFGF and EGF for several weeks. Both differentiated cultured cells were stimulated with 10 μM AMPA, and stimulation-induced glutamate release was detected. We suggest that the new photo- assay device would become useful to detect cell-level neurotransmitter release.

Title: The concentration of extracellular glutamate in the nucleus accumbens

Authors: *D. CHIU, C. E. JAHR;
OHSU, Vollum Inst., Portland, OR

Abstract: Glutamate is present in the extracellular space surrounding neurons and glia, and the concentration of extracellular glutamate has implications for glutamate receptor availability and function. Predicting these effects has been difficult, however, as measurements of extracellular glutamate by different techniques have yielded estimates ranging over 3 orders of magnitude, from 25 nM to >10 μM. One possible explanation for this discrepancy is the existence of a glutamate gradient across the extracellular space, maintained by glutamate transporters (EAATs), with micromolar glutamate in the non-synaptic extracellular space, and nanomolar glutamate in synaptic clefts. In this study we used electrophysiology and two-photon calcium imaging to investigate the concentration and distribution of extracellular glutamate in rat nucleus accumbens (NAc).

In voltage clamp recordings from medium spiny neurons (MSNs) in acute slices, 100 μM D-AP5 blocked a standing current at +40 mV, indicating that NMDARs were activated by extracellular glutamate. The inhibited current corresponded to activation by ~30 nM glutamate, similar to the value obtained by measurements made in hippocampal slices. Using two-photon calcium imaging of dendritic spines, we observed spontaneously occurring, D-AP5-sensitive calcium excursions that were infrequent, consistent with activation of single NMDARs by nanomolar glutamate.

To test if there is compartmentalization of extracellular glutamate, we inhibited EAATs with TBOA. In 100 μM TBOA, with the barrier to diffusion between compartments removed, the rate of observed events increased more than two-fold. Two findings suggest that the increase in synaptic NMDAR activation reflects exposure to nanomolar and not micromolar glutamate. First, the rate of events also doubled in the presence of 5 μM NMDA, which is commensurate with ~100 nM glutamate. Second, the current evoked by 100 μM TBOA at +40 mV was smaller than the current evoked by 10 μM NMDA, indicating that, even with glutamate transport inhibited, the average concentration at all NMDARs is less than 200 nM.

These results indicate that extracellular glutamate in the NAc is in the low nanomolar range, and

are not consistent with the presence of micromolar glutamate in any compartment of the extracellular space.

Title: Synapse specific physiology of somatostatin interneurons is driven by Elfn1 mediated presynaptic recruitment of mGluR7 and GluR6-containing kainate receptors.

Authors: *T. J. STACHNIAK[1], E. L. SYLWESTRAK[2,1,3], B. J. HALL[1], A. GHOSH[4,1]; [1]Roche Innovation Ctr. Basel, Basel, Switzerland; [2]Bioengineering, Stanford Univ., Stanford, CA; [3]Biozentrum, Univ. of Basel, Basel, Switzerland; [4]E-Scape Bio, San Francisco, CA

Abstract: Excitatory synapses onto somatostatin (SOM) interneurons are highly facilitating. Here we show that this facilitation requires assembly of a synaptic protein complex containing Elfn1, metabotropic glutamate receptor 7 (mGluR7), and glutamate receptor 6 subunit (GluR6)-containing kainate receptors. The striking facilitation seen in cortical layer 2/3 (L2/3) and the CA1 region of hippocampus is lost in Elfn1 knockout mice. Notably, synapses onto layer 5 (L5) cortical SOM interneurons that facilitate sub-optimally are less affected in Elfn1 knockout, compared to synapses onto L2/3 or hippocampal interneurons. Application of the GluR6 selective antagonist NS-102 reduces facilitation in L2/3 but not in L5, whereas both synapse types are sensitive to mGluR7 inhibition. Thus we identify GluR6 containing presynaptic kainate receptors as necessary to generate the characteristic facilitation typical of L2/3. Further, the strong synaptic facilitation visible in L2/3 can be attributed to two separate mechanisms: the actions of mGluR7 produce early facilitation within a spike train, while late facilitation in a spike train is primarily GluR6 dependent. As the proteomic content determines synaptic properties in L2/3 and L5, we have identified both an early, constitutive synaptic component and a late, discretionary synaptic component which expand the repertoire of synaptic physiological responses available through a stepwise construction of the synaptic proteome.

Title: vGluT3+ cells in the mouse hippocampus exhibit diverse physiological properties

Authors: *C. A. BURLESON, A. BENZ, S. MENNERICK;
Dept of Psychiatry, Washington Univ. in St. Louis, Saint Louis, MO

Abstract: An essential component of neuron identity is neurotransmitter phenotype, which in turn is defined in part by the vesicular neurotransmitter transporter(s) expressed by the cell. The vesicular glutamate transporter-3 (vGluT3) has been noted for its unique distribution in the rodent brain; vGluT3 is often found in cells co-expressing markers for other neurotransmitter phenotypes. Furthermore, vGluT3 can be found in several cell populations lacking neuronal markers. The vGluT3 expression of the rodent hippocampus exemplifies this heterogeneity; in addition to being found in a neuronal population of CCK+ GABAergic basket cells, vGluT3 has been reported in cells lacking neuronal markers. While this unusual molecular phenotype of basket cells has been noted by several labs, little is known about the physiological characteristics of these cells, and presence of vGLUT3 has proven controversial. Here, we use a mouse line expressing the fluorescent protein tdTomato under control of VGLUT3 (VGLUT3-tdTomato) to study vGluT3+ hippocampal cells in acute brain slices. We first confirmed the presence of vGluT3 in tdTomato cells via immunohistochemistry. Then, based on membrane electrical properties, location, and morphology, we identified three unique cell types expressing vGluT3: 1. basket cell-like spiking neurons predominantly in the mossy fiber pathway of CA3 and stratum radiatum of CA1; 2. glia-like non-spiking, low input resistance cells with negative resting membrane potentials relative to the neuronal population predominantly found in the hilus of the dentate gyrus; and 3. high input resistance cells that responded to current injection with low amplitude “spikelets”, found throughout several hippocampal regions. Furthermore, the spiking

neurons exhibited different membrane properties in different hippocampal subregions . CA3/CA2 spiking neurons exhibited stronger excitability, including higher input resistances and faster spiking rates in response to current injection, compared to those found at the CA1/subiculum border. Most notably, CA3 neurons but not CA1 neurons exhibited depolarizing sag, typically attributed to h-type current, upon negative current injection. Taken together, our work demonstrates the unique distribution of vGluT3 in the hippocampus and begins to dissect the novel roles vGluT3+ cells can play in the hippocampal circuitry.

Title: Ambient glutamate tonically excites cortical interneurons via NMDA receptor activation during early postnatal development: implications for neonatal epileptogenesis

Authors: *E. HANSON, C. DULLA;
Neurosci., Tufts Univ., Boston, MA

Abstract: Astrocytic glutamate transport changes significantly through postnatal development and is highly responsive to injury. Effective glutamate transport is important for regulating concentrations of ambient glutamate, yet surprisingly little is known about both the developmental regulation of ambient glutamate and the effect of neonatal injury on ambient glutamate-mediated tonic excitation. To better understand the role of tonic excitatory signaling in normal cortical development and epileptogenesis we have examined (1) how ambient glutamate is developmentally regulated in the postnatal cortex, (2) cell-type specific tonic excitation mediated by NMDA receptors, and (3) disruptions in ambient glutamate regulation during injury-induced epileptogenesis. First, we used whole-cell voltage clamp electrophysiology to measure relative concentrations of ambient glutamate in the developing cortex of C57 mice. We found that relative concentrations of ambient glutamate are sharply and transiently elevated at P7-P8. To investigate the consequences of elevated ambient glutamate, we used whole-cell current clamp electrophysiology to measure the resting membrane potential and firing properties

of cortical interneurons (INs) and PCs. We found that INs but not PCs are tonically depolarized by NMDAR-mediated currents. Furthermore, in the same cells, blockade of these currents with APV decreased IN but increased PC action potential firing. These results suggest a difference in the voltage dependence of the NMDAR-mediated tonic current between INs and PCs, potentially due to differential expression of NR2C and NR2D NDMAR subunits. We then utilized the neonatal freeze lesion (FL) model to study glutamate regulation during the development of hyperexcitability. Induction of a FL at P0 is followed by a two week latent period during which a microgyrus develops in the cortex under the injury site. By P14 the paramicrogyral zone (PMZ) is hyperexcitable. Intriguingly, immunofluorescence revealed increased expression of the glutamate transporters GLT-1 and GLAST in PMZ during the FL latent period. Using whole-cell voltage clamp electrophysiology, we found that the transient elevation in ambient glutamate is abolished in the PMZ, but maintained in contralateral cortex. Furthermore, preliminary data suggest that the reduction in ambient glutamate corresponds to a decrease in tonic excitation of cortical INs. The consequences for acute network activity and long-term connectivity remain to be investigated, however, these results suggest that reduced tonic excitation of INs is a potential mechanism driving the development of hyperexcitability in the FL cortex.

Abstract: Glutamate is the most abundant excitatory neurotransmitter and plays key roles in normal brain functions, including cognition, memory and learning. It is a nonessential amino acid and does not cross the blood brain barrier. Thus it must be synthesized in neurons from local precursors. Glutamate can be synthesized from glucose through glycolysis and the Krebs cycle, however glutamine is the most recognized precursor for the biosynthesis of glutamate in the synaptic terminals. Alternatively, a possible route for glutamate biosynthesis in the brain is from proline via delta-1-pyrroline-5-carboxylate (P5C) via its tautomer, glutamic-gamma-semialdehyde (GSA). This biosynthetic pathway is sequentially catalyzed by the enzymes proline oxidase/dehydrogenase (POX/PRODH) and P5C dehydrogenase (P5CDH). Moreover, proline metabolism is unique, since P5C, the immediate product of proline catabolism, also serves as the precursor for proline biosynthesis. P5C can be generated from glutamate via the enzymatic activities of P5C synthase (P5CS) and P5C reductase (P5CR). Furthermore, glutamine can also be converted to proline via glutamate. However, the role of these metabolic interconversions in neuronal function is not clearly understood. Therefore, we are investigating the functional link between proline metabolic pathway and glutamine-glutamate metabolism in neurons. To test this we selectively supplemented glutamine to the HT-22 rat hippocampal neurons and measured the effects on the proline metabolic pathway. Our preliminary results revealed that the enzymes of the proline catabolic arm, POX and P5CDH, were minimally affected by glutamine supplementation. In contrast, the enzymes involved in proline biosynthesis from glutamate, P5CS and the two isoforms of P5CR, were induced. We also detected higher intracellular levels of proline in these cells. These results strongly suggest that glutamine is directed toward the biosynthesis of proline most likely via glutamate. Currently, we are conducting experiments to determine the effects of increased biosynthesis of proline in neuronal function.

Title: Stable isotope labeled L-kynurenine (KYN) metabolism investigated using *In vivo* microdialysis coupled with a novel high content LC/MS/MS method

Authors: D. P. BUDAC[1], D. SONG[1], M. CAJINA[1], A. LEE[1], B. M. CAMPBELL[1], G. LI[1], C. SÁNCHEZ[1], *C. FORRAY[1], V. S. PALAMARCHOUK[2], G. N. SMAGIN[1,2];
[1]Lundbeck USA, Paramus, NJ; [2]PsychoGenics Inc, Tarrytown, NY

Abstract: Degradation of the amino acid tryptophan along the kynurenine pathway (KP) yields several neuroactive intermediates regulated by enzymes localized in astrocytes and microglial cells. The limited ability of many KYN-derived metabolites to cross the blood brain barrier suggests that CNS concentrations of these metabolites is largely regulated by local enzyme activity. KYN itself is actively transported into the brain by large neutral amino acids transporter. The fate of KYN in the brain is poorly understood and was investigated using a stable labeled analogue of KYN ([$^{13}C_6$]L-KYN) and in vivo microdialysis A sensitive LC/MS/MS method was developed and utilized to provide a time course for stable isotope labeled metabolite formation. Mice and rats were implanted with guide cannula placed into the striatum. One week after surgery, a microdialysis probe was inserted for the microdialysis experiment. Microdialysis samples were collected for 6 hrs after i.p. administration of 5 mg/kg of [$^{13}C_6$]L-KYN and analyzed for labeled and unlabeled *L*-kynurenine (KYN), kynurenic acid (KYNA), 3-hydroxykynurenine (3-HK), 3-hydroxyanthranilic acid (3-HAA) and quinolinic acid (QUIN), using LC/MS/MS method. In mice, [$^{13}C_6$]L-KYN metabolism showed a stronger kynurenine 3-monooxygenase (KMO) branch response with increased incorporation of ^{13}C label in 3-HK, 3-HAA, and QUIN. [$^{13}C_6$]L-KYN metabolism in rats progressed predominantly down the kynurenine aminotransferase (KAT) pathway as suggested by the higher amounts of labeled KYNA. The results demonstrate the utility of LC/MS/MS analysis of stable isotope labeled KP metabolite from in vivo microdialysis samples since this type of technique can be utilized to delineate the role of central and peripheral KP metabolites in diseases involving dysregulation of kynurenines metabolites. Further studies of brain-penetrable modulators of KP may be beneficial for the treatment of these diseases.

Abstract: Degradation of the amino acid tryptophan (TRP) along the kynurenine pathway (KP) yields several neuroactive intermediates regulated by enzymes localized in astrocytes and microglial cells. Impairment of KP metabolism is functionally significant in a variety of diseases that affect the brain. It is hypothesized that CNS penetrant small molecules which inhibit kynurenine 3-monooxygenase (KMO) normalize central kynurenine dysregulation and will be beneficial for CNS disorders. We identified a CNS penetrant KMO inhibitor Compound A and characterized its effect on central and peripheral KP metabolites after systemic administration. We demonstrated that by extending the analyte capacity of an LC/MS/MS method, dedicated to KP metabolite, to include drug molecules we could simultaneously monitor KP metabolites and drug compounds in one injection. Utilizing this technique alongside in vivo microdialysis allows us to perform direct comparisons of drug levels and their impact on KP metabolites over a time course.
Mice were implanted with the guide cannula placed into the striatum. One week after surgery, a microdialysis probe was inserted for the microdialysis experiment. Microdialysis samples were collected for 6 hrs after 30 and 100 mg/kg administration of Compound A and analyzed for Compound A, L-kynurenine (KYN), kynurenic acid (KYNA), 3-hydrohykynurenine (3-HK) and quinolinic acid (QUIN), using LC/MS/MS Terminal brain and plasma samples were taken for analysis of KP metabolites and compound exposure.
Administration of Compound A decreased concentrations 3-HK to 60% of baseline which co-incided with the increased concentration of Compound A in dialysis samples. Initial decrease in 3-HK concentrations was followed by a two-fold increase after 6 hrs. Concentrations of KYN, KYNA and QUIN in microdialysates collected from the brain increased 75-fold, 350-fold and 2-fold respectively, compared to vehicle control. The increase lasted through the six hour observation period. KYN and KYNA levels were also elevated in terminal brain and plasma

samples collected at the 6 hour mark. The results demonstrate that CNS penetrant KMO inhibitors while affecting both central and peripheral KP metabolites provide an avenue to understanding the biological role of these metabolites in brain disorders. Further studies of brain-penetrating modulators of KP may provide treatment options for such disorders.

Title: Verification of the cross immunoreactivity of A60, a mouse monoclonal antibody against neuronal nuclear protein

Authors: ***M. SHANPING**[1], X. GUOXIANG[2];
[1]Renmin Hosp. of Wuhan Univ., Hubei, China; [2]Dept. of Anesthesiol. and Critical Care Medicine, Children's Hosp. of Philadelphia, Philadelphia, American Samoa

Abstract: A60, the mouse monoclonal antibody against the neuronal nuclear protein (NeuN), is the most widely used neuronal marker in neuroscience research and neuropathological assays. Previous studies identified fragments of A60-immunoprecipitated protein as Synapsin I (Syn I), suggesting the antibody will demonstrate cross immunoreactivity. However, the likelihood of cross reactivity has never been verified by immunohistochemical techniques. Using our established tissue processing and immunofluorescent staining protocols, we found that A60 consistently labelled mossy fiber terminals in hippocampal area CA3. These A60-positive mossy fiber terminals could also be labelled by Syn I antibody. After treating brain slices with saponin

in order to better preserve various membrane and/or vesicular proteins for immunostaining, we observed that A60 could also label additional synapses in various brain areas. Therefore, we used A60 together with a rabbit monoclonal NeuN antibody to confirm the existence of this cross reactivity. We showed that the putative band positive for A60 and Syn I could not detected by the rabbit anti-NeuN in Western blotting. As efficient as Millipore A60 to recognize neuronal nuclei and cell bodies specifically, the rabbit NeuN antibody demonstrated no labelling of synaptic structures in immunofluorescent staining. The present study successfully verified the cross reactivity present in immunohistochemistry, cautioning that A60 may not be the ideal biomarker to verify neuronal identity due to its cross immunoreactivity. In contrast, the rabbit monoclonal NeuN antibody used in this study may be a better candidate to substitute for A60.

Title: Inhibition of large neutral amino acid transporters suppresses kynurenic acid production via inhibition of kynurenine uptake in rodent brain

Authors: A. SEKINE, Y. KUROKI, T. URATA, N. MORI, *T. FUKUWATARI;
Dept. of Nutr., The Univ. of Shiga Prefecture, Hikone, Japan

Abstract: The tryptophan metabolite, kynurenic acid (KYNA), is a preferential antagonist of the α7 nicotinic acetylcholine receptor and *N*-methyl-D-aspartic acid receptor at endogenous brain concentrations. Recent studies have suggested that increases of brain KYNA levels are involved in psychiatric disorders such as schizophrenia and depression, and regulation of KYNA production has become a new target for treatment of these diseases. Kynurenine (KYN), the immediate precursor of KYNA, is transported into astrocytes via large neutral amino acid transporters (LATs). We have recently reported that several LATs substrate amino acids (leucine, isoleucine, phenylalanine, methionine and tyrosine) reduce KYN uptake and KYNA production in rat brain *in vitro* (*SpringerPuls* 2015;4:48). In the present study, the effect of LATs regulation on KYN uptake and KYNA production was investigated *in vitro* and *in vivo* using an LATs inhibitor, 2-aminobicyclo-(2,2,1)-heptane-2-carboxylic acid (BCH). In the *in vitro* study, cortical slices of rat brain were incubated with a physiological concentration of KYN and 3

μmol/L-3 mmol/L BCH. BCH inhibited KYNA production and KYN uptake in a dose-dependent manner, and their IC_{50} values were 90.7 and 97.4 μmol/L, respectively. In the *in vivo* study, mice were administered KYN (50 mg/kg BW) orally and BCH (200 mg/kg BW) intravenously. Administration of KYN increased brain KYN and KYNA levels compared with the mice treated with vehicle, whereas additional administration of BCH suppressed KYN-induced elevations in KYN and KYNA levels to 50% and 70% in the brain, respectively. These results suggest that inhibition of LATs prevented the increase of KYNA production via blockade of KYN uptake in the brain *in vitro* and *in vivo*. LATs can be a target to modulate brain function by regulation of KYNA production in the brain.

Title: Synapse maturation and stabilization of axonal branches is promoted by D-serine in the developing visual system of the Xenopus tadpole.

Authors: *M. VAN HORN[1], A. STRASSER[1], L. POLLEGIONI[2], E. RUTHAZER[1]; [1]Neurol. and Neurosurg., McGill Univ., Montreal, QC, Canada; [2]Dept. of Biotech. and Life Sci., Univ. Insubria, Varese, Italy

Abstract: N-methyl-D-aspartate receptor (NMDAR) activation is essential for establishing and maintaining precise neural circuit refinement. The gliotransmitter D-serine is a co-agonist for NMDARs and modulates synaptic transmission and plasticity mediated by this receptor. Here we investigated the role D-serine plays in modulating synaptic transmission and axonal remodeling in the developing visual system of the Xenopus tadpole. We find that D-serine is an endogenous co-agonist of the NMDAR that is normally present below saturating levels. Using enzymatic biosensors we find that D-serine release in the optic tectum can be driven by glutamatergic activation and find that facilitating NMDAR activation by chronically elevating levels of D-serine promotes the maturation of functional synapses. In particular, we find that tadpoles raised

in D-serine (100 μM) for 2 days have a higher frequency of AMPAR-mediated miniature excitatory postsynaptic currents (mEPSCs) and higher retinotectal synaptic AMPA/NMDA ratios compared to control animals. Moreover, animals raised in D-serine have significantly lower paired-pulse facilitation, consistent with a developmental increase in release probability. In contrast, acute wash-on of D-serine does not change the frequency or amplitude of mEPSCs or the probability of release at retinotectal synapses, indicating that D-serine does not facilitate release simply by acting directly on presynaptic neurons. Decreasing levels of endogenous D-serine, with a local injection of RgDAAO, reduces NMDAR-mediated synaptic transmission and results in deficits in synaptic maturation over 24 h. To examine the effects of D-serine on retinotectal axonal development, *in vivo* 2-photon images of single-transfected GFP-expressing retinal ganglion cell axons were collected daily over 4 days to assess growth and branch elaboration, and at shorter (10 min) intervals to assess branch dynamics. We find that increasing available D-serine results in the hyperstabilization of retinal axon branches. Axonal arbors remain less complex compared to control axons over 4 days of treatment with D-serine. Together, these findings reveal an important role for D-serine in promoting NMDAR-mediated synaptic maturation and stabilization of axonal branches.

Abstract: Background: The D-amino acid, D-alanine, is a N-Methyl-D-Aspartate (NMDAR) co-agonist and a strychnine-sensitive glycine receptor (GlyR) agonist, and is sequestered in adrenocorticotropic hormone (ACTH)-containing cells of the rodent pituitary, and may influence neural function through the modulation of stress hormones such as corticosterone. An exacerbated response of the hypothalamo-pituitary-adrenal (HPA) axis to stress is a common feature of major psychiatric disorders. However, the role of D-alanine in the modulation of the HPA axis is not known. Previous studies have shown that ACTH secretion from pituitary cells involves CREB and ERK1/2 signalling. We have, therefore, investigated the influence of D-

alanine on the levels of signalling proteins in cultures of the AtT20 mouse pituitary tumour cell-line. For comparison, the effect of D-serine, a co-agonist of central NMDARs but not GlyRs, was also examined. **Methods:** In one experiment, cultures of AtT-20 mouse pituitary cell line (2 X 10^5 cells per well) were incubated with control solution (culture media), D-alanine or D-serine (100, 200 and 500μM) for 24 hours. In a second study, cells were incubated with D-serine or D-alanine (500μM) for 24hrs, and then stimulated with CRH (100nM) for 5 and 15mins. At the end of each experiment, cells were lysed and protein extracted using standard procedures. All samples were analysed with western blotting, using specific antibodies against total CREB and ERK1/2, their phosphorylated (active) counterparts (pCREB, pERK1/2), and b-actin. All data were expressed as ratios (pCREB/CREB, pERK/ERK, CREB/β-actin, ERK/β-actin), and subjected to one-way ANOVA statistics. **Results:** Compared to controls, the levels of CREB/β-actin were significantly greater in AtT20 cells incubated with 500μM of D-alanine (+34%, p=0.011) or D-serine (+28%, p= 0.028). The levels of pCREB/CREB were also significantly greater in cells incubated with D-alanine (+25%, p=0.042), but not D-serine. The concentrations of pERK/ERK and ERK/β-actin are currently being assessed in these samples. The stimulation of cells with CRH in the absence or presence of D-alanine did not alter pERK/ERK or ERK/β-actin levels. Studies are now underway to evaluate CREB signalling in these samples, and in the pituitaries, hypothalamus and adrenals of rats administered with D-alanine or D-serine. Our data thus far, show that both D-amino acids stimulate intracellular CREB signalling in a pituitary cell-line, although D-alanine was with greater effect. Since CREB mediates ACTH secretion, manipulation of D-alanine levels in the pituitary may be therapeutically beneficial in stress-mediated disorders.

Title: The ascending projections from the median raphe region are mainly glutamatergic in the mouse forebrain

Authors: *A. SZONYI[1], M. I. MAYER[1], C. CSEREP[1], V. T. TAKACS[1], M. WATANABE[2], T. F. FREUND[1], G. NYIRI[1];

Abstract: The median raphe region (MRR) is thought to be serotonergic and plays an important role in the regulation of many cognitive functions. In the hippocampus (HIPP), the MRR exerts a fast excitatory control, partially through glutamatergic transmission, on a subpopulation of GABAergic interneurons that are key regulators of local network activity. However, not all receptors of this connection in the HIPP and in synapses established by MRR in other brain areas are known. Using combined anterograde tracing and immunogold methods, we show that the GluN2A subunit of the NMDA receptor is present in the synapses established by MRR not only in the HIPP, but also in the medial septum (MS) and in the medial prefrontal cortex (mPFC) of the mouse. We estimated similar amounts of NMDA receptors in these synapses established by the MRR and in local adjacent excitatory synapses. Using retrograde tracing and confocal laser scanning microscopy, we found that the majority of the projecting cells of the mouse MRR contain the vesicular glutamate transporter type 3 (vGluT3). Furthermore, using double retrograde tracing, we found that single cells of the MRR can innervate the HIPP and mPFC or the MS and mPFC simultaneously, and these double-projecting cells are also predominantly vGluT3-positive. Our results indicate that the majority of the output of the MRR is glutamatergic and acts through NMDA receptor-containing synapses. This suggests that key forebrain areas receive precisely targeted excitatory input from the MRR, which is able to synchronously modify activity in those regions via individual MRR cells with dual projections.

Title: Cellular architecture and transmitter phenotypes of neurons of the mouse median raphe region

Authors: *K. E. SÓS, M. I. MAYER, C. CSEREP, F. S. TAKACS, A. SZONYI, T. F. FREUND, G. NYIRI;

Abstract: The median raphe region (MRR, which consist of MR and paramedian raphe regions) plays a crucial role in regulating cortical as well as subcortical network activity and behavior, while its malfunctioning may lead to disorders, such as schizophrenia, major depression, or anxiety. Mouse MRR neurons are classically identified on the basis of their serotonin (5-HT), vesicular glutamate transporter type 3 (VGLUT3), and gamma-aminobutyric acid (GABA) contents; however, the exact cellular composition of MRR regarding transmitter phenotypes is still unknown. Using an unbiased stereological method, we found that in the MR, 8.5 % of the neurons were 5-HT, 26 % were VGLUT3, and 12.8 % were 5-HT and VGLUT3 positive; whereas 37.2 % of the neurons were GABAergic, and 14.4 % were triple negative. In the whole MRR, 2.1 % of the neurons were 5-HT, 7 % were VGLUT3, and 3.6 % were 5-HT and VGLUT3 positive; whereas 61 % of the neurons were GABAergic. Surprisingly, 25.4 % of the neurons were triple negative and were only positive for the neuronal marker NeuN. PET-1/ ePET-Cre transgenic mouse lines are widely used to specifically manipulate only 5-HT containing neurons. Interestingly, however, using the ePET-Cre transgenic mice, we found that far more VGLUT3 positive cells expressed ePET than 5-HT positive cells, and about 38 % of the ePET cells contained only VGLUT3, while more than 30 % of 5-HT cells were ePET negative. These data should facilitate the reinterpretation of PET-1/ePET related data in the literature and the identification of the functional role of a putatively new type of triple-negative neuron in the MRR.

Title: Constitutive phosphomimetic KCC2 inhibition in developing mice causes GABA-dependent network excitability and autistic-like behavior

Authors: *L. I. PISELLA[1], I. KHALILOV[1], D. DIABIRA[1], J. ZHANG[2,3], J. DUAN[3,4], I. MEDINA[1], K. T. KAHLE[4], J.-L. GAIARSA[1,2];

Abstract: Models of epilepsy, intellectual disability, and autism spectrum disorders (ASDs) exhibit an altered GABAergic excitatory-inhibitory (E-I) developmental sequence due to dysregulated neuronal Cl- homeostasis. A post-natal decrease of neuronal $[Cl^-]_i$, establishing fast synaptic inhibition, is mediated by the Cl^-- extruding K+-Cl− cotransporter KCC2. KCC2 is inactive in immature neurons due in part to its phosphorylation at Thr^{906} and Thr^{1007}. During development, Thr^{906}/Thr^{1007} phosphorylation significantly decreases in parallel with an increase in KCC2 activity and a lowering of neuronal $[Cl^-]_I$. To determine the functional importance of regulated Thr^{906}/Thr^{1007} phosphorylation during development *in vivo*, we assessed the neuronal network properties and neurobehavior of KCC2 mice expressing one allele harboring the missense mutations Glu^{906} and Glu^{1007} "(*KCC2*$^{e/+}$)" that mimick constitutive KCC2 Thr^{906}/Thr^{1007} phopshorylation. Field potential and patch-clamp recordings from CA3 pyramidal neurons on acute slices showed that GABAergic responses remained excitatory in *KCC2*$^{e/+}$ mice up to postnatal day 20, indicating a significant delay in the GABAergic E-I sequence. CA3 pyramidal cells from *KCC2*$^{e/+}$ animals also displayed significantly increased seizure-like activity in response to application of 5 µM 4-amidopyridine, and a decreased ratio of spontaneous GABA-driven to glutamate-driven post-synaptic responses. *KCC2*$^{e/+}$pups (P10) emitted more ultra-sound vocalizations than WT littermates when separated from their mother, a characteristic autistic-like behavior. These data demonstrate the importance of regulated phosphorylation of KCC2 at Thr^{906}/Thr^{1007} for Cl^--dependent GABA signaling and neurodevelopment, and suggest alterations in this mechanism may contribute to the synaptic and behavioral excitability of ASDs.

Title: $GABA_A$ receptor reversal potential as a reporter for cation-chloride co-transporter activity in Xenopus oocytes

Authors: *F. KNOFLACH[1], M.-C. HERNANDEZ[1], M. SAXE[1], S. BERTRAND[2], D. BERTRAND[2];
[1]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [2]HiQScreen Sàrl, Geneva, Switzerland

Abstract: Potentiation of the γ-amino-butyric acid receptor type A ($GABA_A$) receptor is the widely recognized mechanism of therapeutically effective drugs like diazepam. However, less is known about the mechanism controlling intracellular chloride concentration, which determines the inhibitory vs excitatory activity of $GABA_A$ receptors. Development of compounds modulating inhibitory neurotransmitter responses requires a better understanding of the exact contribution of the sodium, potassium, and chloride co-transporters, also referred to as CCCs (cation-chloride co-transporters) in establishing and maintaining chloride homeostasis.
While monitoring of the intracellular chloride concentration by ion selective electrodes was shown to be amenable to large cells, this highly invasive technique requires penetration of at least two electrodes. We have assessed an alternative approach consisting in the measurement of the reversal potential of a chloride permeable channel that should allow quantification of the chloride gradient existing across the cell membrane. mRNA encoding for the human NKCC1 or NKCC2 co-transporters was co-injected in *Xenopus* oocytes with mRNAs encoding for the α5, β3 and γ2 $GABA_A$ receptor subunits. Oocyte membrane potential recordings were conducted using an automated system (HiClamp, MultiChannelSystems). Reduction of the extracellular chloride concentration caused a right shift of the reversal potential in line with the theoretical value calculated using the Nernst equation. However, incubation of the oocytes in a gluconate-containing chloride-free medium, caused a leftward shift of the $GABA_A$ reversal potential likely due to a lowering of the intracellular chloride concentration. Upon restoration of the normal chloride medium conditions, the $GABA_A$ reversal potential progressively returned to its initial value, indicative of active inward chloride transport. When the oocytes were incubated in presence of a transporter inhibitor, such as bumetanide, a marked slowing down of the return of the reversal potential towards its normal value was observed, illustrating the contribution of the exogenously expressed human CCCs. In conclusion, the described method provides a direct measurement of CCC activity which is not dependent on radioactive techniques e.g. rubidium flux.

Title: Delineate the serotonin innervation in octopus arm by immunohistochemistry

Authors: *J.-P. BELLIER[1], Y. XIE[3], S. M. FAROUK[4], Y. SAKAUE[2], I. TOOYAMA[1], H. KIMURA[1];

Abstract: The arm of the octopus is a sophisticated structure in that it is composed of a tridimensional array of muscles and a massive sensory system. Its nervous system is the most advanced among invertebrates, and contains 500 millions neurons of which two-thirds are encompassed in its eight arms. To some extent, the octopus arm nervous system appears autonomic, able for instance to generate stereotypic motor activities. However, knowledge concerning neurochemical anatomy including neurotransmitters remains poorly described in the arm of the octopus.
We performed an immunohistochemical study aiming at identifying serotonin (5-HT)-containing structures and their networks in the octopus arm. The specificity of 5-HT antiserum was validated by absorption test. 5-HT immunoreactivity occurred exclusively in nerve cell bodies and fibers. 5-HT-positive cell bodies are found only in the cell layer of the brachial ganglion, whereas 5-HT-positive nerve fibers were distributed widely throughout the arm. While a few smooth or varicose nerve fibers running in the cerebrobrachial tract are likely derived from the central brain, most of other fibers appear to arise from 5-HT-positive cells in the brachial ganglion. These 5-HT-positive nerves join, as minor participants, nerve bundles connecting different nerve centers of the arms, including the intramuscular nerve cords, anastomotic tracts and the ganglia of the sucker. In addition, 5-HT-positive fibers appeared to terminate on sensory cells in the sucker epithelium that are immunostained for the peripheral type of choline acetyltransferase. The result suggests that intrinsic 5-HT nerves of the arm are involved in sensory transmission. A schematic representation of the serotoninergic pathway in the octopus arm will be presented.

Title: Serotonin modulates mitochondrial biogenesis and function in cortical neurons

Authors: *S. E. FANIBUNDA[1], A. SOOD[1], A. D. B. VAIDYA[2], U. SEETHARAM-KOLTHUR[1], V. A. VAIDYA[1];
[1]Dept of Biol. Sci., Tata Inst. of Fundamental Res., Mumbai, India; [2]Med. Res. Centre, Kasturba Hlth. Society, Mumbai, India

Abstract: Serotonin is an evolutionarily ancient molecule that modulates neuronal differentiation, growth and synaptic plasticity. Within neurons, mitochondria also play an important role in influencing specific neuronal functions such as synaptic plasticity, neurotransmission, neuronal excitability and cell death. However, the relationship between serotonin and mitochondrial physiology in neurons is currently poorly understood and explored. We hypothesized that serotonin may impinge on mitochondrial biogenesis and function. In cortical cultures, serotonin evokes a dose dependent increase in mitochondrial biogenesis and content, measured using mtDNA levels, mRNA and protein expression of specific mitochondrial markers and mitotracker staining. Further, serotonin also influences mitochondrial function, increasing ATP production, as scored by biochemical assays that measure cellular ATP content. An increase in mitochondrial output may arise through an increase in biogenesis or through an increase in OxPhos efficiency, and currently experiments are underway to explore these possibilities. We have mechanistically identified the specific serotonin receptors, that mediate the effects of serotonin on mitochondrial biogenesis, using serotonergic receptor specific agonists and antagonists. While the 5HT2A receptor agonist DOI mimics the effects of serotonin, also increasing mtDNA and ATP production, pretreatment with a 5HT2A receptor selective antagonist MDL100,907 prevents the effects of serotonin on mitochondrial biogenesis and function. Downstream of the 5HT2A receptor, the major signalling pathways, that contribute to the effects of serotonin on mitochondrial biogenesis are the phospholipase C and MAP kinase pathways. In contrast, specific inhibitors of the PI3-kinase Akt signalling pathway, did not alter the effects of serotonin on mitochondrial biogenesis. Further, studies using a SIRT1 inhibitor EX-527, implicate SIRT1 in contributing to the effects of serotonin on mitochondrial biogenesis and function. The increase in mtDNA and ATP evoked by serotonin, may mechanistically be mediated by the recruitment of PGC1α, as evidenced by an increased transcription of PGC1α and increased PGC1α levels. Experiments are currently underway, to mechanistically understand the

role of SIRT1 and PGC1α, as key downstream mediators of the effects of serotonin on mitochondrial biogenesis in cortical neurons. These effects of serotonin on mitochondrial physiology may be relevant to the effects serotonin has on aging, growth, plasticity, and neuronal metabolism.

Title: Transcriptomic and functional diversity of serotonin neuron subtypes.

Authors: *B. W. OKATY, M. E. FRERET, B. D. ROOD, V. NIEDERKOFLER, T. E. ASHER, R. DOSUMU-JOHNSON, R. D. BRUST, S. M. DYMECKI;
Genet., Harvard Med. Sch., Boston, MA

Abstract: Serotonergic (5HT) neurons modulate numerous behavioral, cognitive, and physiological processes and are implicated in a variety of clinical disorders. Though often viewed as a single neuron type based on neurochemical identity, phenotypic diversity within the 5HT neuron system has been observed across several parameters – such as neuropeptide expression, electrophysiology, and synaptic connectivity - suggesting the existence of specialized subtypes of 5HT neurons that differentially regulate biological functions. Given that cell phenotypes are strongly determined by cell type-specific gene regulation, global gene expression profiling, or transcriptomics, has emerged as an indispensible tool for classifying neuron subtypes and identifying the molecular underpinnings of their cellular properties. We recently combined intersectional genetic fate mapping, neuron sorting, and genome-wide RNA-Seq to deconstruct the mouse 5HT system at multiple levels of granularity—from anatomy, to genetic sublineages, to single neurons. We found that 5HT neuron transcriptomes cluster into groups

defined by a combination of lineage and anatomy, and that 5HT neuron subtypes with distinct transcriptomes display corresponding differences in electrophysiological properties and neuropeptide receptivity, as well as differential involvement in behaviors. These lineage and anatomy defined subtypes represent a first tier of system organization, and we are now further refining these subclassifications through multi-scale intersectional genetic experiments, combining pairwise driver genes suggested by our RNA-seq data set and performing RNA-seq, electrophysiology, and functional mapping experiments. Through these ongoing studies we continue to characterize the transcriptomic and functional diversity of 5HT neurons, and have uncovered previously undescribed 5HT neuron subtypes expressing unique combinations of co-regulated genes, showing differential responses to signaling molecules, and mapping to restricted sets of functions, such as aggression and social interest.

Title: Histone serotonylation, a novel mechanism of neuroepigenetic plasticity.

Authors: *L. FARRELLY[1], R. THOMPSON[2], S. ZHAO[3], A. LEPACK[1], Y. LU[1], H. ZEBROSKI III[4], O. BERTON[1], H. MOLINA[4], H. LI[3], T. MUIR[2], I. MAZE[1];
[1]Dept. of Neurosci., Mount Sinai, New York, NY; [2]Princeton Univ., Princeton, NJ; [3]Tsinghua Univ., Beijing, China; [4]Rockefeller Univ., New York, NY

Abstract: Monoamines, such as serotonin, dopamine, etc, play a critical role in neuronal plasticity, with alterations implicated in the development and treatment of numerous brain disorders. Although vesicular packaging of monoamines is essential for neurotransmission, recent data have demonstrated the additional presence of reserve pools of extravesicular

monoamines in the nucleus of monoaminergic neurons; it remains unclear, however, whether nuclear monoamines may play roles independent of neurotransmission. Serotonin has previously been shown to form covalent bonds with certain cytoplasmic proteins via transamidation by the tissue transglutaminase 2 enzyme, a process known as serotonylation. As this modification alters the signaling properties of its substrates, we hypothesized that nuclear proteins may similarly be modified to control distinct aspects of their function. Here, we describe histone proteins as novel substrates for monoaminylation in vivo and attempt to delineate the biophysical, biochemical and molecular functions of these novel modifications in the context of neuronal development and plasticity. Utilizing a unique combination of biochemical, genome-wide and functional neurobiological approaches, our data indicate that H3 serotonylation acts to facilitate binding of adjacent H3 methylation binding proteins, thereby promoting neuronal genic activation and the facilitation of neural development. In sum, our data provide the first direct evidence that hydrophobic monoamines in brain contribute directly to neuronal gene expression via a novel, neurotransmission-independent epigenetic mechanism; such phenomena will likely have broad implications within the field of neuroscience and beyond.

Abstract: Drug addiction is a debilitating disease that affects about 25 million Americans–ages 12 and up–with treatment costs averaging >190 billion dollars annually in the United States alone. Drug abuse is characterized by loss of control over drug intake, as well as persistent drug-seeking behaviors despite negative consequences to both the drug abuser and those directly affected by their behavior.
Persistent changes in neuronal gene expression are known to promote physiological alterations implicated in drug addiction. More recently, cell-type and brain region specific 'epigenetic' mechanisms have also been demonstrated to regulate transcriptional programs contributing to addiction-like behaviors; however, our understanding of how these mechanisms mediate life-long addiction remains limited. Dopaminergic neurotransmission in the central nervous system plays a critical role in psychostimulant-induced neural plasticity, with alterations in dopamine production/function being implicated in both the development and treatment of substance abuse disorders. Independent of its role in neurotransmission, we recently identified histone proteins as robust substrates for dopamine transamidation—so-called dopaminylation—*in vivo*. Our data indicate that histone H3 dopaminylation acts to enhance binding of adjacent histone posttranslational modification (PTM) interacting proteins ('readers') and likely plays a direct and critical role in dopamine associated neuronal transcription. Furthermore, our data demonstrate that chronic withdrawal from volitional administration of extended access to cocaine in rodents results in high levels of dopamine accumulation in the nucleus of dopamine producing neurons in the ventral tegmental area, as well as altered expression of TGM2, the H3 dopaminylase. Taken together, these data suggest that persistent states of addiction may result from increased genomic enrichment of H3 dopaminylation, potentiation of aberrant transcriptional plasticity and increased drug seeking behaviors. Using a combination of chemical biology, genome-wide and behavioral approaches, we are fully characterizing the functions of histone dopaminylation, both in the context of normal neuronal function and in rodent models of drug abuse.

Title: GIRK-mediated inhibition of lateral orbitofrontal cortex neurons by monoamines is lost following chronic exposure to ethanol

Authors: *S. NIMITVILAI, M. F. LOPEZ, P. J. MULHOLLAND, J. J. WOODWARD; Dept. of Neurosci. and Addiction Sci. Div., Med. Univ. of South Carolina, Charleston, SC

Abstract: Alcoholism is associated with changes in brain reward and control systems including the prefrontal cortex. In prefrontal areas, the orbitofrontal cortex (OFC) has been shown to be particularly sensitive to acute ethanol and has been suggested to play an important role in the development of alcohol abuse disorders. Recent findings from this laboratory demonstrate that both acute and chronic exposure to ethanol alters the intrinsic excitability of OFC neurons and that ethanol-dependent mice are impaired in a reversal learning task that requires the OFC. The OFC is extensively innervated by monoamine neurotransmitters including dopamine (DA), norepinephrine (NE) and serotonin (5HT), and drugs that target monoamine receptors have been used to treat a number of psychiatric diseases, including alcohol abuse disorders. In this study, we characterized the effect of monoamines on lateral OFC (lOFC) neuronal excitability in naïve mice and those treated with repeated cycles of chronic intermittent ethanol (CIE) exposure. DA, NE and 5HT all produced a dose-dependent (1, 10 and 50 μM) decrease in spike firing of lOFC neurons that was mediated via $G_{i\alpha}$-coupled D2, α2-adrenergic or $5HT_{1A}$ receptors, respectively. Lower concentrations of DA (1 and 100 nM) that had no effect on spiking under control conditions inhibited firing in the presence of the monoamine uptake inhibitor nomifensine. Inhibition of firing by DA or the D2 agonist quinpirole, but not by NE or 5HT, was prevented by the $GABA_A$ receptor antagonist picrotoxin and a picrotoxin-sensitive tonic current was enhanced by DA or the D1 agonist SKF81297, but not by quinpirole. In addition, sIPSC amplitude was increased by quinpirole, but not by dopamine. Monoamine inhibition of firing was suppressed by the GIRK channel blocker barium that itself enhanced spiking while the GIRK channel activator ML297 inhibited current-evoked spiking. In neurons from CIE-treated mice, spike frequency was nearly doubled and these neurons were largely resistant to the inhibitory effect of monoamines for up to at least 7 days of withdrawal. ML297 also had no or little effect on spiking in neurons from CIE-treated animals, despite no obvious change in GIRK1, GIRK2 or Gi/o protein expression. The results of these studies suggest that monoamines, acting via GIRK channels, are important modulators of the intrinsic excitability of lOFC neurons and that this modulation is significantly disrupted following chronic exposure to alcohol. Dysfunction of one or more of these neuromodulators may contribute to impaired OFC function associated with various neuropsychiatric diseases including alcohol dependence. Supported by P50AA010761.

Title: Incomplete marking of cerebral cortical interneuron expression patterns in Drd1 receptor BAC transgenic mice

Authors: *Y. JIN[1], K. M. MONEY[3,4], V. G. FUENTES[5], L. R. ANDERSON[1], G. D. STANWOOD[1,2,5];

Abstract: The use of bacteria artificial chromosome transgenic reporter mice allow for the identification of cell populations not easily labeled otherwise, including low abundance G-protein coupled receptors. In the case of dopamine D1 (Drd1) receptors, Drd1-tdTomato and Drd1-eGFP transgenic mice have greatly enabled electrophysiological and neuroanatomical studies and appear to correctly and unambiguously report D1 receptor expression in most brain regions and cell types. However, in cortical GABAergic interneurons, we report that these D1 receptor reporter lines under-report Drd1 expression in GAD-67-, parvalbumin- and calbindin-expressing GABAergic interneurons in adult mice. Using double-label immunohistochemistry in Drd1-tdTomato (line 6) mice, only 18% of GAD-67+ interneurons also expressed the Drd1-driven transgene, which is far below that previously reported in colocalization studies. The case was even more dramatic for some GABAergic neuron subpopulations, with < 1% of parvalbumin+ cortical interneurons expressing the transgene. We used RNAScope to sensitively measure endogenous Drd1 transcript and found similar levels of Drd1/parvalbumin co-expression to previous reports in rodents (~50%). Transgene expression by excitatory pyramidal neurons closely matched predicted transcript patterns, suggesting that the issue in these lines is specific to interneurons. Thus while the reporter lines continue to be powerful tools to study the localization and connectivity of some D1 receptor-expressing neurons, one cannot assume that the expression patterns are totally congruent with endogenous D1 receptor expression patterns.

Title: Epigenetic regulation of phenyethanolamine N-methyltransferase: implications for adrenaline biosynthesis

Authors: *S. KHURANA[1], S. THARMALINGAM[1], K. VENKATARAMAN[2], T. C. TAI[1,3,4,5]; [1]Med. Sci. Div., Northern Ontario Sch. of Med., Sudbury, ON, Canada; [2]Gerontology, Huntington Univ., Sudbury, ON, Canada; [3]Biol., [4]Chem. and Biochem., [5]Biomolecular Sci., Laurentian Univ., Sudbury, ON, Canada

Abstract: Adrenaline, a neurohormone and neurotransmitter, plays an extensive role in the physiological response to stress, and the sympathetic regulation of blood pressure. Phenylethanolamine N-methyltransferase (PNMT), the terminal enzyme in the catecholamine biosynthetic pathway, directly responsible for adrenaline synthesis, is elevated in hypertensive animals; genetic linkage studies have associated the PNMT gene to the development of hypertension. Epigenetic changes are heritable changes in gene expression that are a consequence of the modification of the DNA (methylation at CpG sites) or histones (e.g. by methylation, acetylation) that facilitate packaging the DNA into nucleosomes. Changes in the epigenome have been associated with incidences of cancer, metabolic disorders and cardiovascular pathologies. In this study, alteration in PNMT expression modifiable by epigenetic regulation was examined using the rat adrenal pheochromocytoma derived PC12 cells. *In vitro* methylation of a PNMT promoter driven luciferase construct, using CpG methylases, consequently lead to a radical decrease in promoter activation, even in presence of dexamethasone (Dex) or Forskolin (Fsk), otherwise potent activators of PNMT expression. Further, the influence of a DNA methylation inhibitor 5-aza-2'-deoxycytidine (5aza2DC), and histone deacetylase inhibitor valproic acid (VPA) was examined. Transcript analysis of endogenous PNMT, and PNMT promoter driven luciferase assays, both revealed that PNMT transcription is elevated in presence of these epigenetic modifiers, and this was synergistic with the activation by Dex or Fsk. The extent of CpG methylation at the promoter of PNMT using bisulphite-sequencing, and transcription factor binding sites that are sensitive to epigenetic modification using site directed mutagenesis, are currently being examined. The data suggests that PNMT regulation is sensitive to epigenetic modification which can have repercussions for adrenaline biosynthesis, and consequently on its role as a neurotransmitter.

Title: Memory, a key component of dementias: serotonergic markers

Authors: *A. MENESES;
Cinvestav - IPN, Mexico, Mexico

Abstract: Dysfunctional memory seems to be a key component of diverse dementias and other neuropsychiatric disorders unfortunately no effective treatment exists for it; probably due to the absence of neural markers accompanying it. Evidence of neural markers and memory continues accumulating, and progress is allowing a better framing of earlier and new evidence. Several neurotransmission systems have implicated in memory, including serotonin. 5-hydroxytryptamine (5-HT) or serotonin has multiple pharmacological tools, well characterized downstream signaling in mammals' species and well-established 5-HT neural markers offering new insights about memory functions and dysfunctions. Serotonin in mammal species has multiple neural markers, including receptors (5-HT1-7), transporter (SERT) and volume transmission; which are present in brain areas involved in memory. For instance, growing number of researchers report that memory, amnesia and forgetting modify neural markers; this influence is bidirectional. Evidence is showing insights and therapeutic targets and diverse approaches support the translatability of using neural markers and cerebral functions and dysfunctions, including memory formation, amnesia. For instance, 5-HT2C, 5-HT4 and 5-HT6 receptors are involved in tau protein hyperphosphorylation in Alzheimer´s disease. In addition, at least, 5-HT1A, 5-HT4, 5-HT6 and 5-HT7 receptors as well as SERT seem to be useful neural markers and therapeutic targets. Hence, available evidence supports the notion that several mechanisms cooperate to achieve synaptic plasticity or memory, including changes in the number of neurotransmitter receptors and transporters.

Title: Proton magnetic resonance spectroscopy assessment of the neurochemical profile in mice genetically depleted of brain serotonin

Authors: *F. GHODDOUSSI[1], D. I. BRIGGS[2,4], D. M. KUHN[2,4], M. P. GALLOWAY[3]; [1]Anesthesiol. & Magnetic Resonance Core, [2]Psychiatry & Behavioral Neurosciences, [3]Psychiatry & Behavioral Neurosciences and Anesthesiol., Wayne State University, Sch. of Med., Detroit, MI; [4]Res. & Develop. Service, John Dingell VA Med. Ctr., Detroit, MI

Abstract: **Introduction**: Serotonin (5HT) neurons originating in the dorsal raphe innervate nearly all areas of the brain. As a neurotransmitter 5HT is involved in mediating neuronal development as well as behavioral and physiological processes including, sleep, aggression, aging , control of food intake and body weight. In addition, the dysfunction in the 5HT neuronal system has been linked to neuropsychiatric conditions such as depression, anxiety, obsessive compulsive disorder and suicide. Serotonin selective reuptake inhibitors (SSRIs) are the most common treatment for depression and their therapeutic effect is generally attributed to their ability to increase the synaptic levels of 5HT. Tryptophan hydroxylase-2 (TPH2), expressed selectively in 5HT neurons, is the initial and rate limiting enzyme in the biosynthesis of 5HT. Genetic ablation of the TPH2 gene provides a hyposerotonergic animal model to examine the influence of 5HT innervation on development and behavior. $TPH2^{-/-}$ mice show intense compulsivity and impulsivity, social communication deficits, exaggerated aggression and decreased levels of anxiety like behavior. 5HT neurons in these mice, although lacking 5HT, retain their characteristic electrophysiological properties as well as relatively normal brain development and elaboration of the 5HT neuronal system. This suggests that behavioral phenotypes of the $TPH2^{-/-}$ may be mediated via the absence of a modulatory effect of 5HT on other neurotransmitter systems such as Glutamate (GLU) and GABA. **Methods:** $TPH2^{-/-}$ mice were generated by deleting exon1 of the Tph2 gene and were on a mixed C57BL/6-Sv129 background. High resolution magic angle spinning (HR-MAS) proton magnetic resonance spectroscopy (^{1}H-MRS) *ex vivo* (translation potential to clinical MRS) was used to assess unbiased neurochemical profiles in different brain regions of 8 week-old WT (n=8) and KO

(n=12) mice. **Results:** MRS analysis showed significant decrease in the GLU/CRE and NAA/CRE ratios in nucleus accumbens (NAc) and significant increase in GLN/CRE & GLN/GLU in anterior cingulate cortex (ACC) in the KO mice in comparison to the WT. **Discussion:** The 5HT innervation of the NAc as well as principle cortico-striatal GLU neurons is substantial. Decreased indices of GLU in the NAc may reflect a developmental insult related to 5HT deficits in the critical period and may be associated with the unique behavioral phenotypes of the $TPH^{-/-}$mouse. Previous studies have established a link between increased glutamate activity in the NAc and depressive behavior while $TPH2^{-/-}$ does not show depression like behavioral phenotypes, therefore maybe the decrease in glutamate levels is a compensatory effect.

Title: Neurochemical profile of dorsal raphe projections to the rat medial prefrontal cortex

Authors: *E. W. PROUTY[1], B. D. WATERHOUSE[2];
[1]Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Cell Biol., Rowan Univ. Sch. of Med., Stratford, NJ

Abstract: Serotonin (5-HT)-containing neurons in the dorsal raphe (DR) nucleus project throughout the mammalian forebrain and are implicated in a host of physiological processes and neuropsychiatric disorders. These neurons have been characterized in terms of their neurochemistry and anatomical organization, but a clear sense of whether these attributes align with specific brain functions or specific forebrain terminal fields is lacking. DR 5-HT neurons can co-express additional neuroactive substances, increasing the potential for individualized regulation of target circuits. The goal of this study was to link the neurochemical profile of DR neurons to a specific functional role by characterizing cells in terms of their efferent connectivity; in this case, cells projecting to the the medial prefrontal cortex (mPFC), a region responsible for higher-order cognition and regulation of emotion. After injecting the retrograde tracer FluoroGold (FG) into the mPFC of Sprague-Dawley rats, brainstem sections containing

the DR from these animals were collected and subjected to immunohistochemical staining for serotonin, glutamate, GABA, or nitric oxide using antibodies targeting tryptophan hydroxylase 2 (TPH2), vesicular glutamate transporter 3 (VGLUT3), glutamate decarboxylase 1 (GAD67), and neuronal nitric oxide synthase (nNOS), respectively. We found that 98% of the 5-HT neurons projecting to the mPFC co-express VGLUT3, 60% co-express nNOS, and 0.1% co-express GAD67. For comparison, we also examined the co-expression patterns of DR 5-HT neurons projecting the lateral geniculate nucleus of the thalamus (a subcortical relay site for visual information). There were no meaningful differences in VGLUT3 or GAD67 co-expression between DR 5-HT neurons projecting to mPFC vs LGN; however, a significantly greater proportion of mPFC-projecting cells co-expressed nNOS (60% vs 22%, $\chi^2 = 178.1$, $p < 0.001$). The co-expression of nNOS is of interest because of its putative role in stress. Overall, these results establish a co-transmitter profile of DR projections to mPFC and raise further questions about how these transmitter combinations, particularly 5-HT and nNOS, impact cortical circuits underlying cognitive function and mood. Ongoing studies will determine if the electrophysiological profile of mPFC-projecting DR neurons differs from that of neurons that project to other DR targets.

Title: Imbalance of serotonin homeostasis during adulthood affects serotonergic neuronal circuitry

Authors: *M. PRATELLI[1], B. PELOSI[1,2], S. MIGLIARINI[1], M. PASQUALETTI[1,3];
[1]Univ. of Pisa, Pisa, Italy; [2]Univ. catholique de Louvain, Inst. of Neurosci., Brussels, Belgium; [3]Ctr. for Neurosci. and Cognitive Systems, Inst. Italiano di Tecnologia, Rovereto, Italy

Abstract: Serotonin (5-hydroxytryptamnine, 5-HT) is a monoaminergic neurotransmitter orchestrating a broad array of cognitive and behavioral processes in the adult brain. The early expression of its receptors during development and the requirement of maternal and placental sources of serotonin to the foetus have led to the hypothesis that 5-HT could act as growth regulator in the fine-tuning of specific morphogenetic events during neurodevelopment. Outcomes from genetic mouse models in which brain 5-HT homeostasis has been perturbed by targeting genes necessary for serotonin reuptake, metabolism or synthesis such as *SERT, MAO-A*

and *Tph2*, respectively, support this hypothesis. However, evidence of a role for 5-HT in adulthood as a growth regulator or its requirement for maintenance of the proper neuronal circuitry, which is known to be susceptible to 5-HT imbalance during early postnatal stages, is still missing. To bridge this gap we used the *Tph2* conditional knock-out (cKO) allele that allows an efficient abrogation of 5-HT synthesis in the adult brain, in combination with the *Tph2::GFP* allele, in which GFP reporter expression highlights 5-HT neuron fibers and somata. Beside previously reported data showing that the lack of brain serotonin in *Tph2* knock-out (KO) mice deeply affects serotonergic circuitry development with a brain region-specific effect, the abrogation of 5-HT synthesis during adulthood produces alterations of serotonergic innervation in rostral brain targets matching those observed in mice with a life-long depletion of brain serotonin. Remarkably, we reported that restoring brain 5-HT signaling in both *Tph2* KO and cKO mice by chronic administration of the serotonin precursor 5-hydroxytryptophan (5-HTP) results in a significant reduction in the extent of serotonergic fiber innervation defects, thus demonstrating an unexpectedly high degree of plasticity of the adult serotonergic system in response to changes of 5-HT homeostasis. Moreover, 3D computer-based analysis of serotonergic axon terminal morphology showed that imbalances in brain 5-HT content exert their growth regulatory activity on 5-HT axon terminals by promoting sprouting. Altogether these data demonstrate that a correct 5-HT homeostasis is life-long required to maintain the proper serotonergic innervation of specific rostral brain regions.

Title: p11 corticostriatal neurons have distinctive 5-HT responses sensitive to chronic social isolation stress and to antidepressant treatment

Authors: *D. SARGIN[1], K. PERIT[1], E. F. SCHMIDT[2], R. C. UTHAIAH[3], N. HEINTZ[2,4], P. GREENGARD[3], E. K. LAMBE[1];
[1]Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada; [2]Lab. of Mol. Biol., [3]Lab. of Mol. and Cell. Neurosci., [4]Howard Hughes Med. Inst., The Rockefeller Univ., New York, NY

Abstract: Major depression affects more than 15% of North Americans in their lifetime. The most commonly prescribed antidepressant medications are selective serotonin reuptake inhibitors (SSRIs) that target the serotonin (5-HT) system. SSRI therapeutic action requires a prolonged period of treatment and is not always effective. To improve therapies for depression, it is essential to fine-tune the mechanisms of antidepressant action. Recently, layer 5a corticostriatal neurons expressing p11 (S100a10) protein were found to be specifically affected in depression and distinctively responsive to antidepressant treatment. Initially identified as an interacting partner for a group of 5-HT receptors, p11 expression is decreased in depression and increased by SSRIs. Yet, the critical mechanisms underlying the antidepressant neurophysiology of p11 remain to be elucidated. To characterize the distinctive neurophysiological properties of p11 expressing neurons, we performed whole cell electrophysiology on acute brain slices of motor cortex from mice with eGFP-labeled p11 expressing neurons. Here, we find p11 neurons have excitatory responses to 5-HT. Subjecting mice to chronic social isolation stress reduces 5-HT excitatory responses in p11 neurons but chronic treatment with the SSRI fluoxetine restores them. We probe the receptors and signaling mechanisms underlying the unique 5-HT responses of p11 neurons. Identification of these underlying regulatory mechanisms will be important for developing novel treatment strategies for depressive disorders.

Title: Serotonin and cortical disinhibition: Novel co-operation between 5-HT_{1A} and 5-HT_{2A} receptors in prefrontal cortex

Authors: *M. K. TIAN, E. K. LAMBE;
Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: In medial prefrontal cortex, layer 6 pyramidal neurons play a critical role in attention and express receptors for serotonin (5-HT), a neuromodulator known to shape and bias attention. In primary sensory cortex, layer 6 neurons exert strong cortical gain control through their excitatory projections to interneurons. This phenomenon has not been investigated in prefrontal cortex. Furthermore, little is known about the direct electrophysiological consequences of 5-HT on layer 6 neurons themselves and on their regulation of local cortical activity. Here, we performed whole-cell recordings and pharmacological manipulations in acute brain slices from transgenic mice expressing either eGFP or a fusion protein of eGFP-channelrhodopsin in prefrontal layer 6 pyramidal neurons. Optogenetic excitation was used to test the effects of 5-HT on the inter-laminar excitatory circuits between layer 6 pyramidal neurons and layer 5 interneurons, which act as critical mediators of cortical inhibition. Prefrontal layer 6 pyramidal neurons are strongly inhibited by 5-HT through activation of 5-HT_{1A} and, surprisingly, 5-HT_{2A} receptors. This direct serotonergic suppression of neuronal excitability in layer 6 is complex, with the inhibition mediated by 5-HT_{2A} receptors strongest near threshold. Optogenetic investigation of the connections between layer 6 pyramidal neurons and both fast- and regular-spiking interneurons in layer 5 reveal a strong suppression on this circuit by 5-HT through both 5-HT1A and 5-HT2A receptors. These findings reveal a novel modulatory role of 5-HT on cortical excitability through strong inhibitory effects on layer 6 and its feedforward projections. Disturbances of normal serotonin signalling in deep cortex would thus have unexpectedly broad consequences for prefrontal cortex activation and signal-to-noise ratios in circuits important to attention.

Title: The role of serotonergic signaling in Daphnia magna swimming

Authors: O. BURT, *M. L. BECKMAN;
Biol., Augsburg Col., Minneapolis, MN

Abstract: *Daphnia magna* are freshwater microcrustaceans that have been used in toxicology research for decades. One common test involves exposing *Daphnia* to a drug or chemical and assessing its movement. Daphnids possess a rich motor program, yet not much is known about the neurochemical control of movement. We sought to use *D. magna* as a model organism to determine the role of serotonin in movement. *Daphnia* were treated with agonist and antagonist drugs targeting 5-HT 1A and 5-HT 7 receptors. Animals were filmed for one minute from above to make 2D movies at various time-points following treatment with 10 μM drug solutions. CTRAX, an open-source software, was used to track *Daphnia* swimming. Statistical analysis showed the effects of two of these drugs on 5-HT 1A receptors significantly affected movement. Xaliproden hydrochloride, a 5-HT 1A receptor agonist showed inhibition by decreasing the total swimming distance; whereas, NAD 299 which is a 5-HT 1A antagonist, increased total swimming distance. Further, application of NAD 299, the antagonist, followed by Xaliproden HCl, the agonist, resulted in control levels of *Daphnia* swimming. These findings indicate that a serotonergic signaling pathway involving 5-HT1A receptors is involved in the neural control of *Daphnia* swimming. Additionally, this research supports that *Daphnia magna* is a viable model organism in studying the role of serotonergic signaling in animal movement.

Title: Adult brain serotonin deficiency causes hyperactivity, circadian disruption, and elimination of siestas

Authors: *M. S. WHITNEY[1], A. M. SHEMERY[2], A. M. YAW[2], L. J. DONOVAN[1], J. GLASS[2], E. S. DENERIS[1];
[1]Neurosciences, Case Western Reserve Univ., Cleveland, OH; [2]Biomed. Sci., Kent State Univ., Kent, OH

Abstract: Serotonin (5-HT) is a critical neuromodulator implicated in many psychiatric disorders. Yet, after decades of study, its role in behavior remains poorly understood, in part, because of a lack of methods to specifically deplete 5-HT from the adult brain. Here, we have developed a genetic approach that achieves near-complete elimination of 5-HT from the adult brain ascending 5-HT system by stereotaxic injection of an adeno-associated virus expressing Cre recombinase (AAV-Cre) into the midbrain of mice carrying a loxP-conditional *tryptophan hydroxylase 2 (Tph2)* allele. We investigated the behavioral effects of a specific loss of brain 5-HT and discovered a novel compound phenotype. Surprisingly, 5-HT deficiency in the adult brain did not affect anxiety-like behavior in open-field, elevated plus maze, or light-dark box testing. However, it resulted in a robust hyperactivity phenotype in novel and home cage environments. In a 30-minute open-field test, 5-HT-depleted (*Tph2-CKO*) mice showed increased rates of activity as compared to control (*Tph2-CON*) mice during the entire test. In two independent cohorts, *Tph2-CKO* mice also exhibited increased activity in the light and dark periods in home cage monitoring studies, as compared to *Tph2-CON* mice. Additionally, *Tph2-CKO* mice displayed increased average and peak rates of activity explicitly during bouts of activity, definitively demonstrating the presence of absolute hyperactivity. Moreover, specific loss of adult brain 5-HT led to an altered pattern of circadian behavior characterized by an advance in the onset and a delay in the offset of daily activity, thus revealing a specific requirement for adult ascending brain 5-HT in the control of daily activity patterns. Notably, after normalizing for hyperactivity, we found that the normal prolonged break in nocturnal activity (siesta), a period of REM and NREM sleep, was absent in all animals in which 5-HT deficiency was verified. Thus, our findings have identified adult ascending 5-HT as a necessary neurotransmitter for siestas, implicating adult ascending 5-HT in sleep-wake homeostasis. Together, our results may have implications for the role of 5-HT in a variety of mental health disorders with hyperactivity and circadian/sleep disruption, including ADHD, Seasonal Affective Disorder, depression, bipolar disorder, and sleep disorders. Furthermore, our findings highlight the importance of our brain-specific 5-HT depletion approach in understanding 5-HT's role in controlling daily activity levels and patterns.

Title: Noradrenaline innervation in the primate thalamus: first order sensory nuclei versus higher order nuclei

Authors: I. PÉREZ-SANTOS, *C. CAVADA;
Univ. Autonoma Madrid, Fac Medicina, Madrid, Spain

Abstract: Noradrenaline (NA) is thought to improve signal-to-noise ratios in sensory systems. This could be particularly relevant in the thalamus, where sensory inputs are transmitted and modulated within the first order sensory relay nuclei. NA also plays a critical role in higher brain functions, including learning and memory. These functions are more related to higher order thalamic nuclei, such as the pulvinar, mediodorsal and intralaminar nuclei; which receive little direct sensory input, and instead participate in extensive cortico-thalamo-cortical pathways.
To shed light on the role of NA in those two types of thalamic nuclei, we have mapped their NA innervation in the macaque monkey using immunohistochemistry against dopamine-beta-hydroxylase (DBH), the NA synthesizing enzyme. Maps of DBH innervation were generated using Neurolucida® software filters to transform real pictures into black and white images. The borders of thalamic nuclei were traced using sections processed for acetylcholinesterase adjacent to the immunoreacted ones.
The first order sensory thalamic nuclei receive a moderate NA innervation. In particular, the less innervated nucleus throughout the thalamus is the lateral geniculate nucleus, the first order visual relay nucleus.
The higher order nuclei receive a denser NA innervation than the first order sensory nuclei. Within the mediodorsal nucleus the most innervated region is its medial sector, which is particularly connected to the orbitofrontal cortex. In contrast, the pulvinar and lateral posterior nuclei receive a moderate NA innervation, similar to that present in first order sensory nuclei. In the parafascicular-centromedian complex the most innervated region is the caudal part of the parafascicular nucleus, which projects to limbic and associative striatum, and is connected with the prefrontal cortex, the frontal eye fields and the supplementary motor cortex. The centromedian nucleus, which projects to sensorimotor striatum and is connected with the precentral motor, premotor and somatosensory cortices, receives a moderate NA innervation.
These results suggest a prominent role for thalamic NA in cortico-thalamo-cortical and cortico-

thalamo-striatal circuits related to cognition and limbic processing, rather than in sensory transmission through the thalamus.

Title: Norepinephrine activates synchronized inhibitory synaptic inputs to BLA principal neurons

Authors: *X. FU, J. TASKER;
Cell and Mol. Biol., Tulane Univ., New Orleans, LA

Abstract: Emotional arousal facilitates memory formation and norepinephrine released in the basolateral amygdala (BLA) during arousal is thought to play an important role in this facilitatory effect. Diverse GABAergic interneurons in the BLA have been shown to be essential for gating the activities of the principle neurons through feed forward inhibition or disinhibition during fear conditioning (Wolff, 2014). Norepinephrine (NE) thus may regulate the activity of the local interneurons to control the concerted neural outputs from BLA. Using whole-cell patch clamp recordings in amygdala slices, we found that norepinephrine application induces a significant increase in the frequency and amplitude of inhibitory postsynaptic currents (IPSCs) in BLA principal neurons. Also, we consistently observed 3 different types of IPSC bursting activity induced by NE. The effects of NE on IPSCs were blocked by pre-application of the a1 adrenergic receptor antagonist prazosin and of the sodium channel blocker TTX, indicating that NE stimulates different subtypes of presynaptic interneurons in the BLA by acting on a1 adrenoceptors. Dual recordings revealed synchronization of the IPSC bursts between pairs of BLA principal neurons. These data suggest that NE can synchronize BLA network activity via a1 receptor-mediated activation of upstream inhibitory interneurons and feedforward synaptic inhibition. Title: The brain serotonin matrix: platelet and microglial elements

Authors: K. A. RIPARETTI, M. E. VICARI, E. J. SOPIRA, S. L. STARR, *S. JANUSONIS; Dept. of Psychological and Brain Sci., Univ. of California, Santa Barbara, Santa Barbara, CA

Abstract: In vertebrate brains, neural computations take place in a dense serotonin matrix, produced by axons (fibers) originating in the rostral raphe nuclei. In the adult brain, these fibers have meandering trajectories and carry bead-like swellings (varicosities), the primary sites of serotonin (5-HT) release and reuptake. Serotonergic signaling has been extensively studied in normal and diseased brains, but little is known about the fine structure of the serotonin matrix. This includes its stochastic properties and its interactions with other ubiquitous brain elements, such as microvasculature and microglia. The serotonin matrix is sensitive to traumatic injury and drugs of abuse (e.g., MDMA), and it is also altered in some mental disorders (e.g., autism). Analysis 1: Serotonergic varicosities in the brain parenchyma and blood platelets in brain microcapillaries share a number of physical and biochemical properties. In particular, both express the same serotonin transporter (SERT) and take up 5-HT from their environment. Recent neuroimmunological research suggests that platelets may be able to exit microvasculature and interact with neural and glial cells. To investigate the potential contribution of platelets to 5-HT signaling in the healthy brain, we selectively depleted platelets in mice and assessed the expression of serotonin receptors and SERT in the neocortex. The mRNA levels of the 5-HT1A, 5-HT2A and 5-HT4 receptors were measured with quantitative reverse-transcription PCR (qRT-PCR), and the protein levels of SERT were measured with Western blotting. Our preliminary data suggest changes in the expression of some of the serotonin receptors. We are currently using the observed effect sizes to guide the analysis of a larger sample. If confirmed, these findings would have clinical implications: for example, selective serotonin reuptake inhibitors (SSRIs) directly affect platelet 5-HT uptake. Analysis 2: Serotonergic fibers may interact with “resting” microglia, resident immune cells in the brain. A number of recent studies have shown that microglia play a major role in neural plasticity. We used double-label immunohistochemistry (5-HT/Iba1) and automated 3D-analyses to investigate physical interactions between serotonergic fibers and microglial cells in the mouse neocortex. We found close appositions between

microglial processes and serotonergic varicosities, which suggests that microglia may control 5-HT signaling. We are investigating the statistical properties of these contacts.

Title: The catecholamine receptors ADBR1 and ADBR2 exhibit differential coupling to the cyclic AMP sensor NCS-Rapgef2

Authors: *L. E. EIDEN[1], A. C. EMERY[1], C. WESTOVER[1], W. XU[1], M. V. EIDEN[2]; [1]Sec Molec Neurosci, [2]NIH, NIMH-IRP, Bethesda, MD

Abstract: The G-protein-coupled receptors (GPCRs) βAR1 and βAR2 for the catecholamines norepinephrine and epinephrine couple to $G_s\alpha$ and thus signal through the second messenger cyclic AMP, and its downstream effectors PKA and the cyclic AMP-activated guanine nucleotide exchange (GEF) proteins Rapgef3 and 4 (Epac1 and Epac2). βAR2 signaling also occurs via engagement of β-arrestin leading to activation of ERK. We have recently characterized a third cAMP sensor, a GEF related to Epac1/2 and to the previously characterized non-cAMP-activated GEF PDZ-GEF1, which we have named NCS (neuronal cyclic AMP sensor)-Rapgef2 (protein product of the Rapgef2 gene). This sensor mediates activation of ERK leading to neuritogenesis in the PC12 and NS-1 neuroendocrine cell lines (Emery et al., Sci. Signaling 6(281), ra51, 2013; Emery et al., J. Biol. Chem. 289: 10125, 2014). We have created NS-1 cell lines stably expressing hβAR1 and hβAR2, and examined signaling to each of the three cAMP sensors present in these cells following treatment with isoproterenol. In hβAR1-expressing cells, isoproterenol treatment caused Epac2/p38-dependent growth arrest; PKA-dependent CREB phosphorylation; and NCS-Rapgef2/ERK-dependent neuritogenesis. In hβAR2-expressing cells, isoproterenol initiated Epac2/p38-dependent growth arrest and PKA-dependent CREB phosphorylation, but not NCS-Rapgef2/ERK-dependent neuritogenesis. We created cognate hβAR1- and hβAR2-expressing NS-1 cell lines that stably co-expressed a luminescent cAMP biosensor (Emery et al., Peptides, 79: 39, 2016) to compare the profiles of cAMP elevation induced by isoproterenol upon activation of either adrenoceptor. Maximum

cyclic AMP activation by isoproterenol occurred within about 10 min and decreased thereafter to less than half-maximal in hβAR2-expressing cells, while cyclic AMP elevation was persistent at maximal levels for at least 40 in in hβAR1-expressing cells. We conclude that there is an inverse relationship between adrenergic receptor desensitization, and engagement of NCS-Rapgef2 of sufficient duration to support sustained activation of ERK, coupled to neuritogenesis, in NS-1 cells. NCS-Rapgef2-independent activation of ERK by hβAR2, as reported by ourselves (Emery et al. Sci. Signaling 6(281), ra51, 2013) and others (Lefkowitz and Shenoy, Science 308: 512, 2005), is likely to occur in a cellular compartment that, unlike NCS-Rapgef2-dependent ERK activation, is not coupled to downstream immediate early genes such as Egr1/Zif268 required for neuritogenesis in PC12/NS-1 cells (Ravni et al., Mol. Pharmacol. 73: 1688, 2008).

Abstract: Vesicular monoamine transporter 1 (VMAT1) in humans and rodents is the primary vesicular transporter in adrenal medulla, but the VMAT1 gene also is expressed in specific areas of brain. Association of the VMAT1 gene SLC18A1 with psychiatric disorders motivated investigation of behavioral differences in VMAT1-/- and VMAT1+/+ (littermate control) mice in this study. Previously, we reported delayed acquisition of learning in an autoshaping task and reduced prepulse inhibition in VMAT1-/- mice at age 4-5 months compared to VMAT1+/+ mice of the same age. Previous immunohistochemical data also confirmed VMAT1 deficiency in the adrenals of VMAT1-/- mice as compared to VMAT1+/+ mice. We now report reduced locomotor activity in VMAT1 knockout mice, but not in wildtype control mice, when the

animals were exposed to mild food deprivation (food reduced to maintain 85% body weight) at 4-5 months of age. Under free-feeding conditions there were no significant differences in wild type and knockout mice in horizontal ambulation or thimotaxia (time spent near the perimeter of the cage), and the knockout mice actually displayed displayed significantly more vertical rearing than wildtype mice. Food restriction significantly reduced horizontal locomotion, thigmotaxia, and vertical rearing in knockout mice but had no significant effects on any of these locomotor behaviors in wildtype mice. We hypothesize that deficiencient storage and release of adrenal epinephrine in VMAT1-/- mice limited metabolic responses of these mice to food deprivation, which impacted locomotor activity. Nevertheless, we cannot rule out central neural effects of VMAT1 deficiency that may affect locomotion responses to the mild stress of food deprivation.

Title: Mechanisms of vesicular monoamine transporter-2 degradation

Authors: *E. K. STACHOWSKI[1], D. O. SAMBO[2], H. KHOSHBOUEI[2], G. E. TORRES[3]; [1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Dept. of Neurosci., [3]Dept. of Pharmacol. and Therapeut., Univ. of Florida, Florida, FL

Abstract: The vesicular monoamine transporter-2 (VMAT2) is essential for monoaminergic homeostasis, packaging monoamines into vesicles for exocytosis. VMAT2 also has a neuroprotective role, given that free monoamines in the cytosol have the potential to auto-oxidize and form dangerous free radicals that can ultimately contribute to oxidative stress. There are several pieces of evidence that low VMAT2 expression increases vulnerability to toxic insults, while VMAT2 overexpression is protective. Despite the importance of VMAT2, little is known about mechanisms involving VMAT2 degradation. The balance of protein synthesis and degradation is vital to maintain normal cellular function and dysregulation of degradation systems can be detrimental to neurons, as evidenced in disorders such as Parkinson's disease. There are two primary organelles responsible for degradation in mammalian cells: the lysosome and the 26S proteasome. Although synaptic vesicle proteins are thought to be degraded by the

lysosome via the endo-lysosomal pathway, little direct evidence exists for this. Furthermore, it remains unclear if these proteins can be differentially regulated or degraded at the vesicle. Utilizing an *in vitro* PC12 cell model stably expressing VMAT2-GFP, we examined whether VMAT2 is degraded primarily through the UPS (ubiquitin-proteasome system) or by the lysosome. Inhibition of the proteasome, but not the lysosome results in accumulation of VMAT2, as assessed by immunoblot and immunocytochemistry. Furthermore, inhibiting the lysosome has no impact on VMAT2 half-life, strongly indicating lysosome activity does not mediate VMAT2 degradation. Our data also suggests this UPS-related degradation of mature VMAT2 is a process independent of endoplasmic-reticulum-associated degradation (ERAD; a quality control mechanism likely involved with degradation of immature VMAT2). Our results strongly indicate that VMAT2 is not degraded via the endo-lysosomal pathway as traditionally believed, but is likely degraded by the UPS system.

Title: Fluoxetine induced behavioral alterations in *Drosophila melanogaster*

Authors: N. ROSA, O. GROVER, M. ASTHA, *P. G. MANDELA;
Dept. of Pharmaceut. Sci., Univ. of St. Joseph, Hartford, CT

Abstract: The overall goal of the project is to develop a reliable and valid model of *Drosophila melanogaster* (fruit fly) for screening selective serotonin reuptake inhibitors (SSRIs). Depression is a wide spread and debilitating illness often treated by targeting the monoaminergic neurotransmitter transporters. Inhibition of serotonin transporter (SERT) by selective serotonin reuptake inhibitors (SSRIs) is the leading strategy employed to treat depression and related neuropsychiatric illness. *Due to the restrictions imposed on the current animal models of depression, Drosophila melanogaster* could be a potential alternative animal model for SSRI screening. Flies have a sophisticated nervous system, containing 40 serotonergic neurons that

facilitate many complex behaviors.
Flies synthesize biogenic amines, pre-synaptic transporters, receptors and signaling pathways that mediate serotonin effects. *dSERT* gene encodes a protein with a topological organization that is analogous to other members of the SLC6 family of transporters including human serotonin transporter (hSERT). Although dSERT facilitates rapid reuptake of 5HT, it differs in pharmacology and substrate specificity in comparison to its mammalian orthologs. However it is not clearly understood how these difference in pharmacological differences would translate into behavioral changes. We embarked on a project to identify behavioral changes that results from selective serotonin reuptake inhibitor (SSRI) treatment. We plan to use these behavioral alterations as a repertoire to screen new SSRI's. We have used imipramine, fluoxetine and bupropion treatments for our behavioral studies. Our results indicate that imipramine was least effective and fluoxetine was the most effective drug in altering behavior in Drosophila Melanogaster.

Inst., Mount Sinai Hosp., Toronto, ON, Canada

Abstract: *N*-Methyl-D-aspartate receptors (NMDARs) are ionotropic glutamate receptors that consist mainly of tetrameric combinations of two subunit families, GluN1 and GluN2A-D. NMDARs are key mediators of synaptic plasticity, while over-activation of NMDARs is implicated in several neurological disorders. Attempts to develop competitive NMDAR antagonists and high affinity channel blockers to treat these disorders have been largely unsuccessful due to side effects associated with complete block of NMDAR function. Current research is driven by the need to develop selective NMDAR antagonists to (1) elucidate the function of the different receptor subtypes in synaptic plasticity, and (2) provide viable therapeutics for neurological diseases. Allosteric receptor sites typically have less amino acid conservation, and thus offer good targets for development of GluN2 subunit selective ligands. Additionally, negative allosteric modulators can function as partial antagonists, which offer better clinical safety compared to full antagonists. Recently work has investigated the GluN2A-D subunits as potential targets for the development of novel subunit selective negative allosteric modulators. A previous study by our group (Costa et al. 2012, Neuropharmacology 62:1730-36) highlighted that compounds based on 3-hydroxy-7-phenyl-2-naphthoic acid (UBP617) had partial antagonist effects on GluN2A and GluN2B but fully blocked GluN2C and GluN2D. Building on this work, we now present the results of our latest structure-activity relationship studies. By varying the substituents on the aromatic moiety at the 7-position of the 2-naphthoic acid ring we have developed a series of novel compounds that induce sub-maximal inhibition of the NMDAR and show a preference for inhibition of GluN2D. Such compounds may have an advantage over previous generations of antagonists, as they are partial antagonists and therefore may block the pathological response without interfering in normal CNS function. In summary, we have developed a series of novel, subunit-selective NMDAR negative allosteric modulators with partial antagonist activity. These compounds are likely to be valuable for studies of NMDAR function and may be valuable leads for the treatment of NMDAR hyperfunction-associated disorders, such as chronic pain.

Title: Activation of light sensitive adenylyl cyclase changes the time course of long-term potentiation at the Schaffer collateral - CA1 synapse in mouse hippocampal slices

Authors: *A. S. AVILA[1], J. GEORGIOU[1], K. OKAMOTO[2,1], G. L. COLLINGRIDGE[3,1]; [1]Mount Sinai Hosp., Sinai Hlth. Syst., Toronto, ON, Canada; [2]Mol. Genet., [3]Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Long-term potentiation (LTP) is a synaptic property regarded as one of the underlying mechanisms of learning and memory. In the hippocampus, and specifically at the Schaffer collateral - CA1 synapse, LTP can be induced by multiple rounds of theta burst stimulation (TBS). Importantly, the interval between these rounds of TBS determines the molecular pathway that is recruited during synaptic plasticity. Specifically, multiple, spaced TBS episodes favour the activation of a protein kinase A (PKA)-dependent LTP. In the present study, we have begun to study the spatial-temporal consequences of cAMP generation in CA1 synaptic plasticity.
We generated and analysed three light-sensitive mouse lines that each expressed Photoactivatable Adenylyl Cyclase (PAC) within the hippocampal subregions in a unique pattern and level. In our initial electrophysiological experiments, we combined TBS with an overlapping blue-light photo-activation of PAC, and found that PAC-Line1 showed an enhanced potentiation of CA1 synaptic responses that persisted for up to an hour after TBS.
The results of this study show that photo-activation of light sensitive adenylyl cyclase during TBS-induced LTP induction changes the extent and time course of LTP. The data are in agreement with the idea that cAMP could act as a primer for the establishment of PKA-dependent LTP. In future experiments we will manipulate the timing and spatial localization of PAC photoactivation to analyse the detailed spatial-temporal requirements and molecular effects downstream of cAMP.

Title: Distinct structural determinants within the GluN2C subunit regulate the surface delivery of NMDA receptors

Authors: *M. KANIAKOVA, K. LICHNEROVA, K. SKRENKOVA, L. VYKLICKY, M. HORAK;
Inst. of Physiol. CAS, Praha, Czech Republic

Abstract: The *N*-methyl-D-aspartate receptors (NMDARs) are ion channels that play an essential role in glutamatergic neurotransmission. The functional NMDARs are heterotetramers composed of GluN1, GluN2A-D and/or GluN3A-B subunits. All NMDAR subunits share the same structural features including four membrane-spanning segments (M1-M4), an extracellular N-terminus and an extracellular loop between M3 and M4, and an intracellular C-terminus. It is expected that the numbers and types of the NMDARs present at neuronal cell surface are regulated at multiple levels including their synthesis, subunit assembly, endoplasmic reticulum (ER) processing, intracellular trafficking and degradation. Although distinct regions within the GluN1 and GluN2 subunits regulate ER processing and the trafficking of functional NMDARs, subunit-dependent differences among the GluN2 subunit types which contribute to the early NMDAR processing have not yet been studied in detail. Here, we investigated the mechanisms that underlie the trafficking of GluN1/GluN2C receptors. By combining confocal microscopy and electrophysiology in heterologous cells and cultured cerebellar granule cells, we found that the surface expression of GluN1/GluN2C receptors is reduced compared to GluN1/GluN2A and GluN1/GluN2B receptors. Furthermore, using mutated GluN2C subunits, we identified three distinct regions in the GluN2C subunit (within the N-terminus, M3 domain, and C-terminus) that regulate the surface expression of GluN2C-containing NMDARs. We conclude that the GluN2C subunit controls the early processing of functional NMDARs by a unique combination of regulatory mechanisms.

Title: The characterization of N-glycans on cerebellar and recombinant NMDA receptor subunits

Authors: *M. HORAK, K. LICHNEROVA, M. KANIAKOVA, K. SKRENKOVA;
Inst. of Physiol. AS CR, Praha-4, Czech Republic

Abstract: *N*-methyl-D-aspartate receptors (NMDARs) are ionotropic glutamate receptors which form heterotetrameric complexes composed mostly of GluN1 and GluN2 subunits. We examined the *N*-glycan composition of cerebellar and recombinant NMDARs using deglycosylating enzymes, lectin-based biochemistry, and electrophysiology. Our results revealed that cerebellar NMDARs associate with 23 different lectins that have unique specificities for glycan structures. Using electrophysiology, we found that three specific lectins altered the functional properties of NMDARs expressed in either cultured cerebellar granule cells or HEK293 cells. Finally, using biochemistry we found that most of the putative *N*-glycosylation sites in GluN1 and GluN2B subunits are occupied by glycans. Together, these data shed light on the glycan composition of NMDARs, revealing potential targets for the development of novel therapeutic approaches.

Abstract: *N*-methyl-D-aspartate receptors (NMDARs) play critical roles in excitatory neurotransmission, synaptic plasticity, and excitotoxicity. Surface expression of NMDA receptors is regulated at multiple levels, which include processing in the endoplasmic reticulum (ER), intracellular trafficking and processing in the Golgi apparatus, internalization, recycling, and degradation. Previous studies have shown that posttranslational modifications as

phosphorylation and palmitoylation regulates NMDA receptor trafficing. However, the role of *N*-glycosylation, one of the most common posttranslational modifications, in regulating NMDAR processing has not been studied in detail. We examined whether the *N*-glycosylation sites present in GluN1, GluN2A, GluN2B and GluN3A receptors are necessary for surface delivery of the receptors. Using a combination of microscopy, biochemistry, and electrophysiology in heterologous cell lines and primary hippocampal neurons, we found that there are two critical *N*-glycosylation sites within the GluN1 subunit (Asn-203 and Asn-368) which are required for releasing of NMDARs from ER. No single *N*-glycosylation site within the GluN2A, GluN2B and GluN3A subunits appear to be essential for the surface delivery of NMDARs. Furthermore, we found that removing *N*-glycans from native NMDAR saltered the receptor affinity for glutamate. Our results suggest a novel mechanism by which neurons ensure that postsynaptic membranes contain sufficient numbers of functional NMDARs.

Title: Structural basis for negative allosteric modulation of GluN2A-containing NMDA receptors

Authors: *F. YI[1], T.-C. MOU[2,3], R. A. VOLKMANN[4], F. S. MENNITI[5], S. R. SPRANG[2,3], K. B. HANSEN[1,2];
[1]Dept. of Biomed. and Pharmaceut. Sciences, Univ. of Montana, Missoula, MT; [2]Ctr. for Biomolecular Structure and Dynamics, Missoula, MT; [3]Div. of Biol. Sci., Missoula, MT; [4]BioPharmaWorks, LLC, Groton, CT; [5]MindImmune Therapeut., Kingston, RI

Abstract: NMDA receptors mediate slow excitatory synaptic transmission and regulate synaptic plasticity in the central nervous system, but their dysregulation is also implicated in numerous psychiatric and neurological disorders. Subunit- selective modulators that only target NMDA receptor subtypes in specific brain regions or cell types could have unique therapeutic potentials.

We evaluated three negative allosteric modulators (NAMs), TCN-201, MPX-004 and MPX-007, all of which selectively inhibit GluN2A-containing NMDA receptors. The negative allosteric modulation is sensitive to the glycine concentration, and mutant GluN1 subunits, in which an engineered disulfide bond locks the ligand binding domain (LBD) in the closed agonist-bound conformation, abolish NAM inhibition. This experiment suggests that NAMs inhibition of GluN2A-containing NMDA receptors stabilizes the *apo*-state of the GluN1 LBD, which is incapable of triggering channel gating. Crystal structures of GluN1/GluN2A LBDs in complex with NAMs show the modulatory binding site in the interface between GluN1 and GluN2A subunits. We also uncover intra- and inter-subunit structural changes induced by NAM binding that correlate with structural and pharmacological differences between the NAMs. This work provides structural and mechanistic insight to allosteric NMDA receptor inhibition, thereby facilitating the development of novel classes NMDA receptor modulators as treatments in neurological diseases.

Title: X11 and X11L regulate the non-synaptic NMDA receptor localization

Authors: *R. MOTODATE, Y. SAITO, T. SUZUKI;
Hokkaido Univ., Sapporo/Hokkaido, Japan

Abstract: X11/Mint1 (Munc18-1 interacting protein 1), X11-like (X11L/Mint2), and X11-like 2 (X11L2/Mint3) are adaptor proteins whose are highly conserved evolutionarily. The X11 family proteins comprise a PTB (Phosphotyrosine binding) and two PDZ (PSD95/discs large/ZO-1)

domains in their carboxyl terminal half along with a poorly conserved N-terminal region [1]. X11 is predominantly and X11L is specifically expressed in brain neurons, while X11L2 expresses ubiquitously in many tissues. Previous reports indicate that X11s regulate localization of NMDA receptor and AMPA receptor *in vitro* or in *C. elegans* [2-4], suggesting that X11 and X11L play an important role in the postsynaptic function, but little is known for their exact roles in the postsynapse *in vivo*. Here, we analyzed X11/X11L double-deficient mice (X11/X11L DKO) to evaluate the role of X11 and X11L in postsynapse. Postsynaptic density (PSD) fraction and non-PSD fraction of mouse cortex and hippocampus regions were prepared with sucrose gradient centrifugation. The amount of NMDA receptor subunits were not changed in PSD, but non-synaptic NMDA receptor subunits were altered in X11/X11L DKO mouse. To evaluate of NMDA receptor function, I measured the activity of CREB in nuclear fraction from mouse cortex and hippocampus. In X11/X11L DKO, the CREB activity was changed. These data suggest that X11 and X11L regulate the non-synaptic NMDA receptor function through the regulation of their localization.

Title: $STEP_{61}$ differentially affects NMDARs and AMPARs

Authors: *S. WON[1], S. INCONTRO[2], R. NICOLL[2], K. ROCHE[1];
[1]NINDS, NIH, Bethesda, MD; [2]Dept. of Cell. and Mol. Pharmacol., Univ. of California, San Francisco, CA

Abstract: NMDARs and AMPARs are expressed throughout the nervous system and responsible for a variety of processes in mammalian brain including neuronal development, excitatory neurotransmission, learning and memory, and synaptic plasticity. NMDARs are heterotetramers formed between GluN1 and GluN2 (A-D) subunits. Calcium influx through NMDARs is thought to be critical in synaptic plasticity, a cellular mechanism for learning and memory. AMPARs are composed of four subunits (GluA1-4), which combine to form tetramers, mostly heterotetrameric. In addition AMPARs conduct the majority of fast synaptic transmission throughout the CNS and their modulation is the critical mechanism that underlies much of the plasticity at excitatory transmission. The precise regulation of NMDAR and AMPAR expression, trafficking, and localization is critical for proper neuronal function. Phosphorylation regulates surface and synaptic expression of NMDARs and AMPARs. In terms of phosphorylation of NMDARs and AMPARs, serine and threonine phosphorylation of NMDARs and AMPARs has been well studied, whereas the potential role of tyrosine phosphorylation of NMDARs and AMPARs has not received as much attention. It has been reported that tyrosine phosphorylation by Src family kinases regulates NMDAR and AMPAR trafficking via endocytosis. STEP (STriatal-Enriched protein tyrosine Phosphatase) is a brain-specific non-receptor tyrosine phosphatase. There have been previous studies that STEP binds to NMDARs and regulates their surface expression via dephosphorylation of Y1472 within endocytic motif of GluN2B. Using STEP knockdown, we now have elucidated a novel mechanism of $STEP_{61}$ regulation of GluN2B-containing NMDARs including regulation of extrasynaptic NMDARs. Indeed we find that STEP and PSD-95 play opposing roles with PSD-95 stabilizing NMDARs and destabilizing STEP, whereas STEP dephosphorylates GluN2B and reduces GluN2B-containing NMDARs via endocytosis. In the case of AMPARs, little is known about potential mechanisms of STEP regulating surface or synaptic expression of AMPARs. We find that $STEP_{61}$ binds to AMPARs in rat cultured cortical neurons and mouse hippocampus synaptosomes. In contrast to previous reports, we have examined AMPAR subunit-specific binding to $STEP_{61}$ showing differential regulation of GluA2 vs. GluA1. We have also investigated AMPAR vs. NMDAR subcellular expression in STEP KO mice showing differential regulation. Taken together, these results reveal a novel mechanism by which $STEP_{61}$ differentially regulates NMDARs and AMPARs.

Abstract: N-Methyl-D-aspartate receptors are localized to synaptic and extrasynaptic sites of dendritic spines and shafts. Here, the ontogenic profiles of GluN3A and GluN3B subunits in the rat brain were determined. A developmental switch from GluN3A to GluN3B proteins was detected within the first two postnatal weeks of crude synaptosomes prepared from forebrain and midbrain. Further fractionation of crude synaptosomes revealed the preferential localization of GluN3B to synaptic regions from P7 onwards. Immunolabeling and biochemical fractionation of rat P7 cultured hippocampal neurons showed that GluN3B was predominantly at synaptic sites. Unlike GluN2A and GluN2B, both GluN3 subunits were mostly associated with peripheral components of the postsynaptic density (PSD) rather than its core. When considering the non-PSD fraction, the overall extrasynaptic/synaptic spatial profile of GluN3B differed from GluN3A. Heterologous expression of GluN3B with GluN1 in HEK293FT cells could not be co-immunoprecipitated with PSD-95 unless co-expressed with a PSD-95-interacting GluN2 subunit, suggesting that anchoring of GluN3B at synaptic sites may require co-assembly with another scaffold-interacting NMDAR subunit.

Title: The nuclear localization of NMDA receptor in human pulmonary artery smooth muscle cells

Authors: Y. DONG, *D. R. LYNCH;
Pediatrics and Neurol., Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA

Abstract: NMDA receptor is ligand-gated ion channel which plays important roles in synaptic plasticity, memory formation, neural development, and many neurological disorders. NMDA receptor is also present in peripheral non-neuronal tissues including lung where NMDA receptor activation is implicated in airway contraction, lung injury and pulmonary arterial contractility. We previously showed that NMDA receptor is expressed in human pulmonary artery smooth muscle cells both in vivo and in vitro. Here we present the evidence that in addition to the plasma membrane localization, NMDA receptor (NR1/NR2A) is also localized in the nucleus of human pulmonary artery smooth muscle cells. Immunocytochemistry using antibodies against either N-terminus or C-terminus of NR2A subunit identifies the nuclear localization of NR2A in cultured human pulmonary artery smooth muscle cells but not in human embryonic kidney 293 cells transfected with NR1 and NR2A subunit. In order to confirm this result, we performed subcellular fractionation and found that both full length NR1 and NR2A subunit appeared in the nuclear fraction of human pulmonary artery smooth muscle cells. In contrast, neither NR1 nor NR2A subunit was detected in the nuclear fraction of rat cortical neurons. These results indicate that the subcellular localization of NMDA receptor is cell type specific. As functional NMDA receptor consists of both NR1 and NR2 subunit, the presence of full length NR1 and NR2A subunit in the nucleus of human pulmonary artery smooth muscle cells suggests that NMDA receptor in the nucleus of human pulmonary artery smooth muscle cells is potentially functional. The biological significance of NMDA receptor in the nucleus of human pulmonary artery smooth muscle cells remains to be investigated.

Title: Adaptation of NMDARs during exposure to HIV-1 Tat requires GluN2A-subunit signalling

Authors: *M. GREEN[1], S. THAYER[2];
[1]Neurosci., [2]pharmacology, Univ. of Minnesota, Minneapolis, MN

Abstract: HIV-associated neurocognitive disorders (HAND) affect about half of HIV-infected patients. Infected non-neuronal cells in the brain release neurotoxic factors such as transactivator of transcription (Tat) which potentiate neuronal NMDA receptor (NMDAR) function. Changes in NMDAR function regulate synaptic changes observed following exposure to HIV proteins such as Tat, which may underlie cognitive impairment in HAND patients. Here we used patch clamp recordings to measure NMDAR-mediated currents to investigate the mechanism of changes in NMDAR function. Exposure to Tat for 4 or 16 h potentiated NMDA-evoked whole cell current and increased the NMDAR:AMPAR ratio of evoked EPSCs. These changes adapted back to baseline amplitudes after 24 h exposure. Inhibition of GluN2A-containing NMDARs with the GluN2A-preferring antagonist, NVP-AAM 007, prevented this adaptation from occurring. Inhibition of GluN2B-containing NMDARs with the GluN2B-preferring antagonist, ifenprodil, did not prevent adaptation of NMDARs. Furthermore, inhibition of the E3 ubiquitin ligase, Mdm2, pharmacologically with nutlin-3, or genetically by expression of p14-ARF, also prevented adaptation of NMDARs. Inhibition of Mdm2 may prevent proteasomal degradation of PSD-95, a scaffolding protein that binds NMDARs and modulates their function. Future studies will investigate changes in NMDAR level and location by using live cell imaging to track expression of NMDAR subunits during exposure to Tat. Adaptation to the continued presence of Tat may be a neuroprotective response that also contributes to the synaptic loss that is a hallmark of HAND.

Abstract: Positive allosteric modulators (PAMs) of NMDA receptors may have therapeutic potential for neuropsychiatric & degenerative disorders. One critical step towards advancing

these compounds to the clinic is to demonstrate target engagement in-vivo. Since NMDA receptor antagonists like MK-801 or SDZ220,581 are known to increase locomotor activity, we reasoned that locomotor measures could also serve to demonstrate in-vivo target engagement for NMDA receptor PAMs. Using drug-drug interaction and pharmacogenetic approaches, we show that GNE-0723, a selective, potent and brain-available PAM that acts on GluN2A subunit-containing NMDA receptors, altered locomotor and rearing activity in a manner indicative of on-target activity. Assays of locomotor activity can serve as simple, yet reliable in-vivo indicators of target engagement for GluN2A NMDA receptor PAMs, and help accelerate early in-vivo profiling of putative novel therapeutics.

Title: Inhibition of NMDA receptors by the uncharged form of memantine

Authors: ***N. G. GLASGOW**, J. W. JOHNSON;
Dept. of Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: NMDA receptors (NMDARs) are a class of ionotropic glutamate receptors with unique biophysical properties including high Ca^{2+} permeability and highly voltage-dependent Mg^{2+} block. Ca^{2+} influx through NMDARs is critical for many types of synaptic plasticity and learning and memory. In contrast, aberrant activation of NMDARs is implicated in many central nervous system disorders. The clinical benefits of the NMDAR open channel blockers memantine and ketamine have spurred hope that NMDARs can serve as useful therapeutic targets. Although NMDAR inhibition by memantine and ketamine share similar features, their clinical effects vary substantially. Further understanding of how each drug inhibits NMDARs may yield insight into their clinical utility. One difference between the drugs' inhibition of NMDARs is that memantine, but not ketamine, inhibits at two sites on the receptor. Both drugs bind at a site deep within the channel pore that overlaps with the Mg^{2+} binding site (the deep site). Only memantine binds at a second site thought to be near the channel gate (the second site). Due to difficulties isolating inhibition at the deep and second sites, it is unclear what role binding of memantine, but not ketamine, to the second site may play in the drugs' differential inhibitory actions. Despite these difficulties, binding at the second site has been correlated with several characteristics of memantine inhibition, including: (a) the ability to bind in the absence of agonist; (b) paradoxically slow unbinding kinetics combined with a high IC_{50}; and (c) minimal voltage dependence. We tested the hypothesis that the uncharged form of memantine binds to the second site on NMDARs, which offers a parsimonious explanation for these characteristics because uncharged memantine: (a) is relatively hydrophobic, and so may be able to access the channel in the absence of agonist; (b) may bind with a very low IC_{50} (consistent with slow unbinding kinetics) that appears much higher at physiological pH where only ~0.1% of memantine is uncharged; and (c) should be insensitive to membrane voltage. To test our hypothesis we compared memantine inhibition of NMDARs at pH 7.2 with inhibition by the same total memantine concentration at pH 9.0, a pH at which uncharged memantine concentration is ~60-fold greater. We found that inhibition at the second site is greatly enhanced at pH 9.0. We also found that channel block by Mg^{2+} occluded memantine inhibition at the second site, suggesting a complex interaction between memantine and Mg^{2+} binding. Modification of pH provides a useful tool to investigate the distinct contributions of the uncharged and charged forms of memantine to NMDAR inhibition.

Title: A novel NMDAR positive allosteric modulator that potentiates currents via interaction with the GluN1 transmembrane domain

Authors: *T.-M. WANG[1], D. H. HACKOS[1], B. M. BROWN[1], B. D. SELLERS[2], P. J. LUPARDUS[3], H. J. A. WALLWEBER[3], E. WONG[1], M. VOLGRAF[2], J. B. SCHWARZ[2], J. E. HANSON[1];
[1]Neurosci., [2]Discovery Chem., [3]Structural Biol., Genentech, South San Francisco, CA

Abstract: Ionotropic glutamate receptors (iGluRs) mediate fast excitatory neurotransmission and are key drug targets in the nervous system. While diverse pharmacological tools have yielded insight into iGluR extracellular domain function, less is known about function of the transmembrane domain (TMD). We have discovered a novel NMDAR positive allosteric modulator, GNE-9278, that stabilizes a high open probability state once receptors are activated. An alanine scan identified residues in the TMD that are critical to GNE-9278 potentiation. Remarkably, swapping 3 critical residues in the GluN1 pre-M1 region from NMDARs to AMPARs was sufficient to confer GNE-9278 sensitivity to AMPARs. Mutation of a single GluN1 M3 residue could convert GNE-9278 effects from positive to negative allosteric modulation. Consistent with a unique mode of TMD action, NMDARs become insensitive to extracellular domain pharmacology during GNE-9278 modulation. These results reveal a new modulatory site in NMDARs and suggest the broader potential of iGluR modulation via the TMD.

Abstract: Since misuse of arylcyclohexylamines, such as ketamine, 'Special K', has become illegal in many countries, research chemicals have been developed to replace the banned substances. Recently the diaryl ethylamine, ephenidine, has become popular among those seeking a dissociative agent. We have investigated this compound as a potential N-methyl-D-aspartate (NMDA) antagonist in electrophysiological and receptor binding assays. Using extracellular recording from rat hippocampal slices, 4 hour of exposure to 1 and 10 μM ephenidine caused 23 ± 3 % and 81 ± 3 % reductions respectively of the NMDA- receptor mediated field epsp but was without effect on that mediated by α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors. In whole cell patch clamp experiments using a magnesium-free artificial cerebro-spinal fluid (aCSF), 10 μM ephenidine caused a greater reduction of inward current relative to outward current resulting in a rectification factor of 2.3 at -40/+40 mV, which compares with the ratio of 1.0 at the same holding potentials in control aCSF. When compared with effects of ketamine, D-2-amino-5-phosphonopentanoate (D-AP5) and magnesium ions on the same electrophysiological parameters, ephenidine's profile was very similar to that of ketamine. In receptor binding studies of rat brain membranes, ephenidine had nanomolar potency versus ^{3}H-MK-801 but less affinity at other neural receptors. Our data show that ephenidine is a selective, potent and voltage-dependent NMDA receptor antagonist, which is likely to explain its dissociative hallucinogenic effects in man and to account for its popularity among the population of party-goers looking for a replacement for ketamine. It may, therefore, suffer from many of the adverse effects associated with ketamine.

Title: Functional interaction between presynaptic receptors on dopaminergic and noradrenergic nerve terminals of the rat central nervous system

Authors: *M. PADOLECCHIA, G. OLIVERO, J. CHEN, A. PITTALUGA, M. MARCHI, M. GRILLI;
Dept. of Pharm., Univ. of Genoa, Genova, Italy

Abstract: It is well known that cross-talk between receptors represent an important mechanism of neuromodulation and plasticity. Although, these interactions have been mostly localized post-synaptically, receptors cross-talk which involves common intracellular pathways have been reported to occur also at the presynaptic level (for a review see Marchi et al 2015). Neuronal nicotinic acetylcholine receptors (nAChRs) in the CNS are located mostly presynaptically and have been implicated in facilitating release of neurotransmitter. It has been shown that dopaminergic and noradrenergic axon terminals in the nucleus accumbens and hippocampus possess nAChRs mediating enhancement of dopamine (DA) and noradrenaline (NA) release respectively. We investigated whether nAChRs and N-methyl-D-aspartic acid (NMDA) receptors interact on the same nerve endings using rat (male Sprague–Dawley, 200–250 g) synaptosomes pre-labelled with [^{3}H]DA or [^{3}H]NA. The *in vitro* short-term pre-exposure of synaptosomes (10 min) to different concentrations of acetylcholine (from 0.01 μM to 10 μM) caused a significant reduction (maximal effect: -54 % at 10 μM) of the 100 μM NMDA-evoked [^{3}H]DA overflow in the rat nucleus accumbens. This inhibitory effect was completely abolished when nerve endings were pretreated with acetylcholine plus dihydro-b-erythroidine indicating a mechanism that involved the activation of β_2* nAChR subtypes. Conversely, the pre-exposure to acetylcholine in presence of atropine (0.1 μM) was ineffective; these results completely excluded a role of muscarinic receptors.
Moreover, the pre-treatment of synaptosomes with nicotine (from 0.01 μM to 30 μM) caused a significant reduction of the 100 μM NMDA-evoked [^{3}H]NA overflow in the rat hippocampus. The pre-exposure of synaptosomes to nicotine or acetylcholine also caused a marked reduction of the nicotine-induced [^{3}H]DA or [^{3}H]NA overflow (-85% and -91.2 % respectively) suggesting that these nAChRs could undergo an agonist-induced receptor desensitization. Washout in vitro experiment clearly demonstrated that the nicotinic modulation of NMDA receptors function was time dependent and completely restored after 16 min.
Our results show that the function of presynaptic NMDA receptors can be dynamically regulated in different neurons trough a brief incubation with endogenous and exogenous nicotinic agonists.

Title: Structural and pharmacological evaluation of a class of GluN2A-selective competitive NMDAR antagonists with novel binding mode

Authors: *G. E. LIND[1], A. PINTO[2], L. TAMBORINI[2], P. CONTI[2], K. B. HANSEN[1];
[1]Univ. of Montana, Missoula, MT; [2]Univ. of Milan, Milan, Italy

Abstract: NMDA receptors (NMDARs) are important targets for glutamate, the primary excitatory neurotransmitter in the mammalian central nervous system. As such, NMDARs are also implicated in many neurological and psychiatric disorders. These heterotetrameric receptors are ligand-gated ion channels formed by glycine-binding GluN1 and GluN3 subunits and glutamate-binding GluN2 subunits. There are four GluN2 subunits (A-D) that endow distinct biophysical properties and physiological roles to the different NMDAR subtypes. Subunit-selective antagonists that distinguish NMDARs based on GluN2-subunit composition are useful pharmacological tools. Recent advances have produced multiple classes of NMDAR modulators with selectivity for the different GluN2 subunits. However, subunit-selective competitive antagonists that can be used as pharmacological tools to study NMDAR subunit composition in synaptic transmission are lacking. NVP-AAM077 is a competitive antagonist at the glutamate binding site of NMDARs and pharmacological evaluation showed that NVP-AAM077 binding affinity is ~5-fold higher for GluN2A- over GluN2B-containing NMDARs. We have developed a series of competitive glutamate-site antagonists with nanomolar binding affinities and using Schild analysis, we show that these compounds possess up to 15-fold greater binding affinity for N2A-containing receptors over N2B-containing receptors. This represents a major improvement over current competitive antagonists with preference for GluN2A. By solving the crystal structure for the GluN1/GluN2A ligand binding domain heterodimer in complex with four of these compounds, we have revealed a novel binding mechanism in the glutamate binding pocket. The crystal structures, in combination with electrophysiological recordings, have been used to evaluate the mechanisms of antagonist binding and subunit selectivity for the compounds. These studies expand our understanding of NMDAR pharmacology and provide a foundation for future ligand design of novel pharmacological tools or compounds with therapeutic potential.

Title: Glun2b-containing nmdars and depression-like behavior: synaptic, cellular, and circuit mechanisms

Authors: *O. H. MILLER[1], B. J. HALL[1,2];
[1]Tulane University, Neurosci. Program, New Orleans, LA; [2]Pharmaceut. Res. and Early Development, Roche Innovation Ctr., Hoffman-La Roche, Basel, Switzerland

Abstract: A single, low dose of the NMDA-receptor (NMDAR) antagonist ketamine results in rapid antidepressant effects in Major Depressive Disorder patients and antidepressant-like behaviors in animal models of depression. Despite its short half-life, ketamine's antidepressant effects sustain up to a week, suggesting that this brief window of NMDAR antagonism initiates changes leading to long-lasting alterations in brain function. Research from our lab and others demonstrates that this single dose of ketamine initiates mTOR-dependent protein synthesis of excitatory synapse-associated proteins, and elevated synaptic inputs onto mPFC pyramidal neurons measured 24 hours later. While the molecular mechanisms underlying this process have been well studied, the field lacks an extensive understanding of the brain regions involved, how ketamine alters connectivity between distributed nuclei, and how alterations in neuronal electrophysiological properties underlie these circuit alterations.
We have previously demonstrated that genetic removal of GluN2B-containing NMDARs from forebrain pyramidal neurons mimics and occludes the antidepressant and synaptogenic effects of ketamine in vivo. Here we demonstrate that post-developmental, viral deletion of GluN2B from mPFC pyramidal neurons is sufficient to recapitulate these antidepressant behavioral effects in the absence of hyperlocomotion ((OFT distance traveled; Control: 901.22 +/- 84.51cm, 2BΔ: 804.08 +/- 16.23cm; ns.) (TST immobility time; Control: 186.40 +/- 11.69s, 2BΔ: 143.21 +/- 11.83s; $p<0.05$.) (FST immobility time; Control: 108.38 +/- 10.17s, 2bΔ: 66.90 +/- 17.12s; $p<0.05$)) and induce alterations both in the inputs received by (sEPSC Amplitude; Control: 12.12 +/- 0.65pA, 2bΔ: 18.38 +/-1.85pA; $p<0.01$) and the outputs distributed from these neurons (AP Frequency; Control: 2.38 +/- 0.86Hz, 2BΔ: 6.44 +/- 0.63Hz; $p<0.01$).
The Medial Dorsal Thalamus is an essential integrator of central nodes of limbic information

including the Dorsal Raphe, Amygdala, and Habenula, and projects to mPFC. Using in vivo stereotaxic injections of viral vectors followed by in vitro optogenetic techniques, we sought to determine if the strength of these inputs are altered by NMDAR antagonism or removal of GluN2B. Our findings potentially provide novel cellular and circuit-level targets for optimizing future preclinical studies and clinical therapies based on the profound antidepressant effects of ketamine.

Title: Presynaptic NMDA receptors contribute to short-term plasticity at mossy fiber-CA3 synapses

Authors: ***P. J. LITUMA**[1], H. KWON[1], R. LUJAN[2], P. E. CASTILLO[1];
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Univ. of Castilla-La Mancha Inst. de Investigacion en Discapacidades Neurologicas (IDINE), Ciudad Real, Spain

Abstract: Neurotransmitter release is a highly regulated process that exquisitely controls the strength of neuronal communication. Presynaptic Ca^{2+} rise is a key component of this process not only for triggering synchronous, action-potential driven transmitter release, but also for facilitating neurotransmitter release during repetitive presynaptic activity. Hippocampal mossy fiber synapses, which carry the main excitatory input to the hippocampus proper, express uniquely robust activity-dependent facilitation. The molecular mechanisms underlying this form of short-term plasticity remain poorly understood, although glutamate autoreceptors may participate. Presynaptic NMDA receptors (preNMDARs) at the mossy fiber bouton have been reported more than three decades ago (Siegel et. al, *PNAS*, 1994) but their role remains unexplored. Here we test the hypothesis that preNMDARs likely due to their high Ca^{2+} permeability contribute to mossy fiber robust short-term facilitation. Using immunoelectron microscopy we identified the obligatory NMDAR subunit GluN1 in rat mossy fiber boutons. To

assess the role of preNMDARs we used electrophysiology, selective pharmacology, and two-photon laser scanning microscopy in acute rat hippocampal slices. Bath application of MK-801 (50 μM) reduced both low-frequency (0.1 to 1.0 Hz steps) and burst-induced (5 stimuli, 25 Hz) facilitation when postsynaptic NMDARs were blocked by loading CA3 pyramidal cells with MK-801 (2 mM). Calcium imaging of mossy fiber giant boutons (200 μM, Fluo5F intracellularly loaded into dentate granule cells) revealed a dAPV-sensitive Ca^{2+} component during brief bursts of activity, suggesting preNMDARs participate in presynaptic Ca^{2+} rise. Together, our findings reveal that during repetitive activity preNMDARs facilitate glutamate release from mossy fiber boutons. Thus, preNMDARs may contribute significantly to dentate gyrus-CA3 information transfer.

Title: Local calmodulin coupling to NMDA receptors mediates their Ca^{2+}-dependent inactivation

Authors: *G. IACOBUCCI, G. POPESCU;
Biochem., State Univ. of New York At Buffalo, Buffalo, NY

Abstract: In the central nervous system, NMDA receptors produce large and highly regulated Ca^{2+} fluxes, which are critical for synaptic development, plasticity, and apoptosis. Among the mechanisms regulating NMDA receptor currents, Ca^{2+}-dependent inactivation (CDI) is a rapid, reversible, and specific process by which intracellular Ca^{2+} reduces channel activity in a calmodulin (CaM)-dependent manner. Impaired NMDA receptor CDI may contribute to epilepsy pathogenesis and the neurologic symptoms of patients with calmodulinopathies, but the process is poorly understood.
Here, we used single-channel and macroscopic current recordings from GluN1-2a/GluN2A receptors expressed in HEK293, under controlled Ca^{2+}-buffering conditions, to identify the CaM molecules responsible for NMDA receptor CDI in response to local Ca^{2+} signals. These results, combined with mathematical models of local Ca^{2+} diffusion indicated that the CaM molecules

mediating NMDA receptor CDI most likely reside within 10 nm from the NMDA receptor pore. This spatial arrangement allows for fast and highly specific auto-inhibition in response to Ca^{2+} influx from the parent channel.
Next, we used a live-cell functional assay using overexpression of engineered CaM molecules to probe the sequence of events mediating NMDA receptor CDI. Our results provide the first evidence in live cells that NMDA receptor-driven Ca^{2+} nanodomains trigger CDI by specifically activating apoCaM molecules that are preassociated to the C0 cassette of the GluN1 subunit, consistent with CaM's proximal location to the pore.
Together, these results begin to dissect the sequence of events underlying NMDA receptor CDI to provide a more rigorous understanding of molecular mechanism that tune NMDA receptor-mediated Ca^{2+} fluxes and the downstream signaling cascades they control.

Title: Activity-dependent postsynaptic signaling in hippocampal neurons is altered by transgenic expression of chimeric NMDA receptor GluN2 subunits

Authors: *S. HUSSAIN[1], J. P. FOTANG[2], M. P. GREER[2], J. M. OILVER[2], M. DARAB[2], G. P. MAI[2], T. C. DUMAS[2];
[1]Biol., [2]George Mason Univ., Fairfax, VA

Abstract: N-methyl-D aspartate receptors (NMDARs) at excitatory synapses in the hippocampus are central players in the synaptic plasticity required for learning and memory. Two predominant signaling properties of NMDARs that have been independently linked to hippocampal plasticity are calcium conductance into the postsynaptic spine and direct intracellular protein interactions. These properties vary with the composition of the NMDAR such that, compared to NMDARs with GluN2A subunits, NMDARs with GluN2B subunits conduct calcium for a longer period after activation and display greater affinity for the obligatory synaptic plasticity protein, CaMKII. Thus, it is not possible to determine the separate influences

of these NMDAR properties by switching the entire GluN2 subunit. To overcome this obstacle, GluN2 chimeras have been created and engineered into transgenic mice. While changes synaptic plasticity and behavior have been documented in these animals, direct measurement of intracellular signaling has not been performed. We generated two transgenic mouse lines, one having the amino (A)-terminus and transmembrane domains (TMDs) of GluN2A fused to the carboxy (C)-terminus of GluN2B (termed ABc) and, vice versa, the other line having the A-terminus and TMDs of GluN2B fused to the C-terminus of GluN2A (termed BAc). These chimeric GluN2 subunits were expressed in transgenic mice using the tet-off expression system with tetracycline transactivator protein (tTA) expression under transcriptional control of the CaMKII minimal promoter. tTA expression was seen in many forebrain regions, but predominantly in hippocampal pyramidal cells. To induce synaptic plasticity in the hippocampus, animals were briefly exposed to a Y-maze in a novel testing environment. We quantified intracellular signaling through immunohistochemistry and analysis of expression level and colocalization of plasticity-related proteins. Pairs of antibodies were applied (anti-pCaMKII and anti-CaMKII or anti-PSD95 and anti-calmodulin). Currently, we observe an increase in the PSD95 signal and an increase in the PSD95 to calmodulin ratio in maze-exposed animals compared to naïve controls. Also, while the number of samples is low, we see no effect of maze or genotype on pCaMKII or CaMKII. These experiments will reveal which functional property of NMDARs is altered to the greatest extent in mice expressing chimeric GluN2 subunits. Findings from this study will begin to clarify how NMDARs regulate synaptic plasticity and learning and memory.

Title: Evaluation of NMDA receptor human mutations suggests a role for pre-M1 helix in gating

Authors: *M. J. MCDANIEL[1], K. K. OGDEN[1], W. CHEN[1], S. A. SWANGER[1], C. HU[1], A. TANKOVIC[1], H. KUSUMOTO[1], G. J. KOSOBUCKI[2], A. J. SCHULIEN[2], Z. SU[1], J. PECHA[1], S. BHATTACHARYA[1], E. AIZENMAN[2], S. F. TRAYNELIS[1], H. YUAN[1];
[1]Pharmacol., Emory Univ., Atlanta, GA; [2]Neurobio., Univ. of Pittsburgh Sch. of Med. and Pittsburgh Inst. for Neurodegenerative Dis., Pittsburgh, PA

Abstract: NMDA receptors are tetrameric complexes of GluN1 and GluN2 subunits. Recently, a number of de novo mutations have been identified in the GRIN gene family encoding NMDA receptor subunits. Several missense mutations have been identified within the pre-M1 two turn helix that lies parallel to the plane of the membrane, is in van der Waals contact with the M3 gate, and is immediately upstream of the first transmembrane domain. We studied GluN1(D552E), GluN1(P557R), GluN2A(A548T), GluN2A(P552R), and GluN2B(P553L), which are de novo mutations found in children with developmental delay and/or epilepsy. Interestingly, no polymorphisms have been identified among the healthy population in the pre-M1 helix, suggesting that missense mutations in this region may contribute to neurological problems. Here we explore the effects of mutations on NMDA receptor expression and surface localization and response time course. Consistent with data implicating this short pre-M1 helix in channel gating, these mutations had functional consequence, with GluN1(D552E), GluN1(P557R), and GluN2A(A548T) showing reduced current responses, GluN2B(P553L) showing complete loss of function, and GluN1(P557R) and GluN1(D552E) showing reduced surface expression when co-expressed with GluN2A and GluN2B, respectively. In addition, there was significantly reduced overall expression of GluN1 (P557R) when co-expressed with GluN2B, but no change in expression levels of GluN2A(A548T). GluN2A(P552R) prolonged the response to brief synaptic-like stimulation and markedly increased charge transfer. Transfection of cultured neurons with GluN2A(P552R) triggered dendritic swelling, consistent with enhanced response of synaptic NMDARs containing GluN2A(P552R). Results from this study suggest that the pre-M1 helix is critical for receptor gating, such that mutations in this region are sufficient to disrupt receptor functioning and, ultimately, neuronal health.

Title: PSD-95 blocks amyloid-beta induced depression by preventing NMDA receptor metabotropic actions

Authors: *K. B. DORE[1], Z. CARRICO[2], R. MALINOW[2];
[1]Neurosciences, [2]UCSD, La Jolla, CA

Abstract: Previous studies show that amyloid-beta (Aβ) depresses excitatory synapses. The underlying mechanisms are not well understood. We observed that PSD-95 overexpression prevented the depressive effects of amyloid-beta on synaptic transmission. This effect was also observed in slices made from GluR1 KO animals suggesting that PSD-95 effects were not due to synaptic incorporation of GluR1 receptors leading to potentiation. Recent evidence suggests that Aβ-induced synaptic depression requires ligand binding to NMDA receptors (NMDARs) but not ion-flux. Here we use FRET-FLIM (Forster resonance energy transfer, fluorescence lifetime imaging) to show that Aβ can modify the conformational configuration of the NMDAR c-terminal domain without ion-flux. Spines of neurons expressing GluN1 subunits tagged with GFP and mCherry were imaged using FLIM. Spines from neurons also expressing a construct that increases Aβ production displayed reduced FRET. The reduced FRET between GluN1 subunits is similar to what was observed upon ion-flux independent chemical long-term depression (cLTD), which supports a common mechanism for Aβ induced depression and cLTD dependent on metabotropic actions of NMDARs. Interestingly, we observed that PSD-95 overexpression froze the NMDAR cytoplasmic domain in a non-depressed conformation, even in the presence of Aβ, possibly through increased PSD-95/NMDAR interactions. These results indicate that PSD-95 prevents the effects of amyloid-beta by interfering with NMDAR metabotropic function.

Title: A long non-coding RNA induced in alcoholics reduces NMDA receptor expression without modifying GABA-A nor glycine receptor expression

Authors: *C. BORGHESE, K. J. LAWRENCE, E. OSTERNDORFF-KAHANEK, S. P. FARRIS, R. A. HARRIS;
Waggoner Ctr. for Alcohol and Addiction Res., Univ. of Texas At Austin, Austin, TX

Abstract: Long non-coding RNAs (lncRNAs) are defined as RNA molecules of more than 200 bases in length with no protein-coding capacity. They have been shown to interact with DNA, RNA and proteins in myriad ways, and their multiple roles are barely beginning to be characterized.
Chronic alcohol exposure led to differential expression of a human lncRNA (LINC01559) and its mouse counterpart (4930425L21Rik) in nucleus accumbens. Weighted Gene Co-Expression Network Analysis (WGCNA) showed that LINC01559 was negatively correlated to a module of genes that included a significant number of genes involved in CNS (glutamatergic) plasticity, which could indicate a regulatory role for LINC01559 in glutamatergic transmission. This lncRNA is located near the gene encoding the GluN2B NMDA receptor subunit in both human and mouse chromosomes, further supporting a link with glutamatergic transmission. We co-injected human LINC01559 (LNC) with cRNA encoding NMDA, $GABA_A$ or glycine receptors in *Xenopus laevis* oocytes, and tested the receptor function using two-electrode voltage clamp. Co-injection of LNC with NMDA receptors (either GluN1+GluN2B or GluN1+GluN2A) resulted in receptors that showed decreased maximal currents but concentration-response curves similar to controls. This suggests that LNC interacted with either the cRNA encoding these subunits or with the protein, ultimately interfering with their expression on the oocyte surface. Co-injection of LNC with $GABA_A$ $\alpha1\beta2\gamma2$ or glycine $\alpha1$ receptors resulted in concentration-response curves and maximal currents similar to controls. Thus, there is a specificity of action of LNC on NMDA receptors.
The precise mechanism by which LNC interacts with NMDA receptors is yet to be determined. However, this is, to our knowledge, the first reported interaction of a lncRNA with a specific receptor RNA or protein. Supported by grants from the National Institutes of Health: AA006399 (RAH) and Training Grant AA007471 (SPF).

Title: Missense mutations reveal a key role for the M4 eukaryotic specific transmembrane segment in NMDA receptor gating

Authors: J. AMIN[1], K. CHAN[2], Q. GAN[2], *L. P. WOLLMUTH[3,4];
[1]Cell and Mol. Pharmacol., [2]Program in Neurosci., [3]Neurobiol & Behavior, [4]Biochemistry& Cell Biol., Stony Brook Univ., Stony Brook, NY

Abstract: NMDA receptors (NMDAR) are glutamate-gated ion channels that have a wide distribution in the nervous system. Dysfunction of NMDARs is implicated in numerous chronic (Parkinson's, Alzheimer's), acute (stroke, epilepsy) and psychiatric (schizophrenia) brain disorders. Recently, a variety of *de novo* missense mutations in NMDAR subunits have been identified that are associated with neurodevelopment disorders. NMDARs are obligate heterotetramers typically composed of GluN1 and GluN2 subunits. Each subunit contributes three transmembrane segments, M1, M3, & M4, and an M2 pore loop to forming the iGluR ion channel. The central core of the ion channel, which is homologous to an inverted K^+ channels, is formed by M1-M3. In AMPA receptors, the M4 segment is involved in receptor assembly whereas in NMDARs it appears to have a more prominent role in facilitating channel opening in the presence of agonist. Highlighting this feature, we find that *de novo* missense mutations in the M4 segment the GluN1 and GluN2A subunits strongly attenuate NMDAR pore opening or gating in the presence of agonist. Notable in the M4 segment is a highly conserved glycine, that is present in >80% of all eukaryotic iGluRs. Missense mutations at this position are found in the GluN1 and GluN2B subunits, and these mutations dramatically attenuate pore opening. Even substitution of alanine at this conserved G impedes the ability of the receptor to open. These results have strong implications for how such disorders are caused at the ion channel level and highlight an important role for the M4 segment in normal NMDAR gating.

Title: Molecular dynamics simulations reveal the importance of glycans on N-methyl-D-aspartate (NMDA) receptors

Authors: *A. SINITSKIY[1], N. STANLEY[1,2], V. PANDE[1];
[1]Chem., Stanford Univ., Stanford, CA; [2]Genentech Inc., South San Francisco, CA

Abstract: N-methyl-D-aspartate (NMDA) receptors (NMDARs) are transmembrane proteins expressed in cells in the nervous system. Malfunctioning of NMDA receptors correlates with various neurological disorders, including schizophrenia, epilepsy, intellectual disability and autism, but specific molecular mechanisms for these correlations remain largely unknown. NMDARs *in vivo* are heavily glycosylated. At least 9 glycans are attached to each GluN1, at least 4 glycans to each GluN2A, and at least 7 glycans to each GluN2B subunit. Surprisingly, glycans attached to NMDARs have not received due attention in previous studies of the structure and function of NMDARs. We hypothesize that an inappropriate glycosylation of NMDARs may contribute to the development of some neurological disorders, such as schizophrenia. We use computational approach, specifically, all-atom molecular dynamics simulations analyzed with machine learning based on Markov state models, which allows us to address important questions about NMDA receptors that current experimental methods alone do not answer. In particular, we predict that glycosylation at specific sites on NMDA receptors, including Asp440 residue in the GluN1 subunit, changes the stability of various conformations of NMDARs, and by doing so, glycans on NMDARs effectively play an agonist-like role. This conclusion could change the state of affairs in the field of ion channel research, where glycans attached to ion channels have not received any significant attention so far. Partially, this gap in knowledge can be explained by tremendous technical difficulties of selectively controlling and measuring glycosylation patterns in ion channels. Overall, computational modeling provides a unique source of information about NMDA receptors, complementary to the information available from modern experimental techniques.

Title: Transient neuronal depolarization induces rapid, NMDA receptor-dependent, endogenously reversible and recurrent fission of the neuronal endoplasmic reticulum in physiology and disease *In vivo*.

Authors: *K. KUCHARZ[1], M. LAURITZEN[1,2];
[1]Univ. of Copenhagen, Copenhagen, Denmark; [2]Glostrup Hosp., Copenhagen, Denmark

Abstract: BACKGROUND: The neuronal endoplasmic reticulum (ER) is the major intracellular Ca2+ store that modulates synaptic transmission and plasticity. The ER maintains structural continuity through all neuronal compartments, allowing long-distance intracellular diffusion of Ca2+ and protein trafficking, and integrates spatially separated synaptic events with gene expression. The transition to discontinuous state of neuronal ER is regarded as a hallmark of cell death. Here, in contrast, we provide the first longitudinal description of ER dynamics *in vivo* and show that the brain has an innate ability to reversibly and recurrently alter neuronal ER continuity in response to synaptic input in physiology and disease with important implications for neuronal function. **METHODS:** We used *in vivo* 2-photon microscopy in transgenic mice expressing soluble EGFP targeted to neuronal ER lumen. The ER was assessed in the

somatosensory cortex during whisker pad stimulation and in pathology during cortical spreading depolarizations (CSD) that accompany stroke, brain trauma and migraine. The ER continuity was monitored using developed real-time profile plot variance analysis and with fluorescence recovery after photobleaching. Intracellular Ca2+ was monitored with the red-shifted Ca2+ indicator and simultaneously with imaging we performed *in vivo* electrophysiological recordings of direct current and local field potentials (LFPs; electrocorticogram, ECoG). **RESULTS:** The neuronal ER in its basal state was continuous, as assessed up to 450 μm below the brain surface, with clear spine-ER morphology. However, during whisker pad stimulation the ER in spines exhibited rapid (<15 s) loss of connectivity with dendritic ER. The process was reversible (<1-2 min) and depended on NMDA receptor activation. In pathology, with neuronal depolarization during CSD, the ER underwent rapid (~10 s) and widespread fission in dendrites into numerous, optically isolated structures. With the repolarization, the ER gradually regained its pre-CSD morphology (~1 min; ER fusion). Interestingly, a fraction of ER remained isolated and the increase and decline in the amount of isolated ER over time after depolarization mirrored the degree of loss and regain of neuronal activity (LFPs/ECoG). The ER fission-fusion could occur multiple times within the same neuron, correlated spatio-temporally with the rise in intracellular Ca2+, and was compatible with cell survival. **SUMMARY:** Rapid ER fission-fusion in the brain is a previously unknown *in vivo* phenomenon that may affect neuronal Ca2+ signaling, homeostasis, synaptic activity and thus many vital aspects of brain function in physiology and disease.

Title: Cav3.1-mediated calcium entry triggers CaM / αCaMKII-dependent CREB activation and potentiation of the parallel fiber EPSP in Purkinje cells

Authors: *H. ASMARA, I. MICU, A. P. RIZWAN, G. SAHU, B. A. SIMMS, F.-X. ZHANG, P. K. STYS, G. W. ZAMPONI, R. W. TURNER;
Cell Biol. & Anat., Univ. of Calgary, Calgary, AB, Canada

Abstract: At the circuit level memory formation is signified as a change in synaptic efficacy as a result of previous activity. A long term potentiation (LTP) of synaptic efficacy depends on calcium influx into the cell that triggers a signaling cascade and initiates gene transcription in the nucleus. Calmodulin (CaM) is an important signalling molecule that regulates a vast array of second messenger cascades that can also lead to gene transcription. Low voltage-activated calcium channels of the Cav3 family have the important role of mediating low threshold calcium influx, but were not believed to interact with CaM. We find a constitutive association between CaM and the Cav3.1 channel at rest that is lost through an activity- and Cav3.1 calcium-dependent CaM dissociation. Moreover, Cav3 calcium influx activates αCaMKII in the cytoplasm and phosphorylation of CREB in tsA-201 cells, cultured hippocampal cells and lobule 9 cerebellar Purkinje cells. Recent work has revealed a Cav3.1 channel-dependent LTP of cerebellar parallel fiber input to Purkinje cells. Optogenetic excitation of parvalbumin-ChR2 expressing Purkinje cells in vitro is sufficient to activate αCaMKII and evoke a Cav3.1-mediated LTP of a simulated postsynaptic EPSP in Purkinje cells. Our findings thus establish that T-type channel calcium influx invokes a novel dynamic interaction between CaM and Cav3.1 channels and triggers a signaling cascade directly relevant to postsynaptic LTP of the parallel fiber EPSP in Purkinje cells.

Title: Densin-180 regulates the cell-surface density of voltage-gated $ca_v1.2$ Ca^{2+} channels

Authors: *S. WANG[1], J. HAGEN[1], R. I. STANIKA[2], G. J. OBERMAIR[2], M. B. KENNEDY[3], R. J. COLBRAN[4], A. LEE[1];
[1]Mol. Physiol. and biophysics, Univ. of iowa, Univ. of Iowa, Iowa City, IA; [2]Div. of Physiol., Innsbruck Med. Univ., Innsbruck, Austria; [3]Div. of Biol., Caltech, Pasadena, CA; [4]Mol. Physiol. and Biophysics, Vanderbilt Univ., Nashville, TN

Abstract: Densin-180 (densin) is an excitatory synapse protein that interacts with and facilitates voltage-gated $Ca_v1.3$ (L-type) Ca^{2+} channels. Mice lacking densin (densin KO) exhibit impaired spatial memory and increased anxiety-related behaviors. Similar phenotypes are found in mice with forebrain-specific knockout of the major L-type channel in the brain, $Ca_v1.2$, but not in mice lacking $Ca_v1.3$. These findings suggest that densin could be a crucial regulator of $Ca_v1.2$ as well as $Ca_v1.3$. Therefore, we tested the hypothesis that densin functionally interacts with $Ca_v1.2$. When expressed in transfected HEK293T cells, densin coimmunoprecipitates with $Ca_v1.2$ channels and increases $Ca_v1.2$ current density in part by increasing the number of functional channels. These results are physiologically relevant since densin coimmunoprecipitates with $Ca_v1.2$ from mouse brain, and Ca_v1-mediated Ca^{2+} currents are smaller in cortical neurons from densin KO than from control mice. Moreover, overexpression of densin increases the clustering of $Ca_v1.2$ channels in dendrites of hippocampal neurons. Cell-surface levels of $Ca_v1.2$ protein are reduced in densin KO brain, which likely explains the reduction in $Ca_v1.2$-mediated phosphorylation of the transcription factor CREB in densin KO neurons. The effect of densin on cell-surface $Ca_v1.2$ channels is likely due to an enhancement of forward trafficking rather than a reduction in endocytosis of $Ca_v1.2$, based on analyses of channel dynamics in transfected HEK293T cells. We conclude that densin is a component of $Ca_v1.2$ complexes in the brain, which augments the number of cell-surface channels that are available for excitation-transcription coupling. Our results underscore the importance of $Ca_v1.2$ channel-protein interactions for neuronal Ca^{2+} signaling, and suggest that dysregulation of such interactions may lead to cognitive and affective phenotypes such as those in densin KO mice.

Title: Cdk5 phosphorylates Cav1.3 channels and regulates its activity.

Authors: ***S. LOYA**[1], R. GONZÁLEZ[2], A. SANDOVAL[3], M. RODRIGUEZ SANCHEZ[1], R. FELIX[3], D. ERLIJ[4], B. FLORÁN[1];

Abstract: Cyclin-dependent kinase 5 (cdk5) has been implicated in neurotransmission. Neurotransmission depends largely on calcium movement across ion permeable channels. Several studies suggest a significant role of cdk5 in direct regulation of various ion channels; in hippocampal synaptosomes, phosphorylation of P/Q type calcium channels prevents its interaction with SNAP25 and synaptotagmin 1, thereby inhibiting glutamate release from these terminals.
In this work, we study the possible regulation by phosphorylation of cdk5 to Cav1.3 calcium channels, which regulate significantly the GABA release of striato-nigral terminals. Also we studied the implication of this phosphorylation in the electrophysiological properties of Cav1.3. Through electrophysiology experiments in HEK293 cells transfected with Cav1.3 channel and its respective auxiliary subunits, we found that, by inhibiting cdk5 with olomoucine (50 μM), there is an increase of current density. This speaks of an inhibitory mechanism exerted on Cav1.3 and is also probably due to phosphorylation by cdk5 of a serine residue located at the carboxyl terminus of this calcium channel.
Our results suggest a novel mechanism of regulation of neurotransmission by a phosphorylation event, whose understanding may be useful for the development of therapeutic alternatives against neurodegenerative diseases such as Parkinson's disease.

Title: Presynaptic alpha2delta subunits of voltage-gated calcium channels modulate postsynaptic $GABA_A$-receptor abundance

Authors: *S. GEISLER, C. L. SCHÖPF, R. STANIKA, L. TRAXLER, G. J. OBERMAIR; Dept. of Physiol., Med. Univ. Innsbruck, Innsbruck, Austria

Abstract: Auxiliary $\alpha_2\delta$ subunits modulate membrane trafficking and current properties of voltage-gated calcium channels and they have been implicated in synapse formation. By employing a cellular $\alpha_2\delta$ triple knockout model in cultured hippocampal neurons, we could recently identify $\alpha_2\delta$ subunits as key regulators of glutamatergic synaptogenesis. In contrast, synapses of GABAergic neurons seemed unaffected by knockout of all three subunits and thus the role of $\alpha_2\delta$ subunits in GABAergic synapses remained unclear. Surprisingly, however, overexpression of $\alpha_2\delta$-2 induced a mismatched localization of postsynaptic $GABA_A$-receptors ($GABA_AR$) opposite glutamatergic terminals. This puzzling observation could be explained in two ways: firstly, since overexpression of $\alpha_2\delta$-2 increases presynaptic calcium channel abundance, postsynaptic $GABA_AR$ may be recruited to compensate for excessive excitatory synaptic activity. In this scenario we expect $GABA_AR$ abundance at inhibitory GABAergic synapses to remain unchanged. Secondly, presynaptic $\alpha_2\delta$-2 may actively participate in the recruitment and/or anchoring of postsynaptic $GABA_AR$. Here, $GABA_AR$ density should be increased both in glutamatergic and GABAergic synapses. In order to distinguish between these two hypotheses we established cultures of striatal neurons, which consist of approximately 95% inhibitory medium spiny neurons (MSN). In line with previous observations the proper maturation of dendritic arbors and spines of MSN required the co-culture with glutamatergic cortical neurons. To test whether $\alpha_2\delta$ subunits affect the composition of GABAergic synapses, we transfected MSN with individual $\alpha_2\delta$ isoforms together with soluble eGFP. Finally, differentiated MSN (DIV24) were immunolabeled for pre- and postsynaptic constituents of GABAergic synapses (vGAT/ $GABA_AR$ $\beta_{2/3}$ subunit). High-resolution fluorescence microscopy revealed a significant increase of both size and intensity of postsynaptic $GABA_AR$ clusters opposite presynaptic terminals of MSN overexpressing $\alpha_2\delta$-2. Conversely, $GABA_AR$ content in $\alpha_2\delta$-3 expressing synapses was strongly reduced when compared with $\alpha_2\delta$-1 transfected or control (eGFP) neurons. Therefore our findings suggest that presynaptic $\alpha_2\delta$ subunits regulate the

postsynaptic composition of GABAergic synapses in an isoform specific manner. Moreover, our results point towards an active involvement of $\alpha_2\delta$-2 in the recruitment and/or anchoring of postsynaptic $GABA_AR$.

Title: Phosphorylation of S1928 controls regulation of L-type Cav1.2 channel activity by the β2-adrenergic receptor in neurons

Authors: *J. L. PRICE[1], T. PATRIARCHI[2], E. HAMMES[1], C.-Y. CHEN[2], F. HOFMANN[3], M. NAVEDO[2], J. HELL[2];
[1]Biomed. Engin. Grad. Group, [2]Dept. of Pharmacol., Univ. of California Davis, Davis, CA;
[3]Pharmacol., Tech. Univ. of Munich, Munich, CA

Abstract: The L-type Ca2+ channel (LTCC) Cav1.2 is the predominant LTCC in the brain. It controls neuronal excitability, gene expression, and NMDA-independent forms of synaptic plasticity in the hippocampus such as mGluR-dependent LTD and LTP induced by a 3 min / 5 Hz stimulus train that coincides with beta adrenergic stimulation (prolonged theta tetanus LTP, PTT-LTP). We have identified a mechanism for specific desensitization of beta-adrenergic upregulation of Cav1.2 activity in neurons. Residue S1928 in the C-terminal tail of Cav1.2 is prominently phosphorylated by PKA upon beta adrenergic stimulation. We found that S1928 is part of the binding site for the beta2 adrenergic receptor and that its phosphorylation displaces the beta1 adrenergic receptor from Cav1.2 for transient desensitization of Cav1.2 regulation by beta2 adrenergic receptor stimulation.. Stimulation of the beta2 adrenergic receptor also induces AMPAR phosphorylation and increases their activity. However it does not result in dissociation of the beta2 adrenergic receptor from the AMPAR complex nor in a refractory period for re-stimulation AMPAR phosphorylation by a second pulse of beta2 adrenergic receptor stimulation. PTT-LTP requires the interaction between the beta2 adrenergic receptor and Cav1.2. Further

work with S1928A knock-in mice is being performed to determine functional significance of this particular site in Cav1.2 regulation.

Title: Glycosylation of Cav3.2 channels contributes to hyperalgesia in peripheral neuropathy of type 1 diabetes

Authors: *S. M. TODOROVIC[1], S. L. JOKSIMOVIC[1], J. G. EVANS[2], P. EGGAN[1], V. JEVTOVIC-TODOROVIC[1];
[1]Anesthesiol., Univ. of Colorado Anschutz Med. Campus, Aurora, CO; [2]Univ. of Virginia, Charlottesville, VA

Abstract: Introduction: Recent studies have implicated plasticity of the Cav3.2 isoform of T-type Ca^{2+} channels in the development of painful peripheral diabetic neuropathy (PDN). Furthermore, inhibitors of glycosylation, such neuraminidase (NEU), fully reverse abnormalities of Cav3.2 channels in nociceptive sensory neurons *in vitro*, and reverse hyperalgesia in mice with Type 2 diabetes *in vivo* (Orestes et al., 2013). Here we investigated if glycosylation of Cav3.2 channels could lead to neuronal hyper-excitability, which could in turn contribute to the development of painful PDN in Type I diabetes.
Methods: We studied *in vitro* effects of NEU on biophysical properties of recombinant human Cav3.2 channels stably expressed in human embryonic kidney (HEK)-293 cells grown in hyperglycemic cell culture medium. For *in vivo* studies, we injected NEU intra-plantary (i.pl.) into peripheral receptive fields of sensory neurons and measured heat sensitivity and mechanical sensitivity of healthy mice and mice with streptazocin (STZ)-induced painful PDN.
Results: Whole-cell recordings of current-voltage relationships demonstrated that Cav3.2 current densities were profoundly decreased (about 2-fold) after NEU treatment. Furthermore, NEU diminished macroscopic current activation and inactivation kinetics, induced a depolarizing shift of around 7 mV in the steady-state activation and steady-state inactivation curves while having very little effect on current deactivation kinetics.

For *in vivo* study 3 cohorts of mice were injected with STZ and developed hyperglycemia ranging from 400-600 mg/dl: C57Bl/6 wild type (WT) mice, $Ca_V3.2$ knock-out (KO mice) and Swiss-Webster (SW) mice. Either 10 µl of 1.5 U/ml NEU (same concentration as used *in vitro* studies) or vehicle (saline) were injected i.pl. in the right hind paws of adult female diabetic mice 14 days post-STZ. We found that injections of NEU, but not vehicle, completely reversed thermal and mechanical hyperalgesia in diabetic WT mice. In contrast, NEU did not affect baseline thermal and mechanical sensitivity in diabetic Cav3.2 KO mice and SW mice, both of which are resistant to the development of painful PDN.
Conclusion: Our results demonstrate that glycosylation-induced alterations in Cav3.2 current kinetics and density can directly influence neuronal excitability and that NEU can be used to ameliorate painful symptoms in Type 1 diabetes. We expect that our studies will lead to a better understanding of the molecular mechanisms underlying painful PDN in an effort to facilitate the discovery of novel treatments for this intractable disease.

Title: Early development of thalamic low-threshold T-type calcium current in the VPM of C57BL/6 mice

Authors: *Q. MIAO[1,2], J. L. NOEBELS[3];
[1]Bayrlor Col. of Med., Dept. of Neurol., Houston, TX; [3]Neurology, Neuroscience, and Mol. and Human Genet., [2]Baylor Col. of Med., Houston, TX

Abstract: Transient (T)-type calcium current plays an important role in regulating the excitability of thalamocortical (TC) neurons and endows the neural network with oscillatory properties that are critical for brain functions. Abnormal T current was demonstrated to be involved in mental diseases, such as childhood absence epilepsy (CAE) which is a common epilepsy syndrome starting between 4-8 years with peak age between 5-7 years. Several lines of evidence support an essential role of T-current in TC relay cells plays in generating CAE. However, it is unclear how T current normally matures in these cells during early development

and how this might affect the functional properties of TC cells. To better understand the normal development of this current, we performed whole-cell recordings of relay cells in the thalamic ventral posteromedial nucleus (VPM) of slices made from mice at postnatal day 19-20 (P19-20). We found that somatic measurement of T current density was highly dependent on whether tetraethylammonium (TEA, 10 mM) and 4-aminopyridine (4-AP, 0.5 mM), two potassium channel blockers, were present in the artificial cerebrospinal fluid (ACSF) (T current density in normal ACSF: 7.83 ± 0.94 pA/pF, n = 10; in ACSF with TEA and 4-AP: 22.21 ± 1.16 pA/pF, n = 12; $p = 9.3\times10^{-9}$). This nearly three-fold increase is consistent with the evidence that T-type calcium channels are densely distributed on thalamic relay cell dendrites, and that potassium channel blockade improves the space clamp of dendritic current in soma recordings. We next investigated the early development of T current from P13 to P21, a time coinciding with the onset of absence epilepsy in tottering mice and other monogenic mouse models of this seizure type. ACSF with TEA and 4-AP was used. Interestingly, we found a significant increase in T current density in the VPM during the early development of wildtype mice (P13-14, 12.75 ± 1.78 pA/pF, n = 13; P19-20, 22.2± 1.2 pA/pF, n = 12; $p = 0.00022$). Analysis of dendritic morphology of recorded neurons is ongoing. Together, these results demonstrate the importance of blocking membrane potassium channels to assess whole cell T currents, and reveal a significant change of thalamic T current in the wildtype mice during the third postnatal week.

Title: Presynaptic R-type (Cav2.3) channels mediate glutamate release at habenulo-interpeduncular nucleus synapses

Authors: *D. VANDAEL, P. BHANDARI, R. SHIGEMOTO, P. JONAS;
Inst. of Sci. and Technol. (IST) Austria, Klosterneuburg, Austria

Abstract: Synapses between medial habenula (MH) and interpeduncular nucleus (IPN) neurons are thought to play crucial roles in sleep, stress, and nicotine addiction, presumably through

corelease of glutamate and acetylcholine (Ren et al., 2011, Neuron 69:445-452; Frahm et al., 2015, Neuron 69:445-452). To address the mechanisms of transmitter release at MH-IPN synapses, we combined electron microscopy with patch-clamp recording in acute slices from 18- to 23-day-old mice. We previously reported predominant presynaptic localization of R-type Ca^{2+} channels (Cav2.3) in these synapses (Parajuli et al., 2012, J. Neurosci. 32:13555-13567). Immunogold labeling revealed 24% of gold particles in the active zone, 10% in the perisynaptic region, and 66% in the extrasynaptic region. Extracellular electrical stimulation of MH axons in the fasciculus retroflexus evoked robust EPSCs in putative GABAergic IPN neurons (-415 ± 80 pA, n=14). Synaptic currents showed a mean latency of 6.8 ± 0.5 ms, a 20-80% rise time of 1.2 ± 0.1 ms, and a decay time constant of 7.8 ± 0.7 ms. During trains of stimuli, MH-IPN EPSCs showed mostly depression, with mean multiple-pulse ratios of EPSC10 / EPSC1 of 0.7 ± 0.2 and 0.84 ± 0.3 for 10 Hz and 50 Hz, respectively. Furthermore, trains of stimuli evoked marked asynchronous release during and after the train. SNX-482 (500 nM - 1 μM) almost completely blocked both synchronous (93%, n=6) and asynchronous release components (76 %, n=6), indicating that evoked release was primarily mediated by R-type Ca^{2+} channels. Although the slow component of transmission was previously attributed to nicotinic receptor mediated currents (Ren et al., 2011), both synchronous and asynchronous EPSCs were fully blocked by 20 μM of the AMPA-type glutamate receptor antagonist CNQX (n=6). Bath application of EGTA-AM (100 μM) blocked 75 ± 2.3 % (n=5) of synchronous release and 34 ± 7 % of asynchronous release, indicating loose coupling between R-type Ca^{2+} channels and release sensors. Thus, MH-IPN synapses show highly specialized transmission properties: Release primarily relies on R-type presynaptic Ca^{2+} channels, and asynchronous release mediates a slow component of synaptic signaling. Our results indicate that asynchronous release of glutamate rather than acetylcholine mediates slow components of synaptic signaling.

Title: Modeling voltage sensor movement in Cav2.1 calcium channels

Authors: *S. ALDRICH[1], M. H. CHENG[2], S. D. MERINEY[1], I. BAHAR[2];
[1]Neurosci., [2]Computat. and Systems Biol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The P/Q-type voltage-gated calcium channel, Cav2.1, is a key player in synaptic transmission. Dysfunction of this channel has been implicated in a variety of neurological diseases, and it is the target for newly developed gating modifiers (GV-58) with therapeutic potential. Therefore, Cav2.1's mechanism of activation is clinically relevant. A well-supported model of activation for all voltage-gated ion channels is the sliding helix model. Briefly, the voltage-sensing S4 segments rotate outward within the depolarized membrane. In this model, the movement of the positively-charged S4 residues through the hydrophobic membrane interior is proposed to be catalyzed by a series of transient electrostatic interactions between these residues and the residues of neighboring segments. It has previously been impossible to determine whether Cav2.1 gates via the sliding helix mechanism, since no crystal structure is available for this channel. Fortunately, the recently-published cryo-electron microscopy structure of a closely related calcium channel, together with the wealth of structural information available on voltage gated sodium channels, make it feasible to predict the structure of Cav2.1 via homology modeling. Using multiple templates, we modeled the resting and active states of the voltage-sensing regions of each of Cav2.1's four heterologous domains. Our resting-state models reveal electrostatic interactions between arginines and lysines in the S4 segment, and conserved residues in neighboring segments. These include salt bridges as well as a cation-pi interaction between a conserved phenylalanine (in S2) and arginine (in S4). These interactions may stabilize the resting state. Computational modeling of voltage sensor domain (VSD) movement reveals a rotation of S4 toward the center of the VSD, coupled with a displacement toward the extracellular region of less than 10 Å. In the process, the cation-pi interaction is broken and the salt bridges are reconfigured. We identified ionic interacting pairs that may stabilize individual conformation states. To refine our model, we are currently using site-directed mutagenesis of expressed channels in HEK293 cells to evaluate the contribution of the predicted electrostatic interactions to the voltage-dependence of channel activation. We will constrain the model based on our results.

Title: Role of R-type calcium channel (Cav2.3) in medial habenula to interpeduncular nucleus pathway

Authors: *P. BHANDARI[1,2], L. K. PARAJULI[2], K. TAKAO[2,3], T. MIYAKAWA[2,4], Y. KOBAYASHI[5], K. F. TANAKA[6], R. SHIGEMOTO[1,2];
[1]Inst. of Sci. and Technol. Austria, Klosterneuburg, Austria; [2]Natl. Inst. for Physiological Sci., Okazaki, Japan; [3]Life Sci. Res. Ctr., Univ. of Toyama, Toyama, Japan; [4]Inst. for Comprehensive Med. Sci., Fujita Hlth. Univ., Toyoake, Japan; [5]RIKEN Brain Sci. Inst., Saitama, Japan; [6]Dept. of Neuropsychiatry, Sch. of Medicine, Keio Univ., Tokyo, Japan

Abstract: Medial habenula (MHb) neurons project almost exclusively to the interpeduncular nucleus (IPN) (Herkenham and Nauta, 1979; Agetsuma et al., 2010). MHb to IPN pathway plays a crucial role in various behavioral domains such as fear responses (Agetsuma et al., 2010), inhibitory control and cognition-dependent executive functions (Kobayashi et al., 2013), nicotine addiction (Frahm et al., 2011) and so on. In situ hybridisation data shows that medial habenula expresses predominantly mRNA transcripts of R-type (Cav2.3) but not P/Q- or N-type calcium channels (Allen Brain Atlas). We previously reported that in sharp contrast to its predominant postsynaptic localization in other brain regions, Cav2.3 is localized predominantly in presynaptic terminals in IPN (Parajuli et al., 2012). To address the role of Cav2.3 in the MHb to IPN pathway, we combined genetic, behavioral and pre-embedding electron microscopy techniques. Pre-embedding immunolabeling revealed specific localization of gold particles for Cav2.3 in presynaptic terminals making glutamatergic synapses in IPN, with densities of 7.31 particles/μm in active zone, 6.94 particles/μm in perisynaptic zone and 3.18 particles/μm in extrasynaptic zone. Behavioral studies in Cav2.3 null knock out (KO) mice showed altered behavior compared with heterozygous control . In open field test, KO mice travelled longer total distance ($p<0.0001$) than control showing hyperactivity. In social interaction test, KO mice showed lesser duration and number of contacts ($p<0.05$) denoting lesser social interaction. There was no significant difference in elevated plus maze test. In fear conditioning test, KO mice showed increased freezing percentage ($p=0.0003$) during conditioning and pretone period with altered context ($p=0.0007$) whereas no change in context testing. To further examine the role of Cav2.3 in MHb to IPN pathway, we used Flexible Accelerated STOP Tetracycline Operator (tetO)-knockin (FAST) technique (Tanaka et al., 2010) to generate Cav2.3 FAST KO mice, which could be rescued by crossing with Cre-driver mouse lines. We selected Gpr151-Cre mouse (Kobayashi et al., 2013) for the rescue of Cav2.3 expression in the MHb to IPN pathway, because Gpr151-Cre is selectively expressed in MHb (Kobayashi et al., 2013). Crossing with Ai9 reporter mice, we found that the majority of Cav2.3 positive terminals in IPN expressed tdTomato in Gpr151-Cre mice, whereas only 12% and 25% of Cav2.3 positive terminals expressed tdTomato in Tac1-Cre and ChAT-IRES-Cre mice, respectively. Preliminary results showed that Gpr151 Cre rescued some of FAST Cav2.3 KO phenotypes, suggesting a role of presynaptic Cav2.3 in the MHb to IPN pathway.

Title: Cacna1a loss-of-function mutations impair synaptic release properties from frontal cortical fast-spiking interneurons and result in cognitive and behavioural impairments in humans and mice

Authors: *A. LUPIEN-MEILLEUR[1,2], X. JIANG[1,2], I. RIEBE[2], L. DAMAJ[1], C. VANASSE[1], L. GAGNON[1], J.-C. LACAILLE[2], E. ROSSIGNOL[1,2];
[1]CHU Sainte-Justine, Montréal, QC, Canada; [2]Univ. de Montréal, Montréal, QC, Canada

Abstract: Loss-of-function mutations in the *CACNA1A* gene, which encodes the α1 subunit of voltage-gated $Ca_V2.1$ channels, result in episodic ataxia (EA2) in humans. These conditions are rarely associated with overt cognitive deficits. We investigated 16 patients from 4 non-consanguinous families carrying different *CACNA1A* loss-of-function mutations and revealed that the majority of them had moderate to significant neurocognitive impairment that includes a spectrum of impulsivity, learning difficulties, intellectual deficiency and autism. Targeted deletion of *Cacna1a* causing an ablation of voltage-gated $Ca_V2.1$ Ca^{2+} channels selectively in forebrain GABAergic interneurons (INs) in mice leads to selective synaptic impairment of parvalbumin (PV) fast-spiking basket cells that is sufficient to induce generalised epilepsy. We therefore, propose that a selective impairment of perisomatic inhibition resulting from PV-INs synaptic dysfunction in neocortical orbitofrontal circuits might contribute to the cognitive deficits observed. To understand the pathological mechanisms underlying these cognitive deficits, we studied the effects of $Ca_V2.1$ channel ablation in PV neurons that are thought to be critical for cognition. We generated mutant mice carrying a targeted heterozygous *Cacna1a* deletion restricted to PV neuronal populations ($PV^{cre};Cacna1a^{c/+}$), which targets cortical PV-INs post-natally. Using optogenetic, we demonstrated that this selective mutation significantly impairs perisomatic inhibition of pyramidal cells in the orbitofrontal cortex (cOF). We assessed the behavioural and cognitive abilities of these mutant mice in the Open Field, the Elevated Plus Maze, the Morris Water Maze and an Attention Set-Shifting Task. These investigations revealed that the haploinsufficiency of *Cacna1a* in PV-INs leads to impulsivity and reduced cognitive flexibility in $PV^{cre};Cacna1a^{c/+}$ mutant mice. Surprisingly, contrary to what we had observed in mice with homozygous *Cacna1a* deletion in cortical pyramidal cells, mice carrying a heterozygous *Cacna1a* deletion in pyramidal cells ($Emx1^{Cre};Cacna1a^{c/+}$) had intact cortical excitability and had no behavioural impairment. Finally, local AAV-Cre injections in the cOF of $Cacna1a^{c/+}$ mice recapitulated the reversal-learning deficit and cognitive rigidity phenotypes. Our results demonstrate that the haploinsufficiency of *Cacna1a* selectively impairs the synaptic

release properties from fast-spiking PV+ basket cells and that it results in significant cognitive and behavioural impairment in humans and mice, in part attributable to disrupted perisomatic inhibition in orbitofrontal circuits.

Abstract: cGMP is a second messenger widely used in the nervous system as well as in other tissues including the vascular smooth muscle and the inner ear. One of the major effectors for cGMP is the serine/threonine protein kinase, cGMP-dependent protein kinase (PKG). PKG has been shown to catalyze the phosphorylation of a variety of physiologically relevant proteins including ion channels. Previously, it has been shown that the cGMP-PKG signaling pathway inhibits the high voltage-gated Ca^{2+} current recorded in rat vestibular hair cells. This current mainly flow through $Ca_V1.3$ L-type calcium channels, and may be important for controlling vestibular hair cell sensory function. However, the role of the PKG phosphorylation in channel function is still poorly defined. In the present report we used a strategy that combines molecular biology with patch clamp recordings to investigate whether the cGMP-PKG signaling cascade regulates recombinant $Ca_V1.3$ channels heterologously expressed in HEK-293 cells. We first evaluated the properties of the whole-cell currents through $Ca_V1.3$ channels, and then tested the action of 8-bromo-cGMP (8-Br-cGMP), a cell-permeable analog of cGMP, on $Ca_V1.3$ channel activity. Our results show that 8-Br-cGMP significantly inhibited the macroscopic current, while KT-5823, a specific inhibitor of PGK, prevented the inhibition generated by 8-BrcGMP. Further, mutating the putative phosphorylation sites to unphosphorylatable residues showed that the relevant PKG site for $Ca_V1.3$ L-type channel regulation centers on a single residue, serine 860, located in the intracellular loop connecting the II and III repeats of the Cavα1 ion conducting

subunit of the channel. These findings suggest a mechanism for how the cGMP-PKG signaling pathway may regulate $Ca_V1.3$ channels.

Title: AChR pre-patterning in early neuromuscular junction development does not require L-type calcium currents

Authors: ***M. M. KAPLAN**[1], N. SULTANA[1], A. BENEDETTI[1], A. DAYAL[2], M. GRABNER[2], N. F. LINDE[3], S. PAPADOPOULOS[3], G. J. OBERMAIR[1], B. E. FLUCHER[1]; [1]Dept. Physiol. and Med. Physics, [2]Dept. of Med. Genetics, Molecular, and Clin. Pharmacol., Med. Univ. Innsbruck, Innsbruck, Austria; [3]Ctr. of Physiol. and Pathophysiology, Inst. of Vegetative Physiol., Univ. of Cologne, Cologne, Germany

Abstract: During development neuromuscular junctions (NMJ) organize within a narrow endplate band in the center of muscle fibers. Whereas nerve-derived factors are important for the formation and stabilization of NMJ, the initial formation of acetylcholine receptor (AChR) clusters in the central endplate band—a process called AChR pre-patterning—occurs prior to the arrival of the nerve by muscle-intrinsic mechanisms. A recent study implicated an essential role of L-type calcium currents (LTCCs) in AChR pre-patterning (Chen et al., 2011, Nat. Neurosci. 14: 570-7). According to this study, LTCCs are required for proper AChR pre-patterning independent of the role of $Ca_v1.1$ as voltage sensor in excitation-contraction (EC) coupling. Our laboratory discovered a developmental splice variant of $Ca_v1.1$, which lacks exon 29 ($Ca_v1.1e$), is expressed at the critical stage for AChR pre-patterning and, at variance with the adult $Ca_V1.1a$ splice variant, conducts sizeable calcium currents (Tuluc et al., 2009, Biophys. J. 96: 35-44).

Here we used a range of genetic calcium channel mouse models to study whether LTCCs through $Ca_v1.1e$ are essential for AChR pre-pattering and how the developmental switch of $Ca_v1.1$ splice variants might contribute to the aggregation of AChR clusters in the endplate band. Consistent with the published evidence total lack of LTCCs and calcium release from sarcoplasmic reticulum (SR) in dysgenic ($Ca_v1.1^{-/-}$) mice led to failed AChR pre-patterning and unrestricted outgrowth of the phrenic nerve in E14.5 diaphragm muscle. In contrast, lack of SR calcium release by itself in dyspedic mice (ryanodine receptor, $RyR^{-/-}$) resulted in normal AChR pre-patterning. If spatial or temporal differences in the expression of the well-conducting $Ca_v1.1e$ and the low-conducting $Ca_V1.1a$ splice variants contributed to the organization of NMJ in the endplate band, AChR pre-patterning should fail in a mouse model in which $Ca_v1.1$ exon 29 is not spliced out during development ($Ca_v1.1\Delta E29$; Sultana et al., 2016, Development, 143: 1547-1559). However this was not the case. Therefore we re-examined the basic hypothesis that LTCCs are required for AChR pre-patterning, using a knock-in mouse model exclusively expressing non-conducting $Ca_v1.1$ ($DHPR^{nc/nc}$; Dayal et al., 2014, Biophys. J., doi: 10.1016/j.bpj.2013.11.748). Unexpectedly, when LTCCs are lacking but EC coupling remained intact, pre-patterning and innervation of AChR clusters were normal. If indeed calcium is involved in the regulation of AChR pre-patterning, calcium signals from either source (LTCCs or SR calcium release) may be sufficient.

Title: Cannabinoid CB1 and CB2 receptors dichotomously modulate L- and T-type Ca^{2+} channels in rat retinal ganglion cells

Authors: *Z. WANG[1,2], W.-J. QIAN[2], N. YIN[2], F. GAO[2], Y. MIAO[2], Q. LI[2], X.-L. YANG[2], X.-H. SUN[2];

[2]Inst. of Brain Science, and Dept. of Ophthalmology at Eye & ENT Hospital, Inst. of Neu, [1]Fudan Univ., Shanghai, China

Abstract: Endocannabinoid signaling system is involved in regulating multiple neuronal functions in the central nervous system by activating G-protein coupled cannabinoid CB1 and CB2 receptors (CB1Rs and CB2Rs). Growing evidence has shown that CB1Rs and CB2Rs are extensively expressed in the vertebrate retinas. Here, we explored possible modulation of Ca^{2+} channels by activating CB1Rs/CB2Rs in acutely isolated rat retinal ganglion cells (RGCs) using patch-clamp techniques. The CB1R agonist WIN55212-2 voltage- and dose-dependently suppressed both peak and steady-state Ca^{2+} currents, with IC_{50} being 9.6 μM and 8.4 μM, respectively. Under our conditions, the high- and the low-voltage-activated Ca^{2+} currents were mainly mediated by L- and T-type Ca^{2+} channels respectively. Immunocytochemistry further confirmed that $Ca_V1.2$ subunit of L-type Ca^{2+} channels, and $Ca_V3.1$, $Ca_V3.2$ and $Ca_V3.3$ subunits of T-type Ca^{2+} channels were expressed in RGCs. Either WIN55121-2 or ACEA, another CB1R agonist, significantly suppressed both L- and T-type Ca^{2+} currents, and accelerated inactivation of T-type one. The effect of WIN55121-2 on L-type Ca^{2+} channels was mediated by intracellular cAMP/protein kinase A (PKA), mitogen-activated protein kinase (MPKA)/extracellular signal-regulated kinase (ERK) and calcium/calmodulin-dependent protein kinase II (CaMKII) signaling pathways, while only CaMKII signaling pathway was involved in the effect of WIN on T-type Ca^{2+} channels. Furthermore, neither CB65 nor HU308, two specific CB2R agonists, had effect on L-type Ca^{2+} currents. In contrast, CB65/HU308 significantly suppressed T-type Ca^{2+} currents, which was mediated by intracellular cAMP/PKA and CaMKII signaling pathways. Our results suggest that activation of CB1Rs and CB2Rs dichotomously modulates L- and T-type Ca^{2+} channels in rat RGCs, which was mediated by the distinct intracellular signaling pathways respectively. These results imply that cannabinoids may inhibit Ca^{2+} channels of RGCs and subsequently modulate visual integrative processing.

Title: Proteolytic processing of the L-type calcium channel Cav1.2 alpha$_1$ subunit occurs mostly at its C-terminus

Authors: *O. BUONARATI[1], P. B. HENDERSON[2], J. W. HELL[2];
[2]Pharmacol., [1]UC Davis, Davis, CA

Abstract: The L-type Ca^{2+} channel $Ca_v1.2$ accounts for 80% of L-type current in neurons and strongly impacts Ca^{2+}-mediated gene expression, neuronal excitability, and synaptic plasticity. Posttranslational modifications that regulate this channel, particularly the pore-forming alpha$_1$ subunit, continue to emerge despite decades of focus. We characterized the main size variants of brain $Ca_v1.2$ using five different antibodies to demonstrate that alpha$_1$ exists mostly as two size forms of ~ 250 and 200 kD in molecular weight. Whole brain tissue and acute slices from mice and rats were homogenized for immunoblot analysis with these antibodies. Our work demonstrates that the alpha$_1$ short form in rodent brain lacks about 350 residues of the distal C-terminus compared to the 250 kDa full length form. Analogous results were obtained after surface biotinylation of slices and pull down with streptavidin. Importantly, specificity of all five antibodies was validated by absence of signal in whole brain lysate from conditional Cav1.2 knock-out mice. Very weak immunoreactivity (<2%) indicated the presence of additional, smaller (<200 kD) forms, although in much lower abundance. Detection of two prominent alpha$_1$ size variants of 250 and 200 kD is consistent with earlier findings that calpain cleaves the long alpha$_1$ C-terminus pretty exactly in its middle to yield a shorter channel form.

Abstract: Alternative splicing (AS) of pre-mRNAs, a process with the potential to expand proteome diversity, is especially prominent in the mammalian nervous system. For example, AS of voltage-gated Ca^{2+} channel (VGCC) α_1 subunits can potentially generate thousands of isoforms with differential properties and expression patterns, but the impact of this molecular diversity on brain function, particularly on synaptic transmission that crucially depends on VGCCs, is unknown.
We have investigated how synaptic transmission and plasticity in hippocampal pyramidal neurons is controlled by two major isoforms of P/Q-type VGCCs. Specifically, we have devised experiments to bi-directionally change their relative abundance in primary hippocampal cultures and in the hippocampus *in vivo*, and used genetically encoded Ca^{2+} indicators (GCaMPs), synapto-pHluorin, electrophysiological recordings and optogenetics to assess how AS of P/Q-type Ca^{2+} channels affects presynaptic Ca^{2+} transients, synaptic vesicle release, synaptic transmission and short-term synaptic plasticity.
We find that alternative splicing of $Ca_v2.1$ affects short-term synaptic plasticity in opposite directions as a consequence of a differential coupling to the neurotransmitter release machinery, with one isoform promoting synaptic depression and the other synaptic facilitation.
We propose that alternative splicing of P/Q-type Ca^{2+} channels is a key mechanism for controlling neurotransmitter release and short-term synaptic plasticity.

Title: The cellular mechanism that controls cell-specific e37a inclusion during alternative splicing of voltage-gated $Ca_V2.2$ channel pre mRNA

Authors: *E. J. LOPEZ SOTO, S. E. ALLEN, K. PATEL, D. M. DUBREUIL, S. DENOME, D. LIPSCOMBE;
Dept. of Neurosci., Brown Univ., Providence, RI

Abstract: Voltage-gated calcium $Ca_V2.2$ channels control transmitter release at nociceptor terminals in the dorsal horn of the spinal cord. Nociception is severely impaired in mice lacking $Ca_V2.2$ channels, and neuromodulators that inhibit $Ca_V2.2$ channel gating via G protein coupled receptors (GPCR) are analgesic. Cell-specific alternative splicing of $Ca_V2.2$ pre mRNA generates $Ca_V2.2$ isoforms that differ by their biophysical properties, trafficking, and modulation by GPCRs. Splicing factors regulate the pattern of exon inclusion or skipping in different types of cells and at different developmental time points. In nociceptors, the pattern of exon inclusion during alternative splicing of $Ca_V2.2$ pre mRNA is different compared to most other neurons. Specifically, e37a rather than e37b is included with higher frequency in $Ca_V2.2$ mRNAs in nociceptors. The resultant $Ca_V2.2$-e37a channels are more efficiently trafficked to the plasma membrane, and more sensitive to GPCR regulation compared to $Ca_V2.2$-e37b channels. This cell-specific splicing event also impacts the efficacy of morphine analgesia against noxious thermal stimulation in naïve animals *in vivo*. Here we elucidate the likely cell-specific mechanism that facilitates inclusion of e37a over e37b during alternative splicing of $Ca_V2.2$ pre mRNA. We analyzed genome-wide chromatin immunoprecipitation and sequencing data in the e37 region of *Cacna1b* and located a strong binding signal for the multi-zinc finger DNA binding protein CCCTC-binding factor (CTCF). CTCF, an insulator of DNA, is implicated in promoting the recognition of weak splice junctions in the CD45 gene. CTCF binding is inhibited by methylation. We find that CTCF binding promotes e37a recognition during splicing and that methylation of DNA inhibits CTCF action. We used electrophoretic mobility shift assays to show that recombinant CTCF binds a 139 bp sequence of *Cacna1b* gDNA containing e37a, 22 bp of the 5' intron, and 20 bp of the 3' intron, but not the equivalent e37b region of gDNA. The major determinant of CTCF binding resides within a 60 bp region of *Cacna1b* containing e37a. We used 10 μM of 5-Azacitidine to inhibit DNA methylation in neuronal-derived F11 cell lines that express $Ca_V2.2$-e37b but not $Ca_V2.2$-e37a mRNAs. Following demethylation we detected e37a-containing $Ca_V2.2$ mRNAs in F11 cells. We generated a 15.3 Kb *Cacna1b* minigene containing e36 through e38. When we transduced this minigene in tsA201 cells, we found that overexpression of CTCF promoted e37a inclusion. Our data support the hypothesis that CTCF binding to *Cacna1b* gDNA within e37a is required to promote e37a recognition and its inclusion in $Ca_V2.2$ mRNA during alternative splicing.

Title: PIP_2 in pancreatic β-cells regulates voltage-gated calcium channels by a voltage-independent pathway

Authors: L. DE LA CRUZ[1], E. I. PUENTE[1], A. REYES-VACA[1], I. ARENAS[1], J. GARDUÑO[1], J. BRAVO-MARTÍNEZ[1], *D. E. GARCIA-DIAZ[1,2];

Abstract: Phosphatidylinositol-4,5-bisphosphate (PIP_2) is a membrane phosphoinositide that regulates multiple physiological processes. Recent evidence has suggested that the PIP_2 molecule is required for the activity of many transporters and ion channels, including voltage-gated Ca^{2+} (Ca_V) channels. Ion channel regulation by PIP_2 has been reported in neurons and in some expression systems, however it has not been tested in insulin-releasing cells. Insulin secretion is primarily due to calcium influx through Ca_V channels. The purpose of this study was to investigate whether Ca_V channels are regulated by PIP_2 hydrolysis in pancreatic β- and INS-1 cells through the activation of a muscarinic pathway by oxotremorine methiodide (Oxo-M). Ca_V channel currents were recorded by using the patch clamp technique in whole cell configuration. Results showed that Ca_V current amplitude was reduced by the activation of muscarinic receptor 1 (M_1R) in the absence of kinetic changes in either pancreatic β- or INS-1 cells. Oxo-M inhibition exhibited the hallmarks of voltage-independent (VI) regulation, which was prevented by diC8-PIP_2 dialysis in pancretic β-cells. PIP_2 localization into the plasma membrane was examined by transfecting INS-1 cells with the pleckstrin homology domain of phospholipase C-δ1 (PH-PLCδ1), which revealed a close time-course relationship between PIP_2 hydrolysis and Ca_V channel inhibition. Furthermore, the depletion of PIP_2 by a voltage-sensitive phosphatase reduced Ca_V currents in a similar way to that observed following M_1R activation. Isolated L-type current was inhibited by M_1R activation suggesting that this current is regulated by PIP_2 as well. We conclude that the activation of the M_1R pathway results in VI inhibition of Ca_V channels in

pancreatic β- and INS-1 cells via PIP_2 depletion. Activation of cytosolic second-messenger pathways is not required for this inhibition on Ca_V channel currents. These findings support the hypothesis that membrane phospholipids regulate ion channel activity by interacting directly with Ca_V channels in insulin-releasing cells.

Title: Loss of regulated Cav2.3 expression in a mouse model of Fragile X Syndrome

Authors: *E. E. GRAY[1], Y. LIU[2], I. TRANG[2], D. A. HOFFMAN[2];
[1]NICHD, [2]NICHD, Natl. Inst. of Hlth., Bethesda, MD

Abstract: Fragile X syndrome (FXS) is the most common form of inherited intellectual disability in humans and arises from the loss of the fragile X mental retardation protein (FMRP), an mRNA binding protein that regulates translation in neurons following activation of group I metabotropic glutamate receptors (GpI mGluRs). When bound to its target mRNAs under basal conditions FMRP acts as a translational repressor, whereas GpI mGluR activity leads to the unbinding of FMRP to allow protein translation. In the FMRP knock-out mouse, expression of target mRNAs is no longer regulated and this ultimately results in aberrant spine formation, enhanced neuronal plasticity, and hyperexcitability. Little is known about which particular mRNAs are abnormally expressed in FXS or how they might impact neuronal function. A recent study found that FMRP binds the mRNA of Cav2.3 (Darnell et al, 2011), a voltage-gated calcium channel capable of generating large calcium spikes and shaping action potentials. Given that neurons lacking FMRP have alterations in calcium spiking and neuronal excitability, we sought to explore the possibility that FMRP regulates the expression of Cav2.3 mRNA. We first examined the basal levels of mRNA isolated from WT and FMRP KO mouse brains using qRT-PCR and found that Cav2.3 mRNA levels were altered in FMRP KO neurons ($p<0.05$). We were curious if this change in mRNA abundance would be reflected in the amount of Cav2.3 expressed in the FMRP KO brain, thus we performed Western blotting and found that Cav2.3 protein levels were significantly enhanced in the FMRP KO ($p<0.01$ vs WT). This FMRP-

dependent change in Cav2.3 expression should impact neuronal physiology; therefore we isolated Cav2.3 currents using whole cell electrophysiology in cultured hippocampal neurons. As predicted from our Western blot data, FMRP KO neurons exhibited greatly enhanced Cav2.3 current amplitudes ($p<0.005$), although the kinetics of the currents remained unchanged. To test the possibility that FMRP-dependent Cav2.3 expression can be further regulated by GpI mGluRs, we treated hippocampal neurons cultured from WT and FMRP KO mice with the GpI mGluR agonist DHPG. Following stimulation, Cav2.3 protein levels were increased in WT neurons ($p<0.005$) but not in neurons lacking FMRP. Taken together, our data suggests that FMRP represses translation of Cav2.3 under basal conditions and that activation of GpI mGluRs disinhibits FMRP to allow for active translation of Cav2.3. The loss of regulated Cav2.3 expression seen in the FMRP KO may underlie the atypical calcium signaling and neuronal excitability seen in FXS, and may be a potential therapeutic target in this disease.

Title: Molecular determinants masking Ca^{2+}-dependent facilitation of $Ca_v2.2$ channels

Authors: *J. R. THOMAS, J. HAGEN, A. LEE;
Dept. of Mol. Physiol. and Biophysics, Otolaryngology Head-Neck Surgery,, Univ. of Iowa, Iowa City, IA

Abstract: Voltage-gated $Ca_v2.1$ (P/Q-type) Ca^{2+} channels undergo Ca^{2+}- dependent inactivation (CDI) and facilitation (CDF), respectively, which contribute to short-term synaptic plasticity. Both CDI and CDF are mediated by calmodulin (CaM) binding to sites in the C-terminal domain of the $Ca_v2.1$ α_1 subunit, including a consensus CaM-binding IQ-domain. Closely related $Ca_v2.2$ (N-type) channels display CDI but not CDF, despite conservation of the IQ-domain and additional sites (Pre-IQ, EF-hand) implicated in regulation of CDF of $Ca_v2.1$. Here, we test the hypothesis $Ca_v2.2$ does not undergo CDF because it lacks additional key elements in the C-

terminal domain that are required for CDF. We find that alternative splicing of exons in the proximal and distal C-terminal domain, which regulates CDF of $Ca_v2.1$, has no effect on CDF of $Ca_v2.2$. However, replacement of the entire C-terminal domain of $Ca_v2.2$ with that of $Ca_v2.1$ produces robust CDF of the chimeric channel. Further analyses reveal that transfer of the proximal C-terminal domain of $Ca_v2.1$, which includes the EF-hand, Pre-IQ- IQ domains, and a downstream CaM-binding domain (CBD), is sufficient to support CDF in chimeric $Ca_v2.2$ channels. Our results highlight the importance of the C-terminal domain in distinguishing Ca^{2+} feedback regulation of $Ca_v2.2$ and $Ca_v2.1$, and underscore how molecular distinctions may underlie the unique contributions of these channels in regulating neurotransmitter release.

Title: Essential oil of Alpinia zerumbet inhibits low and high voltage activated calcium channels in sensory neurons

Authors: *T. SANTOS-NASCIMENTO, K. M. VERAS, A. N. COELHO-DE-SOUZA, L. MOREIRA-JÚNIOR, J. H. LEAL-CARDOSO;
State Univ. of Ceara, Fortaleza, Brazil

Abstract: Among natural products, essential oils and their constituents are promising sources of therapeutic agents with pharmacological efficacy and low toxicity. *Alpinia zerumbet* have widespread use in folk medicine. The essential oil of *Alpinia zerumbet* (EOAZ) is documented to have diverse pharmacological effects, including antinociceptive activity and inhibitory effects on nervous excitability. However, despite its use, little is known about its mechanism of action on excitable tissues, especially on the peripheral sensory nervous system. This study aims to investigate whether EOAz blocks the neuronal voltage-dependent Ca^{+2} current which, believed to be important for several pharmacological effects, is thought to be important for nociception mechanism of action. Dissociated small neurons of the dorsal root ganglion of Wistar rats were

used. The patch-clamp technique in the whole cell configuration was employed. EOAz (major constituents: 1-beta-pinene (23.25% of EO wheight), 1,8-cineole (21.75%), terpinen-4-ol (15.94%), gamma-terpinene (7.85%)) dose-dependently inhibited the High Voltage Activated (HVA) and Low Voltage Activated (LVA) Ca^{+2} currents. At the concentrations tested, OEAz (0.03 to 10 mg/ml) did not completely block LVA Ca^{+2} current; the maximal inhibition and IC_{50} of LVA were 67.88 ± 1.93 % and 1.6 ± 0.19 mg/ml (n = 6). Concerning the HVA Ca^{+2} current, it was completely blocked by OEAz (0.01 to 3 mg/ml) with 0.4 ± 0.3 mg/ml (n = 6) IC_{50}. The results show that the EOAz blocks the two types on voltage-dependent neuronal Ca^{+2} channels, being more efficient and powerful on HVA than LVA Ca^{+2} currents. The alterations in Ca^{+2} channels reported here might partially explain the antinociceptive effect of EOAz.

Title: Protein degradation mechanism of $Ca_V2.1$ (P/Q-type) Ca^{2+} channel

Authors: C.-Y. TANG[1], S.-J. FU[1], *C.-J. JENG[2];
[1]Natl. Taiwan Univ., Taipei, Taiwan; [2]Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: The voltage-gated Ca^{2+} (Ca_V) channel is a multi-subunit membrane protein complex comprising the voltage-sensing, pore-forming α_1 subunit, as well as the auxiliary β and $\alpha_2\delta$ subunits. $Ca_V2.1$ (P/Q-type) is a distinct member of Ca_V α_1 subunit subfamilies that is expressed in central and peripheral neurons. The subcellular localization of $Ca_V2.1$ channels is characterized by their high densities at the active zones on the pre-synaptic membrane. In addition, $Ca_V2.1$ channels are also notably found in the dendrosomatic compartment of postsynaptic neurons, especially in Purkinje cells in the cerebellum. Therefore $Ca_V2.1$ channels play a critical role in regulating neurotransmitter release at presynaptic terminals, as well as setting postsynaptic membrane excitability. Mutations in the gene encoding the α_1 subunit of human $Ca_V2.1$ channels have been associated with the dominantly inherited cerebellar disease

episodic ataxia type 2 (EA2). Several lines of experimental evidence strongly suggest that EA2-associated mutations may result in impaired membrane trafficking and enhanced protein degradation of wild-type (WT) as well as mutant $Ca_V2.1$ α_1 subunits. The molecular nature and mechanistic role of the ubiquitin-proteasome pathway in $Ca_V2.1$ protein biosynthesis is currently unknown. In this study, we aim to ascertain the protein degradation mechanism of WT $Ca_V2.1$ and EA2 mutants by addressing how $Ca_V2.1$ channels are regulated by the ubiquitin-proteasome system. We identified a zinc finger protein that co-exists in the same protein complex and co-localizes with $Ca_V2.1$ channels in rat neurons. Upon heterologous expression in human embryonic 293T (HEK293T) cells, the zinc finger protein regulates the protein level, turn-over rate, and ubiquitination of human $Ca_V2.1$ channels. Disruption of the endogenous expression of the zinc finger protein in HEK293T cells significantly increases protein level of WT human $Ca_V2.1$ channels, as well as reversing the defective protein expression of EA2 mutants. Together our data suggest that the zinc finger protein may serve as a ubiquitin ligase that contributes to EA2-associated protein degradation of human $Ca_V2.1$ channels.

Title: C-terminal splice variation reveals new insights into calmodulin regulation of $Ca_v1.4$ channels

Authors: *B. WILLIAMS[1,2], V. KEROV[2], F. HAESELEER[3], A. LEE[2];
[1]Interdisciplinary Grad. Program in Neurosci., [2]Depts. of Mol. Physiol. and Biophysics, Otolaryngology Head-Neck Surgery, and Neurol., Univ. of Iowa, Iowa City, IA; [3]Dept. of Physiol. and Biophysics, Univ. of Washington, Seattle, WA

Abstract: In synaptic terminals of retinal photoreceptors, $Ca_v1.4$ (L-type) Ca^{2+} channels mediate Ca^{2+} influx that promotes neurotransmitter release. Mutations in $Ca_v1.4$ are associated with multiple vision disorders including congenital stationary night blindness (CSNB2). $Ca_v1.4$ does not undergo Ca^{2+}-dependent inactivation (CDI) – a negative feedback mechanism seen for other L-type channels (e.g., $Ca_v1.2$ and $Ca_v1.3$) mediated by calmodulin (CaM) binding to a consensus IQ domain in proximal C-terminal domain (CT) of the pore-forming subunit. The lack of CDI in $Ca_v1.4$ is due to a C-terminal automodulatory domain (CTM), located in the distal CT of $Ca_v1.4$. The CTM is thought to suppress CDI of $Ca_v1.4$ channels by competing with CaM binding to sites in the proximal CT. A CSNB2-causing mutation (K1591X) in $Ca_v1.4$ that deletes the CTM promotes CaM binding and CDI, but also causes channel activation at more negative potentials than full-length channels ($Ca_v1.4_{FL}$). Here, we demonstrate that similar properties are exhibited by a naturally occurring human $Ca_v1.4$ splice variant lacking exon 47 ($Ca_v1.4\Delta ex47$), and characterize an unexpected role for CaM in the regulation of this channel. By quantitative PCR, we found that $Ca_v1.4\Delta ex47$, which lacks the initial 43 amino acids of the CTM, is highly expressed in primate but not mouse retina. In electrophysiological recordings of transfected HEK293T cells, $Ca_v1.4\Delta ex47$ Ca^{2+} currents activate at more negative voltages and display stronger CDI than $Ca_v1.4_{FL}$, similar to K1591X. These effects were blunted by IQ domain mutations known to disrupt CaM binding to $Ca_v1.4$. Mutations that prevent Ca^{2+} binding to either N- or C-terminal lobes of CaM suppress CDI of $Ca_v1.4\Delta ex47$. However, mutations in the N-terminal but not the C-terminal lobe of CaM abolish the hyperpolarizing effect of exon 47 deletion on voltage-dependent activation of Ca^{2+} currents. We conclude that exon 47 contains key molecular determinants within the CTM for regulating CDI and activation, and that CaM plays distinct roles in these processes.

Title: The role of T-type calcium channels in the development of incisional pain model in rats

Authors: *S. JOKSIMOVIC[1], S. M. JOKSIMOVIC[2], H. OSURU[3], P. EGGAN[3], V. JEVTOVIC-TODOROVIC[3], S. M. TODOROVIC[3];

Med. Campus Univ. of Colorado Denver, Aurora, CO; [3]Anesthesiol., Univ. of Colorado Denver Anschutz Med. Campus, Aurora, CO

Abstract: Introduction: Recent studies have implicated T-type Ca^{2+} channels in regulation of neuronal excitability under physiological conditions, as well as in pathological states, such as epilepsy and chronic pain. However, their role in acute pain resulting from the tissue injury is yet to be established. Therefore, the aim of our study was to investigate if T-type Ca^{2+} channels (T-channels) are involved in development of acute post-operative pain.
Methods: Incisional pain model in Sprague-Dawley rats was developed by performing deep tissue incision of plantar surface of hind paw. To investigate changes in expression of T-channel subtypes in incised vs. sham animals, ipsilateral L4-L6 dorsal root ganglia (DRG) were harvested and tissue samples were analyzed using qRT-PCR. Changes in current densities and kinetic properties of these channels were measured by using a patch-clamp technique on dissociated DRG cells. To assess antihyperalgesic efficacy of selective T-channel antagonist (TTA-P2), hind paw responses were measured after thermal and mechanical stimulation of the plantar paw surface.
Results: Our qRT-PCR experiments revealed a significant increase of mRNA expression levels of all three T-channel subtypes ($Ca_V3.1$, 3.2 and 3.3) 24 h post-incision vs. sham group, with the highest (three-fold) increase of $Ca_V3.1$ isoform. Patch-clamp recordings from dissociated DRG cells showed that current densities for both activation and steady-state inactivation protocols were profoundly increased (about 2-fold) at 2 h post-surgery, as compared to the control (sham) group. The same trend was noticed for the 24 h post-surgery group. When applied intrathecally in healthy rats, TTA-P2 exerted antinociceptive effect to both thermal ($F(1,210)=7.46$; $p<0.001$) and mechanical stimuli ($F(1,198)=7.18$; $p<0.001$). In incised rats, a single preemptive intrathecal injection of TTA-P2 significantly reduced thermal hyperalgesia post-incision ($F(1,60)=11.59$; $p=0.005$). Mechanical hyperalgesia was also reduced ($F(1,36)=13.61$; $p=0.004$) when TTA-P2 was applied in three consecutive post-operative days.
Conclusion: We found increased T-current density in DRG cells from incised rats as well as increased expression of mRNA for all three T-type Ca^{2+} channel isoforms, with $Ca_V3.1$ isoform exhibiting the highest mRNA levels. Furthermore, when applied either before or after skin incision, a significant
analgesic effect of T-channel blocker was detected in *in vivo* study. In conclusion, our results suggest that T-type Ca^{2+} channels play an important role in the development of acute pain and could be considered as new drug target for alleviating postsurgical hyperalgesia.

Title: $\alpha_2\delta2$ controls function and trans-synaptic coupling of $Ca_v1.3$ channels in mouse inner hair cells and is essential for normal hearing

Authors: *J. ENGEL[1], B. FELL[1], S. ECKRICH[1], K. BLUM[1], T. ECKRICH[1], D. HECKER[1], G. J. OBERMAIR[2], V. FLOCKERZI[1], B. SCHICK[1];
[1]Saarland Univ., Homburg, Germany; [2]Div. of Physiol., Med. Univ. Innsbruck, Innsbruck, Austria

Abstract: Auxiliary $\alpha_2\delta$ subunits can modulate the abundance and function of voltage-gated calcium channels. Here we show that of the four $\alpha_2\delta$ isoforms 1-4, $\alpha_2\delta2$ mRNA is expressed in neonatal and mature inner hair cells (IHCs). In a functional $\alpha_2\delta2$ null mouse, the ducky mouse (du), auditory brainstem response (ABR) click and frequency-dependent hearing thresholds were elevated whereas otoacoustic emissions were not impaired. Peak Ca^{2+} channel currents of mature du/du IHCs were reduced by 30% in the lower frequency range and by 40% in the range of best hearing, respectively. Moreover, gating properties such as voltage of half-maximum activation and voltage sensitivity were altered, indicating that $Ca_v1.3$ channels normally co-assemble with $\alpha_2\delta2$ at IHC presynapses. Depolarization-evoked exocytosis in du/du IHCs was reduced, reflecting their reduced Ca^{2+} currents, but Ca^{2+} efficiency of exocytosis was unaltered. $Ca_v1.3$ and $Ca_v\beta2$ protein expression was unchanged in du/du IHCs, forming clusters at synaptic ribbons. However, the close apposition of presynaptic $Ca_v1.3$ clusters with postsynaptic glutamate receptors 4 (GluA4) and PSD-95 clusters was significantly impaired in du/du mice. This implies that in addition to controlling both expression and gating properties of $Ca_v1.3$ channels, the largely extracellularly localized $\alpha_2\delta2$ subunit plays a so far unknown role in mediating trans-synaptic alignment of presynaptic Ca^{2+} channels and postsynaptic glutamate receptors.

Title: Disruption of the Cav1.3 C-terminal auto-modulatory domain attenuates Cav 1.3/BK channel coupling in mouse chromaffin cells

Authors: *L. GUARINA[1], D. H. F. VANDAEL[2], A. MARCANTONI[1], J. STRIESSNIG[3], E. CARBONE[1];
[1]Drug Sci., Univ. Degli Studi Di Torino, Torino, Italy; [2]Inst. of Sci. and Technol. Austria, Klosterneuburg, Austria; [3]Pharmacol. and Toxicology, Univ. of Innsbruck, Innsbruck, Austria

Abstract: Cav 1.3 L-type Ca^{2+} channels play key roles in controlling excitability and pacemaking of central neurons and neuroendocrine cells (*Vandael et al., 2010*). In particular, incomplete Cav1.3 channel inactivation as it occurs in human congenital multiorgan syndrome and "de novo" mutations (*Azizan et al., 2013; Scholl et al., 2013; Pinggera et al, 2015*), lead to marked L-type Ca^{2+} current increases and originate autism and intellectual impairment. To study the role of Cav1.3 channel inactivation in the regulation of cell excitability, we used the Cav1.3DCRD$^{HA/HA}$ knockin (KI) mutant mouse that was generated by replacing part of the "distal C-terminal regulatory domain" (DCRD) in exon 49 of the CACNA1D gene by homologous recombination with an HA-epitope (*Scharinger et al., 2015*). The newly available KI mice possess Cav1.3 channel isoforms with faster and more complete inactivation than wild-type mice. Here, we further investigated the effects of Cav1.3DCRD$^{HA/HA}$ mutation in mouse chromaffin cells (MCCs), that were shown to cause hyperpolarization of resting potential, reduced number of spontaneously firing cells and higher steady-state adapting frequency during sustained stimulation. Our new findings suggest that a major effect on cell excitability could derive from the attenuated coupling of Cav1.3 to BK channels in Cav1.3DCRD$^{HA/HA}$ KI MCCs. BK channels are highly expressed in MCCs and control action potential shape, pacemaking and firing modes (Marcantoni et al., 2010; Vandael et al., 2015). We found that BK channels of KI MCCs preserve their voltage-dependence but lose most of their Ca^{2+}-dependence. BK currents of KI mice change very little when activated by different Ca^{2+} preloading steps either following increasing step depolarizations (-40 to +40 mV) or increasing the duration of preloading steps (10 to 110 ms at +10mV). In few cells, BK currents were even absent. A reduced activation of BK channels was also evident by observing the reduced size of the after-hyperpolarization potential of single APs generated by brief depolarizing pulses (30-120 pA; 5 ms). Our data

suggest that Cav1.3 channels are tightly coupled to BK channels in MCCs and that alteration of the C-terminal modulatory domain can induce profound changes to the Cav1.3/BK channel activation and thus to AP shape, pacemaking and spontaneous firing.

Title: Improved probes for investigating glutamate neurotransmission

Authors: N. HELASSA[1], C. DURST[2], U. ARIF[1], C. SCHULZE[2], T. OERTNER[2], *K. TÖRÖK[1];
[1]SGUL, London, United Kingdom; [2]Inst. for Synaptic Physiol., Hamburg, Germany

Abstract: Genetically-encoded fluorescent glutamate indicator iGlu-'sniffer' (iGluSnFR) has enabled detection of neurotransmitter glutamate release in tissue slice and *in vivo* experiments, however its slow rise and decay rates limit the temporal resolution of glutamate release in response to high frequency action potential firing. To improve the kinetics of iGluSnFR, selected amino acid residues coordinating glutamate at the binding site were mutated, the resulting variant proteins were expressed in *E. coli*, purified and characterised with regard to fluorescence dynamic range, affinity, glutamate association and dissociation kinetics and temperature dependence, using steady-state fluorescence and stopped-flow kinetics. Novel variants with the most improved kinetics were $iGlu_f$ (iGlu fast) and $iGlu_u$ (iGlu ultrafast). F_{max}/F_{min} values of 4 to 5 in solution were comparable to that of iGluSnFR for both $iGlu_f$ and $iGlu_u$. K_d values for glutamate were 140 μM and 600 μM, with 1.5 ms and 0.83 ms decay half-times, respectively, at 34 ^{o}C. In hippocampal slices, CA3 neurons were electroporated with an iGluSnFR construct under the control of synapsin promoter and action potentials were triggered by patch-clamp either by paired pulse ISI with a 48 ms interval or by firing 10 action potentials at 100 Hz. Post-synaptic terminals on the dendritic arbour in CA1 pyramidal neuron were imaged by two-photon microscopy. Glutamate release was detected at pre-synaptic terminals (boutons) in CA1 stratum

radiatum imaged by two-photon microscopy at 34^{o}C using spiral line scans at 500 Hz. Compared to iGluSnFR (tau_{off} of 15 ms), the $iGlu_f$ and $iGlu_u$ variants showed improved time resolution for the detection of glutamate release at the synapse with fluorescence decay times tau_{off} of 5 and 2 ms, making both novel probes suitable for application in high frequency stimulation paradigms. Models are presented for the kinetic mechanism of iGlu variants and for the synaptic handling of glutamate.

Title: An integrated analysis for the dynamical responses of pre- and postsynaptic neurons through synaptic encoding in the *C. elegans* salt-chemotaxis circuit

Authors: *M. KURAMOCHI[1,2,3], M. DOI[1,2];
[1]Biomed. R.I., AIST, Tsukuba-Shi, Japan; [2]Univ. of Tsukuba, Tsukuba-Shi, Japan; [3]JSPS Res. Fellow, Tokyo, Japan

Abstract: Neuronal circuits are an assembly of synaptic connectivity among neurons. Analysis of both the patterns of synaptic connections in a circuit and the roles of each synapse in network activity helps to understand characteristics of a neural encoding for behavioral outputs. Synaptic connectivity in the *C. elegans* nervous system has been identified, but it is not clear how each synapse is contributed for the spatio-temporal responses of each postsynaptic neuron and for behaviors. We have focused on the *C. elegans* salt-chemosensory circuit to understand the role of each synapse on a neural encoding and to describe a computational model on this neuronal circuit. This chemosensory circuit is composed of the salt-sensory neurons ASE, their postsynaptic neurons such as AIB and AIY, and further downstream neurons. To describe the patterns of each neuronal response in the circuit, as a first step, we measured calcium response of the presynaptic ASER sensory neuron triggered by salt concentration changes. The calcium indicator G-GECO was expressed specifically in the ASER neuron, and using this transgenic animal, we collected response patterns of ASER to various patterns of salt concentration change. The ASER had a nonlinear response with the concentration change of salt. Based on these

imaging data, we generated a novel mathematical model representing its activity *in silico*. For the second step, to develop an expanded computational model in a circuit level, we examined activities of the first-layer interneurons which are connecting with the ASER and tried to evaluate the role and meaning of each synaptic connection for their activities.To analyze synaptic communications between the ASER and AIB or AIY neuron, we also monitored calcium responses of these interneurons to salt concentration changes. Our imaging analyses using the wild-type animals or sensory-input defective mutants, indicated that the ASER activates AIB interneurons whereas inactivates AIY interneurons when the salt concentration is decreased. Furthermore, by using synaptic transmission mutants and their cell-specific rescuing animals, we measured the single-input responses in postsynaptic neurons AIB and AIY, and compared their responses in animals showing variable patterns of synaptic connections. These data are used to generate *in-silico* modeling to represent each postsynaptic activity depending on both the presynaptic activity and synaptic patterns. Our analyses will suggest a novel aspect of the relationship between spatial distribution of synapse connectivity and postsynaptic responses in a neuronal circuit.

Title: Differential effects of dopaminergic D2 receptor activation on synaptic responses in a subset of layer V mouse medial prefrontal pyramidal neurons.

Authors: *J. M. LEYRER[1], M. THOMAS[2];
[1]Univ. Of Northern Colorado, Greeley, CO; [2]Sch. of biological sciences, Univ. of Northern Colorado, Greeley, CO

Abstract: In humans, prefrontal cortical areas are known to support executive functions. In mice, these functions are mediated by homologous regions in the medial prefrontal cortex (mPFC). While it is well established that executive processes are critically dependent on optimal levels of dopamine (DA) in the PFC, the cellular mechanisms of DA modulation are incompletely understood. Stable patterns of neuronal activity may be sensitive to frequency dependent changes in synaptic transmission. In this study, we characterized the effects of D2 receptor (D2R) activation on short-term excitatory postsynaptic potential (EPSP) dynamics evoked at varying frequencies in layer V pyramidal neurons in mouse mPFC. Further, we aimed

to determine the effects of D2 receptor activation on the two major subtypes of layer V pyramidal neurons that show distinct axonal projection patterns to either the brainstem (type I cells) or the commissural mPFC (type II cells). We isolated NMDA receptor (NMDAR) and non-NMDAR receptor mediated components of EPSP trains evoked by stimulating fibers within layer V or layer I (tufts). D2R activation significantly decreased NMDAR-mediated EPSPs in type I pyramidal neurons with tuft stimulation, yet had no effect on type II cells. Additionally, D2R activation had no effect on NMDAR-mediated EPSPs with layer V stimulation in type I or type II cells. Interestingly, D2R activation also had no effect on non-NMDAR mediated EPSPS with layer I or layer V stimulation in either cell type. These results suggest that D2 receptor activation may prevent persistent activity, partly through inhibiting coincidence detection, in a specific class of (type I) layer V pyramidal neurons. Additionally, D2R activation may play a role in inhibiting synaptic plasticity and stabilizing top-down signals during working memory tasks. These data provide further insight into mechanisms of dopamine's modulation of executive functions.

Title: A distance-dependent gradient in presynaptic release probability along tapering dendrites

Authors: *F. GRILLO, J. BURRONE;
Kings Col. London, London, United Kingdom

Abstract: Neurons receive a large number of heterogeneous synaptic inputs all along their vast dendritic trees. Although recent advances have shed light on the biased distribution of postsynaptic compartments and their role on neuronal integration, very little is known about the distribution of presynaptic boutons along dendrites. Here, we show that the structure and function of presynaptic boutons along the thin tapering basal dendrites of CA1 pyramidal neurons decreases with distance from the soma. Recordings of EPSCs measured electrophysiologically in response to trains of stimuli delivered at varying locations in the stratum oriens of acute slices showed that distal inputs facilitate more than proximal inputs, suggesting a distance-dependent change in release probability. In agreement with our functional data, we find that the size of the active zone (as well as the volume) of presynaptic terminals also decreased with distance to the soma, as measured by 3D reconstructions of dendrites obtained

from serial block-face scanning electron microscopy (3 view). In parallel, we find that postsynaptic spines and their postsynaptic densities closely followed the distribution of presynaptic boutons, decreasing in size with both distance and dendrite diameter. We propose that the changes in synaptic transmission dynamics (short-term plasticity) linked to the graded distribution of release probability fine-tunes different sections of dendrite to respond to specific input frequencies. Our findings describe a novel form of distance-dependent distribution of synaptic properties that allow neurons to efficiently sample across large frequency domains.

Title: Spine neck morphology shapes postsynaptic potentials in hippocampal neurons

Authors: *J. TONNESEN[1,2], D. CATTAERT[1,3], V. NÄGERL[1,2];
[1]Univ. of Bordeaux, Bordeaux, France; [2]Interdisciplinary Inst. for Neurosci., CNRS UMR 5297, Bordeaux, France; [3]Inst. de Neurosciences Cognitives et Intégratives d'Aquitaine, CNRS UMR 5287, Bordeaux, France

Abstract: It has been a long-standing fundamental question whether the dendritic spine neck influences excitatory postsynaptic potentials and their somatic integration. While the importance of the spine neck for biochemical compartmentalization is well established, its role in electrical signaling remains highly controversial. Two main obstacles have hindered progress. 1) The average spine neck diameter is around 150 nm, which is too small to be resolved by conventional light microscopy; 2) The inaccessibility of the spine head to direct electrophysiological recordings. We have developed a new approach to address this controversy and test the hypothesis that spine necks can provide a sufficient electrical resistance to affect the EPSPs measured at the soma. It is based on a combination of STED microscopy, two-photon glutamate uncaging and patch-clamp electrophysiology in organotypic hippocampal slice cultures. To discriminate between the effects of synaptic conductance and synaptic morphology on measured voltages, we obtained matched electrophysiological recordings of synaptic conductance (g_{syn})

and voltage (V) for the same spine by performing the 2-photon glutamate uncaging both in voltage-clamp and current-clamp. In addition, we acquired super-resolved STED microscopy images to correlate the electrophysiological data to spine morphology. This strategy allowed us to normalize the synaptic EPSP measured at the soma to the strength of the synapse in terms of conductance. The V/g_{syn} ratio (or 'synaptic gain') for a given spine was compared to spine geometry obtained from the corresponding STED image. We identify a correlation between neck geometry and synaptic gain. Specifically, the longer and thinner the neck is, the lower the synaptic gain. We further find that spines with high neck resistances show a more pronounced sub-linear response to repetitive stimulation than neighboring spines with lower neck resistances. Finally, we present numerical simulations to model and explore these relationships in more detail. Our results provide strong new evidence for an influential role of spine geometry in electrical signaling, indicating that high neck resistances boost the spine head voltage to the point of gradual saturation of the synaptic potential. Conversely, spines with low neck resistances (i.e. with shorter and wider necks) can convey larger synaptic currents during strong synaptic stimulation.

Title: Subquantalized synaptic transmission at single active zone contained central synapses

Authors: ***M. KUNPENG**[1,2], J. DAI[1], Q. ZHU[1], P. SAH[3], J. SUN[1];
[1]Inst. of Biophysics,Cas, Beijing City, China; [2]ShanghaiTech Univ., Shanghai, China; [3]The Queensland Brain Institude, the Univ. of Queenland, Brisbane, Australia

Abstract: As the classic Katz's quantal theory proposed, the small all-or-none unit, termed miniature postsynaptic potential or current(mini), in respect to presynaptic vesicle fusion,represents the basic unit or quantum of synaptic signal. However, justification of this notion, particularly the nature of mini events, has never been completed. Emerging evidences pointed out that the uniquantal events, from minis to single vesicle capacitances, are various in

size.Based on analysis ofthe amplitude of minis, it was hypothesized that each Katz's quantum could be composed of smaller subunits. This subquantal hypothesis was rigorously tested and ended in suspense because all the experimental and theoretical studies were not sufficient to support or exclude the existence of the subquantal elements. The major arguments are: all the studies were based on histogram analyses and no confidence limits have been given to evaluate the significance of these subunits; increasing the sample size of recordings decreased, instead of increased, the prominence of subunit in histogram; the subunit sizes estimated from the different subsets of the same recording were different. We attribute these discrepancies to less quantitative analyses and that the minis wererecorded from multiple synapses,because the variation of the subunit amplitude and postsynaptic sensitivity from multiple synaptic recordings prevented the detection of small subunits.Here, we selectively observed the miniatures from single active zone(AZ) contained axo-soma synapses and took the advantage of well electrical access of the somatic whole cell(SWC) recording to quantitatively analyze single quantal events with much less variability of postsynaptic response. Our study revealed significant subquantalized synaptic transmission and strongly suggested that synaptic information could be processed at higher precision and capacity than the estimation by Katz's theory.

Title: Selectivity to temporal information arising from the interaction between dynamic synapses and intrinsic subthreshold oscillations

Authors: *P. VARONA[1], F. BARONI[2], R. LATORRE[1], J. J. TORRES[3];
[1]Univ. Autonoma de Madrid, Madrid, Spain; [2]Sch. of Psychological Sciences, Fac. of Biomed. and Psychological Sci., Monash Univ., Melbourne, Australia; [3]Dept. de Electromagnetismo y Física de la Materia, Univ. de Granada, Madrid, Spain

Abstract: Subthreshold oscillations underlie key mechanisms of information discrimination in single neurons while dynamic synapses provide channel-specific input modulation. Previous studies have shown that intrinsic subthreshold oscillations constitute a biophysical means for the emergence of non-trivial single-cell input/output preferences. It has also been shown that synaptic dynamics, in the form of short-term depression and/or facilitation, can provide a channel-specific mechanism for the enhancement of the post-synaptic effects of temporally specific input sequences. The interplay between intrinsic oscillations and synaptic dynamics can lead to more selective and complex temporal input processing.
Here, we investigated theoretically and computationally how the combination of intrinsic subthreshold oscillations and short-term synaptic dynamics can act together in enabling the emergence of robust and channel-specific selectivity of temporal inputs. We calculated analytically the voltage trajectories and spike output of Generalized Integrate-and-Fire (GIF) model neurons in response to temporally distinct triplets, and analyzed the model output as intrinsic and synaptic parameters were varied.
Our results show that intrinsic and synaptic dynamics interact coactively for the emergence of specific and complex input-output transformations. In particular, precise non-trivial preferences emerge from synergic intrinsic and synaptic dynamics, while broader discrimination selectivity is observed for mismatched neuronal and synaptic dynamics. We discuss the conditions for robustness of the observed input/output relationships, including those under the action of noise, and also show their presence in more realistic biophysical models.
We conclude that the interaction of intrinsic subthreshold oscillations and synaptic dynamic properties can enable complex and channel-specific mechanisms for the emergence of temporal selectiveness in neuronal responses. We also discuss the impact of single-channel/single-neuron input discrimination in the context of information processing based on heterogeneous synaptic and neuronal elements.

Title: Impact of vortioxetine on synaptic integration in prefrontal-subcortical circuits: comparisons with escitalopram.

Authors: *S. CHAKROBORTY[1], E. DALE[2], A. PEHRSON[2], C. SÁNCHEZ MORILLO[2], A. R. WEST[1];
[1]Neurosci., Rosalind Franklin Univ. of Med. and Sci., North Chicago, IL; [2]Lundbeck Res. USA, Inc., Paramus, NJ

Abstract: Prefrontal-subcortical and related limbic circuits support executive functions (e.g., cognition, motivated behaviors, emotional processes) which often become dysfunctional in psychiatric and neurological disorders. Current therapies for these disorders are limited and often produce considerable side effects. Vortioxetine (VORT) is an atypical antidepressant which is currently used in the clinic to treat major depressive disorder. Mechanisms of action of VORT include serotonin (5-HT) transporter blockade, $5HT_{1A}$ receptor agonism, $5HT_{1B}$ receptor partial agonism, and $5HT_{1D}$, $5HT_3$, and $5HT_7$ receptor antagonism. VORT has been shown to facilitate 5-HT transmission in the medial prefrontal cortex (mPFC), however the impact of this compound on 5-HT signaling in related prefrontal-subcortical circuits is less clear. Thus, the current study examined the impact of systemic VORT administration (0.8 mg/kg, i.v.) on spontaneous and afferent driven spike activity of electrophysiologically identified neurons recorded in the anterior cingulate cortex (ACC), medial shell of the nucleus accumbens (msNAc), and lateral septal nucleus (LS) of urethane-anesthetized rats. Similar studies were performed using the selective 5HT reuptake inhibitor (SSRI) escitalopram (ECP; 1.6 mg/kg, i.v.) to enable comparisons between the multimodal actions of VORT and SSRI-mediated effects. VORT did not affect spontaneous or mPFC-evoked spike activity recorded in the ACC, but did induce a decrease in the number of spontaneously active cells recorded per electrode track. Furthermore, following VORT administration putative projection neurons recorded in the msNAc exhibited decreased responsiveness to mPFC stimulation delivered alone, or immediately following, train stimulation (30Hz, 500ms) of the hippocampal fimbria (HF). VORT also decreased spontaneous firing in the LS, an effect which was mimicked by ECP. ECP administration also reproduced the above effects of VORT on HF-evoked firing recorded in the msNAc. In contrast to VORT, ECP administration increased the number of spontaneously active cells recorded per track in the ACC and facilitated mPFC-evoked firing recorded in the LS. Taken together, the current studies indicate that VORT is likely to modulate afferent drive from the HF in the msNAc and spontaneous firing in the LS via 5-HT transporter blockade and increased 5HT transmission. Contrasting effects of VORT and ECP on population firing in the ACC and mPFC evoked firing in the msNAc and LS point to other complex 5HT receptor-dependent effects of VORT which may contribute to its unique impact on the function of prefrontal-subcortical circuits and motivated behavior.

Title: Neurons in the medial entorhinal cortex integrate locomotion speed information from glutamatergic septo-entorhinal projections

Authors: *D. JUSTUS[1], D. DALÜGGE[1], S. BOTHE[1], F. FUHRMANN[1], C. HANNES[1], H. KANEKO[1], D. FRIEDRICHS[1], L. SOSULINA[1], I. SCHWARZ[2], D. A. ELLIOTT[1], S. SCHOCH[3], F. BRADKE[1], M. K. SCHWARZ[2], S. REMY[1];

Abstract: Spatially tuned neurons in the medial entorhinal cortex (MEC), especially grid cells, require information about the instantaneous movement speed. However, the source of this information is yet unknown. Due to its involvement in velocity dependent hippocampal functioning the medial septum and diagonal Band of Broca (MSDB) is an ideal candidate for providing a speed signal to the MEC.
We used extracellular tetrode recordings and cell-type specific fiber-optometric measurements of GCaMP fluorescence to assess the activity of neurons in the MSDB and found a glutamatergic cell population that exhibits strongly speed modulated outputs.
Using mono-transsynaptic retrograde tracing we identified VGluT2$^+$ neurons in the MSDB with projections into MEC layer 2/3. We then characterized these projections and their targets in the MEC by combining in-vitro whole-cell recordings with optogenetic stimulations of ChR2 expressing septo-entorhinal axons.
We found that the septo-entorhinal pathway provides glutamatergic input to several MEC cell types, but most prominently to MEC pyramidal cells. Integrating the precise electrophysiological characterization in a computational model of MEC stellate cells, pyramidal cells and fast-spiking interneurons we demonstrated that this speed-signal excites all L2/3 MEC neurons in a speed dependent manner, but is integrated most effectively by L2/3 pyramidal cells. This is in full agreement with high membrane time constants and slow EPSP kinetics that we observed in pyramidal cells.
Thus, we identified the glutamatergic cell population in the MSDB as a source for the speed-information that is necessary for a spatial representation of the environment by neurons of the MEC.

Title: Disruption of coordinated pre- and postsynaptic maturation underlies the defects in hippocampal synapse stability and plasticity in Abl2/Arg-deficient mice.

Authors: *X. XIAO[1], A. LEVY[1], B. ROSENBERG[1], M. HIGLEY[2], A. KOLESKE[3]; [1]Mol. Biophysics and Biochem., [2]Yale Univ., New Haven, CT; [3]Yale Univ., NEW HAVEN, CT

Abstract: Immature glutamatergic synapses in cultured neurons contain high release probability (*P*r) presynaptic sites coupled to postsynaptic sites bearing GluN2B-containing N-methyl-D-aspartate receptors (NMDARs), which mature into low *P*r, GluN2B-deficient synapses. Whether this coordinated maturation of high *P*r, GluN2B+ synapses to low *P*r, GluN2B-deficient synapses actually occurs in vivo, and if so, what factors regulate it and what role it might play in long-term synapse function and plasticity are unknown. We report that loss of the integrin-regulated Abl2/Arg kinase in vivo yields a subpopulation of "immature" high *P*r, GluN2B+ hippocampal synapses that are maintained throughout late postnatal development and early adulthood. These high *P*r, GluN2B+ synapses are evident in *arg-/-* animals as early as postnatal day (P) 21, a time that precedes any observable defects in synapse or dendritic spine number or structure in *arg-/-* mice. Using focal glutamate uncaging at individual synapses, we find only a subpopulation of *arg-/-* spines exhibits increased GluN2B-mediated responses at P21. As *arg-/-* mice age, these synapses increase in proportion and their associated spines enlarge. These

changes coincide with an overall loss of spines and synapses in the Arg-deficient mice. We also demonstrate that although LTP and LTD are normal in P21 *arg-/-* slices, both forms of plasticity are significantly altered by P42. These data demonstrate that the integrin-regulated Arg kinase coordinates the maturation of pre- and post-synaptic compartments at a subset of hippocampal synapses in vivo and this coordination is critical for NMDAR-dependent long-term synaptic stability and plasticity.

Title: Anatomical and physiological aspects of the cerebellar impact on thalamic relay neurons

Authors: ***S. V. GORNATI**[1], C. B. SCHAEFER[2], C. I. DE ZEEUW[2,3], F. E. HOEBEEK[2]; [1]Neurosci., [2]Erasmus MC, Rotterdam, Netherlands; [3]Netherlands Inst. for Neuroscience, Royal Dutch Acad. for Arts and Sci., Amsterdam, Netherlands

Abstract: The cerebellum has an important role in the control and coordination of movements. The afferents of the cerebellum are the cerebellar nuclei (CN) which project to the spinal cord (via relays in the brainstem) and to upper motor neurons in the cortex via thalamus. Previous anatomical studies showed that the innervation is not confined to the motor thalamus (ventroanterior/lateral (VA/VL) complex), but it is widespread also in other nuclei such as VM, CL and CM which have specialized cortical connectivity. However, a detailed quantification of the anatomical and physiological characteristics of cerebello-thalamic connections with regional differentiation has not been reported. We recorded post-synaptic responses in thalamic cells located in VA/VL, VM, CL and CM in order to reveal if cerebellar output affects similarly the thalamic cells in the different nuclei. To test the strength of the cerebello-thalamic projection we used both electrophysiological and imaging techniques. We injected a virus encoding for Channelrhodopsin in the interposed/medial nuclei and we performed *in vitro* whole cell recordings in voltage- and current-clamp mode in thalamic relay neurons to evaluate the post-synaptic currents and whether or not cerebellar stimulation evoked action potential firing. Electrophysiological recordings revealed that between cells the maximally evoked post-synaptic

response varied substantially in a location-specific manner, i.e., showing greater amplitude in the VA/VL complex compared to the CM, CL and VM nuclei. Nevertheless, all the recordings exhibit paired-pulse depression upon stimulation frequencies higher than 10 Hz. Furthermore, washing in the AMPA blocker NBQX we could reduce EPSCs amplitude and abolish it completely with further addition of the NMDA blocker AP-5.To reconstruct the morphology of the recorded neurons we filled it with biocytin and stained the cerebellar terminals with vesicular glutamate transporter 2 (VGluT2) antibody. Using high-magnification confocal microscopy and deconvolution we analysed the structure and distribution of CN boutons finding that CN afferents synapse consistently onto proximal dendrites. Together these findings help us to better understand how effective CN neurons are in controlling thalamic firing within the different nuclei and thereby differentiate the cerebellar impact on cerebral cortices.

Title: Pathways by which horizontal cell inhibitory amino acid transmitters inhibit cones

Authors: J. C. R. GROVE[1], K. FILER[1], A. A. HIRANO[1], N. C. BRECHA[1,2], *S. A. BARNES[3,1];
[1]UCLA, Los Angeles, CA; [2]VAGLAHS, Los Angeles, CA; [3]Dalhousie Univ., Halifax, NS, Canada

Abstract: *Indirect feedback to photoreceptors:* Release and autoreception by horizontal cells of inhibitory amino acid transmitters (IAA), such as GABA, could mediate a pH shift in the

synaptic cleft (due to the HCO_3^- conductance of the horizontal cell IAA receptors) and this pH shift leads to modulation of photoreceptor Ca channels, which are widely accepted to be the target of inhibitory feedback. To test whether horizontal cells respond to their own GABA/IAA release, Cx57-tdTomato horizontal cells in slices of mouse retina were patch-clamped with solutions containing (mM): (internal) 110 $CsMeSO_4$, 2.8 NaCl, 4 EGTA, 5 TEA-Cl, 4 Mg-ATP, 0.3 Na_3-GDP, 20 HEPES, 10 phosphocreatine; and (external) 120 NaCl, 3 KCl, 1 $MgCl_2$, 1.2 NaH_2PO_4, 10 glucose, 25 $NaHCO_3$. Horizontal cells were voltage clamped in steps from -50 to +40 mV and when currents obtained in 100 μM picrotoxin were subtracted from control currents, inward tail currents (~20 pA) at -60 mV, as well as inward current during steps to -30 mV and reversed outward currents at -10 mV and more positive steps, reaching 30 pA, were observed. To test the effects of removal of GABA/IAA inhibition, mouse, rat and guinea pig cones in slices were patch-clamped (same solutions as above) and responded to superfusion of picrotoxin with increased Ca channel currents, which analysis showed had activation curves whose Boltzmann function midpoints shifted by about -7 mV (-25 mV to -32 mV). HEPES (10 mM) eliminated the midpoint shifts in rat slices. *Direct feedback to photoreceptors:* A direct GABA/IAA-mediated pathway to photoreceptors has been established in the retinas of both mammalian and non-mammalian vertebrates but is refuted in some reports, possibly due to circadian regulation. Some of the experiments described above, carried out during subjective day, showed a two-fold effect during the application of picrotoxin to guinea pig cones. In addition to the modulation of the Ca channels, background conductance between potentials of -80 and -50 mV was reduced during picrotoxin application. These data support the hypothesis that there are two pathways by which GABA/IAA acts on two conductances in photoreceptors. GABA/IAA release in the outer plexiform layer may act 1) directly on photoreceptor GABA/IAA receptors and 2) indirectly on photoreceptor Ca channels, via a cleft pH change caused by HCO_3^- and Cl^- permeable GABA/IAA receptors on horizontal cells.

Title: Identifying genetic markers associated with treatment response to lurasidone ; A genome-wide association study on two independent clinical trials.

Authors: *A. YOSHIKAWA[1], J. LI[2], H. Y. MELTZER[2];
[1]Psychiatry and Behavioral Sci., Northwestern University, Feinberg Sch. of Medici, Chicago, IL;
[2]Psychiatry and Behavioral Sci., Northwestern University, Feinberg Sch. of Med., Chicago, IL

Abstract: Introduction: Schizophrenia (SCZ) is a heterogeneous disorder with a diverse genetic contribution to its etiology and treatment response to antipsychotic drugs (APDs). About one third of patients fail to respond adequately to the standard treatment. There are currently no biomarkers which can predict the response to APDs in SCZ. “Trial and error” in selection of the optimal APD leads to delayed recovery, prolonged suffering, and low adherence of the patients, all of which may worsen the prognosis. Therefore, to identify the genetic markers associated with treatment response is of great interest to triage the patients and disclose the fundamental mechanisms of drug efficacy. Lurasidone is a more potent serotonin $(5\text{-HT})_{2A}$ than dopamine (DA) D_2 receptor blocker; a 5-HT_7 antagonist and 5-HT_{1A} partial agonist. **Material and Methods:** A genome-wide association study (GWAS) on two randomized clinical trials on Caucasian and African-American patients with SCZ was conducted by Affymetrix 6.0 SNP array to identify the genetic biomarkers associated with treatment response to lurasidone at last observation carried forward (LOCF). Genome-wide SNP imputation was performed by IMPUTE2/SHAPEIT. Treatment response was quantitatively evaluated by change in PANSS-Total (delta PANSS-T) from the baseline to LOCF. An unadjusted p value $< 1.0\times10^{-4}$ in the association test with delta PANSS-T was set as cutoff. **Results:** We identified common variants in genes related to synaptic function as the top predictors of response to lurasidone in Caucasians and African-American patients. The identified genomic loci mainly resided in synaptogenic adhesion genes and scaffolding proteins, both essential for synaptic function. *NRXN1* replicates previous findings for prediction of response to clozapine by us and others. Other synaptic genes predicting response included *NRG1/3*, *KALRN*, and neuron-specific splicing regulator, *RBFOX1*. Most of these genes and their associated pathways have been previously linked to SCZ. Decreased gene expression in post-mortem brain areas relevant to SCZ also supports our findings. Some of the top SNPs are potential cis-eQTLs. The expression of some of the top hits is significantly inversely correlated with HTR7 gene expression. **Discussion:** Our non-hypothesis driven GWAS study identified genetic biomarkers which predicted treatment response to lurasidone. As many of the identified genes have been previously reported as risk genes for SCZ, our results may indicate that lurasidone and other atypical APDs act through disease modifying genes. These findings suggest that synaptogenic adhesion and scaffolding proteins will be potential novel drug targets for SCZ.

Title: Dendritic specific integration rules in hippocampal CA1 parvalbumin positive fast spiking interneurons

Authors: *J. CORNFORD, D. M. KULLMANN;
UCL, London, United Kingdom

Abstract: PV+ interneurons make up ~2% of interneurons in the CA1 region of the hippocampus. Despite their rarity, they are fundamental for a range of functions, from basic circuit processes such as the sharpening of principal-cell input coincidence detection, to more complex network operations such as place-cell field regulation (Hu *et al.*, 2014). This central importance of PV+ basket cells stems from their privileged position as mediators of both feedforward and feedback inhibition.
Recent work has shown that basket cells express synaptic receptors in an input specific distribution: local feedback connections onto oriens dendrites display a larger NMDA receptor component than feedforward inputs, which synapse predominately in the stratum radiatum (Le Roux *et al.*, 2013). This raises the possibility that PV+ basket cells handle synaptic input in a dendritic specific manner; synaptic connections from local pyramidal cells might be more able co-operate with each other via NMDA receptors (Branco & Häusser, 2011), whereas forward connections would be integrated in a linear or sub-linear manner.
In order to investigate the distinct expression of rectifying glutamate receptors and the resulting functional implications, we used a combination of compartmental modelling, multi-photon imaging, and immunohistochemistry. We report that dendrites located in the radiatum integrate synaptic inputs in a linear or sub-linear manner. In contrast, oriens dendrites display linear or supra-linear integration rules. We also present pharmacology and modelling experiments detailing the underlying biophysical mechanisms and the functional implications of these dendritic specific integration rules.

Title: Coordinated spiking in CA3 propagates to hilar mossy cells in juvenile mice but only rarely in adult mice

Authors: *T. HEDRICK, W. P. NOBIS, G. T. SWANSON;
Pharmacol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Temporal lobe epilepsy is a disorder of altered hippocampal network activity associated with aberrant excitability and widespread degeneration of hilar mossy cells (HMCs), suggesting that HMCs play an important role in hippocampal network activity. A clearer delineation of excitatory input to HMCs in physiological and pathological conditions will be essential for understanding how these cells contribute to circuit dynamics in the dentate gyrus. HMCs bridge distant hippocampal areas by relaying information from granule cells (GCs) and CA3 pyramidal neurons (CA3) to dentate gyrus; however, many aspects of GC-HMC and CA3-HMC synapses remain uncharacterized. To examine these HMC excitatory inputs, we are recording both spontaneous and evoked EPSCs in HMCs in acute slices from juvenile (~P20) and adult (~P65) mice, detailing excitatory synaptic physiology, the propagation of seizure-like events to HMCs, and how these properties evolve during development.
In vivo administration of certain drugs can induce chronic seizure states, but how HMCs participate in this altered network activity is unknown. We found that acute application of bicuculline and picrotoxin, pilocarpine, or 4-aminopyridine (4-AP) in acute slices induced coordinated firing in CA3 which propagated into the hilus resulting in compound EPSCs (cEPSCs) in HMCs (amplitude: 4255 ± 245 pA). cEPSC frequency was greatly diminished with

aging (juvenile: 2.19 ± 0.25 Hz; adult: 0.20 ± 0.16 Hz), suggesting that developmental changes in hippocampal circuitry diminish the strength of these coordinated bursts or their propagation to HMCs.
To examine if the decrease in cEPSCs with aging could be due to decreased connectivity of HMCs, we examined synaptic physiology at HMC synapses in juvenile and adult mice. We found that HMCs receive significant excitatory input from both CA3 and GCs. Evoked CA3-HMC EPSCs were of small amplitude and facilitated during paired stimulation (paired pulse ratio: 1.95 ± 0.15). In contrast, evoked GC-HMC EPSCs were large amplitude with modest facilitation (paired pulse ratio: 1.66 ± 0.09), which was surprising given that anatomically similar GC-CA3 synapses display much more robust facilitation during paired stimuli of mossy fibers. CA3-HMC and GC-HMC excitatory synaptic function was similar in juvenile and adult mice, suggesting that decreased HMC connectivity likely is unlikely to account for the reduction in cEPSCs with aging. These data show that HMCs receive comparatively weaker synaptic input from CA3 than from GCs, but that strong CA3 input drives the propagation of seizure-like events into the hilus in the presence of pro-epileptic agents.

Title: Measuring the strength nicotinic synapses in rat sympathetic ganglia using stochastic nerve stimulation, voltage-clamp and dynamic-clamp

Authors: *J. P. HORN, P. H. M. KULLMANN;
Dept of Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Synaptic integration in sympathetic ganglia depends upon the strength and number of converging nicotinic synapses and upon intrinsic postsynaptic excitability. Previous efforts to measure synaptic strength have relied on measurements of EPSP amplitude, while not accounting for damage introduced by microelectrode recording (Springer, Kullmann & Horn, J Physiol 2015) or trial-to-trial fluctuations in EPSP size. Here we describe experiments that utilized whole-cell patch electrode recording from the isolated intact superior cervical sympathetic ganglion at 36°C, together with stochastic activation of synapses using minimal presynaptic stimulation at an average frequency of 1 Hz. Synaptic strength was calculated by measuring the average EPSC amplitude at a given synapse under voltage-clamp and converting it

to a synaptic conductance (g_{syn}) using the driving force. Threshold-g_{syn} was then measured under dynamic clamp. We calibrated synaptic strength to excitability by dividing g_{syn} by thresh-g_{syn}. Release dynamics were assessed using 400-600 second trains of 1 Hz stimuli, delivered either at a constant rate or with random exponential timing that mimics physiological activity observed *in vivo*. The strengths of 17 synapses studied this way ranged from 5% to 3,044% thresh-g_{syn}. Interestingly, 5 of these synapses had strengths clustered close to 100% thresh-g_{syn}. The importance of this observation became evident when fluctuations of EPSC amplitude were measured. When regular and stochastic patterns of stimulation were compared, they each evoked similar average amplitudes. However, stochastic stimulation increased the coefficient of variation of EPSCs by up to 60% in 6 of 10 synapses. These results imply that many nicotinic EPSPs in sympathetic ganglia have the capacity to straddle threshold and they reveal for the first time that stochastic synaptic activity in this system produces a form of stochastic resonance that may enhance synaptic amplification (gain) in sympathetic ganglia. The results will be discussed in terms of our previous work on ganglionic gain theory and the implications for autonomic control of cardiovascular function.

Title: Interaction of AMPA and NMDA conductances in transducing synaptic drive into action potential output

Authors: C. LI, *A. T. GULLEDGE;
Physiol. & Neurobio., Geisel Sch. of Med. at Dartmouth, Lebanon, NH

Abstract: Attenuation of synaptic currents within dendrites limits the efficacy of distal excitatory inputs in driving action potential output at the axon. To reduce the impact of distance on synaptic efficacy, neurons employ a range of mechanisms to boost distal synaptic signals, including expression of active dendritic conductances and variations in synaptic structure. Key to excitatory synapses is the expression of ionotropic glutamate receptors, including AMPA and

NMDA receptors, that have distinct kinetics and voltage-dependencies. We used simulated barrages of excitatory input in simplified and morphologically realistic model neurons to explore the interaction of NMDA and AMPA conductances in synapse-spike coupling. Identical series of stochastic synaptic barrages were simulated along progressively more distal stretches of dendrite (100-μm-long, moving in 10 μm increments), while variability in the number and timing of resulting action potentials were measured for each dendritic location. When synapses contained only AMPA or NMDA conductances, the number of action potentials generated during any given trial was highly dependent on the dendritic location of synaptic input, albeit in opposite directions for the two conductance subtypes. In AMPA-only models (500 or 700 pS maximal synaptic conductances), efficacy of synaptic input in driving action potential output dropped precipitously with distance from the soma, while in NMDA-only models (200 pS or 700 pS), excitatory drive peaked when synaptic input occurred at distal locations. These results reflect overall attenuation of synaptic signals with distance from the soma, and enhanced voltage-dependent NMDA receptor activation in distal, high-impedance dendritic compartments. On the other hand, pairing AMPA and NMDA conductances (500 and 200 pS, respectively) reduced the location dependence of synapse-spike coupling relative to models containing either conductance alone. Variability in interspike interval also depended on the composition of conductances at the synapse. When synapses contained only AMPA conductances, spike timings were highly variable, while NMDA conductances, either alone or paired with AMPA, promoted regular firing due to prolonged NMDA decay kinetics. These preliminary results suggest that coexpression of NMDA and AMPA receptors at excitatory synapses may limit location-dependent differences in synapse-spike coupling, and will promote regular firing patterns in response to sustained excitatory drive.

Title: Characterization of a polysynaptic microcircuit involved in sensory vagal afferent activation of dorsomotor vagal neurons in mouse

Authors: *I. AIBA[1], J. L. NOEBELS[2];
[1]Dept. of Neurol., [2]Baylor Col. of Med., Houston, TX

Abstract: Abnormal parasympathetic activity is implicated in sudden unexpected death in epilepsy (SUDEP). Vagal sensory axons entering the brainstem are responsible for the majority of parasympathetic autonomic system input, and abnormal regulation of vagal motor efferents may contribute to the deleterious autonomic deregulation. The dorsomotor vagal (DMV) neurons contribute a majority of the unmyelinated C-fiber efferents, and one of the major regulatory inputs to DMV is the vagal sensory afferent nerve terminating within the dorsal medulla. The present study characterized the regulation of DMV neuron action potential generation by sensory vagal nerve activation in murine acute brainstem slices. Extracellular cell-attached recordings were made from visually identified DMV neurons. DMV neurons showed spontaneous action potentials (AP) with a frequency range between 1-3Hz. AP frequency was increased by bath application of glutamate and eliminated by GABA (0.5mM each). DMV neurons activated by afferent vagal nerve impulses were identified in response to bipolar stimulation of the vagal afferent nerve ending (tractus solitarius). Responsive neurons showed evoked action potentials with a variable probability (51.6±27.6%, n=52) and jitter (7.46±2.9ms). In a subset of recording, evoked EPSCs and IPSCs were subsequently recorded in the same neurons and stimulation by whole-cell recordings. Both evoked EPSCs and IPSCs showed an asynchronous waveform with a large variability in the amplitudes. A regression analysis revealed that the probability of evoked APs significantly correlated with the amplitude of evoked EPSC, but not the evoked IPSC. Inhibition of AMPA receptors with NBQX (5μM) completely abolished both evoked EPSCs and APs, while residual spontaneous EPSCs were still detected. In contrast to the expectation from regression analysis, inhibition of $GABA_A$ receptors (gabazine 10μM), but not glycine receptors (strychnine 1μM), significantly increased the probability of evoked action potential activity. It is likely that polysynaptic inhibitory circuits between sensory vagal and premotor neurons, rather than direct inhibitory monosynaptic current onto the DMV plays a predominant role in regulation of vagal premotor neurons. These results confirmed that glutamate and GABA are the principle excitatory and inhibitory neurotransmitters regulating the vagal afferent to excite DMV efferent neurons.

Title: What are the synaptic input properties *In vivo*? A new method.

Authors: *M. C. VAN ROSSUM[1], M. JELITAI[2], I. DUGUID[2], P. PUGGIONI[3];
[2]Ctr. for Integrative Physiol., [3]Sch. of Informatics, [1]Univ. Edinburgh, Edinburgh, United Kingdom

Abstract: Knowledge of synaptic input is crucial to understand synaptic integration and ultimately neural function. However, in vivo the rates at which synaptic inputs arrive are high, that it is typically impossible to detect single events. We show here that it is nevertheless possible to extract the properties of the events, and particular to extract the event rate, the synaptic time-constants, and the properties of the event size distribution from in vivo voltage-clamp recordings. Applied to cerebellar interneurons our method reveals that the synaptic input rate increases from 600Hz during rest to 1000Hz during locomotion, while the amplitude and shape of the synaptic events are unaffected by this state change. This method thus complements existing methods to measure neural function in vivo.

Title: Voltage-imaging of electrical signaling in dendritic spines.

Authors: J.-Y. WENG, *D. ZECEVIC;
Dept Cell & Mol. Physiol, Yale Univ. Sch. Med., New Haven, CT

Abstract: Thousands of dendritic spines on individual neurons process information and mediate plasticity by generating electrical input signals using a sophisticated assembly of transmitter receptors and voltage-sensitive ion channel molecules. On the conceptual level, a key question that has not been answered is whether the hypothetical electrical isolation of synapses on spine

heads caused by a narrow spine neck is responsible for specific functions which are not supported by synapses on dendrites. The answer to that question is incomplete and controversial because it is mostly based on indirect evidence. To obtained direct evidence, we recently used a technique based on an electrochromic voltage-sensitive dye (JPW3028) applied selectively to individual neurons by intracellular injection. This lipophilic voltage probe binds to neuronal membrane and acts as a transmembrane optical voltmeter with a linear scale capable of recording simultaneously electrical signals from individual spines and parent dendrites. Our measurements demonstrated that synapses on spines of layer 5 pyramidal neurons from both mouse and rat somatosensory cortex are not electrically isolated by the spine neck to a significant extent. Electrically, they behave as if they are located directly on dendrites. Here, we report an extension of these studies to include spines from other neuronal types in the brain. To increase the accuracy of these measurements, we are currently working on improvements in the technique to minimize unwanted effects which result from the interaction of 720 nm light pulses from a femtosecond Ti:Saphire laser utilized to uncage glutamate with fluorescence of voltage-sensitive dye molecules excited by 532 nm light from a diode-pumped, continuous wave laser utilized to provide voltage-dependent fluorescent signals. We found that optical signal related to the EPSP could be contaminated by the stimulated emission depletion (STED) one-photon effect of 720 nm light reducing the intensity of fluorescence from the voltage probe. Additionally, if the uncaging spot is positioned too close to the spine head labelled by the voltage-sensitive dye, the intensity at the edge of the uncaging spot might be high enough to cause 2-photon excitation and subsequent bleaching of the voltage-sensitive dye. The unwanted signals related to one-photon STED effect and 2-photon excitation and bleaching of the voltage dye are in the range of 0% to 10% while the amplitude of the unitary EPSP optical signals are of the order of 1%. Thus, it is mandatory to minimize or eliminate the unwanted signals described above to avoid significant distortions of EPSP signals originating in the spine head.

Title: Inhibitory long term potentiation at parvalbumin expressing pallidal thalamic synapses.

Authors: *M. M. VAN SWIETEN, K. R. TAN;
Biozentrum, Univ. of Basel, Basel, Switzerland

Abstract: The basal ganglia play an important role in procedural learning and motor planning. One of the mechanisms proposed for information storage is long-term plasticity. Over the past two decades great efforts have been performed to describe synaptic plasticity in the basal ganglia. However, most studies have been focused on excitatory corticostriatal synapses, where both long-term potentiation and depression have been observed. Only recently, an interest in inhibitory synaptic plasticity arising from striatal medium spiny neurons has been developed. Nevertheless, synaptic plasticity at inhibitory synapses within and outside the basal ganglia is still underexplored. Synaptic plasticity plays a crucial role in learning and memory.
In the present study we investigated the synaptic properties of a recently identified projection from parvalbumin (PV) expressing neurons in the globus pallidus external segment to the parafascicular nucleus of the thalamus.
Using PV-cre mice with conditional expression of channelrhodopsin combined with in vitro whole-cell patch clamp recording, we showed that this projection is GABAergic and monosynaptic. Furthermore, sustained activation of this synapse (i.e high frequency stimulation) induced a strengthening of this synapse. This long-term potentiation (LTP) relied most probably on a postsynaptic mechanism, as the paired pulse ratio was unchanged. The induction of LTP was independent of NMDA-receptor activation but required a rise in intracellular calcium concentration and activation of the CAMKII signaling cascade. The expression of inhibitory LTP, which could be a result of an increased number of receptors on the cell surface, relied partially on protein trafficking mechanisms and receptors synthesis de novo.
The present study provides new insights in the physiological mechanisms involved at inhibitory plasticity. Moreover, this work is one of the first to investigate the functional synaptic properties of this synapse, which may play an essential role in the basal ganglia function in procedural learning and/or motor planning.

Title: Involvement of NMDAR subunits in the induction of STP and LTP in the GluN2D knockout mouse

Authors: *D. FERNANDEZ-FERNANDEZ[1], A. V. EAPEN[2], E. BURNELL[2], D. T. MONAGHAN[3], D. E. JANE[2], G. L. COLLINGRIDGE[2], A. VOLIANSKIS[4];

Abstract: The specific subunit composition of NMDA receptors (NMDARs) has a strong impact on their intrinsic functionality and therefore can directly determine their ability to induce long-term potentiation (LTP). Indeed, we have recently shown that different di- and tri-heteromeric subtypes of the NMDAR are responsible for the induction of the three temporal components of NMDAR-dependent potentiation in adult rat hippocampal slices, namely, a transient and biphasic short-term potentiation (STP1 decays with τ of ~ 7 min, STP2 with τ of ~ 16 min) that is followed by a sustained LTP phase. The development of UBP145, an antagonist that preferentially targets GluN2D subunit-containing NMDARs, has allowed us to reveal an unexpected role for these receptors in the induction of STP2. STP2 was also sensitive to the GluN2B antagonist, Ro 25-6981, suggesting that the receptor that mediates its induction might be a GluN2B/2D triheteromer (Volianskis et al 2013, 2015). Here, we describe for the first time the functional implications that knocking out the GluN2D subunit exert on the induction of STP and LTP. We find that both STP and LTP can be readily induced by theta-burst stimulation (TBS) in hippocampal slices from GluN2D knockout mice. Moreover, a similar STP and LTP pattern is found after a 30 min long interruption of stimulation following the TBS, showing that decay of STP can be halted during periods without stimulation despite the absence of this NMDAR subunit. In both scenarios, STP decay could be fitted by a monoexponential curve with a τ value of around 8 min, suggesting that STP2, the slower component of STP, is absent in hippocampal slices from GluN2D knockout mice. In support of that, the GluN2D preferring antagonist UBP145 (10 μM) had no effect on induction of STP or LTP in the GluN2D KO mice. This confirms the essential role of GluN2D in the induction of STP2. In addition, Ro 25-6981 (1 μM) had also no effect on STP and LTP in the GluN2D KO mouse. These data support the conclusion that STP2 is mediated by a GluN2B/D triheteromeric receptor and suggest that diheteromeric GluN2B containing receptors are not involved in the induction of LTP. This work was funded by the BBSRC grant number BB/L001977/1 and the National Institute of Mental Health of the National Institutes of Health under Award Number R01MH060252.

Title: Short-term potentiation in the ventral hippocampus

Authors: R. INGRAM[1], L. B. YSSENNAGGER[1], A. T. MICHAEL-TITUS[1], D. E. JANE[2], G. L. COLLINGRIDGE[2,3], *A. VOLIANSKIS[1,2];

Abstract: Synaptic plasticity is most frequently studied in the CA1 area of dorsal hippocampal slices. Here, in response to high-frequency theta-burst stimulation (TBS), the Schaffer collaterals display two phases of potentiation, which are readily induced through activation of NMDA receptors. The initial phase of potentiation, commonly called short-term potentiation (STP), declines in response to low frequency synaptic activation, leading to a permanently enhanced level of synaptic transmission, long-term potentiation (LTP). We have recently shown that STP is not a unitary phenomenon, but consists of two forms, termed STP1 and STP2 (Volianskis et al., 2013; 2015). Induction of STP1 depends on activation of GluN2A and GluN2B containing NMDARs and in this way it appears to be similar to LTP, which in the adult hippocampal slices is induced through GluN2A/2B containing triheteromeric NMDARs. STP2, in contrast to STP1 and LTP, is induced through GluN2B and GluN2D subunit containing NMDARs. In response to stimulation, STP1 decays with a time course ($\tau \sim 7$ min) that is about 2 times faster than that of STP2 (~ 16 min).
STP and LTP can also be induced in slices from the ventral hippocampus. However, not much is known about the properties of STP in this part of the brain and it is generally assumed that the induction of LTP in the ventral hippocampus is less reliable than in the dorsal. We investigated the induction of NMDAR-dependent potentiation in ventral hippocampal slices and show that TBS induced LTP (~ 14%) was about 3 to 4 times smaller than that in the dorsal hippocampus.

Decay of ventral STP, similarly to that in dorsal hippocampus (Volianskis & Jensen, 2003), depended on synaptic stimulation. Ventral STP (~ 20%) decayed with a τ value of ~ 6 min and was very similar to STP1 in dorsal hippocampus. On the basis of these observations we suggest that induction of STP and LTP in ventral hippocampal slices might be mediated exclusively by GluN2A and GluN2B containing NMDARs.

Title: Convergent metabotropic and cholinergic signaling in the facilitation of Hebbian synaptic plasticity

Authors: *C. M. TIGARET, M. C. ASHBY, J. R. MELLOR;
Sch. of Physiology, Pharmacol. & Neurosci., Univ. of Bristol, Bristol, United Kingdom

Abstract: Induction of spike timing-dependent plasticity (STDP) at Schaffer collateral (S/C)-CA1 synapses requires the sequential activation of postsynaptic NMDA receptors (NMDARs) and voltage-sensitive Ca^{2+} channels at dendritic spines(1, 2). NMDAR function and spine Ca^{2+}

signaling during induction of LTP are facilitated by metabotropic glutamate receptor ($mGluR_1$)-dependent inhibition of SK channels(2). In addition, muscarinic M1 receptors facilitate spine Ca^{2+} signalling and induction of theta burst LTP at S/C-CA1 synapses through a mechanism also involving SK channel inhibition(3-5). Here, we show in acute hippocampal slices from adult rats that the highly selective allosteric M1 agonist GSK-5 (1μM) (5) or direct inhibition of SK channels by apamin (100 nM) rescued STDP-LTP induction at S/C-CA1 synapses in the presence of mGluR1 selective antagonist YM 298198 (100 nM). STDP-LTP was induced with a train of 300 STDP stimulations at 5 Hz for 1 min, in whole-cell current clamp at 36°C under $GABA_A$ receptor inhibition (50 μM picrotoxin). Each stimulation consisted of one EPSP evoked in the stratum radiatum followed by two action potentials elicited by somatic current injection at 100 Hz. Using two-photon Ca^{2+} fluorescence imaging in dendritic spines of CA1 pyramidal neurons(2) we show that apamin enhanced both synaptically evoked EPSPs and spine Ca^{2+} transients (EPSCaTs). Spine Ca^{2+} imaging during STDP-LTP-inducing stimulus trains revealed that LTP induction requires a sustained sequence of spine EPSCaTs. GSK-5 amplified the sequence of EPSCaTs during LTP induction to an extent comparable to that of apamin. Furthermore, $mGluR_1$ blockade inhibited the EPSCaTs evoked during the LTP induction trains, and this effect was reversed in the presence of apamin or GSK-5. Our data indicate that SK channels are a common downstream target in a convergent signalling pathway underpinning the facilitation of LTP by metabotropic glutamate and cholinergic neuromodulation.

Title: Thalamo-prefrontal resonance of hippocampal inputs is plastic and attenuated by thalamic silencing

Authors: *L. S. BUENO-JUNIOR, R. N. RUGGIERO, J. E. PEIXOTO-SANTOS, D. B. MARQUES, M. A. V. AVILA, C. LOPES-AGUIAR, J. P. LEITE;
Med. Sch. of Ribeirao Preto, Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: The prefrontal cortex (PFC) receives overlapping terminals from CA1/subiculum (CA1/sub) and mediodorsal thalamus (MD). Because the PFC reciprocates its thalamic afferents, CA1/sub inputs could plastically reverberate in the PFC-MD loop, which we examined through unit activity and synaptic plasticity monitoring. Rats were implanted with electrodes in CA1/sub (electrical stimulation), MD and PFC (recording) for a chronic session with paired-pulse stimulation (0.1 Hz), and high-frequency stimulation (HFS, 250 Hz trains; 30 min baseline, 120 min post-HFS). Both PFC and MD firing responded to CA1/sub pulses with phasic increases (<200 ms), then a transient decrease (200-400 ms). Specifically in the PFC, we observed a delayed-onset increase (400-800 ms) that was potentiated after HFS. CA1/sub pulses elicited distinct field responses in PFC and MD, which underwent long-term potentiation. Moreover, electrophysiological responses were correlated with c-Fos and Zif-268 immunohistochemistry throughout the studied circuit. We further asked whether MD optogenetic hyperpolarization modulates the CA1/sub-PFC recruitment. A rat expressing green light-driven archaerhodopsins in the MD was implanted as above, except for an optrode into MD. When randomly paired with CA1/sub electrical pulses, MD light pulses attenuated PFC delayed-onset responses. Thus, hippocampal inputs seem to plastically resonate within the thalamo-prefrontal loop. These findings contribute to the systems-level understanding of limbic-prefrontal functions (e.g., working memory), and dysfunctions (e.g., psychoses and seizure amplification).

Title: Identification of a novel PKA regulatory site in neuroligin-1.

Authors: *J. JEONG, M. A. BEMBEN, Y. LI, K. W. ROCHE;
NINDS, BUILDING 35, Bethesda, MD

Abstract: Neuroligin-1 is a member of the neuroligin gene family encoding a single-pass transmembrane postsynaptic cell adhesion molecule that is critical for excitatory synaptic assembly and function. The large extracellular domain of neuroligin-1 is responsible for transsynaptic binding with neurexin, a presynaptic cell adhesion molecule, and the short cytoplasmic tail of neuroligin-1 is exposed to a variety of intracellular regulation. Importantly, neuroligin-1 binds to PSD-95, a scaffolding protein at excitatory synapses, through the PDZ ligand in the cytoplasmic tail, which is important for neuroligin-1 clustering at excitatory synapses. In this study, we found protein kinase A (PKA) phosphorylates neuroligin-1, near the PDZ ligand, *in vitro* and in heterologous cells. We generated a phospho-specific antibody, which allows detection of PKA phosphorylated neuroligin-1 and is efficient for immunoprecipitation of native neuroligin-1. Interestingly, a phospho-mimetic mutation at the PKA site significantly reduced the interaction between neuroligin-1 and PSD-95 *in vitro* and *in situ*. Our results establish a novel molecular mechanism that regulates neuroligin-1 and PSD-95 binding in a PKA activity-dependent manner, which can provide insights into excitatory synaptic development and function.

Title: BDNF regains function in hippocampal long-term potentiation deficits caused by diencephalic damage.

Authors: L. C. VEDDER[1], *L. M. SAVAGE, Ph.D.[2];
[1]Psychology, Binghamton University- SUNY, Binghamton, NY; [2]Psychology-Behavioral Neurosci., State Univ. of New York Binghamton, Binghamton, NY

Abstract: Alcoholism is commonly associated with thiamine deficiency that leads to diencephalic damage, hippocampal dysfunction and spatial learning and memory deficits. We studied the effects of thiamine deficiency, in both male and female rats, on hippocampal synaptic plasticity and function. Using the pyrithiamine induced thiamine deficiency (PTD) model, along

with pair-fed controls, we found that following a prolonged recovery period from thiamine deficiency there were decreases in the magnitude of LTP (see A) and paired-pulse facilitation (PPF) at CA3-CA1 synapses in both male and female PTD rats. There were no sex differences in spatial working memory or measures of hippocampal plasticity. Thus, despite a lack of extensive hippocampal cell loss in the PTD model, diencephalic brain damage down-regulates synaptic plasticity within the hippocampus, likely contributing to impaired hippocampal-dependent behaviors. However, both measures of hippocampal plasticity (LTP, PPF) were restored with a BDNF application (20 ng/mL), revealing an avenue for neural and behavioral recovery following diencephalic damage.

Title: Investigating the roles of atg1 and atg8a in glutamate receptor localization

Authors: *K. BERNARD[1], F. LIEBL[2];
[1]Biol. Sci., Southern Illinois Univ. Edwardsville, Edwardsville, IL; [2]Southern Illinois University-Edwardsville, Edwardsville, IL

Abstract: Glutamate is the most abundant excitatory neurotransmitter in the central nervous system. It is implicated in synaptic plasticity including learning and memory and long term potentiation, which are characterized by changes in the number and localization of glutamate receptors (GluRs) in the postsynaptic cell. We have found that proteins important for autophagy, a cellular process that degrades cellular components for reuse, affect the synaptic localization of GluRs at the *Drosophila* neuromuscular junction. Interestingly, mutations in *atg1*, *atg13*, and *atg8a* lead to a reduction in synaptic GluRs suggesting that they either indirectly regulate GluR localization or signal independent of autophagy. In support of the latter, loss of *atg8a* function leads to a more severe reduction in synaptic GluRs than loss of *atg1* function. To examine the effects of Atg8a on glutamate receptor distribution, we preformed tissue specific overexpression and knockdown experiments and are examining the possibility that Atg8a signals downstream of the insulin receptor pathway to regulate GluR localization.

Title: Motor training promotes both synaptic and intrinsic plasticity of layer II/III pyramidal neurons in the primary motor cortex

Authors: *H. KIDA, Y. TSUDA, Y. YAMAMOTO, Y. OWADA, N. ITO, D. MITSUSHIMA; Yamaguchi university Sch. of Med., Ube, Yamaguchi, Japan

Abstract: Motor skill training induces structural plasticity at dendritic spines in the primary motor cortex (M1). To further analyze both synaptic and intrinsic plasticity in the layer II/III area of M1, we subjected rats to a rotor rod test and then prepared acute brain slices. Motor skill consistently improved within two days of training. Voltage clamp analysis showed significantly higher AMPA/NMDA ratios and miniature EPSC amplitudes in 1-day trained rats compared to untrained rats, suggesting increased postsynaptic AMPA receptors in the early phase of motor learning. Compared to untrained controls, 2-days trained rats showed significantly higher miniature EPSC amplitude and frequency. Paired-pulse analysis further demonstrated lower rates in 2-days trained rats, suggesting increased presynaptic glutamate release during the late phase of learning. 1-day trained rats showed decreased miniature IPSC frequency and increased paired-pulse analysis of evoked IPSC, suggesting a transient decrease in presynaptic GABA release. Moreover, current clamp analysis revealed lower resting membrane potential, higher spike threshold, and deeper afterhyperpolarization in 1-day trained rats—while 2-days trained rats showed higher membrane potential, suggesting dynamic changes in intrinsic properties.
Our present results revealed dynamic changes in synaptic plasticity and neural properties after motor training within M1. In the 1-day trained rats, motor training strengthened AMPA receptor-mediated excitatory synapses and drastically reduced presynaptic GABA release probability. In the 2-days trained rats, motor training further strengthened AMPA receptor-mediated excitatory synapses together with NMDA receptors and increased presynaptic glutamate release, while increasing the presynaptic GABA release probability. Based on our findings, we conclude that motor training promotes synaptic plasticity at both excitatory and inhibitory synapses, as well as changes neural properties, such as resting membrane potential and threshold of M1 layer II/III neurons.

Title: Different PKM isoforms in the postsynaptic target neuron contribute to different forms of persistent synaptic plasticity expressed at convergent presynaptic inputs

Authors: *S. SCHACHER[1], K. ADLER[2], M. HASTINGS[3], W. SOSSIN[4], J. HU[2];
[2]Neurosci., [1]Columbia Univ. & NYSPI, New York, NY; [3]Psychology, [4]Neurol. and Neurosurg., McGill University-Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: Synaptic tagging and capture is a potential cellular mechanism mediating some forms of behavioral generalization. Weak stimuli, insufficient to produce a long-term change, evoke long-term memory or synaptic plasticity when temporally paired with strong stimuli that produce long-term memory or synaptic plasticity at a convergent pathway. At the cellular level it is not clear whether persistent plasticity (e.g. facilitation) expressed at each input share the same properties. Here we used the behaviorally relevant sensorimotor synapse of *Aplysia* to examine whether convergent sensory neuron inputs onto a common postsynaptic target (motor neuron L7) use different mechanisms to sustain persistent long-term facilitation (LTF). Two sensory neurons were plated with a single L7 in culture and allowed to form stable synaptic connections. One sensory neuron input received activity paired with a bath application of serotonin (5-HT; strong stimuli), while the other sensory neuron input received the bath application of 5-HT alone (weak stimuli). Two pairings of activity plus 5-HT to the same sensory neuron input (one pairing each day) resulted in persistent LTF (lasting more than 6 days) expressed at both sensory neuron synapses. Two unpaired stimuli presented in the same manner (one set of stimuli per day) failed to induce any form of LTF at either sensory neuron synapse. The persistent LTF evoked at each synapse had different properties. The sensory neuron input that received the paired stimuli expressed a plasticity characteristic of persistent associative LTF, while the other input that received the weak stimuli of two brief applications of 5-HT expressed a plasticity characteristic of persistent non-associative LTF. Selectively blocking the activity of PKM Apl III, derived from the atypical PKC Apl III, in L7 only reversed the persistent plasticity expressed at the sensory neuron input that received the paired stimuli. In contrast, selectively blocking the activity of PKM Apl I, derived from the classical PKC Apl I, in L7 reversed the persistent plasticity expressed at the other input that received the weak stimuli. Thus convergent inputs onto a common target neuron can use different mechanisms initiated in the postsynaptic partner

to maintain persistent LTF. Selective manipulations in the postsynaptic neuron enabled reversals in an input-specific manner.

Title: Quantifying information storage in the hippocampus: Lessons from the dentate gyrus

Authors: *C. BROMER[1,2], T. M. BARTOL[1], W. C. ABRAHAM[3], J. BOWDEN[4], P. GONZALEZ[4], D. HANKA[4], D. HUBBARD[4], M. KUWAJIMA[4], J. MENDENHALL[4], P. PARKER[4], T. J. SEJNOWSKI[1], K. HARRIS[4];

Abstract: Understanding how the amount of information stored at the synapse differs across the hippocampus has profound implications for memory. Our previous work (Bartol et al. eLife, 4:e10778, 2016) demonstrated a tight correlation in size and strength of dendritic spines with a shared presynaptic and postsynaptic history in a 3D reconstruction of hippocampal neuropil from rat CA1 stratum radiatum. In this brain region, when two spines are located on the same dendritic branch and receive input from a single axon, the coefficient of variation (CV) in the size of the

two spines (spine head volume) is 0.083. Using the observed distribution of spines in the sample, the calculated CV and standards from signal detection theory, we predicted this tight level of control over synaptic strength to correspond to ~4.7 bits of information stored at the synapse. In our current study, we examined pairs of spines with a shared presynaptic and postsynaptic history in three layers of dentate gyrus in rat neuropil (inner molecular layer, middle molecular layer and outer molecular layer) under control and long-term potentiation (LTP) conditions. We were not only able to examine differences in information processing across the hippocampus (the dentate gyrus being a region typically perceived as "upstream" of CA1), but also to make predictions about how the high correlation between spine pairs changes in response to activity (in the LTP condition). In electron microscopy images taken 30 minutes after induction, where the contralateral hippocampus (not receiving stimulation) serves as a control, potentiation in the middle molecular layer and concurrent long-term depression (cLTD) in the inner and outer molecular layers provides an opportunity to parse bidirectional changes in synaptic weight relative to control. In particular, the correlation in sizes of spines sharing a presynaptic and postsynaptic history is altered under a stimulation protocol.

Title: KIBRA is an isoform-specific PKM stabilizer in *Aplysia* sensory neurons

Authors: *L. FERGUSON, N. BENFEY, T. DUNN, W. SOSSIN;
Neurol. and Neurosurg., McGill Univ., Montreal, QC, Canada

Abstract: The persistent activity of PKMs has been proposed to be critical to the maintenance of transcription-dependent memory, despite the fact that no links have been established between transcription and PKM maintenance. We have been studying the role of PKM in maintaining memories in the sensory-motor reflex of the marine mollusk, Aplysia californica. In this system, PKM formation is mediated through transcription-independent calpain-mediated cleavage of PKC into PKM. Indeed, PKMs are important in the maintenance of several forms of

transcription-independent intermediate facilitation (Sutton et al, 2004; Bougie et al, 2012). Nevertheless, similar to vertebrates, inhibitors of PKM can erase transcription-dependent forms of memory and synaptic facilitation, suggesting that transcriptional events can prolong the lifetime of PKM activity (Cai et al, 2011). We are examining the kidney-brain adaptor protein, KIBRA, as a possible link between transcription and PKM. KIBRA has been implicated in human episodic memory and has been shown to stabilize PKMs in rodent hippocampus and to be required for long-term memory formation (Vogt-Eisele et al., 2014). We have cloned the Aplysia orthologue of KIBRA and found that the PKC/PKM-binding domain (as well as the WW and C2 domains) is highly conserved between mammalian and Aplysia KIBRA. Quantitative PCR experiments demonstrate that KIBRA mRNA is upregulated during learning (Ferguson et al., SfN 2015 poster). We show that removing the putative PKM binding domain of KIBRA abolishes stabilization of PKM Apl III, but surprisingly increases stabilization of PKM Apl I, whose levels are not increased by expression of wild-type KIBRA. This suggests distinct KIBRA domains required for stabilization of different PKMs and competition in cells for KIBRA binding. Additionally, KIBRA lacking the PKM binding domain acts as a dominant negative that destabilizes PKM produced through cleavage of overexpressed PKC Apl III. We will determine whether this differential stabilization is due to differential binding of PKM isoforms, and whether KIBRA overexpression in the postsynaptic neuron of Aplysia sensory-motor neuron co-cultures is sufficient to prolong intermediate-term facilitation. We will also investigate KIBRA's role in localizing PKM to its synaptic targets by exploring KIBRA's colocalization with postsynaptic AMPA receptors. Confirming KIBRA's role in prolonging PKM's half-life in the potentiated synapse will broaden our understanding of the relationship between transcription-independent PKM formation and transcription-dependent synaptic facilitation.

Title: Cell-specific PKM isoforms are required for maintaining different forms of persistent synaptic plasticity at a behaviorally relevant synapse

Authors: *J. HU[1], K. ADLER[1], C. A. FARAH[2], M. HASTINGS[3], W. SOSSIN[2], S. SCHACHER[1];
[1]Dept. of Neurosci., Columbia Univ. Med. Ctr. & NYSPI, New York, NY; [2]Neurol. and Surgery, [3]Psychology, McGill University-Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: Long-term changes in synaptic strength contribute to long-term memory. There is little information about the role of specific molecules in both the presynaptic and postsynaptic partner in maintaining persistent plasticity. The sensorimotor synapse of *Aplysia* expresses both non-associative and associative forms of persistent long-term facilitation (LTF) that are cellular analogs of long-term sensitization and classical conditioning, respectively. Although several kinases contribute to the expression of different forms of LTF, constitutive PKC activity is required for maintaining both non-associative and associative LTF. *Aplysia* neurons express three isoforms of PKC - Apl I (classical), Apl II (novel) and Apl III (atypical) – that are also cleaved in a calpain-dependent manner into constitutively active forms PKM Apl I, PKM Apl II and PKM Apl III, respectively. We examined the cell-specific roles of the PKMs in maintaining persistent non-associative and associative LTF by overexpressing dominant negative forms of each PKM In either the sensory neuron or the motor neuron L7. Constructs were injected into the cell 48 hours after the last stimuli, and synaptic strength was monitored over the next 3-4 days to determine the consequences of the cell-specific overexpression of each dominant negative construct on control synaptic baseline and on the maintenance of persistent LTF evoked by the different stimuli. PKM activities were not required for maintaining control synaptic baseline. However, the maintenance of persistent non-associative LTF selectively required PKM Apl II and PKM Apl III activities (but not PKM Apl I) in sensory neurons and PKM Apl I activity (but not PKM Apl II and PKM Apl III) in motor neuron L7. In contrast, the maintenance of persistent associative LTF selectively required PKM Apl II and PKM Apl III activities (but not PKM Apl I) in motor neuron L7 and PKM Apl II activity (but not PKM Apl I and PKM Apl III) in sensory neurons. The classical calpain in L7, one isoform of calpain known to cleave the PKC isoforms into the PKMs, was not required for maintaining either form of persistent plasticity. These results indicate that different stimuli inducing different forms of persistent synaptic plasticity regulate the cell-specific activation of different PKM isoforms for maintaining different forms of persistent plasticity.

Abstract: Long-term potentiation (LTP) and depression (LTD) are the mechanisms by which neurons modulate their inherent synaptic plasticity and support the storage and recovery of memories in the mammalian brain. The ability to potentiate a synapse declines significantly in neurodegenerative disorders and is related to deficiencies in LTP. In addition to deficiencies in synaptic plasticity, degenerating neurons display acute and chronic mitochondrial dysfunction, suggesting that dysregulated mitochondria play a hand in synaptic dysfunction in addition to their known role in apoptotic death. Our previous work shows that the anti-apoptotic protein Bcl-xL not only prevents somatic cell death, but it also enhances synaptic responses. Here, we show that Bcl-xL is responsible for dramatic changes in ATP levels at synapse-specific sites in hippocampal neurons. Using fluorescent imaging of an ATP-FRET construct in living cells, we find that LTP induction in isolated hippocampal neurons causes a short decrease in ATP levels followed by a persistent long term increase in ATP production. This suggests that after high frequency or intense synaptic stimulation, neurons may become metabolically more active and possibly more efficient; oxygen consumption rates during LTP are now being performed to confirm or refute the proposed change in efficiency. The long-term increase in ATP levels in LTP-stimulated synapses is blocked when we inhibit Bcl-xL and when ATP synthase activity is blocked with oligomycin, suggesting that mitochondria are required to produce the increased ATP levels. Bcl-xL inhibition also prevents a long-term increase in surface glutamate receptor insertion. We are completing studies to see what effect blocking ATP synthase activity has on glutamate receptor insertion. In hippocampal slice recordings, inhibition of Bcl-xL greatly impairs early stage LTP and prevents late stage LTP. We suggest that long term changes in mitochondrial efficiency brought on by activity-dependent translocation of Bcl-xL to mitochondria are required for LTP. Our studies shed light on the role of changes in mitochondrial metabolic efficiency in the acute induction and long term maintenance of learning and memory storage. If such mitochondrial changes fail to occur, synaptic dysfunction associated with neurodegeneration may ensue. Our study places mitochondria and Bcl-x_L at the center of synaptic metabolism and synaptic plasticity.

Title: Metabotropic glutamate receptor 4 (mGluR4) determines plasticity and associativity in hippocampal area CA2

Authors: *A. DASGUPTA, L. YU JIA, S. SREEDHARAN;
PHYSIOLOGY, NATIONAL UNIVERSITY OF SINGAPORE, Singapore, Singapore

Abstract: Mammalian brain is well known for its 'plasticity' i.e. the ability of an experience generated neural activity to alter the strength and efficacy of its neural circuits and has been widely studied in hippocampal area CA1. However, area CA2 is starting to garner attention in recent years, due to better characterization of the boundaries of CA2 and greater understanding of its unique physiological, molecular and genetic properties that differentiate it from CA1 and CA3.
Entorhinal cortex projections on CA2 (EC→CA2) express robust Long-Term Potentiation (LTP) on high-frequency stimulation whereas Schaffer collateral synapses (SC→CA2) on this area lack this activity dependent plasticity under the normal high-frequency stimulation protocols. However, not much about the mechanisms and pathways involved in restricted plasticity within CA2 has been elucidated. Presence of a plasticity regulating protein RGS 14 and excessive calcium buffering could be the attributing factors. The metabotropic glutamate receptor 4 (mGluR4) is highly expressed in area CA2 compared to other regions of the hippocampus. In this study, we hypothesize that over-expression of mGluR4 could be one of those regulating factors restricting plasticity at Schaffer collateral synapses. Thus, inhibition of mGluR4 might help in restoring plasticity in this area. Therefore, the pharmacological blockade of mGluR4 on induction of LTP in Schaffer collateral CA2 synapses is investigated using electrophysiological techniques. Inhibition of mGluR4 results in significant late-LTP when a strong tetanus is given. This LTP is N-methyl-D-aspartate (NMDA) receptor-dependent and has a late-phase which is reliant on protein synthesis. The induced LTP also shows preliminary support for synaptic tagging and capture.
Hence, it can be concluded that the identification of mGluR4 as a player in the regulation of synaptic plasticity helps bridge the gap in understanding the plasticity regulation in area CA2.

Sch. of Medicine, Osaka Univ., Osaka, Japan; [7]Dept. of Systems Life Engineering, Maebashi Inst. of Technol., Gunma, Japan

Abstract: Phosphoinositides, such as phosphatidylinositol 3,4,5-triphosphate (PIP_3) and phosphatidylinositol 4,5-bisphosphate (PIP_2), are essential regulators for diverse range of biological events. For synaptic plasticity, involvement of PIP_3 and/or PIP_2 for LTP as well as LTD is reported, yet how they regulate the subsequent molecular machineries mostly remains elusive. We show here that Phldb2, of which PH domain is one most sensitive to PIP_3, controls synaptic plasticity responding to membrane phosphoinositides. Phldb2 kept an interaction between NMDA receptor and CaMKII last long, which is critical for LTP induction and maintenance, and contributed to AMPA receptor accumulation at the postsynaptic membrane responding to PIP_3. Indeed, LTP was impaired, from an early phase to the late phase (memory formation), in the Phldb2 knockout mice. Although Phldb2 was unstable in the presence of activated CaMKII, it was more stable in the presence of GluA1 or GluA2, suggesting a crucial role of AMPA receptor for long-lasting LTP. Furthermore, Phldb2 was essential for LTD: Phldb2 bound to AP2 for receptor endocytosis as well as to PSD-95. In conclusion, Phldb2 is a versatile, but is critical mediator for synaptic plasticity and its function, responding to dynamic membrane phosphoinositides.

Title: Extracellular matrix heparan sulfates contribute to pyramidal cell excitability and synaptic long-term potentiation

Authors: *D. MINGE[1], O. TIKHOBRAZOVA[2], G. KOCHLAMAZASHVILI[2], A. DITYATEV[2], C. HENNEBERGER[1,3,4];
[1]Inst. of Cell. Neurosciences, Univ. of Bonn, Med. Sch., Bonn, Germany; [2]Mol. Neuroplasticity Group, German Ctr. for Neurodegenerative Dis., Magdeburg, Germany; [3]German Ctr. for Neurodegenerative Dis. (DZNE), Bonn, Germany; [4]Inst. of Neurol., Univ. Col. London (UCL), London, United Kingdom

Abstract: Heparan sulfates (HS) are a heterogeneous group of extracellular glycosaminoglycans consisting of sulfated disaccharide repeats. Within the extracellular matrix (ECM) of the adult central nervous system, the majority of HS are attached to a variety of core proteins and form the complex group of heparan sulfate proteoglycans (HSPG). HSPGs have been suggested to play a pivotal role in maintaining various aspects of hippocampal neuron function. Therefore, acute loss of HS/HSPG is expected to modify synaptic and intrinsic properties of neurons within the hippocampus and also their long-term plasticity. This was tested by treating acute hippocampal slices obtained from five to seven week old C57BL/6 mice with *Heparinase I*, an enzyme that specifically cleaves HS, and combining electrophysiology and two-photon excitation fluorescence intensity and lifetime microscopy. Enzyme treatment led to an impairment of long-term potentiation (LTP) at CA3-CA1 Schaffer collateral synapses induced by theta burst

stimulation (TBS). This impairment persisted when GABAergic inhibition was pharmacologically blocked and did not result from altered excitatory synaptic transmission. Nonetheless, individual CA1 pyramidal neurons showed decreased dendritic and spine Ca^{2+} influx during TBS. Further experiments revealed, that Ca^{2+} entry evoked by back-propagating actions potentials (b-APs) and direct depolarization in voltage clamp and also resting Ca^{2+} concentrations were not affected by heparinase treatment. In contrast, the number of APs generated by CA1 pyramidal cells during TBS was significantly lower after heparinase treatment. Therefore, heparinase treatment impairs LTP by reducing CA1 pyramidal cell excitability during TBS with no detectable effect on voltage-dependent Ca^{2+} influx at spines/dendrites. Somatic current injections mimicking TBS also resulted in fewer APs in heparinase treated slices suggesting that HS maintain pyramidal cell excitability. Analysis of spiking behavior revealed a selective effect of heparinase treatment on the threshold of spikes evoked by strong, repetitive stimuli. In contrast, various other parameters of neuronal excitability like sag potential and afterhyperpolarization were not affected. This suggests that heparinase treatment may reduce axonal excitability. Thus, heparan sulfates support high-frequency firing of CA1 pyramidal cells. They indirectly promote Ca^{2+} influx during induction of synaptic plasticity using TBS and thereby support synaptic long-term plasticity.

Title: Input-timing dependent plasticity provides a general synaptic learning rule in hippocampal CA1 and CA2 regions

Authors: *F. LEROY, D. H. BRANN, S. A. SIEGELBAUM;
Neurosci., Columbia Univ., New York, NY

Abstract: Classical hippocampal long-term synaptic plasticity is homosynaptic, induced by tetanic stimulation of a single input pathway. In contrast, input-timing dependent plasticity (ITDP) is a circuit-based form of heterosynaptic plasticity induced by low-frequency paired stimulation of the direct entorhinal cortex (EC) inputs to CA1 pyramidal neurons (PNs) precisely

20 ms prior to activating their CA3 Schaffer collateral (SC) inputs. This pairing results in the long-term depression of SC-evoked feedforward inhibition (iLTD) mediated by cholecystokinin (CCK)-expressing basked cells through the activation of CB1 endocannabinoid receptors. As CA2 PNs also receive direct EC and SC inputs, we asked whether ITDP may represent a general synaptic learning rule. Paired activation of EC and SC inputs at the 20 ms pairing interval also induced a robust ITDP in CA2 PNs as a result of iLTD. However, contrary to CA1, the EC-evoked PSP also displayed a moderate but significant increase. Furthermore, ITDP in CA2 relies on δ-opioid receptor activation rather than CB1 receptors, suggesting that the iLTD was mediated by parvalbumin-expressing interneurons. Additionally we show that pairing of electrical stimulation of the SC inputs with optogenetic stimulation of defined EC inputs is sufficient to induce ITDP in CA2 PNs, confirming the importance of the EC inputs in ITDP. Thus, precise temporal pairing of EC and SC inputs may provide a general synaptic learning rule whose precise cellular ad molecular mechanisms are tuned to the specific local inhibitory circuitry.

Title: Sleep slow-wave activity induces long-term potentiation of thalamocortical responses and increase memory consolidation in mice

Authors: *I. V. TIMOFEEV, B. LOBO DE FRANCA, A. OZUR, J. SEIGNEUR, S. CHAUVETTE;
CRIUSMQ, Univ. Laval, Quebec, QC, Canada

Abstract: It is well known that sleep contributes to consolidation of different forms of memory. It is apparent that synaptic reorganization plays a role in sleep-dependent memory consolidation. The proposed patterns of cortical synaptic reorganization spanned from sleep-dependent synaptic down scaling to sleep-dependent synaptic facilitation. We previously demonstrated that sleep slow waves induce potentiation of intracortical synapses. Here we ask: Does slow-wave sleep

potentiate thalamocortical synapses and does an increase in slow-wave activity facilitate memory formation in mice? To test these hypotheses, we used B6Cg-Tg(Thy1-COP4/EYFP)18Gfng/J mice, which express channelrhodopsin 2 channels in the vast majority of cortical and thalamic neurons. We used cortical (frontal or occipital cortex) or thalamic (MD nucleus) LED stimuli delivered via a fiber-optic microcannula and recorded neuronal or field potential responses in either anesthetized or behaving animals. To test the memory formation, we used the novel object recognition test because it represents a model of declarative memory, which does not have spatial (hippocampal) component. MD thalamic stimulation induced short-latency spikes in the vicinity of stimulating fiber-optic microcannula and 3-5 ms later it triggered evoked potential in the frontal cortex. The onset of neuronal depolarization in different neurons corresponded to different components of evoked potential. The amplitude of the earliest depth-negative component of evoked potential was always enhanced after a period of slow-wave sleep, suggesting synaptic potentiation. Optogenetic stimulation of frontal cortex induced local excitation followed by a slow wave that propagated to motor, somatosensory, visual, and retrosplenial cortices. We used rhythmic blue light stimulations for 4 hours of the frontal cortex at the onset of light period with a frequency mimicking slow-wave sleep (1 Hz), which significantly enhanced LFP delta power. Novel object recognition test done at the end of dark cycle shows that both stimulated and not stimulated mice spent much more time exploring the novel object than the old one. However, mice from the stimulated group spent much less time exploring the old object, suggesting that they remembered more the old object than the sham group of mice. These results show that slow-wave sleep induces synaptic potentiation of thalamocortical synapses and enhanced slow-wave activity increases memory consolidation.

Title: The synaptic role of GSK3 isoforms in adult mouse brain synapticity

Authors: *T. MIYATA[1,2], A. AVILA[1], J. GEORGIOU[1], G. L. COLLINGRIDGE[1,3], J. WOODGETT[1,2];
[1]Lunenfeld Tanenbaum Res. Inst., Toronto, ON, Canada; [2]Med. Biophysics, [3]Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Glycogen synthase kinase 3 (GSK3) is a serine/threonine protein kinase implicated in normal brain development and a variety of brain and other disorders. For example, GSK3 is required for proper formation of axons, the signalling arms of neurons (Garrido et al., 2007). Moreover, the most commonly prescribed mood-stabilizing drug for patients with bipolar disorder, lithium, directly inhibits GSK3 activity (Freland and Beaulieu, 2012). However, the mechanisms by which GSK3 orchestrates its effects on brain function and dysfunction in psychiatric and cognitive disorders are poorly understood. This study was designed to investigate the role of the two mammalian isoforms of GSK3 (GSK3α and β) by selective inhibition of their expression in the adult brain of mice. To evaluate the effects of inactivation of each isoform individually or together, the genes for GSK3α and GSK3β were inactivated using a Cre-LoxP strategy; in these GSK3-Cre knockout (KO) mice, Cre recombinase expression is driven in the adult forebrain by the calmodulin-dependent protein kinase II promoter (CamMK2). Phenotypes of GSK3-Cre KO and control mice were compared at around P50 using electrophysiological measures of hippocampal synaptic function and plasticity. Preliminary findings from electrophysiology experiments revealed that the effect of GSK3 suppression on synaptic plasticity was isoform specific such that hippocampal brain slices from GSK3α-Cre KO mice, but not GSK3β-Cre KO, exhibited impaired maintenance of long-term potentiation (LTP) and also long-term depression (LTD), as compared to control slices. These findings illustrate the unique function of GSK3 isoforms on adult hippocampal synaptic plasticity in an adult excision model where early neurodevelopmental effects are not likely to confound the conclusions. The results exemplify the utility of combining genetic approaches with electrophysiological approaches for investigating the molecular mechanisms of disorders that affect cognitive function. Future work will include pharmacological and behavioural analysis to elucidate drug actions according to gene dosage.

Title: Disentangling negative regulators of plasticity in CA2 pyramidal neurons

Authors: *K. CARSTENS[1], D. LUSTBERG[2], S. M. DUDEK[2];
[1]Neurobio. Lab., NIEHS, Rtp, NC; [2]NIEHS, RTP, NC

Abstract: CA2 pyramidal neurons are molecularly distinct from neighboring CA1 and CA3 subfields as early as embryonic development in the mouse. Interestingly, glutamatergic synapses in stratum radiatum (SR) of CA2 are resistant to some forms of synaptic plasticity, specifically to the induction of long-term potentiation (LTP). Perhaps not coincidently, during early postnatal development, several negative regulators of synaptic plasticity appear in CA2 pyramidal cells but not in CA1 or CA3. CA2 synapses still however have the capacity for LTP, for example, a knock-out of regulator of G-protein signaling 14 (RGS14), a negative plasticity regulator in CA2, enables LTP in CA2. We studied the developmental expression pattern of several negative plasticity regulators in CA2 and whether they may function together to dampen plasticity in CA2 later in development. Recently, we identified another negative plasticity regulator in CA2, the specialized extracellular matrix perineuronal nets (PNNs), that also suppresses LTP at CA2 excitatory synapses. Degradation of PNNs in acute hippocampal slices between postnatal day 14 (PN14) and PN18 was sufficient to enable LTP in CA2. Immunohistochemical analysis indicates that the PNN component, aggrecan, first appears in CA2 at PN14 and is absent at PN11; however, other negative plasticity regulators are present at PN11, such as RGS14 and Purkinje cell protein 4 (Pcp4). To disentangle which negative plasticity regulators are necessary to block LTP induction in CA2, we tested LTP in CA2 at younger ages when PNNs are absent. We found that LTP is expressed at CA2 SR synapses between PN8-11, suggesting that RGS14 is not sufficient to suppress LTP at younger ages. Finally, we investigated how PNNs and other negative plasticity regulators may be altered during early development in a mouse model of Rett Syndrome (MECP2 KO mice). We found that PNNs are increased in the MECP2 KO mouse surrounding excitatory CA2 pyramidal cells from PN14 to adulthood and that PNNs develop abnormally early in CA2 compared to control littermates, suggesting that synapse stabilization and synaptic plasticity may be prematurely dysregulated in CA2 during critical windows of development. Taken together, these results may reveal a mechanism behind the severe hippocampal-dependent learning impairments that emerge during postnatal development in Rett syndrome infants.

Title: Investigating the role of the retromer, an endosomal sorting complex, in long-term potentiation in the adult mouse hippocampus

Authors: *P. TEMKIN, W. MORISHITA, D. GOSWAMI, R. MALENKA;
Psychiatry and Behavioral Sci., Stanford, Stanford, CA

Abstract: The retromer is an endosomal sorting complex that has been shown to be involved in several regulated and specialized endosome to plasma-membrane trafficking pathways. Furthermore, malfunction of the retromer has been linked to two prominent neurodegenerative diseases, Alzheimer's and Parkinson's disease. In this study we investigated the role of the retromer complex in the function of excitatory synapse in adult mouse hippocampus. To do so we made whole-cell voltage-clamp recordings from CA1 pyramidal cells in acutely prepared hippocampal slices from adult mice that, 2-3 weeks previously, had received injections of lentivirus containing shRNA against VPS35, a key component of the retromer complex. We find that VPS35 knockdown (KD) severely impairs NMDA receptor-dependent long-term potentiation (LTP), without altering basal synaptic properties or other NMDA receptor mediated forms of synaptic plasticity. Experiments in knockout mice lacking the amyloid precursor protein (APP) reveal that the impairment of LTP due to VPS35 KD is independent of the retromer's influence on APP processing. We also find that in vivo expression of shRNA-resistant wildtype VPS35 rescues the LTP deficit caused by VPS35 KD, while expressing VPS35 containing a familial Parkinson's mutation does not rescue this phenotype. Lastly, live imaging experiments, performed on cultured hippocampal neurons expressing superecliptic-GFP tagged GluA1, show that VPS35 KD prevents insertion of AMPA receptor after induction of chemical LTP. These results suggest that retromer function is necessary to support AMPA receptor trafficking during LTP. Further experiments will be necessary to determine whether this novel retromer-dependent membrane trafficking pathway contributes to its pathological role in Alzheimer's and Parkinson's diseases.

Title: The role of schizophrenia risk gene dysbindin in stress induced anxiety and aggression

Authors: *Q. GU;
NIH, Bethesda, MD

Abstract: Schizophrenia is a serious psychiatric disorder which affects how people feel, think and act. It has 1% prevalence in the population. Many schizophrenia risk genes have been identified, but their effect sizes are small. Environmental factors, such as stress, also contribute to the onset of schizophrenia. However, it is not clear whether schizophrenia risk genes also confer vulnerability to environmental factors. Sandy mice are mutant mice null for the schizophrenia risk gene dysbindin-1. They have working memory impairment but do not exhibit anxiety or abnormal social behavior. Here we tested whether sandy mice are vulnerable to traumatic stress by shocking with 14 strong electric-shocks in variable intervals during an 85-min period. One week after foot-shock, we tested the mice for locomotion, anxiety, social interaction, aggressive behavior and depression. Interestingly, we found that stressed sandy mice are anxious and aggressive. Because amygdala is a structure which is involved in anxiety, emotion and aggressive behavior, we hypothesize that dysbindin is involved in the stress response of the amygdala. To test this hypothesis, we use electrophysiology, calcium imaging and optogenetics to study the synaptic function and neuronal circuit in amygdala, aiming to uncover the cellular mechanism underlying the behavior changes induced by traumatic stress.

Title: N-Acetylcysteine inhibits cue-induced nicotine seeking and relapse-associated rapid, synaptic plasticity

Authors: *G. L. POWELL[1,2], Y. M. KUPCHIK[3], S. SPENCER[4], C. GARCIA-KELLER[4], N. STANKEVICUITE[4], D. SCHWARTZ[4], A. DEL FRANCO[1,2], J. GOENAGA[1], C. D. GIPSON[1]; [1]Dept. of Psychology, [2]Sch. of Life Sci., Arizona State Univ., Tempe, AZ; [3]Dept. of Med. Neurobiology, Fac. of Med., Hebrew Univ. of Jerusalem, Jerusalem, Israel; [4]Dept. of Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Cigarette smoking is a leading cause of preventable death, and addiction to nicotine produces long-lasting changes in brain synaptic physiology that potentially contributes to a vulnerability to relapse. Targeting glutamatergic signaling has shown somewhat effective in preventing cocaine relapse, yet there is limited utilization of compounds targeting the dysregulation of glutamatergic signaling in promoting smoking cessation. Additionally, existing smoking cessation treatments are insufficient as relapse rates remain high within the population. Cues associated with nicotine can precipitate nicotine-seeking behavior, and recently we showed that cue-induced nicotine seeking is associated with rapid, transient synaptic plasticity in the nucleus accumbens core (NAcore). It was unknown, however, if N-Acetylcysteine (NAC), an antioxidant and cystine prodrug that has shown promise as a pharmacotherapy in the treatment of various mental health disorders, could restore nicotine-induced alterations in glutamatergic signaling and synaptic plasticity thought to underlie relapse vulnerability. Chronic administration of NAC (100 mg/kg, i.p., across five sessions) during extinction from nicotine self-administration caused a significant reduction in cue-induced nicotine seeking using a preclinical model of relapse (reinstatement) after 15 min (T (time) = 15). Additionally, NAC inhibited the rapid cue-induced increase in NAcore AMPA/NMDA ratio and dendritic spine head diameter compared to vehicle treated rats. NAC also inhibited the increase in NMDA current decay associated with cue-induced nicotine seeking at T=15. As withdrawal from nicotine self-administration has been associated with a decrease in NAcore expression of glial glutamate transporter (GLT-1), we examined the ability of a lower dose of NAC (30 mg/kg) to restore sodium-dependent glutamate uptake as well as expression of GLT-1 protein. Although a significant decrease in GLT-1 function was found in nicotine-withdrawn animals compared to yoked saline, the lower dose of NAC did not restore GLT-1 protein expression or function perhaps due to bioavailability issues which have been observed in humans. We will next determine if a possible NAC-induced GLT-1 restoration is dose-dependent.

Title: Activity-dependent trafficking of lysosomes in dendrites

Authors: ***M. GOO**, L. SANCHO, B. L. BLOODGOOD, G. N. PATRICK;
UCSD, San Diego, CA

Abstract: In eukaryotic cells, lysosomes handle a large majority of membrane protein turnover. In neurons, the lysosome has been primarily shown to exist in somatic and axonal compartments, with little understanding of lysosomal trafficking and function in distal dendrites. However, tight control of protein stability and turnover in these distinct compartments is crucial to normal synaptic function. How then are membrane proteins degraded by the lysosome in distal dendrites? Using a combination of static and live confocal microscopy and electron microscopy, we show that lysosomes are found in distal dendrites and dendritic spines and that perturbing actin or microtubule networks affect lysosomal distribution and trafficking. Moreover, we find that lysosomes can traffic to dendritic spines in response to synaptic activity. Strikingly, 2-photon glutamate uncaging at a single spine recruits a lysosome to that spine. Our findings provide the first evidence that synaptic activity can promote the trafficking and recruitment of lysosomes into dendritic spines.

Title: Symmetric spike timing-dependent plasticity at recurrent synapses optimizes storage and recall in autoassociatve CA3 networks

Authors: R. K. MISHRA[1], S. KIM[2], S. J. GUZMAN[1], *M. FROTSCHER[3], P. JONAS[1];
[1]Inst. of Sci. and Technol. (IST) Austria, Klosterneuburg, Austria; [2]Dept. of Physiol., Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of; [3]Inst. for Structural Neurobiology, Ctr. for Mol. Neurobio., Univ. of Hamburg, Hamburg, Germany

Abstract: Hippocampal CA3 pyramidal neurons play a critical role in recall of memories by incomplete or degraded cues, a process termed pattern completion. Because genetic ablation of N-methyl-D-aspartate receptors (NMDARs) in CA3 neurons impairs recall of associative memories, it is suggested that plasticity at CA3-CA3 synapses play a key role in pattern completion. However, the conditions and mechanisms necessary to modify recurrent collateral CA3 synapses are largely unknown. Thus, without knowledge of plasticity rules between CA3 neurons, it is not possible to evaluate how effective the storage of memories in autoassociative memory models of the CA3 network is.
We examined the induction rules of synaptic plasticity by performing patch-clamp recordings on CA3 pyramidal neurons and by stimulating the recurrent collateral synapses in an acute hippocampal slice preparation. We found that low frequency (1 Hz) pairing of presynaptic activity (i.e. excitatory postsynaptic potentials, EPSPs) followed by postsynaptic action potentials (APs) induced long-term potentiation (LTP) of the recurrent CA3 synapses (178.0 ± 22.1% of control). Interestingly, reversing the pairing sequence (i.e. pairing APs with EPSPs) induced LTP of comparable magnitude (159.3 ± 11.5%). LTP magnitude was reduced when the delay between EPSP and AP was longer. This led to a symmetric relationship between the LTP magnitude and the time between pre- and postsynaptic activity, characterized by a Gaussian function with a half-width of ~150 ms. Induction of LTP was mechanistically identical in the EPSP-AP and the AP-EPSP sequence. It required activation of NMDARs, since LTP was prevented in the presence of 20 μM D-APV (101.2 ± 5.2% for the EPSP-AP sequence and 100.5 ± 4.2 % for the AP-EPSP sequence). Additionally, dialysis of CA3 cells with 20 mM EGTA prevented LTP (101.8 ± 7.2% and 103.0 ± 9.0% for pre-post and post-pre, respectively) suggesting that a rise in $[Ca^{2+}]_i$ was necessary. Accordingly, we found supralinear $[Ca^{2+}]_i$ transient responses in CA3 spines when pairing AP-EPSP and EPSP-AP events. In both cases, supralinear $[Ca^{2+}]_i$ summation decreased when increasing the time between pre- and postsynaptic events. In an autoassociative network model of 3000 integrate-and-fire cells, storage of binary memory patterns was more efficient with the symmetric rule when compared with the conventional asymmetric rule containing long-term depression (LTD). Accordingly, recall of patterns upon incomplete cues was better and the capacity of the network was greatly enhanced. Thus, a symmetric plasticity rule performs better storage and recall of memories in autoassociative networks.

Title: Correlation between AMPAR trafficking and probability of neurotransmitter release during DHPG-LTD at CA1 hippocampal synapses

Authors: *T. M. SANDERSON[1,2], S. J. KIM[2], G. L. COLLINGRIDGE[1,2,3,4];
[1]Sch. of Physiology, Pharmacol. and Neurosci., Univ. of Bristol, Bristol, United Kingdom; [2]Dept. of Brain and Cognitive Sci., Seoul Natl. Univ., Seoul, Korea, Republic of; [3]Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada; [4]Lunenfeld-Tanenbaum Res. Inst., Mount Sinai Hosp., Toronto, ON, Canada

Abstract: AMPA receptor (AMPAR) trafficking is an important mechanism by which the strength of synaptic connections is modulated. One highly heterogeneous property of synapses is their probability of neurotransmitter release (P(r)). How this property is related to AMPAR trafficking in synaptic plasticity is unknown. Here we measured P(r) using the styryl dye FM 4-64 and AMPAR trafficking using a version of the AMPAR subunit GluA2 tagged with the pH sensitive probe super ecliptic pHluorin (SEP). We studied a form of long-term depression that is induced by activating group I metabotropic glutamate receptors (mGluRs) with the agonist dihydroxyphenylglycine (DHPG-LTD).
In organotypic slices DHPG-LTD resulted in responses of 45 ± 8 % of baseline (n = 8). It was blocked by the selective mGluR1 antagonist YM 298198 (2 μM; 92 ± 12 %; n = 7; $p < 0.0001$), but not by the selective mGluR5 antagonist MPEP (10 μM; 55 ± 9 %; n = 6; $p > 0.05$). This form of plasticity did not result in a change in P(r), as PPF was unchanged following DHPG application (99 ± 11 % of baseline; n = 6). Analysis of changes in SEP-GluA2 fluorescence at synapses revealed that DHPG resulted in a leftward shift in a cumulative probability plot with respect to untreated control cells, indicating a decrease in GluA2 containing AMPARs. Comparing these changes to the P(r) of the synapses under study revealed a correlation such that AMPAR internalization was greater at low P(r) synapses (Spearman's rs, 0.48, $p < 0.001$, n = 58 spines from 8 cells).
These findings suggest that synapses are not equal in their potential for undergoing a postsynaptic form of synaptic plasticity, but are differentially susceptible depending on their P(r).

Title: Inhibition of GSK-3 inhibits NMDAR-LTD *In vivo* and enhances accuracy of spatial memory in mice

Authors: *Y. LEE[1,2], Z. BORTOLOTTO[1], B.-K. KAANG[2], G. COLLINGRIDGE[1,2,3,4]; [1]Univ. of Bristol, Bristol, United Kingdom; [2]Cognitive and Brain Sci., Seoul Natl. Univ., Seoul, Korea, Republic of; [3]Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada; [4]Lunenfeld-Tanenbaum Res. Inst., Toronto, ON, Canada

Abstract: Synaptic plasticity is a property of synapses in which connections get stronger or weaker in response to activity. Synaptic plasticity appears in several different forms and it is widely thought to be the main mechanism underlying memory formation. In the hippocampus where spatial information is processed, dysregulation of synaptic plasticity could lead disruption of spatial learning and memory. Among a large number of ser/thr kinases, glycogen synthase kinase 3 (GSK-3), which is constitutively active and abundant in the CNS, was found to be the only ser/thr kinase involved in N-methyl-D-aspartate receptor-dependent long-term depression (NMDAR-LTD) in the hippocampal CA1 region *in vitro*. Here, we have examined the effect of the GSK-3 inhibitor, CT99021, on NMDAR-LTD *in vivo* and on spatial memory using the Morris water maze test (MWM) in C57BL/6J mice. We found that CT99021 (25mg/kg, i.p), blocked the induction of NMDAR-LTD *in vivo* in a reversible manner. In the MWM it decreased the path length to the hidden platform during training session. In a probe test CT99021 increased the time spent near the platform and the number of crossing. In contrast, contextual fear memory, spatial working memory and reversal learning were unaffected. Taken together, these data raise the possibility that activation of GSK-3, possibly due to its involvement in NMDAR-LTD, may impede the rate of spatial learning and the accuracy of spatial memory.

Title: Stimulus regularity differentially influences synaptic plasticity outcome in control rats vs rats with mild traumatic brain injury

Authors: *Q. S. FISCHER, D. KALIKULOV, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Typical protocols for inducing synaptic plasticity use stimulus patterns with constant interstimulus intervals (ISIs), while neurons *in vivo* receive synaptic input with irregular ISIs. A study of more physiologically salient stimulation patterns is important to understand the role that stimulus temporal pattern may play in synaptic plasticity induction. Here we evaluate how stimulus regularity influences synaptic plasticity induction in the visual cortex of 10-12 week old normal rats and rats which received a mild traumatic brain injury (mTBI) 2-3 weeks prior. We applied a defined pattern of stimulation to layer 4 in acute slices and made whole cell patch recordings of evoked postsynaptic potentials (PSPs) from 122 layer 2/3 pyramidal cells. Conditioning stimulation consisted of 900 pulses, at a mean frequency of 1Hz, with 1 of 3 different patterns of ISI regularity defined by the coefficient of variation (CV): regular (CV=0), slightly irregular (CV=0.2), or highly irregular (CV=1). PSP peak amplitudes evoked by 0.1Hz stimulation were measured before and after conditioning stimulation, and the post- to pre-conditioning ratio was used to assess plasticity. Plasticity outcome distributions differed significantly between mTBI and control rats for CV=1 (1.21±0.15 vs 0.85±0.07; P=0.03, t-test), but not CV=0 (0.88±0.07 vs 0.87±0.06; P=0.94, t-test) or CV=0.2 stimulation (0.73±0.06 vs 0.75±0.05; P=0.85, t-test). For CV=1 stimulation, this reflected an increase in the incidence of individual neurons that underwent long-term potentiation (LTP; 38% vs 16%), and a decrease in the incidence of neurons that underwent long-term depression (LTD; 47% vs 31%) for mTBI vs control rats. Moreover, PSP amplitudes at the beginning (first 90 sec) and the end (last 90 sec) of the conditioning stimulation period were both significantly increased in mTBI (123±10% and 107±14% of baseline, respectively) vs control rats (93±6% and 71±5% of baseline, respectively; P<0.03, t-tests). In addition to the peak amplitudes, we also compared PSP waveform characteristics including half width, rise time, decay time, and latency before and after CV=1 conditioning stimulation. In mTBI rats, PSP half-width and decay time increased only for cells expressing LTP (P<0.05, t-tests). In contrast, for control rats PSP half-width and latency decreased only for cells expressing LTD (P<0.05, t-tests). Finally, preconditioning somatic

calcium levels were significantly increased in mTBI vs control rats (91.2±5.5 nM vs 63.2±3.2 nM, P<0.001, t-test). These results suggest that stimulus regularity modifies the efficacy of synaptic plasticity induction and that mTBI can alter this interaction.

Title: Role of the temporal pattern of 10 Hz synaptic conditioning stimulation on induction of synaptic plasticity in visual cortex after mild traumatic brain injury

Authors: *D. KALIKULOV, Q. S. FISCHER, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Deep brain stimulation (DBS) is an effective treatment for a variety of disorders. However, the most effective therapeutic stimulation parameters, including specific combinations of stimulation frequency and the temporal pattern of stimulating pulses for DBS are not well delineated. We investigated several temporal patterns of synaptic conditioning stimulation to evaluate their effects on synaptic plasticity in visual cortex in control (normal) rats, sham operated rats, and rats with mild traumatic brain injury (mTBI). Whole cell recordings were made at 10-12 weeks, with sham or mTBI treatments performed 2-3 weeks prior. Highly irregular conditioning stimulation consisted of an interstimulus interval distribution coefficient of variation of 1.0 with either a continuous train of 900 pulses at 10 Hz for 90 sec, or a discontinuous train of 9 bursts of 100 pulses each at 10 Hz with a pause between each burst. Baseline postsynaptic potential (PSP) responses were evoked at 0.1 Hz for 10 minutes preconditioning and for 20 minutes postconditioning. We successfully recorded from 38 control, 34 sham, and 38 mTBI cells**.** For continuous conditioning, controls showed a net LTD (PSP amplitude post-/pre- conditioning = 0.86±0.04; n=19, while individual cells either underwent statistically significant LTD, no significant change (NC) or LTP (0% LTP, 42% NC, 58% LTD); shams, exhibited no net change (0.96±0.04; n=20; 15% LTP, 55% NC, 30%LTD), but mTBI rats showed a net LTP (1.26±0.11; n=20; 50% LTP, 30% NC, 20% LTD). For discontinuous conditioning, controls showed net LTD (0.63±0.07; n=19; 5% LTP, 5% NC, 90% LTD), shams also showed net LTD (0.72±0.07; n=14; 7% LTP, 14%NC, 79%LTD), but mTBI rats showed net

LTP (1.17±0.12; n=18; 50% LTP, 22% NC, 28% LTD). PSP waveform analyses show that for continuous stimulation in cells from mTBI rats that underwent LTD there was a significant increase in PSP latency ($P<0.01$, t-test). For discontinuous stimulation, control cells that expressed LTD showed a significant decrease in PSP half width ($P<0.05$, t-test). Additionally, for continuous conditioning, we analyzed the changes in PSP amplitude during the course of the conditioning train. Those amplitudes (averaged over the last 9 sec of conditioning as compared to the preconditioning baseline) showed a significant decrease for control or sham vs mTBI rats ($P<0.01$, t-test), with no difference between control and sham rats. Thus, a highly irregular stimulus pattern shifts a net LTD in cells from control rats to a net LTP in cells from mTBI rats and should be considered in selecting therapeutic approaches to chronic brain stimulation to potentially rebalance weights of altered synaptic circuits after mTBI.

Title: Soman-induced alterations in plasticity at the hippocampal ca1-schaffer collateral synapse following acute nerve agent exposure

Authors: *K. M. HOFFMAN, M. R. NELSON, D. L. NGUYEN, M. R. EISEN, P. M. MCNUTT;
US Army Med. Res. Inst. of Chem. Def., Aberdeen Proving Ground, MD

Abstract: Organophosphorus nerve agents (NAs) irreversibly block acetylcholinesterase function, causing accumulation of excess acetylcholine in cholinergic synapses. If untreated, the resulting overstimulation of cholinergic receptors elicits prolonged seizures known as *status epilepticus* (SE), which result in brain damage and neuropsychiatric deficits in survivors. Although central nervous system responses to NA have been studied in animal models using electrical recordings of whole brain activity, the acute changes in synaptic physiology that are the basis for these pathological circuit dysfunctions have not been described. Therefore to better understand the acute synaptic response to NA exposure, we conducted field recordings at the Schaffer collateral-CA1 synapse in hippocampal coronal slices following soman application. Perfusion of soman (10 μM) rapidly elicited a stable reduction of field excitatory post-synaptic

potential (fEPSP) amplitudes that persisted after wash-out. The concomitant increase in paired-pulse ratios (PPR; n = 6 for each, $p \leq 0.01$) suggests that soman-induced long-term depression (s-LTD) results from decreased pre-synaptic release probabilities. s-LTD was blocked by co-administration of the non-selective muscarinic receptor (mAChR) antagonist atropine (n = 7, ns versus control) or the M1 mAChR-selective VU-255035 (n = 5, ns versus control), confirming the role of cholinergic overstimulation in s-LTD. To further investigate mechanisms responsible for s-LTD, we pharmacologically dissected pre- and post-synaptic signaling pathways characteristically involved in receptor-mediated plasticity. s-LTD was refractory to APV treatment, demonstrating that NMDAR currents are not required for s-LTD. Alternatively, s-LTD was completely blocked by AM-251, which is a reverse agonist of the cannabinoid type 1 receptor (CB1R). These findings suggest that soman activation of M1 mAChR evokes retrograde endocannabinoid signaling that reduces pre-synaptic release probability via CB1R. Based on these data, we hypothesize that endocannabinoid signaling represents a potential therapeutic modality to mitigate acute and persistent neurological responses to NA exposure. We are further exploring the endocannabinoid signaling system as a target for pharmacological intervention to delay seizure onset or increase survival.

Title: Regular and irregular (Poisson) conditioning trains induced synaptic plasticity between individual neurons in layer 4 of mouse visual cortex

Authors: *J. WU, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Visual information is transmitted from retina through LGN_d to primary visual cortex (V1). The majority of geniculocortical axon fiber terminals project to V1 Layer 4 (L4). Information is initially processed in L4 and then routed to supra- and infragranular cortical layers. Within L4, ~45% of neurons receive synaptic input from their neighboring neurons, such that local synaptic integration of early visual information processing occurs in L4 that has been

hypothesized to act as an amplifier of thalamocortical inputs. To better understand the plasticity of synaptic connections between L4 neurons and the effect of different temporal patterns of synaptic input on plasticity, we performed dual and triple whole cell patch clamp recording from L4-L4 pairs or triplets in visual cortical slices from P25~35 C57B1/6 mice. A pair of action potentials was repeatedly elicited in one L4 presynaptic neuron with two square depolarizing pulses at 0.1Hz. The uEPSCs were recorded from the postsynaptic neuron. Two different protocols were used to induce synaptic plasticity: a 15min 10Hz Poisson distributed spike train of interstimulus intervals having a coefficient of variation (CV) = 1.0 and a 15min 10Hz regular spike train protocol (CV=0). A total of 27 pairs of synaptically coupled neurons were recorded. The synaptic strength, failure rate and paired pulse ratio (PPR) were: 14.1 ±3.5pA, 31±6% and 0.91±0.06, respectively. Short term plasticity was heterogeneous: 7 pairs exhibited PPF, 10 pairs exhibited PPD and 10 pairs did not exhibit any short term plasticity (NC). Among the 27 pairs, 22 underwent the Poisson protocol, the net synaptic strength and PPR decreased, while the failure rate increased. One pair switched from NC to PPF; two pairs switched from PPF to either PPD or NC; two pairs remained unchanged; for the remaining 17 pairs, PPD increased. Among the 22 pairs, 16 underwent LTD, 2 remained unchanged , and 4 displayed LTP. Another 5 pairs of connection underwent the regular protocol, the net synaptic strength and PPR decreased and the failure rate increased. One pair switched from NC to PPF; one pair from NC to PPD and in the other 3 pairs, PPD increased. All the 5 pairs of connections exhibited LTD. In summary, both conditionings increased synaptic failure rate and decreased synaptic strength. For short term plasticity, both augmented PPD in ≥60% of pairs, while in the other 40% pairs, short term plasticity either remained unchanged or switched from PPD to PPF or NC. For long term plasticity, Poisson conditioning induced ~70% pairs to undergo LTD, ~20% pairs to undergo LTP and ~10% pairs remained unchanged, while the regular conditioning induced all recorded pairs to undergo LTD.

Title: Activity and transcription-dependent priming of mGluR-LTD: Mechanisms and alterations in a Fragile X Syndrome mouse model

Authors: *K. KIM[1], J.-Y. JOO[2], T.-K. KIM[2], K. M. HUBER[2];

Abstract: Brief novelty experience or neuronal activity rapidly induces the immediate-early gene *Arc* in hippocampal CA1 neurons. Arc protein stimulates endocytosis of AMPA-type glutamate receptors and is required for a form of long-term synaptic depression (LTD) induced by metabotropic glutamate receptors (mGluR1/5). This suggests that brief novelty experience or activity-patterns that induce *Arc* may cause synaptic weakening or LTD. To test this idea, we used optogenetics to stimulate CA1 neurons in organotypic hippocampal slice cultures to fire in a pattern mimicking that observed during exploration of a novel environment. CA1 neurons in slice cultures, were sparsely (<1%) transfected with ChETA, and stimulated with blue light to fire action potentials in brief bursts of high-frequency action potentials, or Burst Photo-Stimulation (BPS). Although BPS activated an *Arc* transcriptional reporter (SARE-GFP) in CA1 neurons, it did not weaken excitatory synaptic transmission, as measured by evoked and miniature (m) EPSCs. However, neurons that received BPS displayed enhanced LTD magnitude in response to subsequent synaptic or pharmacological (DHPG) activation of mGluR1/5. BPS-induced priming of LTD required transcription as well as translation of *Arc*. BPS induced *Arc* enhancer (e) RNA (Kim et al., Nature, 2010) and mRNA, as measured with qPCR in dissociated hippocampal cultures, but did not increase Arc protein. DHPG treatment of cultures after BPS induced a robust increase in Arc protein, in comparison to control cultures. These results suggest that *Arc* mRNA, induced in response to brief neuronal activity, is translationally-suppressed until stimulated by mGluR1/5. To test the role of translational suppression of Arc, we examined BPS-induced priming of LTD in the mouse model of Fragile X Syndrome, *Fmr1* KO, which encodes an RNA binding protein and translational suppressor, FMRP. In slice cultures of *Fmr1* KO mice, LTD magnitude is robust regardless of prior BPS, indicating that *Fmr1* KO synapses are insensitive to the activity history of the neuron. These results suggest a synaptic mechanism by which novelty-induced *Arc* promotes plasticity and learning of new environments and reveals a deficit in novelty associated plasticity in a cognitive disorder.

Title: The developmental regulation of cofilin in hippocampal long-term depression

Authors: *F. CAO[1,2,3], Z. ZHOU[1,2,3], W. XIE[3], Z. JIA[1,2];
[1]Neurosci. and Mealth Hlth., The Hosp. For Sick Children, Toronto, ON, Canada; [2]Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada; [3]Inst. of Life Sci., Southeast Univ., Nanjing, China

Abstract: Long-lasting synaptic plasticity, a key mechanism for memory, involves both structural and functional changes, but how these changes are coordinated to achieve input-specific, persistent plasticity remains elusive. Cofilin is an actin-binding protein critical for the regulation of the actin reorganization, a key process essential for the structural plasticity of the synapse. We have previously shown that cofilin-mediated actin changes are required for mGluR-dependent long-term depression (LTD), but whether the involvement of cofilin in plasticity is developmentally regulated remains unknown. In this study, we systematically investigated the role of cofilin in LTD in both young (2-3 weeks) and mature (2-3 months) mice by using electrophysiological recordings and biochemical assays. We found that the expression of cofilin in the brain is developmental regulated, being much higher in young than mature mice. Interestingly, the inhibition of cofilin blocks LTD in mature but not young mice. These results reveal a developmental switch in the molecular mechanisms underlying hippocampal LTD, which may play a key role in coordinating structural and functional changes during synaptic plasticity.

Title: The expression of mGluR5 predicts interneuron plasticity in the stratum radiatum

Authors: *T. M. NUFER[1], C. MERILL[3], L. FRIEND[1], Z. HOPKINS[4], J. EDWARDS[2]; [1]Physiol. and Developmental Biol., [2]Brigham Young Univ., Provo, UT; [3]Univ. of California Irvine, Irvine, CA; [4]Univ. of Utah Sch. of Med., Salt Lake City, UT

Abstract: Changes in synaptic strength in hippocampal CA1 pyramidal cells are thought to be responsible for the acquisition and retention of short-term memory. This plasticity is modulated by feedforward inhibitory interneurons in the stratum radiatum which are composed of many subtypes including, among others, parvalbumin-containing axo-axonic cells, calretinin-containing interneuron-selective cells, and cholecystokinin/calbindin positive basket cells. While radiatum interneurons exhibit long-term depression (LTD), short-term depression (STD), or lack of plasticity (McMahon & Kauer, 1997, Neuron), it is not known whether these types of plasticity correlate to specific interneuron subtypes. Using whole cell electrophysiology and real time quantitative PCR, we characterized the plasticity expressed by different hippocampal interneuron subtypes in correlation with their mRNA expression patterns to determine cell subtype using calcium binding proteins and neuropeptide CCK. We also assessed the expression of endocannabinoid (eCB) biosynthetic enzymes including diacylglycerol lipase α, N-acyl-phosphatidylethanolamine-specific phospholipase D, and 12-lipoxygenase, as well as metabotropic glutamate receptor subunits known to mediate plasticity. Cells exhibiting LTD tended to express mRNA for at least one of the eCB biosynthetic enzymes (4 of 5 cells) and the metabotropic glutamate receptor subunit mGluR5 (3 of 5 cells). mGluR5 was not expressed by cells exhibiting STD or no plasticity (0 of 10 cells). Cells that exhibited short-term depression tended to express mRNA for at least one of the eCB biosynthetic enzymes (4 of 6 cells), but not mGluR5 (0 of 6 cells). This suggests that stratum radiatum interneuron plasticity can be predicted based on cell subtype and mGluR expression, and that these different types of plasticity may have some importance in hippocampal function.

Title: The interaction of Gβγ and SNAP-25 promotes the expression of presynaptic long-term depression (LTD) of synaptic transmission

Authors: *K. R. GOPAUL[1], M. IRFAN[2,1], O. MIRY[1], G. SUBAH[1], L. R. VOSE[1], X.-L. ZHANG[1], C. BARK[2], P. K. STANTON[1];

Abstract: Episodic and spatial memories are thought to be encoded by long-term potentiation (LTP) and LTD at hippocampal and neocortical synapses. Multiple receptors and messengers have been suggested to mediate synapse-specific alterations in synaptic transmission that contribute to LTP and LTD at both presynaptic and postsynaptic terminals. Mechanisms involved in presynaptic expression of LTD are much less studied than postsynaptic alterations. Two receptors involved in induction of presynaptic LTD are group II metabotropic glutamate receptors (mGluRII), and N-methyl-D-aspartate receptors (NMDAR). The G protein-coupled receptor (GPCR), mGluRII, reduces neurotransmitter release from presynaptic vesicles through a cascade requiring dissociation of Gα and Gβγ subunits. Activation of NMDARs also elicits presynaptic LTD by modifying release of glutamate via postsynaptic production of the intercellular messenger nitric oxide, which drives presynaptic synthesis of cyclic guanosine monophosphate. We have previously shown that Gβγ, released from a GPCR, such as mGluRII, binding to the C-terminus of the 25kDa synaptosomal-associated, SNAP REceptor (SNARE), protein SNAP-25, is necessary for the induction of presynaptic LTD. SNAP-25 is alternatively spliced to adolescent (SNAP-25a) and adult (SNAP-25b) isoforms. Our hypotheses are: 1) differential interaction of the SNARE complex with SNAP-25 splice variants and Gβγ during development alters the expression of LTD of transmitter release at glutamatergic synapses, and perhaps GABAergic synapses, and 2) mGluRII and NMDAR have a final common pathway that mediates presynaptic LTD of vesicular release. Using mutant mice expressing only SNAP-25a, we examined how isoforms of SNAP-25 differentially affect plasticity of vesicular release. The presence of only SNAP-25a reduced neurotransmitter release and altered paired-pulse facilitation, compared to wildtype. These SNAP-25a mice showed impaired LTP, but enhanced LTD, of synaptic strength that varied with age. SNAP-25a mice exhibited both mGluRII- and NMDAR-dependent forms of LTD. We elucidate the functional roles of SNAP-25 isoforms by comparing behavioral phenotypes (locomotion, anxiety, learning and memory) of mice expressing SNAP-25a versus wildtype controls. Our findings suggest that the balance of presynaptic LTP and LTD, important to learning and memory, are functionally altered by isoforms of SNAP-25. These results give insight on how long-term regulation of neurotransmitter release contributes to cognition, learning and memory, and the potential of SNAP-25 as a regulatory target in diseases involving defects in synaptic transmission.

Title: Increasing O-GlcNAcylation induces AMPAR internalization at CA3-CA1 synapses

Authors: *L. T. STEWART[1], A. U. KHAN[2], M. L. OLSEN[2], J. C. CHATHAM[3], L. L. MCMAHON[2];

Abstract: Regulated trafficking of AMPARs at mammalian excitatory synapses is a fundamental mechanism required for acquisition and storage of new information. Evidence suggests that AMPARs containing GluA2/3 subunits undergo constitutive recycling at hippocampal synapses, while those containing GluA1/2 subunits undergo activity dependent insertion or removal during many forms of long-term plasticity required for learning and memory. This activity dependent trafficking is modulated by serine/threonine phosphorylation of AMPAR subunits. We recently reported that another dynamic post-translational modification at serine/threonine residues involving the O-linkage of β-*N*-acetylglucosamine, termed O-GlcNAcylation, induces a novel form of LTD at CA3-CA1 synapses. In recent studies, we found that acute increases in O-GlcNAcylation also dampen hyperexcitability in vitro and in vivo. We previously showed that GluA2, but not GluA1 subunits are O-GlcNAc modified, that O-GlcNAc transferase co-immunoprecipitates with GluA2 subunits, and O-GlcNAc LTD is absent in GluA2 KO mice. Because serine phosphorylation of GluA2 subunits drives AMPAR endocytosis during expression of NMDAR-dependent LTD, we investigated whether expression of O-GlcNAC LTD is due to AMPAR endocytosis and used the endocytosis blocking peptide, TatGluR23Y. In preliminary experiments we find that O-GlcNAc LTD at CA3-CA1 synapses is inhibited in the presence of the peptide but is normal in the presence of the scrambled peptide, suggesting O-GlcNAcylation of GluA2 subunits drives endocytosis similar to phosphorylation. Additional experiments will test the requirement of AMPAR GluA2 subunit in O-GlcNAc mediated dampening of neuronal hyperexcitability. Based on our current and previously published work, the hexosamine biosynthetic pathway is an important mechanism in the modification of synaptic efficacy at hippocampal synapses, via targeted O-GlcNAcylation of synaptic protein substrates.

Title: A unified molecular mechanism of bidirectional plasticity at cerebellar parallel fiber-Purkinje cell synapses

Authors: *A. R. GALLIMORE, E. DE SCHUTTER;
Computat. Neurosci. Unit, Okinawa Inst. of Sci. and Technol., Okinawa, Japan

Abstract: The expression of postsynaptic long-term depression (LTD) and long-term potentiation (LTP) in cerebellar Purkinje cells results from the internalisation or insertion, respectively, of postsynaptic AMPA receptors (AMPAR) [1,2]. LTD is induced by concurrent parallel fiber and climbing fiber stimulation of Purkinje cells, and is regulated by a complex intracellular signalling network that suppresses phosphatase activity leading to activation of a positive feedback loop that maintains PKC activity for at least 30 minutes [3]. LTP is dependent on nitric oxide [4], produced during parallel fibre stimulation [5,6], which nitrosylates N-ethylmaleimide-sensitive factor (NSF) and promotes exocytosis of AMPARs by actively disrupting the interaction between AMPAR-GluR2 and protein interacting with C-kinase 1 (PICK-1) [7,8]. Using a new differential equation model of Purkinje cell signalling and AMPAR trafficking, we have developed the first unified molecular mechanism of bidirectional plasticity at PF-PC synapses. Using this model, we explain the induction of both LTP and LTD under low and high calcium conditions, respectively, and predict an automatic shut down of the positive feedback loop once the early phase of LTD induction is complete. We also explain the dual role of nitric oxide in LTP and LTD, as well as the observation that deletion of β-CaMKII results in the switching of LTD to LTP under LTD induction conditions [9]. 1 Wang, Y. Title: JAK/STAT signalling underlies leptin-induced LTD at temporoammonic-CA1 synapses in adult hippocampus

Authors: *G. MCGREGOR, J. HARVEY;
Div. of Neurosci., Univ. of Dundee, Dundee, United Kingdom

Abstract: Increasing evidence indicates that the adipocyte-derived hormone leptin has the ability to regulate excitatory synaptic transmission within the hippocampus as well as regulating satiety as a means to maintain energy expenditure (Irving and Harvey, 2014). Recent investigations indicate that leptin can modulate synaptic plasticity in an age-dependent manner at hippocampal schaffer collateral (SC)-CA1 synapses (Moult and Harvey, 2011). However, leptin also regulates the anatomically distinct temporoammonic (TA) input to CA1 synapses, as leptin can induce a novel form of long term potentiation (LTP) at juvenile hippocampal TA-CA1 synapses (Luo et al. 2015). However the effects of leptin on excitatory synaptic transmission at adult hippocampal TA-CA1 synapses is unknown. Here, we used standard extracellular recordings to investigate the effects of leptin on excitatory synaptic transmission in male adult (12-24 week) rats. Selective inhibition of synaptic transmission by dopamine (100 μM; 5 min) confirmed TA stimulation (Luo et al. 2015; Otmakhova & Lisman, 1998). Addition of leptin (25 nM; 15 min) induced a persistent depression of synaptic transmission (long term depression; LTD) at TA-CA1 synapses (to 76 ± 5% of baseline; $n = 4$; $P < 0.001$). This effect was NMDA receptor-dependent as blockade of NMDA receptors with 50 μM D-AP5 inhibited leptin-induced LTD ($n = 5$). The signalling pathways underlying leptin-induced LTD were also examined and were found to involve JAK2/STAT3 signalling as inhibitors of JAK/STAT signalling such as AG490 (95 ± 9% of baseline; $n = 5$; $P > 0.05$) and stattic (104 ± 5% of baseline; $n = 5$; $P > 0.05$) blocked leptin-induced LTD. In parallel immunocytochemistry studies, leptin-induced LTD was also examined

in hippocampal cultures. In the presence of low Mg^{2+}, leptin resulted in a reduction in GluA1 surface expression (to 79 ± 5% of control; $n = 3$; $P < 0.01$) suggesting that leptin increased the internalisation of AMPA receptors. Moreover the ability of leptin to reduce GluA1 surface expression was blocked by inhibitors of JAK/STAT signalling (e.g. 97 ± 4% and 92 ± 4% of control in the presence of AG490 and stattic respectively; $n = 3$; $P > 0.05$ for each). Accumulating evidence suggests that the JAK/STAT pathway is involved in neuroprotection and Alzheimer's disease (AD; Chiba et al. 2009). Moreover leptin prevents the detrimental actions of amyloid beta at hippocampal synapses (Doherty et al, 2013). Thus the ability of leptin to regulate excitatory synaptic strength at TA-CA1 synapses is likely to have important implications for the role of the leptin system in health and CNS-driven disease.

Title: Analyses of cell-surface amount, individual endo- and exocytosis of AMPA receptors, revealed suppression of exocytosis is important in hippocampal LTD

Authors: *S. FUJII, H. TANAKA, T. HIRANO;
Dept. Biophys.,Grad. Sch. Sci. Kyoto Univ., Kyoto, Japan

Abstract: Synaptic plasticity is critical in learning, memory, psychiatric and neurological disorders. At excitatory synapse, AMPA-type glutamate receptors (AMPARs) dynamically move into and out of synapses, and the increase or decrease in number of cell-surface AMPARs by exocytosis and endocytosis has been regarded as a main cellular mechanism for long-term potentiation (LTP) or depression (LTD). Here, we clarified AMPAR trafficking during LTD in a hippocampal culture preparation with total internal reflection fluorescence microscopy (TIR-FM). First, we attempted to estimate the change of amount of AMPARs on the cell-surface using

super-ecliptic pHluorin (SEP; pH-sensitive GFP variant). However, a recent study showed that significant SEP-AMPAR signals come from inside of a neuron, and that the intensity of such signal changes with intracellular acidification caused by neuronal activities. Therefore, we applied rapid pH exchange methods using U-tube and estimated accurately the amount of AMPARs by subtracting the signal intensity at pH 6.0 corresponding to the intracellular signal from that at pH 7.4. By this way, we revealed that the amount of AMPARs on both post- and extrasynaptic membrane gradually decreased during 5 min NMDA application. Next, we attempted to clarify the frequencies of endo- and exocytosis during LTD by observing individual events. Discrete endocytosis events were visualized by changing extracellular pH intermittently to an acidic condition. At pH 6.0, cell-surface AMPAR-SEP signals were quenched, and only signals derived from endocytosis vesicles were detected. NMDA application transiently (within 1 min) increased the frequency of clathrin/dynamin-dependent AMPAR endocytosis. On the other hand, the frequency of exocytosis showed gradual decrease during 5 min NMDA application. Considering the time courses of cell-surface receptor amount, and frequencies of exocytosis and endocytosis, we suggest that LTD is expressed not by the increase in endocytosis frequency but by the decrease in exocytosis frequency of AMPAR.

Title: Uniform electric field stimulation induces region-specific long-term modulation of cortical excitability in mouse primary motor cortex *In vitro*

Authors: *Y. SUN, S. C. DHAMNE, A. ROTENBERG;
Dept. of Neurol. and the F.M. Kirby Neurobio. Ctr., Boston Children's Hosp., Boston, MA

Abstract: Background: Transcranial direct current stimulation (tDCS) is a method for focal noninvasive in vivo brain stimulation, which leads to lasting changes in cortical excitability, resembling long-term potentiation or long-term depression (LTP/LTD). Although widely used in human studies, the anatomic tDCS effects at cortical layer resolution are incompletely understood. We applied direct current stimulation (DCS) in vitro to test whether DC field stimulation modulates cortical excitability uniformly throughout the cortical thickness. **Methods:** DCS was delivered to isolated mouse primary motor cortical (M1) slices through Ag/AgCl electrodes over a range of DC field orientations relative to the neuronal projections. Cortical excitability was monitored by field excitatory postsynaptic potentials (fEPSPs) evoked by stimulating layer V of the M1 slice using an 8X8 microelectrode array which spanned across all cortical layers. The %change in fEPSP slope throughout the M1 slice, 1 hour after DCS, was plotted as an interpolated two-dimensional color map. **Results:** With the cathode positioned above the pial surface, an LTD-like effect (DCS-LTD) on excitatory synaptic strength was reliably present in superficial cortical layers, while an LTP-like effect (DCS-LTP) was observed in layers V/VI below the stimulating site. Similarly, DCS-LTP was nearly uniform, except a small region of LTD in layer V/VI after DCS with the anode positioned over the pial surface. These modulatory patterns of the synaptic strength were specific to DCS, which was not found in either chemically or conventional pulsatile electrical protocols for LTP or LTD induction in M1 slices. Further, we identified an mGluR5-dependency of DCS-LTD induced by cathodal DCS. Bath application of mGluR5 negative allosteric modulator 2-chloro-4-((2,5-dimethyl-1-(4-(trifluoromethoxy)phenyl)-1H-imidazol-4-yl)ethynyl)pyridine (CTEP, 10 μM) selectively blocked DCS-LTD while DCS-LTP was preserved. **Conclusion:** DCS effects on cortical excitability are not uniform throughout the cortex. Rather, DCS induces pathway-specific and layer-specific changes in excitatory synaptic strength that are reliant on distinct molecular mechanisms.

Title: Roles of SUMOylation in hippocampal synaptic plasticity

Authors: *E. BRAKSATOR[1], K. A. WILKINSON[2], Z. I. BASHIR[3], J. M. HENLEY[4]; [1]Sch. of Physiology, Pharmacol. & Neurosci., [2]Biochem., [3]Physiology, Pharmacol. and Neurosci., [4]Univ. of Bristol, Bristol, United Kingdom

Abstract: SUMOylation is a lysine-targeted posttranslational modification in which members of the small ubiquitin-like modifier (SUMO) family are covalently bound to target proteins to alter their function. SUMOylation is involved in multiple neuronal signalling cascades and is strongly implicated in many neurological and neurodegenerative diseases. Fast excitatory synaptic transmission in the CNS is mediated by AMPARs and their tightly regulated trafficking underlies the cellular basis of learning and memory. Long-term potentiation (LTP) and long-term depression (LTD) of synaptic efficacy are mediated by the activity-dependent increase or decrease in surface expressed postsynaptic AMPARs respectively. We have shown recently that SUMOylation is required for AMPAR trafficking in synaptic scaling and LTP. In this study we investigated whether SUMOylation is also required for mGluR- and/or NMDAR- dependent-LTD of AMPAR transmission in the CA1 area of the hippocampus. AMPAR excitatory post-synaptic currents (EPSCs) were recorded from CA1 pyramidal neurons using whole-cell patch-clamp electrophysiology in hippocampal slices obtained from postnatal day 13-15 male Wistar rats. mGluR-LTD was induced by the mGluR agonist DHPG (100μM) as well as by a paired-pulse low frequency stimulus protocol (PP-LFS). NMDAR-LTD was induced by low frequency stimulation (LFS). We found that reducing protein SUMOylation either by infusing a constitutively active form of SENP or a dominant negative form of the essential SUMO conjugating enzyme Ubc9 via the patch pipette, significantly reduced DHPG-induced LTD but not NMDAR-LTD. Interestingly, PP-LFS induced mGluR-LTD was not significantly changed when protein SUMOylation was reduced. These data show that SUMOylation regulates DHPG-induced LTD but not NMDAR-LTD in the CA1 area of the hippocampus. Future experiments will investigate the mechanisms by which SUMOylation regulates mGluR-LTD and whether the aberrant LTD observed in Alzheimer's disease models can be altered by SUMO modification.

Title: Synaptic plasticity during cortical slow oscillations *In vitro*

Authors: *M. KAHN, J. BARTRAM, S. TUOHY, E. MANN;
Physiology, Anat. and Genet., Univ. Oxford, Oxford, United Kingdom

Abstract: It has been proposed that a key function of slow-wave sleep is to provide a period of net synaptic weakening. While there is evidence in support of this idea, it remains unclear what mechanisms could mediate such a function. Here we explore this question by means of a slice model of the slow oscillation in mouse entorhinal cortex. We find that the depolarised phase of the slow oscillation (UP state) depresses subthreshold inputs unless they are immediately followed by a postsynaptic spike. Analysis of the coefficient of variation suggests this weakening may be predominantly expressed presynaptically. However, its initiation is sensitive to inhibition of postsynaptic NMDA receptors. We are currently further characterising the molecular requirements for this process. The UP state dependent depression we describe here could be an important mechanism contributing to synaptic plasticity during slow-wave sleep. Therefore, identifying its molecular requirements may enable us to test the functional importance of synaptic weakening during sleep.

Title: CaMKII regulates the depalmitoylation and synaptic removal of AKAP79/150 to mediate structural LTD

Authors: *K. WOOLFREY, H. CABALLES, D. GOODELL, M. DELL'ACQUA, U. BAYER;
Pharmacol., Univ. of Colorado Denver, Aurora, CO

Abstract: Long term depression (LTD) is a process essential for regulating synaptic strength, but its underlying mechanisms have not been fully elucidated. Intriguingly, there is substantial overlap in the molecular players that mediate both LTD and long term potentiation (LTP), which is an opposing form of synaptic plasticity. A recently described example of this pathway commonality is Ca2+/calmodulin (CaM)-dependent protein kinase II (CaMKII). Here we explore the role of CaMKII in the cellular processes that support LTD. We identify the synaptic scaffold AKAP79/150 as a direct substrate of CaMKII and find that phosphorylation disrupts AKAP79/150 association with F-actin and facilitates its removal from spines. We further explore the importance of AKAP79/150 depalmitoylation and removal from spines in support of LTD and establish CaMKII as a critical regulator of AKAP79/150 palmitoylation state. Together, these findings provide mechanistic insight into how CaMKII mediates LTD and provide the first direct evidence for a function of the well-described LTD-induced trafficking of AKAP79/150.

Title: Ethanol has age- and region-dependent effects on synaptic plasticity in the hippocampus.

Authors: *S. SAWCHUK, J. D. SHIN, B. R. CHRISTIE;
Div. of Med. Sci., Univ. of Victoria, Victoria, BC, Canada

Abstract: The role of particular NMDA subunits in long-term depression (LTD) remains a controversial subject. NMDA receptors are composed of four distinct subunits, two obligatory GluN1 subunits, and two GLuN2 (A,B,C,D) or GluN3(A,B) subunits. Variation within these latter two subunits direct many of the ionotropic properties for the NMDA receptor. Previous studies have indicated that ethanol and the GluN2B subunit antagonist ifenprodil enhances LTD in the CA1 subfield (Hendricson et al., 2002), while other studies conclude that both ethanol and ifenprodil inhibit the induction of LTD (Izumi *et al,* 2005). Furthermore, studies investigating the role of specifically blocking GluN2B subunit containing NMDA receptors with ifenprodil found

no evidence to support any particular role for specific NMDA subunits in directing synaptic plasticity (Morishita et al., 2007). Factors contributing to the confounding results may stem from the wide ranges of ages studied, as well as variable concentrations of ethanol used during the experiments. We hypothesized that differential expression of GluN2 subunits in the hippocampus during such a wide age range might be an influencing factor in these results. To examine this issue we obtained field recordings from transverse hippocampal slices (350 micron) from animals at three distinct post-natal day time points (PND 14, 21 or 28). We found that ethanol (either 50 or 100 mM) did not significantly influence the induction of LTD in the Dentate Gyrus (DG) of animals at any age. Conversely, LTD induction in the CA1 subfield was significantly reduced in slices at PND14 and 28, but not PND21, and exposure to 3uM ifenprodil had no influence on the induction of LTD in the CA1 at PND28. These results indicate that ethanol can have region- and age-specific effects on long-term depression in the hippocampus.

Title: Mechanism of ethanol-induced disinhibition of nucleus accumbens core

Authors: *M. H. PATTON, B. M. ROBERTS, T. AKINTOLA, B. N. MATHUR;
Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: Alcoholism is characterized by an enhancement of incentive salience attributed to alcohol related cues. This is likely due to alterations in signaling within the nucleus accumbens (NAc), an integration center for motivational circuitry. The NAc receives glutamatergic and GABAergic inputs from various brain regions and the balance between excitation and inhibition onto NAc principal medium spiny neurons (MSNs) is critical in shaping the output of this structure. While ethanol depresses inhibition onto MSNs in the nearby dorsal striatum, whether ethanol affects GABAergic signaling in the ventral striatum (NAc) that may induce hyper-motivated states remains unexplored. Here, we test the effects of ethanol on inhibitory synaptic strength onto NAc MSNs using whole-cell patch-clamp electrophysiology in acute mouse slices. We find a postsynaptically expressed, concentration-dependent ethanol-induced depression of inhibitory inputs onto MSNs. Further, MSN disinhibition is occluded following *in vivo* ethanol

exposure, suggesting a role for inhibitory synapses in the NAc during acute intoxication. These data represent a novel mechanism through which ethanol modulates NAc output, which could contribute to the rewarding properties of alcohol.

Title: Function consequences of structural heterogeneity in hippocampal CA2 pyramidal neurons.

Authors: *T. D. HELTON, M. ZHAO, S. M. DUDEK;
Neurosci. Lab., Natl. Inst. of Envrn. Hlth. Sci., Research Triangle Park, NC

Abstract: The hippocampus is critical for many cognitive functions, including certain forms of learning and memory, and recent evidence shows that CA2 pyramidal neurons play a role in social recognition memory (Hitti, 2014; Smith 2016). Interestingly, anatomical studies in guinea pig (Bartesaghi, 1999) and *in vivo* recordings in rat (Kay, 2016) suggest that CA2 pyramidal neurons are heterogeneous in their dendritic branching patterns and firing properties, respectively. In addition we reported that induction of long-term depression (LTD) is similarly heterogeneous (Zhao, 2007). We therefore sought to determine whether the dendritic branching patterns in CA2 confer functional properties that underlie differences in synaptic plasticity as well as the relative effectiveness of different synaptic inputs. Long-term potentiation (LTP) cannot readily be induced at excitatory synapses in CA2 stratum radiatum (SR) in response to pairing or high-frequency synaptic stimulation (HFS, 100 Hz) and LTD is expressed in only some of CA2 neurons in response to a low-frequency stimulation (LFS, 2Hz). However, we can more accurately describe the synaptic plasticity as falling into a richer array of 'plasticity phenotypes': 1) responding to LFS with LTD; 2) unresponsive to LFS, but expressing LTD in response to HFS; 3) unresponsive to LFS or HFS; or less frequently, 4) potentiating in response to either type of stimulation. In this study we have confirmed the presence of four CA2 pyramidal neuron morphologies in rat and have attempted to correlate the structural subtypes to the plasticity phenotypes. Although we observed some differences in the distributions of plasticity for each cell morphology type, they were not informative into the nature of the

relationship between morphology and synaptic plasticity. We noted however that one of the morphological cell types (Mb) had a significantly greater number secondary of branches within the SR. We therefore tested whether synaptic inputs in the SR (largely from CA3 neurons) were relatively more effective than synapses stimulated in the stratum lacunosum-moleculare (SLM; largely from entorhinal cortex) in these neurons compared with the other morphological types. Indeed, when recording from Mb cells, we found that EPSCs evoked with SR stimulation were roughly 3 fold larger than those evoked in SLM. In contrast, EPSCs recorded from Ma, Mc, and B cells were roughly similar when either the SR or SLM was stimulated. These results indicate that the relative effectiveness of different synaptic inputs in the SR and SLM can vary in the four morphological cell types and perhaps underlie the diverse firing properties of CA2 neurons in vivo.

Abstract: The pattern of gene expression in neuronal network is believed to be the essential element for memory formation. Especially, immediate early gene Arc is known to be deeply involved in modulation of synaptic plasticity. The expression of Arc occurs in a highly activity-dependent manner through various signaling pathways such as PKA, CamK and MAPK/ERK. Arc PBS KI mouse is a mouse line developed for single Arc mRNA imaging by knocking in 24 tandem arrays of PP7 binding site (PBS) in 3′ untranslated region (3′ UTR) of Arc gene. In this study, we observed the transcription of Arc in live hippocampal primary cultures. By simultaneously imaging relative Ca^{2+} concentrations and Arc mRNA transcription in various conditions induced by electrical stimulation and pharmacological reagents such as TTX and

bicuculline, we attempt to reveal the relationship between the activity of neurons and expression of Arc with single mRNA resolution. This study may elucidate new perspectives about the mechanism of synaptic plasticity in transcriptional level.

Abstract: A major quest in neuroscience is to understand the remarkable dynamics of the structure and function of the brain in response to sensory experience. Detailed investigation of synaptic plasticity *in vitro* have yielded exquisite molecular mechanisms, while new *in vivo* imaging techniques have enabled high resolution exploration at the functional level of small neuronal circuits. However, it is still unknown what molecular mechanisms the brain utilizes to encode experience-dependent plasticity. In order to address this question, we have established an imaging based approach to enable *in vivo* 2 photon Fluorescence lifetime imaging (2pFLIM) measurements of protein activity in the mouse cerebral cortex. In order to measure molecular dynamics at the level of single cells, we have established and characterized a FLIM sensor for CREB, a well-known transcription factor which plays a vital role in long term memory and synaptic plasticity. This system allows us to perform chronic 2pFLIM based measurements of CREB activity levels in single cell resolution in cortical layer 2/3 cells. Using this technique we were able to demonstrate a dynamic increase in CREB activity during enriched sensory environment. Furthermore, we have established a novel dual-color FLIM imaging method using

CyRFP, a red shifted RFP well suited for FLIM. Using EGFP/CyRFP dual imaging in hippocampal spines, we show differential RhoA and CaMKII activity during structural LTP in a single spine. We are now using this method to establish FLIM based measurements of single spine molecular dynamics *in vivo*. This approach may help to uncover the molecular mechanisms underlying experience dependent plasticity in the living brain.

Title: Translation dynamics of single mrnas in live neurons

Authors: *B. WU, C. ELISCOVICH, Y. J. YOON, R. H. SINGER;
Albert Einstein Col. of Med., Bronx, NY

Abstract: Translation is the fundamental biological process that converts the mRNA information into proteins. Local production of protein is essential for axon guidance, synaptic plasticity as well as learning and memory. Single molecule imaging in live cells has illuminated the dynamics of RNA transcription, however, it is not yet applicable to translation. We report here the development of Single molecule Imaging of NAscent PeptideS (SINAPS) to assess translation in live neurons. As with transcription assays, the approach provides direct readout of the initiation frequency, the elongation rate and the location of translation sites within the cell. Single molecule fluorescence recovery after photobleaching provides direct measurement of elongation rates. We applied SINAPS in cultured primary hippocampal neurons. The results indicate that mRNAs are translated in proximal dendrites, but are repressed in distal dendrites with occasional "bursting" translation. Quantitative fluctuation analysis reveals the dynamics of these bursts. This technology enables the quantitative spatial and temporal analysis of translation of single mRNAs in living neuron and provides a new tool for addressing the mechanism of local translation in dendrites and axons.

Title: Visualization of transcription dynamics of immediate early gene Arc in hippocampal neurons

Authors: *S. DAS[1], B. WU[1], Y. YOON[1], H. PARK[2], R. SINGER[1];
[1]Albert Einstein Col. of Med., Bronx, NY; [2]Dept. of Physics & Astronomy, Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Neuronal activity triggers the transcription of many Immediate Early (IE) genes. Among them, Arc (activity-regulated cytoskeletal-associated), also known as Arg 3.1, has garnered particular interest due to its crucial role in long-lasting synaptic plasticity and memory consolidation. The primary regulation of Arc is at the level of its transcription and targeting of its mRNA to potentiated synapses. While most *in vivo* studies provide insights about the spatial regulation of Arc mRNA, however, the dynamics of endogenous Arc mRNA in response to neuronal activity or LTP induction has not been characterized with high temporal resolution. We have generated a transgenic mouse by knocking in 24 tandem arrays of bacteriophage-derived PP7-binding sites (PBS) into the 3'-untranslated region (3'-UTR) of the Arc gene. These PBS stem loops are recognized by their cognate binding PP7 coat protein (PCP), tagged with a fluorescent molecule, therefore allowing for dynamic visualization of active Arc loci as well as individual transcripts. Using single molecule fluorescent *in situ* hybridization (smFISH) performed on hippocampal neurons from this mouse, we can detect and quantify individual mRNAs after triggering neuronal activity. Furthermore, real-time measurements of transcription and dendritic mRNAs reveal the kinetic profile of Arc transcription and the localization of these mRNAs. Overall, our results provide interesting insights about the induction of Arc transcription from ensemble level to single cell and finally to single genetic locus level. This approach allows for detailed examination of neuronal activity-regulated gene expression in response to different stimulation paradigms.

Title: Localization of newly synthesized proteins within dendritic spine microdomains

Authors: *Y. J. YOON[1], B. WU[2], R. H. SINGER[2];
[1]Anat. and Structural Biol., [2]Albert Einstein Col. of Med., Bronx, NY

Abstract: Long-lasting synaptic plasticity in neurons requires protein synthesis. However it is not clear where and how newly translated proteins can effect changes in synaptic compartments. To test whether newly synthesized synaptic proteins exhibit discrete localization within spine heads, we performed Halo-labeling on a variety of synaptic proteins to determine differences in subspine localization of new and preexisting proteins. We observed newly synthesized β-actin proteins discretely positioned at the periphery of dendritic spines following glutamate uncaging stimulation. Sorting of new actin to a microdomain within spine heads demonstrated that stimulation-dependent synthesis of actin could mediate long-lasting structural modification of spines. Our results indicate that the location of newly translated proteins may indicate local function of new proteins and provide a link to the essential role of protein translation during synaptic plasticity and spine remodeling.

Title: Novel splice variants of gtf2i expressed in the neuronal dendrites of rat brain.

Authors: Y. SHIRAI[1], *T. SUZUKI[1,2];
[1]Shinshu Univ. Grad. Sch. Med., Matsumoto, Japan; [2]Biol. Sci. for Intractable Neurol. Dis., Inst. Biomed. Sci, Shinshu Univ., Matsumoto, Japan

Abstract: We have reported that a variety of mRNAs are attached to post-synaptic density (PSD) purified from cerebral cortex of rat brain (Suzuki et al., Neurosci.Res. 57, 61-85). More than one hundred among thousands of PSD-mRNAs code not only synaptic proteins but also nuclear proteins. General transcription factor II-I (Gtf2i) is one of such PSD-mRNAs coding nuclear proteins. Gtf2i is a transcription factor and one of the genes implicated in Willams-Beuren syndrome, an autism spectrum disorder. We are studying molecular mechanisms of dendritic localization and local-translation of Gtf2i mRNA, and nuclear translocation of Gtf2i protein and its function in long-term synaptic plasticity. In this study, we investigated splice variants of the Gtf2i gene in both the 5'untranslated region (5'UTR) and the coding region. To search for novel 5'UTRs of Gtf2i, we utilized the cap analysis gene expression database of the mouse. We identified seven novel Gtf2i transcripts with alternatively spliced 5'UTRs in the rat brain. We also identified four novel splice variants in the coding sequence of Gtf2i. Furthermore, we identified a selective usage of certain types of 5'UTR by coding variants. In situ hybridization demonstrated a differential pattern of expression of Gtf2i mRNAs with alternatively spliced 5'UTRs among neuronal cells, and the localization of one of the variants in neuronal dendrites in the rat brain. Immunohistochemistry also demonstrated a distribution of Gtf2i-immunoreactivity in the dendrites. These results suggest multiple pathways of expression of Gtf2i gene in the brain. The expression patterns may be under the control of alternative promoters coupled to the alternative splicing in the coding region. Differential localization of mRNA to neuronal dendrites suggests spatiotemporal specific translation at the post-synaptic sites that is involved in transfer of synaptic activity to expression of specific sets of genes in the nucleus.

Title: Synaptically generated changes in CRTC1 and its role in activity-dependent transcription

Authors: *S. L. BONANNO[1], M. DESALVO[2], C. CHRONIS[2], T. J. O'DELL[3], K. PLATH[2], K. C. MARTIN[2];
[2]Biol. Chem., [3]Physiol., [1]UCLA, Los Angeles, CA

Abstract: CRTC1 is a potent co-activator of gene expression and has been show to be necessary for the maintenance of long-term potentiation in the hippocampus. CRTC1 acts as a retrograde signaling molecule that travels from synapse to nucleus, where it modulates CREB-mediated gene expression. Previous work revealed that CRTC1 undergoes dramatic and complex post-translational modifications following NMDA receptor activation, which correlate with its nuclear transport. Present work shows that distinct plasticity-inducing stimuli generate distinct profiles of CRTC1 post-translational modification with distinct levels of nuclear accumulation in cultured hippocampal neurons. Current work is aimed at correlating specific patterns of CRTC1 modification with different programs of gene expression using RNA sequencing and chromatin immunoprecipitation sequencing (ChIP-seq).

Title: Activity-driven phosphorylation of ribosomal protein S6 is differentially regulated in dendrites vs. cell bodies

Authors: *P. SALGADO[1], O. STEWARD[2];
[1]Neurobio. and Behavior, Univ. of California Irvine Dept. of Neurobio. and Behavior, Irvine, CA; [2]Neurobio. and Behavior, Univ. of California Irvine, Irvine, CA

Abstract: Induction of perforant path long-term potentiation triggers phosphorylation of ribosomal protein S6 (rpS6) in the region of activated synapses (middle molecular layer) and also in cell bodies of dentate granule cells. Our previous studies demonstrate that activation of rpS6

phosphorylation in both dendrites and cell bodies is blocked by NMDA receptor antagonists. Also, phosphorylation of rpS6 within cell bodies is selectively blocked by wortmannin, an inhibitor of phosphatidylinositol 3-kinase (PI3-K), suggesting involvement of the PI3-K/AKT/mTOR pathway. The signaling pathways that regulate rpS6 phosphorylation within dendrites are poorly understood, but one candidate is the mitogen-activated protein kinase/extracellular signal-regulated kinase (MAPK/ERK) pathway, which is strongly activated by perforant path stimulation. Here, we assess the respective roles of MAPK/ERK vs. AKT/mTOR in regulating phosphorylation of rpS6 at synapses vs. neuronal cell bodies. As in previous studies, phosphorylation of rpS6 was induced by repeated delivery of high frequency stimulation to the perforant path in anesthetized rats. During stimulation, selective pharmacological inhibitors were locally infused via a glass microelectrode placed in the granule cell layer of the dentate gyrus, which also served to record responses generated by perforant path stimulation. Phosphorylation of rpS6 was assessed by immunohistochemistry using phospho-specific antibodies that recognize subsets of serine residues, ser235/236 and ser240/244. Local infusion of the MEK inhibitor, U0126, attenuated rpS6 phosphorylation in the dendritic laminae but did not affect rpS6 phosphorylation in granule cell bodies. Local infusion of the mTOR inhibitor, rapamycin, attenuated rpS6 phosphorylation in both the dendritic lamina and within granule cell bodies. These results support the concept that induction of rpS6 phosphorylation at activated synapses is regulated predominately via MAPK/ERK signaling, whereas activation of rpS6 phosphorylation in granule cell bodies is regulated predominately by PI3-K/AKT signaling. This offers a mechanism by which local protein synthesis may be selectively regulated in dendrites following synaptic stimulation to accomplish specific molecular pathway-dependent functions.

Title: Npas4 as a marker of recent neuronal activity

Authors: *D. G. WHEELER[1], Y. BEAVER[1], J. LAPIRA[1], P. M. ARDESTANI[2], K. MARUYAMA[1], F. SERNEO[1], D. ELOW[1], K. BAUMGAERTEL[1], R. SCOTT[1], M.

SHAMLOO[2], M. PETERS[1];
[1]Dart NeuroScience, San Diego, CA; [2]Stanford Univ., Palo Alto, CA

Abstract: Memory formation engages a specific set of neurons activated by environmental stimuli to initiate a cascade of activity-dependent signaling that alters gene expression. Identification and isolation of those neurons is critical to the study of memory and excitation-transcription coupling in the nervous system. This has traditionally been achieved through investigation of a subset of immediate-early genes (IEGs) such as cFos, Arc and Egr1 (Zif268) using techniques such as *in situ* hybridization, immunostaining or transgenic reporter animals. While proving to be useful as tools for marking activated neurons, the expression of these genes may not be entirely tuned to neuronal activity alone. IEG activation in neurons is linked to Ca^{2+} entry and synaptic activity, but it is also regulated by growth factor signaling, neurotrophins and neuromodulators. In contrast, Npas4 is expressed in a neuron-specific manner and is induced selectively by neuronal activity *in vitro*, suggesting that it may be a better marker of neuronal activation *in vivo*. In RNA-Seq experiments on primary cortical cultures, we found that *Npas4* mRNA levels increase dramatically in response to synaptic activity, but not in response to cAMP elevation by forskolin. This was paralleled *in vivo* by Npas4 induction in the hippocampus and retrospenial cortex in response to contextual learning, and with faster kinetics than observed for other IEGs. Interestingly, non-specific stressors such as restraint and vehicle injection failed to induce Npas4, while cFos, Arc and Egr1 expression were all elevated. Systemic administration of the NMDA receptor antagonist MK-801 blocked memory formation and completely prevented training-induced Npas4 expression, but it only partially inhibited induction of other IEGs. Thus, Npas4 couples to neuronal activity and memory formation but lacks the sensitivity of other IEGs to non-specific stressors. To mark recently active neurons we developed a rabbit monoclonal antibody against Npas4. Npas4 immunoreactivity in unstimulated cultured neurons was found to be low, and it was strongly induced by depolarization but not cAMP elevation. *In vivo*, immunoreactivity was observed in a sub-set of neurons after contextual fear conditioning. In addition, we observed strong induction of Npas4 immunoreactivity following ischemia in mice. Critically, we validated the specificity of our Npas4 antibody using Npas4 knock-out animals and found no cross-reactivity with other targets. Our data demonstrate that Npas4 is uniquely tuned to respond to neuronal activity and that our newly developed monoclonal antibody can be used to identify recently activated neurons *in vivo*.

Title: Transient elevations in neuronal activity induce a subset of the neuronal activity-regulated gene program defined by MAPK/ERK-dependent enhancers.

Authors: *K. TYSSOWSKI, J. M. GRAY;
Genet., Harvard Med. Sch., Boston, MA

Abstract: Brief neuronal activation can strengthen synapses, whereas sustained neuronal activation weakens them. Yet in each case synaptic plasticity is dependent on activity-regulated gene expression. We therefore asked whether neuronal gene expression differs in response to transient versus sustained activity. Using RNA-Seq, we found that transient neuronal activity induces expression of only a subset of the activity-regulated genes that are induced by sustained activity. This subset includes true immediate early genes (IEGs) but not the more slowly induced delayed primary response genes (dPRGs) or late response genes (LRGs). Two distinguishing features of genes induced by transient activity are a requirement for MAPK/ERK signaling and the presence of nearby enhancers whose enhancer RNA induction is also MAPK/ERK-dependent. We also used genome-wide experiments to investigate the mechanism of enhancer activation by MAPK/ERK. We found that enhancer RNA induction but not histone acetylation at IEG enhancers requires MAPK/ERK, indicating that MAPK/ERK functions downstream of histone acetylation to activate neuronal enhancers. Our data reveal a mechanism by which distinct patterns of neuronal activity may encode distinct biological outcomes.

Title: Single cell analysis of neuronal activity-dependent gene transcription shows role for chromatin regulation at distal enhancers in transcriptional inducibility

Authors: *A. E. WEST[1], L.-F. CHEN[2], M. G. YANG[2], A. ZHOU[2];
[1]Neurobiol, Duke Univ. Hosp., Durham, NC; [2]Neurobiol, Duke Univ., Durham, NC

Abstract: Although the mechanisms of neuronal activity-dependent gene transcription have been well characterized by population based biochemical assays, very little is known about how individual neurons behave in response to neuronal activity. Understanding transcription at the single neuron level is important because many neuronal activity-regulated genes encode proteins that modulate the strength and function of neuronal connections; thus the degree of cell-to-cell variation in activity-dependent gene transcription has direct consequences for neuronal network plasticity. We have performed single-molecule RNA fluorescence in situ to quantify mRNA transcript numbers and active gene loci of two neuronal activity regulated genes (*Fos* and *Npas4*) in cultured embryonic mouse hippocampal neurons following a uniform membrane depolarization stimulus. Even among neurons that experience the same upstream activation we find substantial gene to gene and allele to allele variation in transcriptional induction, suggesting a gene local mechanism of variability in the transcriptional response. We hypothesized that variation in the activation state of distal enhancers could underlie these differences in the inducibility of activity-dependent genes. To test this hypothesis, we recruited a dCas9-p300 fusion protein to distal enhancers of the *Fos* gene to locally induce histone acetylation. Enhancer recruitment of dCas9-p300 was sufficient to both activate *Fos* transcription in unstimulated neurons and increase the induction of *Fos* expression in activated neurons in a manner that was dependent on the histone acetyltransferase activity of p300. Taken together, these data establish a causal relationship between enhancer chromatin state and neuronal activity-inducible gene transcription at the level of single neurons.

Title: Functional modulation of activity-dependent gene expression by non-coding enhancer RNAs

Authors: *R. C. SIMON, N. V. N. GALLUS, K. E. SAVELL, F. A. SULTAN, J. J. DAY; Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Enhancers are DNA regulatory elements that contribute to establishment of cell identity during development by modulation of gene expression both *in cis* and *in trans*. Arising from enhancers are recently-discovered noncoding RNAs, coined enhancer RNAs (eRNAs). While evidence suggests eRNAs are involved in transcriptional pausing, their potential role in activity-dependent neuronal function and development remains unclear. Here, to investigate eRNA function *in vitro*, we selected an eRNA site upstream of *Fos*, an immediate early gene that codes for a transcription factor implicated in neuronal plasticity and cognitive processes. Consistent with previous studies, we show that neuronal activation leads to recruitment of RNA Polymerase II (PolII) to the *Fos* enhancer, resulting in bidirectional RNA PolII-dependent eRNA synthesis. In addition, neuronal silencing with tetrodotoxin decreases *Fos* eRNA expression and blocks the ability of glutamate receptor agonists to upregulate *Fos* eRNA. To determine whether eRNAs have a functional role in expression of the associated protein-coding *Fos* mRNA, we employed a selective eRNA knockdown approach using stable anti-sense oligonucleotides. Remarkably, whereas *Fos* mRNA knockdown had no effect on eRNA levels, eRNA knockdown resulted in a concomitant downregulation of protein-coding mRNA, suggesting a functional role for this non-coding transcript. Moreover, single-molecule RNA FISH revealed that *Fos* eRNAs are restricted to the nuclei of neurons. Finally, we employed mobility shift assays to show that *Fos* eRNAs bind directly to epigenetic modifiers conventionally believed to bind DNA. These findings indicate that eRNAs directly modulate gene expression and suggest that activity-driven induction of eRNAs could be an important regulatory mechanism in the central nervous system.

Title: Gene regulatory networks activated by pattern-specific generation of action potentials in dorsal root ganglia neurons

Authors: *P. R. LEE[1], J. E. COHEN[2], D. A. IACOBAS[3], S. IACOBAS[3], R. D. FIELDS[1]; [1]NIH/NICHD, Bethesda, MD; [2]Centerfor Biologics Evaluation and Res., FDA, Silver Spring, MD; [3]Dept. of Pathology, New York Med. Col. Sch. of Med., Valhalla, NY

Abstract: Development and plasticity in the nervous system are regulated by specific patterns of neural impulse activity. Patterned activity orchestrates spatial and temporal changes in the expression of networks of genes and their translated products. These gene regulatory networks underlie the long-term changes in cell specification, growth of synaptic connections, and adaptation that occur throughout neonatal and postnatal life. Here we show that the temporal nature of action potentials and downstream signaling differentially regulates the expression of hundreds of neuronal genes through distinct gene regulatory networks. Analysis of upstream regulatory regions showed enrichment in transcription factor binding sites for NF-Kappa B that was action potential pattern specific. Gene-set ontology enrichment of specific pathways for growth and development of neurons is also shown to be action potential pattern dependent. Beyond widely used bioinformatics approaches to understanding transcriptomic data we have used prominent gene analysis and pair wise topology measurements to quantify transcription networks which are sensitive to the timing of action potential bursting. Our new findings demonstrate spike-frequency decoding by action potentials at the transcriptional level by pattern-specific activation of transcription factors and associated gene-regulatory networks that operate to adjust the modalities of sensory neurons.

Title: The role of a brain specific tRNA isodecoder in neuronal function

Authors: *M. KAPUR[1,2], G. NAGY[3], S. ADAMSON[4], J. H. CHUANG[4], C. ROSE[5], S. GYGI[5], S. L. ACKERMAN[1,2];

Abstract: The genomes of higher eukaryotes contain hundreds of transfer RNA (tRNA) genes. Surprisingly, while numerous genetic disorders have been linked to mutations in enzymes that process or modify tRNAs, a disease-linked mutation in a nuclear-encoded tRNA gene has not been reported. Until recently, the prevailing view was that isodecoder tRNAs, that is, tRNAs that share the same anticodon and differ only in their body sequence, were functionally redundant, and thus could compensate for a mutated tRNA. However, growing evidence indicates that isodecoder tRNAs may have different functional efficiencies.
Our lab recently identified the first tissue-specific mammalian tRNA gene, *n-Tr20*. *n-Tr20* is one of 5 isodecoders in the nuclear encoded $tRNA^{Arg}_{UCU}$ family, and in contrast to the other members of this family, is specifically expressed in the nervous system. Loss of *n-Tr20* in mice dramatically reduced the $tRNA^{Arg}_{UCU}$ pool in the nervous system, resulting in ribosome stalling on the cognate AGA codons. This stalling was severely exacerbated in the absence of the ribosome recycling factor GTPBP2, leading to widespread neurodegeneration.
Here, we find that expression of this single tRNA gene modulates complex phenotypes such as seizure susceptibility, and surprisingly, that loss of this tRNA results in widespread transcriptional reprogramming. This study sheds light on the role of individual tRNA isodecoder genes, and their possible role in human disease.

Title: Synaptic vesicles contain small ribonucleic acids (sRNAs) including transfer RNA fragments (trfRNAs) and micro-RNAs (miRNAs)

Authors: *M. L. HARLOW, H. LI, C. WU, R. ARAMAYO, M. S. SACHS;
Biol., Texas A&M Univ., College Station, TX

Abstract: Protein synthesis is necessary for both the consolidation of new memories and the reconsolidation of existent memories. In neurons, much of the protein synthesis occurs away from the cell body at specialized regions within the dendritic arbor and postsynaptic boutons, and is referred to as local protein synthesis. Local protein synthesis at the synapse is regulated by the presynaptic activity of synaptic vesicles (SVs), and requires a host of translation factors, ribosomes, mRNAs, and small non-coding RNAs (sRNAs; 20-50 nucleotides [nt] in length). We have demonstrated that, in addition to neurotransmitters, cholinergic SVs isolated from the peripheral nervous system (PNS) of the model organism *Torpedo californica* (Pacific electric ray) and heterogeneous SVs isolated from the central nervous system (CNS) of Mus musculus (mouse) also contain sRNAs - primarily the 5' fragments of transfer RNAs (tRNAs) termed tRNA fragments (trfRNAs). trfRNAs, once thought to be degradation products, have recently been implicated in the paternal influence on offspring metabolism, the post-transcriptional regulation of protein synthesis, and the suppression of cancer cell metastasis. In addition to trfRNAs, SVs contain micro RNAs (miRNAs) known to be involved in transcriptional and translational regulation. The discovery that SVs contain sRNAs suggests that, in addition to inducing changes in local dendritic excitability through the release of neurotransmitters, SVs may, through the release of specific trfRNAs and miRNAs, directly regulate local protein synthesis. We believe these findings have broad implications for the study of chemical synaptic transmission.

Title: The effect of sumoylation on the transactivation capacities of different human NFAT isoforms in neurons

Authors: *H. VIHMA, T. TIMMUSK;
Tallinn Univ. of Technol., Tallinn, Estonia

Abstract: The nuclear factor of activated T-cells (NFAT) family of transcription factors encompasses four closely related calcium-regulated members, NFATc1, NFATc2, NFATc3, and NFATc4, that upon activation by the calcium-dependent phosphatase calcineurin translocate from cytosol to the nucleus and regulate their target genes. In the nervous system, NFAT-dependent gene regulation has been shown to be involved in axonal growth and guidance, synaptic plasticity, and neuronal survival. We have previously shown that there are a number of alternative splice variants of NFAT genes expressed in the brain and that the transcriptional activity of different human NFAT proteins in neurons in response to membrane depolarization is isoform specific. For example, NFATc3 and NFATc4 are the strongest transcriptional activators in neurons, and NFATc1 and NFATc2 display isoform-specific transcription activation capacities. Here, in an attempt to identify the motifs responsible for isoform-specific transactivation of different human NFAT proteins, we looked at the effect of sumoylation as a potential regulator of transcription. Protein sumoylation is a post-translational modification in which a member of the small ubiquitin-like modifier (SUMO) family of proteins is covalently coupled to lysine residues in target proteins and sumoylation has been shown to regulate many cellular processes including repression and activation of transcription. For that, we mutated lysine residues to arginine of all predicted sumoylation sites on different human NFAT isoforms and studied the transactivation capacities between the potentially SUMO-modified wild-type and unmodified mutant forms of NFAT isoforms in rat primary cortical or hippocampal neurons in response to membrane depolarization and compared the induced transactivation levels in neurons to those obtained from HEK293FT and BHK21 cells in response to calcium signaling. Our results showed that the effect of sumoylation on the transactivation capacities of NFAT isoforms

was dependent on the amount of sumoylation sites on specific isoform and varied between cell types.

Title: Transcriptional regulation of BDNF exon IX: Role of Nuclear respiratory factor 2 (NRF-2)

Authors: *B. A. NAIR, M. WONG-RILEY;
Cell Biology, Neurobio. and Anat., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Brain-derived neurotrophic factor (BDNF) is considered as the most abundant and active neurotrophin expressed throughout the nervous system. BDNF plays an important role in synaptic transmission, plasticity, neuronal proliferation, differentiation, survival, and death. A distinct feature of the BDNF gene is the existence of multiple non-coding exons and a single coding exon (exon IX). Although the regulation of BDNF expression by neuronal activity has received a great deal of attention, little is known about the transcriptional regulation of the BDNF gene itself, nor about transcription factor candidates that may play such a role. The goal of the present study was to begin an in-depth investigation of the key transcription factor/s that regulate/s the single coding exon IX of the rat BDNF gene. Our initial in silico analysis revealed tandem binding sites for nuclear respiratory factor 2 (NRF-2) on the promoter of exon IX. NRF-2 is of special significance because we have previously found it to co-regulate the transcriptional expressions of mediators of energy metabolism (cytochrome c oxidase) and mediators of neuronal activity (glutamatergic receptors). To test our hypothesis that NRF-2 also regulates the BDNF gene, we performed electrophoretic mobility shift assay (EMSA), chromatin immunoprecipitation (ChIP), promoter cloning and site-directed mutagenesis, real-time quantitative PCR, and western blotting. Results indicate that NRF-2 functionally regulates exon IX of the rat BDNF gene. The binding sites of NRF-2 are conserved between rats and mice. Over-expressing NRF-2 up-regulated the expression of BDNF exon IX, whereas knocking down NRF-2 down-regulated such expression. These findings are consistent with our hypothesis that NRF-2, in addition to regulating the coupling between neuronal activity and energy metabolism,

also regulates the expression of BDNF, which is intimately associated with energy-demanding neuronal activity.

Title: Differential genomic expression analysis of neurons mediating the *Aplysia* californica siphon/gill-withdrawal reflex.

Authors: *C. BOSTWICK[1], Q. YANG[2], A. B. KOHN[3], R. D. HAWKINS[2], L. L. MOROZ[4]; [1]Neurosci., Univ. of Florida Whitney Lab. for Marine Biosci., Saint Augustine, FL; [2]Neurosci., Columbia Univ., New York, NY; [3]Whitney Lab., [4]Neurosci., Univ. of Florida, Saint Augustine, FL

Abstract: A major goal of modern neuroscience is to gain a comprehensive understanding of the molecular processes necessary for the formation and maintenance of long-term memories using identified neural circuits known to mediate behaviors. We sampled individual neurons comprising the sensory, motor, and interneuronal components of the defensive siphon/gill-withdrawal reflex from the abdominal ganglion of the sea hare *Aplysia californica* to determine each neuron's unique transcriptome.

We identified transcripts that are differentially expressed between the different neuron subtypes of the reflex circuit as well as differential expression between the motor neurons controlling siphon and gill withdrawal, respectively. Hundreds of transcripts are differentially expressed when comparing the sensory LE cells to their downstream motor or interneurons. We found nearly 300 molecules to be differentially expressed between sensory neurons and the L29 interneurons of the reflex. Some of these transcripts encode structural proteins, enzymes, transcription factors, and regulatory kinases and phosphatases. Many of these differentially expressed transcripts are "uncharacterized", meaning their function or cellular role is currently unknown. These transcripts may serve a variety of roles, including regulating gene expression, cellular processes, or modifying RNA after it is transcribed. Additionally, these transcripts could

potentially be neuronal-specific noncoding RNAs that mediate other unknown regulatory roles within the nervous system. Our study of the molecular processes and players involved in the formation and potential maintenance of long-term memory in *Aplysia californica* is vital to understanding the fundamentals of memory formation and learning in other organisms.

Title: Estrogen prevents input-deprivation related down-regulation of gene expression in the proestrus female rat barrel cortex: RNA-Seq

Authors: *J. J. ORCZYK[1], A. GORE[1], R. BATKA[1], P. E. GARRAGHTY[1,2];
[1]Psychological and Brain Sci., [2]Program in Neurosci., Indiana Univ., Bloomington, IN

Abstract: Our laboratory studies the central effects of peripheral denervation in rats and previously in squirrel monkeys. Previous results have led us to investigate the role of gonadal hormones in denervation-associated sensory plasticity. Prior work has demonstrated the primary somatosensory cortex undergoes topographic reorganization in response to the loss of input from a specific peripheral location, such as in the case of limb amputation or denervation. We hypothesized that reorganization is driven by a mixture of homeostatic and use-dependent plasticity mechanisms. Interestingly, estrogen activates the same cAMP-response element binding proteins (CREB) as neural activity. Thus, we investigated the effects of unilateral infraorbital nerve (ION) transection on gene expression in the female rat barrel cortex using RNA seq in both proestrus and gonadectomized female rats (N = 7 in each group) after a 24-h survival duration. In gonadectomized females, 109 genes are down-regulated and 3 are up-regulated when comparing gene expression in the input-deprived barrel cortex with input-intact cortex. In contrast, 5 genes are down-regulated and 23 are up-regulated in the proestrus female rat barrel cortex after input-deprivation. Genes down-regulated in the gonadectomized female cortex include GABA receptor subunits, neurotrophins, and dopamine release and reuptake proteins. Genes up-regulated in the proestrus rat female barrel cortex include prolactin, NHLH1, and C1QL2. Despite the differences in gene expression, the functional outcome is predicted to be similar in both proestrus and gonadectomized females. In both cases, a reduction in both excitatory and inhibitory neurotransmission, and in the number of synapses is expected to occur

although by disparate mechanisms. In the gonadectomized females, neuronal atrophy is expected to be the primary driver of a reduction in the number of synapses. In the proestrus females, changes in gene expression favor the activation of microglia that consume inactive synapses, perhaps recognizing them through a tagging mechanism mediated by C1QL2. Other researchers have implicated a microglia response in sensory-deprivation associated plasticity. Further research is required to determine the extent to which C1QL2 may be involved in mediating adult synaptic plasticity. A consequence of our results is the necessity to take hormonal status into account as a dependent variable when performing animal research. A further corollary is that sex absolutely must be taken into consideration when designing animal research as differing hormonal environments between the sexes almost surely influence gene expression.

Title: Haloperidol modulates glutamate system functional connectivity: results from a translational immediate early gene based network study.

Authors: *E. F. BUONAGURO, G. LATTE, C. TOMASETTI, F. MARMO, C. AVAGLIANO, L. VELLUCCI, F. IASEVOLI, A. DE BARTOLOMEIS;
Univ. Federico II, Napoli, Italy

Abstract: Schizophrenia has been conceptualized both as a synaptic plasticity and a functional connectivity disorder. Antipsychotic drugs, such as haloperidol, are mainstays of schizophrenia pharmacotherapy. Although extensively studied, the effects of haloperidol are not completely understood at a network level, as well as its role in synaptic plasticity and functional connectivity. Homer1a (*H1a*) is an Immediate Early Gene (IEG) expressed in an activity-dependent manner, coding for a protein involved in the activity-induced reorganization of glutamatergic synapses. Its expression may be induced by acute antipsychotic administration, and may be affected by dopaminergic or glutamatergic psychotomimetic compounds. We tested the hypotesis that acute haloperidol would modulate functional connectivity in the glutamate system among brain regions relevant to schizophrenia pathophysiology. We used *H1a* expression as a molecular tool to assess putative changes in brain regional interactivity after acute treatment

with haloperidol. Sprague-Dawley rats were randomly assigned to two treatment groups (n=23), receiving vehicle (NaCl 0.9%; VEH) or haloperidol 0.8 mg/kg (HAL) i.p. injection. *H1a* induction was evaluated by means of *in situ* hybridization. Signal intensity analysis was performed in 11 Regions of Interest (ROIs) in the cortex, in the caudate-putamen and in the nucleus accumbens. Student's t-test was used to detect treatment effects. A signal correlation analysis was performed, computing all possible pairwise Pearson correlations among ROIs separately in the two groups. Using significant correlations, two networks were created for HAL and VEH group, and their network, node and edge properties were assessed. Consistent with previous observations, haloperidol induced *H1a* in all striatal ROIs. The VEH and the HAL network showed differences in network parameters (connected components, diameter, radius, characteristic path length), node attributes (degree, eccentricity, closeness, radiality, betweenness, stress, centroid, eigenvector, bridging centralities) and edge attributes (edgebetweenness). The HAL network showed enhanced interactivity between cortical and striatal regions, and reduced interactivity between caudate-putamen and nucleus accumbens. The main result of this work is the characterization of two distinct large-scale cortico-subcortical brain networks after VEH or HAL acute administration. These functional connectivity changes are potentially related to neural activity and synaptic plasticity within the glutamate system, and may play a role in haloperidol therapeutic and side effects.

Abstract: Communication between cells in the brain occurs at specialized sites of contact called synapses. The specific formation, removal, and efficacy of synaptic connections are dynamically regulated and modified by experience. Each neuron is made up of collections of proteins (called the proteome) that harbor characteristic turnover profiles of synthesis and degradation. The ability to alter a neuronal proteome, for example through changes to protein stability, is a fundamental factor affecting overall brain function, learning and memory. Recent advances in techniques to manipulate or monitor brain function have enabled scientists to study cellular and molecular mechanisms underlying learning and memory. However, cell biological mechanisms of proteostasis such as synthesis, degradation, modification, trafficking (or delivery) and stability of proteins during learning and memory or global neuronal activity changes remain poorly understood. While large differences in protein stability can be observed in the brain, the precise role of protein stability modification in the long-term maintenance of brain function is unclear. Here we explored dynamics of a rodent model system synaptic proteome and their modifications using sub-cellular fractionation, biochemistry and quantitative proteomics. We provide a system-wide identification of proteins in mouse forebrain synaptosomes and their half-lives during environmental enrichment using the Stable Isotope Labeling in Mammals (SILAM) technique and high-resolution mass spectrometry. We also observed that synaptic proteins underwent stabilization or destabilization dynamically during exposure to enriched environment. These findings will provide critical evidence to elucidate basic molecular mechanisms that regulate synaptic plasticity, receptor trafficking and long-term memory formation in terms of protein turnover and protein modifications such as phosphorylation. Furthermore this study can help to find targets that have significant relevance for many neurological disorders resulting from abnormal synaptic transmission and synaptic plasticity.

Title: Human ApoE ε2 promotes regulatory mechanisms of bioenergetic and synaptic function in female brain: a focus on V-type H^+-ATPase

Authors: *L. ZHAO[1], S. WOODY[1], H. ZHOU[2], S. IBRAHIMI[1], Y. ZHANG[2];
[1]Sch. of Pharm., Univ. of Kansas, Lawrence, KS; [2]Sch. of Med., Univ. of Kansas, Kansas City, KS

Abstract: Humans possess three major isoforms of the apolipoprotein E (ApoE) gene encoded by three alleles: ApoE ε2 (ApoE2), ApoE ε3 (ApoE3), and ApoE ε4 (ApoE4). It is established that the three ApoE isoforms confer differential susceptibility to Alzheimer's disease (AD); however, an in-depth molecular understanding of the underlying mechanisms is currently unavailable. In this study, we examined the cortical proteome differences among the three ApoE isoforms using 6-month-old female, human ApoE2, ApoE3, and ApoE4 gene-targeted replacement mice and two-dimensional proteomic analyses. The results reveal that the three ApoE brains differ primarily in two areas: cellular bioenergetics and synaptic transmission. Of particular significance, we show for the first time that the three ApoE brains differentially express a key component of the catalytic domain of the V-type H^+-ATPase (Atp6v), a proton pump that mediates the concentration of neurotransmitters into synaptic vesicles and thus is crucial in synaptic transmission. Specifically, our data demonstrate that ApoE2 brain exhibits significantly higher levels of the beta subunit of Atp6v (Atp6v1B2) when compared to both ApoE3 and ApoE4 brains, with ApoE4 brain exhibiting the lowest expression. Our additional analyses show that Atp6v1B2 is significantly impacted by aging and AD pathology and the data suggest that Atp6v1B2 deficiency could play a role in the progressive loss of synaptic integrity during early development of AD. Collectively, our findings indicate that human ApoE isoforms differentially modulate regulatory mechanisms of bioenergetic and synaptic function in female brain. A more efficient and robust status in both areas could serve as a potential mechanism contributing to the neuroprotective and cognition-favoring properties associated with the ApoE2 genotype.

Title: Human ApoE isoforms differentially modulate brain bioenergetic metabolism

Authors: *L. WU[1], L. ZHAO[1,2];
[1]Pharmacol. & Toxicology, [2]Neurosci. Grad. Program, Univ. of Kansas, Lawrence, KS

Abstract: Alzheimer's disease (AD) is an irreversible neurodegenerative disorder characterized clinically by progressive loss of memory and cognitive decline. There are two types of AD: early-onset and late-onset (LOAD); LOAD account for over 95% of all AD cases. Humans possess three genetic isoforms of apolipoprotein E (ApoE)—ApoE2, ApoE3 and ApoE4—that confer differential risk for LOAD; however, the underlying mechanisms are poorly understood. This study was sought to investigate the impact of human ApoE isoforms on brain energy metabolism, an area significantly perturbed in preclinical AD. A Taqman custom array was performed to examine the expression of a total of 43 genes involved in glucose and ketone body uptake, transport and metabolism in human ApoE gene-targeted replacement mice (hAPOE-TR). Consistent with our previous findings, ApoE2-bearing brains exhibited the most robust while ApoE4 brains were associated with the most deficient profile on both the uptake and metabolism of glucose, the primary fuel for the brain. In particular, the three ApoE genotypes significantly differed in the expression of facilitated glucose transporters, which mediate the entry of glucose into neurons, and hexokinases, which act as the "gateway enzyme" in glucose metabolism by converting glucose to glucose-6-phosphate, the initial step in the glycolysis, glycogen synthesis and pentose phosphate pathway. Interestingly, on the uptake and metabolism of ketone bodies, the secondary energy source for the brain, ApoE2 and ApoE4 brains exhibited a similar level of robustness, while ApoE3 brains presented a relatively deficient profile. Moreover, ingenuity pathway analysis (IPA) indicated that PPAR-γ/PGC-1α signaling pathway could be activated in the ApoE2 brain and inhibited in the ApoE4 brain. Taken together, our data provide additional evidence that human ApoE isoforms differentially modulate brain bioenergetic metabolism, which could serve as a potential underlying mechanism contributing to their discrete risk impact in AD. A therapeutic approach that promotes glucose uptake and glycolytic metabolism may hold the promise to reduce the AD risk in ApoE4 carriers; however, a ketogenic strategy may provide a more meaningful benefit in ApoE3 than in ApoE4 carriers.

Title: Redistribution of brain clusterin (CLU) isoforms in neurodegeneration

Authors: *S. K. WOODY, L. ZHAO;
Univ. of Kansas - Sch. of Pharm., Lawrence, KS

Abstract: Clusterin (CLU), also known as apolipoprotein J (APOJ), has recently been identified as the third most significant genetic risk factor for the development of late-onset Alzheimer's disease (LOAD). As approximately 36% of the population carries two copies of the CLU AD-risk variant (rs11136000 C allele; CLU-C), this gene is of great significance to public health. However, despite the clinical importance, an extensive gap exists in the literature pertaining to the basic properties of CLU in the brain. In this study, we demonstrate that CLU, which is predominantly expressed in the brain, exists as two isoforms: mature CLU (mCLU) and nuclear CLU (nCLU). Of particular significance, our data indicate the localization of nCLU in brain and neuronal mitochondria; a novel finding in the CLU research field. Additionally, our analyses demonstrate a rapid rearrangement of neuronal CLU isoforms in response to neurotoxic insult, including a significant removal of cytosolic mCLU and an accumulation of nCLU in the cytosol that appears to result from declining nCLU levels in the mitochondria. These initial findings suggest that: 1) Contrary to the long-held notion that nCLU is a stress-inducible and solely pro-apoptotic protein, nCLU may play an important regulatory role in neuronal homeostasis; 2) Neurodegenerative challenge induces redistribution of neuronal CLU isoforms; this redistribution results in intracellular CLU dyshomeostasis and mitochondrial instability which may account for the pro-apoptotic properties attributed to nCLU following cellular stress.

Title: APOE epsilon-4 knock-in rat model of Alzheimer's disease - gender differences in cognitive behavior and gray matter microarchitecture: Insights on the neuropathology of disease progression using MRI.

Authors: *P. P. KULKARNI[1], J. HONEYCUTT[2], M. S. TRIVEDI[3], H. BRENHOUSE[2], M. NEDELMAN[4], K. GAMBER[5], C. F. FERRIS[1];

Abstract: The most prevalent genetic risk for sporadic Alzheimer's disease is the allele Ɛ4 of the apolipoprotein E4 (APOE Ɛ4). The many neuropathological findings that define AD are associated with APOE Ɛ4 carriers together with general cerebrovascular impairment and neuroinflammation. There are reports from human imaging studies that suggest the apoE4 protein could affect neurodevelopment many years before the onset of AD. Indeed, brain structure alterations may precede overt cognitive impairment in AD by several decades. Early detection of these alterations holds inherent value for the development and evaluation of preventive treatment therapies.In collaboration with Horizon Discovery (St Louis) we characterized the brain and cognitive development of male and female APOE Ɛ4 knock-in (KI) rats, a preclinical model of Alzheimer's disease. Testing memory in the novel preference task showed no difference between WT and KI females at seven months of age, but a significant loss of memory in KI males as compared to WT males. Using a newly developed non-invasive technology combining quantitative anisotropy and computational analysis of 174 brain areas of the rat we identified subtle changes in gray matter microarchitecture between genotypes. There were only 6 areas with significant differences in indices of anisotropy (IA) values, e.g. fractional anisotropy (FA), radial diffusivity (RD), axial diffusivity, between female genotypes. In contrast, there were 33 brain areas showing significant changes in FA values between male genotypes. 17 of these areas included cerebral cortex, 8 the cerebellar complex and 5 the primary olfactory system. The same pattern was reflected in the RD values - very few differences in females with 55 differences between male genotypes strongly favoring the cerebellum, cortex and olfactory system. Areas that showed little change were the thalamus, amygdala, hypothalamus, basal

ganglia and to our surprise hippocampal complex. The precise molecular and biochemical processes contributing to these putative microarchitectural changes in gray matter are being studied in postmortem brain samples collected from this study. In summary, male but not female APOE Ɛ4 rats showed deficits in memory. Putative changes in gray matter microarchitecture across 174 brain areas were both gender and genotype specific. Male but not female rats, expressing the APOE Ɛ4 protein showed significant differences in cerebellum, cerebral cortex and primary olfactory system, but not the hippocampal complex.

Abstract: In the central nervous system, apolipoprotein E (APOE) is produced in glia and functions in the transport of cholesterol to neurons via APOE receptors. The absence or dysregulation of this lipoprotein increases risk for vascular disorders and Alzheimer's disease (AD). The recent development of transgenic homozygous APOE -/- knock out (KO) rats

provided an opportunity to apply a new imaging methodology "in vivo neuropathology" to non-invasively study subtle changes in gray matter microarchitecture in WT and KO female and male rats using quantitative anisotropy across 174 brain regions. In addition, T1 and T2 relaxivity measures were collected across these brain regions and comparisons made between gender and the APOE genotype. All studies were done on a Bruker 7T MR scanner while rats were anesthetized with 2% isoflurane. Both males and female APOE KO rats showed over 40 brain areas with altered T1 relaxivity as compared to gender matched WT controls. The entire cerebellum and deep cerebellar nuclei were affected as were many of their afferent and efferent connections in brainstem and pons. There was little difference in T1 measures between genders. Changes in T2 relaxivity between APOE genotypes were less pronounced and numbered only 10 in females and18 in males. Again areas of the cerebellum and their afferent and efferent connections were involved. Quantitative anisotropy showed clear male/female differences. In the males this imaging technique complemented the relaxivity measures as the cerebellum again showed differences between APOE genotypes for fractional anisotropy and radial diffusivity. In addition, many thalamic areas and their cortical connections were altered. In females the changes were fewer and localized primarily to hypothalamus and amygdala. In this study multiple non-invasive MRI protocols were used to identify putative changes in gray matter microarchitecture across 174 brain areas in a rat model of AD. The changes were both gender and APOE specific. Rats, male and female, lacking apolipoprotein E showed significant differences in cerebellum and its afferent and efferent connections for measures of T1. This profile was consistent for males for T2 and indices of anisotropy but different for females. There was little evidence of any changes in the hippocampal complex between gender and APOE genotype. Brains were harvested and are undergoing immunhistochemical analysis for glial fibrillary associated protein and activated microglia to assess neuroinflammation in areas identified with these imaging protocols.

[3]Ekam Imaging, Boston, MA; [4]Lundbeck, Valby, Denmark

Abstract: Combination therapies are being developed to improve memory in cases of mild cognitive impairment and early stage Alzheimer's. To this end, we followed changes in brain activity caused by a serotonin receptor antagonist given alone or in combination with an acetylcholinesterase inhibitor using functional magnetic resonance imaging (fMRI) in the awake rat. Studies were performed on a Bruker 7T MRI scanner using a restraining system and RF coil design customized for awake rat imaging. Rats were acclimated to restraining system prior to imaging. During the scanning session the compounds were given intravenous and BOLD (Blood Oxygen Level Dependent) fMRI used to study activation in 171 predefined regions of the brain. The serotonergic antagonist alone had only a modest effect on brain activity affecting 8 brain regions primarily localized to the ventral forebrain. The acetylcholinesterase inhibitor activated 19 brain areas when given alone affecting the serotonergic raphe nucleus, areas of cholinergic neurotransmission and areas associated with the hippocampal complex. When both drugs were given together, there was a robust activation pattern of 36 brain regions. The pattern of significantly activated brain regions could be reconstructed into three integrated neural networks - Extended Amygdala, Striato-Pallidum and Septo-Hippocampus, and interestingly much of the primary olfactory system. This example of a potential combination therapy shows a clear synergistic effect of both compounds that extended beyond the effects of each alone. The combination treatment recruits a constellation of integrated neural circuits associated with cognition, emotion and motivation as well as extroceptive (olfaction) and introceptive cues (brainstem). These may collectively contribute to cognition, by enriching learning and memory processes with motivational salience and the context of the extroceptive and introceptive worlds. Studies are presently underway to test this combination therapy in the APOE epsilon 4 knock-in rat model of Alzheimer's that presents with deficits in learning and memory.

Title: First capillary blood volume full-brain atlas and absolute functional CBV measurements using QUTE-CE MRI in sprague dawley rats: Preliminary results in the APOE Epsilon 4 knock-in rat model of Alzheimer's disease.

Authors: *C. A. GHARAGOUZLOO[1], L. TIMMS[2], J. QIAO[3], Z. FANG[2], J. NNEJI[4], A. V. VEN[2], P. KULKARNI[5], C. F. FERRIS[5], K. GAMBER[6], S. SRIDHAR[2];
[1]BioEngineering, Northeastern Univ., Medford, MA; [2]Physics, [3]Mechanical and Industrial Engin., [4]BioEngineering, [5]Psychology, Northeastern Univ., Boston, MA; [6]Horizon Discovery, St. Louis, MT

Abstract: Cerebral blood volume (CBV) is an important indicator of tissue health and function. Dynamic susceptibility contrast (DSC) MRI is commonly used for measuring CBV values but requires accurate determination of the arterial input function (AIF), or GBCA concentration versus time curve which is typically 15-30% inaccurate. Furthermore a fast acquisition protocol (such as echo-planar imaging [EPI]) must be employed, which inherently limits both the spatial resolution and the signal-to-noise ratio (SNR). It has been shown that CBV measurements with DSC-MRI are even more inaccurate in ischemic tissue because of late, unpredictable arterial arrival of CA. Other techniques for measuring the CBV, such as steady-state susceptibility contrast mapping (SSGRE), steady state CBV (SS_CBV), and ΔR2 all utilize T2 and T2* effects, which are susceptible to intra- and extra-voxular dephasing as well as flow artifacts. We have developed a quantitative blood volume atlas of the rat brain using the **Q**uantitative **U**ltra-short **TE** **C**ontrast **E**nhancement (QUTE-CE) MRI technique based on an absolutely quantitative signal and partial voluming. Unlike usual techniques that render only semi-quantitative raw MR signal[9], QUTE-CE is insensitive to extravoxular susceptibility and motion/flow artifacts. We

employ superparamagnetic iron-oxide nanoparticles (SPIONs) for intra-vascular contrast enhancement, and our technique provides clearly delineated positive contrast of the vascular compartment compared to the commonly employed T2-weighted techniques which produce negative contrast. We develop the Atlas both in terms of absolute CBV and capillary blood volume, and demonstrate that the technique can be utilized for quantitative steady-state functional imaging by measuring changes in CBV in Sprague Dawley rats induced by a 5% CO2-challenge and anesthesia by 3% isoflurane. A reference 3D MRI atlas with 174 segmented and annotated regions was utilized to construct the vascular atlas. In collaboration with Horizon Discovery we ran preliminary studies on capillary density measures in male and female APOE Ɛ4 knock-in (KI) rats and found gender differences in the hippocampus and cortex. At 7 months of age male KI, but not female KI, showed deficits in memory as compared to gender-matched, wild-type controls. Female KI showed significantly higher capillary densities in the hippocampus (CA1, CA3 and dentate gyrus) and cortex as compared to KI males but no difference from WT females. These preliminary findings may reflect the positive influence of estrogen on angiogenesis, aging and early disease progression.

Title: Particulate air pollutants accelerate neurodegeneration in EFAD mice

Authors: *M. CACCIOTTOLO[1], A. SAFFARI[2], C. SIOUTAS, 90089-0191[2], M. LADU[3], T. E. MORGAN[1], C. E. FINCH[1];
[1]USC Davis Sch. of Gerontology, Los Angeles, CA; [2]USC Viterbi Sch. of Engin., Los Angeles, CA; [3]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Particulate air pollutants are increasingly recognized for their neurotoxic impact in human populations and in experimental rodent studies but very little is known about the

mechanisms involved and interaction with the apoE ε4 risk factor for Alzheimer disease (AD). To evaluate the mechanism behind air pollutant neurotoxicity, we exposed 20 female EFAD transgenic mice (5xFAD+/-/human APOE ε3 or ε4 +/+) to nanosized urban airborne particulate material (nPM) for 225h (5h/day, 3d/wk, 15wks, at a dose of 340ug/m3 nPM) and analyzed brain tissues for hallmarks of AD pathology. nPM exposure induced 2.8-fold greater increment in cortical plaque load in E4FAD mice than in E3FAD mice. However, both APOE alleles responded with Aβ oligomer increases in soluble extracts of cerebral cortex. Silver staining showed selective neuronal atrophy in response to nPM in the hippocampus, restricted to CA1 neurons, without significant changes in the contiguous CA2/3 neurons, or in the dentate gyrus (DG). The selective morphological changes in CA1 neurons with nPM exposure paralleled their vulnerability in AD pathogenesis. At the protein level, nPM exposure induced a robust decrease of GluR1 protein levels in both genotypes. No changes were detected in other glutamatergic receptor subunits (GluR2, NR2A and NR2B) or in other common synaptic proteins (pre-synaptic: synaptophysin; post-synaptic: PSD95). These findings support the hypothesis that particulate air pollutants accelerate pathological brain aging, with potentially greater impact in APOE ε4 carriers. We propose that the underlying mechanisms of neurotoxicity involve increased cerebral Aβ production and glutamatergic remodeling.

Title: APOE modulated cerebrovascular dysfunction in Alzheimer’s disease

Authors: *L. M. TAI[1], F. M. MAROTTOL[1], K. P. KOSTER[1], A. MORRIS[1], R. THOMAS[2]; [1]Anat. and Cell Biol., [2]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Cerebrovascular (CV) dysfunction is emerging as a critical component of Alzheimer disease (AD). Although CV damage is well documented in AD, the extent is variable and this variability may be related to the ability of known AD risk factors to affect CV function. Our research is focused on the role of known AD risk factors in CV dysfunction: *APOE* and female sex. *APOE4* is the greatest genetic risk for sporadic AD, with a greater effect in females.

Therefore, the role of *APOE* and female sex in CV dysfunction was assessed in novel EFAD transgenic mice, which express human *APOE3* or *APOE4* and overproduce human Aβ. Our data demonstrate that *APOE4* and Aβ induce cognitive impairments and increase CV leakiness in female mice (E4FAD mice) at 8 months of age.In female E4FAD mice, cognitive defects correlated with vessel degeneration. Angiogenic signaling in brain endothelial cells (BECs) is key for controlling vessel degeneration and the complex metabolic, transport and signaling functions of the CV. Therefore, angiogenic growth factors (GFs) may ameliorate CV dysfunction in AD. Our comparison of the main angiogenic GFs demonstrate that EGF protects against Aβ-induced disruption of vessel formation and vessel degeneration in single BEC cultures. EGF also protects against Aβ42-induced vessel degeneration in triple cultures (astrocytes, pericytes and BECs) designed to mimic the blood-brain barrier (BBB). Additionally, EGF receptor ligands induced functional effects in all cell types of the BBB for Aβ-induced activation. Based on the *in vitro* findings, we treated female E4FAD mice with EGF (300µg/kg/week) from 6-8 months in a prevention paradigm. EGF prevented the age-dependent cognitive decline as assessed by spontaneous alternation (Y-maze), novel object recognition and platform latency (Morris water maze) and prevented CV leakiness and vessel degeneration. Collectively these data support that *APOE4 and Aβ predispose the CV to damage with an "accelerating hit", which can be ameliorated by EGF.*

Sci., Little Rock, AR; [6]Geriatric Res. Educ. and Clin. Ctr., Central Arkansas Veterans HealthCare Syst., Little Rock, AR; [7]Pathology, Univ. of Toledo Hlth. Sci. Campus, Toledo, OH

Abstract: Autophagy is a major protein and organelle degradation pathway that is often preferentially affected in neurodegenerative diseases. Autophagy is regulated to a great degree by the transcription factor TFEB, which in turn is regulated at the lysosome by its phosphorylation state: This determines if TFEB can be bound to 14-3-3 and remain in the cytoplasm, or be transported to the nucleus for transcriptional upregulation of autophagy genes. The APOE ε4 allele is the single greatest genetic risk factor for development of Alzheimer's disease, with no single mechanism yet agreed upon, while the APOE ε3 allele is considered normal risk. Using RT-PCR on human hippocampal tissue, we have found that autophagy genes LC3B, LAMP2, and SQSTM1/p62 transcripts are significantly higher in the hippocampus of those with Alzheimer's disease with two copies of APOE ε3 compared to those homozygous for APOE ε4. Based on confocal immunofluorescence and *in situ* proximity ligation assay in human hippocampus, both AD groups had elevated nuclear levels of TFEB compared to age-matched controls, along with lower levels of the cytoplasmic 14-3-3 and TFEB complex, but were not significantly different from each other. We found further evidence in western blot of epilepsy brain tissue, as we noted that those patients with at least one copy of APOE ε4 have a great amount of nuclear TFEB without a corresponding increase in autophagy mRNAs. This implies a dysfunction in transcriptional upregulation of autophagy at a point between nuclear translocation and transcription. We have found that *in silico* simulations of ApoE4 protein have a stronger binding to the conserved nucleotide sequence for TFEB promotor regions, and therefore hypothesize that ApoE4 increases risk for disease, at least, in part by inhibiting compensatory upregulation of autophagy transcription. Supported in part by NIA AG12411, the Windgate Foundation, and STOP Alzheimer's.

Title: Integrated systems approach identifies gene networks in APOE3 & APOE4 expressing mice in response to HFD

Authors: *K. NAM[1], A. MOUNIER[1], C. M. WOLFE[1], N. F. FITZ[1], J. SCHUG[2], I. LEFTEROV[1], R. KOLDAMOVA[1];
[1]Envrn. and Occup. Heath, Univ. of Pittsburgh, Pittsburgh, PA; [2]Dept. of Genet., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Alzheimer's disease (AD) is a complex multifactorial disease with a significantly increased incidence of its late onset form in ε4 carriers, in individuals exposed to various risk factors, including diet, and higher prevalence in females. It has been demonstrated that high fat diet (HFD) exacerbates memory deficits and amyloid pathology also in APP transgenic mice. To get further insight in the effect of ApoE on the response to HFD, young APP mice expressing human ApoE3 or ApoE4 isoforms were fed HFD for 3 months and Morris Water Maze (MWM) task performed to assess spatial learning and memory retention. Following the behavior testing, brain tissue was collected for histological analysis and RNA-seq. To determine how ApoE isoforms and diet affect amyloid deposition, we measured compact and diffuse plaques by X-34 and 6E10 staining in hippocampus and cortex. To assess the effect of diet and ApoE isoform on the transcriptome, in APP mice genome-wide, we applied RNA-seq followed by Weighted Gene Co-expression Network Analysis (WGCNA). WGCNA organizes genes in functional groups (*modules*) based on topological overlap. We identified 15 modules associated with diet, APOE genotype and gender and further characterized 3 of them, representing immune response (GO:0006955), protein localization (GO:0015031) and regulation of transcription (GO: 0016481). We determined that immune response positively correlated to diet and APOE4 genotype in female mice. In contrast regulation of transcription was positively associated to diet in male mice. Highly connected hub genes, identified in each module (Trem2, Tyrobp, B2m, Cx3cr1 – immune response; Tgfb1, Cst, Nr2f6 – regulation of transcription; Appbp2, Med13, Ube3a – protein localization) were used to generate high connectivity gene networks. Selected genes within the hub gene networks were validated by RT-QPCR and western blot. The results clearly demonstrate that APOE isoform and gender affect the response to diet on transcriptional level.

Title: Dietary cholesterol increases neurodegenerative pathology through the blood-cerebrospinal fluid barrier in rabbits

Authors: *F. OBATA, R. MINAI, C. WANG, B. NING, M. NIIMI, J. FAN;
Univ. Yamanashi, Dept. Mol Pathol, Yamanashi, Japan

Abstract: Rabbit has been used as cholesterol-sensitive Alzheimer's disease (AD) model. We fed Japanese white rabbits with 0.3 % cholesterol diet for 16 weeks, which is a condition to induce hypercholesterolemia as well as atherosclerosis in aorta, but less severe condition than reported 1-2 % cholesterol diet AD models. And we used Watanabe Hereditary Hyperlipidemic (WHHL) rabbits as a high serum cholesterol control as they are hypercholesterolemic from very beginning of their lives. Bielschowsky's silver stain was performed to rabbit brains and neurodegenerative changes were recognized in cerebral cortex and hippocampus of WHHL rabbits in high degree but less in 0.3 % cholesterol diet group. In the choroid plexus, lipid-laden foam cells and cholesterol crystal lesions were apparent in WHHL, whereas small lesions of foam cells were recognized in 0.3 % cholesterol diet group. Normal chow diet group (0 % cholesterol control) had no foam cells in the choroid plexus. Rabbit macrophage-specific marker RAM11 immunohistochemisty (IHC) revealed that these foam cells are macrophagic origin. Apoliporotein CIII (ApoCIII) IHC showed positivity in the foam cells, choroid plexus epithelial cells and cilia of ependymal cells in 0.3 % cholesterol group and WHHL rabbits in which intensity of the stain was higher in WHHL. As ApoCIII is a component of very low-density lipoprotein (VLDL), which increases in hypercholesterolemia, and VLDL receptor is known to be expressed at the choroid plexus, the result suggests accumulation and transportation of cholesterol through the blood-cerebrospinal fluid barrier (BCSFB). On the other hand, Apoliporotein E (ApoE) IHC signals were increased in neuronal and glial cytoplasm but not in the choroid plexus and ependymal cells in hyperlipidemic rabbits. Upregulation of intrabrain ApoE under high serum cholesterol suggests that brain parenchyma senses increased cholesterol signal. Current study suggests that the BCSFB may serve as a novel route for cholesterol to enter brain parenchyma.

Title: Impaired cholesterol homeostasis contributes to the increased secretion of β-amyloid peptide in Familial Alzheimer's disease-associated presenilin mutant

Authors: *Y. CHO, O.-H. KWON, H. OH, S. CHUNG;
Sungkyunkwan Univ., Suwon, Korea, Republic of

Abstract: Cerebral deposition of amyloid β-peptide (Aβ) is crucial in the pathogenesis of Alzheimer's disease (AD). The highly amyloidogenic 42-residue Aβ (Aβ42) is the first species to be deposited in both sporadic and familial AD (FAD). Mutations in FAD-associated presenilin1 (PS1) and 2 (PS2) increase the ratio of Aβ42 over 40-residue (Aβ40). A PS mutant reportedly elevates the level of cholesterol due to the increased expression of CYP51, which is critical for cholesterol biosynthesis. Since elevated cholesterol is a well-known risk factor for AD, it may contribute to the increased Aβ production in PS1 mutant cells. However, this possibility has never been directly examined. In this study, we confirmed that the expression of CYP51 and cholesterol level were elevated in CHO cells transfected with PS1 ΔE9 mutant, compared to cells transfected with PS1 wild type (WT). The elevated cholesterol level in PS1 ΔE9 cells was decreased to a level comparable to that in PS1 WT cells by incubating cells with CYP51 specific inhibitor, tebuconazole. In PS1 ΔE9 cells, tebuconazole significantly decreased secreted level of Aβ42, but not that of Aβ40, confirming that the increase cholesterol level contributes to the increased Aβ42 from PS1 ΔE9 cells . In PS1 WT cells, however, levels of Aβ42 and Aβ40 were not affected by tebuconazole. When cholesterol was depleted by incubating cells in lipid depleted serum, the amount of decreased Aβ42 was larger than of Aβ40, suggesting that cholesterol level and Aβ42 level is closely linked. These results suggest that the impaired cholesterol homeostasis in FAD PS mutants contributes to increased Aβ42 production.

Title: Bexarotene discontinuation maintains behavioral improvement independent of changes in amyloid pathology

Authors: *B. CASALI, G. LANDRETH;
Neurosci., Case Western Reserve Univ., Cleveland, OH

Abstract: Treatment of Alzheimer's disease (AD), a neurodegenerative disorder characterized by pathological hallmarks of beta-amyloid (Aβ) plaque deposits, inflammation, and cognitive decline, remains a clinical obstacle in part due to the disease's lack of successful targeted therapies. Our lab established that short-term treatment with the RXR agonist bexarotene ameliorates amyloid pathology and reverses cognitive deficits in murine models of AD, but long-term treatment resulted in enhanced cognition despite no changes in amyloid plaque burden. This suggests that improved cognition may not strictly correlate with decreases in the pathological hallmarks of AD. Using the APP/PS1 murine model of AD, we find that not only does bexarotene improve short-term memory deficits after two weeks of treatment, but that this cognitive improvement is maintained despite a two-week discontinuation of bexarotene. Paradoxically, cognitive improvement was independent of changes in plaque burden and insoluble Aβ species, despite engagement of RXR target genes with bexarotene in both the two-week bexarotene treated and the bexarotene discontinued animals. *In vitro* studies modeling bexarotene discontinuation in primary astrocytes resulted in enhanced LXR target genes, confirming our *in vivo* findings. These data suggest that bexarotene may exert cognitive benefits in AD mouse models through different mechanisms from those classically observed previously. These findings may inform future clinical studies involving RXR agonists.

Title: Apolipoprotein E4 inhibits cerebral insulin signaling and insulin-regulated glucose metabolism

Authors: *N. ZHAO, C.-C. LIU, C. M. LINARES, M. M. PAINTER, G. BU;
Mayo Clin. Jacksonville, Jacksonville, FL

Abstract: Diabetes and impaired insulin signaling in the brain have been linked to the pathogenesis of Alzheimer’s disease (AD). Epidemiological studies show that diabetic patients are at higher risk for AD. The ε4 allele of the apolipoprotein E (*APOE*) gene is the strongest genetic risk factor for late-onset AD. Interestingly, the association between diabetes and amyloid pathology is stronger among *APOE4* carriers. In addition, recent clinical trials revealed that intranasal insulin administration significantly improves the cognitive function of AD patients in a manner that depends on *APOE* genotype. *APOE4* carriers, either as healthy adults or with dementia, have lower cerebral glucose metabolism in FDG-PET studies. Despite these observations in humans, the mechanism by which apoE isoforms differentially regulate brain insulin signaling and glucose metabolism remain unclear. Here we report apoE isoform-dependent glucose metabolism and insulin signaling in human apoE-targeted replacement (TR) mouse models. We found that cerebral blood flow was reduced in aged apoE4-TR mice compared with apoE3-TR mice. Aged apoE4-TR mice also had impaired insulin signaling and reduced capacity to metabolize cerebral glucose upon glucose challenge when examined by *in vivo* microdialysis. These effects were further exacerbated when apoE4-TR mice were fed with high-fat diet (HFD). At the cellular level, we found that apoE4 inhibited insulin signaling and insulin signaling-regulated mitochondrial respiration and glycolysis in primary neurons, likely by reducing the amount of insulin receptor at the cell surface. Together, our studies provide novel insights into the pathogenic mechanisms of apoE4 and insulin resistance in AD and have implications in
designing apoE-targeted therapy to improve cerebral insulin signaling and glucose metabolism to treat AD.

Title: Effect of apoe e4 variant on progression from mild cognitive impairment to alzheimer's disease

Authors: *B. P. TAYLOR[1], S. RISACHER[3], J. KRANTZ[2];
[2]Psychology, [1]Hanover Col., Hanover, IN; [3]IUPUI Neurosci. Ctr., Indianapolis, IN

Abstract: Alzheimer's disease is a very prevalent and fatal disorder in older adults, and Mild Cognitive Impairment is often seen as a precursor to Alzheimer's disease. Alzheimer's disease is a form of Dementia that is characterized by loss of cognitive abilities while aging. It is ultimately fatal. Mild Cognitive Impairment is more of an intermediate stage between normal mental decline with aging and the more serious decline of dementia. The ApoE E4 gene has been shown to be highly correlated with a greater likelihood of acquiring late-onset Alzheimer's disease. This study looked to see the effect that the ApoE E4 gene has on the rate of brain volume loss (specifically in the hippocampus, entorhinal cortex, and cerebral cortex) in patients who transition from Mild Cognitive Impairment to Alzheimer's disease. This was done by comparing people, gathered from the Alzheimer's Disease Neuroimaging Initiative, with Mild Cognitive Impairment who test positive for the E4 allele vs. those with Mild Cognitive Impairment who test negative for the E4 allele, to see which group has a faster loss of brain volume to Alzheimer's disease. My study found that testing positive for the E4 allele led to faster neurodegeneration in both people with Mild Cognitive Impairment who converted to Alzheimer's and even those who did not convert to Alzheimer's. This study is beneficial because it could provide further insight into the potential genetic cause of Alzheimer's disease, especially if the study is replicable. It is unique from other studies of this nature because it involves a new cohort.

Title: An HDL-mimetic peptide increases secretion and lipidation of human apoE

Authors: *D. S. CHERNICK[1], G. W. REBECK[3], L. LI[1,2];
[1]Pharmacol., [2]Exptl. and Clin. Pharmacol., Univ. of Minnesota, Minneapolis, MN; [3]Neurosci., Georgetown Univ., Washington, DC

Abstract: The Apolipoprotein E (apoE) ε4 allele is the primary genetic risk factor for late-onset Alzheimer's disease (AD). ApoE in the brain is produced primarily by astrocytes and microglia. Once secreted, apoE binds lipids and forms high-density lipoprotein (HDL)-like particles in the interstitial and cerebrospinal fluid. ApoE interacts with Aβ, and the level and lipidation state of apoE affects Aβ aggregation and clearance pathways. ApoE may also play a role in AD via effects on cholesterol/lipid metabolism, synaptic plasticity, cell signaling, and inflammation. Apolipoprotein A-I (apoA-I) and HDL levels are inversely correlated with AD risk and severity, and overexpression of human apoA-I attenuated memory deficits in a mouse model of AD. ApoA-I has been shown to increase apoE secretion in both peripheral macrophages and primary mixed glia. We have previously shown that 4F, an apoA-I mimetic peptide, increases both secretion and lipidation of apoE in primary murine glial cells. The current study aims to determine the ability of 4F to recapitulate this effect on human apoE. In order to perform these studies we have used immortalized human targeted-replacement apoE3 and apoE4 mouse astrocytes. Preliminary experiments show that 4F increases secretion and lipidation of both apoE3 and apoE4 in these astrocytes. Future studies aim to elucidate whether the effects of 4F on apoE3 and apoE4 are differential, and whether the increase in apoE lipidation occurs *in vivo*. ApoE as a therapeutic target for AD remains controversial due to the detrimental potential of increasing apoE4 levels. However, by improving the lipidation status of apoE4, many of its deleterious effects may be ameliorated. Finally, we will determine whether 4F is capable of reducing pathology and memory deficit in mouse models of AD.

Title: Tocotrienols for Alzheimer's disease: vitamin E beyond tocopherols

Authors: *W. XIA[1,2], C.-L. SHEN[3], H. MO[4];
[1]Dept. of Pharmacol. & Exptl. Therapeut., Boston Univ. Sch. of Med., Boston, MA; [2]Grecc, ENR Mem. Veterans Hosp., Bedford, MA; [3]Pathology, Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [4]Nutr., Georgia State Univ., Atlanta, GA

Abstract: Neuropathological hallmarks in brains of Alzheimer's disease (AD) patients include amyloid β protein containing neuritic plaques and Tau containing neurofibrillary tangles. Multiple therapeutics have been tested to reduce the pathological burden and to maintain cognitive function. However, currently there is no cure for AD. One promising therapeutic direction is based on the observation that lower incidents of AD and mild cognitive impairment (MCI) have been reported in populations exposing to higher levels of vitamin E, particularly tocotrienols, but not tocopherols. In this study, we compared tocotrienols to statins, which target 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase and decrease downstream levels of farnesyl pyrophosphate (FPP) and geranylgeranyl pyrophosphate (GGPP), intermediate products of cholesterol metabolism. In murine 3T3-F442A adipocytes, tocotrienols induced a dose-dependent reduction of the membrane HMG-CoA reductase. As a consequence of tocotrienol-mediated depletion of FPP and GGPP, prenylation of small GTPase is impaired, rendering unprenylated Ras prone to degradation; in human melanoma cells, we found that tocotrienols induced dose-dependent reduction of Ras protein. We analyzed levels of Aβ and Tau after chronic dosing with tocotrienols in a high-fat-diet induced obese mice for 3 months. Tocotrienols exhibited efficacy similar to statins that reduce Aβ in cells and animals. Our studies will provide results from cellular and animal studies to explore whether tocotrienols exert protection against AD without the dose-limiting toxicities of statins.

Title: Molecular mechanism and functional effect of apoE-TREM2 interaction in microglia

Authors: *Y. ATAGI, M. M. PAINTER, C.-C. LIU, J. D. FRYER, G. BU;
Neurosci., Mayo Clin. Florida, Jacksonville, FL

Abstract: Mutations in the triggering receptor expressed on myeloid cells 2 (TREM2) have been identified as risk factors for late-onset Alzheimer’s disease (LOAD). In the central nervous system (CNS), TREM2 is expressed primarily in microglia, and shown to play important roles in controlling neuroinflammatory events including phagocytosis and production of pro-inflammatory cytokines. Recently, we have identified apolipoprotein E (apoE), a lipid carrier and the strongest genetic risk factor for LOAD, as a novel, endogenous ligand of TREM2. Interestingly, AD risk-associated TREM2 variants have reduced binding to apoE, which promotes phagocytic uptake of apoptotic neurons by microglia in a TREM2-dependent manner. In this study, we have further characterized the molecular mechanism and functional importance of apoE-TREM2 interaction. Using biochemical approaches, we have defined TREM2-binding domain on apoE. As phospholipids have also been shown to bind to TREM2, we further investigated the biochemical relevance and functional significance of apoE-TREM2 interaction using reconstituted liposomes containing defined amounts of phospholipid, cholesterol, and apoE. Our studies provide molecular insights into the apoE-TREM2 interaction and have implications in designing strategies targeting apoE-TREM2 interaction to treat AD.

Title: Effects of Liver X receptor agonist treatment on Alzheimer's disease-like phenotype and neuronal regulatory networks in human APOE3 and APOE4-targeted replacement mice

Authors: *N. F. FITZ[1], A. MOUNIER[1], C. W. WOLFE[1], A. Y. CARTER[1], K. NAM[1], J. SCHUG[2], I. LEFTEROV[1], R. KOLDAMOVA[1];
[1]Envrn. and Occup. Hlth., Univ. of Pittsburgh, Pittsburgh, PA; [2]Functional Genomics Core, Dept. of Genet., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Inheritance of ε4 allele of APOE is the major genetic risk factor for late-onset Alzheimer disease (AD), however, the true biochemical mechanisms underlying this association remain elusive. Epidemiological and clinical studies have suggested a link between cholesterol metabolism and AD pathology. In the CNS, cholesterol and lipoprotein metabolism is important for normal neuronal function as well as for Aβ aggregation and clearance from the brain. The liver X receptors (LXRs) and Retinoid X Receptors (RXR) are transcription factors that control the expression of genes involved in cholesterol and lipoprotein metabolism. One of the major LXR/RXR target genes is ATP binding transporter A1 (ABCA1) that regulates cholesterol efflux and is essential mediator of HDL level in plasma and brain. We have shown that the lack of ABCA1 in APP transgenic mice results in almost complete absence of HDL, diminished ApoE and correlated increase in parenchymal amyloid plaques and oligomeric Aβ. We previously confirmed that RXR agonist treatment resulta in reversal of memory deficits in APP/PS1ΔE9 mice expressing human APOE3 or APOE4 to the levels of their nontransgenic controls and significant increase in Aβ clearance, but no effects on amyloid deposition. Furthermore, we were the first to show RXR agonist treatment affected signaling pathways associated with neurogenesis and neuron projection development and can ameliorated the damaged dendrite complexity and loss of neurites caused by $A\beta_{42}$. Here we wanted to examine the therapeutic potential of a LXR ligand to ameliorate AD phenotype, in APP/PS1ΔE9 mice expressing human APOE3 and APOE4. Furthermore using Abca1 deficient mice expressing APOE3/4 determine if

the therapeutic potential of LXR ligands is mediated through Abca1. All mice were treated for 1 month with T0901317 (20mg/kg mouse; T0) in the normal rodent chow starting at 5 months of age. The mice were compared for behavioral, amyloid deposition, and transcriptional profiles in the brain. Our data demonstrate that T0 is able to reverse behavioral deficits in both APOE isoforms compared to mice fed control diet. There was no significant change in the levels of amyloid deposition. The results of this study will reveal transcriptional changes initiated by LXR activation and how these modifications impact AD pathology. The ability to associate changes at gene expression level, or transcript enrichment within gene networks and clusters, to pathogenic phenotypes of AD will have a significant impact on defining the therapeutic mechanisms of LXR ligands in AD.

Title: Apolipoprotein E and ageing: How is genetic risk and resilience for Alzheimer's disease represented within the resting brain?

Authors: *S. SURI[1], N. FILIPPINI[1], A. TRACHTENBERG[1], V. HEISE[1], E. ZSOLDOS[1], A. MAHMOOD[1], A. SINGH-MANOUX[2], M. KIVIMAKI[2], K. EBMEIER[1], C. MACKAY[1]; [1]Univ. of Oxford/Department of Psychiatry, Oxford, United Kingdom; [2]Dept. of Epidemiology & Publ. Hlth., Univ. Col. London, London, United Kingdom

Abstract: The apolipoprotein E (*APOE*) gene has three alleles (ε2, ε3, ε4) that differently influence lifetime risk for developing late-onset Alzheimer's disease (AD). *APOE* ε4 is the best-established genetic risk factor for sporadic AD, whereas the ε2 allele may be protective. We (and others) have previously shown that ε4 influences brain function decades before potential cognitive decline, but that its effects on cognition and brain activity may vary with age. Paradoxically, the ε4 allele appears to confer a cognitive advantage in younger ages, and exert its deleterious effects in later life. However, little is known about the equivalent for ε2, which remains largely under-investigated. Studying ε2 would not only complement our current understanding of the complex effects of ε4, but could also lend valuable insights into why ε2 carriers lead relatively long and healthy lives.

Here, we present the first comprehensive analysis of functional connectivity (FC) of the brain in carriers of all three *APOE* alleles. AD patients exhibit disruptions in FC, measured as correlations in spontaneous activity between remote regions within the resting brain. Accordingly, altered resting-state FC, particularly within a network called the "default mode network", has gained attention as a potential biomarker of the neurodegenerative process. We therefore asked whether genetic risk and protection for AD were differently represented within the resting brain across the lifespan, with a particular focus on "default mode" areas.

Fifty-four cognitively healthy younger (20-40 years, 17ε2/19 ε3/18ε4 carriers), 84 middle-aged (40-55 years; 25ε2/24ε3/35ε4 carriers) and 291 older individuals (60-85 years; 36ε2/191ε3/64ε4 carriers) received a 3T resting-state functional MRI scan. *APOE*-related differences were studied using FSL tools. We performed a detailed examination of FC using (1) a seed in the posterior cingulate cortex, which is a key hub of the default mode network, (2) large-scale resting-state networks, and (3) recently developed network modeling techniques that allow for a richer analysis of network connections (FSLNets). We find that like ε4, the effects of ε2 on FC appear to be age-specific. Thus while younger ε2 carriers show significantly lower FC of the posterior cingulate cortex relative to ε3 homozygotes and ε4 carriers, the opposite effect is observed in older individuals ($P<0.05$, corrected for voxel-wise multiple comparisons). We suggest a critical "transition" phase (40-60 years) during which the effects of ε2 and ε4 on FC appear to cross over. This may be a particularly useful age-range for participants of clinical trials targeting preventative treatments.

Abstract: Introduction: Alzheimer's disease (AD) is associated with white matter (WM) microstructure abnormalities revealed by diffusion tensor imaging (DTI) method. The apolipoprotein-E epsilon4 (APOE-ε4) allele is a major genetic risk factor for AD, which may also impact WM microstructure such as demyelination and axonal damage. However, the current DTI model suffers from the partial volume effect, therefore preventing accurate quantification of WM abnormalities in AD patients. Free-water (FW) imaging can solve this problem by differentiating the water compartment in the extracellular space from the tissue compartment in a voxel-based manner using DTI data. Here, using FW techniques in subjects with no cognitive impairment (NCI), mild cognitive impairment (MCI), and AD, we hypothesized that APOE-ε4 carriers and non-carriers would have differential trajectories of WM damage along the AD progression.
Methods: 167 subjects (13 NCI carriers, 50 non-carriers; 22 MCI carriers, 35 non-carriers; and 18 AD carriers, 29 non-carriers) underwent DTI scans (Siemens Tim Trio, 3T, 61 diffusion directions at b=1150 s/mm^2 and 7 b0 maps). The DTI data were preprocessed using FSL. FW method was applied to derive the individual FW and tissue compartment maps. To access the group difference in FW and tissue compartments (carriers vs. non-carriers in NCI, MCI and AD),

we carried out voxel-wise statistics on the FW and tissue compartments images using two-sample t-tests. All analyses were controlled for age, gender, handedness, and ethnicity. **Results:** There was no difference in FW and tissue compartments between carriers and non-carriers in AD and NCI group. In MCI group, carriers had higher WM FW mostly at posterior temporal/parietal and occipital regions compared to non-carriers. Tissue compartment did not differ. Moreover, we extracted the mean FW values of these significant regions identified from the MCI group and compared the carriers and non-carriers across the three groups. Differential trajectories of WM FW in carriers and non-carriers across the three groups were observed: in carriers, there was WM FW increase in MCI compared to the NCI; in contrast, in non-carriers, there was WM FW increase in AD compared to MCI stage but not MCI compared to NCI. **Conclusion:** Our findings suggest that APOE genotype influences the FW concentration of WM in MCI. APOE-ε4 carriers may feature an early increase in neuroinflammation, making them more vulnerable to Alzheimer's disease.

Title: A03 reverses ApoE4-induced reductions in SirT1 *In vitro*

Authors: J. CAMPAGNA[1], P. SPILMAN[1], D. BAI[1], H. ROLLINS[2], R. DAMOISEAUX[3], J. PHAM[4], T. BILOUSOVA[1], B. JAGODZINSKA[1], M. JUNG[4], D. E. BREDESEN[1], *V. JOHN[5]; [1]Neurol., [3]MSSR, [4]Chem., [2]UCLA, Los Angeles, CA; [5]Neurol., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Expression of apolipoprotein ε4 (ApoE4) is the major genetic risk factor for sporadic, late-onset Alzheimer's disease (LOAD). The recent studies of Theendakara et al. (2013, 2015) have shown that one of the contributing factors to increased AD risk is likely reduction expression of the major longevity determinant sirtuin 1 (SirT1) in ApoE4-positive individuals. As patients suffering from AD have lower SirT1 (Kumar et al. 2013), lower prodromal levels may put individuals closer to a threshold for disease development. Thus, therapeutics that can increase SirT1 in the presence of ApoE4 my confer protection against disease development or

may be of therapeutic benefit after Mild Cognitive Impairment (MCI) or AD onset. To identify such a compound, we screened a small clinical compound library using human neuroblastoma A172 cells transiently transfected with ApoE4 and found selective serotonin-reuptake inhibitor alaproclate ("A03") increased SirT1 as determined by AlphaLISA (Perkin-Elmer). A03 was validated using stably ApoE4-transfected N2a cells. In addition, A03 increase trophic amyloid precursor protein (APP) fragment soluble APP alpha (sAPPα). A03 showed good brain-penetance and a good brain:plasma ratio in *in vivo* pharmacokinetics studies comprising oral and subcutaneous (SQ) injection of adult wildtype mice with A03 at 10 mg/kg and euthanasia of mice at 1, 2, 4, 6, and 8 hours post-dosing. A03 levels in brain and plasma were measured at Integrated Analytical Solutions (IAS), and Pk parameters were calculated using PK Solutions software (Summit PK). Pilot *in vivo* efficacy studies were run using ApoE4 targeted replacement (ApoE4 TR) and ApoE4 TR x 5XFAD (APP with 3 mutations, presenilin 1 with two mutations) mice, with dosing by SQ injection at 10 mg/kg/day for 28 days. Levels of SirT1 were determined in frontal and parietal cortex of study mice as it has been reported that SirT1 is lower in frontal cortex of ApoE4 TR mice (Lattanzio et al. 2014). There was a trend toward SirT1 and sAPPα increases in ApoE4 TR mice and no observable side-effects or toxicity. A03 is the first compound reported to increase SirT1 and sAPPα *in vitro* in presence of ApoE4 expression. The trends towards SirT1 and sAPPα enhancement *in vivo* were promising as well as the absence of any apparent toxicity. Future studies will be directed toward identification of additional SirT1 enhancers, as well as to A03 analog development to identify a lead compound with greater *in vivo* efficacy.

Title: APOE genotype effects on cortical folding of Alzheimer's Disease patients, MCI and healthy people

Authors: *A. FANG[1], R. TORO[2], J. LEWIS[1], A. EVANS[1];
[1]Montreal Neurolog. Institute, McGill Univ., Montreal, QC, Canada; [2]Inst. Pasteur, Paris, France

Abstract: Objectives To examine the relationship between APOE genotype and cortical folding degree. **Methods** Data from the Alzheimer's disease Neuroimaging Initiative (ADNI) was used. A fully automated structural MRI image processing pipeline (CIVET 2.0) was utilized for data analysis of totally 510 AD, late mild cognitive impairment (LMCI), early mild cognitive impairment (EMCI), and age-matched healthy controls (NC) from the longitudinal Alzheimer's Disease Neuroimaging Initiative (ADNI), of whom 198 were homozygous for the APOE ε3 allele, 166 were homozygous for the APOE ε4 allele, while 146 were heterozygous for the APOE ε3 and ε4 alleles. Cortical folding degree analysis was done with software package "Surface Ratio". Statistical analysis was performed with MATLAB software. **Results** In all four groups, the cortical folding degrees of the people with different genotypes decreased with the development of the disease. In NC and EMCI groups, the cortical folding degrees of both APOE ε3 homozygous carriers and APOE ε3ε4 heterozygous carriers were significant larger than APOE ε4 homozygous carriers (All $p<0.01$, Table 1&2). In LMCI and AD groups, the cortical folding degrees of and APOE ε3ε4 heterozygous carriers were significant larger than APOE ε4 homozygous carriers (LMCI: $p<0.01$; AD $p<0.05$, Table 1&2).

	ε3 homozygous	**ε3 ε4 heterozygous**	**ε4 homozygous**
AD	3.86 ± 0.02	3.76 ± 0.06	3.75 ± 0.01
LMCI	3.90 ± 0.02	3.84 ± 0.02	3.81 ± 0.02
EMCI	3.94 ± 0.02	3.92± 0.02	3.91 ± 0.02
NC	3.96 ± 0.02	3.92 ± 0.02	3.85 ± 0.02

Table 1. Cortical folding degrees of different group/genotype

AD ε3 ε3 vs. ε3 ε4	**AD ε3 ε3 vs. ε4 ε4**	**AD ε3 ε4 vs. ε4 ε4**
P=0.05	P=0.75	P<0.05
LMCI ε3 ε3 vs. ε3 ε4	**LMCI ε3 ε3 vs. ε4 ε4**	**LMCI ε3 ε4 vs. ε4 ε4**
P=0.14	P=0.50	P<0.01
EMCI ε3 ε3 vs. ε3 ε4	**EMCI ε3 ε3 vs. ε4 ε4**	**EMCI ε3 ε4 vs. ε4 ε4**
P=0.27	P<0.01	P<0.01
NC ε3 ε3 vs. ε3 ε4	**NC ε3 ε3 vs. ε4 ε4**	**NC ε3 ε4 vs. ε4 ε4**
P=0.12	P<0.01	P<0.01

Table 2. p-values between different group/genotype **Conclusions** The preliminary results suggest an effect of the APOE ε4 allele on cortical folding degrees. APOE genotype may play a critical role in human gyrification indices. APOE ε4 carriers might have less folding in the brain from very early stages of AD, even there is no disease onset. Investigation of the relation between APOE genotype and cortical folding degrees may lead us to predictive biomarkers and drug targets of dementia.

Title: Sex and ApoE e4 gene dose effects on lateralized hippocampal volumes in older adults with normal cognition, mild cognitive impairment, and Alzheimer's disease

Authors: *Z. HOBEL, B. SHEN, J. PA;
Mark and Mary Stevens Neuroimaging and Informatics, Los Angeles, CA

Abstract: The apolipoprotein E epsilon 4 allele (APOE4) is the major genetic risk factor for late onset Alzheimer's dementia (AD) and is associated with smaller hippocampal volume. A previous study suggests that, in individuals with mild cognitive impairment (MCI), reductions in hippocampal volume may be related to sex and APOE4 gene dose. However, the effect of sex and APOE4 gene dose on lateralized hippocampal volumes in a large cohort has not been examined. We investigated the relationship between sex, APOE4 genotype, and both left and right hippocampal volumes in older adults with normal cognition (NC), MCI, and AD.
T1 MRI data and demographics for NC, MCI and AD subjects were acquired from 4 large, publicly available cohorts (ADNI, AIBL, NACC, and PPMI; n=2464). Hippocampal segmentation and volume measurements were completed using FreeSurfer and visually inspected for accuracy. Hippocampal volumes (HCV) were adjusted for age and total intracranial volume. ANOVA and posthoc t-tests were performed to compare HCV across APOE4 genotypes within each diagnosis group and sex.
Our main finding is that NC subjects showed a lateralized, APOE4-related reduction in HVA which was dose-dependent in women. For NC women, the left HCV was significantly smaller with increasing APOE4 alleles, while the right HCV was only smaller with 2 alleles. NC Men had significantly smaller right HCV only with both 1 and 2 APOE4 alleles when compared to

non-carriers, and did not show a APOE4 dose effect. In subjects with MCI, the APOE4 dose effect was observed in women in both the left and right HCV, while men showed an APOE4 dose effect in only the left HCV. A trend for a dose effect was observed in the left HCV of both male and female AD patients. Regardless of diagnosis or sex, APOE4 carriers had smaller left and right HCV compared to non-carriers. This trend was true for all subjects, although it did not reach significance for the left HCV of NC men.
In the absence of cognitive symptoms, the APOE4 allele appears to have a differential effect on male and female HCV, associated with smaller left hippocampus in women and right in men. In terms of an APOE4 dose effect, NC and MCI women showed this effect in both hippocampi, while NC men showed no dose effect and MCI men only had a dose effect in the left HCV. AD men and women both exhibited the dose effect in left HCV but not right. Taken together, our results suggest that hippocampi of NC and MCI women are more negatively affected by the presence of 2 APOE4 alleles than men. Longitudinal studies of these cohorts are needed to examine the differential impact of sex, APOE4 alleles, and baseline left and right hippocampal volumes on future cognitive function and conversion to dementia.

Title: Mechanism for APOE4-induced Alzheimer’s disease risk predicts therapeutic targets

Authors: *N. C. COLLINS[1], J. GEORGE[1], S. GHURA[1], A. VALENCIA[1], L. VAN ELDIK[2], M. LADU[1];
[1]Anat. and Cell Biol., Univ. of Illinois At Chicago, Chicago, IL; [2]Sanders-Brown Ctr. on Aging, Univ. Of Kentucky, Lexington, KY

Abstract: Alzheimer's disease (AD) is the most common form of dementia, representing a significant social and financial burden. Soluble forms of the amyloid-β (Aβ) peptide, including oligomeric Aβ (oAβ) and Aβ42, are likely the proximal neurotoxins in AD. The greatest genetic risk factor for AD is the *APOE4* allele of apolipoprotein E (apoE), which increases risk up to 15-fold compared to the more common *APOE3* allele. Aβ levels are higher with *APOE4* than *APOE3*, evidence that apoE isoforms differentially modulate the aggregation and clearance of Aβ. Our overall hypothesis is that apoE4 is less lipidated than apoE3, leading to lower apoE4/Aβ complex levels and higher soluble Aβ levels, resulting in synaptic loss and eventual dementia. In EFAD mice (transgenic mice that overexpress human Aβ42 and express one of the human apoE isoforms), apoE4 is less lipoprotein-associated than apoE3, based on the reduced levels of apoE4 extracted in the lipid-soluble extraction fraction. In addition, apoE/Aβ complex levels are lower and soluble Aβ levels are higher in E4FAD mice compared to E3FAD mice. Using human brain samples from our collaboration with the University of KY, the goal of this study is to validate these observations in control and AD samples with genotypes *APOE3/3, APOE3/4,* or *APOE4/4.* Analysis demonstrated that lipoprotein-associated apoE is significantly lower in AD patients with the *APOE4/4* genotype vs. *APOE3/3* AD patients and all genotypes in the control cohort. Soluble Aβ (oAβ and Aβ42) levels are higher in the AD cohort compared to the control cohort, and are highest in AD patients with an *APOE4/4* genotype. Finally, apoE/Aβ complex levels are higher in both control and AD subjects with *APOE3/3* than complex levels in both control and AD subjects with *APOE4/4*. These results are consistent with the hypothesis that *APOE4* causes a reduction in apoE lipidation and apoE/Aβ complex, resulting in inefficient clearance of soluble Aβ, synaptic loss, and dementia. Together, these results suggest apoE lipidation as a potential therapeutic target for *APOE4*-induced AD risk.

Title: Apolipoprotein E4 drives amyloid pathology in an inducible mouse model - Effects at different stages of amyloid pathology

Authors: *C.-C. LIU, N. ZHAO, N. WANG, J. ROGER, C. LINARES, C.-W. TSAI, G. BU; Neurosci. Res. Dept., Mayo Clin., Jacksonville, FL

Abstract: Accumulation of amyloid-β (Aβ) peptide in the brain is a critical and perhaps initiating event in the pathogenesis of Alzheimer's disease (AD). Aβ accumulation leads to the formation of Aβ aggregates which disrupt synaptic functions and may lead to eventual neurodegeneration. Among the three polymorphic alleles, the ε4 allele of the apolipoprotein E (*APOE*) gene is the strongest genetic risk factor for sporadic AD. In addition to increasing the prevalence of AD, the presence of *APOE4* also lowers the age of onset. Although there is strong evidence from both humans and animal models that apoE4 enhances amyloid pathology, the critical period when apoE4 has the strongest effects on amyloid pathology is not clear. We have developed cell type-specific, inducible mouse models in which the expression of apoE isoforms can be turned on or off in a cell type-specific manner. Using these models, we found that overexpression of apoE4 in astrocytes during the initial seeding stage as oppose to the rapid growth period is critical for its effect on accelerating amyloid and promoting astrogliosis and microgliosis in the background of $APP_{SWE}/PS1_{\Delta E9}$ amyloid model mice. By measuring Aβ half-life using *in vivo* microdialysis, we found that apoE4 inhibits Aβ clearance. Overexpression of apoE3 did not affect the amyloid plaque load or Aβ clearance, but did enhanced synaptic plasticity measured by long-term potentiation. Together, our results define a critical role of apoE4 in driving amyloid pathology during the initial seeding period, likely by inhibiting Aβ clearance and promoting Aβ aggregation. Our findings provide novel mechanistic insights into differential functions of apoE isoforms in amyloid pathogenesis and have implications for designing mechanism-based, apoE-targeted AD therapy.

Title: Alterations in the density of neurotransmitter receptors in the brain of the zQ175KI mouse model of Huntington's disease

Authors: T. HUHTALA[1], J. RYTKÖNEN[1], *T. PARKKARI[1], P. J. SWEENEY[1], O. KONTKANEN[1], L. C. PARK[2], L. MRZLJAK[2];

Abstract: Huntington's disease (HD) is a neurodegenerative genetic disorder that affects brain functions, muscle coordination and leads to cognitive decline and psychiatric problems. In HD patients, changes in expression of receptors for neurotransmitters, such as glutamate, dopamine, GABA, acetylcholine and adenosine, have been reported. In order to determine if similar changes can be also detected in the zQ175KI knock-in mouse model of HD, we applied autoradiography to compare receptor densities of dopamine 1 (D1R), dopamine 2 (D2R), cannabinoid 1 (CB1) and gamma-aminobutyric acid (GABA) receptors in the brain of wild-type (WT) and heterozygous (HET) mutant male mice at the age of 6, 9, 12 and 15 months. For receptor density analysis, coronal brain sections were prepared and Bmax values of corresponding tritiated ligands to D2R (^{3}H-raclopride), D1R (^{3}H-SCH-23390), CB1 (^{3}H-MePPEP) and $GABA_A$ (^{3}H-flumazenil) receptors were measured. Specific binding of each ligand in the globus pallidus, substantia nigra, striatum, somatomotor cortex and cingulate cortex was calculated as the difference between total and non-specific binding. Bmax values were determined using non-linear regression analysis. We observed significantly ($P < 0.05$) lower densities of D2R and D1R in the striatum of HET mice compared to values detected in WT. Furthermore, the density of CB1 receptors in the globus pallidus, substantia nigra and striatum was also lower in HET mice. In contrast, a significant increase in the $GABA_A$ receptor density was noted in the globus pallidus, substantia nigra, striatum and cingulate cortex of HET mice. We conclude that alterations in the density of several neurotransmitter receptors in the brain of the zQ175KI mouse HD model largely replicate clinical findings in humans.

Title: Changes in cerebral blood flow in conscious zQ175KI Huntington’s disease mouse model mice

Authors: *T. HUHTALA[1], J. RYTKÖNEN[1], L. TOLPPANEN[1], P. J. SWEENEY[1], T. PARKKARI[1], O. KONTKANEN[1], L. C. PARK[2], L. MRZLJAK[2];
[1]Charles River Discovery, Kuopio, Finland; [2]CHDI Management/CHDI Fndn., Los Angeles, CA

Abstract: Huntington's disease (HD) is a neurodegenerative genetic disorder that affects brain functions, muscle coordination and leads to cognitive decline and psychiatric problems. Glucose

metabolism and cerebral blood flow (CBF) are useful correlates of brain functions, as changes in these parameters are often associated with clinical symptoms in neurodegenerative disorders. In HD patients, cerebral artery flow is significantly lower than in control subjects. In order to determine if similar changes can be also detected in a mouse HD model, we used autoradiography to compare brain perfusion in conscious zQ17KI heterozygote (HET) and wild-type (WT) male mice at the age of 9 and 12 months. One of the major challenges to study neurological function in rodents is the necessity to use restraint, anesthesia or paralyzing agents, all of which impact neuronal function. Delivery of a radiotracer that reaches cerebral equilibrium within a short time frame may allow imaging of an immediate neuronal effect with great temporal resolution. One of the most applicable tracers in this regard is ^{14}C-iodoantipyrine, whose concentration is strictly linearly dependent on tissue radioactivity and CBF when data are captured within a brief interval (~10 s) after the tracer injection. Therefore, in this study, we applied ^{14}C-iodoantipyrine as a radiotracer to study CBF in conscious WT and HET mice. To be able to capture CBF of conscious animals, mice were cannulated into the jugular vein. After the mice had recovered from the surgery, they were connected to a tether, and the radiotracer was injected followed by immediate dosing of the terminal solution. Brains were collected, sectioned in the coronal plane at a 100-µm interval and radioactivity was quantified by autoradiography. We observed that in the 9-month-old zQ175KI HET mouse brains, a lower amount (by 3-25 %) of the perfusion tracer was detected in all studied regions (cortex, striatum, hippocampus and cerebellum), compared to the levels determined in WT mice. In the subsequent study, a similar comparison will be carried out between the brains of 12-month-old zQ175KI HET and WT mice to understand how disease progression affects CSF in this animal model.

Abstract: Huntington's disease (HD) is a fatal neurodegenerative genetic disorder characterized by movement and psychiatric impairment as well as cognitive decline. The genetic background of HD contains the abnormal expansion of the glutamine repeats in the huntingtin gene (HTT) in addition to dysregulated expression profiles of several other key genes, such as dopamine receptors, cannabinoid receptor, dopamine and cAMP-regulated phosphoprotein and phosphodiesterase 10A (PDE10A). Branched DNA (bDNA) signal amplification technology enables the multiplex measurement of 3-80 target genes directly from tissue homogenates or from RNA samples with unparalleled accuracy and precision. In this study, the bDNA methodology was used to analyze the cortex and striatum homogenate samples from two separate animal models of HD; 6 and 12 weeks old wild-type and transgenic R6/2 mice as well as 3, 6, 9, 11 and 16 months old wild-type and heterozygote zQ175 knock-in (HET zQ175 KI) mice. The expression levels of several typical target genes related to HD were analyzed and compared to standard qPCR methodology in terms of robustness and data variability. The use of bDNA technology showed statistically significant ($p < 0.05$) changes in the expression levels of several HD key genes in the HET zQ175KI male mice when compared to the WT mice. For example, PDE10a, Drd2 and Cnr1 expression levels in 9 mo HET zQ175 KI mouse brains are expressed at 61 %, 67 % and 32 %, respectively, compared to those in aged-matched WT. Furthermore, the data from bDNA methodology was similar to data from qPCR but showed less variation even when using small number of samples. The current study demonstrates the value of the bDNA methodology as a useful tool for the assessment of gene expression changes in genetically modified animals.

Title: Episodic memory and cognitive flexibility in the Hdh^{Q111} mouse model of Huntington's disease

Authors: *A. MARIANO[1], O. MONTEIRO[1], E. MOSS[1], C. BRAZAITIS[1], V. BROWN[2], J. LAMBERT[1], R. LANGSTON[1];

[1]Div. of Neurosci., Univ. of Dundee, Dundee, United Kingdom; [2]Sch. of Psychology and Neurosci., Univ. of St Andrews, St Andrews, United Kingdom

Abstract: Huntington's disease (HD) is a progressive, fatal neurodegenerative disorder caused by an unstable trinucleotide (CAG) repeat expansion within the Huntingtin gene, which initiates a chain of downstream toxic events affecting brain function. Although HD is mainly known as a motor disease and is usually associated with movement dysfunctions, recent finding have provided evidence that cognitive deficits can appear up to 15 years before the motor symptoms, during the prodromal phase of the disease. Our mouse model of HD, the heterozygous Hdh^{Q111} mouse ($Hdh^{Q111+/-}$), accurately recapitulates the protracted prodromal disease phase and provides a window of time during which the cognitive phenotype of this mouse can be characterized. Using a battery of memory tests that rely upon spontaneous novelty detection in mice, we have shown substantive deficits in hippocampus-dependent episodic-like associative memory by 10-12 weeks of age in the $Hdh^{Q111+/-}$ mouse. However, using the Morris water maze paradigm, we do not observe any impairment in hippocampal-dependent spatial learning or long-term memory at the same age (3 months) or even by 10 months of age. When presented with a serial reversal learning task, 10-month old $Hdh^{Q111+/-}$ mice showed mild deficits in memory flexibility compared to wild type littermates. *When trained to criterion, in fact,* $Hdh^{Q111+/-}$ mice take significantly longer to learn a new platform location. It has previously been shown that water maze training is associated with a mild stress reaction and increased corticosterone levels that might affect learning performance of the mice. Therefore, detection of corticosterone levels in blood samples is underway to determine whether a difference in the stress response between tasks and/or between genotypes could be the reason for the apparent discrepancy in hippocampal learning and memory performance in these different behavioural conditions.

Title: Adaptation of a home-cage motor learning task to assess behaviour in the YAC128 model of Huntington's disease

Authors: C. L. WOODARD, F. BOLAÑOS, J. D. BOYD, G. SILASI, T. H. MURPHY, *L. A. RAYMOND;
Dept Psychiatry and Ctr. for Brain Hlth., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Behavioural testing of disease models in rodents can be useful in assessing the extent of cognitive and physical impairment, as well as evaluating the efficacy of potential interventions. However, many traditional behavioural paradigms involve testing the animal for short periods in stressful or unfamiliar environments, often during times of the day when they would typically be sleeping, and this can introduce significant variability to the data. To address this problem, we have adapted a new paradigm to identify behavioural phenotypes in models of chronic, progressive neurodegenerative disease. This paradigm involves the incorporation of a lever pull task into the mouse home-cage, allowing continuous access to the task in a naturalistic environment. Task difficulty can be changed dynamically based on performance by requiring the mouse to hold the lever in a more narrow range, or for a longer period, to receive a water reward. Additionally, kinematic analysis of lever movement can be used to assess motor control and persistence during task performance. Video and lever pulling data is collected automatically, allowing for minimal human interaction and continuous assessment of multiple animals over long periods. We have used this paradigm to investigate behavioural phenotypes in the YAC128 mouse model of Huntington's disease at 2 months (presymptomatic), 4 months (early symptomatic) and 6 months (symptomatic) of age. Specifically, we have obtained measures of motor learning and control, as well as cognitive flexibility and memory, in order to further define the deficits seen in these animals. We hope that this will prove to be an effective tool, more generally, for increasing the sensitivity and automation of cognitive and motor assessments in models of neurodegenerative disease. *Funded by the Canadian Institutes for Health Research.*

Abstract: Huntington's disease (HD) is a genetically inherited neurodegenerative disorder characterized by severe motor dysfunction, cognitive decline and psychiatric disturbances, associated with profound striatal and cortical loss. Altered dopaminergic transmission is thought to play a key role in HD pathophysiology, and has been reported in HD patients as well as in rapidly-progressing rodent models of HD. To enhance our understanding of such differences, we aimed to characterize dopamine dynamics in the slower-progressing knock-in zQ175 mouse model of HD.
Electrically-evoked striatal dopamine release from anesthetized 7 month old heterozygous zQ175 and WT mice was detected by fast-scan cyclic voltammetry. Oxidative currents were measured in the ventral striatum while increasing intensities of electrical stimulation were delivered to the VTA/SNc after vehicle and after raclopride (D2 antagonist; 1 mg/kg) i.p. injection. Dopamine levels detected from WT and Q175 mice after vehicle treatment were not significantly different. However, raclopride-evoked enhancement of phasic dopamine release was attenuated in Q175 animals as compared with WT. There was no difference in the rate of reuptake between genotypes as measured by Tau75. These results indicate presynaptic D2 receptor dysfunction in Q175 mice, and suggest that similar functional alterations may exist at the postsynaptic level, impairing striato-pallidal indirect pathway transmission.

Title: Early olfactory behavior deficits associated with olfactory bulb atrophy and caspase-8 activation in HD rodent models

Authors: *R. K. GRAHAM[1], M. LAROCHE[1], M. LESSARD-BEAUDOIN[1], M. GARCIA-MIRALLES[2], C. KREIDY[2], L. YU-TAGER[3], M. R. HAYDEN[4], H. NGUYEN[3], M. A. POULADI[2];

Abstract: Olfactory dysfunction and altered neurogenesis are observed in several neurodegenerative disorders including Huntington disease (HD). These deficits are an early symptom and correlate with decline in cognitive performance, depression and degeneration of olfactory regions in the brain. Despite clear evidence demonstrating olfactory dysfunction in HD patients, only limited details are available in murine models and the underlying mechanisms are unknown. We have previously shown decreased olfactory cortical volume in the YAC128 HD model. We now examined odor investigation behaviors and show that at 1 and 3 months YAC128 mice do not habituate to the odor as quickly in trial 2 ($p<0.05$), and at 5 months the YAC128 mice investigate trial 1 odors longer than WT littermates ($p<0.05$). Initial data also show an increase in GFAP and Iba-1 in the olfactory bulb (OB) in post-symptomatic YAC128 compared to WT. Furthermore, an increase in the active form of caspase-6 and caspase-8 are observed at 3 months in YAC128 OB vs WT. We also assessed the rat BACHD model. In the BACHD model, early increases in NeuN and atrophy of the OB (ANOVA $p=0.02$) are observed. In addition, an increase in caspase-8 (ANOVA $p=0.02$) expression at 6 months is observed vs. WT. Supporting this, we detect an increase in casp8 activation in the OB at 3 months of age. Identification of early markers for HD will help inform therapeutic approaches and will clarify the utility of olfactory function tests in at risk HD individuals.

Title: Longitudinal assessment of cortico-striatal projections in the zQ175 mouse model of Huntington's Disease

Authors: *N. FOSTER, H. HINTIRYAN, M. BECERRA, I. BOWMAN, K. COTTER, M. BAY, M. ZHU, M. S. BIENKOWSKI, M. Y. SONG, L. GOU, S. YAMASHITA, H. DONG; USC, Los Angeles, CA

Abstract: The zQ175 mouse is a recently developed knock-in model of the neurodegenerative, genetically based Huntington's Disease (HD). The heterozygous zQ175 mouse closely mimics the mutant genotype in most human patients with HD and thus has good genetic validity. In humans with HD and other mouse models of the disease, both cortex and striatum are severely affected. One possible mechanism underlying the dysfunction seen in HD is degeneration of axonal projections between brain regions, or connectopathy. We endeavored to assess whether connectopathic changes were occurring in the cortico-striatal axonal connections in these mice. Injections of anterograde axonal tracers were made into the primary motor cortex, secondary motor cortex, and medial prefrontal cortex in groups of zQ175 and their wild type littermates. Axonal terminations that were labeled by these injections were quantified in the dorsal striatum and compared between groups. Additionally, groups of zQ175 and wild type mice at 2-, 6-, and 12-months of age were used to observe the development of any connectopathic changes occurring during progression of the Huntington's phenotype.

Title: Basal ganglia pathology in heterozygous 18 month-old Q175 knock-in Huntington's disease mice

Authors: *Y. DENG, H. WANG, M. JONI, A. REINER;
Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Progressive basal ganglia neurodegeneration is a well-known feature of Huntington's disease (HD). The Q175 knock-in mouse is a slowly progressing HD model, but its basal ganglia

pathology is not well characterized. Using stereology, quantitative immunohistochemistry, and in situ hybridization histochemistry, we examined striatal projection neuron, striatal interneuron, and striatal projection system pathology, as well as pallidal, nigral and subthalamic nucleus pathology in 18 month-old heterozygous Q175 mice. We found that although total striatal neuron numbers and striatal volumes revealed by stereology were not significantly changed in 18 month-old Q175 mice, DARPP32-positive striatal projection neurons were significantly reduced in abundance by 40%. Enkephalin (ENK) message in indirect pathway striatal projection neurons (iSPNs) was also significantly decreased, but substance P (SP) message in direct pathway striatal projection neurons (dSPNs) was unchanged, suggesting the DARPP32 perikaryal reduction was preferential for ENK iSPNs. Consistent with this, we found reduction in DARPP32 in the striatal terminals in globus pallidus externus (GPe) but not in striatal terminals in globus pallidus internus (GPi) or substantia nigra pars reticulata (SNr). Despite the reduced ENK message and unaltered SP message in striatum, ENK was increased in striato-GPe terminals and SP was increased in striatal terminals in GPi and SN, likely reflecting striatal neuron dysfunction and decreased neurotransmitter release in striatal target areas. Of note, the DARPP32 reductions in striatal neuron abundance and striato-GPe fibers, and ENK and SP retention in terminals in striatal target areas were all correlated with motor abnormalities detected by rotarod testing and open field testing. The abundance of striatal parvalbuminergic (PARV), cholinergic and NOS-containing interneurons were not changed in 18 month-old Q175 mice, nor were PARV neuron numbers in GPe, GPi and SNr. Neuron abundance in the subthalamic nucleus and dopaminergic neuron abundance in substantia nigra pars compacta (SNc) were also unaltered. Our results suggested that Q175 knock-in mice resembles a very early stage of adult onset human HD and could be useful for testing HD therapeutics.

Title: HdhQ200/200 mouse model displays rapid Huntington’s Disease-like behavior and pathology

Authors: *J. K. CAO, K. SWINNEY, L. ZWEIFEL, N. STELLA;
Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Huntington's Disease (HD) is a devastating inherited autosomal dominant neurodegenerative disease with no known cure and few palliative treatment options available. Characterized by progressive deterioration of motor and cognitive functions, the average survival time is 15-25 years after disease onset and end-stage patients are profoundly demented and debilitated. The HdhQ mouse model was developed by inserting pathogenic-sized CAG repeats into the *Hdh* gene, the mouse homolog of the HD gene. An allelic series of the HdhQ mouse model has been generated with 200 CAG repeats in length that recapitulate critical components of HD pathogenesis. Here we characterized in further detail several behavioral and pathological impairments that are reliably measured in the homozygous HdhQ200/200 model. Longitudinal studies of behavioral phenotypes and histology revealed disease onset as early as 6 months of age and end stage at 12 months. Female and male HdhQ200/200 animals showed deficits in weight, grip strength, motor coordination, and circadian activity by 8 months of age. Analysis of pathology by semi-quantitative immunohistochemistry at 12 months of age revealed reduced DARPP-32 and CB_1R expression. There was also indication of increased mutant huntingtin aggregates in the striatum of these mutants. Using *in vivo* calcium imaging with GCaMP calcium indicator technologies, we found pronounced alterations in activity-dependent calcium dynamics in medium spiny neurons of 10-month-old HdhQ200/200 mice. Previous work suggests that chronic cannabinoid treatments may alleviate behavioral and pathological deficits seen in other HD models. Our next set of experiments is designed to target the endocannabinoid signaling system and test its potential therapeutic effect in this model. Our study will disclose detailed behavioral and pathological changes in the HdhQ200/200 mouse line and whether cannabinoid treatments alleviate these changes. Title: Axonal injury is protein kinase JNK3 dependent in a murine model of Huntington's disease.

Authors: *R. G. GATTO[1], M. KANG[1], Y. CHU[2], H. FRIEDECK[1], B. KIM[1], J. H. KORDOWER[2], S. T. BRADY[1], G. A. MORFINI[1];

Abstract: Huntington's disease (HD) is an autosomal dominant disease resulting from expansion of a polyglutamine tract in mutant huntingtin (*mhtt*). Our previous work showed that mhtt promotes deficits in axonal transport, a cellular process critical for the appropriate maintenance of axonal connectivity, further demonstrating a role of the protein kinase JNK3 and its toxic effect. These findings prompted us to assess the contribution of JNK3 to mHtt-induced pathology in-vivo by analyzing R6/2 mice featuring genetic ablation of JNK3. Collectively, results from these studies demonstrate a major role of JNK3 on the axonal pathology induced by *mhtt in vivo*.

Title: Investigation of corticostriatal synaptic transmission and cerebellar Purkinje neuron firing in the R6/2 mouse model of Huntington's disease by using multi-electrode arrays

Authors: *M. KOPANITSA, O. KONTKANEN, A. NURMI, P. SWEENEY;
Charles River Discovery, Kuopio, Finland

Abstract: Many clinical manifestations of Huntington's disease are likely caused by degeneration of striatal medium-sized spiny neurons (MSNs). It has been suggested that certain behavioral disturbances in individuals with Huntington's disease (HD) may arise due to derangement of synaptic transmission in the striatum that occurs prior to pronounced neuronal loss. For this reason, corticostriatal synaptic transmission in genetic mouse models of HD has been a subject of intense investigation. Changes such as increased membrane input resistance and a reduction in membrane capacitance of MSNs as well as presynaptic phenotypes have been noted in several HD mouse models. We sought to determine if electrophysiological phenotypes in the striatum can be also detected by measuring field excitatory postsynaptic potentials (fEPSPs) evoked by stimulation of corticostriatal pathways with multi-electrode arrays (MEAs) in horizontal brain slices of 8-week old R6/2 male mice. We found that while input-output

relationships and LTP induced by theta-burst stimulation were similar in slices from R6/2 and WT mice, paired-pulse facilitation (PPF) at an interpulse interval of 100 ms was higher in mutants (127.5 ± 4.5) than in WTs (112.8 ± 2.6; $P = 0.005$, Mann-Whitney test). This observation is in line with previous reports of increased PPF in genetically altered mice bearing several HD-related mutations (Milnerwood and Raymond, 2007). There have been some disagreement as to whether motor symptoms in HD may be also caused by dysfunction of the cerebellum. Some evidence of impaired Purkinje neuron functions in R6/2 mice have been reported (Dougherty et al., 2012). Using MEA-based recordings, we examined tonic spontaneous discharges of individual Purkinje neurons in parasagittal slices from 8-week old R6/2 and WT mice. We found that Purkinje neurons from mutant mice exhibited a trend toward a lower firing rate and had a significantly higher coefficient of variation of the interspike interval (R6/2: 0.31 ± 0.02; WT: 0.18 ± 0.01; $P = 0.016$, 3-level nested ANOVA). We conclude that MEA-based approach provides a convenient, easy-to-multiplex setting for detecting relevant electrophysiological phenotypes in brain slices from mouse models of HD. Title: Direct and indirect striatal output pathways differentially affect their targets in mouse models of Huntington’s Disease

Authors: *J. BARRY, C. CEPEDA, M. S. LEVINE;
IDDRC, Semel Inst. for Neurosci. and Human Behavior, BRI, UCLA, Los Angeles, CA

Abstract: Huntington’s disease (HD) is a hereditary neurological disorder characterized by chorea, cognitive deficits and psychiatric symptoms. As HD progresses there is a massive loss of medium-sized spiny neurons (MSNs) in the human striatum. MSNs expressing dopamine (DA) D1 receptors project to the substantia nigra (SN) (direct pathway), whereas MSNs expressing DA D2 receptors project to the external segment of the globus pallidus (GPe) (indirect pathway). It is believed that MSNs of the indirect pathway are affected earlier than MSNs of the direct

pathway. To examine how these two pathways are altered in HD, channelrhodopsin (ChR2) was injected into the striatum of symptomatic R6/2 (2-3 month) and symptomatic (12 month) YAC128 mice or their wildtype (WT) littermates, which were crossed to either D1- or D2-Cre expressing mice. These mice then express ChR2 in either the direct (D1-Cre) or indirect (D2-Cre) striatal output pathways. Recording in brain slices, we examined spontaneous excitatory (sEPSC) and inhibitory (sIPSC) postsynaptic currents, and IPSCs evoked by optogenetic stimulation of direct or indirect pathway terminals in either the SN or the GPe to determine alterations in the neurons of output structures. sIPSC frequency was reduced in the SNr of both R6/2 and 12 month-old YAC128 D1-Cre mice, while sIPSC amplitude was significantly decreased in R6/2 mice only. Optogenetically-evoked IPSCs by activation of direct pathway terminals showed a significant decrease in amplitude and charge in R6/2 and 12 month-old YAC128, while the kinetics (half-amplitude duration, rise and decay times) were not significantly altered. In GPe neurons, sIPSC frequency was decreased in R6/2 mice while sIPSC kinetics were unchanged in both R6/2 and YAC128 mice. Evoked IPSC responses to optogenetic stimulation of indirect pathway terminals displayed a significant increase in decay time in both R6/2 and 12 month YAC128 neurons. In contrast, sEPSC frequency and kinetics of both SNr neurons and GPe neurons were unchanged in both mouse models. In summary, the decrease in evoked GABAergic response amplitude in the SN (direct pathway) may be due to reduced inputs from MSNs, whereas the increase in GABA response decay time and charge in the GPe may be due to changes in GABA reuptake or postsynaptic receptor subunit composition. In conclusion, the direct and indirect pathways are differentially affected and these differences are consistent across two HD models.

Title: Altered function of Parvalbumin-expressing interneurons in mouse models of Huntington’s disease

Authors: *L. GALVAN, S. M. HOLLEY, C. CEPEDA, M. S. LEVINE;
IDDRC, Semel Inst. for Neurosci. and Human Behavior, BRI, UCLA, Los Angeles, CA

Abstract: Huntington's disease (HD), a neurodegenerative disorder caused by a mutation in the HD gene, is characterized by dysfunction and ultimate degeneration of striatal medium-sized spiny neurons (MSNs). Although it was thought that interneurons were relatively spared in HD, recent studies have shown significant alterations in parvalbumin (PV)-expressing interneurons. These interneurons display fast-firing properties and mediate feed-forward inhibition in the striatum. Previously we showed using optogenetics to specifically activate PV-expressing interneurons that alterations in GABAergic input from PV-expressing interneurons may contribute to MSN dysfunction in HD. Here we used a similar optogenetic paradigm to further examine alterations in PV-expressing interneuron inputs to MSNs in the R6/2 and the Q175 models. We examined whether PV-expressing interneuron responses in R6/2 mice were differentially affected in direct versus indirect pathway MSNs. R6/2 mice were crossed with PV-Cre mice and D1 tomato mice to identify direct and indirect pathway MSNs. The data show that PV-expressing interneurons induced a larger GABAergic response in direct compared to indirect pathway wildtype (WT) MSNs. In symptomatic R6/2 mice, direct pathway MSNs displayed a smaller response compared to the WT direct pathway response. Q175 mice were crossed with PV-Cre mice to examine the progression of response alterations in MSNs at 2 (presymptomatic) and 8 (beginning of symptomatic stage) months. In 2 month Q175 mice, there were no differences between genotypes. In contrast, in 8 month Q175 mice, activation of striatal PV-expressing interneurons evoked significantly smaller MSN GABAergic responses with a faster decay time than in WTs. We also compared the effects of activation of endocannabinoid receptor 1 (CB1) in the two models. The CB1 agonist, WIN 55,212-2 decreased PV-induced responses in both Q175 and WT MSNs but not in the symptomatic R6/2 MSNs as previously described. Together, these findings suggest that alterations in function of PV-expressing interneurons differ in the R6/2 and Q175 mice but will contribute to neuronal microcircuit alterations in the striatum.

Title: Impaired functional dynamics of motor cortex microcircuits in mouse models of Huntington's disease

Authors: *A. M. ESTRADA SANCHEZ[1], E. DONZIS[1], T. INDERSMITTEN[1], C. TRAN[1], C. WANG[1], D. CASTRO[1], M. NEDJAT-HAIEM[2], C. CEPEDA[1], P. GOLSHANI[2], M. S. LEVINE[1];
[1]IDDRC, Semel Inst. For Neurosci. and Human Behavior, BRI, UCLA, [2]Dept. of Neurology, David Geffen Sch. of Medicine, UCLA, West Los Angeles VA Med. Ctr., UCLA, Los Angeles, CA

Abstract: Huntington's disease (HD) is a neurological disorder characterized by motor and cognitive disturbances. Most research on neuronal dysfunction in HD models focuses on the striatum, but it has become clear that the cortex is also affected. Therefore, it is critical to understand functional changes to cortical circuits in HD models. Here, we used the symptomatic R6/2 (2-3 mo) and Q175 (>12 mo) mouse models to examine network changes in pyramidal neurons and interneurons in motor cortex using 2-photon Ca^{2+} imaging. During recordings, the mouse is head-restrained but the body is able to freely move on a spherical treadmill providing comparisons of network activity during periods of locomotion and rest. When measuring activity of individual neurons, we found a shift towards lower amplitude Ca^{2+} transients but higher frequencies in both R6/2 and Q175 mice compared to wildtype littermates (WTs). While locomotion did not affect amplitudes and frequencies, the proportion of Ca^{2+} transients near the initiation of motion was altered. In the R6/2 model, WTs displayed an increase in proportion of Ca^{2+} transients occurring immediately before locomotion initiation but a similar increase occurred immediately after locomotion initiation in R6/2 mice. In the Q175 model, the proportion of Ca^{2+} transients decreased at the initiation of locomotion compared to WTs. To examine network changes we measured significant pairs (determined using a Monte Carlo simulation) of intercorrelations of neurons. Both R6/2 and Q175 had a greater proportion of significantly correlated neuron pairs compared to their respective WTs. Differences between the R6/2 and Q175 model emerged when separating network activity into locomotion and rest periods. In the R6/2 model, the average correlation values decreased during periods of locomotion compared to WTs and increased during rest. In the Q175 model, the average correlation increased compared to WTs regardless of locomotion. This divergence may be due to differences in the amount of time the HD models spent in motion. R6/2 mice spent significantly more time in motion and Q175 mice spent significantly less compared to their respective WTs. Differentiation of interneurons and pyramidal neurons in R6/2 mice showed a significant decrease in interneuron intercorrelations but a significant increase in pyramidal cells. These data suggest an uncoupling of the pyramidal and interneuron network activity resulting in dysregulation of cortical synchronization. Additionally, the disruption in the occurrence of Ca^{2+} transients in relation to locomotion initiation suggests that the HD models may utilize different network dynamics to initiate locomotion.

Title: Somatostatin interneurons contribute towards increased striatal inhibition in the Q175 mouse model of Huntington's Disease

Authors: *S. M. HOLLEY, L. GALVAN, T. KAMDJOU, C. CEPEDA, M. S. LEVINE; IDDRC, Semel Inst. for Neurosci. and Human Behavior, BRI, UCLA, Los Angeles, CA

Abstract: Huntington's Disease (HD) is a heritable neurological disorder that affects cognitive and motor function in patients carrying the mutated huntingtin gene. In mouse models of HD, previous reports showed an increase in GABA neurotransmission to striatal medium-sized spiny neurons (MSNs). Here using optogenetics we examined the role of GABAergic, somatostatin (SOM)-expressing interneurons in HD using the Q175 (heterozygote) mouse model. These mice are a slowly progressing knock-in model carrying only one copy of the mutated HD allele and more closely mimic the human condition. Using patch clamp electrophysiology in voltage clamp mode, we recorded from MSNs in brains slices of presymptomatic (2 month) and symptomatic (8 and 12 month) Q175 mice and wildtype (WT) littermates. The amplitudes of responses evoked by activating SOM-expressing interneurons were similar in MSNs at both ages but differences in response kinetics occurred in MSNs from symptomatic mice. Since SOM interneurons are constitutively active in striatal brain slices, we also examined the effects of acutely silencing these neurons with halorhodopsin (eNpHR). Optically silencing SOM-expressing interneurons resulted in a decrease in the frequency of spontaneous IPSCs (sIPSCs) in a subset of MSNs from both WT and Q175 mice. The sIPSC frequency decrease during eNpHR activation was more pronounced in symptomatic Q175 MSNs compared to WT MSNs, suggesting that SOM interneurons contribute to the overall increased inhibition in HD MSNs. Additionally, CB1 receptors were activated with the agonist WIN 55,212-2 to determine if alterations in endocannabinoid-regulated neurotransmitter release is changed when SOM-

expressing interneurons are activated. WIN-55 effectively decreased the overall sIPSC frequency in both WT and Q175 MSNs. When selectively activating SOM-interneurons in the presence of WIN-55 the magnitude of the evoked IPSC in MSNs was decreased and this change was significantly reduced in symptomatic Q175 MSNs. Overall, these findings show that aberrant neurotransmitter release from SOM interneurons contributes to the increased striatal inhibition found in HD mouse models and that dysregulation of the endocannabinoid system may contribute to this effect.

Title: Synaptic alterations in direct and indirect pathway spiny projection neurons in the Q175 mouse model of Huntington's disease.

Authors: J. SANCHEZ-PADILLA[1], G. TOMBAUGH[1], S. GELMAN[1], K. KRETSCHMANNOVA[1], J. PALMA[1], A. GHAVAMI[1], V. BEAUMONT[2], *R. CACHOPE[2]; [1]Psychogenics Inc, Tarrytown, NY; [2]Translational Biol., CHDI Mgmt. / CHDI Fndn., Los Angeles, CA

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder resulting from an extended number of CAG repeats in the *Huntingtin* (*Htt*) gene, for which no disease-modifying therapy is currently available. HD comprises several cognitive and affective symptoms, as well as uncontrolled movement (chorea), which have been hypothesized to arise from a preferential vulnerability of indirect pathway spiny projection neurons (iSPNs) preceding dysfunction of the direct pathway SPNs (dSPNs) in the striatum. In order to characterize this possible imbalance, we performed in vitro brain slice whole patch-clamp recordings from the Q175 heterozygous knock-in HD mouse model expressing GFP under the control of the D2 receptor promoter to identify dSPNs (GFP-negative) and iSPNs (GFP-positive). We asked to what extent alterations in intrinsic and synaptic properties in Q175 mice were selectively affected in each SPN subtype. Using whole-cell path clamp, both dSPNs and iSPNs from Q175 6-month old mice showed elevated membrane resistance and reduced rheobase current,

consistent with previous reports of SPN hyperexcitability in mouse models of HD. Membrane resistance and rheobase in both dSPN and iSPNs from 2-month old Q175 mice did not significantly differ from Wild-type (WT) dSPN and iSPNs respectively, suggesting that deficits in SPN excitability emerged largely in parallel in each subtype. Analysis of mEPSC properties in SPNs revealed a significant decrease in mEPSC frequency only in iSPNs from 6-month old Q175 mice, with no genotypic differences in mEPSC amplitude in either cell type. Amplitude and frequency of mEPSCs were unchanged in 2-month old Q175 mice compared to WT. Finally, we examined LTP at corticostriatal synapses in 6-month old mice using a Hebbian protocol consisting of 4 trains of 100 Hz presynaptic stimulation paired with postsynaptic depolarization. We found that corticostriatal LTP was decreased in dSPNs, while LTP expression in iSPNs was unchanged. Altogether, these results suggest that HD progression is not equally expressed in the indirect and direct pathways. Additional studies are, however, necessary to better understand such differential impairment.

Title: NT-3 effects on corticostriatal plasticity

Authors: *E. HERNANDEZ-ECHEAGARAY, Dr[1], V. GÓMEZ[2], E. MENDOZA[2];
[1]Univ. Nacional Autonoma de Mexico, Mexico City, Mexico; [2]FES-I UNAM, Mexico, Mexico

Abstract: In previous work we have described that during the first week of postnatal development in mice, neurotrophin-3 (NT-3) is present in corticostriatal pathway, and after 42 days old, NT-3 is expressed in cell somas of mice striatum. We also have shown that expression levels of mRNA and immune localization of NT-3 and its receptor, the TrkC are altered in striatal damage induced with an *in vivo* treatment with 3-Nitropropionic Acid (3-NP) a mitochondrial toxin used to mimic the histopathology of Huntington's disease (HD). Therefore, we were interested in evaluating modulatory effect of NT-3 on corticostriatal synaptic transmission, as well as, striatal synaptic plasticity induced with high frequency stimulation (HFS; 100Hz), in both control and in damaged striatum. Our results indicated that NT-3 modulates both; synaptic transmission and plasticity in the striatum, nonetheless synaptic plasticity is modify with the 3-NP treatment, instead of producing striatal LTD, LTP is obtained, moreover the administration of NT-3 in the recording bath recovered the plasticity observed in control conditions (LTD) in this model of striatal degeneration. The mechanisms responsible for the striatal plasticity recovery are discussed.

Title: *In vivo* characterization of the cortico-basal ganglia connectivity in the zQ175 heterozygous knock-in mouse model of Huntington's disease

Authors: *S. ZHONG[1], A. GHAVAMI[1], R. CACHOPE[2], V. BEAUMONT[2];

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder resulting from an extended number of CAG repeats in the Huntingtin (Htt) gene, for which no disease-modifying therapy is currently available, and comprises several cognitive and affective symptoms, as well as uncontrolled movement (chorea). HD symptoms are thought to be the result of impaired cortico - thalamo - basal ganglia (BG) function; especially a misbalance between the direct and indirect pathways, while the potential dysfunction of the hyperdirect pathway has not been examined. The purpose of the current study was to characterize hyperdirect pathway transmission and its relationship with direct and indirect pathway (dys)function as a contributing factor to HD. We performed in vivo anesthetized electrophysiological extracellular recordings in the anesthetized Q175Het mouse model of HD vs. WT (6 months old).
First, we identified a decreased response of Q175 STN neurons to electrical stimulation of the motor cortex (M1), suggesting impaired hyperdirect pathway transmission. Next, we explored the triphasic response patterns (excitation-inhibition-excitation) of single units in the SNr and/or GP evoked by M1 stimulation, which have been proposed to represent hyperdirect, direct and indirect pathway function, respectively. Our key finding is that in Q175Het mice, the amplitudes for both early and late excitation of SNr neurons to cortical stimulation were significantly decreased compared to WT mice, as revealed from population peristimulus histograms. Our results also revealed that the inhibition phase of SNr neurons was increased in Q175Het but with no change in either latency or duration of the evoked response. For GP neurons in Q175Het mice, amplitudes for both early and late excitation were decreased as in SNr neurons but this did not reach statistical significance. No differences in firing inhibition, response latency or duration were observed. The proportion of neurons showing triphasic responses were decreased for both SNr (39% to 22%) and GP (23% to 19%) in Q175 mice compared to WT mice. Spontaneous firing rates in Q175Het mice showed a modest increase in both SNr and GP neurons compared to the WT but did not reach statistical significance.
These results indicate that a complex dysfunctional interplay between the hyperdirect, direct, and indirect pathways occurs in HD. Genotypic differences established here can be used to monitor basal ganglia circuitry dysfunction in HD models with the potential to evaluate pathway-selective effects of pharmacological treatments.

Title: Characterization of ipRGC impairment in Huntington's disease

Authors: *M.-S. LIN[1], C.-P. CHANG[1], S.-K. CHEN[2], Y. CHERN[1];
[1]Inst. of Biomed. Science, Academia Sinica, Taipei City, Taiwan; [2]Inst. of Zoology, Natl. Taiwan Univ., Taipei City, Taiwan

Abstract: Intrinsically photosensitive retinal ganglion cells (ipRGCs), which express the photopigment melanopsin, respond to light stimulation and regulate the non-image forming visual functions including the photoentrainment of circadian rhythm, pupil light reflex, and sleep. ipRGCs are reported as the resistant cell types in some inherited blindness, but are affected in glaucoma optic neuropathy and aging, which is associated with impaired circadian rhythm regulation. It is still unclear whether the functional properties of ipRGC are altered during neurodegenerative conditions. Previous studies showed that mice (R6/2 and $_{Z}$Q175) with Huntington's disease (HD) exhibited disrupted circadian behaviors without abnormal oscillation of PER1 and PER2 in the suprachiasmatic nucleus (SCN). We hypothesized that dysfunction of ipRGC might attribute to such circadian disruption during HD pathogenesis. We found that the number of melanopsin-expressing ipRGCs was significantly decreased during disease progression in two HD mouse models (R6/2 and N171-82Q). Interestingly, the five different subtypes of ipRGC (M1-M5) appeared to be differentially inflicted during HD progression. Under bright light stimulation, R6/2 mice showed attenuated pupil light reflex and enhanced activity in the light phase after 4-hour light dark (LD) phase advance during jet lag. It appeared that R6/2 mice are relatively insensitive to light stimulation compared to WT mice, and this behavioral change might be associated with the progressive loss of ipRGCs. In summary, we uncovered the degeneration of ipRGC in HD, which might cause the impairment of non-image forming visual functions, and contribute to the non-motor behavioral deficits (such as sleep problem) in HD.

Title: The relationship between adult neurogenesis and interval timing is altered in a transgenic Huntington's Disease rat model

Authors: *A. PEREZ[1], J. FISCHETTI[2], D. GARCES[1], S. WODINSKY[2], A. TOROSSIAN[2], C. TSIRIS[1], J. ROJAS[2], B. BROWN[1,2], N. HEMMES[1,2], C. L. PYTTE[1,2], J. ARONOWITZ[2]; [1]Psychology, The Grad. Center, City Univ. of New York, New York, NY; [2]Psychology, Queens Col. of the City Univ. of New York, Flushing, NY

Abstract: The hippocampus processes experience in space and time and contributes to the frontal-striatal system in modulating time perception on the seconds-to-minutes scale. In certain neurodegenerative disorders, such as Huntington's disease (HD), there is an impaired ability to perform tasks that require intact interval timing. The neuropathology of HD is characterized by neurodegeneration in the striatum, cerebral cortex, and hippocampus, as well as altered new neuron addition to the striatum and hippocampus. Here we examined the relationship between hippocampal neurogenesis and measures of temporal discrimination in a transgenic Huntington's disease (tgHD) rat model. Temporal discrimination was measured using a peak interval (PI) paradigm. The peak interval procedure is a variant of the fixed interval (FI) schedule of reinforcement. Peak interval trials were non-reinforced trials presented for 3x the FI-criterion duration. We divided the peak rate of lever press responding by the average smoothed response rate across the PI trial to obtain a ratio measure. Ratios equal to 1 indicate a lack of temporal discrimination (e.g., a flat function when response rate is plotted as a function of elapsed time into the trial) and ratios greater than 1 indicate stronger temporal discrimination. New neurons were labeled with antibody to the neuron-specific protein doublecortin, and numbers of new neurons in the dorsal hippocampus were compared with behavior. Interestingly, we found that in wild-type rats, there was an inverse relationship between new neurons and temporal discrimination. More new neurons corresponded to worse discrimination. This relationship did not exist in tgHD rats. Rather, there was a positive correlation between new neurons and temporal discrimination. These findings suggest that the relationship between new neurons and timing behavior are differentially associated in tgHD rats and healthy, control rats.

Title: IP-MS and CLIP-seq define an extensive RBM45 interactome network

Authors: *Y. L. LI[1], M. COLLINS[2], J. AN[2], K. GARCIA[3], P. PIRROTTE[3], R. BOWSER[2]; [1]Neurol., [2]Barrow Neurolog. Inst., Phoenix, AZ; [3]TGen, Phoenix, AZ

Abstract: The pathological accumulation of RNA-binding proteins (RBPs) within inclusion bodies is a hallmark of amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). RBP aggregation results in both toxic gain and loss of normal function. Determining the protein and RNA binding partners and normal functions of disease-associated RBPs is necessary to fully understand molecular mechanisms of RBPs in disease.
RBM45 is a recently characterized RBP found in inclusions in ALS, FTLD and AD [1]. These inclusions are positive for TDP-43, and RBM45 physically interacts with TDP-43 and FUS in vitro [2]. To delineate protein binding partners of RBM45 and putative biological functions of the protein, we used an immunoprecipitation coupled to mass spectrometry (IP-MS) approach to comprehensively characterize RBM45 protein-protein interactions (PPIs) within HEK293 cells [3]. We identified 132 RBM45 PPIs by IP-MS, including PPIs with many RBPs. Select PPIs were validated by immunoblot and immunocytochemistry, demonstrating that RBM45 associates with a number of other RBPs primarily via RNA-dependent interactions in the nucleus. Analysis of the biological processes and pathways associated with RBM45-interacting proteins indicates enrichment for nuclear RNA processing/splicing and cytoplasmic RNA translation. Moreover, several other ALS-linked RBPs, including TDP-43, FUS, Matrin-3, hnRNP-A1, and hnRNP-A2/B1, interact with RBM45, consistent with prior observations of these proteins within intracellular inclusions in ALS/FTLD. We also used CLIP-seq approach to study the RNA binding targets of RBM45. The RNA targets bound by RBM45 and several ALS-linked RBPs are compared to determine RNA targets co-regulated by RBM45 and these RBPs. Collectively, our results shed new light on RBM45 interactome, biological functions, and contributions to neurodegeneration in ALS/FTLD. **References:** 1. Abstract: [Purpose] Accumulating evidence suggests that detergent-resistant, ubiquitinated, and phosphorylated TAR DNA-binding protein of 43 kDa (TDP-43) is a major pathogenic protein in sporadic amyotrophic lateral sclerosis (ALS) when misfolded and mislocalized in the cytosol. The aim of this study is to investigate the therapeutic potential of intrabody against pathogenic TDP-43 species. [Methods] We have recently reported that a novel monoclonal antibody, 3B12A, against peptides containing Asp247 in TDP-43 reacts specifically with TDP-43 inclusions in sporadic ALS patients and with misfolded or mislocalized TDP-43 in cultured cells. To introduce 3B12A efficiently inside cells, we constructed single chain variable fragment of 3B12A (scFv-3B12A) as intrabody against misfolded TDP-43. We also constructed scFv-3B12A containing proteasome localizing signal (scFv-3B12A-CL1) or chaperone-mediated autophagy localizing signal (scFv-3B12A-CMA) for protein disassembling signals. We investigated the specificity and the clearance effects of those scFv-3B12A intrabodies in cultured cells. [Results] Immunoprecipitation and confocal microscopy analysis showed that scFv-3B12A interacted specifically with mislocalized or aggregated forms of TDP-43. CL1 and CMA signals promoted the degradation of scFv-3B12A at the proteasomes and the lysosomes, respectively. In HaloTag-recombinant TDP-43 chase assay, scFv-3B12A and scFv-3B12A-CMA degraded mislocalized cytosolic TDP-43 significantly, but not wild-type or aggregated TDP-43. For the next step, we sought to explore several reported molecular chaperone inducers to refold aggregated forms of

TDP-43 to be targeted by the scFv-3B12A. Some molecular chaperone inducers showed a remarkable reduction of aggregated species of TDP-43 in cultured cells. [Conclusion] Our findings indicated that scFv-3B12A functioned as an intrabody to react with and degrade misfolded/mislocalized TDP-43 inside cells, so far as to be the pre-aggregated form. The combinations therapy with molecular chaperone inducers might be a more promising strategy to step forward the therapy.

Title: Antifibrotic approach targeting the tgfß system

Authors: *S. KUESPERT, S. PETERS, E. ZITZELSPERGER, R. HEYDN, T.-H. BRUUN, U. BOGDAHN;
Dept. of Neurol., Univ. Hosp. Regensburg, Regensburg, Germany

Abstract: TGF-ß is involved in a number of processes like e.g. cell proliferation, migration, wound healing, angiogenesis and cell-cell interactions. It´s known from several studies, that this factor is often elevated during pathogenesis of several disorders including neurodegenerative diseases, pulmonary fibrosis and diabetic nephropathy. These disorders are related to pathogenic modifications of extracellular matrix (ECM) and the actin-cytoskeleton. Often, these observed alterations correlate with severity of disease progression. Connective tissue growth factor (CTGF) is a downstream-mediator of TGF-ß and transfers fibrotic effects of TGF-ß. It has been shown that CTGF leads to an induced deposition of ECM and modulates reorganization of actin-cytoskeleton.
To investigate whether TGF-RII specific antisense-oligonucleotides (ASOs) contribute to a resolution of fibrotic processes by inhibiting TGF-ß signaling, CTGF levels were evaluated in addition to Fibronectin (FN) and Collagen IV (ColIV), representing two main components of ECM in several different organ systems. Furthermore, effects of ASOs on CTGF, FN, actin-cytoskeleton and proliferation were examined in different cell lines as neural precursor (ReNcell CX™) and human lung cancer (A549) cells. Data were obtained by quantitative real-time RT-

PCR, immunoblotting, immunocytochemistry and cell counting. Results indicate that blocking cellular TGF-ß signaling by selective ASO`s leads to reduction of fibrotic deposition and a re-modulation of actin-cytoskeleton. Thus, TGF-RII-ASO`s seem to be promising candidates for an anti-fibrotic treatment approach.

Title: Glutamate receptors mediate p-glycoprotein upregulation at the blood brain barrier in amyotrophic lateral sclerosis

Authors: *L. A. MOHAMED, S. MARKANDAIAH, P. PASINELLI, D. TROTTI; Deparment of Neurosciences, Thomas Jefferson Univ., Philadelphia, PA

Abstract: Recent studies showed that the ABC transporter, P-glycoprotein (P-gp), expressed at the blood brain barrier (BBB) and the blood spinal cord barrier (BSCB) may contribute to progressive pharmacoresistance in amyotrophic lateral sclerosis (ALS). Riluzole, the only drug which has been approved by the food and drug administration (FDA) for treatment of ALS, has been shown to improve survival by a few months in some patients; however, progressive pharmacoresistance has been reported. Spinal cord tissue samples from ALS patients showed higher P-gp expression specifically at the capillary endothelials of the BSCB compared to healthy individuals. Our lab has shown previously that Riluzole brain penetration is higher in P-gp knockout mice, and P-gp deletion in an ALS mouse model increased brain level of Riluzole and improved survival. We have also demonstrated one of the underlying mechanisms of P-gp mediated pharmacoresistance using in vitro models of BBB. We found that P-gp overexpression was associated with activation of NF-kB-dependent pathways and was regulated by astrocyte secreted factors. Following our previous findings, our overall goal is to fully characterize the molecular mechanisms of P-gp overexpression in ALS utilizing our optimized patient-derived induced pluripotent stem cells (iPSC) BBB cellular model. We have tested the hypothesis that high extracellular glutamate level observed in ALS may induce P-gp expression through stimulation of N-methy-D-aspartic acid (NMDA) receptors at the BBB. Using our BBB model,

our initial findings indicated that co-culture of endothelial cells with patient-derived astrocytes induced P-gp expression and enhanced transport of P-gp probe substrate LD800. This increase in LD800 transport was completely abolished when cells were pre-treated with 100μM MK801, an NMDA receptor antagonist. Our findings suggest that P-gp expression at the BBB could be regulated by several upstream molecular pathways that eventually converge into activation of NF-kB.

Medicine, Unit of Human Physiology, Univ. of Genoa, Genoa, Italy

Abstract: Glutamate(Glu)-mediated excitotoxicity plays a major role in motor neurons (MN) degeneration in amyotrophic lateral sclerosis (ALS). Impaired glial uptake and abnormal exocytotic release are responsible for the excessive extracellular Glu. The main goal of this work was to investigate the mechanisms that support the excessive Glu exocytosis in pre-symptomatic SOD1^{G93A} mice. Synaptic terminals were isolated from the spinal cord of SOD1 and SOD1^{G93A} mice and studied for Glu release, intra-terminal Ca^{2+} concentration, synaptic protein expression and phosphorylation state. The basal release of Glu is increased in pre-symptomatic SOD1^{G93A} mice compared to control animals. Exposure to high KCl or ionomycin provoked a Ca^{2+}-dependent exocytotic Glu release that was augmented in SOD1^{G93A} mice. Also the hypertonic sucrose-induced Ca^{2+}-independent Glu exocytosis was abnormally elevated in SOD1^{G93A} mice, suggesting the involvement of the readily releasable pool (RRP) of glutamatergic vesicles. Molecular biology experiments revealed an increased number of assembled SNARE complexes

at the nerve terminal membranes, with no changes of the three SNARE proteins involved. Also the expression of Synaptotagmin-1 and β-Actin, but not that of many other pre-synaptic proteins involved in exocytosis was increased. We found elevated the presynaptic cytosolic Ca^{2+} levels and the phosphorylation of Synapsin-I at the relevant sites for synaptic vesicle mobilization to the RRP of vesicle. Also glycogen synthase kinase-3 phosphorylation at the inhibitory sites was higher in $SOD1^{G93A}$ mice, an event that may favor SNARE protein assembly. The excessive glutamate release was prevented by blocking Synapsin-I phosphorylation with specific antibodies, thus supporting the role of Synapsin-I hyper-activation in the excess of Glu release. Our results highlight that the abnormal Glu exocytosis in the spinal cord of pre-symptomatic $SOD1^{G93A}$ mice is mainly based on the increased size of the RRP of vesicles and is supported by plastic changes of specific presynaptic mechanisms. The precociousness of the event support the idea that the increase of Glu release, also recorded later during pathology, may represent a causative factor rather than a consequence of disease progression.

Abstract: Charcot-Marie-Tooth 2A (CMT2A) is a common inherited polyneuropathy, characterized by motor and sensitive neuron degeneration, and caused by mutations in Mitofusin 2 gene (*MFN2)*, which encodes a mitochondrial membrane protein critical in maintaining mitochondrial network. Since MFN2 is ubiquitously expressed, the reason for selective motor

neuron (MN) degeneration in CMT2A is unknown. To address this question, we differentiated MNs from induced pluripotent stem cells (iPSCs) derived from CMT2A patients, developing an *in vitro* disease model. CMT2A iPSC-derived MNs (CMT2A-MNs) presented a reduction in mitochondrial content and localization, without significant differences in survival and axon elongation. RNA sequencing and proteomic analyses of key components of the apoptotic program demonstrated that CMT2A-MNs are more resistant to apoptosis than wild-type MNs. Analyzing the balance between mitochondrial biogenesis and the regulation of autophagy-lysosome transcription, we detected an augmented autophagic flux in CMT2A-MNs that was linked with up-regulation of PINK1, PARK2, BNIP3, and a splice variant of BECN1 that was recently showed to be a trigger for mitochondrial autophagy. Our data suggest that the mitochondria reduction in MNs expressing mutant MFN2 is not the result of impaired biogenesis, but more likely the consequence of enhanced mitophagy. Thus, these pathways represent potential novel molecular therapeutic targets for the development of effective cure for CMT2A.

Title: Mitochondria associated er membranes in amyotrophic lateral sclerosis

Authors: *D. LARREA[1], E. RHODES LOWRY[2], J. SMERDON[2], H. WICHTERLE[2], E. AREA-GOMEZ[1];
[1]Neurol., [2]Pathology, Columbia Univ., New York, NY

Abstract: Amyotrophic Lateral Sclerosis (ALS) is characterized by progressive degeneration of primary motor cortex neurons, anterior horn cells and lower motor neurons. Mutations in specific genes, such as *SOD1, FUS, VAPB, C9orf72, TARDBP, and SIGMAR1* cause familial forms of ALS, representing only the 5-10% of cases. While implicated in different pathways, these mutations share common pathogenic mechanisms that result in motor neuron degeneration and muscle denervation. Among these, endoplasmic reticulum (ER) stress and mitochondria

dysfunction, alterations in calcium and lipid homeostasis, defective autophagy and protein aggregation have been described, however the cause of these seemingly unrelated phenotypes is unknown. Mitochondria-associated ER membranes (MAMs) are a subdomain of the ER connected physically and biochemically to mitochondria, and are involved in the regulation of several key cellular functions such as lipid metabolism, calcium homeostasis, mitochondrial function, ER-stress and unfolding protein response regulation. Alterations of these functions have been shown to occur early in ALS, although the role of ER-mitochondria interactions has not been systematically studied in this disease. We have studied MAM function measured as (i) the synthesis and conversion of phosphatidylserine to phosphatidylethanolamine (ii) cholesterol esterification by ACAT1 (acylCoA:cholesterol acyltransferase; gene *SOAT1*) activity, (iii) lipid droplet accumulation and mitochondrial respiration in cells and tissues from ALS mouse models and iPS-derived motor neurons from ALS patients. Our results showed decreased levels of (i) phospholipid synthesis (ii) ACAT activity and (iii) significantly lower amounts of lipid droplets. Also, oxygen consumption was decreased in ALS mouse mutant cells and in isolated mitochondria, when compared with controls. Altogether our studies indicate a significant and early alteration in MAM activity and ER- mitochondria cross talk in ALS pathogenesis.

Title: Histopathological findings in an adult Down syndrome patient presenting with ALS

Authors: *B. PARÉ[1], N. DUPRÉ[2], P. GOULD[2], F. GROS-LOUIS[2];
[1]Laval Univ., Quebec, QC, Canada; [2]Laval Univ., Québec, QC, Canada

Abstract: A connection between Alzheimer's disease and Down syndrome has been described extensively in the literature. The higher risk for Alzheimer's disease in people with Down syndrome has been attributed to increased production of amyloid beta due to an extra copy of chromosome 21, but other genes on chromosome 21 may also play a role, such as superoxide dismutase (SOD1). Little is known about the consequences of trisomy 21 for other neurodegenerative diseases. We present the case of a 49-year-old male diagnosed with trisomy 21 at an early age, who developed severe intellectual deficiency and progressive muscle weakness of the upper limbs at the age of 47. He also complained of pain in the shoulders, and

became unable to move his right arm within months. The symptoms worsened over the following year. He progressively stopped walking, developed dysphagia, further impairment of the lower limbs and eventually died. At the autopsy, the patient presented characteristic craniofacial morphological features of Down syndrome. Macroscopic examination of the brain showed atrophy of the superior temporal gyrus and the frontoparietal cortex, a small hippocampus and dilatation of the lateral ventricles. Microscopic examination of the brain showed typical features of Alzheimer's disease with amyloid deposits in the cerebral cortex, basal ganglia and cerebellar cortex. Gallyas staining showed the presence of numerous neuritic plaques at the level of the hippocampus. Immunohistological stains for alpha- synuclein did not reveal the presence of Lewy bodies. CD68 immunohistochemistry revealed abundant macrophages in the medullary pyramids and lateral columns and an associated microglial reaction. TDP-43 immunohistochemistry showed a filamentous staining in the cytoplasm and a loss of nuclear staining within motor-neurons. Ubiquitin immunohistochemistry showed weak staining of some spinal nerve roots. SOD1 immunohistochemistry showed a staining in the cytoplasm colocalizing with TDP-43. The present case shows that neurodegenerative disease in Down syndrome patients can take other forms besides Alzheimer’s disease, including amyotrophic lateral sclerosis. In familial ALS (FALS), any one of the reported SOD1 inherited mutations in the SOD1 gene can lead to misfolding of the protein exerting its toxic gain of function. As cytoplasmic TDP-43 inclusions in mutant SOD1-related FALS cases are relatively rare, the presence of cytoplasmic misfolded SOD1 colocalizing with TDP43 suggests that the present case is sporadic in nature and that non-native conformers of SOD1-linked ALS and SALS might converge on a common pathogenic pathway.

Abstract: Amyotrophic lateral sclerosis (ALS) is a rapidly progressive neurodegenerative disorder which is due to the selective loss of motor neurons in the motor cortex, brainstem and spinal cord. In 10% of patients, ALS is a familial disease. One of the important genetic causes of familial ALS are mutations in the FUS gene. How these mutations cause the disease is still unknown. To model FUS-ALS in a dish, we generated integration-free induced pluripotent stem cells (iPSCs) from ALS patients with different FUS mutations. Fibroblasts from three ALS patients with an R521H and one patient with a P525L point mutation in FUS, as well as from their unaffected family members were infected with the CytoTune-2 Sendai-virus reprogramming kit. Immunostaining, quantitative RT-PCR, teratoma formation analysis and integration assays were used to identify the pluripotency of the iPSC, and the absence of Sendai viruses. Motor neurons were derived from the iPSCs by inhibiting the SMAD pathway and by activating the Hedgehog signaling (SHH) pathway. Highly pure motor neurons were successfully generated from these iPSCs. Mislocalisation of FUS was observed in the ALS patient derived motor neurons, especially in the ones derived from the P525L line. Axonal transport was measured using MitoTracker Red. The relative amount of moving and stationary mitochondria, as well as transport velocities could be analyzed on kymographs. This clearly showed a progressively lower amount of moving mitochondria as a function of the time of differentiation in the ALS patient samples. These results indicate that mutations in FUS lead to axonal transport defects which is in line with the ‘dying back theory’ as this axonal dysfunction could lead to the retraction of the motor axon.

Abstract: Like all neuronal types, lower motor neurons have a particular electrophysiological identity according to their synaptic inputs and ion channel constitution. Disease modeling using human pluripotent stem cell-derived motor neurons (hPSC-MNs) has shown that there are abnormalities in the intrinsic excitability of hPSC-MNs from patients with amyotrophic lateral sclerosis (ALS), suggesting a change in ion channel function. While the phenotypes seen in ALS patient-derived hPSC-MNs are promising avenues for further investigation, a roster of the specific channels that determine motor neuron excitability is needed. In addition, it is important to confirm that hPSC-MNs functionally resemble *bona fide* motor neurons, given that they are derived in an artificial environment and little broad functional characterization has been performed in hPSC-derived neurons. To better elucidate the determinants of motor neuron excitability, we cultured hPSC-MNs and primary mouse motor neurons (mMNs) on microelectrode arrays (MEAs), grids of extracellular electrodes that allow us to record the baseline firing and response to a host of drugs in large motor neuron populations. Using receptor and channel-selective pharmacological agents as well as ALS candidate therapeutics, we developed a profile of responses that indicate both synaptic and voltage-gated channel contributions to excitability. Spike rate, burst rate, and network burst rate were examined before and after treatment with each agent. When neurotransmitter receptors were investigated, we found that both glutamate and nicotinic acetylcholine receptor blockers stopped the network activity in the cultures. Among the ion channel blockers, Kv7 channel, L-type calcium channel, and HCN channel blockers all consistently modulated activity metrics measured from the hPSC-MNs and mMNs. The pharmacological profile that is emerging through these experiments provides a framework for comparing motor neuron models and identifying ion channel families underlying motor neuron physiology and disease phenotypes.

Title: Cell-to-cell transmission of C9orf72-linked dipeptide repeat proteins

Authors: *T. R. WESTERGARD, B. JENSEN, X. WEN, P. PASINELLI, D. TROTTI; Thomas Jefferson Univ., Philadelphia, PA

Abstract: Intronic hexanucleotide repeat expansions in the *C9orf72* gene are the most common genetic cause for amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). RNA transcripts of these expansions can undergo RAN translation to form five dipeptide repeat proteins (DPRs): poly(GA), poly(GP), poly(GR), poly(PA), and poly(PR). DPR aggregates are found throughout the CNS of C9orf72-ALS/FTD patients and cause neuronal degeneration and dysfunction in cell and animal models. While DPR toxic mechanisms continue to be investigated, the potential for DPR aggregates to spread has yet to be determined. Utilizing different experimental platforms, we found evidence for cell-to-cell transmission for each DPR with varying frequencies and modality of spreading. One mechanism behind transmission is *via* exosomes. Exosomes isolated from DPR-expressing cells showed varying amounts of DPRs and evidence of transmission to neurons. DPR transmission also occurred through exosome-independent pathways. These studies demonstrate cell-to-cell transmission of C9-DPRs, which is potentially relevant to disease.

Title: Astrocyte dysfunction in fus-linked amyotrophic lateral sclerosis

Authors: *K. MCAVOY, K. KRISHNAMURTHY, D. TROTTI, P. PASINELLI;
Thomas Jefferson Univ., Philadelphia, PA

Abstract: Mutations in Fused in Sarcoma (FUS) are linked to Amyotrophic Lateral Sclerosis (ALS), a fatal neurodegenerative disease affecting both upper and lower motor neurons. FUS mutations account for approximately 5% of familial (fALS) and rare cases of sporadic ALS (sALS) while FUS-positive pathological inclusions have been identified in fALS and sALS. It is well established that in ALS, non-neuronal cell types such as astrocytes contribute to motor neuron degeneration and disease progression. We have previously reported that FUS mutations alter astrocyte function and cause astrocytes to become neurotoxic. We identified NF-kB, TNFα signaling, and neuronal AMPA receptors as important mediators of this toxicity. Here, we explore the mechanisms and molecular changes underlying mutant FUS-linked astrocyte dysfunction *in vitro*. Further, we tested the consequences of astrocyte-specific expression of mutant FUS *in vivo* using AAV-mediated delivery of the FUS variant R521G into the cervical spinal cord of adult mice.

Title: Investigating the cortical aspects of ALS in mouse and human stem cell models

Authors: ***M. C. FRANQUIN**[1], H. PENG[2], B. PONROY[1], C. ERNST[2], D. STELLWAGEN[1]; [1]Ctr. For Res. In Neurosci., McGill Univ., Montreal, QC, Canada; [2]Psychiatry, Douglas Mental Hlth. Univ. Institute, McGill Univ., Montreal, QC, Canada

Abstract: Amyotrophic lateral sclerosis (ALS) is a progressive neuromuscular disease involving neurodegeneration of upper (cortical) and lower (spinal and brainstem) motor neurons, as well as other cortical areas. Data from ALS patients indicates cortical hyperexcitability and the most commonly used mouse model of ALS ($SOD1^{G93A}$) shows cortical alterations at the pre-symptomatic stage of the disease in the layer V of primary motor cortex (M1) including hyperexcitability and increased miniature excitatory post-synaptic current (mEPSC) frequency. This could be driven by changes in astrocyte function, as neuronal-only expression of mutant SOD1 does not lead to an ALS phenotype and reactive astrocytes have been observed in patients with ALS. Reactive astrocytes would produce inflammatory signaling, which could trigger changes in homeostatic synaptic plasticity and lead to a perturbed E/I balance in the cortical cells and hyperexcitability.
We are studying this possibility in two models of ALS: the $SOD1^{G93A}$ mouse model and a human model based on the differentiation of induced pluripotent stem cells (iPSCs) from patients into neurons and astrocytes. We are performing electrophysiological as well as morphological analysis in layer V of M1 in the $SOD1^{G93A}$ mouse model to determine the contribution of inflammatory signaling to the changes in synapses. Further, we are characterizing the electrophysiology changes in iPSC-derived neurons, grown in conjunction with wildtype or mutant iPSC-derived astrocytes. The homeostatic synaptic plasticity capacities of neurons from patients with ALS will also be assessed, as well as the contribution of inflammatory signaling particularly tumor necrosis factor alpha (TNF).
Overall, this work would provide new insights into the cortical aspects of ALS and the implications of the different cell types in the pathogenesis with allegations found in the pre-symptomatic mouse model being verified in a human model of the disease.

Inst., Sydney, Australia

Abstract: Amyotrophic lateral sclerosis (ALS) is a devastating fatal neurodegenerative disorder with no effective treatment or direct diagnosis. A proportion of patients also develop clinical or subclinical frontotemporal dementia (FTD). Genetic defects are the only proven cause of ALS, but the primary molecular pathways underlying ALS remain unclear. Recently, we identified ALS-linked mutations in cyclin F (encoded by CCNF), an E3 ubiquitin ligase that mediates ubiquitination of protein substrates for degradation by the proteasome. The objective of this study is to investigate the functional consequences of cyclin F mutations in post-mortem tissue and cell models. To investigate whether ALS-linked cyclin F mutations lead to proteostatic dysfunction, we performed a flow cytometry based ubiquitin-proteasome system (UPS) GFPu reporter assay. The GFPu reporter consists of a 16 amino acid CL1 degron sequence that ensures rapid degradation via the UPS. Thus over-accumulation of GFPu, as measured by GFP fluorescence intensity, indicates UPS dysfunction or overload. The GFPu construct and either mutant cyclin F, wild type cyclin F, or cyclin F with known polymorphisms identified in ALS/FTD patients, including those in public databases were co-transfected into the motor neuron-like NSC-34 cell line. Cells were harvested 48 hr after transfection and the GFP fluorescence intensity was analysed using flow cytometry. Significantly higher levels of GFPu fluorescence were observed for cyclin F with ALS/FTD mutations ($P<0.05$), indicating UPS dysfunction. It was found that the presence of mutant cyclin F, but not wild type cyclin F, nor the cyclin F polymorphisms, caused GFPu to aggregate in the cytoplasm, and cyclin F was sometimes present in these GFPu positive inclusions. Using a flow cytometry based cytotoxicity assay, we also found that cells expressing mutant cyclin F showed a significantly higher percentage of cell death compared to wild type cyclin F and the cyclin F polymorphisms. Ubiquitin-positive cytoplasmic inclusions are a characteristic pathological feature seen in the affected neurons of the brain and spinal cord of both familial and sporadic ALS and ALS-FTD patients. Using immunohistochemical staining, we observed mislocalisation of TDP-43 from the nucleus to cytoplasm, and ubiquitin- and TDP-43-positive cytoplasmic inclusions in post mortem brain stem and spinal motor neurons of a patient with an ALS-linked CCNF mutation. Taken together, we have provided in vitro observations of aberrant cyclin F function that mimic pathogenic features seen in familial and sporadic ALS and support dysfunction of the proteostasis network in ALS pathogenesis.

Abstract: The aim of this study was to produce spinal motor neurons from human induced pluripotent stem cells (iPSCs) with sufficient purity for use in a multitude of downstream assays including electrophysiological recordings using a multi-electrode array (MEA) system. In particular we wanted to produce motor neurons that could be cultured in defined conditions over long periods of time, without being hampered by outgrowth from proliferative cell types. Using an optimized 3D differentiation protocol that improves upon published methods, we were able to produce motor neurons from iPSCs at greater than 60% purity as measured by Isl 1/2 and Tuj1 positive staining. These cells can be stored frozen, thawed, and cultured in media without glia for extended periods, simplifying experimental design and data interpretation. We collected ICC, qPCR and MEA data to characterize the motor neuron cells and used iPSC lines from multiple donors to demonstrate a robust protocol that produces motor neurons independent of donor iPSC line. In addition, genetically modified iPSC lines were generated to create an isogenic disease model for Amyotrophic Lateral Sclerosis. These data show the characteristics and utilization of motor neurons produced from iPSC.

Abstract: Amyotrophic lateral sclerosis (ALS) is associated with hyperexcitability in cortical and spinal motor neurons. We have demonstrated a hyperexcitability phenotype in motor neurons derived from ALS patient iPSC lines that harbor SOD1 and FUS mutations and C9orf72 repeat expansions and have shown that inhibition of this hyperexcitability using the potassium channel (Kv7) opener retigabine, reduces motor neuron cell death, supporting a pathogenic role (Wainger et al., Cell Reports, 2014). However, the mechanisms responsible for the hyperexcitability remain unresolved. To tackle this we have recently developed patch-seq and patch-RT-qPCR techniques for linking neuronal excitability and gene expression at the single cell level, collecting RNA after whole cell patch clamp recordings from motor neurons and performing single cell next generation sequencing or high-throughput multiplex qPCR. Single cell gene expression profiling in functionally characterized neurons was conducted on HB9::GFP sorted iPSC-derived motor neurons from an ALS patient carrying the SOD1 A4V mutation (39b) and isogenic control motor neurons with the mutation corrected (39b-cor). We found by whole cell current clamp recording that 39b motor neurons have larger cell sizes and robust hyperexcitability compared to 39b-cor motor neurons. Both single cell RNA-seq and ion channel targeted multiplexed high throughput qPCR analysis independently show a significant down-regulation of a K channel in hyperexcitable ALS motor neurons from this patient and its expression is negatively correlated with neuronal excitability. The hyperexcitability and the K channel subtype down-regulation were replicated in an independent batch of motor neurons from the same line. These results suggest the reduced expression of a K channel as a molecular mechanism for the increased excitability in familial ALS.

Title: Dynactin mutations associated with amyotrophic lateral sclerosis and their effect on axonal transport and neuromuscular junction formation

Authors: *V. BERCIER[1,2], T. O. AUER[3], K. DUROURE[1], F. DEL BENE[1,2];
[1]Inst. Curie-Research Ctr., Paris, France; [2]École des Neurosciences de Paris-Ile-de-France, Paris, France; [3]Ctr. for Integrative Genomics, Univ. of Lausanne, Lausanne, Switzerland

Abstract: Amyotrophic lateral sclerosis (ALS) is an adult-onset neurodegenerative disease, which is mainly sporadic in nature. This progressive pathology has an estimated incidence of 1:1000 and generally leads to death within 2-5 years of diagnosis due to muscle wasting and severe motor neuron loss. Over the last years, mutations have been identified in both sporadic and familial ALS patients, interfering with the function of many genes, including *DCTN1*, which encodes for a subunit of the motor protein complex component dynactin. The dynactin complex serves as an adaptor for the dynein motor complex, responsible for retrograde axonal transport, and it is believed to regulate dynein activity and the binding capacity for cargos. Interestingly, axonal transport deficits have been reported in various neurodegenerative diseases owing to the fact that neurons are highly polarized cells that depend on active axonal transport for growth, establishment and maintenance of synapses.
Defects in transport of material for development or clearance of detritus in the axon can lead to neuronal stress and cell death and could arise from different causes: preferential type of transport, varying load size, and depletion or dilution of the motor protein populations.
In order to determine how retrograde axonal transport is involved in the pathogenesis of ALS, we are characterizing a mutant zebrafish line for *dctn1* with regard to axonal development of primary motor neurons, formation and stability of the neuromuscular junction (NMJ) and the behavioral phenotype produced in embryos.
Fast axonal transport defects are quantified in primary motor neurons using the GAL/UAS bipartite system and fusion protein tracking *in vivo* by confocal timelapse microscopy. We are investigating the transport dynamics of cargos such as endosomes, mitochondria, synaptic vesicles and neurotrophic receptors in the motor neurons of wild-type versus *dctn1* mutant

embryos *in vivo*, and over time. As dynactin was reported to be essential to synapse stability, we are examining the formation and maintenance of the NMJ with techniques such as immunohistochemistry, GCaMP calcium imaging, and muscle-motor neuron paired recordings. We hope to elucidate key molecular mechanisms in ALS etiology by revealing the role of dynein in NMJ maintenance and identifying novel regulatory events in axon degeneration and muscle atrophy along disease progression.

Abstract: Our preliminary investigations showed that fractions from catfish skin preparations (CSP) from the Arabian Gulf Catfish (Arius bilineatus, Val.) exhibit potent anti-inflammatory and healing properties as shown in our previous clinical trials for the healing of non-healing diabetic foot ulcers, chronic back pain, and some other neurological disorders. In this study, we examined the neurobehavioral parameters and histomorphological changes in the sciatic nerve crush injury model following CSP treatment. **Methods:** Adult (4 months) male Wistar rats (n= 8) were randomly assigned to five groups: (i) Control naïve (NAIVE) group; (ii) Control Sham (SHAM) group; (iii) Sciatic nerve crush+Saline (CRUSH) group; (iv) Sciatic nerve crush+CSP1 subcutaneously (s.c.) injected (CRUSH+CSP1) group; (v) Sciatic nerve crush+CSP2 intraperitoneally (i.p.) injected (CRUSH+CSP2) group. Rats in CRUSH+CSP1 and two groups underwent surgery where in sciatic nerve was crushed but treated with 6 mg/Kg CSP s.c. and i.p., respectively, for 11 days. **Results:** Administration of CSP s.c. or i.p. to the nerve injured rats significantly improved their performance on different neurobehavioral functional tests. CRUSH+CSP1 and CRUSH+CSP2 groups showed significant recovery in foot position and toe-

spread analyses following injury. Likewise, CSP-treated animals exhibited improvements in motor recovery as measured by the extensor postural thrust (EPT) and hopping response. The CRUSH+CSP groups showed a significant reduction in the mechanical hyperalgesia threshold, heat withdrawal reflex and tail flick withdrawal latency tests compared to the CRUSH group. CSP treatment remarkably ameliorated the neurodegenerative changes seen in Cresyl violet stained ventral gray horn region of the spinal cord sections ipsilateral to the nerve injury. Further, CSP treatment significantly prevented the decrease in the number of the NeuN immunoreactive spinal neurons ipsilateral to the crush injury. The stereological evaluation revealed significant histomorphological evidence of neuroregeneration in the sciatic nerve of the CRUSH+CSP groups compared to controls at 4 and 6 weeks postoperatively. CSP treatment increased the axon area, myelin thickness, fiber diameter to axon diameter ratio and the myelin thickness to axon diameter ratio. **Summary:** The data analysis supports our hypothesis that CSP treatment lessens neurobehavioral deficits and stimulates regeneration of the axons and histomorphological alterations following nerve injury. Further, CSP protects spinal neurons and enhances subcellular recovery after peripheral nerve injury and thus improves nerve regeneration.

Title: Galectin-3 as a cytoprotective molecules in Schwann cells under diabetic conditions

Authors: *H. YAKO, N. NIIMI, M. TSUKAMOTO, K. SANGO;
Dept. of Sensory and Motor Syst., Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan

Abstract: Accumulation of advanced glycation end products (AGEs) is involved in the pathogenesis of diabetic complications, such as neuropathy, nephropathy and retinopathy. Galectin-3 (GAL-3), a member of a family of β-galactoside binding animal lectins, is identified as an AGE-binding protein and appears to play a protective role against diabetic nephropathy by the removal of the increased amounts of glomerular AGEs. However, functional roles of GAL-3

in the peripheral nervous system (PNS) remain unclear. In this study, we aimed to elucidate the precise localization and possible functions of GAL-3 in the PNS under normal and diabetic conditions. Immunohistochemical analysis revealed that the GAL-3 was predominantly expressed in isolectin B4-binding small non-peptidergic neurons and some of S100-positive Schwann cells in the sections of adult rat dorsal root ganglia (DRG). Next, we conducted western blot analysis to investigate the protein expression of GAL-3 in immortalized adult rat Schwann cells IFRS1 under normal and diabetic conditions. Exposure of the IFRS1 cells to 30 mM of glucose or 0.2 mM of an AGE precursor 3-deoxyglucosone (3-DG) for 7 days up-regulated the expression of GAL-3, 2.1-fold and 2.5-fold as compared with control (5.6 mM of glucose), respectively. The high glucose-induced up-regulation of GAL-3 was suppressed by co-treatment with an anti-glycated agent aminoguanidine (0.2 mM) or an antioxidant trans-resveratrol (20 nM). In addition, treatment of the IFRS1 cells with recombinant GAL-3 (1 μg/mL) for 2 days significantly up-regulated the expression of an anti-apoptotic marker Bcl-2 and down-regulated the expression of an oxidative stress marker 4-hydroxynonenal, 1.5-fold and 0.7-fold as compared with control, respectively. Furthermore, knockdown of GAL-3 mRNA expression by RNA interference resulted in the significant decreases in the cell viability ratios after 7 days exposure to the diabetic conditions as compared with mock (transfected control siRNA); from 0.83 to 0.69 at 30 mM of glucose, from 0.72 to 0.57 at 0.2 mM of 3-DG, and from 0.64 to 0.37 at 0.5 mM of 3-DG, respectively. These findings imply that GAL-3 induced by glycation and oxidative stress under the diabetic conditions exhibit a cytoprotective property in Schwann cells.

Title: A small heat shock protein protects against vincristine-induced peripheral axonal damage in mice.

Authors: *V. B. CHINE[1], G. KUMAR[1], C. H. E. MA[1,2];
[1]Dept. of Biomed. Sci., City University of Hong Kong, Kowloon, Hong Kong; [2]Ctr. for Biosystems, Neuroscience, and Nanotechnology, City Univ. of Hong Kong, Kowloon, Hong Kong

Abstract: Development of sensorimotor painful peripheral neuropathy is evident in cancer patient treated with Vincristine often results in the withdrawal of cancer treatment. Vincristine is commonly used for treatment of lung cancer, leukemia, and blood-related disorders. Vincristine depolymerizes microtubules resulting in disruption of microtubule dynamics. This disruption leads to inefficient axonal transport and thereby causing peripheral nerve degeneration. Our previous study reported the reduced axonal growth and disruption of cytoskeleton in dorsal root ganglia (DRG) neurons after Vincristine treatment. Vincristine causes terminal arbor degeneration and axonal loss which results in decreasing intra-epidermal nerve fiber density (IENFD). Reduction in sensory nerve action potential (SNAP) amplitude, nerve conduction velocity (NCV) and compound muscle action potential (CMAP) were observed, which was consistent with the development of mechanical allodynia detected in mice after Vincristine treatment. Heat shock protein 27 (Hsp27) is a ubiquitously expressing chaperone acting as anti-oxidant and anti-apoptotic in cellular stress conditions. Previously we have shown accelerated axonal regeneration in mouse with better motor and sensory functional recovery by overexpression of human Hsp27 (hHsp27) specifically in both sensory and motor neurons. Vincristine induced peripheral neuropathy model was developed by injecting vincristine sulfate intraperitoneally to hHsp27 transgenic (hHsp27 Tg) and their littermate (LM) mice while vehicle control (VH) mice were injected with saline. We assessed mechanical and cold allodynia and found that hHsp27 Tg group recovered significantly from allodynia while in LM group both mechanical and cold allodynia persisted till day 28. Moreover immunohistochemical evaluation of IENFD, myelin basic protein and neuromuscular junctions analysis also showed significant protection in hHsp27 Tg mice than in LM mice. A number of electrophysiological parameters such as SNAP, NCV and CMAP were better preserved in hHsp27 Tg compared with LM controls after treated with vincristine. Our results clearly showed that overexpression of hHsp27 can protect against vincristine-induced peripheral neuropathy in mice. Further studies offer possible therapeutic opportunities to prevent the devastation caused by CIPN.

Title: Neuroprotective effects of P7C3-A20 in a model of paclitaxel-induced peripheral neuropathy

Authors: P. M. LOCOCO, H. R. SMITH, J. C. ZAMORA, T. A. CHAVERA, K. A. BERG, *W. P. CLARKE;
Univ. Texas Hlth. Sci. Ctr., San Antonio, TX

Abstract: Paclitaxel (PTX), a microtubule-targeting anticancer agent, produces a debilitating peripheral neuropathy that is accompanied by neuropathic pain. Because effective therapies do not exist, patients often choose to reduce life-saving chemotherapy to cope with the pain. We have reported that the aminopropyl carbazole, P7C3-A20, prevents the development of PTX-induced neuropathic pain in rats. To further characterize the neuroprotective efficacy of P7C3-A20, we performed a dose-response study using our rat behavioral model of PTX-induced peripheral neuropathy. P7C3-A20 (2.2, 6.6, or 20 mg/kg, i.p., q.d.) or vehicle was administered to male Sprague-Dawley rats over a 16-day period. After two days of treatment, PTX (11.7 mg/kg, i.p.) or vehicle was injected every other day for three days. Nociceptive thresholds to mechanical and cold stimuli were measured periodically throughout the experimental period. P7C3-A20 dose-dependently attenuated PTX-induced mechanical and cold allodynia. Immunohistological analysis of intraepidermal nerve fiber (IENF) density in paw biopsies revealed that the PTX-induced reduction of IENF density was also dose-dependently reduced by P7C3-A20. Statistical analyses indicated strong correlations between IENF density and nociceptive threshold to mechanical and cold stimuli. Previously, P7C3-A20 was shown in vitro to stimulate NAMPT, a critical enzyme in the NAD salvage pathway. Thus, we sought to determine whether the protective effects of P7C3-A20 could be antagonized in vivo by the selective NAMPT inhibitor, FK866. Using the same paradigm, we incorporated daily injections of FK866 (0.5 mg/kg, i.p., b.i.d.) along with P7C3-A20 (10 mg/kg). As before, P7C3-A20 prevented the development of mechanical allodynia compared to PTX controls. By contrast, rats co-injected with FK866 and P7C3-A20 displayed persistent mechanical allodynia, indicating that FK866 blocked the protective effects of P7C3-A20. Analysis of IENF densities revealed that FK866 also blocked preservation of nociceptive fibers by P7C3-A20. Collectively, these data suggest that the protective effects of P7C3-A20 require function of NAMPT.

Abstract: Methamphetamine (Meth) is the most abused drug and often consumed for pleasure in healthy and/or people suffering from endocrine or cardiovascular diseases. Meth induces severe oxidative stress in the brain leading to brain pathology. Likewise oxidative stress also induces brain damage in diabetics. Whether Meth use in diabetics results in exacerbation of brain damage is still unclear. In this investigation we examined Meth induced brain damage and oxidative stress in diabetes in our rat model.
Rats were made diabetic by administration of streptozotocine (75 mg/kg/day for 3 days, i.p.)

resulting in blood glucose level to 22 to 26 mM/L within 4 to 6 weeks. In these diabetic rats Meth was administered 10 mg/kg, s.c. and brain pathology, e.g., blood-brain barrier (BBB) breakdown to Evans blue albumin and radioiodine ($^{[131}$-I]), brain edema formation and neuronal, glial and axonal injuries were examined. Immunostaining for Myelin basic protein (MBP) and histological staining of Luxol Fast Blue (LFB) to study axonal degradation, glial fibrillary acidic protein (GFAP) for astrocytic activation and histopathological techniques of Nissl or H&E stain for neuronal injuries were carried out on paraffin sections. Immunohistochemical analyses of enzymes responsible for free radical gas nitric oxide i.e., neuronal nitric oxide synthase (nNOS) and inducible nitric oxide synthase (iNOS) were examined on paraffin sections.
Our observations showed about 3- to 5 fold higher BBB breakdown and 2- to 4-fold greater volume swelling and brain edema formation was seen in diabetic rats after Meth exposure as compared to healthy animals. Interestingly, neuronal, glial cell and axonal injuries were exacerbated by 4- to 6-fold in Meth treated diabetic rats as compared to normal healthy animals. Thus, neuronal damage, astrocytic activation and myelin vesiculation were most prominent in the hippocampus, thalamus, hypothalamus, cerebellum and cerebral cortex. These brain areas also exhibited marked increase in nNOS and iNOS expression. The magnitude and severity of iNOS and nNOS expression was 2- to 3-fold higher in diabetic rats after Meth administration. These neuropathological changes and NOS expression in diabetic rats were significantly reduced by TiO2-nanowired delivery of H-290/51 (50 mg/kg, i.p.) 30 min after Meth administration in diabetic rats. Whereas normal H-290/51 was enough to induce neuroprotection in Meth treated healthy animals. These observations are the first to point out that diabetes exacerbate Meth induced neuropathology via oxidative stress and nanodelivery of antioxidant compound is needed for neuroprotection in such situation, nor reported earlier.

Title: Central insulin attenuates diet-induced hypothalamic inflammation

Authors: *A. MAY[1], N. D. BEDEL[2], D. J. CLEGG[3], M. WORTMAN[2], S. WOODS[2], M. LIU[2]; [1]Pathology, [2]Univ. of Cincinnati, Cincinnati, OH; [3]Cedars-Sinai, Los Angeles, CA

Abstract: Inflammation of the hypothalamus promotes weight gain in rodent models of diet-induced obesity and directly contributes to the co-morbidities of obesity, including type II diabetes and cardiovascular disease. Insulin acts within the brain to prevent inflammation in mouse models of LPS-induced sepsis and Alzheimer's disease. However, the effect of insulin on diet-induced inflammation is not yet known. Several clinical studies have demonstrated that intranasal insulin directly enters the brain and effectively reduces body weight and improves cognition in humans. This same approach might also be effective at preventing diet-induced inflammation. Here, we tested the hypothesis that centrally-administered insulin acts as an anti-inflammatory signal in the hypothalamus of rodents during diet-induced inflammation. First, we examined the effects of insulin on inflammatory signaling in cultured hypothalamic neurons. Physiological levels of Insulin increased the phosphorylation of the inflammatory signaling molecule, IKKβ, which is indicative of increased activation of the NF-κB signaling pathway. Since cell culture exposes neurons to levels of glucose and other nutrients that are not physiologically-relevant, we followed-up on these findings *in vivo*, by injecting insulin directly into the third cerebral ventricle to target the hypothalamus of conscious rats. The dose of insulin used in this study has been demonstrated to reduce food intake and body weight in our lab. In contrast to our findings from cell culture, insulin did not induce inflammation relative to controls injected with artificial cerebrospinal fluid (aCSF). In contrast, rats injected with LPS at the same time had significantly higher levels of inflammatory cytokines within this same timeframe. These results provide strong evidence that insulin does not induce hypothalamic inflammation. We next examined the effects of insulin administration into the brain during high-fat diet feeding. Several rodent studies have demonstrated that a 60% high-fat diet reliably induces hypothalamic inflammation within just 1-3 days, relative to controls fed a standard chow diet. We surgically implanted rats with intracerebroventricular cannulas targeting the lateral ventricle and provided a 2-week recovery period prior to the study. As expected, short-term high-fat-diet feeding increased hypothalamic inflammation relative to chow-fed rats. Under these conditions, repeated insulin administration attenuated hypothalamic inflammation relative to aCSF-injected controls, suggesting that insulin may provide clinical benefits by reducing hypothalamic inflammation.

Title: Dietary restriction promotes cell survival in a mouse model of normal tension glaucoma

Authors: *X. GUO, K. NAMEKATA, A. KIMURA, T. NORO, G. AKIYAMA, Y. AZUCHI, C. HARADA, T. HARADA;
Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan

Abstract: Glaucoma, one of the leading causes of vision loss in the world, is characterized by progressive degeneration of retinal ganglion cells (RGCs) and their axons. Glaucoma is usually associated with elevated intraocular pressure, but there is a subset of glaucoma termed normal tension glaucoma (NTG) that presents with statistically normal intraocular pressure. We previously reported that loss of glutamate transporters (EAAC1 or GLAST) in mice leads to RGC degeneration that is similar to NTG and these animal models have been useful in examining potential therapeutic targets.
Dietary restriction has been reported to increase longevity and has some benefits in injury and disease. Among them, every-other-day fasting (EODF), a form of dietary restriction, has been shown to be neuroprotective when being implemented after rat cervical spinal cord injury. Here we investigated the effects of EODF on RGC protection in EAAC1 KO mice.
In the EAAC1 KO mouse retina, the number of RGCs was significantly decreased and this effect was suppressed with EODF treatment. We also visualized retinal layers in living mice using spectral-domain optical coherence tomography (SD-OCT), a noninvasive imaging technique that can be used to acquire cross-sectional tomographic images of the retina in vivo. The average thickness of the inner retinal layers was decreased in EAAC1 KO mouse eyes, but it was unchanged in EODF treated eyes. Consistent with histological analyses, the visual impairment observed in EAAC1 KO mice, as assessed by multifocal electroretinograms (mfERGs), an established noninvasive method for reliably measuring visual function, was inhibited with EODF treatment, indicating the functional significance of the neuroprotective effect of EODF. We then explored possible mechanisms associated with EODF-mediated neuroprotection. As expected, blood β-hydroxybutyrate levels, a ketone known to be neuroprotective and a histone deacetylase inhibitor, were increased significantly on the fasting days. Consistently, acetylation of histones was upregulated in the EODF retina, and so were the expression levels of neurotrophic factors such as the basic fibroblast growth factor (bFGF) and brain-derived neurotrophic factor (BDNF), and catalase, an antioxidant gene. Furthermore, 4-hydroxynonenal (4-HNE), which represents

oxidative stress levels, was reduced in the EODF retina. Our findings suggest that EODF, a safe, non-invasive, and low-cost treatment, may be available for RGC protection during glaucoma.

Title: PDGF-AA-mediated retinal ganglion cell neuroprotection results from its interaction with retinal astrocytes and/or a subtype of amacrine cells

Authors: *S. I. TOMAREV[1], S. TAKAHAMA[1], M. O. ADETUNJI[1], T. ZHAO[2], W. LI[2]; [1]SRGCB, LRCMB, [2]RNS, NEI, NIH, Bethesda, MD

Abstract: Glaucoma, a group of chronic, degenerative optic neuropathies, is a major cause of blindness worldwide. Retinal ganglion cell (RGC) death is one of the pathogenic features of glaucoma. Our previous study showed that treatment of retinae with platelet-derived growth factor AA (PDGF-AA) rescued RGCs from death in a rat glaucoma model and retinal explant cultures. PDGF-AA acts through interaction with PDGF receptor alpha (PDGFRα). However, the molecular mechanisms of PDGFRα-mediated neuroprotection in the retina are poorly understood. To elucidate these mechanisms, we used RGC primary cultures and PDGFRα-EGFP mice in which nuclear-targeted EGFP is expressed under the control of the PDGFRα promoter. RGCs isolated using a standard immunopanning protocol from postnatal day 4-6 mice did not express PDGFRα, and addition of PDGF-AA to RGC cultures did not protect RGCs, while addition of a mixture of known neuroprotective factors, BDNF and CNTF, improved survival of RGCs. Similarly, no expression of PDGFRα was detected in RGCs in the adult mouse retina. PDGFRα was detected in astrocytes in the RGC layer and in a GABAergic subtype of amacrine cells localized to the inner nuclear layer. These data suggest that the neuroprotective effect of PDGF-AA is mediated by astrocytes and/or a subtype of amacrine cells that secrete factors protecting RGCs.

Title: Visual imput is a necessary condition in enriched environment induced neuroprotection against acute retinal ischemia

Authors: *D. DORFMAN, M. L. ARANDA, M. F. GONZÁLEZ FLEITAS, M. S. CHIANELLI, M. I. KELLER SARMIENTO, H. H. DIEGUEZ, P. H. SANDE, R. E. ROSENSTEIN;
Sch. of Medicine, UBA, CEFYBO/CONICET, Capital Federal, Argentina

Abstract: Enriched environment (EE) constitutes a strategy that boosts locomotor, exploratory, visual, and cognitive activities, as well as social interaction and voluntary physical exercise. Ischemia is a key component of several retinal diseases that are leading causes of irreversible blindness. In previous work, we have shown that the exposure to EE protects the retina against acute unilateral ischemia in adult rats. In this work, we analyzed the involvement of visual processing in the protection induced by EE against retinal ischemic damage. Methods: Adult male Wistar rats were submitted to acute unilateral or bilateral ischemia by increasing intraocular pressure to 120 mm Hg for 40 min. After unilateral ischemia, animals were exposed to a standard environment (SE), a novelty environment (NE), or an EE for 3 weeks. NE consisted in standard laboratory cages, housing 2 animals and containing novelty objects that were weekly substituted, while EE consisted of big cages housing 6 animals, and containing food hoppers, wheels and different objects repositioned once/day and fully substituted once/week. Animals submitted to bilateral ischemia were exposed to SE or EE for 3 weeks. Retinal function (electroretinography, ERG), and histology were analysed at 3 weeks post-ischemia. Locomotor activity in EE was analysed in animals exposed to unilateral or bilateral ischemia. The expression of c-fos (immunofluorescence) in the retino-recipient layers of the superior colliculi (SC) was assessed in control animals, and animals submitted to unilateral or bilateral ischemia at 24 h of exposure to EE. Results: Unilateral ischemia induced a significant decrease in scotopic ERG response, and clear histopathological alterations. NE was ineffective in protecting the retinal function and structure against unilateral ischemia. EE, which preserved retinal function and histology against unilateral ischemia, did not protect the retina when ischemia was bilaterally induced, regardless that locomotor activity did not differ among groups. In animals submitted to unilateral ischemia, EE induced c-fos expression in the SC superficial layers receiving projections from control and

ischemic eyes. However, when ischemia was bilaterally induced, c-fos expression was absent in the superficial layers of the SC receiving projections from both retinas. Conclusions: These results suggest that, at least for the visual pathway, the protection induced by EE could involve visual processing.

Title: Neuroprotective functions of apolipoprotein E-containing lipoproteins in neurons and glia of retina

Authors: *H. HAYASHI, M. MORI, Y. BAN, B. YUAN, N. TAKAGI;
Tokyo Univ. of Pharm. and Life Sci., Tokyo, Japan

Abstract: Lipoproteins play crucial roles for maintaining lipid metabolism and transport in the peripheral circulation as well as the central nervous system (CNS). In the CNS, glia secrete lipoproteins in high density lipoprotein-like particles containing apolipoprotein E (apo E). It has been reported that cholesterol included in apo E-containing lipoproteins induces synaptogenesis in CNS neurons and apo E-containing lipoproteins produced by glia promote axon growth of retinal ganglion cells (RGCs) in a low density lipoprotein receptor-related protein 1 (LRP1)-mediated process. It has also been known that alpha2-macroglobulin (a2M), one of the LRP1 ligands, is increased in aqueous humor of glaucoma patients, and we also detected the increase of a2M in vitreous humor of glutamate-aspartate transporter-deficient mice, an animal model of glaucoma. Here, we show evidence that apo E-containing lipoproteins protect RGCs via LRP1 from apoptosis induced by glutamate in vitro and in vivo and decrease a secretion of alpha2-macroglobulin (a2M) from primary cultured glia. The neuroprotective effect of apo E-containing lipoproteins via LRP1 was provided by blocking calcium overload through *N*-methyl-D-aspartate receptor in primary cultured RGCs. This protective effect was interfered with a2M, but exogenous treatment of apo E-containing lipoproteins overcame the inhibition. In addition, intravitreal administration of apo E-containing lipoproteins prevented retinal degeneration led by

N-methyl-D-aspartate injection into vitreous humor of rats. On the other hand, apo E-containing lipoproteins attenuated mRNA and protein expressions of a2M in primary cultured retinal glia. A2M secretion from cultured glia to conditioned medium was also decreased by addition of apo E-containing lipoproteins. These findings indicate a potential therapeutic approach of apo E-containing lipoproteins or LRP1 agonists as treatment for nerve injuries and neurodegenerative disorders in the retina.

Title: Tubastatin A, a specific inhibitor of histone deacetylase 6, protects retinal cells against oxidative stress

Authors: *J. LEYK, U. JANSSEN-BIENHOLD, C. RICHTER-LANDSBERG;
Dept. of Neurosci., Carl Von Ossietzky Univ. of Oldenburg, Oldenburg, Germany

Abstract: Retinal degenerative disorders, such as age-related macular degeneration and retinitis pigmentosa (RP) are characterized by progressive loss of photoreceptors. Recent studies suggest a role for histone deacetylases (HDACs) in neuro- and retinal degeneration. In a mouse model for RP excessive HDAC activation was observed and inhibition of HDAC activity prevented photoreceptor cell death. Within the HDAC family, HDAC6 is unique since it mainly deacetylates non-histone proteins like α-tubulin, heat shock protein (HSP) 90 and the redox regulatory protein peroxiredoxin 1 (Prx1), which is involved in the reduction of hydrogen peroxide (H_2O_2). HDAC6 plays a role in cellular stress responses and its inhibition has been demonstrated to be protective in models for neurodegeneration. The aim of the present study was to elucidate the influence of HDAC6 inhibition by tubastatin A (TST) in 661W cells, a cell line with characteristics of cone photoreceptors, and its protective role during oxidative stress. The presence of HDAC6 was investigated in retina lysates and slices of C57BL/6 mouse retinae. Immunohistochemistry revealed that HDAC6 is present in the retina of C57BL/6 mice and prominently expressed in photoreceptor inner segments as well as in the outer plexiform layer. It is present in 661W cells and its inhibition by TST results in hyperacetylation of α-tubulin. In

661W cells oxidative stress, exerted by treatment with H_2O_2, caused cytotoxic responses. Preincubation with TST promoted cell survival after H_2O_2 treatment and enhanced the expression of HSP25 and HSP70 by activating HSF1 (heat shock factor 1). The protective effect, however, is not causally related to the induction of HSF1, as demonstrated by incubation with KRIBB11, an HSF1-inhibitor. Immunoblot analysis revealed that H_2O_2 treatment leads to a strong overoxidation and thereby to the inhibition of Prx1. This effect was significantly reduced after preincubation with TST. Thus, HDAC6 inhibition by TST is protective against oxidative stress by regulating the activity of Prx1. In conclusion, HDAC6 inhibition provides a protective means against a stress situation which occurs in retinal degenerative diseases.

Title: Caspase-9 inhibition abrogates retinal edema and provides functional neuroprotection

Authors: M. I. AVRUTSKY[1], Y. Y. JEAN[1], S. SNIPAS[3], G. S. SALVESEN[3], *C. M. TROY[2]; [1]Dept Pathology, [2]Dept Pathol & Neurol, Columbia Univ. Medl Ctr., New York, NY; [3]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA

Abstract: Macular edema results from fluid accumulation in the macula due to leaky blood vessels, and is a common complication of diabetes and retinal vein occlusion (RVO). Despite available therapies, an estimated 50% of patients do not respond to treatment. We have identified caspase-9, a protease traditionally associated with apoptosis, as an essential component in edema formation. To test the therapeutic potential of modulating caspase-9 activity in retinal edema, we developed a highly-specific caspase-9 inhibitor. We employed a mouse model of central retinal vein occlusion (CRVO). CRVO was achieved by tail-vein injection of rose bengal, followed by laser photocoagulation of retinal veins. In vivo analyses – optical coherence tomography (OCT), fluorescein angiography and electroretinography (ERGs) - were conducted with the Micron IV system (Phoenix Research Labs). CRVO induces acute retinal edema, which peaks during the first 24 hours following injury. Expression of caspase-9 and VEGF are increased as measured by

western blot and immunohistochemistry. Caspase-9 localizes with endothelial cell markers. Over a 7 day time course the edema resolves, revealing a permanent retinal thinning. At 2 days post-CRVO, TUNEL+ cells indicate significant cell death in the outer nuclear layer. To inhibit caspase-9 activity we employed our novel cell permeant caspase-9 inhibitor and delivered it topically using eyedrops. Topical delivery provides rapid uptake of the inhibitor by the retina. Treatment of animals with the caspase-9 inhibitor eyedrops immediately after induction of CRVO provides morphologic, biochemical and functional protection. Caspase-9 inhibition abrogates the increase in retinal thickness, fewer TUNEL+ cells are detected, and ERGs show functional neuroprotection. Our studies indicate that active caspase-9 plays an essential role in regulating edema pathogenesis. Moreover, our novel cell permeant caspase-9 inhibitor abrogates the edema and may be a potential novel therapy for individuals suffering from macular edema.

Title: Brain-derived neurotrophic factor-mediated neuroprotection of retinal and cognitive function in exercised diabetic rats

Authors: *A. HANIF[1], R. ALLEN[1], M. GOGNIAT[1], B. PRALL[1], R. HAIDER[1], M. AUNG[1], M. PRUNTY[1], L. MEES[1], C. SIDHU[2], L. HE[2], M. IUVONE[2], M. PARDUE[1,2,3];

Abstract: While exercise has been shown to have protective effects in the retina and in diabetes, the effects of exercise on retinal and cognitive function in diabetes have not been studied. We hypothesized that treadmill exercise would reduce early visual, retinal and cognitive deficits in the STZ (streptozotocin) rat model of Type I diabetes. We further hypothesized that if BDNF mediates the protective role of exercise in diabetes, treatment with the TrkB inhibitor ANA-12 would abolish this protective effect. Long-Evans rats were assigned to one of four diabetic or control groups (n = 7-36): active + vehicle, inactive + vehicle, active + ANA-12, and inactive + ANA-12. Hyperglycemia was induced using STZ (100mg/kg) with fed glucose levels greater than 250 mg/dL considered diabetic. Rats received treadmill exercise for 30 minutes a day, 5 days per week, at a speed of 0 m/min (inactive groups) or 15 m/min (active groups) for 8 weeks. ANA-12, a TrkB BDNF receptor antagonist, or vehicle was injected 2.5 h before exercise training. Spatial frequency and contrast sensitivity were assessed via optokinetic tracking at 0, 2, 4, 6, and 8 weeks post-STZ. Retinal function was assessed via electroretinogram at 4 and 8 weeks. Cognitive function and exploratory behavior were assessed via y-maze at 8 weeks. Compared with non-diabetic controls, diabetic rats showed reduced spatial frequency ($p < 0.001$) and contrast sensitivity ($p < 0.001$) on an optokinetic tracking task by 4 wks post-STZ, delays in oscillatory potential ($p < 0.05$) by 4 wks post-STZ, and flicker ERG implicit times ($p < 0.05$) by 8 wks post-STZ. Reduced cognitive function ($p < 0.001$) and exploratory behavior ($p < 0.01$, Main effect) on a y-maze task were observed by 8 weeks post-STZ in the diabetic rats. Exercise significantly reduced these deficits in diabetic rats for all tests ($p < 0.05$ to 0.001), with the exception of exploratory behavior. Furthermore, treatment with ANA-12 prior to exercise reduced the protective effects of treadmill exercise in diabetic rats ($p < 0.05$ to 0.001).Exercise treatment protected against early visual, retinal and cognitive dysfunction in a Type 1 rat model of diabetes. Blocking the TrkB pathway reduced exercise's protective effect, suggesting that BDNF signaling may mediate exercise protection in diabetes. Exercise is a promising candidate for treatment of early visual, retinal and cognitive defects in diabetes.

Title: DHA regulation of PMP22 in Schwann cells during lipotoxicity.

Authors: *M. A. SERRANO ILLAN, J. D. FIGUEROA, K. CORDERO, M. DE LEON; Loma Linda Univ., Loma Linda, CA

Abstract: Traumatic neuronal injury induces major cellular dysfunction which may include lipid overload and lipotoxicity. These disturbances in turn can adversely affect Schwann cell (SC) viability and disrupt normal myelination. However, it is the type of long-chain fatty acid (LCFA) that reaches the PNS that determines the effect on SCs. Palmitic acid (PA), a saturated LCFA, induces cell death, whereas docosahexaenoic acid (DHA), a polyunsaturated LCFA, promotes survival. This study expands on these findings and examines the regulation of Peripheral myelin protein 22 (PMP22), a protein important for normal SCs maintenance and myelination during this procces. Our studies address the question of whether DHA neuroprotection of SCs during lipotoxicity can modulate PMP22 gene expression.
Quantitative real time polymerase chain reaction (QRT-PCR) analysis showed that Schwann cells treated with DHA (DHA50: BSA 150uM) significantly repressed PMP22 mRNA in a time dependent manner after 24H of exposure. This decrease in PMP22 mRNA results in an increase in cell proliferation. In contrast, treatment of these cultures with a palmitic acid (PA) overload (PA300:BSA150uM) significantly upregulates PMP22 mRNA, a decrease in cell proliferation and an increase in cell death at 48H. Co-treating these cultures with DHA and PA stabilizes the expression of PMP22 mRNA levels and restores normal cell viability.
In vivo experiments involved the use of sciatic nerves from Sprague-Dawley rats on diets rich in omega-3 fatty acids or rich in omega-6 fatty acids for 60 days before undergoing contusive SCI or a spinal cord laminectomy (sham). QRT-PCR and Western blot analyses showed a significant downregulation of PMP22 in rats on the omega-3 PUFA diet. Taken together these data suggest that DHA confers neuroprotection in the event of lipotoxicity, and that this is positively correlated with the downregulation of PMP22 both *in vitro* and *in vivo*.

Title: Cell therapy increases the survival and regeneration of retinal ganglion cells after optic nerve injury in adult rats

Authors: L. A. MESENTIER-LOURO, L. C. TEIXEIRA-PINHEIRO, A. J. DA SILVA-JUNIOR, F. GUBERT, P. DOMIZI, G. NASCIMENTO-DOS-SANTOS, C. TEIXEIRA, F. TOVAR-MOLL, M. F. SANTIAGO, *R. MENDEZ-OTERO;
UNIVERSIDADE FEDERAL DO RIO DE JANEIRO, Rio De Janeiro, Brazil

Abstract: The effects of one intravitreous injection of mesenchymal stromal cells were investigated after optic nerve crush (ONC), in adult pigmented rats. Lister Hooded rats underwent unilateral ONC followed by an intravitreal injection of 5 x 10^5 MSC (treated) or the vehicle (untreated). MSCs were labeled with iron-oxide particles for *in vivo* and *ex vivo* cell tracking. RGC number was estimated by counting $Tuj1^+$ and/or $Brn3a^+$ cells, and optic nerve regeneration was investigated after anterograde labeling with cholera toxin B conjugated to Alexa 488. The reconnection of RGC axons to the neurons in the superior colliculus (SC) was analyzed by the expression of the nerve growth factor-induced gene A (NGFI-A, driven by light stimulation) and the visual function was analyzed using an optomotry apparatus to evaluate the optokinetic reflex. The retinal expression of FGF-2, IL-1β was analyzed 14 days after ONC. MSCs remained mostly in the vitreous body for 18 weeks and protected ~2x more RGC when compared to vehicle injection, for at least 60 days after crush (dac). Regenerated axons up to 1.0 mm beyond the injury site were ~2x more numerous in MSC-treated animals (28 dac) and, in one one of them, there were visible axons up to the SC, 60 dac. $NGFI\text{-}A^+$ cells were 2-fold increased in the MSC-treated groups (60 dac), while the optokinetic reflex was partially recovered in 30% of MSC-treated and in only 9% of untreated animals (80 dac). MSCs increased the expression of FGF-2 and IL-1β in the retina. Our results suggest that RGC degenerate overtime in both groups, but the number of cells is higher in the treated animals for at least 60 days after injury. In addition, NGFI-A expression was increased in the SC of treated animals, suggesting that axons regenerated and made synapses to their target cells in the brain. Further analysis will be performed at 240 days after treatment.

Title: Reproductive experience improves memory and learning of the spontaneously hypertensive female rats

Authors: *V. CABRERA PEDRAZA[1], C. SOLIS[2], R. VAZQUEZ-ROQUE[2], F. DE LA CRUZ[1], S. ZAMUDIO[1], M. GOMEZ-VILLALOBOS[2], G. FLORES[2];
[1]Escuela Nacional De Ciencias Biologicas, IPN, Ciudad de México, D.F., Mexico; [2]Benemerita Univ. Autonoma de Puebla, Puebla, Mexico

Abstract: Hypertension (HT) is a disease characterized by a sustained increase in blood pressure. This condition is a major risk factor for suffering cerebrovascular disease, such as ischemic or hemorrhagic stroke, microvascular injury, cognitive impairment and vascular dementia. Experimentally, the model of spontaneously hypertensive (SH) rats has been widely used to study alterations at the anatomical, physiological and behavioral items, which develop by the progression of HT. The SH animals have been showed an increase in the blood pressure after second month affecting brain areas such as hippocampus and prefrontal cortex, important areas for congnition. Specifically, it has shown that the pyramidal neurons of these areas exhibited retraction of the dendritic arborization and reduced number of the dendritic spines (Vega et al., 2004). In females, its well known that neuroprotective effects of hormones and stimuli associated with reproduction, protect against neuronal damage and enhance cognitive processes such as learning and memory in females rats, both short and long-term (Gatewood et al., 2005; Kinsley et al., 2005). Previously, we have shown that Cerebrolisyn treatment, a drug with neurotrophic properties, improves cognitive performance on a task learning and spatial memory and also, increases the length, arborization and density of dendritic spines in prefrontal cortex and hippocampus (Solis et al. 2016). In the present report, we compared the effect of reproductive experience on the memory and learning measured by Water-Morris test, and neural morphology of neurons from CA1 and dentate gyrus (DG) of the dorsal hippocampus, and piramidal neurons from layers III and V of prefrontal cortex by using Golgi-Cox stain, in spontaneously

hypertensive female rats CBL or vehicle-treated. Our results shown that RE improved learning and memory in the SH rats, even, better than cerebrolisyn. In addition, pyramidal neurons of layers III and V of the PFC and, CA1 and DG of dorsal hippocampus of the SH rats which received CBL or vehicle, shown more arborization and lenght in rats with RE compares with virgin rats. Also, CA1 shown an increase in the number of dendritic spines. Our results suggest that reproductive experience induce cerebral plasticity to long term and improved cognitive impairment caused by HT.

Title: Source of optic nerve metabolic vulnerability in a mouse model of glaucoma

Authors: *D. M. INMAN[1], A. H. JASSIM-JABOORI[1], V. GEVORGYAN[2], P. G. PALMER[3]; [1]Pharmaceut. Sci., [2]Northeast Ohio Med. Univ., Rootstown, OH; [3]Bio-Med Sci. Acad., Rootstown, OH

Abstract: Physiological changes that precede axon degeneration can be driven by metabolic dysfunction. We observed lack of resilience to oxygen-glucose deprivation to a degree that correlates with magnitude of intraocular pressure exposure in a mouse model of glaucoma. These experiments investigated the source of energy vulnerability by examining energy storage (glycogen and creatine kinase activity), energy exchange (monocarboxylate transporters (MCT), glucose transporters), and metabolic substrate utilization (lactate dehydrogenase activity) in the optic nerve. DBA/2J (D2) mice that develop glaucoma-related optic neuropathy and age-matched DBA/2J$^{wt\text{-}gpnmb}$ (D2G) control eyes were injected with cholera toxin B to assess axon transport status. Mice were grouped by age (3, 6, and 10 months) and extent of transport deficit; mRNA was isolated, and gene expression analyzed in optic nerve by qPCR. Optic nerves were also isolated and analyzed for glycogen levels and creatine kinase activity. Energy storage analysis indicated significant decreases in glycogen (10m D2 versus D2G, $p=0.027$) and creatine kinase activity (10m D2 with axon transport deficit versus D2G, $p=0.0288$). Significant increases in MCT-2 and -4 gene expression levels were observed in 10m D2 optic nerve compared to age-

matched control D2G (t-test, p=0.0036, p=0.0376, respectively); MCT-2 is preferentially expressed in axons, and MCT-4 in astrocytes. Upregulation of Glut3, a glucose transporter specific to axons, was observed in 3m D2 versus D2G (p=0.0007), in 10m D2 with normal transport versus D2G (p=0.0017), and in 10m D2 with transport deficit versus D2G (p=0.0081). Astrocyte-specific lactate dehydrogenase-A (LDH-A) was significantly upregulated in 10m D2 with axon transport deficit compared to 10m D2 with normal transport (p=0.0439). Axon-specific LDH-B was significantly upregulated in 3m D2 versus D2G (p=0.0052), and in 3m D2G versus 10m D2 with ($p<0.0001$) or without axon transport (p=0.0147). Decreased glial-specific expression of MCT-1 in the context of axon transport deficit accompanied increased LDH-A expression, indicating that glial cells may be making more lactate or utilizing it, precluding its transport to dysfunctional axons. In functional 10m D2 axons, increased MCT-2 and -4 expression suggests a drive to obtain lactate. The energy vulnerability observed in D2 optic nerve may be traced to the significant decrease in glycogen storage and creatine kinase activity, despite increased opportunity for lactate exchange through MCT upregulation in functional axons.

Title: Establishment of a spontaneously immortalized Schwann cell line IKARS1 from aldose reductase-deficient mice

Authors: *K. SANGO[1], N. NIIMI[1], H. YAKO[1], M. TSUKAMOTO[1], H. MIZUKAMI[2], S. K. CHUNG[3];
[1]Tokyo Met Inst. Med. Sci., Tokyo, Japan; [2]Dept Pathol Mol Med, Hirosaki Univ., Hirosaki, Japan; [3]Dept Anat, Univ. of Hong Kong, Hong Kong, China

Abstract: Aldose reductase (AR), the first enzyme of the polyol pathway, converts glucose to sorbitol, and galactose to galactitol. Sorbitol is further converted to fructose by sorbitol dehydrogenase (SDH). The increased glucose flux into the polyol pathway via AR in Schwann cells and subsequent accumulation of sorbitol and fructose is recognized as a major contributing factor for the pathogenesis of diabetic neuropathy. The accumulation of galactitol as a consequence of galactose feeding in animals can be a cause of 'galactosemic' neuropathy. In contrast to these pathogenic roles, AR contributes to osmoregulation and aldehyde detoxification under normoglycemic conditions; however, little is known about its physiological roles in the peripheral nervous system (PNS). We established spontaneously immortalized Schwann cell lines from long-term cultures of aldose reductase (AR)-deficient and normal C57BL/6 mouse dorsal root ganglia (DRG) and peripheral nerves. These cell lines, designated as immortalized knocked out AR Schwann cells 1 (IKARS1) and 1970C3, showed distinct Schwann cell phenotypes, such as spindle-shaped morphology and immunoreactivity for S100 and p75 low-affinity neurotrophin receptor. Conditioned medium obtained from these cells exhibited potent biological activity for the promotion of survival and neurite outgrowth of cultured adult mouse DRG neurons. Exposure to 25 mM of galactose for 24 h resulted in a drastic increase in intracellular galactitol contents in 1970C3, but not in IKARS1. However, we failed to detect significant up-regulation of sorbitol and fructose contents by exposure to high glucose (30 mM) for 24 h in the both cell lines . By using DNA microarray and subsequent real time RT-PCR analyses, we observed significant down-regulation of mRNA expression for the polyol pathway-related enzymes, such as SDH and ketohexokinase, in IKARS1 as compared with 1970C3. In contrast, significant up-regulation of mRNA expression for aldo-keto reductases Akr1b7 and Akr1b8 in IKARS1 as compared with 1970C3 was detected. Furthermore, exposure to the reactive aldehydes, such as 3-deoxyglucosone (0.5 mM), methylglyoxal (0.25 mM) and 4-hydroxynonenal (2.5 μM), significantly (>2.5 fold) up-regulated the mRNA expression for Akr1b7 in IKARS1, but not in 1970C3. Because we observed no significant differences between the two cell lines in the viability after exposure to these aldehydes, the detoxification function might be taken over by Akr1b7 and other aldo-keto reductases in the absence of AR. These Schwann cell lines can be useful tools for the study of polyol metabolism and functional roles of AR in the PNS.

Title: Blockade of gap junctions preserves structural <and> for> functional integrity of the retina in a mouse model of glaucoma

Authors: *A. AKOPIAN[1], S. KUMAR[1], H. RAMAKRISHNAN[1], S. VISWANATHAN[1], S. BLOOMFIELD[2];
[1]Biol. and Vision Sci., [2]SUNY Col. of Optometry, New York, NY

Abstract: We reported recently that gap junction (GJ)-mediated bystander effect plays a significant role in the propagation of cell loss in retina under a various insult conditions (Akopian et al., 2015). Here we show that GJ-mediated cell death forms a critical mechanism in the progressive loss of inner retinal neurons seen in glaucoma. Experimental glaucoma was induced in adult C57BL/6 (WT) and connexin 36 knockout ($Cx36^{-/-}$) mice by raising IOP with intracameral injections of polystyrene microbeads. Elevated IOP in WT mouse resulted in reactive gliosis, as assessed by GFAP immunolabeling as well as 34% reduction in retinal ganglion cells (RGCs) and a 17-50% reduction in different subpopulations of amacrine cells (ACs). In addition, there was a significant degenerative change in RGC dendritic tree and axons, which preceded cell death. Glaucoma was then induced in WT mouse treated with meclofenamic acid (MFA) to block gap junctions or in $Cx36^{-/-}$ mice, which showed elevated IOP to levels comparable to untreated WT mouse. Blockade of GJs by (MFA) or ablation of Cx36 significantly attenuated reactive gliosis and offered substantial protection of inner retinal neurons. The ERG scotopic threshold response (STR) and oscillatory potentials (OPs), which reflect activity of RGCs and ACs, respectively, were markedly reduced in glaucomatous eyes of untreated WT mice. The time course of ERG changes correlated well with the loss of the inner retinal cells. In contrast, the ERG remained largely unchanged in MFA-treated WT mice or in $Cx36^{-/-}$ mice. Axonal integrity was assessed by confocal microscopy both within retina and in optic nerve (ON) cross sections. The ON of glaucomatous eyes of WT mice showed a disruption of the honeycomb pattern of GFAP-positive astrocytic processes and SMI32-positive axonal bundles with a 45% ($p<0.001$) reduction in the density of axons. In contrast, the glaucomatous ON of $Cx36^{-/-}$ mice showed a staining pattern and axonal density comparable to those in WT mice. Finally, the visual evoked potential (VEP) in glaucomatous WT mice was reduced by 71%, whereas VEPs recorded in MFA-treated mice or $Cx36^{-/-}$ mice had amplitudes comparable to controls. Our data show that experimental glaucoma produced electrophysiological changes that mirrored the loss of inner retinal neurons and axons in the optic nerve. Moreover, blockade or ablation of GJs preserved structural and functional integrity of the retina and ON in glaucomatous eyes. Our results strongly indicate that neuronal GJs form novel therapeutic targets for neuroprotective treatments directed at reducing the progressive loss of neurons and axons in glaucoma, thereby preserving visual function.

Title: JNK-JUN signaling is important for RGC axonal injury induced soma degeneration

Authors: *S. SYC, K. A. FERNANDES, R. T. LIBBY;
Univ. of Rochester, Rochester, NY

Abstract: Glaucoma is an optic neuropathy characterized by retinal ganglion cell (RGC) death and optic nerve degeneration. The focus of this study was to identify the molecular signaling pathway(s) critical for ocular hypertension-induced RGC degeneration. Previously, we showed that JNK-JUN signaling is a major regulator of RGC death after axon injury, a crucial insult to RGCs after an ocular hypertensive insult. In DBA/2J ocular hypertensive mice, JUN and JNK are expressed in a temporal and spatial pattern consistent with these genes functioning during the window of RGC death. To test the importance of this pathway in glaucomatous neurodegeneration, a floxed allele of *Jun* and *Six3*-cre (a neural retina cre) were backcrossed into the DBA/2J mouse. To ensure genetic background did not alter the protection afforded by $Jun^{-/-}$ for RGC death after axonal injury, controlled optic nerve crush (CONC) was performed in young DBA/2J *Jun* deficient mice (D2.$Jun^{-/-}$) and littermate controls (D2.$Jun^{+/+}$ with and without cre). Similar to the protection from CONC observed on the C57BL/6J background, D2.$Jun^{-/-}$ protected 76% of RGCs 35 days after CONC compared to 25% survival seen in D2.$Jun^{+/+}$ mice ($n=6$, $p<0.001$). To ensure *Jun* deficiency did not alter the intraocular pressure (IOP) profile of DBA/2J mice, IOPs were measured at 3, 9, 10.5, and 12 months. No significant difference was seen between D2.$Jun^{-/-}$ and D2.$Jun^{+/+}$ mice ($p>0.05$; $n\geq36$ for each genotype and time point). To assess the influence of $Jun^{-/-}$ on ocular hypertension induced axonal degeneration, optic nerves from aged D2 mice were stained and graded on a scale measuring optic nerve damage (mild, moderate or severe). Preliminary data suggests the proportion of nerves with mild and moderate

axonal damage was increased in *Jun*$^{-/-}$ mice, but nerves with severe axonal damage were observed in all genotypes at 12 months (16 D2.*Jun*$^{+/+}$, 18 D2.*Jun*$^{-/-}$ nerves). *Jun* deficiency did protect 69% of RGC somas as compared to only 20% survival in control eyes in eyes with severely damaged optic nerves (severe grade; n=7, $p<0.001$). The somal protection conferred by *Jun* deficiency may be even higher since ~17% of RGCs still express JUN (incomplete recombination of the *Jun* allele). As *Jun*$^{-/-}$ did not provide complete protection, mice deficient in both *Jun* and *Chop*, the endoplasmic reticulum (ER) stress target gene previously shown to be a major regulator of axon-injury induced RGC death, were generated. Inhibiting these two pathways appears to have an additive effect on RGC survival, providing near complete protection 60 days after CONC (n=4, $p<0.001$). These results suggest that together JNK-JUN and ER stress signaling are important for axonal injury induced RGC death.

Title: Profiling mitochondrial defects from nucleoside/nucleotide reverse transcriptase inhibitors in neurons: potential contribution to HIV-associated neurocognitive disorders

Authors: K.-M. HUNG, *M. CALKINS;
Inst. of Clin. Med., Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: A cornerstone of current HIV treatment are nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs). however patients who receive long term treatment with NRTIs often develop severe side effects, including painful neuropathy. The potential contribution of NRTI-mediated toxicity to HIV-associated neurocognitive disorders (HAND) has not been fully explored. NRTI toxicity is thought to be mediated through mitochondrial DNA polymerase γ (pol γ) inhibition, which impairs mitochondrial DNA (mtDNA) synthesis and leads to various mitochondrial dysfunctions. To evaluate the relationship between NRTI-mediated pol γ inhibition and mitochondrial toxicity in neurons, we systematically investigated mitochondrial regulation in NRTI-treated primary cortical neurons by measuring parameters related to mtDNA

content, retrograde signaling responses and mitochondrial homeostasis. The effects of six different NRTIs with variable pol γ inhibitory activity and mitochondrial toxicity were assessed. The strong pol γ inhibitors, ddC and ddI, abolished mtDNA synthesis and greatly reduced mtDNA content. However, mtDNA transcription was not as severely affected, and only ddC treated cells showed mild deficits in oxidative phosphorylation. Detrimental effects on mitochondrail motility and morphology were observed after AZT and d4T treatment in the absence of mtDNA depletion or inhibition of mtDNA synthesis. The results suggest that individual NRTIs induce distinct profiles of mitochondrial dysfunction in neurons which likely reflect multiple mechanisms of toxicity. Furthermore, primary cortical neurons appear to tolerate major reductions in mtDNA content before mitochondrial dysregulation is detectable. Four of the six NRTIs induced mitochondrial disruptions indicating a clear potential for CNS neurotoxicity and suggesting that HAND etiology may be affected by NRTI treatment.

Title: Rapid recovery from several morphological and biochemical effects of chemotherapy-induced neuropathy following paclitaxel and eribulin in mouse sciatic nerves

Authors: *B. M. COOK[1,2], S. J. BENBOW[3,2], K. M. WOZNIAK[4], B. S. SLUSHER[4], Y. WU[4], B. A. LITTLEFIELD[5], M. A. JORDAN[3,2], L. WILSON[3,2], S. C. FEINSTEIN[3,2];

Abstract: Improvements in cancer treatment with microtubule-targeting agents (MTAs) have led to a growing population of cancer survivors. The reversibility of chemotherapy-induced peripheral neuropathy (CIPN), a disabling and potentially permanent side effect of MTAs is

becoming increasingly important. The time to onset and frequency of severe CIPN varies among different MTAs. Previously, we found that after 2 weeks of maximum tolerated doses (MTD) in mice, paclitaxel treatment resulted in a 30% reduction in sciatic nerve axons per unit area while eribulin generated a 21% reduction compared to controls. Paclitaxel also increased the frequency of myelin abnormalities more significantly than did eribulin (6.6% and 2.2% of total axons, respectively). Biochemically, paclitaxel and eribulin both induced α-tubulin expression (1.9- and 2.5-fold, respectively) and tubulin acetylation (5- and 11.7-fold, respectively). Eribulin but not paclitaxel induced EB1 expression 2.2 fold. We are currently extending these comparative studies to acquire a more detailed understanding of the recovery from drug treatment. Mice were dosed with MTD doses of eribulin (1.2 mg/kg), paclitaxel (30 mg/kg), ixabepilone (2 mg/kg), and vinorelbine (11 mg/kg), or their respective vehicles, each being administered intravenously 3 times per week for 2 weeks and followed for 6 months after the cessation of dosing. Preliminary evaluation of sciatic nerve morphology 2 weeks after cessation of paclitaxel or eribulin treatment indicated that paclitaxel treated animals continued to exhibit a 30% reduction in axons per unit area whereas eribulin treated animals had recovered to axon numbers similar to control. Myelin abnormalities had largely recovered but were still present in both paclitaxel and eribulin treated animals (0.82% and 0.64% of total axons, respectively). Quantification of sciatic nerve biochemistry 2 weeks after cessation of paclitaxel or eribulin indicated that axonal levels of α-tubulin, acetylated tubulin, and EB1 rapidly return to control levels. In summary, we found that (i) morphologically, sciatic nerve axons recover more rapidly in eribulin treated animals than in paclitaxel treated animals and (ii) biochemically, drug-induced increases in gene expression following paclitaxel and eribulin treatment are relatively transient. Overall our data in mice suggest a milder onset and faster recovery with eribulin treatment than for paclitaxel. Ongoing analyses of animals 3 and 6 months after cessation of treatment will reveal the extent to which these effects persist.

Title: Mitochondrial complex I deficiency decreases canonical Wnt signaling in retinas

Authors: *L. SONG, A. YU, G. CORTOPASSI;
Univ. of California Davis, Davis, CA

Abstract: Mitochondrial complex I deficiency is the most common mitochondrial disorder and contributes to neurodegenerative diseases such as Leber's hereditary optic neuropathy (LHON), Leigh syndrome, and Parkinson's disease, yet the mechanism by which complex I deficiency causes neurodegeneration remains poorly understood. Wnt signaling pathway plays a critical role in retinal development and neurodegeneration. To address whether the altered activity of the Wnt signaling pathway is responsible for neurodegeneration induced by mitochondrial complex I deficiency, we use Ndufs4 knockout (Ndufs4-/-) mice as a model of neurodegeneration. Ndufs4 is a key complex I subunit and its deletions cause complex I deficiency. RNA-seq analysis showed that Wnt2b was gradually decreased in retinas of Ndufs4-/- mice from p23 to p30, which precedes retinal ganglion cell loss. Furthermore, we found that both total β-catenin and active β-catenin were dramatically decreased in retinas of Ndufs4-/-mice and LHON cybrid cells with complex I deficiency. In addition, we found that the enhanced activation of Wnt signaling increases the viability of cybrid cells untreated and treated with complex I inhibitor. These data strongly suggest that Wnt signaling may play a crucial role in retinal neurodegeneration induced by mitochondrial dysfunction.

Title: Focused ultrasound-mediated delivery of intravenous immunoglobulins modulates neuroinflammation in an amyloidosis mouse model

Authors: *S. DUBEY[1,2], B. KIM[2], A. BURGESS[1], J. MCLAURIN[1,2], D. R. BRANCH[2], K. HYNYNEN[1,3], I. AUBERT[1,2];

Abstract: Intravenous immunoglobulins (IVIg), natural antibodies collected from the plasma of thousands of healthy blood donors, are currently being tested for efficacy in the treatment of Alzheimer's disease (AD). Its ability to target different pathological markers in AD, combined with its excellent safety profile in humans, makes it an attractive treatment option for AD. IVIg is a limited resource with a high demand for treating several different diseases, which necessitates the requirement of a therapy that will increase IVIg efficacy in the brain while minimizing the therapeutic dosage. To enhance the delivery of systemically administered IVIg to brain regions most affected by Aβ pathology, we used transcranial focused ultrasound (FUS), guided by magnetic resonance imaging (MRI). Previous data from our laboratory indicate that combined FUS and IVIg treatment significantly increases IVIg delivery, reduces amyloid plaque load and increases neurogenesis in the hippocampus. The objective of the present study was to further investigate the effect of combination FUS and IVIg therapy on neuroinflammatory markers in the brain and cytokine levels in the periphery. Using a mouse model of amyloidosis, we administered IVIg intravenously, with or without application of FUS. FUS was performed once a week, for two consecutive weeks, and was targeted bilaterally to the hippocampus. After treatment, blood and tissue was collected for biochemical analysis of mRNA and protein expression using qPCR and western blot analysis. Our results indicate that compared to animals treated with FUS or IVIg alone, FUS and IVIg treated animals have altered levels of cytokines and chemokines in the brain and peripheral blood. Levels of pro-inflammatory chemokines such as CXCL-10 and CXCL-1KC were unchanged while anti-inflammatory chemokines such as RANTES were increased. These findings shed light on the inflammatory effects of combinatorial FUS and IVIg therapy in a mouse model of AD.

Abstract: For decades the ozone (O_3) has been recognized as dangerous pollutant which causes respiratory, cardiovascular and neurodegenerative diseases. The oxidant power of O_3 affects lipids, proteins, carbohydrates and nucleic acids. Curcumin (CUR) is a natural antioxidant isolated from the rhizome of *Curcuma longa Lynn*. Its activity has been tested *in vitro* and *in vivo* assays. The aim of this work is to determine the level of oxidized lipids and proteins during exposure to O_3 and analyze the antioxidant activity of CUR. Methods: Fifty male Wistar rats were distributed into five groups. The groups intact, CUR (5.6 mg/Kg) and exposed to O_3 served as controls. The experimental groups were defined as: the therapeutic group exposed to 0.7 ppm of O_3 seven days before administration CUR in the diet and the preventive group that received CUR seven days before to O_3 exposure. All groups were divided into the acute exposure that lasted 15 days and the chronic exposure lasted 60 days. At the end of the acute and chronic exposure the animals were sacrificed and the hippocampus was dissected to prepare a homogenate in PBS with antiprotease cocktail and butylhydroxytoluene. For lipid peroxidation (LPO) the concentration of malondialdehyde and 4-Hydroxynonenal was measured by espectrophotometry. For protein oxidation (PO) the kit of Oxyblot was used to detect carbonilation. Results of LPO were analyzed by ANOVA and Kruskal-Wallis as post-hoc test. Results of oxidized proteins were analyzed by estimated marginal means (EMM) and the

Bonferroni's post-hoc test. The acute and chronic exposure to O_3 increased significantly LPO and PO when compared versus the intact and CUR groups. The dietary administration of CUR decreased significantly the LPO and PO during the acute and chronic exposure to O_3. As well, the therapeutic and preventive administrations of CUR were effective to revert and prevent the oxidative damage caused by O_3. Thus, CUR could be effective to confer neuroprotection against damaged caused by O_3.

Title: Altered gene expression following whole brain irradiation in nonhuman primates

Authors: R. ANDREWS, R. HAMPSON, L. METHENY-BARLOW, D. HANBURY, J. D. BOURLAND, A. PEIFFER, J. M. CLINE, *S. A. DEADWYLER;
Wake Forest Sch. of Med., Winston Salem, NC

Abstract: Fractionated Whole Brain Irradiation (fWBI) is used in the treatment of intracranial neoplasia in nearly 200,000 people per year. Despite delivering the total radiation dose in smaller fractions spaced over days to weeks, the principal complication is delayed injury to normal (non-neoplastic) tissues, cognitive/memory impairment, cerebrovascular injury and white matter degradation.
To evaluate molecular effects of radiation-induced brain injury, quantitative RT-PCR was performed on dorsolateral prefrontal cortex (DLPFC), hippocampus and temporal white matter from 4 male Rhesus macaques (age 6-10 years) that had received fWBI (40 Gy total, 8 fractions @ 5 Gy each, 2x/week). All animals developed neurologic impairment (decline in working memory performance) between 4-12 months post WBI, and brain injury was confirmed by

histopathology revealing neurovascular lesions and necrosis of white matter. Ninety target genes were selected for RT-PCR based on their roles in neurotransmission, blood brain barrier integrity, inflammation, angiogenesis, extracellular matrix deposition and hypoxia. Findings were compared to sex and age matched non-irradiated control animals (n=3). Changes in relative expression ≥2-fold, and p-values <0.01 were considered biologically and statistically significant, respectively.
With respect to PFC neural function and white matter injury, the most prominent changes were decreased expression of synaptophysin ($p < 0.005$), NMDA receptor 2-alpha ($p < 0.009$), and AMPA4 receptor ($p < 0.006$), which may contribute to impaired excitatory neurotransmission. Surprisingly, there was no significant change in these genes in hippocampus. Markers of macrophage/microglial-mediated neuroinflammation were increased within the DLPFC (MCP1, $p < 0.002$) and white matter (MCP1: $p < 0.004$; CD68: $p < 0.003$). PECAM1, associated with endothelial inflammation was upregulated within white matter ($p < 0.0007$). A three-fold up-regulation of lactate dehydrogenase A was suggestive of white matter hypoxia ($p < 0.002$). Factors associated with vascular remodeling were up-regulated within white matter (SERPINE1: $p < 0.0007$; fibronectin: $p < 0.0001$; vascular endothelial cell growth inhibitor (VEGI): $p < 0.003$) but not in DLPFC or hippocampus.
We infer from these data that impaired hippocampal function was largely due to impaired connectivity with other brain areas via white matter degradation and impaired neurotransmission in DLPFC. These changes were coupled to pathologic vascular remodeling, due to neurovascular and endothelial inflammation and hypoxia, yielding combined neurological and vascular pathologies following fWBI.

Title: shRNA-mediated knockdown of α-synuclein in brain regions targeted by MRI-guided focused ultrasound.

Authors: *F. NABBOUH[1], K. XHIMA[2], K. MARKHAM-COULTES[2], P. NAGY[2], A. BURGESS[3], K. HYNYNEN[3], I. AUBERT[2], A. TANDON[1];
[1]Inst. of Med. Sci., Univ. of Toronto, Toronto, ON, Canada; [2]Biol. Sci., [3]Physical Sci., Sunnybrook Res. Inst., Toronto, ON, Canada

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder characterized pathologically by misfolded and aggregated α-synuclein (α-syn) protein. Decreasing the expression of α-syn therefore has considerable therapeutic potential. However, noninvasive drug delivery to affected brain regions presents a significant barrier to the treatment of PD. MRI-guided focused ultrasound (MRIgFUS) combined with microbubbles injected into the bloodstream can briefly increase the permeability of the blood-brain barrier (BBB) in selective brain regions. Using this approach, therapeutics administered through the circulatory system can efficiently cross the BBB without the use of invasive surgery. In this experiment, we used a viral vector expressing short hairpin RNA (shRNA) to knockdown α-syn gene expression in a mouse model of PD. MRIgFUS was targeted to the olfactory bulb and dorsal motor nucleus of the vagus nerve. We quantified α-syn expression levels using immunohistochemistry to evaluate the efficacy of its knockdown. We found that α-syn immunoreactivity was decreased in brain regions targeted with MRIgFUS and α-syn-shRNA in comparison to control mice that received scrambled shRNA. Our results demonstrate that MRIgFUS can effectively deliver shRNA targeting α-syn directly into brain areas that are particularly vulnerable to pathogenesis. In addition, FUS-mediated BBB opening in the olfactory bulb and dorsal motor nucleus were effectively targeted for the first time in this study.

Title: Temporal modulation of sonic hedgehog after microtubule disruption in the striatum of mice

Authors: *T. DUARTE, G. H. D. ABREU, E. DEL BEL;
Dept. of Morphology, Physiol. and Basic Pathology, FORP, Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: There is increasing evidence that microtubule dysfunction plays a role in the neurodegeneration observed in Parkinson's disease (PD). Recent studies, for example, have shown that interruption of the anterograde transport of sonic hedgehog (Shh) results in a progressive model of PD. In this study, we quantify Shh expression in multiple brain regions of mice after unilateral administration of colchicine, a well-known microtubule disruptor, into the striatum. Examination of changes in the chemical signature of specific cell types in the striatum in the injected and control sides was also performed. Briefly, animals were sacrificed at 3, 14 and 21 days post-injection, and the striatum was analyzed immunohistochemically for tyrosine hydroxylase (TH), Chat, nNOS, IBA (microglia), and GFAP (astrocytes). Western Blot experiments were done to assess the time course of changes in Shh in both the striatum and cortical areas. We found that the density of TH-positive fibers in striatum on the colchicine-treated side significant decreased on day 14 and 21 at the same time that we observed massive striatum atrophy. Chat and nNOS staining revealed the loss of these neurons in the colchicine-treated side on day 14 post-injection when compared with the contralateral side. Quantitative study confirmed the significant increase of reactive microglia on day 3 and further activation on day 14 post-colchicine. The reactive astrogliosis was also observed 3 days post-colchicine injection, and this increase was also observed 14 and persists until 21 days. The modulation of Shh protein beginning 3 days post-lesion and reach maximal by 14 days post-lesion, with recovery by 21 days post injection. Experiments are in progress to further clarify the source and the effects of Shh in the adult forebrain after colchicine induced neurotoxicity.

Title: CDK5 activator protein p25 preferentially binds and activates GSK3β

Authors: *J. ZHANG;
Xiamen Univ., Fujian, China

Abstract: Glycogen synthase kinase 3β (GSK3β) and cyclin-dependent kinase 5 (CDK5) have overlapping substrate targets and influence many of the same functions. Their 3-dimensional structures are remarkably similar; both are tau kinases and have been proposed to contribute to the pathogenesis of Alzheimer's disease. This led us to hypothesize that both might be capable of bindingcyclin proteins - the activating cofactors of all CDKs. CDK5 is normally activated by the cyclin-like proteins, p35 and p39, but can nonetheless bind all major cyclins. By contrast, we show that GSK3β does not bind to p35, nor cyclin A or D which share similar structures, but unexpectedly binds to calpain cleavage product of p35, p25. Indeed,over-expressed GSK3β out-competes CDK5 for p25, while CDK5 is the preferred p35 partner. FRET analysis in primary cortical neurons reveals nanometer apposition ofGSK3β:p25 in cell soma as well as in synaptic regions. Interaction with p25 aberrantly altered GSK3β substrate specificity. The GSK3β:p25 interaction leads to enhanced hyperphosphorylation of tau. However, *in silico* modeling suggests the docking site for p25 on GSK3β is the Axin-binding domain. Consistent with this idea, p25 inhibits the formation of the gsk3β/axin/apc destruction complex resulting in decreased phosphorylation of β-catenin. Co-expression of GSK3β and p25 in cultured neurons, results in a neurodegeneration phenotype that exceeds that observed with CDK5 and p25. When p25 is transfected alone, the resulting neuronal damage is blocked more effectively with a specific siRNA against gsk3β, than with that against cdk5. We propose that the effects of p25, though normally attributed to activate CDK5, may be mediated in part by elevated GSK3β activity.

Title: Zebrafish as a model for translational neurobiology: implications for drug discovery

Authors: *A. SUDWARTS, A. BROCK, C. BRENNAN;
SBCS, Queen Mary, Univ. of London, London, United Kingdom

Abstract: Recent years have seen an increase in the prevalence of many neurological disorders. However, the discovery and development of new drugs to tackle these conditions has been relatively insufficient. This is largely due to the financial and ethical costs incurred by using mammalian model organisms in translational neurobiology. Thus, the development and validation of non-mammalian screening assays would facilitate lead identification.
Here we assessed the potential of adult zebrafish as a model for drug discovery. We have established scalable automated assays of both appetitive and aversive classical conditioning tasks. Analysis of the performance of a mutant hAPP knock-in mutant fish showed reduced aversion learning, following conditioning. We also assessed molecular and behavioural responses to known a neurotoxin, aluminium. qPCR expression analysis in neurotoxin-treated and control animals reveals regulation of conserved molecular pathways. We discuss these results and their implications for drug discovery in light of behavioural analysis.

Title: Theoretical study of the quantum-chemical behavior of molecules involved in parkinson

Authors: *E. M. GARCIA[1], C. BARRIENTOS-SALCEDO[2];
[1]Univ. Veracruzana, Boca Del Rio, Mexico; [2]Bioanalisis Fac., Univ. Veracruzana, Veracruz, Mexico

Abstract: Parkinson's disease (PD) is a neurodegenerative síndrome and the most prevalent movement disorder amongst the elderly population. Cardinal motor symptoms result from preferential loss of a subset of dopaminergic neurons within the substantia nigra pars compacta. Molecular changes associated with this neuronal cell loss include mitochondrial dysfunction, reduction in protein homeostasis, oxidative and inflammatory damage and mishandling of celular calcium. It's an appealing disease model for expanding research towards a better understanding of the interrelationship between genes and environment (the 'exposome'). Since 2005, exists an

increasing interest in Quantum Information Theory (QIT) using electronic structures and revealing chemically relevant regions shown in energy profiles, while in neurosciences has been used in a regular basis for contrasting experimental data and predictive models. Between DNA, RNA and proteins, the latter have been chosen because of their key involvement in the diseases' pathology. Our objective is to perform a theoretical study of the quantum-chemical behavior of molecules involved in PD. We hipothesize that proteins that converge in their pathways will have similar quantum-chemical behavior.
For methodology, we used databases such as: KEGG, BioGRID, PDGene, etc. and incorporated them using Cytoscape to find relevant pathways. Then, we compiled Protein Data Bank structures, followed by specific regions thought to contribute to these diseases. Energy minimization was achieved employing GROMACS and Gaussian with puntual calculations using set basis HF 6-31+G** B3LYP accompanied by NBO assessment of the extent of amidecarbonyl sigma/pi separation and bondbending. We included characterization of the physicochemical properties, to identify chemical reactivity through some quantum chemical descriptors. Finally, we employed Shannon Entropy, Fisher Information and complexity calculations in order to formulate a prediction algorithm.
We found over 1,000 molecules related to PD, which where narrowed down to those with genome-wide significant ($p < 1x10-5$). In a merge network of PD molecules betweeness centrality gave us 0.261 R-squared, which indicates low control that molecules exert over the interactions of other molecules in the network. Energy minimization varied between GROMACS and Gaussian and ranged from -2.10E+05 to -6.30E+06. The latter showing disparity in both energy minimization and geometry optimization.

Title: Slowing disease progression in ALS with a targeted neuregulin antagonist

Authors: *F. SONG[1], J. LIU[1], E. H. SIMPSON[2], J. A. LOEB[1];
[1]Dept. of Neurol. and Rehabil., Univ. of Illinois at Chicago, Chicago, IL; [2]Columbia Univ., New York, NY

Abstract: ALS is a neurodegenerative disease that spreads up and down the spinal cord until patients succumb. At present time there are no effective treatments to slow disease progression. We previously reported that neuregulin (NRG) receptors are activated on microglia in the ventral horn and corticospinal tracts of ALS patients and in SOD1 mice (1,2). We have developed a targeted NRG antagonist (HBD-S-H4) that is a humanized fusion protein between NRG's heparin-binding domain and a decoy HER4 receptor (3). This fusion protein blocks microglial activation in vivo in a model of chronic pain (4). In the present study, we tested the therapeutic effects of HBD-S-H4 in the ALS-SOD1 mouse model. We found that expression of HBD-S-H4 in the central nervous system (CNS) delays disease onset and prolongs survival in GFAP-tTA:tetO-HBD-S-H4:SOD1 transgenic mice in correlation with different levels of HBD-S-H4 expression in the CNS. We also delivered recombinant HBD-S-H4 into the CNS through implanted intracerebroventricular (icv) cannulas which had no toxic effects, delayed disease onset, and prolonged survival in two strains of SOD1 G93A mice (SJL.B6 and B6 strains). Mechanistically, the drug hit its target producing a significant reduction of both small and large sized microglia in the ventral horn. While the exact mechanisms of how NRG receptor activation modulates microglial activation is still under study, the lack of toxicity and clear therapeutic effect of HBD-S-H4 provides important preclinical data supporting its use in clinical trials in patients with ALS to slow disease progression.

Title: Amyloid precursor protein (APP) is modulated after cranial radiotherapy to the developing mouse brain

Authors: *Y. F. ERIKSSON, M. KALM;
Dept. of Neurosci. and Physiol., Univ. of Gothenburg/Sahlgrenska Acad., Goeteborg, Sweden

Abstract: Objective
Brain tumours are one of the most common childhood cancers. Among young adults, 1 in 600 are childhood cancer survivors in Sweden today. Cranial radiotherapy is one of the strategies used to treat brain cancer, but it can also lead to permanent damage in the survivors and have a negative impact on their quality of life. The so called late effects after irradiation include perturbed growth, late puberty and cognitive impairment. Alleviating these late effects would have a huge impact in the lives of patients. However, the damages induced by radiotherapy have no cure and there are still no effective interventions available to help the survivors. Amyloid precursor protein (APP) is a membrane protein found in tissues throughout the body. Although mostly associated with Alzheimer's disease where it is the main component of the extracellular amyloid plaques, it has many functions in the normal brain where it is suggested to be involved in synaptogenesis, neurite outgrowth and cell adhesion, to name some. In a pilot study the levels of soluble APP decreased in the cerebrospinal fluid following cranial radiotherapy in patients. Here, APP and its potential role after cranial radiotherapy was studied in the developing mouse brain.
Methods
Male and female mice were exposed to a single dose of 8 Gray to the brain at postnatal day 14. Areas involved in memory and learning were investigated when the irradiation-induced injury was well established. Relative expression levels of APP were measured using quantitative reverse transcription polymerase chain reaction. Immunohistochemistry was used to quantify APP in the thalamus after irradiation.
Results
There was no difference between irradiated mice and controls regarding APP gene expression, neither in the thalamic region nor in the hippocampus. However, irradiation caused a significant accumulation of APP in the thalamus where irradiated male and female mice had a higher density of APP-positive cells than controls. The effect was biggest in male mice, where the

density of APP-positive cells increased by 99 % ($P \leq 0.01$) after irradiation. In females the density increased 57 %, but did not reach a significant level. The size of the thalamus was not affected by irradiation in either of the sexes.

Conclusion

There is a higher number of APP-positive cells in the thalamus after irradiation but the expression levels are not increased. These results suggest that it is either a change in APP metabolism or thalamic accumulation of elsewhere produced APP that is responsible for the observed accumulation of APP in the thalamus of irradiated animals.

Title: Proline isomerization controls toxic amyloid formation

Authors: *J. D. BAKER[1,2], L. B. SHELTON[1,2], D. ZHENG[1], J. J. SABBAGH[1,2], L. J. BLAIR[1,2], A. DARLING[1], C. DICKEY[1,2];

Abstract: Controlling aberrant amyloid aggregates associated with neurodegenerative disorders including Alzheimer's disease (AD), Parkinson's disease (PD), and amyotrophic lateral sclerosis (ALS) is critical to their prevention. Understanding the mechanisms by which amyloidogenesis occurs is key to finding new treatments for myriad neurological disorders and further we must determine the toxic species responsible for neurodegeneration. Because it is known that amyloid, rich in ß-sheet secondary structure, often contains structurally essential proline residues, we hypothesize that enzymes capable of isomerizing these important amino acids may affect aggregation kinetics of diverse amyloid substrates. Here we have characterized well-studied peptidyl-prolyl isomerases (PPIases) and report on their enzymatic effect on P301L tau and

A53T α-synuclein, associated with AD and PD respectively. By combining thioflavin T fluorescence assays with nanoparticle tracking analysis (NTA), a technique allowing us to characterize aggregate size profiles, we have found that PPIases have opposing effects not only on aggregation kinetics, but also on aggregate species formation. These tools allow us to determine not only how chaperones interact with amyloid, but more importantly help us to control proteotoxic amyloid formation.

Title: The sigma-1 receptor binds hexanucleotide repeat expansions of C9orf72: Implication in ALS and FTD

Authors: *P.-T. LEE[1], T.-P. SU[2];
[1]Cell. Pathobiology Section, Integrative Neurosci. Res. Br., IRP/NIDA/NIH, Baltimore, MD;
[2]Cell. Pathobiology Section, Integrative Neurosci. Res. Br., IRP/NIDA/NIH, BALTIMORE, MD

Abstract: The GGGGCC (G_4C_2) hexanucleotide expansions in the non-coding region of *C9orf72* gene have been reported in cases of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). G_4C_2 RNA repeats cause toxicity and accumulations of dipeptide repeat proteins (DRP) via the repeat–associated non-AUG (RAN) translation. Recent studies from large-scale genetic screen in *Drosophila* have shown that G_4C_2 repeat expansion compromises the nucleocytoplasmic transport at the nuclear pore complex (NPC) that represents a newly discovered mechanism of neurodegeneration. Sigma-1 receptors (Sig-1Rs) are ligand-regulated membrane proteins that function as molecular chaperones in the endoplasmic reticulum (ER) and are known to be a pluripotent modulator in living systems. Previous studies showed that a missense mutation at Sig-1R amino acid residue 102 (E102Q) was seen in familial ALS patients. The cytoplasmic TAR DNA binding protein (TDP-43)-positive inclusions were seen in motor neurons of ALS patients. Overexpression of Sig-1R mutants (E102Q) led to the extra-nuclear localization of TDP-43 via nucleocytoplasmic shuttling in Neuro2A cells. However, whether Sig-1Rs are involved in G_4C_2 repeats-mediated ALS/FTD is unknown. Here we firstly found that Sig-1Rs exist at the ER and plasma membrane but also at the NPC. Further, by using the biotin pull-down assay we found that biotin-labeled $(G_4C_2)_{10}$ RNA repeats binds and interacts

with Sig-1R-YFP in Neuro2A cells. The endogenous Sig-1R in rat liver microsomes was also found to bind the $(G_4C_2)_{10}$ RNA repeats. To further dissect the interaction domains between Sig-1R and G_4C_2 RNA repeats *in vitro*, we generated recombinant glutathione S-transferase (GST)-tagged proteins including full-length and three truncated fragments of mouse Sig-1R. The pull-down assay revealed that full-length of recombinant Sig-1R (amino acids 1 to 223) physically interacts with G_4C_2 RNA repeats, but not GST alone. The majority of the Sig-1R-$(G_4C_2)_{10}$ RNA interaction occurs on the N-terminal (amino acids 1 to 79) and C-terminal fragments (amino acids 174 to 223) of the recombinant Sig-1R. We propose here a novel regulatory mechanism that Sig-1R may participate in the regulation of hexanucleotide repeat expansions in *C9orf72* by serving as a molecular "sponge" in a manner to reduce the toxicity of the RNA repeats. The dysfunction of Sig-1R may thus relate to the disease state of ALS and FTD. (This work was supported by IRP/NIDA/NIH/DHHS)

Title: Intrathecal delivery of rAAV9-ABCD1 by osmotic pump in a mouse model of X-ALD

Authors: *A. BERENSON[1], Y. GONG[1], R. KOK[1], N. SASIDHARAN[1], D. MU[1], A. VOLAK[1], X. O. BREAKEFIELD[1], C. A. MAGUIRE[1], G. GAO[2], F. EICHLER[1];
[1]Massachusetts Gen. Hosp., Boston, MA; [2]Gene Therapy Ctr., Univ. of Massachusetts, Worcester, MA

Abstract: X-linked adrenoleukodystrophy(X-ALD) is a devastating neurological disorder caused by mutations in the ABCD1 gene that encodes a peroxisomal ATP-binding cassette (ABC) transporter. The mouse model of X-ALD with ABCD1 deficiency develops phenotype similar to adrenomyeloneuropathy(AMN), the most common phenotype of X-ALD manifesting spinal cord axon degeneration and peripheral neuropathy but so far lacking therapeutic options. We previously reported successful transduction of central nervous system cells in vitro and in vivo using recombinant adeno-associated virus serotype 9 (rAAV9) vector for delivery of the human ABCD1 gene (ABCD1). Unfortunately, intravenous delivery in young mice was associated with cardiac toxicity due to transgene overexpression. We therefore set out to optimize delivery to the spinal cord while minimizing systemic leakage using intrathecal osmotic pump. Self complementary AAV9 GFP(scAAV9GFP) and rAAV9 encoding ABCD1 (rAAV9-ABCD1)

were delivered to Abcd1-/- mice intrathecally (IT) at spine region between L4-L5 using either gas-tight Hamilton syringe attached to a 33-gauge steel needle in 2mins duration, or osmotic pump in 24h duration with PBS injection as sham control. Two weeks after injection, mice were sacrificed and perfused with 4% PFA. Tissues were then collected, sectioned and stained for immunoflurescence analysis. scAAV9-GFP delivered intrathecally by osmotic pump leads to widespread expression across CNS and dorsal root ganglia (DRG) in a dose dependent manner, with spinal cord and DRG showing higher expression compared to brain. rAAV9-mediated ABCD1 gene transfer via intrathecal osmotic pump leads to widespread gene delivery to CNS with reduced leakage into the systemic circulation compared to intrathecal bolus and intravenous injection. rAAV9-mediated ABCD1 gene transfer via intrathecal osmotic pump targets mainly astrocytes and endothelial cells in the SC and both satellite cells and neurons in the DRG. ICV benefits despite localized expression in brain. Therefore we anticipate even better performance using intrathecal pump delivery. We conclude that rAAV9-mediated ABCD1 gene transfer via intrathecal osmotic pump leads to more uniform and widespread gene delivery to CNS with reduced leakage into the systemic circulation compared to intrathecal bolus injection.

Abstract: Introduction: With improvements in non-central nervous system (CNS) cancer survival, cognitive deficits associated with cancer itself and its treatment, known as cancer-related cognitive impairment (CRCI), has been increasingly recognized. There is little understanding of the biological mechanisms underlying CRCI as well-powered neuroimaging studies of CRCI have yet to be performed. However, a large amount of clinical brain MRI data performed to exclude the possibility of CNS metastases exists. These MRIs generally use contrast agents and image acquisition parameters that are difficult to use with standard automated imaging protocols. We performed a cross-sectional pilot study to examine neuroanatomical differences in patients with cancers compared to controls using imaging data from clinically-indicated contrast-enhanced MRIs.
Methods: We used whole-brain contrast enhanced T1-weighted (T1w) MRIs of adults < 60 years of age with cancers (cases) and without cancer (controls) performed on 5 different scanners. We performed voxel-wise cortical thickness (CT) estimates and tensor-based morphometry (TBM) with advanced normalization tools (ANTs) CT and registration schemes. T1w scans were initially denoised. Scanner specific minimal deformation targets (MDTs) were made and used to create an overall study MDT. Gray matter parcellations were conducted with FreeSurfer for CT analysis. Full skull stripped T1w scans from all individuals were warped to the MDTs for TBM analysis.
Results: Seventy-one MRI scans were analyzed. No statistically significant differences in CT or TBM were found between cases and controls after voxelwise multiple comparisons correction, however, there were regions of suggestive associations (uncorrected $p < 0.01$) within the posterior cingulate and insula (Figure 1).
Conclusions: Our pilot study suggests pooling heterogeneous scans from multiple different clinical scanners may be a promising approach to perform well-powered neuroimaging studies of CRCI. We are currently analyzing a larger cohort of 213 scans to validate our findings.

Title: Mitophagy in the immature brain after hypoxic-ischaemic injury

Authors: *C. THORNTON[1], K. SOBOTKA[3], R. VONTELL[2], S. NAIR[3], A. A. BABURAMANI[2], P. GRESSENS[4], H. HAGBERG[2];
[2]Perinatal Brain Injury Group, [1]King's Col. London, London, United Kingdom; [3]Sahlgrenska Acad., Univ. of Gothenburg, Gothenburg, Sweden; [4]INSERM U1141, Paris, France

Abstract: Perturbation of mitochondrial function is a key hallmark in neonatal hypoxic-ischemic (HI) brain injury, both in animal models and in term infants. Not only is ATP production impaired, but dysregulation of calcium homeostasis and the generation of reactive oxygen species from defective mitochondria result in greater damage than in adult brain due to an immature antioxidant defence system. Mitophagy (mitochondrial recycling) offers a mechanism of efficient disposal of deficient mitochondria which are subsequently replaced through biogenesis. However, unregulated mitochondrial turnover (too much / too little) could be particularly critical in the immature brain as it may affect not only short- and long-term structural and functional recovery but also brain development. This study aims to characterise the molecular players and the efficiency of mitophagy as a protective mechanism after HI in the immature brain. Mitochondrial fission is required as a precursor to mitophagy. We find that after oxygen/glucose deprivation *in vitro* or HI in immature mice *in vivo*, mitochondria undergo rapid fission, characterised by alterations in location and phosphorylation state of the fission mediator Dynamin-Related protein (Drp)1 and a reduction in length and volume of mitochondria. Immunohistochemistry performed on *ex vivo* HI brain sections reveals a colocalisation between mitochondria and autophagosomes (as detected by TOM20 and LC3-II respectively) suggesting an increase in mitochondrial recycling. In addition, we detect changes in both the expression and regulation of mitophagy facilitators such as BNIP3, PINK1 and Parkin. We are currently investigating the temporal regulation and the specific receptors implicated so that we can completely understand the molecular basis of mitophagy in the immature brain. Only then will we be able to determine whether mitophagy offers a new avenue for therapeutic intervention for the babies who suffer life-long disabilities as a result of birth asphyxia.

Title: Drp1 association with Fis1 is a critical mediator in microglial activation and neurodegeneration

Authors: A. U. JOSHI[1], M.-H. DISATNIK[1], *D. MOCHLY-ROSEN[2];
[1]Chem. & Systems Biol., [2]Stanford Univ., Stanford, CA

Abstract: Neuroinflammation is a common feature of many neurodegenerative diseases, including Huntington's disease (HD). Activation of microglia cells in the brain contributes to neurodegenerative processes promoted by many neurotoxic factors such as pro-inflammatory cytokines and nitric oxide (NO). Mitochondria are critical for ATP production, intracellular Ca^{2+} signaling, generation of reactive oxygen species and programmed cell death. A balance between fission and fusion maintains mitochondrial quality control and enables meeting energy demands in various subcellular compartments. Previous studies demonstrated increased proinflammatory cytokines in brain tissue and plasma of HD mice and patients. Increased activities of dynamin-related protein 1 (Drp1), disrupted mitochondrial structure and dynamics have also been observed in HD samples. Hyperphosphorylated Drp1 is recruited to the mitochondria by fission1 (Fis1) protein promoting excessive mitochondrial fragmentation. In this study, we observed increased Drp1/Fis1 interaction in lipopolysaccharide (LPS)-stimulated BV2 microglial cell line. We further found that Drp1 oligomerization occurs as an early event under inflammatory conditions in BV2 microglial cells and eventually increased mitochondrial fragmentation and dysfunction. Inhibition of mitochondrial fragmentation by treatment with P110, that selectively inhibits Drp1/Fis1 interaction alone, effectively suppressed the level of mitochondrial ROS and NO. P110 treatment also significantly prevented LPS-induced increase in the TNF-α, IL-1β, IL-6, iNOS and Cox-2 in BV-2 microglial cells. Furthermore, LPS-induced suppression of mitochondrial ROS generation also regulated inhibitor of kappa Bα (IκBα) activation and nuclear factor-κB (NF-κB) nuclear localization. Notably, P110 treatment did not alter mitochondrial fission and function under basal conditions. In R6/2 mice, inhibiting Drp1/Fis1 interaction reduced activation of astrocytes and microglia. ELISA analyses showed that P110 decreased elevated levels of TNFα and Il-6 in plasma and brain tissue in R6/2 mice. Further, inhibiting Drp1/Fis1 interaction improved survival in R6/2 mice. Collectively, our findings suggest that an effective and selective treatment targeting mitochondrial dysfunction is a potential therapeutic strategy for HD.

Title: Cognitive impairment in male offspring exposed to gestational diabetes is associated with hippocampal neuronal changes & neuroinflammation

Authors: *T. M. KAUPPINEN[1,3], B. VUONG[2], G. ODERO[2], M. STEVENSON[2], S. ROZBACHER[2], S. KERELIUK[2], T. PEREIRA[2], V. DOLINSKY[2,4];
[1]Kleysen Inst. for Advanced Med., [2]Pharmacol. and Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada; [3]Neurosci. Res. Program, Kleysen Inst. for Advanced Med., Winnipeg, MB, Canada; [4]The Children's Hosp. Reserach Inst. of Manitoba, Winnipeg, MB, Canada

Abstract: Gestational diabetes mellitus (GDM) is the most common complication of pregnancy. Population health studies have demonstrated a link between GDM and impaired cognitive abilities and psychiatric disorders in the offspring. GDM and diets containing excess fats and sugars promote inflammatory responses. Prolonged inflammation can impair the fetal neuronal circuitry development resulting in lifelong effects on cognitive functions. We hypothesized that GDM causes adverse inflammatory responses contributing to derangement of fetal developing neuronal networks, and impairing the neurocognitive abilities of the offspring. We induced GDM by exposing rat dams to diets high in sucrose and fatty acids 6 weeks prior and throughout their pregnancy. Neonatal (20E) and 15 week old (=young adult) male offspring from GDM and lean dams were examined. The neurocognitive abilities of 15 week old offspring were evaluated in Open field, Morris Water Maze and with Novel Object Recognition test, and the brains from both age groups were analyzed by immunohistochemistry. Complementing i*n vitro* experiments involved analyzing microglial responses to elevated levels of glucose and/or fatty acids. Offspring from GDM dams had impaired memory. Fetal GDM exposure combined with a postnatal HFS diet triggered atypical explorative behaviour in open field test. Analysis of brain tissues from neonatal and young adult offspring of GDM dams showed increased astroglial GFAP expression, increased morphological transformation towards amoeboid microglia, and reduced expression of synaptic vesicle protein. Young adult offspring also had disorganized CA1 pyramidal layer and reduced CX3CR1 expression. Postnatal junk food diet further promoted GDM induced abnormalities. Cultured microglia exposed to high glucose and/or fatty acids (palmitate) transformed into activated, amoeboid morphology, significantly increased nitric oxide and superoxide production, and changed cytokine release profile. Both in vitro and *in vivo* data strongly supports our hypothesis that GDM induces chronic inflammatory responses in the offspring brain. Microglia culture experiments confirmed that excess glucose and/or fatty acids induce pro-inflammatory responses. Detrimental pro-inflammatory responses combined with impaired microglial neurotropic functions could explain hippocampal neuronal derangement and synaptic degradation, predisposing offspring for behavior changes, and memory and learning impairments.

Title: Possible prolonged endoplasmic reticulum (ER) stress following neonatal hypoxia-ischemia (HI)

Authors: *F. J. NORTHINGTON[1], R. CHAVEZ-VALDEZ[1], D. FLOCK[1], O. AVERITT[1], L. J. MARTIN[2];
[1]Pediatrics and Neonatalogy, [2]Pathology and Neurosci., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: ER stress is associated with multiple adult onset neurodegenerative and other chronic illnesses and is considered a therapeutic target for many of these diseases. Sporadically over time, several laboratories have identified ER stress in response to neonatal hypoxia-ischemia and other forms of excitotoxicity. Salubrinal and other small molecules have been shown to inhibit both the markers of ER stress and provide neuroprotection in experimental animal models. Recently we found marked acute ER stress and more prolonged ER pathology extending >5 days following neonatal HI. Whether this ER stress persists into the chronic phase and effects delayed injury and repair after HI is completely unknown. We used the Rice-Vannucci model to induce cerebral HI in C57B6 mice at p10 with unilateral carotid ligation and 45min of hypoxia (FiO_2=0.08). Mice n=6/gp were survived to p40 and perfused for analysis of injury, immunohistochemistry and electron microscopy (EM). Injury was graded on a 0-3 scale in hippocampus, striatum and cortex and brains with score of 3 in any region were excluded from any further analysis. Calcium binding proteins, calreticulin (CR) and calbindin (CB) were assayed immunohistochemically sections and adjacent sections sub-dissected for regions within the ipsilateral hippocampal circuit and processed for ultrastructure. CR is used frequently as an ER marker. CR and CB are expressed throughout the hippocampal circuit but differentially. Multiple regions within the ipsilateral hippocampal circuit displayed enhanced immunoreactivity(IR) for CR compared to their contralateral counterpart, including cigulate

cortex, hippocampus and dentate gyrus, entorhinal cortex and hypothalamus. IR was present in neurons and non-neuronal cells. Within neurons, enhanced IR manifests as thickened-darkened IR in the cell periphery with areas of swelling and in some neurons, the area of the nucleus is IR with swellings contiguous to the nuclear membrane. No such differences were noted in CB expression. EM revealed some neurons with darkened cytoplasm, autophagocitic bodies and mildly swollen ER in the ipsilateral cingulate. Rare dilations of the ER similar to that seen in the subacute phase were noted in the ipsilateral cingulate. Microglia were also frequently seen on EM in the ipsilateral cingulate. No obvious differences in CR IR or ER ultrastructure was noted in the white matter. Chronically altered ER structure within the ipsilateral hippocampal circuit is noted following neonatal HI. Whether this represents ongoing repair and recovery or persistent vulnerability of the hippocampal circuit to further damage following neonatal HI is unknown.

Title: Lipopolysaccharide induces mitochondrial fission and a metabolic shift in microglia

Authors: S. NAIR[1], C. MALLARD[1], C. THORNTON[3], K. SOBOTKA[1], *H. HAGBERG[2,4]; [1]Neurosci. and Physiol., [2]Perinatal Ctr., Göteborg, Sweden; [3]Ctr. for the Developing Brain, [4]Dept. of Perinatal Imaging and Hlth., London, United Kingdom

Abstract: Mitochondrial integrity and inflammation are critical in neonatal brain injury (1). Microglia are nervous system-specific immune cells influencing brain development, inflammation and repair.

The aim was to explore mitochondrial morphology in relation to energy metabolism and cytokine release in primary microglia after stimulation with the TOLL-like receptor 4 agonist lipopolysaccharide (LPS).
We examined specific bioenergetic features of primary microglia under LPS stimulation using doses eliciting a moderate (50 ng/mL) and marked (100 ng/mL) cytokine/chemokine response. LPS administration for 3 to 24 h was followed by measurement of oxygen consumption rate and extracellular acidification rate using the XFp extracellular flux analyzer (Seahorse Bioscience). Changes in mitochondrial morphology in LPS-treated microglia prepared from COX8-GFP mice were studied quantitatively using a Zeiss ELYRA SR-SIM high resolution microscope.
We obtained high resolution visualization of mitochondrial structure using SR-SIM microscopy. LPS (100 ng/mL) induced fission of mitochondria (Figure. left: control; right: LPS) i.e. the number of fragmented (<1 um) was significantly increased whereas tubular (1-3 um) and elongated (>3 um) mitochondria were decreased. These morphological changes were accompanied by a shift from mitochondrial respiration to aerobic glycolysis. We are currently exploring the effect of pharmacological inhibition of mitochondrial fragmentation on the metabolic and inflammatory phenotype. We hypothesize that further understanding of the role of energy metabolism and mitochondrial fusion-fission events in inflammatory cells is critical for development of neuroprotective strategies in the immature brain.

Title: Role of the alpha,beta-unsaturated carbonyl moiety of curcumin and its bis-demethoxy derivative for inhibition of lipopolysaccharide-induced Toll-like receptor 4 activation and inflammatory response in microglia

Authors: *P. F. GIUSTI[1], F. BELLUTI[3], C. MARINELLI[2], E. CARACCIOLO[2], R. LO[4], S. STIFANI[4], S. MORO[2], M. ZUSSO[2];

Abstract: Toll-like receptors (TLRs) play a key role in the recognition of both invading pathogens and endogenous danger signals to induce inflammatory responses both in peripheral organs and in the central nervous system (CNS). TLR4, a receptor responsible for the recognition of lipopolysaccharide (LPS), serves as the primary mediator of immune responses. An exaggerated inflammatory response can be detrimental to normal CNS functioning and is widely associated with the pathogenesis of numerous neurodegenerative and psychiatric disorders. Identification of molecules capable of interfering with TLR4 activation and understanding the molecular mechanisms modulating TLR4 activity may be a viable strategy for attenuating the severity of CNS inflammatory conditions. An increasing number of studies show the anti-inflammatory properties of curcumin; however, the underlying mechanism has not been clearly identified. In this study, bis-demethoxycurcumin (**GG6**) and its cyclized pyrazole analogue (**GG9**) (which lacks the α,β-unsaturated carbonyl moiety) were synthesized and examined for their binding affinity to the TLR4-MD-2 complex. Molecular docking experiments were carried out to assess the possible LPS-competitive accommodation of both **GG6** and **GG9** into the TLR4-MD-2 complex. As for curcumin, both analogues could conceivably bind to the hydrophobic region of the MD-2 pocket. However, only curcumin and **GG6**, presenting the α,β-unsaturated carbonyl moiety, inhibited LPS-induced TLR4 dimerization, activation of mitogen-activated protein kinase and nuclear factor-κB pathways and secretion of the pro-inflammatory cytokines interleukin-1β and tumor necrosis factor-α in primary cortical microglia. To investigate the mechanisms underlying the anti-inflammatory activity of curcumin and **GG6**, microglial cells were cultured in a low Mg^{2+} environment and exposed to curcumin, **GG6** and **GG9** before LPS stimulation. LPS-induced TLR4 dimerization and pro-inflammatory cytokine release were significantly decreased compared to normal Mg^{2+} culture medium. Curcumin and

GG6 also markedly and concentration-dependently reduced cytokine output in contrast to the pyrazole analogue **GG9**. These data demonstrate that the α,β-unsaturated carbonyl moiety of curcumin, by binding divalent cations such as Mg^{2+}, plays a critical role in curcumin anti-inflammatory responses.

Title: Vra4 locus mediated effects on microglial activation and dopaminergic neurodegeneration induced by overexpression of alpha synuclein.

Authors: *I. JIMENEZ FERRER[1], M. JEWETT[1], A. TONTANAHAL[1], M. ROMERO-RAMOS[2], M. SWANBERG[1];

Abstract: Increasing evidence supports the role of inflammation as an important contributor to disease pathology in Parkinson's disease (PD). Understanding the genetic link between neurodegeneration and specific immune responses is therefore crucial to identify novel biomarkers of early stages of the disease and to devise tailored neuroprotective interventions by targeting critical inflammatory pathways. Single nucleotide polymorphisms in the MHC-II locus are associated with idiopathic PD, implicating its importance in disease pathogenesis. We have previously identified the Vra4 locus in rats with high linkage to MHCII expression. Vra4 was fine-mapped to the MHCII transactivator gene (*Mhc2ta*), which was shown to modulate susceptibility to neuroinflammation and experimental autoimmune encephalomyelitis as well as to be associated to human inflammatory disease. Microglial activation is prevalent in PD and occurs since early stages of the disease progress, MHCII expression on the surface of activated microglia could modulate the overall quality of the inflammatory response leading to a

differential degree of dopaminergic neurodegeneration. A congenic strain was created, which is identical to the DA parental strain except for having PVG alleles in the Vra4 locus, and thus lower MHCII expression. This Vra4 congenic strain is a highly physiologically relevant tool to study quantitative MHC effects on neurodegeneration and microglial response, since it is not a transgenic or knock-out, but based on a natural allelic variant. We have used the rAAV-alpha-syn PD model in Vra4-congenic and parental rats to determine the impact of naturally varying MHCII expression on microglial activation, degeneration of dopaminergic neurons, axonal pathology and motor impairment. This project is the first to address the impact of physiological differences in MHCII expression on PD-related pathology. By defining the mechanisms behind MHCII effects on microglial activation in PD, we may identify new targets for neuroprotective therapies.

Title: Erythropoietin in the brain reduces high fat-diet induced microglial activation and regulates glucose metabolism

Authors: S. DEY[1], J. CABAN[1], Z. CUI[2], O. GAVRILOVA[2], M. GASSMANN[3], *C. T. NOGUCHI[1];
[1]Mol. Med. Branch, NIDDK, MMB, NIDDK, Natl. Inst. of Hlth., Bethesda, MD; [2]Mouse Metabolism Core Lab., NIDDK, Bethesda, MD; [3]Inst. of Vet. Physiol., Univ. of Zurich, Zurich, Switzerland

Abstract: High fat-diet (HFD) feeding adversely affects hypothalamic regulation of energy homeostasis. Saturated fatty acids present in HFD can activate microglial cells of the hypothalamus, and induce them to proliferate, leading to enhanced local inflammatory cytokine production. Microglial cells express the receptor for erythropoietin (Epo), a cytokine produced centrally by astrocytes. Epo, produced peripherally by the kidneys is known to be necessary for erythropoiesis and can inhibit obesity-induced white fat inflammation in mice. However, Epo and its receptor (EpoR) function in microglial cells are not characterized. We hypothesized that

Epo signaling in brain could regulate HFD-induced microglial activation and thereby maintain metabolic homeostasis. To study the effect of Epo in the brain, we examined a mouse model of chronic over-expression of human *EPO* transgene in brain (*Tg21*). The *Tg21* mice exposed to 3 week HFD-feeding gained less fat mass and body weight, and had lower fasting blood glucose compared to wild-type (WT) mice. Moreover, Tg21 mice showed a small but significantly lower food intake and a trend towards higher total activity compared to WT mice. Immunofluorescent staining of the arcuate nucleus region of hypothalamic sections showed lower inflammatory cytokine TNFα and activated microglia marker Iba1 in Tg21 compared to WT mice. Acute intracerebroventricular administration of Epo (Epo ICV) in WT mice also prevented HFD-induced fat mass and weight gain relative to saline-controls (saline ICV). Epo ICV mice also showed lower fasting blood glucose, but hematocrits similar to saline ICV, suggesting no peripheral effects of Epo ICV. In contrast to Tg21 mice, Epo ICV mice did not show any difference in food intake compared to saline ICV, but showed lower gene expression for inflammatory markers *TNFα*, *IL6*, *IL1α*, *SOCS3* and higher expression of anti-inflammatory *IL10*. In summary, our studies suggest an important regulatory role of Epo in the brain in preventing high fat diet-induced fat gain, inflammation and microglial cell activation, combined with modulating food intake and activity in mice.

Title: Non-invasive mitochondrial modulation: a novel approach to reduce cerebral injury following neonatal hypoxia-ischemia

Authors: *T. H. SANDERSON[1], C. A. REYNOLDS[1], E. GRULEY[1], C. STRUBAKOS[1], M. HUTTEMANN[2];
[1]Emergency Med., [2]Ctr. for Mol. Med. and Genet., Wayne State Univ., Detroit, MI

Abstract: Insufficient oxygen delivery to the brain can promote significant neonatal brain injury. While prompt re-oxygenation is critical in the management of affected neonates, the reintroduction of oxygen can potentiate injury by promoting reactive oxygen species (ROS) generation within the mitochondria. While mitigating ROS damage may serve as a common therapeutic avenue for cerebral reperfusion injury, traditional attempts to scavenge ROS have failed. This failure is thought to be due to inherent difficulties in delivery to the brain and sub-cellular targets within the early minutes of reflow. Accordingly, we developed a non-pharmacologic therapy that targets cytochrome c oxidase (CcO) using specific wavelengths of infrared light (IRL) that circumvents these delivery barriers. We discovered 2 specific IRL wavelengths that penetrate the brain and reversibly reduce the activity of CcO. We proposed that these wavelengths will inhibit ROS generation by stabilizing the mitochondrial membrane potential following neonatal hypoxia/ischemia. We tested this hypothesis in parallel cell culture and neonatal rat models. All IRL wavelengths that reduce CcO activity reduced neuronal death following oxygen-glucose deprivation (OGD) in cell culture ($n = 7$, $p<0.05$). IRL also directly modulated mitochondrial respiratory rate, reduced $\Delta\Psi_m$ in a switch-like manner, and blocked mitochondrial ROS production, providing preliminary insight into the mechanism of action. Next, the 2 wavelengths that reduce CcO activity were evaluated for neuroprotection in the Vannucci neonatal HIE model with unilateral carotid ligation followed by 180 min of hypoxia (8% O_2). Pups were randomly enrolled into IRL treatment groups (n=21-33), initiated immediately upon relief of hypoxia. Mean infarct volume was reduced 48 hours after injury with treatment of a single IRL wavelength (29.3% infarct) and dual wavelength treatment (23.6% infarct) when compared with untreated-controls (44.4% infarct; $p<0.05$). An additional cohort was randomly enrolled in treatment with dual wavelength IRL or non-treatment for analysis of infarct progression with MRI, behavioral analysis, and long-term (28 day) histology. In agreement with our short-term outcome studies, our preliminary data demonstrate an improvement in infarct volume measured by MRI and histology 28 days post-HIE. In addition, IRL-treated rats also had preservation of function, as demonstrated by a 40% improvement in the rotorod test ($n = 10$-15, $p<0.05$). These data demonstrate the neuroprotective effect of non-invasive reduction of CcO activity with specific IRL wavelengths and may provide a novel strategy for the treatment of neonatal HIE.

Title: Sex differences in microglia morphology, phagocytic marker CD11b, and cytokines in the adult healthy brain among male, female and post-menopause model mice.

Authors: K. YOUNG[1], *H. MORRISON[2];
[2]Col. of Nursing, [1]Univ. of Arizona, Tucson, AZ

Abstract: Microglia cells are constitutively active and attuned to immediately detect and respond to changes in their microenvironment through constant contact with neurons and glia. A highly ramified morphology and phagocytic capacity is central to efficient microglial surveillance and response. It is unknown if, preceding injury, microglia ramified morphology, phagocytic capacity and cytokine concentrations are different between sexes and if additional differences exist within the female population according to estrus cycle and reproductive status. The purpose of this study was to elucidate sex differences in constitutive microglia-associated neuroinflammation: ramified morphology, phagocytosis and brain cytokine concentrations. In addition, we employ a clinically relevant postmenopause mouse model to test for differences among healthy female pre- and postmenopause mice. For postmenopause model, we injected 4-vinylcyclohexene diepoxide (160mg/kg i.p.) into 6wk old female mice for 21 days. Brain tissue was collected from healthy euthanized C57Bl/6 (16wk) male (N=8), diestrus female (N=16), estrus female (N=10) and postmenopause female (N=18) mice for immunohistochemistry (IHC) methods and Multiplex immunoassay. Image analyses of confocal images were used to quantify microglia ramified morphology (anti- IBA-1; number of microglia process endpoints/cell and process length/cell) and phagocytic marker CD11b among groups. Multiplex data allowed for simultaneous measurement of brain cytokine concentrations among groups. Data analysis reveal that summed microglia process length/cell is increased in the female postmenopause mouse versus male ($p<0.002$) and diestrus or estrus females ($p<0.0001$ and $p=0.0002$, respectively). The number of microglia process endpoints/cell is increased in males versus estrus females ($p=0.01$). In females, endpoints/cell is increased in the postmenopause female versus estrus or diestrus females ($p<0.0001$ and $p=0.006$, respectively). Microglia CD11b is increased in diestrus female microglia versus males ($p=0.05$). Concentrations of brain cytokines (IL1β, IL6, IL4, IL10) were increased in males versus all female groups with largest effect size observed between male and postmenopause female mice. In summary, microglia ramified morphology, presence of phagocytic receptor CD11b and brain inflammatory milieu is different among healthy male, female and female postmenopause mice. We suggest that observed sex-differences in

constitutive microglia-associated neuroinflammation are an important consideration when determining the trajectory and magnitude of microglia responses to injury.

Title: CNS effects of neonatal Staphylococcus epidermidis infection

Authors: *C. MALLARD[1], J. LAI[1], P. SVEDIN[1], X. WANG[1], T. STRUNK[2], A. CURRIE[2], M. PETTENGILL[3], O. LEVY[4];

Microbiology, Univ. of Rochester, New York, NY; [4]Div. of Infectious Dis., Boston Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: Background and objective: Neonatal sepsis is a serious problem in neonatal intensive care units, causing increased hospitalization costs and prolonged hospitalization stays. The coagulase-negative staphylococcus, Staphylococcus epidermidis (SE), has emerged as the predominant pathogen of late-onset neonatal sepsis in premature infants, accounting for up to 78% of neonatal late-onset sepsis. We previously determined that intravenous injection of SE in postnatal day (PND) 1 mice induces systemic cytokine production and impairs brain development. In this study we have tested the response of older neonatal mice to the bacteria, so

as to determine the vulnerability window for infection-induced brain injury in neonates.
Methods: SE grown to mid-log phase was administered intraperitoneally into PND4 mice. Animals were monitored over time for body weight and temperature changes and long-term survival. Bacterial colony-forming units from the peripheral blood, liver and spleen was determined by spot plating. Cytokine production was determined by multiplex cytokine bead array analysis. Immunohistochemistry of brain sections assessed effects of the infection and inflammation in the brain.
Results: Injection of SE led to bacteremia within two hours in a dose-dependent manner. Pro-inflammatory cytokines were significantly up-regulated in the peripheral blood of infected animals from 2 to 24 hours post infection, and tapered down by 48 hours, in association with the clearance of the bacteria from the blood. Neutrophil and monocyte chemotactic cytokines (CXCL1 and CCL2), granulocyte-colony stimulating factor, and caspase-3 activity were also significantly elevated in the brain by 14 hours post infection. There was a dose-dependent decrease in body weight gain after the infection. No difference in brain gray and white matter volume was detected 10 days after the infection compared to saline injected mice.
Conclusions: Although intraperitoneal injection of *S. epidermidis* in PND4 animals led to a similar infection pattern and response compared to intravenous infection of PND1 animals, no gross morphological injury in the brain was detected. These data raise the possibility that vulnerability of the immature brain to infection and inflammation is age- and/or route-dependent. Comparing and delineating the difference between neonatal mice of different ages will provide insight into factors leading to brain injury upon infection and inflammation, informing development of therapeutic treatments for infants affected by these conditions.

Title: Acute and chronic allergic reactions differentially affect immune signaling in the hippocampus

Authors: *B. KLEIN[1,2], B. ALTENDORFER[1,2], B. HAMMER[1,2], J. THALHAMER[3], S. SCHEIBLHOFER[3], R. WEISS[3], L. AIGNER[1,2];
[1]Inst. of Mol. Regenerative Med., [2]Spinal Cord Injury and Tissue Regeneration Ctr., Paracelsus Med. Univ., Salzburg, Austria; [3]Allergy and Immunology, Dept. of Mol. Biol., Univ. of Salzburg, Salzburg, Austria

Abstract: Allergic diseases cause systemic inflammation and affect almost one quarter of the world-wide population. Although it has been shown that immune responses in the periphery have effects on the brain, the impact of allergies on the CNS needs further investigation. For this reason, we analyzed acute (3 days challenge) and chronic (4 weeks challenge) grass pollen allergy models. Mice were sensitized twice and challenged with the clinically relevant grass pollen allergen Phl p 5. The allergic mice showed no behavioral differences in the Open Field test and the Elevated Plus Maze. Blood samples were obtained 4 days after the second sensitization and at the end of experiment. In the sera, T_H2 cytokines (e.g. IL-4, IL-5) were elevated in the acute and chronic allergy models. Additionally, in the chronic allergy model pro-inflammatory cytokines (e.g. IFN-γ, TNF-α) were increased. In both allergy models, we analyzed the effects of the T_H2-polarized immune responses on the expression of immune mediators in the hippocampus, in comparison to the olfactory bulb and the cerebellum, using RT-qPCR. Results showed a significant down-regulation of immune mediators (e.g. IL-1β, IL-13, H2-Aa) in the hippocampus in the chronic allergy model. On histological level, we observed similar changes, e.g. a reduced number and soma size of microglia/macrophages. This data indicates that chronic allergy modulates CNS immune signaling.

Abstract: Pre-exposure to sub-threshold hypoxia confers increased tolerance to neonatal cerebral hypoxic-ischemic (HI) injury, a phenomenon known as preconditioning. We have recently found that $MgSO_4$ (0.6 mg/kg) also induces powerful preconditioning in the immature brain. Intraperitoneal $MgSO_4$ was given 6 days, 3 days, 24h or 12h prior to neonatal HI induced in rats at postnatal day 7. This treatment reduced brain injury in all areas, but particularly in the cerebral cortex, by as much as 50-80%. $MgSO_4$ given 3h, 30min prior to or 1h post HI had no effect on brain injury. These results suggest that $MgSO_4$ induces changes that requires some time ($\geq$12h) to develop CNS resistance to a subsequent insult, which may imply that gene transcription or epigenetic alterations are required. In order to explore the mechanisms behind this protective response we initially studied effects on cerebral blood flow. Using iodoantipyrine, we found that cerebral blood flow was not affected by $MgSO_4$ 24h after drug administration, nor after exposure to 30 min or 60 min of HI. We next sampled cerebral cortex 3h and 24h after $MgSO_4$ and analyzed global gene transcription with Affy mRNA array 2.0 STv1 (36,685 genes) and Affy miRNA 4.0 (Genomic Centre, KCL, London) as well as with Next Seq, Illumina (Genetic Center, Gothenburg). The results show that many mRNA and miR related to mitochondria were affected and combined network and pathway analysis (IPA software) revealed that genes upregulating metabolism were suppressed and that those downregulating metabolism were increased. We next isolated mitochondria from cerebral cortex 24h after $MgSO_4$ treatment as well as immediately after HI (30 min or 60 min duration) and finally 3h after the insult. There was no difference in respiratory control ratio (RCR) in $MgSO_4$ vs. control mitochondria 24h after administration. However, after 30 min of HI the RCR was significantly higher after $MgSO_4$ (4.4 ± 0.6) compared to control (2.7± 0.4) $p<0.05$. In summary, intraperitoneal $MgSO_4$ provides profound preconditioning protection to neonatal HI if given 12h-6 days prior to the insult. Global mRNA and MiR analysis and experiments in isolated mitochondria indicate that $MgSO_4$ suppresses mitochondrial metabolism making mitochondria more resistant to respiratory deterioration during HI. We are currently performing metabolomic analysis to better understand the mito-protective effect of $MgSO_4$ pre-administration.

Title: Generation of an *In vivo*-like phenotype of primary murine microglia cells in culture

Authors: *H. CYNIS[1], S. BARENDRECHT[1], H.-U. DEMUTH[1], R. EICHENTOPF[1], B. HIETEL[1], C. PÖSEL[2], S. SCHILLING[1], D.-C. WAGNER[2];
[1]Fraunhofer IZI-MWT, Halle, Germany; [2]Fraunhofer IZI, Leipzig, Germany

Abstract: Microglia cells are resident phagocytes of the CNS derived from primitive macrophages of the yolk-sac. The cells populate the CNS early during embryogenesis and are important for brain homeostasis by scanning the surrounding tissue for cellular damage. Microglia cells also support the formation of neural circuits and may contribute to cognitive impairment by actively eliminating complement-tagged synapses. Since these cells operate within the complex environment of CNS tissue, *in vitro* studies are hampered by a rapid loss of the microglial phenotype in culture presumably due to the lack of input from other cells of the CNS.
In the present study, we were interested in microglia gene expression signatures in culture obtained by different isolation methods and the establishment of specific culture conditions to retain and/or restore an *in vivo*-like phenotype.
The applied methods comprised different isolation techniques of primary microglia including FACS sorting from adult and newborn mice, density gradient isolation and shaking from mixed glia cultures. The microglial gene expression was characterized by RNA microarray analysis and qRT-PCR. To influence the microglial phenotype, the cells were co-cultured with primary neurons or stimulated using different combination of cytokines and growth factors and again analyzed by RNA microarray analysis and functional assays such as quantification of microglial phagocytosis.
The microglial signatures obtained by gene expression analysis greatly depend on the method used for cell isolation and culture. Specific combinations of factors important for microglial function, such as CX3CL1, IL-34 and TGF-beta are able to influence gene expression signatures generating a phenotype resembling microglia cells *in vivo*.
The results will help to establish protocols to enable in depth-analysis of native microglia functions *in vitro* such as their contribution to phagocytosis of beta-Amyloid peptides in Alzheimer's disease.

Title: MicroRNAs influence microglia-mediated phagocytosis of $A\beta_{1-42}$ *In vitro*

Authors: *M. S. ALOI[1], W. SU[2], S. FUNG[2], S. DAVIDSON[2], S. JAYADEV[2], G. A. GARDEN[2];
[1]Pathology, [2]Neurol., Univ. of Washington, Seattle, WA

Abstract: Neuroinflammation is a hallmark of acute and chronic CNS injury, including traumatic brain injury and neurodegenerative diseases. Microglia are the innate immune cells of the CNS that effect rapid phenotypic changes by utilizing powerful post-transcriptional modulators, such as microRNAs (miRNAs). Recent studies have implicated two miRNAs known to regulate inflammatory responses, miR-146a and miR-155, in the pathogenesis of several neurodegenerative disorders including multiple sclerosis, ALS, familial Parkinson's disease, and Alzheimer's disease (AD). Expression of both miR-155 and miR-146a is altered in AD mouse models. Interestingly, miR-146a promotes anti-inflammatory functions and deletion of miR-146a leads to an accelerated aging phenotype, which can be abrogated by conditional deletion of miR-155 in T cells. We have also observed that miR-146a expression in microglia is regulated by presenilin 2, a protein mutated in familial AD. We hypothesized that miR-155 and miR-146a modulate microglial inflammatory phenotypes, thereby regulating microglia mediated internalization amyloid beta (Aβ). To evaluate the role of miR-155 and miR-146a in microglia activation, we successfully developed an Adeno-Associated Virus (AAV) serotype 2 vector to introduce CMV-Cre into floxed-miR155 (miR-$155^{flx/flx}$) microglia and flox-stop-flox miR-155 conditionally overexpressing neonatal microglia (*mbic-fsf*). We observed that in cultured microglia, conditional overexpression of miR-155 significantly upregulated miR-146a. Furthermore, conditional deletion of miR-155 in cultured microglia promotes phagocytosis of oligomerized $A\beta_{1-42}$ *in vitro* as measured by flow cytometry, while overexpression of miR-155

decreases oligomerized $A\beta_{1-42}$ internalization. Taken together, our results support the hypothesis that miR-155 and miR-146a modulate microglia-mediated phagocytosis and clearance of $A\beta_{1-42}$. Understanding how miRNAs modulate microglia activation and phagocytosis of $A\beta_{1-42}$ will further elucidate the molecular pathways regulating neuroinflammation in AD pathology.

Title: The sympathetic side of phagocytes

Authors: *I. SHAKED;
Univ. of California At San Diego, LA Jolla, CA

Abstract: The nervous system and the immune system sustain profound communication, which ensures homeostasis and health. On the other hand, brain to immune miscommunication may lead to neuroinflammation and pathology.
In a recent work we identified the nuclear receptor Nr4a1 as a link between the sympathetic nervous system and the immune system, which controls production of norepinephrine (NE) in monocyte-derived macrophages. Using a mouse model of CNS autoimmunity, we have demonstrated a novel role for NE-producing phagocytes in neuroinflammation. Moreover, Nr4a1-dependent patrolling monocytes monitor and maintain the brain vasculature under normal condition and following laser-induced focal injury to the brain (model of ischemic stroke). Our study suggests a new role for phagocytes as a crucial translators and amplifiers of neuronal signaling to endothelial and immune cells, and which therefore, by “spreading the neuronal word” play a crucial role in controlling neuroinflammation.

Title: Concordance between cortical atrophy and distribution of microglia in primary progressive aphasia with TDP-43 inclusions

Authors: G. KIM[1], T. GEFEN[1], Z. PARTON[1], N. LALEHZARI[1], F. RAHMANI[1], *S. WEINTRAUB[2], E. H. BIGIO[1], E. ROGALSKI[1], M.-M. MESULAM[1], C. GEULA[1]; [1]Cognitive Neurol. and Alzheimer's Dis. Ctr., Northwestern University, Feinberg Sch. of Med., Chicago, IL; [2]Northwestern Feinberg Sch. of Med., Northwestern Univ. Med. Sch., Chicago, IL

Abstract: Primary progressive aphasia (PPA) is a neurodegenerative clinical dementia syndrome characterized by a gradual dissolution of language. The asymmetric nature of the language network and focal atrophy render PPA an excellent model for investigation of the relationships between the regional distribution of pathologic markers, cortical atrophy, and clinical phenotype. At autopsy, approximately 30% of PPA patients have TAR-DNA binding protein-43 (TDP-43) pathology (PPA-TDP). We previously reported concordance between microglia activation and cortical atrophy in PPA-TDP participants with progranulin mutations. The current study investigated whether a similar concordance exists in PPA-TDP participants without progranulin mutations. Whole hemisphere sections from three PPA-TDP cases were immunohistochemically stained for HLA-DR, a marker of activated microglia. Using unbiased stereology, densities of activated microglia were quantified in the following regions: inferior frontal gyrus (IFG), middle frontal gyrus (MFG), inferior parietal lobule (IPL), superior temporal gyrus (STG), middle or inferior temporal gyrus (MTG or ITG), entorhinal cortex (ERC), and hippocampus (HIP). Cortical atrophy was assessed using one of three methods: 1) structural MRI scans collected close to death analyzed using the FreeSurfer software, 2) clinical MRI scans, or 3) raw images of the postmortem brain. Case 1, a right-handed male, displayed substantial asymmetry of microglia distribution, greater in the left hemisphere in all cortical areas. This showed concordance with atrophy patterns visualized by quantitative MRI. Case 2, a left-handed male, had reversed asymmetry of atrophy and right hemisphere language dominance; clinical scans exhibited severe atrophy of the right temporal lobe. Microglia density displayed substantial asymmetry in right hemisphere cortical areas, with greatest asymmetry in STG and ITG, concordant with patterns of atrophy on MRI. Microglial counts in Case 3, a right-handed male participant, were fairly

symmetric across all cortical regions, aligning with the absence of visible left-sided asymmetric atrophy in most cortical areas. These findings demonstrate significant microglial activation in PPA-TDP that match patterns of atrophy. It remains to be determined whether microglial activation contributes to cortical damage in PPA-TDP.

Title: Analysis of microglia population dynamics in the healthy and diseased brain

Authors: *D. E. MARZAN[1], W. GAN[3], J. SALZER[2];
[2]Neurosci., [1]NYU Sch. of Med., New York, NY; [3]Dept. of Physiol. and Neurosci., Skirball Inst. of Biomolecular Med., New York, NY

Abstract: Microglia are the resident immune cells of the central nervous system (CNS) that arise from yolk sac progenitor cells and colonize the brain during early embryonic development. In the healthy adult brain, these cells exist as a distinct population without infiltration of peripheral monocytes and macrophages. Although these cells are long lived with a slow turnover, the exact identity of the source(s) of microglia in the adult remains unclear. Here we offer direct evidence that microglia are a self-renewing population and do not arise from a progenitor and/or stem pool. In our studies, we utilized a genetic strategy to differentially label endogenous CNS microglia from myeloid cells in the peripheral immune system. We ablated 99% of microglia in

the brains of these mice by using a well characterized inhibitor of the Colony Stimulating Factor 1 Receptor. As previously reported (Elmore et al., Neuron 2014), there is a rapid repopulation of microglia in the brain upon removal from this inhibitor. We have determined that these repopulated cells originated from the surviving resident microglia. This finding supports the theory that the few microglia surviving ablation are sufficient to repopulate the entire brain. Moreover, using the same labeling strategy in a model of demyelination, we also observed that almost all macrophages in the CNS are microglia in origin with little to no contribution from peripheral myeloid cells. To corroborate this data, experiments are underway in mice that lack the ability for monocytes to be recruited into the inflamed CNS. These studies provide new insights into microglial biology in both the healthy and diseased brain.

Title: Optical control of microglial APC function using Cas9 effectors

Authors: *P. MILLER-RHODES, R. WYCALLIS, S.-M. LU, H. GELBARD;
Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: Human immunodeficiency virus-1 (HIV-1) associated neurocognitive disorder (HAND) describes the neurocognitive impairment observed in up to half of HIV-1 infected individuals. HAND is refractory to combination antiretroviral therapy; thus, adjunctive therapies for HAND remain a critical unmet medical need. Recent efforts by our laboratories have identified therapeutic strategies that target both innate and adaptive immune effectors, including GM-CSF and vasoactive polypeptide receptor type 2 receptor 2 (VPAC2) agonists. Increasing evidence shows that these agents resolve microgliosis and the correlated destruction of synaptodendritic networks by promoting regulatory T cell (Treg) responses over effector T cell (Teff) responses. While we have shown previously that these agents promote Treg expansion and/or stabilization, we reasoned that this immune transformation is sustained in part by the

direct effects of GM-CSF and/or VPAC2 agonism on APC populations. Specifically, we hypothesized that VPAC2 agonism/GM-CSF induces a tolerogenic APC phenotype in microglia. We approached this hypothesis mechanistically by generating a series of microglia and T cell lines that stably express programmable Cas9 effectors capable of modulating gene expression in a spatially and temporally controlled manner. To this end, we chose two Cas9 effector systems: (1) the "Suntag" effector, which uses a peptide array to recruit ten copies of the transcriptional activator VP64 to genome-targeted, nuclease-deficient Cas9 (dCas9):sgRNA complexes, and (2) the light-activated Cas9 effector system (LACE), which leverages the light-inducible heterodimerization of Cry2 and CibN, which are fused to VP64 and dCas9, respectively, in order to recruit two copies of the transcriptional activator module to the dCas9-sgRNA complex. We used these Cas9-effector cell lines to identify and interrogate genes that are central to the transformation of activated microglia into tolerogenic APCs.

Title: Dock8 deficiency suppresses microglial migration and neuroinflammation

Authors: *K. NAMEKATA, X. GUO, A. KIMURA, C. HARADA, T. HARADA;
Tokyo Metropolitan Inst. of Med. Sci., Tokyo, Japan

Abstract: The Rho subfamily GTPases (Rac1, Cdc42 and RhoA) are best documented for their roles in actin dynamics, and they regulate a variety of cellular processes, including cell migration, morphogenesis, neuronal development, gene expression and cell division and adhesion. The Dock family proteins (Dock1-11) of atypical guanine nucleotide exchange factors (GEFs) activate Rac1 and/or Cdc42, but not RhoA. The Dock family proteins are involved in various disorders, including Parkinson's disease and Adams-Oliver syndrome. Recently, Dock8

functions and signaling have gained attention due to the discovery of a combined immunodeficiency syndrome caused by Dock8 mutations in humans. Accumulated evidence revealed that Dock8 deficiency leads to multiple defects in immune cells, such as T cells and B cells. Microglia, the resident immune cells in the CNS, have important roles in neuroinflammation. In the CNS, microglia are activated by several disorders and injury, and accumulate at the lesion site in order to initiate immune responses. Activated microglia are associated with the progression of several neurodegenerative diseases, such as Alzheimer's disease. Therefore, microglia are one of the key targets for therapeutic intervention. To date, the function of Dock8 in microglia is unknown. In this study, we generated Dock8-deficient mice and investigated the function of Dock8 in microglia. To examine which cell types abundantly express Dock8 in the CNS, we performed immunoblot analysis using primary cultured cells (neuron, astrocyte and microglia). Immunoblot analysis showed Dock8 is expressed in microglia but not in neurons and astrocytes. The chemotaxis assay revealed the reduced cell migration ability in Dock8-deficient microglia. We also found that the formation of podosomes, actin-associated adhesion structures involved in the cell migration, is suppressed in Dock8-deficient microglia, suggesting that Dock8 regulates microglial migration via actin dynamics. In addition, Dock8-deficiency reduced microglia accumulation at the lesion site and ameliorated the clinical signs in experimental autoimmune encephalomyelitis (EAE) mice, an animal model of multiple sclerosis (MS). These findings suggest that Dock8 stimulates migration of microglia, which leads to severe CNS inflammation. Thus, manipulation of Dock8 signaling might be a novel therapeutic strategy against diseases associated with neuroinflammation including MS and optic neuritis.

Title: Chronic ethanol increases toll-like receptor 7-induced neuroinflammation and neurodegeneration in C57BL/6 mice

Authors: *L. QIN, F. T. CREWS;
Bowles Ctr. Alcohol Studies, Univ. North Carolina, Sch. Med., Chapel Hill, NC

Abstract: Toll-like receptor (TLR) 7 triggers production of proinflammatory cytokines when activated by viral singe-stranded RNA or the small molecule agonist imiquimod (R837). We investigated the effects of chronic ethanol (ETOH, 5 g/kg/day, i.g., daily for 10 days) on TLR7 expression in brain and imiquimod (2.5 mg/kg, i.p.) induction of neuroinflammation and neurodegeneration in male C57BL/6 mice. ETOH increased levels of TLR7 mRNA and protein, determined by real-time PCR and entorhinal cortex immunohistochemistry. Confocal microscopy revealed that TLR7 was expressed in NeuN+IR neurons and Iba1+IR microglia, but not in GFAP+IR astrocytes. Chronic ethanol treatment increased p-NF-κB p65 immunoreactivity, an indicator of increased neuroimmune signaling and HMGB1, a neuroimmune signaling molecule. Imiquimod, the TLR7 agonist increased TLR7 mRNA and IHC similar to ethanol, whereas ETOH treatment followed by a single imiquimod treatment further increased TLR7 expression. Ethanol pretreatment potentiated imiquimod-induced brain mRNA levels of TNFα (535 %), IL-1β (186%), IL-6 (236%), and MCP-1 (369%), compared with imiquimod alone treatment consistent with ETOH induction of TLR7. Increased levels of brain cytokines coincided with increased microglial activation, NOX $gp91^{phox}$, and markers of neurodegeneration: activated caspase-3 and Fluoro Jade B. Ethanol potentiation of imiquimod was associated with ethanol-increased expression of both TLR7 and the endogenous TLR agonist HMGB1 in the brain. These studies indicate that ETOH increases TLR7 and TLR7 agonist induced increase in brain cytokines, chemokines and NADPH oxidase that contribute to neurodegeneration.

Title: The TLR7 agonist imiquimod induces neurotoxicity via HMGB1-let-7 signaling in brain slice cultures: ethanol potentiation and neuroprotection of rifampin

Authors: *J. Y. ZOU, L. G. COLEMAN, F. T. CREWS;
Univ. North Carolina, Chapel Hill, Chapel Hill, NC

Abstract: Activation of the RNA-sensing Toll-like receptor (TLR) 7 induces neurodegeneration through neuronal TLR7. The present study used an *ex vivo* model of organotypic hippocampal-entorhinal cortex (HEC) slice cultures to investigate the role of danger signaling molecule HMGB1 and miRNA let-7b in TLR7 agonist imiquimod-induced neurotoxicity as well as the effects of ethanol and MD2 inhibitor rifampin. Imiquimod treatments of HEC slices caused neuronal cell death in concentration-dependent manner, with 10mg/ml and 20mg/ml imiquimod causing a 67% and 152% increase in PI uptake (index of neuronal death) respectively. Measurements of media HMGB1 levels revealed that imiquimod (10mg/ml) caused rapid active release of HMGB1 (3 fold increase at 8hr) and gradually reached peak in correlation with neuronal cell death. Inactivation of HMGB1 with inhibitor glycyrrhizin significantly reduced imiquimod-induced neuronal death, suggesting that actively released HMGB1 contributes to TLR7-activated neuronal cell death. MicroRNA let-7b is known to serve as an endogenous ligand that activates neuronal TLR7 causing neuro-immune activation and neurodegeneration. Measurements of extracellular miRNAs from microparticles isolated from culture media indicated that imiquimod treatments increased release of miR-let-7b and miR-155. Using the assay of HMGB1 immunoprecipation followed by RT-PCR for miRNAs, we detected that HMGB1 is mainly associated with let-7b but not miR-155, suggesting HMGB1 coupling with let-7b leading to activation of intracellular neuronal TLR7. Eliminating microglia with CSF-1 receptor inhibitor PLX3397 appears not to reduce release of extracellular let-7b and the expression of HMGB1 mRNA level as well as imiquimod-induced neuronal cell death, further indicating neuronal origin of HMGB1 and let-7b. We further test the effects of ethanol and rifampin on imiquimod-induced neuronal death. Ethanol (100mM) prime for 48hrs significantly enhanced neuronal vulnerability to imiquimod (10mg/ml), causing a 38% increase in PI uptake relative to imiquimod alone. Combination of ethanol and imiquimod also increased increase the association of let-7b with HMGB1 by 50% above control. Furthermore, the presence of rifampin (10uM) completely blocked imiquimod-induced neurotoxicity as well as the release of HMGB1 and let-7b. Together, these novel results identify the mechanisms underlying activation of intracellular neuronal TLR7.

Title: The injury-induced up-regulation of glial aromatase is cyclooxygenase dependent in the zebra finch (Taeniopygia guttata).

Authors: *C. J. SALDANHA[1], A. L. PEDERSEN[2], C. J. GOULD[2];
[1]Biol. and Psychology, [2]Behavior Cognition & Neurosci., American Univ., Washington, DC

Abstract: Aromatase expression is induced in astrocytes following brain damage in homeotherms. The consequences of induced astrocytic aromatization are well studied, but little is known about the factor(s) that induce glial aromatase. Central application of an inflammagen is sufficient to induce astrocytic aromatase, suggesting a causative link between inflammation and glial aromatase expression. To test this hypothesis, we administered lipopolysaccharide (LPS) or vehicle peripherally to adult zebra finches of both sexes and observed their behavior 2 or 24 hr later. The birds were then sacrificed, and the central transcription of pro-inflammatory cytokines (TNFα, IL-1β and IL-6) and aromatase was measured, as was telencephalic aromatase activity (24hr time point only). Two hours post LPS resting behavior increased ($p = 0.002$) and locomotor behaviors decreased ($p = 0.03$) in both sexes relative to controls and pretreatment observations. But 24 hours later, the behavior of LPS birds was similar to controls ($p = 0.81$). Two hours post LPS injection, IL-1β was higher in both sexes ($p = 0.0003$), but only females showed higher TNFα mRNA ($p =0.03$). However, 24 hours post LPS, cytokines had returned to baseline, but aromatase mRNA ($p = 0.004$) and activity were elevated in both sexes ($p = 0.01$). No changes in IL-6 were detected in either sex following treatment. These data suggest that neuroinflammation following peripheral LPS administration may be sufficient to induce central aromatase expression. To test the necessity of this association, we measured the neural aromatase expression and estradiol content (E_2) of adult females injected with the cox1/2 inhibitor (indomethacin) or vehicle into contralateral telencephalic hemispheres, 6 or 24hr post injury. An EIA for prostaglandin E_2 (PGE_2) revealed lower PGE2 in the lobe injected with indomethacin relative to the contralateral lobe at both time points ($p=0.004$). Next, aromatase transcription was measured relative to GAPDH using qPCR and revealed lower aromatase expression in the lobe treated with indomethacin at 6 ($p = 0.006$), but not 24 hours post injury ($p = 0.39$). Correspondingly, the lobe injured in the presence of indomethacin had lower levels of E_2 relative to the vehicle-treated hemisphere at 6 ($p=0.02$), but not 24hr post injury ($p=0.82$). These data suggest that inflammatory signaling, specifically cyclooxygenase activity and consequent PGE2 synthesis and secretion, may be necessary for injury-induced increases in aromatization and central E_2. Future studies will test the cell-specificity of aromatase expression following peripheral LPS and central inhibition of PGE2 synthesis.

Title: Estrogen therapy modulates inflammatory and apoptotic protein expression in estrogen receptor knock down female rat hippocampus

Authors: *P. KUMAR, P. DHAR;
Anat., AIIMS, New Delhi, India

Abstract: Background: Estrogen is an essential female sex hormone known to exert pleiotropic effects on different tissues including the central and the peripheral nervous system. It also plays a significant role in immune functions by influencing the inflammatory response. Decreased levels of this hormone have long been associated with cognitive decline and neurodegenerative changes in the brain areas associated with learning and memory. It is also known that neurodegenerative changes and inflammatory responses in the brain go hand in hand.
Aim and Objectives: To evaluate the immunoregulatory and protective role of estrogen replenishment therapy in estrogen receptor knock down female rat hippocampus with the help of immunohistochemical, western blot and molecular biology techniques.
Materials and Methods: Adult female wistar rats (4-5 months) were divided into various groups (n=6/group) such as gp-I-ovary intact control; gp-II ERα knock down; gp-III ER β knock down; gp-IV ERα and ER β knock down; gp-V ERα knock down + 17β-estradiol; gp-VII ERα and ER β knock down + 17β-estradiol. 17β-estradiol (E2) was administered daily by s.c. injection (0.1 mg/kg body wt. in 0.1 ml sesame oil) for 30 days. shRNA/siRNA Lentiviral particles was used for inhibition of expression of corresponding estrogen receptors.
Results: Depletion of the ovarian hormone (E2) resulted in upregulation of Bax, complement proteins (C3 and C1q), pro-inflammatory cytokine (TNF-α) and microglial activation in hippocampus. However, the anti-apoptotic protein (Bcl2) expression was down regulated. E2 therapy to ovx rats reversed the expression of all above mentioned immuno and apoptotic marker proteins to nearly the ovary-intact-like state. Concomitant changes in the ERα and β expression with hormone depletion/replacement therapy substantiate it to be a hormone-mediated process. In conclusion, the results indicate that the conservation of immune function in brain may be affiliated with the hormone interactions.

Title: Peripheral chronic Interleukin-1 exacerbates neuroinflammation via endothelial Interleukin-1 Receptor 1

Authors: *D. NEMETH, X. LIU, D. DISABATO, N. QUAN;
Inst. For Behavioral Med. Res., Columbus, OH

Abstract: Peripheral inflammation is known to induce neuroinflammation which can contribute to the neuropathologies present in neurodegenerative diseases, such as Alzheimer's disease and Multiple Sclerosis. In addition, these neurodegenerative diseases can also upregulate Interleukin-1β (IL-1β) expression in the central nervous system (CNS). Although central and peripheral IL-1β are known to contribute to the development of inflammation, peripheral IL-1β alone is insufficient to induce neuroinflammation. In the present study, we examine the effects of chronic central IL-1β expression and concurrent central and peripheral IL-1β induced inflammation. Human IL-1β expressing adenoviral vector (adIL-1) was injected into the CNS alone or simultaneously into both CNS and circulation. Central, but not peripheral, adIL-1 was able to induce dose dependent microglial activation, leukocyte infiltration, and increased blood brain barrier permeability at the injection site. We then utilized transgenic mouse lines, in which Interleukin-1 Receptor 1 (IL-1R1) is restrictively expressed on endothelial cells, peripheral myeloid cells, microglia, astrocytes or not expressed (Tie2Cre-IL-1R1$^{r/r}$; LysMCre-IL-1R1$^{r/r}$; CX3CR1Cre -IL-1R1$^{r/r}$; GFAPCre-IL-1R1$^{r/r}$; IL-1R1$^{r/r}$, respectively). Results show chronic IL-1β expression can induce localized neuroinflammation through the abovementioned cell types. Interestingly, extensive distribution and magnitude of microglia activation and leukocyte infiltration was observed in the Tie2Cre-IL-1R1$^{r/r}$ mice, indicating endothelial cells may be a crucial mediator of IL-1β induced neuroinflammation. The addition of peripheral adIL-1 simultaneously with central adIl-1 exacerbated aforementioned pathologies in WT and Tie2Cre-IL-1R1$^{r/r}$ but not IL-1R1$^{r/r}$ animals. This study suggests that peripheral inflammation can augment the magnitude of existing central neuroinflammation via endothelial IL-1R1.

Title: Elevated dopamine levels and reduced dopamine turnover in the striatum after Toxoplasma gondii infection

Authors: *J. B. EELLS[1], S. GUO-ROSS[1], D. BRAMLETT[1], D. S. LINDSAY[2], A. VARELA-STOKES[1];
[1]Mississippi State Univ., Mississippi State, MS; [2]Dept. of Biomed. Sci. & Pathobiology, Virginia-Maryland Regional Col. of Vet. Med., Blacksburg, VA

Abstract: Infection with the protozoan parasite *Toxoplasma gondii* has been linked with an increased risk of several neuropsychiatric disorders, including schizophrenia, obsessive compulsive disorder and attempted suicide. Additionally, *T. gondii* infection is associated with more severe symptoms and exacerbated pathological changes in the brains of schizophrenia patients. In rodents, *T. gondii* infection alters behaviors that include elevated activity, reduced levels of anxiety and loss of aversion to cat urine. One mechanisms proposed through which *T. gondii* alters behavior is via effects on dopamine neurotransmission. Previous studies have shown that *T. gondii* can increase whole brain dopamine levels and that two tyrosine hydroxylase enzymes, the rate limiting step in the synthesis of dopamine, are expressed by *T. gondii*. The current study was designed to investigate the relationship between striatal dopamine levels and localization of *T. gondii* cysts. Mice were infected with *T. gondii* and euthanized 8 weeks later. The striatum was isolated from one side of the brain for the measurement of dopamine and metabolites. Tissue sections through the striatum from the other side of the brain were stained with H&E and examined for *T. gondii* cysts. *Toxoplasma gondii* infected mice had significantly higher tissue dopamine levels but reduced dopamine turnover (DOPAC/Dopamine) as compared to uninfected controls. On tissue sections, *T. gondii* cysts were identified in the cortex, but no cysts were observed in the striatum of infected mice. These data demonstrate that *T. gondii* infection can alter dopamine neurotransmission in the striatum. Therefore, *T. gondii* cysts are unlikely to be the direct source of the elevated dopamine levels as a substantial number of cysts would be needed to significantly add to the high dopamine production in the striatum. Neuroinflammation or direct effects on dopamine neurons are other potential mechanisms through which *T. gondii* infection could alter dopamine neurotransmission.

Title: Lipopolysaccharide-induced changes in neurotransmitters in the striatum and prefrontal cortex of freely moving animals.

Authors: *N. MOORE, A. RASSOULPOUR, A. ARANOV, H. KOOIJKER, Y. CHANG, L. YU, H. JANSSENS, C. CIARDELLO, M. VAN DER HART;
Brains On-Line LLC, South San Francisco, CA

Abstract: Systemic administration of the endotoxin lipopolysaccharide elicits a rapid innate immune response. This systemic inflammatory response also impacts the central nervous system, including changes in cytokines and possibly neurotransmitters. The changes in specific neurotransmitters, however, remains unclear (Mohankumar etal, 1999, Van Heesch et al,2014). The current set of experiments was designed to further explore regional effects of systemic LPS treatment on changes in dopamine (DA), serotonin (5HT), norepinephrine (NE), gamma-aminobutyric acid (GABA), glutamate (Glu) and glycine (Gly) in the prefrontal cortex (PFC) and striatum of the same animals. Adult male mice were bi-laterally implanted with microdialysis probes in the PFC and striatum, and after the collection of a stable baseline were treated with 0.3 mg/kg of LPS. LPS treatment resulted in a differential response among neurotransmitters and brain regions. NE, DA, and 5HT were all elevated to varying degrees in the prefrontal cortex (97%, 117%, 36% respectively). However, striatal DA levels were not affected by LPS treatment while NE and 5HT increased similar to the PFC. The levels of Glu, GABA, and Gly were unchanged in the 4 hour period after treatment in both brain regions.. Future studies will extend out the current study design to 24 hour to determine if an increase in the amino acids may occur at a later time point. Together, the results demonstrate a clear regional control of monoamines in the CNS of mice following systemic LPS treatment.

Title: Microglial activation in the developing rodent brain following single-day moderate binge-alcohol exposure

Authors: *M. J. RUGGIERO, K. BOSCHEN, A. KLINTSOVA;
Univ. of Delaware, Newark, DE

Abstract: Developmental exposure to alcohol has been shown to activate microglia, which may contribute to deficits in cognitive functions in humans with Fetal Alcohol Spectrum Disorders (FASDs) and behavioral deficits in animal models of FASDs. This current study focuses on the brain's short-term immune response to neonatal alcohol exposure (AE), by expanding the timeline of microglial activation through measurement of microglia cell number and pro-inflammatory cytokine expression in the developing rat hippocampus. We hypothesized that neonatal AE would lead to an increase in microglial cell counts and inflammatory cytokine release, and that sex differences would be observed. Male and female rat pups were given alcohol (5.25 g/kg/day) through intragastric intubation on postnatal day (PD) 4 to model a single binge-like exposure during the third trimester in humans. Suckle control (SC) rats remained with the dam undisturbed, and sham-intubated (SI) animals were intubated without receiving alcohol to account for potential stress effects of the procedure. Rats were sacrificed on PD5 or PD8 and the hippocampus processed for the various assays. Cell number was estimated in three subregions of each of the three hippocampal subfields: DG, CA1, and CA3. The results support our hypothesis: on PD5, an increase in microglial number was seen in AE male rats in the hilus and molecular layer of the dentate gyrus compared to SC. Males generally had higher levels of microglia in all hippocampal subregions. Interestingly, female pups exhibited a decrease in microglia number following AE in the dentate gyrus granule cell layer and molecular layer when compared to SI controls. For gene expression assays, preliminary data shows that expression of the pro-inflammatory cytokines CCL4 and IL-1β in AE animals on PD5 were not statistically significant compared to controls when male and female pups were analyzed separately. When the data from both sexes were combined, significant increases in CCL4 expression were seen in AE and SI animals compared to SC. In summary, we are observing immediate, short-term effects of AE on microglial activation as seen by cell counts in males, and pro-inflammatory cytokine gene expression in both males and females. These findings are significant as they add to our knowledge of specific sex-dependent effects of alcohol on microglia in developing brain.

Title: Angiotensin II receptor blockers differentially regulate LPS-mediated microglial activation

Authors: *Z. C. JANATPOUR[1], K. AFFRAM[2], R. SHARMA[2], A. J. SYMES[2];
[2]Pharmacol., [1]Uniformed Services Univ., Bethesda, MD

Abstract: Traumatic brain injury (TBI) results in acute inflammation that impacts on the ability of the brain to recover from the initial insult. Thus, pharmacologic interventions that reduce neuroinflammation should be beneficial. Angiotensin II (Ang II), signaling through its AT1 receptors (AT1R), has pro-inflammatory effects in many different organ systems including the brain. AT1R antagonists, angiotensin receptor blockers (ARBs), have anti-inflammatory actions in addition to reducing other negative sequelae of Ang II signaling. Using LPS-stimulation of microglia as a model of microglial activation, we have shown that the ARB telmisartan reduced expression of the pro-inflammatory genes iNOS and IL-1β in primary microglial culture. However, direct Ang II treatment of microglia did not result in induction of pro-inflammatory mediators, and telmisartan maintained its anti-inflammatory activity in microglia cultured from AT1R knockout mice, suggesting that blockade of angiotensin was not the mechanism through which telmisartan reduced expression of pro-inflammatory genes.
Several ARBs are FDA approved to treat hypertension. They all block signaling through the AT1R. However, their effects on other pathways vary significantly. For example, telmisartan, candesartan, and losartan, but not eprosartan, have PPARγ agonist activity, which may reduce inflammation. However, we did not observe any reduction of telmisartan's anti-inflammatory effects in the presence of the PPARγ antagonist, T0070907. A recent publication showed that telmisartan's ability to inhibit microglial activation is dependent on AMPK activation. We show

that candesartan has anti-inflammatory activity in LPS-stimulated microglia. The mechanisms through which this and other ARBs reduce inflammation in microglia are not known. We therefore treated primary rat microglia or the murine microglial cell line, BV2, with LPS in the presence or absence of either telmisartan, candesartan, olmesartan, losartan, ibresartan, valsartan or eprosartan. All ARBs reduced the LPS-induced expression of iNOS and IL-1β mRNA, showing that they share anti-inflammatory activity, though telmisartan was the most potent anti-inflammatory agent. However, we found that only telmisartan stimulated AMPK activity, whereas valsartan, irbesartan and olmisartan decreased it. This dissociation between anti-inflammatory activity and AMPK activation suggests that there are AMPK independent mechanisms through which ARBs act to reduce microglial activation. Understanding the mechanisms through which different ARBs act will assist in determining which ARB is the best candidate for treating TBI.

Title: Microglial activation and associated pathways as therapeutic targets for Alzheimer's disease

Authors: *C. N. VILLEGAS LLERENA, M. MATARIN, J. HARDY, J. POCOCK;
Mol. Neurosci., UCL Inst. of Neurol., London, United Kingdom

Abstract: Neuroinflammation is one of the main pathological hallmarks of Alzheimer’s disease (AD) and it is well recognized that microglia are pivotal for the immune response observed in AD. In the brain, microglia act as sentinel cells attacking and removing pathogens and cell debris, but have been shown to become reactive in AD. A likely connection between microglia and AD neurodegeneration is Amyloid Beta (Aβ). This protein accumulates and forms the characteristic plaques that are present in the brains of AD patients and has been reported as a potent activator of microglia. Despite this, little is known about how Aβ alters microglial genetic expression and impacts their reactivity.
In recent times, Genome Wide Association Studies (GWAS) have allowed identification of more than 20 genetic risk associations for AD. Many of the associated genes highlight the importance

of immune pathways in AD pathology. Even more recently, the identification of mutations in TREM2 - a gene almost exclusively expressed by microglia in the brain - as AD risk factors has increased the efforts to understand neuroinflammation and microglia in the context of AD. Our study focuses on understanding how microglial activation status (M1, M2 or other) may influence the expression of genes that have been identified as AD risk factors. In particular we are interested in how different Aβ conformations can alter microglia whole-genome expression profile. To this end, we used different gene expression profiling approaches and the BV2 murine cell model to assess gene expression changes during activation using different stimuli, including Aβ and other classic M1/M2 activators. In this study, we found that different microglial activators can modify gene expression profiles of many AD associated genes in a manner that could potentially contribute to AD progression. This study revisits possible roles for microglial activation in AD pathogenesis and progression and focusses on candidate pathways as therapeutic targets for AD.

Title: Oxygen-glucose deprivation reduces cortical arteriole lumen diameter by generating 20-hydroxyeicosatetraenoic acid

Authors: *L. LU[1,2,3], P. LU[1,2,3], C. M. ANDERSON[1,2,3];
[1]Univ. of Manitoba, Winnipeg, MB, Canada; [2]Kleysen Inst. for Advanced Med., Winnipeg, MB, Canada; [3]Hlth. Sci. Ctr., Winnipeg, MB, Canada

Abstract: Brain ischemia and reperfusion is associated with secondary neuronal death resulting from prolonged regional hypoperfusion, in part mediated by constriction of arterioles and capillaries. The mechanisms behind ischemic constriction are not clear but it was recently shown that brain slice capillaries constrict in response to simulated ischemia without reperfusion, in a manner dependent on pericyte contraction and death. We hypothesized that brain ischemia also constricts pre-capillary arterioles in a manner dependent on shifted balances of arachidonic acid (AA) metabolites.
Acute cortical slices were exposed to oxygen-glucose deprivation (OGD) and analyzed by two-photon microscopy to monitor arteriolar diameter and corresponding dynamic changes in intracellular Ca^{2+} of adjacent astrocytes, which are known to influence lumen diameter. OGD caused significant arteriolar constriction, starting at 10 min and reaching -15.8 ± 2.8% of baseline lumen diameter after 20 min (9 vessels). The cumulative constriction response, assessed as area under the time course lumen diameter curve from 10-20 min, was 4.3-fold greater than control. 20-hydroxyeicosatetraenoic acid (20-HETE) is the ω-hydroxylation product of AA and is a potent physiological and pathophysiological inducer of smooth muscle contraction. OGD significantly increased cortical slice 20-HETE content from 18.93 ± 2.37 to 36.59 ± 4.67 ng/mg protein at the 20 min time point, suggesting it could be a mediator of constriction. Consistent with this, bath application of the ω-hydroxylase inhibitor, HET0016 (1 μM), reduced the 20 min OGD-induced reduction in lumen diameter from -15.8 ± 2.8% to -9.4 ± 2.5%. OGD increased perivascular astrocytic Ca^{2+} levels by 1.6-fold of baseline at 10 min, commensurate with reduced arteriolar lumen diameter and increased 20-HETE production. We can't yet directly link astrocytic function with OGD-induced arteriolar constriction and AA. This will be an important component of ongoing experiments.

Title: Protective effect of LBP on cortical neurons exposed to OGD by reducing glutamic excitotoxicity Protective effect of LBP on cortical neurons exposed to OGD by reducing glutamic excitotoxicity

Authors: *L. T. TING[1,2], Z. SHI[2], L. ZHU[2], L. XIA[2], X. HAN[2], K.-F. SO[3], Y. RUAN[2]; [1]Jinan Univ., Guangdong, China; [2]Jinan Univ., Guangzhou, China; [3]Hongkong Univ., Hongkong, China

Abstract: Lycium barbarum polysaccharides (LBP) is an extraction from Lycium barbarum fruit, which has been reported various biological activities such as anti-oxidation and anti-apoptosis. Glutamic excitotoxicity has been believed the major cause of ischemic neuronal death. Based on our recent results that 80-90% cortical neurons were protected by LBP when these neurons exposed to oxygen-glucose deprivation (OGD) in vitro, we hypothesized that LBP may play a protective effect against hypoxia/ischemia by reducing glutamic excitotoxicity. In the present study, we investigated changes in NMD receptor subunit NR2A and NR2B signaling pathways after OGD. The results showed that LBP could antagonize the increase in expression of NR2B, nNOS, Bad, CytC and cleaved caspase3, and inhibit the decrease in expression of NR2A, pAkt and p CREB. Also, LBP could block excessive calcium influx induced by administration of NMDA when neurons were exposed to OGD for 1 hour. Furthermore, NR2A inhibitor or NR2B co-agonist could attenuate the protective effects of LBP. Our results suggest that LBP can be as a candidate of Chinese medicine to be applied to treatment for the stroke patients in the future.

Title: 24S-hydroxycholesterol and 25-hydroxycholesterol differentially impact neuronal survival following oxygen-glucose deprivation in primary hippocampal neuronal culture

Authors: *M.-Y. SUN[1], A. TAYLOR[1], C. ZORUMSKI[1,2,3], S. MENNERICK[1,2,3];
[1]Psychiatry, [2]Neurosci., Washington Univ. in St. Louis, Saint Louis, MO; [3]Taylor Family Inst. for Innovative Psychiatric Res., Saint Louis, MO

Abstract: N-methyl-D-aspartate receptors (NMDARs), a major subtype of glutamate receptors mediating excitatory transmission throughout the CNS, participate in ischemia-induced neuronal death. Unfortunately, undesired side effects have limited the strategy of inhibiting/blocking NMDARs as therapy. Targeting endogenous positive allosteric modulators of NMDAR function may offer a strategy with fewer downsides. Here, we explored whether 24S-hydroxycholesterol (24S-HC), an endogenous positive NMDAR modulator characterized recently by our group, participates in NMDAR-mediated excitotoxicity following oxygen-glucose deprivation (OGD) in primary neuron cultures. 24S-HC is the major brain cholesterol metabolite produced exclusively in neurons near sites of glutamate transmission. By selectively potentiating NMDAR current, 24S-HC may participate in NMDAR-mediated excitotoxicity following energy failure, thus impacting recovery after stroke. In support of this hypothesis, our findings indicate that exogenous application of 24S-HC exacerbates NMDAR-dependent excitotoxicity in primary neuron culture following OGD, an ischemic-like challenge. Similarly, enhancement of endogenous 24S-HC synthesis reduced survival rate. On the other hand, reducing endogenous 24S-HC synthesis alleviated OGD-induced cell death. We found that 25-HC, another oxysterol that antagonizes 24S-HC potentiation, partially rescued OGD-mediated cell death in the presence or absence of exogenous 24S-HC application, and 25-HC exhibited NMDAR-dependent/24S-HC-dependent neuroprotection, as well as NMDAR-independent neuroprotection. Our findings suggest that both endogenous and exogenous 24S-HC exacerbate OGD-induced damage via NMDAR activation, while 25-HC is neuroprotective through both NMDAR-dependent and independent mechanisms.

Title: L-type voltage gated calcium channel blockers reduce the severity of spreading depolarizations in murine brain slices

Authors: *B. S. MEAD[1], B. E. LINDQUIST[1], K. M. REINHART[1], A. P. CARLSON[2], C. W. SHUTTLEWORTH[1];
[1]Neurosci., [2]Neurosurg., Univ. of New Mexico, Sch. of Med., Albuquerque, NM

Abstract: Spreading Depolarizations (SD) are coordinated waves of neuronal and glial depolarization that propagate slowly (2-5 mm/min) through brain tissue and are characterized by dramatic Ca^{2+} influx, increases in metabolic demand and changes in vascular supply. SDs have been implicated in the pathophysiological progression of ischemic injury following subarachnoid hemorrhage (SAH). L-type voltage gated calcium channel (L-VGCC) blockers have been shown to improve outcomes in SAH, but the cellular target(s) are poorly defined, and have commonly been assumed to be vascular. However, L-VGCCs are also expressed on neurons and glia, and thus may alter properties of SD. Therefore, we evaluated the effects of nicardipine, an L-VGCC antagonist, on properties of SD elicited by focal application of K^+ in normoxic conditions, or by global oxygen-glucose deprivation (OGD), simulating ischemia. Experiments were conducted in acute brain slices, a system which allows examination of parenchymal (neuronal and glial) responses independent of vascular perfusion. We evaluated SD incidence, latency, propagation rate, and direct current (DC) shift, together with intrinsic optical signals (IOS) in C57Bl/6 brain slices and fluorescent signals in slices from transgenic mice expressing a Ca^{2+} indicator (GCaMP). SD was readily initiated in the hippocampal CA1 region by KCl microinjection in the presence of nicardipine (10 μm), and the propagation rate was unchanged when compared to vehicle control (4.8 ± 0.5 vs 4.8 ± 0.4 mm/min, veh vs nicardipine, p=0.96, n=7,8). However, DC shift duration was shortened relative to within-slice controls (-17.0 ± 3.5 vs. -34.0 ± 6.4% change, veh vs nicardipine, p=0.02, n=8,9). Similarly, nicardipine decreased Ca^{2+} influx into neuronal cell bodies as measured by the duration of GCaMP fluorescence transients (45.0 ± 7.9 vs 21.0 ± 3.2 s, veh vs nicardipine, p=0.01, n= 7,6) and area under the curve (1337 ± 88 vs 2028 ± 256 AFU·s, veh vs nicardipine, p=0.02, n=7,6). In OGD, nicardipine did not affect SD

incidence or latency (11.5 ± 0.8 vs 10.9 ± 0.8 min, veh vs nicardipine, p=0.62, n=4,4) nor propagation rate (10.3 ± 2.8 vs. 15.0 ± 5.9 mm/min, veh vs nicardipine, p=0.50, n=4,4). Thus L-VGCCs can contribute to the duration of tissue depolarization and Ca^{2+} influx during SD in acute brain slices, in normoxic but not in ischemia-like conditions. These results support the possibility that clinical benefits of L-VGCC blockers may be in part due to direct effects on neuronal Ca^{2+} loading during SD, in addition to the more commonly assumed effects on vascular smooth muscle cells.

Title: Title: Increased intra-ischemic acidosis in recurrent hypoglycemia exposed rats may activate acid-sensing ion channels in vascular smooth muscle cells.

Authors: *V. SHUKLA, A. K. REHNI, K. R. DAVE;
NEUROLOGY, MILLER SCHOOL OF MEDICINE, UNIVERSITY OF MIAMI, Miami, FL

Abstract: More than 29 million Americans suffer from diabetes. Recurrent hypoglycemia (RH) is common in treated diabetics. Earlier we observed that prior exposure to RH increases cerebral ischemic damage in insulin treated diabetic (ITD) rats. We also observed pronounced intra-ischemic acidosis and post-ischemia hypoperfusion in RH-exposed ITD rats compared to the control group. The goal of the present study was to determine if increased intra-ischemic acidosis contributes to severe hypoperfusion in RH-exposed ITD rats. We hypothesized that increased intra-ischemic acidosis leads to activation of acid-sensing ion channels (ASICs) in vascular smooth muscle cells (VSMCs) contributing to pronounced hypoperfusion in RH-exposed ITD rats. This hypothesis was tested using VSMCs cell line A7r5. We determined contribution of ASICs in Store Operated Calcium Entry (SOCE) at different pH, and in presence and absence of inhibitors of ASIC-1 (PcTX-1) and ASIC-3 (APETx2). Freshly grown A7r5 cells were loaded with Ca^{2+} sensitive fluorescent indicator Fluo-4AM in presence of pluronic acid in calcium medium (135 mM NaCl, 5.9 mM KCl, 1.5 mM $CaCl_2$, 1.2 mM $MgCl_2$, 11.5 mM glucose and 11.6 mM Hepes, pH=7.3) and incubated for 40 minutes at 37^{o}C and then for an additional 20

minutes at room temperature. We measured SOCE at three different pH (7.4, 6.5 and 6.0). Fluo-4AM loaded cells were super fused with Ca^{2+} free medium with respective pH (135 mM NaCl, 5.9 mM KCl, 1.2 mM $MgCl_2$, 11.5 mM glucose and 11.6 mM Hepes, 50 μM diltiazem, and 10 μM cyclopiazonic acid). The changes in Fluo-4 AM florescence from the baseline, as an indicator of SOCE induced increase in [Ca2+]i, was determined upon repletion of extracellular Ca^{2+} (1.5 mM) in presence of diltiazem and cyclopiazonic acid for 30 min. The experiment was performed in presence of PcTX-1, APETx2, or respective vehicle controls. As expected, we observed pH dependent SOCE in A7r5 cells. We also observed that lower pH-induced increase in intracellular Ca^{2+}: an indicator of SOCE was inhibited by APETx2. The intracellular Ca^{2+} influx was reduced significantly ($p<0.05$) to 40 % at pH 6.0 in presence of APETx2 but no significant difference was observed at pH 7.0 and pH 6.5 compared to respective vehicle control. Also, no significant difference in intracellular Ca^{2+} influx was observed at any pH (7.4, 6.5 and 6.0) in presence of PcTX-1 when compared to respective vehicle control. We conclude that activation of ASIC-3 *via* increased intra-ischemic acidosis may contribute to increased cerebral ischemic damage in RH-exposed ITD rats.

Title: Influence of tissue metabolic status on Ca^{2+} and glutamate accumulation during spreading depolarization in brain slices

Authors: *K. M. REINHART, C. W. SHUTTLEWORTH, R. A. MORTON;
Dept. of Neurosciences, Univ. of New Mexico, Sch. of Med., Albuquerque, NM

Abstract: Spreading depolarization (SD) is a slowly propagating (~2-4 mm/min) wave of neuronal and glial depolarization, which occurs with high incidence in the stroke brain. SD is closely linked to secondary injury expansion that is likely mediated by substantial glutamate release and excitotoxic Ca^{2+} influx through N-methyl-D-aspartate receptors (NMDARs). We

utilized electrophysiological and fluorescence recordings in brain slices to test the hypothesis that progressive metabolic compromise enhances glutamate and Ca^{2+} accumulation during SD. Transients in healthy preparations were compared to responses in slices with intermediate or profound metabolic compromise. Extracellular glutamate levels were detected using a glutamate-sensing fluorescent reporter (iGluSnFR). Virus containing the iGluSnFR construct was delivered *in vivo* via stereotaxic injection into the hippocampus of C57Bl/6 mice, and brain slices were prepared ~2-4 weeks post injection. Neuronal Ca^{2+} transients were assessed in brain slices from mice expressing the intracellular Ca^{2+}-sensitive fluorescent protein (GCaMP5G). Under healthy conditions, SD initiated by KCl microinjection resulted in large glutamate transients that returned to baseline levels within ~20s (n=8). In these conditions, Ca^{2+} transients persisted longer, but still fully recovered within ~55s (n=10). Intermediate metabolic compromise was achieved by reducing O_2 and glucose availability. Under these conditions, the majority of slices did not recover from SD generated by KCl microinjection (~14% survival; n=7). Here, glutamate transients were prolonged, but returned to baseline levels after SD. In contrast, Ca^{2+} transients were markedly extended and remained ~35% above baseline levels 2 minutes post SD (n=5). Under conditions of complete metabolic depletion (oxygen and glucose deprivation; OGD) SDs were generated spontaneously, with glutamate and Ca^{2+} transients both sharply increasing at the onset of SD, and were irrecoverable throughout the duration of recordings (~10 min). We next evaluated the effect of the NMDAR antagonist ketamine (30μM) on intracellular Ca^{2+} loading. In healthy slices, this concentration of ketamine did not block SD, but reduced Ca^{2+} transient duration (P=0.01; n=4). In intermediately compromised conditions, ketamine prevented tissue death (6/6) and attenuated Ca^{2+} dysregulation after SD ($P<0.05$). These results provide evidence that slice metabolic status influences both glutamate and Ca^{2+} accumulation during SD. Furthermore, our findings with ketamine support the clinical utility of this drug as an intervention that can reduce deleterious consequences of SD.

Title: Function of perivascular stromal cells in stroke injury

Authors: K. K. KELLY[1], A. MACPHERSON[1], F. STRNAD[2], M. KANE[3], P. S. HERSON[2], *J. SIEGENTHALER[1];
[1]Pediatrics, Univ. of Colorado Denver, Aurora, CO; [2]Pharmacol., Univ. of Colorado, Denver, Aurora, CO; [3]Univ. of Maryland, Sch. of Pahrmacy, Baltimore, MD

Abstract: Stroke is a leading cause of death in the United States and costs $34 billion yearly. Current treatments for stroke are few and require application soon after the onset of symptoms. The development of novel therapies with broader application times that treat acute and chronic stages of stroke is an active area research. Recent work has shown that a little understood cell type termed perivascular stromal cells (PSC) is a major component of the cellular milieu of the stroke lesion, appearing within days of ischemia and persisting long after the initial injury. In the uninjured brain, PSCs are infrequent and occupy the perivascular niche around large diameter blood vessels. PSCs are delineated by Collagen 1a1 (Col1a1) expression and the *Col1a1-GFP* transgenic mouse line has been an instrumental tool to describe PSC post-injury fibrosis. Following injury, PSCs undergo significant cellular transformation, substantially expand their numbers and play a major part in post-injury fibrotic scar formation. The signal(s) that activate PSCs following injury has not been identified and potential functions for PSCs beyond fibrosis have not been explored. Our research characterizing perivascular cell development and vascular post-injury response has identified a separate, non-fibrotic function of PSCs following ischemic stroke. We have found that PSCs express Raldh1 and Raldh2, enzymes capable of synthesizing bioactive Retinoic Acid (RA), a neuro-protective hormone. Moreover, we have a developed a PSC cell culture platform to aid in our efforts to understand PSC activation and function following stroke injury. Our over-arching *hypothesis* is that PSCs are activated by signals in the stroke environment and, once activated, secrete protective signals like RA that are 'sensed' by neurons, glial, vascular and inflammatory cells in and around the stroke lesion. The goal of our ongoing experiments is to create a model of how PSCs fit into the milieu of cell-cell interactions within the stroke environment and knowledge of molecular pathways stimulated during PSC activation. This will provide a framework for future studies testing PSC activation and function in preclinical models of stroke.

Title: Systemic administration of adenosine A1 receptor agonist produces hippocampal-dependent spatial memory deficits: role of microglia activation

Authors: *F. S. CAYABYAB[1], J. STOCKWELL[1], X. QIN[1], O. FRIESEN[1], Z. MING[1], Z. CHEN[1], W. WALZ[2];
[1]Dept. of Surgery, [2]Dept. of Psychiatry, Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: Previously, we reported that hypoxia/reperfusion injury and in vivo focal cortical ischemia models both lead to adenosine A1 receptor (A1R)-dependent hippocampal neuronal damage, which was partially mediated by clathrin-induced internalization of GluA2-containing AMPA receptors (AMPARs). In the present study, we investigated whether microglia activation by A1R stimulation contributes to hippocampal neuronal damage and learning deficits in stroke-like conditions. Intraperitoneal injections of the A1R agonist CPA (5mg/kg) for 2-7 days produced hippocampal neurodegeneration, which was prevented by the GluA2 endocytosis inhibitor Tat-GluA2-3Y peptide, the A1R antagonist DPCPX (5mg/kg), or the general inhibitor of microglia activation minocycline (45mg/kg). Similarly this A1R-dependent neurodegeneration was also observed in pial vessel disruption (PVD) stroke model. Tat-GluA2-3Y peptide, DPCPX and minocycline all reduced the CPA-mediated GluA2- and GluA1-containing AMPAR internalization, implicating microglia activation in the hippocampal neurodegeneration. Chronic CPA injections or PVD also produced deficits in chemically induced long term potentiation (evoked by forskolin and rolipram), which was prevented by Tat-GluA2-3Y, DPCPX and minocycline. Increased microglia activation, as reflected by increased CD-11 and CD-68 staining in the hippocampus after CPA treatment, was prevented by DPCPX or minocycline. Rats treated with CPA alone or PVD alone showed significant hippocampal-dependent spatial memory deficits, as assessed by Y-maze assays, which was not observed by prior treatments of animals with Tat-GluA2-3Y peptide, DPCPX, or minocycline. These results indicate that A1R stimulation of microglia in stroke-like conditions contributes to hippocampal neurodegeneration

and hippocampal-dependent spatial memory deficits. Whether peripheral effects of A1R stimulation include activation and subsequent infiltration of peripheral immune cells to the brain is currently under investigation.

Title: Hypoxia-induced changes in neural stem cell and microglia characteristics

Authors: *M. K. TOBIN[1], A. M. BARTHOLOMEW[2], O. LAZAROV[1];
[1]Anat. and Cell Biol., [2]Surgery, Bioengineering, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Despite the proliferative burst of neural stem cells (NSC), neurogenic mechanisms fail to repair damaged brain tissue following ischemic stroke. The mechanisms leading to this failure are largely unknown but loss of trophic support as well as contribution of post-ischemia inflammation have been posited as important mediators of the failure of endogenous repair mechanisms. To address these issues, we examined the effect of hypoxia on NSC proliferation. We found that 24 hours after oxygen-glucose deprivation (OGD) there is a significant increase in NSC proliferation; however, this increase falls back to normal levels beyond 24 hours. Further, mRNA expression of GDNF, IGF-1, BDNF, NT-3, and NGF are all significantly increased after 24 hours of OGD with levels of GDNF, IGF-1, and BDNF declining to below basal levels at 48 hours. These data could account for the initial proliferative burst followed by the decline after 48 hours. Next, because of their ability to interconvert microglia from an inflammatory to a regenerative phenotype, we utilized mesenchymal stem cells (MSC) to investigate whether the pro-inflammatory phenotype of microglia following hypoxia can be changed. For this purpose, microglia were grown in conditioned media from both naïve MSCs (nMSC) as well as interferon-γ (IFN-γ)-activated MSCs (aMSCγ). Interestingly, microglia treated by aMSCγ conditioned media exhibited a reduction in expression of the pro-inflammatory cytokines IL-1β,

IL-6, and TNF-α up to 48 hours in culture and had increased expression of the pro-regenerative cytokines IL-10 and IL-4 up to 7 days in culture. Additionally, MSCs secrete numerous neurotrophic factors suggesting that they could be directly beneficial to the NSCs as well. Interestingly, when co-cultured with aMSCγ for 24 hours, there is a significant increase in NSC mRNA expression of GDNF with trending increases in BDNF, NT-3, and NGF, demonstrating that MSCs could help sustain the neurotrophic loss experienced by NSCs following hypoxia. Taken together, these results suggest that neural progenitor cells may be beneficial for neuronal survival and repair following an ischemic event, and that MSCs may have the capacity to modulate both neurogenesis and post-ischemia inflammation to enhance brain repair.

Title: Changes in excitation-inhibition balance after focal cortical ischemia

Authors: *N. V. POVYSHEVA[1], M. E. ROSE[2], F. ZHANG[2], S. H. GRAHAM[2], G. BARRIONUEVO[1];
[1]Neurosci., Univ. of Pittsburgh Dept. of Neurosci., Pittsburgh, PA; [2]Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Cerebral ischemia produces devastating changes in neurons that include persistent depolarization of neurons, spreading waves of neuronal depression, and eventually leads to neuronal death in the ischemic core. Neurons in the penumbra, while being able to survive the initial insult, sustain chronic pathological changes that are still not quite understood. In particular, it is not clear how the balance between excitation and inhibition (E/I) is affected (Clarkson et al., 2010; Wang, 2003). Here we address pathophysiological changes of the E/I balance in neocortical neurons produced by the middle cerebral artery occlusion (MCAO) in mice. MCAO and sham surgeries were performed as previously described (Poloyac et al., 2006), and physiological properties of penumbral neurons were assessed 7 days later. Whole-cell recordings were made from pyramidal neurons in layer 2-3 of the mouse neocortex located in the close proximity to the ischemic core in the MCAO and in the similar location in the sham mice. During recordings neurons were filled with fluorescent dye for morphological analysis.

Comparative analysis of intrinsic membrane properties revealed lower excitability of the MCAO (n=8) as compared to the sham neurons (n=14). The former demonstrated more negative resting membrane potential (-72±1 mV vs. -67±2 mV, $p<0.01$), less negative spike threshold (-35±1 mV vs. -39±1 mV, $p<0.05$), lower firing frequency (19±1 Hz vs. 25±2 Hz, $p<0.01$) and lower input resistance (87±7 MΩ vs. 130±14 MΩ , $p<0.01$). Spontaneous excitatory postsynaptic currents (sEPSCs) recorded at the holding potential -70 mV in the presence of gabazine (10 μM) had lower frequency in the MCAO (n=8) as compared to the sham neurons (n=14) (2.3±0.8 Hz vs. 5.8±2.5 Hz, $p<0.05$), as well as the mean current estimated as average charge transfer*frequency of events (257±80 pA vs. 642±243 pA, $p<0.05$). To directly estimate the E/I ratio, neurons were held at -55 mV, a membrane potential that allowed detection of both excitatory and inhibitory events. E/I ratio, estimated as mean excitatory current/mean inhibitory current, was lower in MCAO (n=4) than in control mice (n=8) (1.9±0.4 vs. 10.6±4.0, $p<0.05$). Morphological analysis did not reveal any differences between the MCAO and sham neurons. Thus, our data indicate that the E/I balance in penumbra is shifted away from excitation.

Title: Intracellular zinc increase is required for initial increase of mitochondrial ROS during hypoxia

Authors: K. SLEPCHENKO[1], Q. LU[2], H. HARAGOPAL[3], *Y. V. LI[1];
[1]Biomed. Sci., [2]Mecular & Cell. Biol., [3]Biol., Ohio Univ., Athens, OH

Abstract: Reactive oxygen species (ROS) have been linked to pathology of ischemia, of special interest are ROS produced by mitochondria. Zinc accumulates during ischemia in neurons and also have been implied in recent years as major players of hypoxic damage. To determine the temporal relationship between these two important events, we have employed fluorescent imaging of live cells during chemical hypoxia with oxygen scavenger sodium dithionite. The zinc increase (detected by FluoZin-3, AM) was observed within 60 seconds of induction of hypoxia and lasted about 2 minutes, then the zinc transient sharply decreased, resembling a

calcium wave, This transient wave of intracellular zinc surge resemble to the well documented calcium wave. Accumulation of mitochondrial ROS (detected by MitoSOX Red) was observed within 4.5 minutes of hypoxia and continued to increase for the duration of observation (10 minutes). When zinc was chelated with TPEN during the hypoxia, the increase in mitochondrial ROS was not significant, we suggest that zinc wave is required for the initial mitochondrial ROS increase. In addition, the exogenous application of zinc induced mitochondrial ROS in normoxic conditions. Inhibition of NADPH oxidase with apocynin, during application of exogenous zinc, showed significant reduction in zinc induced mitochondrial ROS. We showed that initial zinc increase during hypoxia (zinc wave) precedes increase in mitochondrial ROS and zinc wave is required for initial increase in ROS. We proposed that NADPH oxidase may be a major contributor to zinc induced mitochondrial ROS accumulation.

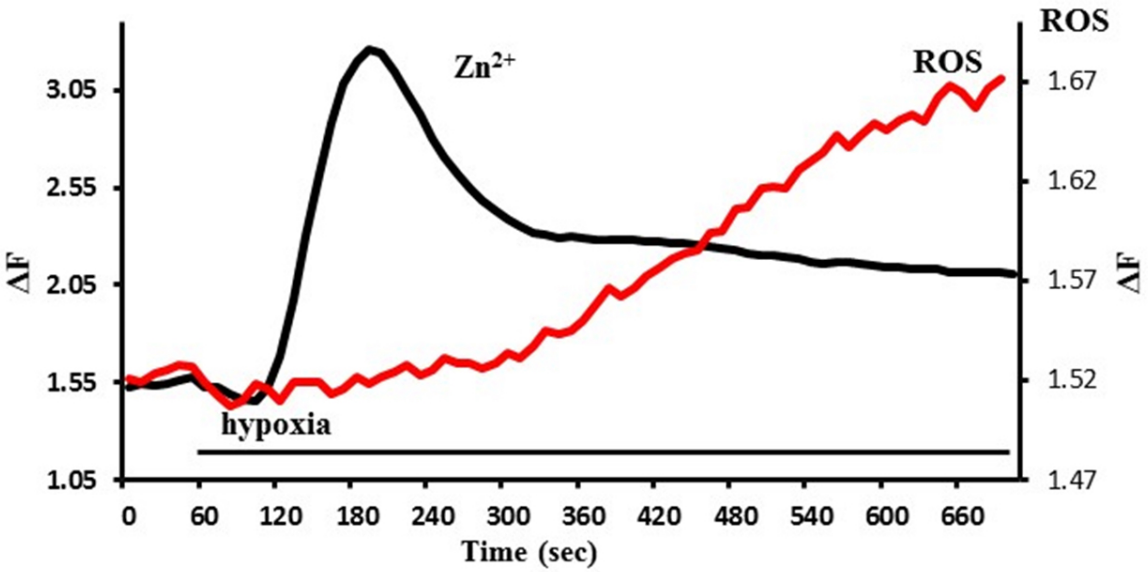

Figure legend: Two representative traces of zinc and ROS accumulation showing the relationship between zinc and the ROS transients during hypoxia. Zinc concentration is on the left y-axis, and ROS concentration is on the right y-axis.

Title: Proliferation and differentiation of NG2-glia following different types of brain disorders

Authors: *D. KIRDAJOVA[1,2], P. HONSA[1,3], M. ANDEROVA[1,3];
[1]Dept. of Cell. Neurophysiol., Inst. of Exptl. Med. AS CR, Prague 4, Czech Republic; [2]Fac. of Science, Charles University,, Prague, Czech Republic; [3]2nd Fac. of Medicine, Charles Univ., Prague, Czech Republic

Abstract: NG2-glia, a fourth major glial cell population, are present in the adult central nervous system and display distinct morphology, antigens and functions from other mature glial cell types. Recently, many studies have shown that these cells are multipotent in vitro and they also display wide differentiation potential under pathological conditions in vivo, where they give rise predominantly to reactive astrocytes.
The aim of this study was to identify the rate of proliferation and differentiation after different types of brain disorders, such as global and focal cerebral ischemia (GCI, FCI), stab wound (SW) and demyelination (DEMY). We used transgenic Cspg4-cre/CAG-tdTomato mice, which after administration of tamoxifen express red fluorescent protein (tdTomato) in NG2-glia and cells derived therefrom. Proliferation and differentiation potential of tdTomato positive ($tdTomato^+$) cells in sham-operated mice (controls) and those after injury were determined by immunohistochemistry - e.g. proliferating cell nuclear antigen (PCNA), glial fibrillary acidic protein (GFAP). FCI was induced by middle cerebral artery occlusion, GCI by carotid occlusion with hypotension, SW by sagittal cortical cut and DEMY by feeding mice with copper chelator cuprizone. To determine the phenotype of $tdTomato^+$ cells, the coronal brain slices were used from controls and mice 3 and 7 days after FCI, GCI, SW or DEMY. The percentage of cells that were double positive for tdTomato and PCNA or GFAP was estimated in the cortex (FCI, SW), in the hippocampus (GCI) or in the corpus callosum (DEMY).
We have shown that NG2-glia increase their proliferation rate after all four types of brain disorders as after ischemia, cortical injury as well as after demyelination. In case of acute injuries (FCI, GCI, SW) the highest proliferation rate was observed three days after the insults and even seven days after injury the proliferation rate was increased compared to controls. In case of

DEMY the proliferation increases seven days after withdrawal of cuprizone diet. In accordance with previous studies, differentiation of NG2-glia into astrocytes was almost absent in uninjured nervous tissue, however, the type of injury significantly influenced NG2-glia differentiation towards astrocytes. After FCI, 32.7±2.6% of tdTomato^{+} cells expressed markers of reactive astrocytes, while after SW or GCI this number was only 2.8±1.2% and 3.3±0.5%, respectively. Taken together, increased proliferation of NG2-glia is the typical feature after all types of pathological conditions, while differentiation into astrocytes depends on the type of injury.

Title: Knocking down SIRT3 preserved mitochondrial function and prevented brain injury after stroke

Authors: *T. I. GUDZ[1], S. A. NOVGORODOV[1], C. L. RILEY[1], J. A. KEFFLER[1], J. YU[1,2], W. B. MACKLIN[2];
[1]Dept Neurosci., Med. Univ. South Carolina, Charleston, SC; [2]Univ. of Colorado, Aurora, CO

Abstract: Experimental evidence supports the role of mitochondrial ceramide accumulation as a cause of mitochondrial dysfunction and brain injury after stroke. We report that SIRT3 regulates mitochondrial ceramide biosynthesis via deacetylation of ceramide synthase (CerS) 1, 2 and 6. Reciprocal immunoprecipitation experiments revealed that CerS1, CerS2 and CerS6, but not CerS4, are associated with SIRT3 in cerebral mitochondria. Furthermore, CerS1, 2 and 6 are hyper-acetylated in the mitochondria of SIRT3-null mice and SIRT3 directly deacetylates the ceramide synthases in a NAD^{+}-dependent manner that increases enzyme activity. Investigation of SIRT3 role in mitochondrial response to brain ischemia/reperfusion (IR) showed that SIRT3-mediated deacetylation of ceramide synthases increased enzyme activity and ceramide accumulation after IR. Functional studies demonstrated that absence of SIRT3 rescued the IR-induced blockade of the electron-transport chain at the level of Complex III, decreased ROS generation and protein carbonyls in mitochondria. Importantly, Sirt3 gene ablation protected the brain from IR injury. These data support the hypothesis that IR activates SIRT3, resulting in the deacetylation of ceramide synthases and the elevation of ceramide which could inhibit Complex

III, leading to increased ROS generation and brain injury. The results of these studies highlight a novel mechanism of SIRT3 involvement in modulating mitochondrial ceramide biosynthesis and suggest a critical role of SIRT3 in promoting mitochondrial dysfunction and brain injury after stroke.

Title: Differential vulnerability of CA1 vs CA3 pyramidal neurons after ischemia: possible relationship to sources of Zn^{2+} accumulation and its entry into and prolonged effects on mitochondria

Authors: Y. MEDVEDEVA, *J. H. WEISS;
Dept. of Neurol., Univ. of California Irvine, Irvine, CA

Abstract: Excitotoxic mechanisms contribute to the degeneration of hippocampal pyramidal neurons (HPNs) after recurrent seizures and brain ischemia. However, susceptibility differs, with CA1 neurons preferentially degenerating after global ischemia, and CA3 neurons after limbic seizures. Whereas most studies address contributions of excitotoxic Ca^{2+} entry, it is apparent that Zn^{2+} also contributes, reflecting accumulation in neurons either after pre-synaptic release and entry through post-synaptic channels or upon mobilization from intracellular Zn^{2+} binding proteins like metallothionein-III (MT-III). Using hippocampal slices to study acute oxygen glucose deprivation (OGD) triggered neurodegeneration, we find evidence for early contributions of both excitotoxic Ca^{2+} entry and Zn^{2+} accumulation in both CA1 and CA3, as supported by the ability of Zn^{2+} chelators or Ca^{2+} entry blockers to delay pyramidal neuronal death in both regions. However, use of knockout animals lacking vesicular Zn^{2+} transporter, ZnT-3 or MT-III revealed substantial differences between these neurons. The Zn^{2+} contribution to acute OGD induced death of CA3 neurons appeared to depend substantially upon pre-synaptic Zn^{2+} release and its permeation through Ca^{2+} permeable AMPA channels, which are also highly Zn^{2+} permeable. In contrast, mobilization of Zn^{2+} from MT-III appeared to contribute importantly to the death of CA1 neurons. To assess consequences of the cytosolic Zn^{2+}

accumulation, we employed OGD exposures slightly shorter than those causing acute neuronal death; under these conditions, cytosolic Zn^{2+} rises persisted for ~10-30 min after OGD, followed by recovery over ~40-60 min. Furthermore, the recovery appeared to be accompanied by mitochondrial Zn^{2+} accumulation, largely via the mitochondrial Ca^{2+} uniporter, in CA1 but not in CA3 neurons. This late Zn^{2+} accumulation was substantially diminished in MT-III knockout mice, suggesting that it depended upon Zn^{2+} mobilization from intracellular stores bound to this protein. These data are consistent with observations of prominent mitochondrial dysfunction as a critical early event in the delayed degeneration of CA1 neurons after ischemia, and with the idea that mitochondrial Zn^{2+} accumulation in the early reperfusion period, resulting largely from mobilization of MT-III bound pools, may be a key and potentially targetable trigger of the events leading to the delayed injury.

Title: Systemic administration of adenosine A1 receptor agonist increases leukocyte specific protein-1 (LSP-1) expression in hippocampus: role in hippocampal neurodegeneration

Authors: *J. STOCKWELL[1], L. HAO[2], R. TENEYCKE[1], S. NOSIB[1], O. FRIESEN[1], L. LIU[2], F. S. CAYABYAB, S7N 5E5[3];
[2]Pharmacol., [3]Surgery, [1]Univ. of Saskatchewan, Saskatoon, SK, Canada

Abstract: The leukocyte specific protein-1 (LSP-1) is a critical Ca^{2+}- and F-actin-binding protein that was first identified in hematopoietic immune cells, including B and T lymphocytes, monocytes, macrophages, and neutrophils. LSP-1 is also a substrate of p38 MAPK and PKC, and contributes to tissue inflammation and vascular permeability. Recently, we reported that LSP-1 was expressed not only in neutrophils but also in endothelial cells that line the cremasteric

vasculature, and contributes to neutrophil transmigration and tissue inflammation. However, the distribution and role of LSP-1 in the brain have not yet been investigated. Since we previously showed that adenosine A1 receptor (A1R) leads to p38 MAPK activation and neurodegeneration of rat hippocampus, we sought to characterize the cellular distribution of LSP-1 before and after A1R stimulation with the A1R agonist CPA. Systemic administration of CPA (5mg/kg) in rats increased LSP-1 expression in NeuN-positive CA1 pyramidal neurons and also in NeuN-negative cells in the stratum radiatum and stratum oriens. CPA also increased colocalization of LSP-1 with CD-11 and CD-68-positive cells (macrophage/microglia markers) and with GFAP-positive cells (astrocyte marker). Together, these imaging results indicate that LSP-1 is also expressed in hippocampal neurons, astrocytes and the monocyte-derived resident immune cells, the microglia. We also recently showed that CPA intraperitoneal injections increased microglia activation, which contributed to hippocampal neurodegeneration. We therefore hypothesized that expression of LSP-1 in the brain could regulate hippocampal-dependent learning behavior. Compared to wild type mice, LSP-1 knockout mice with or without systemically administered CPA produced similar levels of hippocampal-dependent memory deficits in the Y-maze test. Together, these results show for the first time that LSP-1 is normally expressed in CNS neurons, astrocytes and microglia, to regulate inflammatory response, hippocampal neurodegeneration, and learning and memory.

Title: Cell division of hypoxic-ischemic cortical neurons by overriding mitotic safeguards

Authors: *I. AJIOKA[1,2], M. OSHIKAWA[1];
[1]Ctr. for Brain Integration Res. (CBIR), Tokyo Med. and Dent. Univ. (TMDU), Tokyo, Japan;
[2]Presto, JST, Saitama, Japan

Abstract: Neuronal differentiation and cell cycle exit are tightly coordinated, even in pathological situations. When pathological neurons re-enter the cell cycle and progress through the S phase, they undergo cell death instead of division. However, the mechanisms of mitotic safeguard are mostly unknown. The Retinoblastoma protein family (Rb, p107, p130) plays a central role in preventing cells from entering the S phase. When Rb family expression is lost in neuronal progenitor cells, the subsequent coordination of cell-cycle exit and neuronal differentiation is lost, and neurons can divide in some cases such as retinoblastoma (Ajioka et al., *Cell* 2007). We recently developed a technique for conditionally inactivating all of the Rb family members in mouse cortical progenitors, either before or immediately after cell-cycle exit, by electroporation with Cre-expressing plasmids containing a ubiquitous pCAG promoter or a neuron-specific pMAP2 promoter (Oshikawa et al., *Development* 2013). When the Rb family is inactivated using pCAG-Cre, immature neurons generated from the pCAG-induced Rb-TKO (*Rb−/−; p107−/−; p130−/−*) progenitors divide. In contrast, the pMAP2-induced Rb-TKO immature neurons enter the S phase, but undergo cell death. Thus, once progenitor daughter cells exit the cell-cycle and initiate neuronal differentiation, they are prevented from undergoing cell division, and maintain mitotic resistance even after acute Rb family inactivation. These findings led us to hypothesize that hypoxic-ischemic neurons in the S phase undergo cell death by activating mitotic safeguards. In this presentation, we will show and discuss such mitotic safeguards. We will also demonstrate the cell division of dying hypoxic cortical neurons in the S phase by overriding mitotic safeguards. Our results may represent a novel strategy for treating neurological disorders.

Title: Upstream modulation of Insulin/IGF signaling-mediated neuroprotection in a nematode model of excitotoxicity

Authors: *A. CHOWDHURY[1,2,4], S. PRASHAD[3], I. MANO[2];
[1]City Col. CUNY, New York, NY; [2]Physiol Pharm & Neurosci, The CUNY Sch. of Med., [3]Biochem., City College, The City Univ. of New York, New York, NY; [4]Psychology, The Grad. Ctr. of The City Univ. of New York, New York, NY

Abstract: Glutamate (Glu) excitotoxicity is the leading cause of neurodegeneration following ischemic stroke and an important contributing factor in neurodegenerative diseases such as Parkinson's, Alzheimer's and Huntington's. Diminished function or reduced expression of Glu transporters in these conditions causes dysregulation and accumulation of Glu in the synaptic region, leading to excitotoxic Glu signaling; activating neurodegenerative pathways. Recent studies suggest that the GluR-triggered neurodegenerative processes is partially counterbalanced by pro-survival cascades. Investigation into neuroprotective pathways, partially active under excitotoxicity, will allow us to target pathways and proteins to counterbalance the neurodegenerative pathways overly active under these circumstances. The Insulin/IGF Signaling (IIS) cascade, which regulates FoxO/DAF-16 (a transcription factor known to regulate animal longevity and cell stress resistance), may play a role in maintaining neuroprotective balance. We study excitotoxicity in *C. elegans*, allowing us to follow GluR-triggered neuronal necrosis in a more simplified and less redundant system where core mechanisms are conserved, allowing to decipher important signaling pathways homologous to those found in mammals. The IIS cascade is one such pathway highly conserved in *C. elegans* and mammals, making nematodes an ideal organism for our research. Our lab created a nematode excitotoxicity model where a deletion of a Glu transporter gene (*glt-3*) in a sensitized background results in high levels of GluR-dependent necrotic cell death that can be visualized in live worms as vacuole-like structures. Using our excitotoxic strain, we have recently shown that inhibition of the IIS pathway (i.e., increased FoxO/DAF-16 nuclear activity) *reduces* necrotic neurodegeneration under excitotoxicity. Furthermore, we found that the Cytohesin/GRP-1 complex is an important upstream regulator of IIS signaling in excitotoxicity. We now investigate the possibility of further upstream regulation of IIS/FoxO-mediated neuroprotection. We also investigate how IIS pathway and the upstream regulator affect localization of FoxO/DAF-16 to further solidify the neuroprotective pathway regulated under excitotoxicity. We expect that if these experiments are successful, we will be able to point at a new mechanism regulating IIS signaling and susceptibility to excitotoxicity. The results from our studies might further be carried over to mammalian research and suggest novel directions in therapeutic drug targets to promote neuroprotection under excitotoxicity.

Title: The mitochondrial calcium uniporter is essential for hypoxic preconditioning but not ischemic brain injury

Authors: *M. J. NICHOLS[1], P. A. ELUSTONDO[2], A. THIRUMARAN[3], E. V. PAVLOV[4], G. S. ROBERTSON[5];
[1]Pharmacol., [2]Physiol. and Biophysics, Dalhousie Univ., Halifax, NS, Canada; [3]Pharmacol., Dalhousie university, Halifax, NS, Canada; [4]Basic Sci., NYU, New York, NY; [5]Pyschiatry and Pharmacol., Dalhousie, Halifax, NS, Canada

Abstract: Hypoxic preconditioning (HPC) activates calcium (Ca^{2+}) signaling pathways that confer profound resistance to ischemic brain damage. Mitochondria are strategically positioned to sense and respond rapidly to elevations in cytosolic Ca^{2+} concentrations that regulate neuronal cell death and survival. Mitochondrial Ca^{2+} uptake into cardiac myocytes by the mitochondrial Ca^{2+} uniporter (MCU) has recently been shown to play a pivotal role in regulating susceptibility to ischemic heart injury. In view of the considerable implications of these findings for ischemic brain damage, we have examined the effects of global MCU (G-MCU) deficiency on HPC in a model of hypoxic-ischemic (HI) brain injury. Both Ca^{2+} uptake and Ca^{2+}-induced permeability transition pore activity were inhibited in forebrain mitochondria isolated from G-MCU nulls. Despite evidence that these effects should be protective, G-MCU null mice were not resistant to HI-induced brain damage and sensorimotor deficits. Cortical neurons derived from G-MCU nulls were also not protected from *in vitro* ischemic cell death produced by oxygen glucose deprivation (OGD). Oxygen consumption rates were comparable for cortical neuron cultures derived from G-MCU null and wild-type (WT) mice but spare respiratory capacity was reduced in G-MCU deficient neurons. This was accompanied by increased glycolysis that may compensate for impaired ATP production by oxidative phosphorylation in G-MCU neurons. Although G-MCU deficiency did not alter HI brain injury, the protective effects of HPC against HI-induced brain injury and sensorimotor impairments were completed blocked by G-MCU ablation. G-MCU deficiency produced exactly the same induction patterns for genes encoding MT apoptosis-regulators (BCL-XL, BAX), sodium (Na^{+})/Ca^{2+} exchangers-1, -2, and -3 and the plasma membrane Ca^{2+} ATPase-2 (PMCA2) in the hippocampus as did HPC in WT mice. Apart from a modest increase in hippocampal expression of PMCA-2 (50%), HPC failed to further elevate mRNA levels for these genes. G-MCU deficiency therefore engaged the same protective mechanisms as HPC that oppose impairments in MT function and cytosolic Ca^{2+} handling implicated in ischemic brain damage. Such adaptations likely compensate for impaired Ca^{2+} handling in G-MCU nulls. This conclusion is consistent with evidence that activity-induced preconditioning protects cultured neurons from excitotoxicity by transcriptional repression of the

MCU. However, saturation of these protective mechanisms may also have impaired HPC in G-MCU nulls.

Title: Examination of conditioned suppression in rodents after frontal tbi with an intervention of magnesium

Authors: *J. YOUNG[1], M. PRICE[2], E. JACOBS[2], M. HOANE[1];
[1]Restorative Neurosci. Lab., [2]Operant Learning Lab., Southern Illinois Univ. Carbondale, Carbondale, IL

Abstract: Conditioned suppression is a respondent conditioning procedure that leads to a conditioned emotional response. Abnormal emotional responses, such as heightened or reduced fear, are symptoms after traumatic brain injury (TBI) that can affect the daily activities of a person. This procedure in conjunction with a magnesium treatment after TBI has yet to have been examined. Magnesium is a multimodal treatment that can decrease apoptosis, decrease breakdown of the blood brain barrier, and lessen brain edema after a TBI, which can affect the recovery of a patient. This study will explore, magnesium's outcome on fear expression after frontal TBI. Conditioned suppression will take place in a standard two-lever operant chamber, which has been adapted to emanate sound as well as to generate an electric shock. A single subject design will be utilized in order to focus on the evaluation of conditioned suppression fear in rodents after TBI rather than on a comparison of group differences. 10 Sprague-Dawley rats about 3 months of age will be divided into groups; MAG/TBI, VEH/TBI, and Sham. Rats will first be trained to lever press on a variable interval (VI) schedule of 30 seconds for multiple 30 minute sessions. The injury induction will be a severe bilateral frontal injury, after which they will receive 2 mmol/kg injections of magnesium chloride (MAG) or a saline solution (VEH). Injections will be given i.p. and start four hours after injury, then at 24 hours, and again at 72 hours. After a week recovery, rats will be reintroduced to lever pressing on a VI of 30 seconds. Fear conditioning training will take place over two 30 minute sessions, during which rats will be given four 30 second tones that will co-terminate with an electric shock. Electric shock duration will be 0.5 seconds at 0.5 mA. Conditioned inhibition of lever

pressing for food will be the measure of fear for this study. To examine conditioned suppression, a tone will be presented at 4 different time points during 30 minutes. Presentation of the tone will last for 30 seconds. This phase will occur for ten days with one session occurring each day. It is hypothesized that rats who receive the magnesium treatment after TBI will exhibit less conditioned inhibition compared to injured rats who will receive the vehicle treatment. Sham animals will not show conditioned inhibition and will quickly extinguish the behavior. It is expected that injured rats will take longer to extinguish or to not extinguish the behavior.

Title: Exogenous addition of sphingomyelin restores impairments in hippocampal synaptic transmission and plasticity in a mouse model of traumatic brain injury

Authors: *K. WHITNEY[1], L. BUITRAGO-SOTO[1], J. IQBAL[2], M. HUSSAIN[2], H. MORENO[1], P. J. BERGOLD[1];

Abstract: The closed head injury (CHI) mouse model of traumatic brain injury (TBI) produces a heterogeneous gray and white matter injury. Experimental TBI produces a persistent increase in hippocampal sphingomyelin (SM) levels (Abdullah, et al). We therefore measured SM in multiple brain regions to ask whether SM levels change soon after injury. Two days after injury, multiple sphingolipid species increased in cortex and hippocampus proximal to the injury site, but decreased at cerebellum which is distal to the injury. Hippocampal SM had the greatest increase which may reflect either disrupted sphingolipid transport (efflux) or metabolism. CHI also impairs long term potentiation (LTP) at the CA3-CA1 synapse. We examined whether altered SM levels in hippocampus are, in part, responsible for impaired LTP. Unexpectedly, impaired LTP was partially restored by exogenous addition of SM, but not by an abundant phospholipid, phosphatidylcholine. Spontaneous excitatory activity induced by the GABA-A antagonist picrotoxin was further increased by exogenous SM in the subiculum, dentate gyrus and medial entorhinal cortex in slices from injured animals. These effects of SM were not seen in hippocampal slices isolated from uninjured animals. Our data suggests that CHI induces alterations in SM metabolism or transport that likely impair excitatory synaptic transmission and

plasticity. The deficits in SM metabolism or transport contribute to electrophysiological and, perhaps, behavioral deficits seen after CHI.

Title: Choice impulsivity is increased following mild, closed head injury in rats

Authors: *K. M. MARTENS, C. WINSTANLEY, C. WELLINGTON, C. VONDER HAAR; Univ. of British Columbia, Vancouver, BC, Canada

Abstract: *Background:* Traumatic brain injury (TBI) is associated with numerous deleterious consequences, including chronic changes in cognitive function. Persons with brain injury frequently show sub-optimal or even deleterious choice behavior, resulting in considerable financial, social, and work-related strain. Despite the obvious problems for human patients, many animal studies have neglected the study of decision making following TBI. *Methods:* The current study followed up previous work exploring shifts in impulsive choice behavior using the delay discounting paradigm following open-skull TBI. In the current study, rats were trained on the delay discounting task for 35 sessions. Once choice behavior had stabilized, they were given a closed head injury or sham procedure using the CHIMERA system, a non-surgical closed head impact acceleration model that produces primarily diffuse axonal injury as a result of unconstrained head movement after impact. Rats were then re-tested for a period of two weeks followed by a second CHIMERA injury. This pattern continued for a total of four injuries in eight weeks, with behavioral testing between each. *Results:* CHIMERA injury increased impulsive choice in injured rats. The effect was initially small and affected very few rats. However, after subsequent injuries, there were larger increases in impulsivity and more rats showed changes in choice. *Discussion:* In the current study, we show that choice impulsivity is increased in rats following closed head injury. This resembles reports in the clinical literature regarding impulse control problems in human patients. By examining decision making in

animals following a TBI, we are able to more closely mimic the human condition, which could lead to novel and/or improved treatments for brain injury.

Title: Effects of repeated mild traumatic brain injury on hippocampal synaptic plasticity

Authors: *C. PINAR-CABEZA[1], C. J. FONTAINE[1], B. R. CHRISTIE[1,2];
[1]Div. of Med. Sci., Univ. of Victoria, Victoria, BC, Canada; [2]Dept. of Cell. and Physiological Sci., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Traumatic brain injury (TBI) is the leading cause of disability in individuals under 45 years of age, with concussion, or mild TBI (mTBI), accounting for up to 75% of all brain injuries occurring annually in the US. Growing evidence indicates that repeated concussions may result in cumulative and long-term behavioural symptoms, neuropathological changes and neurodegeneration. The juvenile brain may be particularly vulnerable to mTBI as it is in a period of robust synaptic reorganization and myelination. In these studies we have focused on the hippocampus, a brain structure that can be affected by mTBI, producing some of the cognitive and affective deficits that are characteristic of mTBI clinical presentation.
Several models have been developed to mimic the clinical consequences of repeated mild TBI, however, most of these models use anesthesia or surgical procedures to induce the injury, which might confound the interpretation of these studies. To examine this issue in the juvenile brain, we assessed changes in hippocampal synaptic plasticity using an awake closed-head mTBI model. Following 4 closed-head mTBI in Long-Evans rats (25-28 days of age) synaptic plasticity of field excitatory post-synaptic potentials (fEPSPs) was assessed using in vitro electrophysiology at either one day, three days, five days or seven days post-injury in the dentate gyrus (DG) region of the hippocampus. Our results indicate that repeated mTBI can impact bidirectional synaptic plasticity in the hippocampus of juvenile animals.

Title: Functional deficits are attenuated in human alpha synuclein BAC-transgenic rats after traumatic brain injury

Authors: *C. DIXON[1], Z. M. TAPP[2], S. W. CARLSON[2];
[1]Neurosurg., [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Traumatic brain injury (TBI) can produce synaptic protein loss that may contribute to functional deficits. We previously reported that a scaffold protein necessary for the assembly of synaptic SNARE proteins, cysteine string protein alpha (CSPα), is reduced after experimental TBI (Carlson, et al., J. Neurotrauma, 2016). Ruiz, et al., (Neuropharmacology, 2014) has shown that a genetic knock-down of CSPa produces impaired synaptic SNARE protein assembly that can be reversed by upregulation of alpha synuclein (αSyn). While αSyn has been speculated to have some linkage between TBI and chronic TBI-associated Parkinsonism, we posit an acute role in preserving the machinery of SNARE-mediated vesicle trafficking after TBI. This functional outcome experiment determined the effects of TBI in transgenic rats that carry the wild type (WT) human αSyn and have elevated αSyn levels in young adults (Nuber, et al., Brain, 2013). Twenty three adult (3-4 mo) male Sprague Dawley rats were prepared for controlled cortical impact (CCI) (4 m/sec, 2.8 mm deformation) or sham. Rats were divided into three groups: CCI in BAC human αSyn transgenic rats (Taconic) (n=7), CCI in WT rats (n=8), or Sham WT rats (n=8). Functional outcomes were tested via Beam Balance Task and Beam Walking Test (days 1-5), Morris water maze (MWM) acquisition (days 10-14) followed by a probe test. In the Beam balance task the transgenic rats have significantly longer latencies that the WT rats after CCI ($p=0.001$). For the Beam walking test the transgenic rats have significantly shorter latencies that the WT rats after CCI ($p>0.0001$). For the MWM test the transgenic rats

have significantly shorter swim latencies than the WT rats after CCI ($p>0.01$). There were differences in the probe test. Transgenic rats with human αSyn are less sensitive to CCI vs. WT rats on tests of motor and cognitive performance. αSyn may be a novel target for acute post-traumatic dysfunction.

Title: Unique neurocognitive and affective impairments in mouse models f TBI, PTSD and co-morbid TBI-PTSD

Authors: *A. FESHARAKI[1], J. MIYAUCHI[2], S.-A. E. TSIRKA[3], P. BERGOLD[4];
[1]SUNY Downstate Med. Ctr. Col. of Med., Brooklyn, NY; [2]Stony Brook Univ., Stony Brook, NY; [3]Stony Book Univ., Stony Brook, NY; [4]SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Traumatic brain injury (TBI) is frequently co-morbid with post-traumatic disorder (PTSD). Both TBI and PTSD produce a long-lasting inflammation in the brain. Key questions are whether neuroinflammation differs between TBI, PTSD and co-morbid TBI and PTSD and does this neuroinflammation contribute to cognitive and affective impairment. C57Bl/6mice (28g) received either closed head injury (CHI), a model of TBI; chronic variable stress (CVS), a model of PTSD; or CHI followed by CVS, a model of co-morbid TBI/PTSD. CHI consisted of a single strike to the skull over the parietal lobe. CVS consisted of four days of variable chronic stress consisting of cold-water swim, transient restraint, cage tilt, wet cage, intermittent white noise, and food deprivation. Seven days after sham-CHI or CHI, the mildly aversive Barnes Maze (BM) and more aversive Active Place Avoidance (APA) assayed cognition and memory. Elevate Plus Maze (EPM) assayed basal anxiety and Acoustic Startle Response (ASR) assayed fear potentiated anxiety. CORT levels were assessed after injury and at the end of behavioral testing. Assay of additional parameters of neuroinflammation in plasma and brain tissue are in progress. Mice in the CHI, CVS, and CHI/CVS groups had similarly acquisition of BM and APA as sham-CHI, sham-CVS mice, suggesting no differences in cognition. Mice in the CHI group had a significantly shorter time to 1st entrance than the other 3 groups. These data suggest a memory deficit in the CHI group that was not when mice received both CHI and CVS. This

suggested that CHI/CVS mice had a heightened ability to recall aversive stimuli as compared to CHI mice. The CVS and CHI/CVS group showed SIGNIFICANTLY higher basal anxiety as assessed by less time and fewer entrances into the open arm of the EPM. On ASR, CHI mice had significantly more freezing while CVS and CHI/CVS mice trended toward exaggerated startle amplitude. CORT levels in the CHI and CVS groups trended to be lower than sham-CHI, sham-CVS but not in the CHI/CVS groups. These data suggest that CHI, CVS and CHI/CVS are present a unique spectra of behavioral and endocrine outcomes. Studies in progress will determine if this is accompanied by unique patterns of neuroinflammation.

Abstract: Mild traumatic brain injury (mTBI) and posttraumatic stress disorder (PTSD) were modeled in male C57Bl/6 mice in order to determine the co-morbid effects of mTBI and PTSD on learning and other behaviors and neuroinflammation and neurodegeneration. Mice with mTBI induced by fluid percussion injury (FPI) at one of three intensity levels (1.0, 1.5 or 2.0 atmospheres) were subsequently fear conditioned and assessed for spatial learning performance over two post-operative recovery weeks. Following completion of behavioral testing, brains were harvested to quantify inflammation and neuropathology in naive control mice as well as craniotomy sham surgery and FPI exposed groups. Neurological severity scoring revealed no

deficits in balance, movement, or physical vigor in the immediately after surgery or FPI exposure. Similarly, acquisition/expression of fear conditioning and general exploratory/locomotor behavior did not vary as a function of treatment group over the two week testing period. In contrast, spatial learning acquisition in the Morris Water Maze task was significantly slowed and attenuated in FPI mice relative to controls during 4 daily trials and the degree of impairment was enhanced by increasing injury severity. Immunocytochemical staining of pan-T cell marker CD3, activated macrophage/microglia marker CD68, and pro-inflammatory marker TNF-alpha or IL-1beta showed that there were infiltrating T cells and activated macrophage/microglia present in parietal and subcortical brain regions as a consequence of mTBI. Evidence from this mouse model of FPI with co-occurring fear conditioning reveals a short-term cognitive impairment accompanied by neuroinflammatory and degenerative neural changes in cortical and hippocampal regions. Future studies will examine these behavioral and neural changes at later term time points post-injury. Title: Effect of mild TBI on specific cognitive dysfunction with *In vivo* hippocampal activity

Authors: *R. PATERNO[1], H. METHENY[2], G. XIONG[2], A. S. COHEN[2];
[1]Children Hosp. of Philadelphia, Philadelphia, PA; [2]Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Cognitive impairment caused by traumatic brain injury (TBI) can lead to devastating consequences for both patients and their families. The underlying neurological mechanism(s) for TBI-induced cognitive dysfunction remain unclear. However, many lines of research have implicated the hippocampal dysfunction in the pathophysiology of traumatic brain injury. In

order to investigate the effects of traumatic brain injury on specific cognitive dysfunction involving the hippocampus, we used a lateral fluid percussion injury animal model and recorded *in vivo* electrophysiological activity in the hippocampi of mice. Specifically, we simultaneously measured local field potentials in areas CA1 and CA3 of the hippocampus during a spatial recognition task in TBI and Sham animals. In vivo electrophysiological recordings showed increased theta activity in both CA1 and CA3 during exploration versus resting states in both TBI and in Sham animals. Furthermore, we found that the overall broadband power in area CA1 and CA3 was decreased in TBI animals compared to Sham control group during exploration of a new object compared to resting activity. Also, we found differential activity in CA1 versus CA3 in a complex relationship depending on behavior performance between TBI animal group compared to the Sham control group. These findings indicated for the first time that both area CA1 and CA3 of the hippocampus are impaired after TBI and further explores the neural basis underlying cognitive dysfunction.

Title: Disrupted entrainment of CA1 hippocampal neurons to hippocampal theta after traumatic brain injury

Authors: *P. KOCH[1], R. RUSSO[1], M. WEBER[1], D. H. SMITH[1], V. E. JOHNSON[1], J. A. WOLF[1,2];
[1]Dept. of Neurosurgery, Ctr. for Brain Injury and Repair, Univ. of Pennsylvania, Philadelphia, PA; [2]Corporal Michael J. Crescenz VA Med. Ctr., Philadelphia, PA

Abstract: Network level mechanisms of persistent memory impairment after TBI are poorly understood. Studies using the lateral fluid percussion injury (FPI) model of TBI in rodents have reported reduced theta power in the hippocampus (HC) coupled with memory impairment after

injury, although power reductions may recover. Reciprocal connections between HC and medial septum (MS) are important contributors to HC theta. Presumed disruption of this network is implicated in spatial memory deficits after FPI. Limited recovery of such deficits has been reported with fornix and MS stimulation at theta frequencies. However, precisely how MS-HC interactions are disrupted after TBI, and how this may influence memory-relevant HC processing is unknown. Male Sprague-Dawley rats (n=21, 350-425g) were trained on the Morris Water Maze (MWM, test of spatial memory) and then underwent FPI (n=11, 2.01-2.38 atm), or sham injury (n=10). MWM testing on post-injury day (PID) 2 revealed a significant reduction in memory performance (p=0.005). Rats (n=5 per group) underwent simultaneous MS and HC recordings under isoflurane anesthesia on PID 7. HC recordings were performed with a laminar 32 channel probe (NeuroNexus) spanning HC CA1 from str. oriens to str. radiatum, while MS recordings were performed with high impedence tetrodes (Thomas Rec). There was no difference in theta power (4-10 Hz) between sham and injured rats, nor in recording time dominated by theta. Overall firing rates of CA1 neurons were not significantly different between sham (n=117) and injured (n=86). The majority of CA1 neurons were significantly entrained to HC theta in both sham (71.8%) and injured (83.7%) groups. Further, approximately one third of recorded MS neurons were synchronized to HC theta in both groups. However, while the distribution of preferred phases of the theta cycle among entrained sham CA1 neurons showed a wide distribution with a peak at ~0.7 rad, the distribution of preferred phases among injured CA1 neurons revealed 2 sharp peaks at ~0 rad and 2.45 rad. Persistence of abnormal and possibly exaggerated CA1 theta entrainment, but normal CA1 firing rates, normal theta power, and persistent MS-HC synchronization at PID 7 could be due in part to a corrective increase in the "gain" of CA1 neurons in response to a loss of afferent input due to axonal injury. This could result in a stereotyped, hyperexcitable HC response and failure to appropriately coordinate inputs under conditions of high demand such as memory performance. Aberrant entrainment of CA1 neurons may underlie aspects of memory disruption following TBI as encoding of memory is presumed to require appropriate entrainment to the theta oscillation.

Title: Pre-enriched housing impacts progesterone's effect on functional recovery in male rats after traumatic brain injury.

Authors: *Z. BOWERS, N. SANISLO, N. ALAM, M. SEARLES, J. SMITH;
Saginaw Valley State Univ., University Center, MI

Abstract: In the United States 1.7 million people receive a TBI annually and it is estimated there are 5.3 million people in the U.S. living with long term disabilities. Currently, there are no clinical treatments that are effective in alleviating the functional deficits of TBI. Progesterone (PROG), a neurosteroid with pleiotropic effects has been shown to be beneficial in multiple brain injury models. The purpose of this study was to investigate the neurologically protective effect of progesterone following traumatic brain injury in animals reared in Enriched Environments (EE). The current study used 27 male Long-Evans rats purchased at post-natal day 25 and reared to maturity in EE. After 91 days, 18 subjects received a bilateral controlled cortical impact (CCI) placed over the medial frontal cortex to produce a moderately severe injury. Rats were administered intraperitoneal injection of either 10mg/kg PROG or vehicle injections (peanut oil) 4h post-injury and every 12h for 72h following the initial injection. Seven days post-injury the rats were tested on several behavioral tasks including the open field test, Barnes maze, Morris water maze, rotor-rod task, elevated plus maze, and forced swim task. Results from behavioral testing suggest that overall the intact animals performed significantly better than injured animals. Contrary to the established literature we found an intermediate effect of PROG when animals were tested on the MWM and rotor rod tasks, where intact animals performed significantly better than untreated group. An interesting additional finding using Elevated plus maze (EPM) to assess anxiety-like behaviors, overall intact animals spent significantly greater time in the closed arms than the injured groups. Analysis of the behavioral data from this study has shown that enriched housing before injury can impact behavior tasks in intact animals as well as functional recovery in injured animals when in combination with PROG. Future research should explore potential mechanisms related to pre-enriched housing that may influence recovery from TBI.

Title: A la-icpms time course analysis of changes in cerebral metals following a controlled cortical impact in young and aged mice.

Authors: *S. D. PORTBURY[1], D. HARE[1], C. SGAMBELLONI[1], D. P. BISHOP[2], P. A. DOBLE[2], D. FINKELSTEIN[1], P. A. ADLARD[1];
[1]Neurodegeneration, Florey Inst. of Neurosci. and Mental Hlth., Parkville, Australia; [2]Elemental Bio-imaging, Univ. of Technol. Sydney, Sydney, Australia

Abstract: Traumatic brain injury (TBI) is complicated by the prominent involvement of the biological transition metals iron (Fe), copper (Cu) and zinc (Zn). Non-heme bound Fe has been demonstrated to be abnormally elevated immediately after TBI, and the toxic liberation of Zn after brain injury has also been confirmed in many studies. Similarly, Cu has been shown to be deficient following brain trauma. Taken together, these alterations in brain metal levels are likely to contribute to the hallmark pathologies that occur within the brain post-injury (such as cell death and diffuse axonal injury) and also to both the acute and chronic neuropsychological sequelae (such as depression, anxiety and cognitive loss) that are prominent in brain-injured patients. In order to determine whether the reported increased susceptibility to adverse TBI-related outcomes in the elderly population may involve a differential modulation of metals across age (metals are known to be critical in the pathogenesis of a number of neurodegenerative disorders and other brain dysfunction), we have surveyed Fe, Zn and Cu levels using laser ablation-inductively coupled plasma-mass spectrometry (LA-ICPMS). The ipsilateral hemisphere in 3 and 24 month old mice subject to a controlled cortical impact was compared to contralateral hemisphere and regional metal analyses performed. Significant spatial elevations of Fe, Zn and Cu were detected immediately and up to 28 days after TBI in both age groups. Significantly, the elderly group exhibited an appreciably enhanced and persistent elevation of all metals in every region surveyed, potentially contributing to the accelerated onset of neurodegeneration observed in the aged population subsequent to brain injury. These data point to the potential importance of maintaining metal ion homeostasis across the time course of injury in both young, and particularly older, TBI casualties in order to ameliorate the associated behavioural deficits that are potentially mediated by these alterations in metal levels.

Title: Manipulating cognitive reserve: pre-injury environmental conditions influence the severity of concussion symptomology and pathophysiology.

Authors: *R. M. MYCHASIUK[1], H. HEHAR[2], I. MA[2], K. YU[2], K. YEATES[2];
[1]Neurosci., [2]Psychology, Univ. of Calgary, Calgary, AB, Canada

Abstract: Neuroplasticity, the brain's propensity to change in response to experience, is the key process involved in maintaining cognitive reserve. An individual's cognitive reserve is believed to be a 'summation' of all positive and negative changes in neuroplasticity, whereby positive experiences increase reserve and negative experiences reduce the plastic abilities of the brain. As post-concussion symptomologies develop when the brain is not able to adequately repair and compensate for injury-induced dysfunction, premorbid differences in cognitive reserve likely contribute to individual heterogeneity in concussion susceptibility. To examine this, rats received a single concussion while maturing in one of 3 different environmental conditions that manipulated cognitive reserve; a high stress, high fat diet condition (NEG); an enriching, socially and physically stimulating condition (POS), and a standard condition (STD). Rats underwent a behavioural test battery shown to assess post-concussion syndrome (PCS), and brain tissue was harvested at sacrifice to investigate epigenetic and genetic markers of plasticity, injury, and repair. The study found that manipulating pre-injury conditions increased heterogeneity in PCS whereby POS and NEG experiences differentially influenced outcomes. For example, POS environmental conditions eliminated cognitive impairments in the novel context mismatch task that were identified in control males following a concussion. Conversely, the NEG environmental condition exacerbated the anxiolytic effect identified in control rats with a TBI, significantly reducing anxiety in the elevated plus maze, while the POS environmental condition increased anxiety in the same task post-injury. In addition, examination of *BDNF, FGF-2, GFAP* and *Tau,* from the prefrontal cortex, hippocampus, and nucleus accumbens, demonstrate similar changes whereby manipulation of premorbid cognitive reserve influenced the brain's pathological response to the injury. This study indicates that POS environmental conditions do not always improve PCS outcomes just as NEG conditions do not always exacerbate deficits; rather manipulation of pre-injury reserve appears to increase variability in symptomology, contributing to the heterogeneity in individual susceptibility to PCS.

Title: Affective outcomes following traumatic brain injury in mice

Authors: *J. POPOVITZ, H. ADWANIKAR;
Johns Hopkins Univ., Baltimore, MD

Abstract: The molecular and signaling mechanisms that mediate affective disorders following traumatic brain injury (TBI) are poorly understood. Here, we investigate the behavioral, neuroanatomical and molecular changes after a controlled cortical impact injury in mice. Specifically, we track anxiety-like behaviors, as well as spontaneous behavior exhibited in a familiar context, for a period of eight weeks following injury. Assessments include metrics from the open field test, elevated zero maze test (EZM), elevated plus maze test (EPM) and home-cage behaviors. We observe changes in measures of anxiety with no deficits in general motor behavior. Following this, we perform immunostaining and volumetric measurements in the amygdala, an area that is considered to be important in the control of affective behaviors. Results will begin to address the mechanisms linking TBI and affective outcomes. *Key-words*: traumatic brain injury, anxiety behaviors, amygdala, controlled cortical impact

Title: Frontal traumatic brain injury alters risky choice on a rodent analog of the Iowa gambling task

Authors: *C. VONDER HAAR, C. A. WINSTANLEY;
Psychology, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Traumatic brain injury is associated with numerous long-term deficits and increased risk for psychiatric comorbidities. Some of the most difficult and chronic problems are those associated with cognitive functioning. Despite this, animal models of TBI have historically not addressed cognitive functions such as decision-making. In the current study, rats were trained on a rodent version of the Iowa Gambling Task, a method for assessing decision-making in humans. Rats make choices across four options, each associated with a specific risk/reward profile which provides either sugar pellets, or a time-out from responding. After stable baseline behavior was obtained, rats received either a moderate controlled cortical impact bilaterally over the frontal cortex (depth: 1.7 mm @ 2 m/s) or sham procedures. After one week of recovery, rats were re-assessed on the rodent gambling task for six weeks. Brain injury chronically affected choice behavior. Initially, brain-injured rats avoided the high-risk, high-reward options in favor of the option with the lowest probability of punishment. Over the course of several weeks, choice behavior largely normalized with the exception of a reduction of choice for the option with the largest punishment. This study is one of the first to examine a choice behavior with more than two choices in brain-injured animals. Surprisingly, the injured animals did not replicate the typical shift towards increased risky choice that is seen in human TBI populations. This may be due to procedural differences - specifically the fact that humans are almost exclusively tested in acquisition, while the current study examined animals already at steady-state performance. Additionally, this data suggests that injured rats are more averse to punishment, which has rarely been examined in TBI studies. Further studies will be required to determine whether acquisition testing replicates what is observed in human patients and to what degree the aversion to punishment observed in the current study generalizes.

Title: Plasticity of retinal ganglion cell axon terminals in dorsal lateral geniculate nucleus following traumatic brain injury

Authors: *V. C. PATEL, C. W. D. JURGENS, T. E. KRAHE, J. T. POVLISHOCK;
Neuroanatomy and Neurosci., Virginia Commonwealth Univ., Richmond, VA

Abstract: Diffuse axonal injury (DAI) is a consistent feature of traumatic brain injury (TBI) and is strongly associated with morbidity. Little is known however, regarding the downstream consequences of DAI. Previous publications by our lab demonstrated that even mild TBI can induce DAI within the optic nerve, resulting in diffuse and scattered axonal disconnection, with the caveat that a large fraction of axons within the optic nerve remained intact despite this diffuse injury. In the current study, we sought to evaluate if the axon terminals of these intact retinal projections redistribute or undergo adaptive reorganization in their downstream target, the dorsal lateral geniculate nucleus (dLGN), following injury. We utilized anterograde tracing, fluorescent immunohistochemistry (FIHC), and epifluorescent, confocal, and electron microscopy to study retinogeniculate axon terminals in dLGN over a 20 day post-injury period. Using 9-12 week old C57BL/6J mice, we performed mild central fluid percussion injury (cFPI) with the use of sham controls. On post-injury days 1, 7, and 17, a subset of mice underwent anterograde axon terminal labeling through the use of recombinant cholera toxin subunit B (CTB) conjugated to different Alexa dyes for each eye followed by perfusion with fixative 72 hrs later. All other mice underwent perfusion at 4, 10, and 20 days following sham surgery or injury with coronal sections processed for VGLUT2, a selective marker for retinogeniculate axon terminals within dLGN. Through this approach, we found within dLGN scattered loss of both CTB and VGLUT2 positive axon terminals at 4 day post-injury, with significant increases in both VGLUT2 and CTB positive axon terminals compared to sham, 10 days, and 20 days post-injury ($p < 0.05$). These quantitative evaluations were supported by parallel EM studies which confirmed extensive axon terminal loss and Wallerian debris followed by axon terminal recovery. Through the CTB studies, we observed that the axon terminal sprouting retained the organization of ipsilateral and contralateral eye distributions within dLGN. We also observed within the contralateral eye zone of dLGN that the core vs shell appeared particularly vulnerable to axon terminal loss following cFPI. In addition, the core underwent axon terminal repopulation over the period of 20 days post-injury, although this recovery did not reach sham levels. In conclusion, axon terminals of intact retinogeniculate projections are capable of adaptive reorganization in dLGN of adult mice following TBI-induced DAI. Future efforts will include electrophysiologic studies of functional relevance of our observed structural plasticity.

Title: Changes in rodent emotionality following repeated subconcussive head rotational accelerations

Authors: *B. D. STEMPER[1], N. LETKO[2], A. SHAH[2], R. CHIARIELLO[2], A. GLAVASKI[2], M. MCCREA[2], F. PINTAR[2];
[1]Med. Col. of Wisconsin Dept. of Neurosurg., Milwaukee, WI; [2]Med. Col. of Wisconsin, Milwaukee, WI

Abstract: Understanding the effect of subconcussive head impact exposure on concussive injury tolerance and cognitive/emotional changes in humans is complicated by a number of factors, including concussion history and variation in head impact characteristics (number/severity). In general, significant subconcussive head impact exposure is thought to decrease biomechanical tolerance for concussion and was associated with changes in cognitive performance, even in the absence of concussion, although the strength of those conclusions is tempered by individual variability. A biomechanically accurate preclinical model of subconcussive exposure can delineate mechanisms of cumulative damage and decreased concussive tolerance without the confounding variables present in humans. Accordingly, this study developed a rat model of subconcussive head impact exposure using the MCW Rotational Injury model. Anesthetized rats received 25 (n=40) or 50 (n=30) exposures to subconcussive head rotational acceleration (SCHRA) (167+/-12 krad/s^2). Acceleration magnitude was defined in our prior studies as head rotational acceleration that did not produce remarkable differences from shams following single exposure. A separate cohort of sham rats (n=48) were exposed to the entire experimental protocol, including anesthesia, without exposure to head rotational acceleration. SCHRA and sham procedures were performed over a 5-day period (5 or 10 per day). Rats were then exposed to behavioral testing during days 3-7 (acute) or days 24-28 (chronic) following the final SCHRA, consisting of the elevated plus and Morris water maze assessments. Separate cohorts were used for each assessment period. Exposure to 25 or 50 SCHRA resulted in no significant cognitive deficits at acute or chronic time points. However, significant changes in emotionality were evident. Rats receiving 25 and 50 SCHRA demonstrated significantly increased ($p<0.005$) activity during the acute phase measured as total arm changes and distance traveled, and a trend of increased activity ($p<0.1$) during the chronic phase. In terms of emotionality, rats receiving SCHRA demonstrated significantly increased ($p<0.01$) open arm time per entry (OATPE) acutely and decreased open arm time per entry during the chronic phase. Changes in emotionality were dose dependent, with acutely increasing and chronically decreasing OATPE

from controls to the 25-exposure group to the 50-exposure group. This study has produced a preclinical model of subconcussive head impact exposure in the rat using realistic and scalable biomechanics that has produced significant and dose-dependent behavioral changes following 25 and 50 exposures.

Title: Learning and memory deficits in a *Drosophila* model of traumatic brain injury

Authors: H. ZUCKER[1], J. ROBBINS[1], S. WU[2], *H. K. LEHMAN[3];
[1]Neurosci. Program, [2]Biochem. Program, [3]Biol. Dept., Hamilton Col., Clinton, NY

Abstract: Traumatic brain injury (TBI) is characterized by the loss of normal brain function following an external, injurious force that may lead to a host of adverse long-term behavioral effects, including impaired cognition and memory, sensorimotor deficits, mood disorders, and in extreme cases, neurodegenerative diseases like chronic traumatic encephalopathy. The mechanisms that underlie the myriad of pathologies, however, remain illusive. The fruit fly, *Drosophila melanogaster*, has proved to be a useful model system to study various human neurodegenerative disorders, and indeed, fly models of TBI have been recently developed (Katzenberger et al., 2013; Barekat et al., 2016). Our present study investigated learning and memory deficits in this TBI model. Specifically, wild-type flies were subjected to mechanical TBI, trained under a classical conditioning paradigm with an olfactory conditioned stimulus

(CS), and tested for motor skills, learning and memory behavior, and anatomical changes. Brain-injured flies performed normally on motor skill tasks, but significantly worse than control flies on the olfactory learning task, suggesting they had an impairment in learning and memory attributable to TBI. Furthermore, we observed morphological correlates to TBI and learning impairments. These behavioral and physical attributes of brain-injured Drosophila align with observations of human TBI and thus further validate the efficacy of this TBI model. Therefore, the present work may enable future studies focused on TBI pathophysiology, symptomatology, and treatment.

Title: Parvalbumin interneuron axonal damage after mild traumatic brain injury (mTBI): structural evidence implicating GABAergic input loss in neocortical circuit disruption

Authors: *M. VASCAK, J. POVLISHOCK;
Dept. of Anat. and Neurobio., Virginia Commonwealth University, MCV Campus, Richmond, VA

Abstract: A major feature of human mTBI is the presence of diffuse axonal injury (DAI) in the absence of any gross focal pathology. Historically, DAI has been studied in white matter, where long-distance projections are susceptible to the forces of injury. Recent clinical and experimental evidence however, suggest the involvement of inhibitory neurons within neocortical gray matter. The current investigation sought to determine if mTBI alters locally projecting axons from neocortical GABAergic interneurons. We evaluated parvalbumin (PV)-expressing interneurons, which control pyramidal neuron output and regulate neocortical excitatory-inhibitory balance. PV-cre mice were crossed with the Ai9 cre-dependent reporter line (PV-cre;Ai9) to genetically label PV interneurons with tdTomato. PV-cre;Ai9 mice subjected to either sham or mild central fluid percussion injury were sacrificed after 3 or 24 h and then prepared for confocal and ultrastructural analyses. Importantly, this model of mTBI induces DAI without any overt gross pathology. By 3 h post-mTBI, evidence of DAI was found in tdTomato+ perisomatic axonal swellings observed throughout the somatosensory cortex. Continuous with their soma of origin,

the proximal swellings were associated with their distal detached segments revealing pathology consistent with axonal degeneration. Ultrastructural analysis corroborated these findings. PV interneuron DAI was further confirmed via the colocalization of tdTomato+ axonal swellings with APP, an established marker of DAI. These tdTomato+/APP+ axonal swellings also colocalized with the GABA-synthesizing enzyme GAD67, which undergoes fast axonal transport. Quantitative analysis of GAD67/APP colocalization indicated that GAD67 is a sensitive and specific marker of DAI. Lastly, the majority of these GAD67+/APP+ swellings colocalized with tdTomato. This same tdTomato+ perisomatic axotomized population showed activation of c-Jun, a known regulator of axon regeneration. By 24 h post-mTBI, a 5-fold increase in phospho-c-Jun+/tdTomato+ cells occurred, corresponding to an overall injury burden of approximately 10% of total tdTomato+ cells. These observations reveal for the first time that locally projecting GABAergic interneurons are susceptible to DAI, with the majority of the injured population represented by PV interneurons. We further have characterized a novel marker of DAI specific to neocortical GABAergic interneurons. Together, our study has major implications for circuit disruption and unbalanced excitation-inhibition after mTBI, providing investigators with a new tool to explore a previously unrecognized gray matter neuropathology.

Title: Effects of TBI on the limbic system in a differential fear conditioning model of PTSD

Authors: C. D. ADAM[1,2], R. J. RUSSO[1], M. T. WEBER[1], V. E. JOHNSON[1], *J. A. WOLF[1,2]; [1]Neurosurg., Univ. of Pennsylvania, Philadelphia, PA; [2]Corporal Michael J. Crescenz VA Med. Ctr., Philadelphia, PA

Abstract: Traumatic Brain Injury (TBI) is considered the signature injury of recent US military conflicts, with approximately 15% of deployed service members experiencing single or multiple TBIs. Post-Traumatic Stress Disorder (PTSD) is a frequent comorbidity with TBI, with almost 35% of TBI-exposed Veterans reporting qualifying symptoms associated with their service in

theater. Previous animal studies have shown increased acquisition and decreased extinction of conditioned fear following TBI. Studies have also shown differential roles of the hippocampus (HC), basolateral amygdala (BLA), basomedial amygdala (BMA), and medial prefrontal cortex (mPFC) in the acquisition and extinction of conditioned fear; however, the effects of TBI on these regions leading to the observed behavioral changes are unknown. This study sought to characterize behavior following TBI using a differential fear conditioning model of PTSD in rats, and investigate structural and functional changes within and between the mPFC, BLA, BMA, and HC that may underlie these changes. This study used lateral fluid percussion to induce a mild to moderate (1.8-2.0 atm) TBI in rats. Animals were tested in the Morris Water Maze 2 days post injury in order to demonstrate HC dependent memory deficits. Differential fear conditioning began 13 days post injury and consisted of 2 days of training followed by a day of contextual extinction then 2 days of cued extinction. During training, auditory stimuli consisting of 50ms white noise or pure-tone sound pips were delivered at 1Hz for 30 seconds and either co-terminated with a mild (0.6mA, 1 sec) shock (CS+) or were unpaired (CS-). Each day of training, rats were presented with 5 CS+ and 5 CS- in a random order. During contextual extinction rats were placed in the same context as in training, but no auditory stimuli were presented and no shocks were delivered. During each day of cued extinction, rats were placed in a novel context and were presented with the same CS+ and CS- auditory cues (five of each in a random order); however, no foot shocks were delivered. Freezing was used as the behavioral measure during all phases of differential fear conditioning. We found that injured rats had higher freezing to the CS+ during both days of training, indicating they acquired the conditioned response faster than sham animals. We also found that injured rats had lower freezing during contextual extinction, indicating they were unable to associate their context with the aversive stimulus. Electrophysiological recordings and neuropathology are currently being utilized to investigate structure/function relationships underlying the neurophysiological basis of these TBI induced changes.

Title: Increased aggression and social contact following traumatic brain injury in male zebra finches.

Authors: *K. A. DUNCAN, E. KELLMAN;
Biol., Vassar Col., Poughkeepsie, NY

Abstract: Traumatic brain injury (TBI) is associated with a wide range of both physiological and behavioral changes. The behavioral changes may include memory and attention deficits as well as emotional disorders such as anxiety, depression, aggression, impulse control, and decreased social cognition. While mechanisms underlying the physiological changes are better known, the mechanisms behind the behavioral changes are poorly understood. Following injury in the zebra finch brain, an upregulation of steroidogenic enzymes (aromatase; estrogen synthase) and receptors (androgen and estrogen) help to promote neurogenesis and neuronal survival. However, what role if any these increased steroidal products have on behavior has yet to be determined. Thus, the goal of this study was to determine the effect of injury on social behavior in male zebra finches. Behavioral testing (stress, social contact, and colony behaviors) was conducted at three times during the study (pre-injury, 1 week post-injury, and approximately 2 months post-injury). Following TBI, a significant increase in social contact and aggression suggests that social behavior is altered following injury. This effect was still present 2 months following injury. Interestingly, active coping stress was not significantly different following TBI. These data suggest that injury does alter behavior by promoting a shift from more affiliative behaviors to aggressive behaviors.

Title: Effects of TRPV1 receptor antagonism on orthodontic force induced pain

Authors: *N. HASEGAWA[1], A. SASAKI[1], T. TSUCHIYA[1], N. SUDA[1], H. SAKAGAMI[2], K. ADACHI[2];
[1]Orthodontology, [2]Parmacology, Meikai Univ. Sch. of Dent., Sakado, Japan

Abstract: Recently, we have reported that the jaw-opening reflex (JOR) excitability is increased in 1-3 days and is decreased in 7 days after orthodontic force application in rats. Because this temporal alteration of the JOR excitability is similarly observed in the clinical reports for the orthodontic pain, this animal model may allow us to investigate the novel approach to treatment of orthodontic pain. The aim of this study was comparison of analgesic effect of common analgesics (aspirin and acetaminophen) and TRPV1 antagonist on the orthodontic pain in rats. In this model, general anesthetized rats were applied continuous orthodontic force by Ti-Ni coil spring to only right maxillary first molar. Aspirin (25, 50 and 100 mg/kg/day), acetaminophen (100 mg/kg/day), A-889425 (1.25, 2.5, 5.0 μmol/kg/day) and vehicle (CMC) were repetitively administrated (i.p., 3 times/day) from immediately after orthodontic force application. In one day, rats were generally anesthetized and electrical current (200 μs) was applied to bilateral maxillary first molar to compare the threshold for inducing JOR and those physiological features (latency, duration and AUC of anterior digastric muscle activity) between left and right sides. The maxillary tooth arch of each animal was impressed by silicone impression paste before application of coil spring and after JOR investigation to obtain study casts. The amount of tooth movement were obtained by measuring the study cast with vernier caliper. In vehicle treated animals, the JOR threshold in right side was significantly ($P < 0.05$) lower compared with that of left side. In comparison with vehicle, aspirin (100 mg/kg) and A-889425 (5.0 μmol/kg) significantly ($P < 0.05$) increased the right side JOR threshold. On the other hand, acetaminophen failed to increase the right side JOR threshold. Loading of continuous orthodontic force induced medial movement of the first molar and any treatments did not alter of the tooth movement. These data suggest that both NSAIDs and TRPV1 receptor antagonist, but not acetaminophen, are able to reduce orthodontic pain, however, both agents are known as mediators of osteoclast differentiation. Further studies to investigate the effects of prolongation of drug, in particular A-889425, treatment period on morphological alterations (e.g., tooth movement and expression of mature osteoclasts) and physiological features are required.

Title: New tools to interrogate molecular mechanisms in pain transduction.

Authors: M. ARTERO[1], F. TABERNER[2], G. FERNÁNDEZ-BALLESTER[1], *A. V. FERRER-MONTIEL[3];
[1]Inst. of Mol. and Cell. Biology, UMH, Elche, Spain; [2]Inst. of Pharmacology, Heidelberg Univ., Heidelberg, Germany; [3]Univ. Miguel Hernandez, Elche, Spain

Abstract: Disentangling the mechanisms driving pain sensation is a notable challenge in neurobiology. Pain is the result of a complex processing of biochemical and molecular signals at different levels of the peripheral and central nervous systems. The high heterogeneity of peripheral nociceptors represents a large handicap to understand the cellular and molecular mechanisms implicated in nociceptor sensitization by pro-algesic agents. Thus, there is a need to develop new tools that help to identify specific subpopulations of neurons and to investigate their role in pain transduction. Members of the family of Transient Receptor Potential channels (TRP) are key players in the transduction of nociceptive stimuli in somatosensory neurons. We have designed a knock-in mouse model, which expresses the yellow fusion protein (YFP) bound to N-terminal of TRPV1 (YFP-TRPV1), aimed at labelling cells that express the thermoTRP channel. After confirming the knock-in model through genetic analysis, our preliminary results point out to a tissue, cellular and subcellular distribution of the YFP-TRPV1 similar to wild type. Likewise, channel functionality and pharmacology was not affected. The implications of our preliminary results will be discussed in the context of the potential application of the knock-in model to investigate the molecular and cellular mechanisms underlying algesic sensitization of nociceptors.

Title: Inhibition of TRPM3 ion channels by G-protein beta-gamma subunits

Authors: *T. ROHACS, D. BADHEKA, Y. YUDIN, I. BORBIRO;
Rutgers New Jersey Med. Sch., Newark, NJ

Abstract: Transient Receptor Potential Melastatin 3 (TRPM3) channels are activated by heat, and chemical activators such as pregnenolone sulphate and CIM0216. Here we show that activation of receptors coupled to heterotrimeric Gi proteins inhibits TRPM3 currents in a mammalian expression system. This inhibition was alleviated by co-expression of proteins that act as sinks for the βγ subunits of heterotrimeric G-proteins (Gβγ). Co-expression of Gβ1γ2, but not a constitutively active mutant of Gαo inhibited TRPM3 channel activity induced by pregnenolone sulphate. TRPM3 currents were also inhibited by purified Gβγ proteins applied to excised inside out patches, indicating a direct effect. Baclofen and somatostatin, agonists of Gi coupled receptors, inhibited Ca^{2+} signals induced by pregnenolone sulphate and CIM0216 in dorsal root ganglion (DRG) neurons. The GABAB receptor agonist baclofen also inhibited CIM0216-induced currents in DRG neurons, and nocifensive responses elicited by this TRPM3 agonist *in vivo*. Our data show that Gi-coupled receptors regulate TRPM3 channels via direct inhibition by Gβγ.

Title: SHANK3 regulates TRPV1 signaling in mouse and human primary sensory neurons

Authors: *Y. KIM[1], Q. HAN[1], X. WANG[2], D. LIU[1], Y. ZHANG[1], T. BERTA[1], Y.-H. JIANG[2], R.-R. JI[1];
[1]Anesthesiol., [2]Pediatrics, Duke Univ. Med. Ctr., Durham, NC

Abstract: SHANK3 is a postsynaptic scaffold protein in the central nervous system. *SHANK3* mutation/deletion is implicated in autism spectrum disorder (ASD). *SHANK3* maps to the critical chromosome region of 22q13.3. Clinical and genomic evaluation of 201 patients with Phelan-McDermid syndrome, also known as 22q13 deletion syndrome which includes the deletion of entire *SHANK3* gene, showed a decrease in pain sensitivity in 77% of patients and this problem sustains with increased age. However, the molecular mechanisms of pain dysregulation in ASD are unclear. We found SHANK3 expression in primary sensory neurons of mouse and human dorsal root ganglia (DRG). SHANK3 is heavily co-localized with TRPV1 in DRG neurons. Capsaicin-induced inward currents in DRG neurons, as well as capsaicin-induced spontaneous pain are substantially reduced in *Shank3* knockout mice. Finally, knockdown of *SHNAK3* expression in human DRG neurons also abrogates TRPV1 function. Our findings reveal a novel peripheral mechanism of SHANK3, which may underlie pain deficits via functional downregulation of TRPV1 in *SHANK3*-related autism.

Title: Tyrosine residue at 511 position in the TRPV1 tightly fasten vanilloids to delay channel deactivation

Authors: *R. KUMAR, A. PRIEL;
The Hebrew Univ., Jerusalem, Israel

Abstract: **Background:** Capsaicin is a naturally occurring vanilloid that cause a hot, pungent sensation. It is an agonist to the TRPV1 receptor, a well characterized ion channel expressed on primary afferent neurons to sense both pain and heat. TRPV1 is a polymodal activated cation

channel acting as a key sensor of pain. The past few years have witnessed a tremendous progress in the structural elucidation of TRPV1. Recent developments in high-resolution cryo-EM have paved the way towards structural visualization of TRPV1 in both resting and ligand-bound states. The highly conserved tyrosine in position 511 (Y511) of the rat TRPV1 (rTRPV1) was the first residue to be identified as a necessary participant in vanilloid-mediated receptor activation, and the receptor cryo-EM structures point to a close proximity of this residue to the agonist. Furthermore, rotation of this residue and its steric function during vanilloid binding was proposed, still the usefulness of its rotation in vanilloid sensitivity and channel activation has not been fully examined.
Objective: We aim to understand the mechanism through which rTRPV1 Y511 residue participates in vanilloid-evoked receptor activation.
Methods: We generated an array of rTRPV1 mutants, containing the whole spectrum of Y511 substitutions, and tested their response to the exo-vanilloid capsaicin and the endo-vanilloid N-Arachidonoyl dopamine (NADA) by calcium imaging and electrophysiology.
Results: Our analysis indicates that, Y511 substitutions to only aromatic amino acids retained rTRPV1 sensitivity to vanilloids, although ligand binding was impaired. Interestingly, while activation rate was unaffected in rTRPV1 mutants carrying Tryptophan or Phenylalanine, the ligand washout rate was significantly faster than wild type.
Conclusion: Our findings indicate that, the Y511 residue in rTRPV1 enhances agonist sensitivity and channel activation by entrapping vanilloids in the binding pocket. Thus, the Y511 residue is required for vanilloid-evoked TRPV1 activation and pain sensation by stabilizing ligand-receptor interaction.

Title: New mechanisms of EP1 and EP4 receptors in enhancing the functionality of TRPV1 in dorsal root ganglia (DRG) neurons

Authors: *S. M. JAFFAL;
McGill Univ., Montreal, QC, Canada

Abstract: Transient Receptor Potential Vanilloid 1 (TRPV1) is a non-selective cation channel that is modulated by inflammatory mediators (e.g., prostaglandin E2, PGE2) in the pain pathway through mediating the cell surface insertion of the channel and/or enhancing its activity. The experiments in this study were conducted using DRG neurons from male Sprague Dawley rats, different inhibitors, agonists [50 μM 17PGE2 -an agonist for EP1- or 50 μM PGE1OH -an agonist for EP4] & cobalt (Co^{+2}) assay. The results show that the pre-treatment of DRG neurons with an inhibitor of extracellular calcium (100 μM BAPTA) strongly inhibited the enhancement of capsaicin induced Co^{+2} influx by the 2 agonists. Similar effect was obtained when different types of the voltage dependent calcium channels (VDCCs) were inhibited using a cocktail of inhibitors (10 μM Amlodipine, 1 μM ω-Conotoxin & 1 nM SNX-482) in an indication that VDCCs are activated as a source of calcium entry in this pathway. In contrast, the mechanisms of the 2 receptors differed significantly with respect to the involvement of the synaptosomal-associated protein 25kDa (SNAP25 protein) which has a crucial role in vesicle fusion. SNAP25 inhibitor reduced the enhancement of capsaicin induced Co^{+2} influx by EP1, but not EP4. Accordingly, the results suggest that TRPV1 insertion to the surface of DRGs is a prerequisite for EP1 in the enhancement of TRPV1 functionality and that EP1 follow the same route, in this context, of other inflammatory mediators (NGF, ATP and IGF-1) as mentioned in previous studies. The involvement of SNAP25 in this pathway/tissue is in an agreement with my results (presented at the Canadian Association of Neuroscience meeting, CAN2015; poster # 2-D-109) that suggest the switch in the type of the t-SNARE protein during dmPGE2 induced trafficking of TRPV1 from the DRGs to the periphery [SNAP25 was the t-SNARE involved in this trafficking in DRG neurons while syntaxin-1 was the t-SNARE involved in the periphery: sciatic nerve and skin of the hindpaw of the rats]. Finally, my data show- in agreement with the literature- that the pre-treatment of the DRGs with 10 μM PKCε-V1-2 inhibitor or 50 μM H89 inhibitor abolished the augmentation of capsaicin induced Co^{+2} influx by EP1 and EP4 respectively indicating that the effect of EP1 involves protein kinase C epsilon (PKCε) while the effect of EP4 requires protein kinase A (PKA).
In conclusion, the current and previous results shed the light on the differential mechanisms of EP1/EP4 recptors in mediating the functionality and surface availability of TRPV1 in DRG neurons and can be of therapeutic value.

Title: Calcium-dependent ablation of trpv1-lineage axonal terminals by capsaicin

Authors: S. WANG[1], S. WANG[1], J. JOSEPH[1], J. RO[1], F. WEI[1], J. CAMPBELL[2], *M.-K. CHUNG[1];
[1]Neural & Pain Sci., Univ. of Maryland Dent. Sch., Baltimore, MD; [2]the Centrexion, Baltimore, MD

Abstract: Capsaicin, the principal pungent ingredient of spicy peppers, activates the transient receptor potential vanilloid 1 (TRPV1) expressed on the cell surface membrane of nociceptors. Although capsaicin acutely induces intense burning pain by activating TRPV1, it has also been used as an analgesic due to enduring effects on nociceptive terminals. Topical capsaicin is FDA approved for treating post-herpetic neuralgia, and injection of capsaicin into painful tissues also shows analgesic efficacy. Peripherally administered vanilloids induce ablation of nociceptive terminals limited to the treated area without ablation of the cell body. Although Ca^{2+}- and mitochondria-dependent capsaicin-induced cell death has been shown, mechanisms underlying capsaicin-induced ablation of nociceptive terminals are less known. By combination of TRPV1-lineage reporter mice and multicompartmental culture, we established a method to monitor capsaicin-induced changes of TRPV1-lineage afferent terminals in real-time, limited to afferent terminals without affecting soma. We found that Ca^{2+} influx through TRPV1 is necessary and sufficient for capsaicin-induced ablation of nociceptive terminals. Notably, cyclosporin A or TRP19622 (inhibitors of the mitochondria transition pore) and phenyl alpha-tert-butyl nitrone or antioxidant supplement (scavenger of reactive oxygen species), did not attenuate capsaicin-induced ablation. Ablation of TRPV1-lineage nociceptive terminals in mouse hindpaw skin following the local injection of capsaicin was sustained for more than a month and reversed after two months. This ablation in vivo was substantially prevented by the chelation of Ca^{2+} but was not affected by cyclosporin A. These results suggest that TRPV1/Ca^{2+}-dependent signaling plays dominant roles in capsaicin-induced ablation of nociceptive terminals *in vitro* and *in vivo*. This study should lead to a better understanding of the molecular mechanisms and further improvement of capsaicin-induced analgesia.

Title: The complement system component C5a produces thermal and mechanical hyperalgesia via macrophage-to-nociceptor signaling that requires TRPV1

Authors: *C. WARWICK[1], L. P. SHUTOV[1], T. M. WOODRUFF[2], A. J. SHEPHERD[3], D. P. MOHAPATRA[3], Y. M. USACHEV[1];
[1]Pharmacol., Univ. of Iowa, Iowa City, IA; [2]Sch. of Biomed. Sci., Univ. of Queensland, St. Lucia, Australia; [3]Washington Univ. Pain Ctr., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: The complement system is a principal component of innate immunity. Recent studies have highlighted the importance of C5a and other components of the complement system in inflammatory and neuropathic pain, although the underlying mechanisms are largely unknown. In particular, it is unclear how the complement system communicates with nociceptors and which ion channels and receptors are involved. Here we propose that the complement fragment C5a triggers macrophage-to-neuron signaling which involves TRPV1 sensitization and ultimately leads to thermal and mechanical sensitization. The inflammatory thermal and mechanical hyperalgesia induced by intraplantar injection of complete Freund's adjuvant (CFA) was accompanied by upregulation of C5a in the hindpaw and was markedly reduced by C5a receptor (C5aR1) knock-out or treatment with the C5aR1 antagonist PMX53. Administration of C5a into the mouse hindpaw produced mechanical and thermal hyperalgesia in a dose-dependent manner with C5aR1 KO mice showing no hyperalgesia. Immunohistochemistry of mouse plantar skin revealed that C5aR1 was expressed primarily in resident skin macrophages. Additionally, C5a evoked strong Ca^{2+} mobilization in cultured macrophages dependent upon C5aR1 activation of Gβγ-phospholipase Cβ signaling and Ca^{2+} mobilization from ER calcium stores. Drug-induced macrophage depletion in transgenic macrophage Fas-induced apoptosis (MAFIA) mice abolished C5a-dependent thermal and mechanical hyperalgesia. Examination of inflammatory mediators following C5a injection revealed a rapid upregulation of numerous factors including NGF, a mediator known to sensitize TRPV1. Preinjection of an NGF-neutralizing antibody or Trk inhibitor GNF-5837 prevented C5a-induced thermal hyperalgesia. Notably, NGF-induced thermal hyperalgesia was unaffected by macrophage depletion. Interestingly, both thermal and mechanical hyperalgesia produced by C5a were absent in TRPV1 knock-out mice, and were blocked by coadministration of TRPV1 antagonist AMG9810. As TRPV1 is a noxious heat

sensor and is unlikely to directly mediate mechanical sensation, these data suggest that C5a produces heat hyperalgesia by sensitizing TRPV1 to heat stimuli while C5a-induced mechanical hyperalgesia is potentially dependent upon neurogenic inflammation originating from TRPV1 containing fibers. The potential for C5a induced neurogenic inflammation is currently being tested. Collectively, our findings highlight the importance of macrophage-to-neuron signaling in pain processing and identify C5a, NGF, and TRPV1 as key players in this cross-cellular communication.

Title: Alleviating neuropathic pain by selective expression of trpv1 interfering peptide aptamer in primary sensory neurons

Authors: *H. YU, Z. LIU, F. WANG, H. XIANG, G. FISCHER, B. PAN, Q. H. HOGAN; Anesthesiol., Med. Col. of Wisconsin, Milwaukee, WI

Abstract: The transient receptor potential channel vanilloid type 1 (TRPV1), a non-selective cation channel highly expressed in the primary sensory neurons, is an important molecular sensor and mediator of pain signals. Interfering peptide aptamers (iPA) are designed as short fragments of endogenous protein encompassing a domain with high affinity and specificity in binding to cognate sites of target protein, whereby iPA can function as a decoy peptide to specifically inhibit endogenous protein function by interfering with associated protein-protein interaction. Several studies have identified TRPV1-specific iPAs that exert dominant-negative effects on TRPV1 functions by interfering with subunit organization and/or desensitizing TRPV1 binding to interaction proteins. In this study, we constructed an adeno-associated viral (AAV6) vector expressing a recombinant fluorescent TRPV1iPA, using an iPA derived from a 38mer tetrameric assembly domain (TAD) ranging the residues 735-772 of rat TRPV1 and fused to the C-terminus of enhanced green fluorescent protein (EGFP). Functional analysis of primary sensory neurons expressing EGFP-TRPV1iPA (EGFP-TAD), using the Ca^{2+}-sensitive dye fura-2 to measure intracellular [Ca^{2+}] and patch-clamp recording of TRPV1 channel activation, revealed decreased functional TRPV1 channel activity in response to capsaicin (a potent and selective TRPV1 agonist), compared to control neurons from naïve rats or expressing EGFP alone. To examine the

potential for inhibiting development of neuropathic pain, AAV-EGFP-TAD (AAV-TAD) was injected into lumbar (L) 4 and L5 DRGs of rats with neuropathic pain following tibial nerve injury (TNI). Results showed that AAV-mediated selective expression of EGFP-TAD in L4/L5 DRG neuron somata and their peripheral and central axonal projections is effective in persistent attenuation (8 weeks) of TNI-induced neuropathic pain including hypersensitivity to heat and mechanical stimulation. These observations indicate that AAV-encoded analgesic iPAs for selective inhibition of TRPV1 activity in the primary sensory neurons may have potentials for development as a gene therapy strategy to treat neuropathic pain.

Title: NSAIDs attenuate hyperalgesia induced by TRP channelagonists

Authors: *M. G. TSAGARELI, I. NOZADZE, N. TSIKLAURI, G. GURTSKAIA;
Ivane Beritashvili Exptl. Biomedicine Ctr., Tbilisi, Georgia

Abstract: Transient receptor potential (TRP) cation channels have been extensively investigated as targets for analgesic drug discovery. Because some non-steroidal anti-inflammatory drugs (NSAIDs) are structural analogs of prostaglandins and NSAIDs attenuate heat nociception and mechanical allodynia in models of inflammatory and neuropathic pain, we examined three widely used NSAIDs (diclofenac, ketorolac, and xefocam) on the activation of TRPA1 and TRPV1 channels using thermal paw withdrawal (Hargreaves) and mechanical paw withdrawal (von Frey) tests in male rats. Thermal withdrawal latencies and mechanical thresholds for both hind paws were obtained with 5, 15, 30, 45, 60, and 120 min intraplantar post-injection of TRPA1 agonists, allyl isothiocyanate (AITC) (a natural compound of mustard oil) and cinnamaldehyde (CA), and TRPV1 agonist capsaicin or vehicle. Twenty minutes prior to the start of the experiment with TRP agonists, diclofenac, ketorolac or xefocam were pre-injected in the same hind paw and animals were examined by these two tests. After pretreatment of all three NSAIDs in the ipsilateral (injected) hindpaw that produced strong antinociceptive effects, AITC, CA, and capsaicin caused significant decreases in latency of the thermal withdrawal reflex

compared with vehicle or the contralateral hindpaw. The same findings were observed for the paw withdrawal threshold. In approximately 30 min the effects of CA, AITC, and capsaicin returned to baseline. The data are different from our previous evidence, where TRPA1 agonists AITC and CA and TRPV1 agonist capsaicin produced hyperalgesia for nearly 2 h and resulted in facilitation of these withdrawal reflexes (Tsagareli et al., Neurophysiol., 2013, 45:329-39; Nozadze et al., Behav. Pharmacol., 2016, 27:29-36). Our results, thus, showing that NSAIDs suppress thermal and mechanical hyperalgesia following TRP activation could presumably due to inactivation or desensitization of TRPA1 and TRPV1 channels by NSAIDs.

Title: 17-beta-Estradiol enhances serotonergic neuromodulation of the transient receptor potential vanilloid 1 channel-expressing subpopulation of trigeminal sensory neurons

Authors: *S. LULLA, R. H. BESHER, W. L. BENTON, S. ANANTH, D. L. AVERITT; Biol., Texas Woman's Univ., Denton, TX

Abstract: Many pain conditions occur predominantly in women making pain a major women's health issue. The peripheral activity of the monoamine neurotransmitter serotonin or 5-Hydroxytryptamine (5HT) is implicated in many pain conditions more prevalent in women. 5HT can elicit pain via nociceptors that express the transient receptor potential vanilloid 1 channel (TRPV1), activated by noxious heat and capsaicin and results in the release of calcitonin gene-related peptide (CGRP). 5HT potentiates capsaicin-evoked calcium influx and CGRP release from male nociceptors. This pain mechanism may be under hormonal modulation as 5HT potentiates capsaicin-evoked CGRP release from female human nociceptors during the luteal phase of the menstrual cycle. In support, we recently reported that peripheral 5HT evokes greater pain behaviors in female rats during stages of the estrous cycle when gonadal hormones are fluctuating. Yet it remains unclear whether estrogen enhances or attenuates this serotonergic pain mechanism. We hypothesized that 17-β-estradiol (E2) enhances the potentiating effect of 5HT on the TRPV1-expressing population of cultured trigeminal sensory neurons. Sprague-Dawley female rats (~200g) were ovariectomized and rapidly decapitated 2 weeks later following hormone dissipation. Trigeminal ganglia (n=3 rats/6 ganglia per plate; performed in duplicate per condition) were extracted, dissociated with trypsin and collagenase, and neurons were grown on 24 well poly-D-lysine coated plates. Cultures were maintained for 5 days with media containing nerve growth factor. Cells were then washed and treated with HBSS for 15 minutes. Fractions were collected as basal release and cells were then pretreated with E2 (50 nM) or vehicle prior to treatment with E2 + 5HT (100 μM), E2 only, 5HT only, or vehicle followed by stimulation with capsaicin (50 nM). CGRP release was measured per fraction by ELISA and reported as percent basal release. Here we report that capsaicin excited and 5HT inhibited CGRP release from trigeminal nociceptors, while E2 alone had no effect. When trigeminal nociceptors were treated with both 5HT and E2, capsaicin-evoked CGRP release was significantly increased. These data indicate that estrogen may enhance the pain-provoking effects of 5HT on trigeminal nociceptors, which may provide one mechanism underlying the greater prevalence of pain disorders in women. Our current studies are aimed at analyzing the underlying anatomical substrate for E2 and 5HT activity on trigeminal nociceptors by co-labeling 5HT receptor mRNA, TRPV1 protein, and E2 receptors localized on female trigeminal sensory neurons.

Title: Behavioral characterization of CRISPR generated TRPA1 knockout rats

Authors: R. M. REESE, *S. D. SHIELDS, M. DOURADO, X. WU, E. SUTO, W. P. LEE, A. BALESTRINI, L. RIOL BLANCO, D. HACKOS;
Genentech, South San Francisco, CA

Abstract: The ion channel TRPA1 detects noxious chemical and environmental irritants as well as endogenous inflammatory factors, is present in primary nociceptors, and has been proposed to contribute to inflammatory pain, chemotherapy-induced peripheral neuropathy (CIPN), and asthma. To investigate the involvement of TRPA1 in these disorders and its potential as a therapeutic target, we generated a line of rats that harbors a null mutation in the gene encoding TRPA1 (TRPA1 KO rats) using CRISPR technology and characterized them in a battery of behavioral tests of neurological and sensory function and pain models. TRPA1 mRNA was undetectable in dorsal root ganglion of KO rats by RT-PCR and loss of functional TRPA1 channels was confirmed by calcium imaging. Neither male nor female TRPA1 KO rats showed significant difference from littermate controls in locomotor activity and neurological function exams; baseline sensitivity to noxious heat, mechanical, and cold stimulation was also normal. Additionally, TRPA1 KO rats showed no significant protection from mechanical and heat hypersensitivity in two separate models of inflammatory pain, Bradykinin and Complete Freund's Adjuvant. In two models of neuropathic pain, chronic constriction injury and Bortezomib-induced CIPN, no significant difference was detected in mechanical hypersensitivity between KO rats and controls. Notably, TRPA1 KO rats do not display nocifensive behavior after intraplantar injection of allylisothiocyanate (AITC), a TRPA1 agonist, but no difference from wildtype rats in display of nocifensive behavior after intraplantar injection of capsaicin, a TRPV1 agonist. Inhibition of AITC-induced behavior can be recapitulated pharmacologically with potent small molecule inhibitors, and we have developed this test as a reliable TRPA1 target engagement assay. TRPA1 is also essential for multiple mechanisms of action in asthma, including sensory neuron-triggered airway hyperresponsiveness and smooth muscle contraction. When challenged in the ovalbumin model of asthma TRPA1 KO rats have a striking reduction in eosinophils and neutrophils present in bronchoalveolar fluid compared to littermate controls. Thus, TRPA1 is an attractive target for the treatment of asthma and possibly certain types of pain. To the best of our knowledge, this is the first reported characterization of TRPA1 gene deletion in the rat.

Title: The pain receptor TRPV1 displays agonist-dependent activation stoichiometry

Authors: *A. HAZAN, R. KUMAR, H. MATZNER, A. PRIEL;
Pharmacol., The Hebrew Univ. of Jerusalem, Hadssah Ein Kerem, Israel

Abstract: The nociceptive pathway faces the unique challenge of detecting innumerable amounts of noxious stimuli descending onto a limited number of receptors. This creates polymodality, the ability of a single receptor to detect multiple different agonists, which can be attributed to the multiple binding sites all along the receptor sequence. One notable polymodal receptor, Transient Receptor Potential, Vanilloid 1 (TRPV1), was originally described as the heat and capsaicin detector. Comprised of four identical subunits that organize into a non-selective cationic permeable channel, this receptor is now known to have a variety of binding sites responsible for detecting their respective agonists such as protons, capsaicin, inflammatory mediators such as anandamide, peptide toxins and others. Although its physiological role as a chemosensor has been described in detail, TRPV1 stoichiometry of activation by its different ligands remains unknown. Here, we reconstructed the TRPV1 channel as a tetrameric concatemer harboring a set numbers of mutated binding sites in either the proton or vanilloid binding sites. In doing so, we were able to apply patch-clamp recordings in order to determine the stoichiometry for TRPV1 activation through the vanilloid binding site and the outer-pore domain by capsaicin and protons, respectively. We showed that, while a single capsaicin-bound subunit was sufficient to achieve a maximal open-channel lifetime, all four proton-binding sites were required. Thus, our results demonstrate a distinct stoichiometry of TRPV1 activation through two of its different agonist-binding domains.

Title: Citral enhances spontaneous excitatory transmission in adult rat spinal substantia gelatinosa neurons by activating TRPA1 channels

Authors: L. ZHU, *T. FUJITA, C.-Y. JIANG, C. WANG, T. YU, R. HIRAO, R. SUZUKI, N. MAGORI, E. KUMAMOTO;
Saga Med. Sch., Saga, Japan

Abstract: Transient receptor potential (TRP) channels are involved in modulating nociceptive transmission in spinal dorsal horn lamina II (substantia gelatinosa; SG) neurons that play a pivotal role in regulating the transmission from the periphery. We have previously reported that the TRP channels are activated by various plant-derived chemicals such as capsaicin, allyl isothiocyanate, resiniferatoxin, piperine, eugenol, zingerone, carvacrol, thymol, (-)-carvone, (+)-carvone, 1,4-cineole and 1,8-cineole, resulting in an increase in the spontaneous release of L-glutamate onto SG neurons in spinal cord slices. Citral, which is abundantly contained in lemongrass, has various actions including spasmolysis, anti-inflammation, nerve conduction inhibition, antinociception and the activation of TRP vanilloid-1 (TRPV1), TRP vanilloid-3 (TRPV3), TRP ankyrin-1 (TRPA1) and TRP melastatin-8 (TRPM8) channels expressed in heterologous cells. It has not been examined yet how citral affects synaptic transmission. It is unknown what types of TRP channel in native neurons are activated by citral. With a focus on TRP activation, we examined the effect of citral on glutamatergic spontaneous excitatory transmission at a holding potential of -70 mV by applying the whole-cell patch-clamp technique to SG neurons of adult rat spinal cord slices. Citral superfused for 3 min increased the frequency of spontaneous excitatory postsynaptic current (sEPSC) in a concentration-dependent manner (half-maximal effective concentration, EC_{50} = 0.58 mM) with a small increase in its amplitude. The sEPSC frequency increase produced by citral was repeated at a time interval of 30 min, albeit this action recovered with a slow time course after washout. The presynaptic effect of citral was inhibited by a TRPA1 antagonist HC-030031 (50 μM) but not by a voltage-gated Na^+-channel blocker tetrodotoxin (0.5 μM), a TRPV1 antagonist capsazepine (10 μM) and a TRPM8 antagonist BCTC (3 μM). In conclusion, as with many plant-derived chemicals, citral increased the spontaneous release of L-glutamate onto SG neurons by activating TRPA1 channels. Their efficacy sequence for the TRPA1 activation was thymol (EC_{50} = 0.18 mM) > citral (0.58 mM) ≥ carvacrol (0.69 mM) ≥ (+)-carvone (0.72 mM) > 1,8-cineole (3.2 mM) ≥ eugenol (3.8 mM). This result may serve to know the property of TRPA1 channels located in the central terminal of primary-afferent neuron in the SG. The citral activity as revealed in the present study could contribute to at least a part of its modulatory action on nociceptive transmission in the SG.

Title: Identification of the molecular target of crotamiton, an anti-itch agent

Authors: *H. KITTAKA[1], M. TOMINAGA[1,2];
[1]Div. of Cell Signaling, Okazaki Inst. for Integrative Biosci., Okazaki, Japan; [2]Natl. Inst. of Physiological Sci., Okazaki, Japan

Abstract: The sensation of itch is defined as "an unpleasant cutaneous sensation provoking a desire to scratch". For most people, itch sensation is not lethal, but it is clear that long-lasting itch can be felt torturous and decreases their quality of life. Crotamiton (*N*-ethyl-*o*-crotonotoluidide) was initially found as a scabicide and has been used as an anti-itch agent for human for more than 50 years. Regardless of the long use of crotamton, the mechanism of how crotamton acts as an itch relief remains unknown. We first compared chemical structure of crotamiton with other chemicals composing commercially available anti-itch ointments. As a result, we found that crotamiton is not like steroids, and it doesn't have antihistaminic, local anesthetic and anti-inflammatory effects. In addition, the chemical structure is not like natural compounds such as menthol and camphor, which are commonly used in ointments.
Therefore, we hypothesized that crotamiton could have effects on other targets including transient receptor potential (TRP) channels expressed in the peripheral sensory neurons and the skin. We focused on and screened TRPV (vanilloid) 1, TRPV2, TRPV3, TRPV4, TRPA (ankyrin) 1 and TRPM (melastatin) 8 because they are frequently reported to be involved in the itch sensation, and the involvement in crotamiton's action is not clear. We first examined if crotamiton activates or inhibits these TRP channels in a heterologous expression system using human embryonic kidney 293T cells. We found that crotamiton activated none of the TRP channels and strongly inhibited TRPV4 channel, suggesting that TRPV4 expressed in the peripheral sensory neurons and/or the skin is involved in itch sensation.
We also investigated the detailed mechanism about how crotamiton inhibits TRPV4, focusing on the washout currents from its inhibition, in which extremely large TRPV4 currents were observed. Comparing single-channel open probability and current amplitudes of TRPV4, increases in the both parameters were found to contribute to the washout currents. Because the change in current amplitudes suggested pore dilation of TRPV4, we examined the possibility with experiments of cation replacement and those observing shift of reversal potentials. We found that both larger cation influx and shift of reversal potentials upon crotamiton application to

the cells expressing TRPV4, suggesting the pore dilation of TRPV4 in its disinhibition state. From these results, we identified the molecular target of crotamiton, and moreover, we revealed pore dilation of TRPV4 upon washout of crotamiton. Our clarification of crotamiton effects on TRPV4 would be useful for the future understanding of itch sensation.

Title: Store-operated calcium channels are involved in the function of TRPV1 in dorsal root ganglion neurons

Authors: *D. WEI, H. HU;
Dept. of Pharmacol. and Physiol., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Store-operated Ca^{2+} channels (SOCs) are highly Ca^{2+} selective cation channels that mediate Ca^{2+} entry in many different cell types. Our previous studies have shown that YM-58483 (a SOC inhibitor) attenuates thermal and capsaicin (an agonist of transient receptor potential vanilloid type 1, TRPV1)-induced pain. Additionally, it has been indicated that the function of SOCs in sensory neurons is enhanced under painful nerve injury, suggesting that SOCs may be involved in peripheral sensitization. However, it remains elusive how SOCs impact peripheral sensitization and influence the pain process. Here we demonstrate that the SOC family is expressed in dorsal root ganglia (DRG) neurons, and that both STIM1 and STIM2 are important in mediating SOC entry (SOCE) in mouse DRG neurons. While Orai1 is the only subunit mediating SOCE in most cell types, including cortical and spinal cord neurons, we strikingly found that Orai3 is also responsible for SOCE in DRG neurons. Interestingly, depletion of intracellular Ca^{2+} stores-induced SOCE was more robust in small diameter DRG neurons (< 34μm) and TRPV1 positive DRG neurons. TRPV1 is a non-selective cation channel considered to act as a transducer and molecular integrator of nociceptive stimuli in the periphery. It has been shown that activation of TRPV1 causes Ca^{2+} release from the ER in cell lines expressing TRPV1 and native rodent DRG neurons. To determine whether TRPV1-induced Ca^{2+} release from the ER can activate endogenous SOCs, we examined the effects of two SOC inhibitors, YM-58483 and Synta66, on capsaicin-induced Ca^{2+} influx. Our data show that YM-

58483 and Synta66 partially decreased the sustained Ca^{2+} entry, but not Ca^{2+} release. To confirm that SOCs are involved in the function of TRPV1, we tested TRPV1-induced Ca^{2+} responses in DRG neurons from Orai1-/- mice. We found that capsaicin-induced Ca^{2+} influx was significantly reduced in DRG neurons from Orai1-/- mice when compared to those from WT mice. More importantly, capsaicin-induced nociception was significantly attenuated in Orai1 -/- mice. Taken together, our novel findings reveal that activation of TRPV1 leads to SOC entry, suggesting SOCs may play an important role in the transmission and modulation of pain.

Title: Expression and distribution of TRPM4 channels in mouse prefrontal cortex

Authors: *E. LEIVA-SALCEDO[1], C. VILLEGAS[2], H. VALENZUELA[2], D. RIQUELME[1]; [2]Dept. de Biologia, [1]Univ. de Santiago, Santiago, Chile

Abstract: TRPM4 is non-selective cation channel activated by intracellular Ca^{2+}, but impermeable to divalent cations. TRPM4 participates in several physiological and pathophysiological processes, such as neuronal bursting in preBötzinger nucleus, afterdepolarization currents in Purkinje neurons, dendritic depolarization in CA1 pyramidal neurons and ischemic neuronal death. TRPM4 is assembled as a tetramer with 6 transmembrane regions with the N and C-terminal in the intracellular side, with several sites of post-translational modification. Their sensitivity to Ca^{2+} is given by calmodulin through its 5 calmodulin binding sites. TRPM4 is expressed in numerous brain areas like mitral neurons in accessory olfactory bulb, in the hypothalamus in a subset of neurons in the supraoptic and paraventricular nuclei. Recently, *in situ* hybridization experiments demonstrated the expression of TRPM4 in the *stratum pyramidale* of hippocampal CA1 area. Moreover, the expression of TRPM4 prefrontal cortex has not been completely characterized and only their expression layer 5 has been reported.

Despite of this information, the detailed TRPM4 expression in the prefrontal cortex or the type of neurons expressing the channels or their distribution in neuronal subcompartments (axon, dendrites, and soma) has not been fully described. In this study we performed a immunohistochemical characterization of TRPM4 expression and different neuronal markers (Neurogranin, MAP2, GAD67, Ankyrin G, NeuN) in the medial prefrontal cortex of adult mice (4-8 weeks). We found that TRPM4 is widely expressed through all cortical layers of the prefrontal cortex, moreover, TRPM4 expression is located mainly in the somatodendritic region of the principal neurons. The expression pattern of TRPM4 in prefrontal regions could bring insight in the properties of the neurons and how they can contribute to different neuronal responses through the modulation of the intracellular Ca^{2+} and then to the neuronal excitability.

Title: Group I metabotropic glutamate receptors increase excitability of layer III entorhinal pyramidal neurons and changes in excitability involve the activation of a TRPC4/5-like current

Authors: *N. I. CILZ[1], B. HU[2], S. LEI[2];
[1]Pharmacology, Physiology, & Therapeut., [2]Univ. of North Dakota, Grand Forks, ND

Abstract: The entorhinal cortex (EC) mediates the majority of the cortical input to the hippocampus and is a critical structure for both limbic function and memory. Axons from layer III EC pyramidal neurons form the temporoammonic pathway, which synapses onto region CA1, and these EC neurons are modulated by metabotropic receptors for glutamate. We chose to focus on the neuromodulatory role of group I receptors on these EC neurons. Bath application of the group I agonist DHPG (10 μM) resulted in a significant increase in the action potential firing frequency of layer III EC pyramidal neurons. The calculated EC_{50} for this response was 1.74 μM. Pretreatment and continuous bath application of either the mGluR1 antagonist LY367385 or mGluR5 antagonist MPEP significantly reduced, but did not block, DHPG-induced increased AP

firing. Only in the presence of both antagonists was DHPG-induced increased action potential firing blocked, suggesting the functional presence of both receptors in the EC. Western blot analysis of EC lysates confirmed protein expression for both group I receptors in the EC. In addition to increased action potential firing, DHPG-induced increased excitability was also evidenced by a significant depolarization of the resting membrane potential by about ~4.5 mV and the generation of an inward current of about ~-25 pA. We investigated the ionic mechanism mediating this increased subthreshold excitability by measuring changes in holding current at -60 mV under various ion substitution conditions. Replacement of intracellular K^+ with Cs^+ failed to significantly reduce DHPG-induced inward currents. Reduction of extracellular Na^+ but not Ca^{2+} significantly reduced DHPG-induced currents, suggesting a non-selective cation channel (NSCC) is involved. Consistent with involvement of NSCC, inward currents were sensitive to flufenamic acid, extracellular but not intracellular 2-APB, and were potentiated by extracellular La^{3+} and Gd^{3+}. The selective TRPC4/5 blocker ML204 significantly reduced DHPG-induced inward currents. These currents were significantly reduced in the presence of PLC inhibitors U73122 or edelfosine but remained unaffected by the PKC inhibitor GF109203X. These results suggest that DHPG acting via group I receptors increased excitability of EC neurons and that PLC but not PKC was required for the activation of a TRPC4/5 like current, which may underlie the DHPG-induced increased excitability.

Title: Peripheral nerve injury-induced synaptic rearrangement in the spinal dorsal horn revealed by cross-correlation analysis

Authors: T. ASAKAWA[1], Y. TAKEMURA[1], T. FUJIWARA[2], K. AKAGAWA[2], *Y. HORI[1]; [1]Physiol. and Biol. Information, Dokkyo Univ. Sch. Med., Tochigi, Japan; [2]Cell Physiol., Kyorin Univ. Sch. Med., Tokyo, Japan

Abstract: Syntaxin 1A (STX1A) is a membrane protein that is involved in exocytosis and membrane trafficking. It has been reported that the knockdown of STX1A results in axonal elongation and sprouting of cultured central neurons, including spinal dorsal horn neurons. Additionally, we have previously shown that partial sciatic nerve ligation (PSNL) decreased the expression of STX1A and increased the number of synapses on neurons in the spinal dorsal horn

(DH). Based on these observations, it is suggested that PSNL-induced downregulation of STX1A results in rearrangement of the synaptic connection between neurons in the DH. In order to examine this hypothesis, we evaluated the effects of PSNL on the functional connectivity between neurons in the DH by means of cross-correlation analysis. Furthermore, comparison was made between STX1A knockout (KO) mice and wild-type (WT) littermate control mice. Experiments were performed on 6-7-week-old mice. PSNL was performed under halothane anesthesia and the development of mechanical allodynia was accessed by von Frey filaments. Under ketamine/xylazine anesthesia, the lumbar spinal cord was removed and transverse slices (400 μm in thickness) were made. The slices were placed into a recording chamber with multi-electrode array (Multi Channel Systems, Germany). Electrodes were arranged 30-200 μm apart in an 8x8 pattern. The signals from the MEA electrodes were sampled at 25 kHz. Cross-correlograms between spontaneous spike trains of simultaneously recorded neurons in the DH were constructed off-line using DataView (Heitler, 2009) and Matlab R2010b. The observed pattern of cross-correlograms included a flat histogram (which indicates no synaptic connection between neurons), a histogram with a central peak (common excitatory synaptic input to neurons), a histogram with a lagged peak (monosynaptic excitatory interaction between neurons), and a histogram with a lagged trough (monosynaptic inhibitory interaction between neurons). The incidence of histograms with a central peak, lagged peak and lagged trough was increased in mice subjected to PSNL. Additionally, the effects of PSNL on the patterns of cross-correlograms were more prominent in STX1A KO mice compared to WT control mice. The present observations seem to indicate that neurons in the DH make excitatory and/or inhibitory synapses on the nearby neurons, and that synaptic connections among neurons in the DH might change significantly after peripheral nerve injury. Furthermore, such synaptic rearrangement is at least partly attributed to the function of STX1A.

Title: Long-term effects of neonatal surgical injury in rats: sexual dimorphism in response to neonatal microglial inhibition

Authors: *O. MORIARTY[1,2], Y. TU[3], M. W. SALTER[3], S. BEGGS[1,2], S. M. WALKER[1,2]; [1]Univ. Col. London, London, United Kingdom; [2]UCL Inst. of Child Hlth., London, United Kingdom; [3]The Hosp. for Sick Children, Toronto, ON, Canada

Abstract: Adult incision-related hyperalgesia is enhanced following neonatal incision, with associated increased spinal microglial reactivity. As neuroimmune responses are sexually dimorphic in adult rodents, we investigated effects of microglial inhibition with minocycline at the time of neonatal injury, and evaluated sex-dependent effects on adult re-incision hyperalgesia. We also investigated the somatotopic extent of neonatal incision-induced hyperalgesia.

Male and female rat pups underwent left plantar hindpaw incision on postnatal day 3 (P3) with perioperative saline or minocycline (45mg/kg 30 min pre-incision, 22.5mg/kg 24h and 48h post incision). Following re-incision of the same hindpaw in adulthood, we evaluated spinal reflex sensitivity (thermal/mechanical withdrawal thresholds, EMG). Acute microglial reactivity (Iba1) and cell death were assessed in neonatal lumbar spinal cord. To investigate the anatomical extent of enhanced hyperalgesia following neonatal injury, male neonatal rat pups underwent incision of left or right hind or forepaws, or left thigh. As adults, all rats underwent left hindpaw incision, and spinal reflex sensitivity was evaluated. All procedures were carried out under licence during isoflurane-in-oxygen anaesthesia, and investigators were blinded to treatment groups.

Mechanical hyperalgesia was enhanced in rats with prior neonatal incision (hyperalgesic index, single incision + saline vs. repeat incision + saline: male 234 ± 15 vs. 435 ± 22, $p<0.001$; female 264 ± 9 vs. 378 ± 16, $p<0.001$). Neonatal minocycline attenuated this repeat incision-induced increase in male but not female rats (repeat incision + minocycline: male 286 ± 18, $p<0.01$ vs. repeat incision + saline; female 371 ± 33, not significant). The same pattern was evident for thermal hyperalgesia and EMG responses. Minocycline did not alter acute hyperalgesia following neonatal incision (P3-6), but attenuated the incision-induced increase in Iba1 in the medial ipsilateral lumbar dorsal horn only in male rats (P6). Neonatal incision increased spinal neuronal cell death in both sexes, and was not altered by minocycline treatment. Enhanced hyperalgesia following adult incision varied with location of neonatal incision, being greatest with neonatal incision at the same site, and least with neonatal incision of the contralateral forepaw.

Pain during critical neonatal periods is associated with long-term functional consequences. Our results extend previous findings of sexually dimorphic microglia-neuronal signalling. Neonatal minocycline treatment modulates adult injury response in male but not female rats.

Title: Plasticity and circuitry of spinal pathways after peripheral nerve injury: An *In vivo* patch-clamp recording.

Authors: *M. KURABE, H. BABA, T. KOHNO;
Div. of Anesthesiol., Niigata, Japan

Abstract: Background: Plasticity of excitatory and inhibitory transmission in the spinal dorsal horn (SDH) is thought to be a key mechanism in neuropathic pain. Several studies have shown that these mechanisms are associated with nociceptor sensitization, ectopic firing of primary afferent and with changes in the molecular expression of ion channels, neurotransmitters and receptors in the nociceptive axons. Moreover, these changes may involve the dysregulation of the inhibitory neurons in the SDH and the descending modulatory pathways. Despite the expectation of synaptic plasticity in the SDH, *in vivo* patch-clamp studies to determine whether functional synaptic plasticity is involved in the SDH in neuropathic pain mechanisms have not been reported. We evaluated the plasticity by using *in vivo* patch-clamp technique in SDH neurons and recorded excitatory postsynaptic currents (EPSCs), inhibitory postsynaptic currents (IPSCs), and evoked EPSCs by noxious or innoxious stimuli in chronic constriction injury (CCI) rats.
Results: In the voltage clamp mode, both frequency and amplitude of spontaneous EPSCs from CCI rats significantly increased compared to naïve. In contrast, neither the frequency nor the amplitude of spontaneous IPSC from CCI rats changed compared to naïve. We next observed evoked EPSCs induced by direct peripheral noxious or innoxioius stimuli to rat hindlimb. We classified these neurons in three types; response to only noxious stimuli, response to only innoxious stimuli and response to both noxious and innoxious stimuli. In the CCI model, the neurons in response to only innoxious stimuli decreased and the neuron in response to both stimuli significantly increased.
Conclusions: In this study, we showed that enhancement of excitatory inputs and no change of inhibitory inputs to SDH in the CCI model. By using *in vivo* patch-clamp technique, we could compare their properties and demonstrate changes in properties of SDH neurons in the CCI model. Our results suggest that changes of property of SDH neurons contribute to behavioral hyperalgesia/allodynia after peripheral nerve injury.

Title: Quantitative analysis of spatial distribution of cell bodies in feline dorsal root ganglia

Authors: *Z. J. SPERRY[1,2,3], A. K. OSTROWSKI[1,3], G. E. KULIK[1,3], T. M. BRUNS[1,2,3]; [2]Biointerfaces Inst., [3]Biomed. Engin., [1]Univ. of Michigan, Ann Arbor, MI

Abstract: A neural interface with dorsal root ganglia (DRG) could be beneficial both for stimulating and recording peripheral neural activity. An ideal electrode interface for DRG should account for the specific spatial distribution of neural tissue. Although this distribution has previously been described qualitatively, no quantitative analysis has been performed. To accomplish this, we used light microscopy to image transverse cross-sections of feline sacral-level DRG stained with hematoxylin and eosin. These images were oriented dorsal-ventrally, and the locations of cell bodies manually labeled. Using a custom MATLAB program, the images were transformed to normalized polar coordinates so the cross sections could be directly compared. The normalized images were split into 10,000 annular sectors, and cell distribution was modeled as the proportion of each sector which consisted of cell body pixels. JMP statistical software was used to partition the sectors for greatest differences in both the radial and angular dimension. Angular dimension was defined from dorsal to ventral (0° to 180°), ignoring left-right orientation. The partition model suggested that the greatest proportion of cells was to be found in the outer 24% of the DRG, with a vertical angle of less than 81°, that is, mostly on the dorsal side. The mean proportion of cells in this region was found to be 36%, as compared to 18% for all sectors combined. ANOVA and Tukey HSD test confirmed that for the four regions produced by this split (i.e. inner-dorsal, outer-dorsal, inner-ventral, outer-ventral), the outer-dorsal region had a significantly higher proportion of cell bodies than all but the outer-ventral, with $p < 0.02$ (proportion was non-significantly higher for outer-dorsal than for outer-ventral, $p = 0.08$). These results demonstrate that the distribution of cell bodies in DRG is non-uniform and concentrated on the dorsal surface. The methodology for normalization is potentially useful for other quantitative anatomical studies involving somewhat round perimeters (ex. bone, vasculature, intracellular environments). Future work will involve analyzing additional feline

DRG from other spinal levels, progressing from 2D to 3D distributions, and analyzing human DRG.

Title: Activation of spinal dorsal horn astrocytes modulates the processing of tactile sensation

Authors: ***Y. KOHRO**[1], R. KATSURAGI[1], T. OKA[1], S. MUNETA[1], R. TASHIMA[1], H. TOZAKI-SAITOH[1], K. INOUE[2], M. TSUDA[1];
[1]Dept. of Life Innovation, Grad. Sch. of Pharmaceut. Sci., [2]Dept. of Mol. and Syst. Pharmacology, Grad. Sch. of Pharmaceut. Sci., Kyushu Univ., Fukuoka, Japan

Abstract: Spinal dorsal horn (SDH) astrocytes have an important role in several chronic diseases like neuropathic pain. Accumulating evidence indicates that SDH astrocytes become reactive states in chronic pain conditions, which is crucial for pathology. However, under normal conditions, little is known about how much SDH astrocytes actively influence sensory information processing *in vivo*. The aim of the present study was to establish the selective manipulation of activity of SDH astrocytes *in vivo* and to clarify their role in the processing of sensory information. Recently, several studies have shown that intracellular Ca^{2+} elevation is crucial factor for astrocytic activity change, we used Gq-DREADD technology for manipulating intracellular Ca^{2+} level *in vivo*. For selective introduction of Gq-DREADD into SDH astrocytes, we used *Gfap-Cre* mice in combination with our established microinjection technique of adeno-associated virus into the mouse SDH. We found that activation of Gq-DREADD expressed in astrocytes induced transient intracellular Ca^{2+} increases in acute spinal cord slices. Gq-DREADD stimulation *in vivo* induced transient tactile allodynia (pain hypersensitivity to innocuous stimuli) without producing spontaneous pain behaviors or affecting sensitivities to other noxious stimuli. Moreover, Gq-DREADD-induced tactile allodynia was suppressed by pre-treatment with antagonists for NMDA but not AMPA or P2 receptors. Furthermore, a pharmacological blockade of Aβ-fibers inhibited Gq-DREADD-induced tactile allodynia, and electrical stimulation of Aβ-fibers under Gq-DREADD activation increased the number of c-Fos-positive neuron in the superficial layers of SDH. Together, our findings imply that activation of SDH astrocytes under a

normal condition is sufficient to convert innocuous mechanical information to pain and propose a control of modality-specific sensory information processing by SDH astrocytes.

Title: Latent Sensitization: contralateral hyperalgesia and its suppression by mu-opioid receptors develop simultaneously and involve descending pathways

Authors: *J. G. MARVIZON[1], W. CHEN[1], W. M. WALWYN[2];
[1]Dept. of Med., UCLA / VA GLA HS, Los Angeles, CA; [2]Psychiatry and Biobehavioral Sci., UCLA, Los Angeles, CA

Abstract: Latent Sensitization (LS) is new paradigm that proposes that chronic pain is a departure from normal pain transmission characterized by an enduring state of hyperalgesia that is suppressed by the continuous activation of opioid receptors. Although the injury that induces LS produces hyperalgesia ipsilaterally, blockade of mu-opioid receptor (MOR) constitutive activity by the inverse agonist naltrexone (NTX) reinstates the hyperalgesia bilaterally (Walwyn et al., 2016, J. Neurosci. 36:204). This suggests the involvement of descending pain modulatory pathways in both hyperalgesia and its suppression.
First, we determined when hyperalgesia appears in the contralateral hindpaw and whether it develops in the forepaws. Rats were injected with complete Freund's adjuvant (CFA, 50 µl; saline for controls) in one hindpaw and then were injected with NTX (1 mg/kg s.c.) on days 3, 7, 14, 21 and 28. At each of those days, responses of all four paws to von Frey filaments were measured before NTX and 15, 30, 60 and 120 min after NTX. Unexpectedly, the repeated injections of NTX caused progressive hyperalgesia in all paws of the CFA-injected and control rats. In the contralateral paw of the CFA-injected rats (panel A), NTX induced robust acute (at 15 min) hyperalgesia starting at day 7. In the ipsilateral paw, CFA induced hyperalgesia that

started subsiding at day 14 but was reinstated by NTX (panel A). Reinstatement by NTX was absent or small in the forepaws (panel B) of the CFA-injected rats or in any paw of the control rats (panels C, D). Therefore, in LS hyperalgesia and its suppression are bilateral but segmental, and appear in the first week after injury.

Second, we determined whether descending pain modulatory pathways are involved in LS. We used a cervical block of descending signals consisting of intrathecal lidocaine (10%, 1 µl) at the cervical level (C8-T1). Rats received 50 µl CFA in one hindpaw and von Frey responses were monitored until return to baseline. Intrathecal lidocaine, but not saline, reinstated hyperalgesia. Therefore, a descending pathway is involved in suppression of hyperalgesia in LS.

Title: Does the allodynic spinal cord have a specific colour?

Authors: *M. R. HUTCHINSON[1,2], V. STAIKOPOULOS[1,2], M. GOSNELL[4,3], A. ANWAR[5,3], S. MUSTAFA[1,2], E. GOLDYS[5,3];

Abstract: The endogenous autofluorescence of biological samples, is generated by endogenous fluorescent molecules within the tissue. This background “colour” is usually the bane of immunofluorescence based image acquisition, as this can interfere with distinguishing the specific antibody tagged fluorescent signal. However, employing hyperspectral imaging of this endogenous tissue “colour” by using spectral and spatial imaging information, can provide novel target detection and classification at nanoscale level. For example, hyperspectral imaging can be used as label free method to resolve changes in endogenous fluorescent molecules such as flavins, bound and free NADH and retinoids that are involved in cell metabolism. Moreover, unguided phenotyping of spectral patterns can be employed to provide novel “fingerprinting” of specific disease states. Here we employed postmortem hyperspectral imaging of mouse brain and spinal cord in a graded model of chronic constriction injury induced allodynia to identify novel spectral features that changed proportional to the extent of allodynia. By using an endogenous source of contrast, subtle metabolic variations were detected within the somatosensory regions examined, making it possible to distinguish between animals from allodynic and non-allodynic groups. Data will be presented exploring the neuroanatomical location of the allodynia correlated features. The impact of sex on these features will also be explored.

Abstract: Optogenetic approaches have revolutionized the field of neuroscience by enabling temporal and spatial control of neuronal function. Recent technological advances have enabled implementation of optogenetics in freely moving, untethered animals. However, challenges in device durability, together with substantial expenses associated with implementation of these tools have limited their use, particularly for long-term implementation. Near-field wireless communication (NFC) technology offers unprecedented opportunities to deploy miniaturized implantable systems that offer long-term durability for spinal and peripheral applications. Here, we present durable wireless NFC-powered optoelectronics with robust, chronic stability for long-term operation for use in spinal and peripheral systems. Our devices support the use of various colors of μLEDs, allowing for wireless stimulation and inhibition of spinal and peripheral sensory circuits, with sustained operation in animal over periods of several weeks, and without the need for attachment to bony anchor points. Proof-of-concept experiments demonstrate robust operation in chronically implanted mice for the study of spinal and peripheral pain circuitry using excitatory and inhibitory opsins. The low-cost electronics required for control of the systems and durability of these wireless devices will allow broad application in future studies of spinal circuits, as well as various peripheral targets.

Title: Channel Rhodopsin assisted circuit mapping of calretinin neurons in the superficial dorsal horn

Authors: *K. M. SMITH[1], D. I. HUGHES[2], P. JOBLING[1], R. J. CALLISTER[1], C. V. DAYAS[1], B. A. GRAHAM[1];
[1]Univ. of Newcastle, Callaghan, Australia; [2]Univ. of Glasgow, Glasgow, United Kingdom

Abstract: The spinal dorsal horn (SDH) is a key region in the processing of sensory information, including nociception and pain. Within the SDH substantial neuron diversity makes identification and subsequent analysis of discrete neuron populations difficult. In the current study we have used channel rhodopsin-2 (ChR2) assisted circuit mapping to identify and study the connectivity of a population of dorsal horn interneurons expressing the calcium binding protein calretinin (CR). Despite CR being generally used as a marker of excitatory interneurons, we previously identified both excitatory (90%) and inhibitory (10%) populations of CR positive neurons (Smith et al, 2015). Transgenic mice (n=20) expressing ChR2 in CR positive neurons were anaesthetised (ketamine 100mg/kg) and parasagittal spinal cord slices were obtained (200μm). Targeted whole cell patch clamp recordings were made from identified CR positive, CR control and putative lamina I neurons. Local circuit connectivity was assessed in slices using brief photostimulation (1ms, 490nm) every 10 seconds. Photostimulation-evoked excitatory inputs (CNQX sensitive) were observed in 27/33 recordings from CR positive neurons and 16/18 CR negative neurons. Furthermore, photostimulation also evoked excitatory input to unidentified lamina I neurons (9/9). Under inhibitory recording conditions (CsCl-based internal) photstimulation evoked inhibitory input in 8/9 CR positive and 11/16 CR negative neurons. These connections were predominantly bicuculline sensitive suggesting GABAergic inhibition dominates in CR circuits. Finally, to assess the function of CR positive neurons in the intact nervous system we developed techniques to photostimulate CR neurons in freely behaving mice. Briefly, CRChR2 animals are anaesthetised and paraspinal musculature is retracted from the T12 and T13 vertebra. A fibre optic probe was secured between these vertebra and animals were allowed to recover for 1 week. Photostimulation (10s, 10mW @ 10Hz) of CRChR2 neurons evokes reliable and reproducible nocifensive behavioural responses directed to the ipsilateral hindpaw (n =10). This is consistent with our in vitro data showing CR neuron interconnectivity

and connections with laminae I. Together these results support an important role for CR positive interneurons in spinal nociceptive signalling. The high level of connectivity between excitatory CR neurons places them in an ideal position to amplify incoming sensory information before relay to higher brain regions.

Title: Genetic dissection of spinal circuits processing different forms of sensory modalities

Authors: *T. HUANG[1], B. DUAN[1], L. CHENG[1], Y. ZHANG[1], Y. ZHANG[1], M. GOULDING[2], Q. MA[1];
[1]Dana-Farber Cancer Institute, Harvard Med. Scho, Boston, MA; [2]Salk Inst., La Jolla, CA

Abstract: The goal of this study is to identify spinal neurons that process and transmit specific sensory modalities. In the past decade and half, our lab and other investigators have characterized the developmental origins of a large cohort of spinal excitatory and inhibitory neurons. Based on this knowledge and in collaboation with Dr. Martyn Goulding and his colleagues at the Salk Insitute, we have jointly developed an intersectional genetic strategy to mark and ablate these molecularly defined excitatory or inhibitory neurons. Subsequent behavioral and electrophysiological studies have identified excitatory neurons necessary for the transmission of different sensory modalities. Spinal neurons marked by the expression of the neuropeptide somatostatin (SOM) represent local excitatory interneurons enriched in laminae II/III. Mice with ablation of spinal SOM neurons fail to sense 1) light punctate stilumi evoked by von Frey filaments, 2) intense mechanical stimuli evoked by pinprick or pinch, or 3) itch evoked by lightest mechanical stimuli, without affecting thermal responses. Additionally, these mice fail to generate both filament-evoked static and brush-evoked dynamic forms of mechanical allodynia (pain by low theshold mechanical stimuli) induced by nerve lesions or inflammation.

Other molecularly defined spinal excitatory neurons are requried to transmit more specific forms of sensory information. Firstly, spinal neurons marked by calretin-Cre are requried to transmit light punctate stimuli, but dispensable for acute intense mechanical pain or chronic allodynia. Secondly, spinal neurons marked by Vglut3-Cre (a knock-in Cre that marks neurons not identifical to those marked by the transgenic *Vglut3-Cre* used by the Seal group) transmit both acute light punctate mechanical information and dynamic allodynia, but not acute intense mechanical pain or chronic static allodynia. Finally, our preliminary analyses have suggested the existence of another group of spinal excitatory neurons required selectively to sense acute intense mechanical pain. These studies suggest distinct spinal substrates for the transmission of different sensory modalities.

Title: NMDA receptors and large conductance calcium-activated potassium channels in enkephalinergic neurons in mouse spinal superficial dorsal horn

Authors: *E. KATO, Y. TAKEMURA, Y. HORI;
Dept Physiol & Biol Inf, Dokkyo Med. Univ., Tochigi, Japan

Abstract: Enkephalins (Enks) are endogenous opioid pentapeptides derived from the preproenkephalin (Penk) precursor. Enks are involved in the modulation of nociceptive synaptic transmission in the central nervous system, including the superficial dorsal horn (SDH) of the spinal cord. We characterized Enk-containing neurons in the SDH of transgenic mice that expresses GFP fluorescence under the control of the *Penk* gene promoter (BMC Neurosci, 2011). The present experiments investigated the pharmacological properties of Enk-containing neurons in an attempt to further understand how the activity of Enk-containing neurons is regulated in the SDH.
The experiments were performed on 5- to 8-week-old male ICR mice. The spinal cord was removed under ketamine/xylazine anesthesia. Transverse slices of 350 μm in thickness were prepared at the lumbar enlargement. Tight-seal whole-cell recordings were obtained from neurons localized in the SDH under infrared differential interference contrast (IR-DIC) microscopy. L-glutamate (Glu, 200 μM) was dissolved in Kreb's solution and was applied by

pressure ejection through a glass pipette placed near the recorded neurons. All recordings were made in the presence of strychnine and bicuculline. After the electrophysiological experiments, the recorded neurons were aspirated into a collecting glass pipette. Then, single cell real-time RT-PCR was performed to analyze the expression profile of the *Penk* mRNA, the large-conductance calcium-activated potassium (BK) channel alpha subunit (*Kcnma1*) of mRNA, and the NMDA receptor subunits 1 (*Grin1*), 2A (*Grin2a*) and 2B (*Grin2b*) mRNAs in single SDH neurons.
Puff application of Glu evoked an inward current at a holding potential of -70 mV, which was abolished by bath application of CNQX (an antagonist against a non-MNDA receptor). When holding potential was depolarized, Glu evoked an outward current of long duration, which follows the inward current. Adding APV (an NMDA receptor antagonist) to the perfusate abolished the outward current. The outward current was also abolished by TEA (a potassium channel antagonist) and iberiotoxin (a selective BK channel antagonist). Single cell real-time RT-PCR analysis revealed that
single SDH neurons expressing the *Penk* mRNA also expressed the *Kcnma1*, *Grin1*, *Grin2a* and *Grin2b* mRNAs.
These results might suggest that calcium ion influx through NMDA receptors activates BK channels and hyperpolarizes Enk-containing SDH neurons, which might be involved in the regulation of the release of enkephalin in the SDH.

Title: PLA_2-prostaglandin signaling mediates spike timing-dependent LTP at primary afferent synapses onto spinal projection neurons

Authors: J. LI, *M. L. BACCEI;
Anesthesiol, Univ. Cincinnati, Cincinnati, OH

Abstract: Recent evidence suggests that spike timing-dependent long-term potentiation (t-LTP) at primary afferent synapses onto spinal projection neurons involves an increase in the probability of glutamate release (P_r). Chelation of intracellular Ca^{2+} within projection neurons

prevented both the induction of t-LTP and the accompanying changes in P_r following highly correlated presynaptic and postsynaptic activity, suggesting that the release of a retrograde messenger contributes to t-LTP at these synapses. However, the nature of these retrograde signals remains unclear. The present study addressed this issue using in vitro patch clamp recordings from identified lamina I spino-parabrachial neurons in the adult mouse spinal cord. As reported previously, Pre → Post pairings at an interval of 10 ms (Δt = -10 ms) consistently produced t-LTP of monosynaptic, primary afferent-evoked EPSCs in ascending projection neurons. The application of the nitric oxide (NO) scavenger cPTIO during the pairing protocol failed to prevent the induction of t-LTP, arguing against a critical role for NO in regulating spike timing-dependent plasticity (STDP) at sensory synapses onto spinal projection neurons. In contrast, the administration of the phospholipase A_2 (PLA_2) inhibitor $AACOCF_3$ during the pairing protocol abolished the generation of t-LTP. Since it is known that PLA_2 can regulate synaptic efficacy via the downstream synthesis of prostaglandins such as PGE_2, and that PGE_2 can function as a retrograde messenger at CNS synapses, we next investigated a potential role for prostaglandin receptors in the generation of t-LTP in the superficial dorsal horn (SDH). Importantly, bath application of the selective EP2 receptor antagonist PF 04418948 also suppressed t-LTP at afferent synapses onto mature projection neurons. Collectively, these results demonstrate that PLA_2-prostaglandin signaling modulates activity-dependent synaptic plasticity in the key output neurons of the SDH network and thereby shapes the ascending flow of nociceptive information to the brain.

Title: A role for somatostatin in itch

Authors: J. HUANG[1], J. SOLINSKI[1], M. KRIEGBAUM[1], P.-Y. TSENG[1], *M. HOON[2]; [1]NIDCR, NIH, Bethesda, MD; [2]NIDCR, Bethesda, MD

Abstract: Itch is an unpleasant sensation that in chronic forms severely affects the quality of life of patients. However, the mechanisms which control itch sensation are still poorly understood. Here we examined the contribution of the neuropeptide somatostatin in modulating this sense in

mice. We find that somatostatin is expressed by a select population of DRG neurons and as has been reported previously is expressed by a large number of dorsal horn spinal cord neurons. The somatostatin positive DRG neurons exclusively co-express several molecular markers of itch and these neurons specifically innervate outer layers of the skin with free nerve fibers. These neurons also project afferent fibers to superficial lamina in the spinal cord. Chemogenetic and pharmacological investigation of the pathways that utilize somatostatin demonstrate that it activates specific targets in the itch sensory circuit in the spinal cord. Conditional elimination of somatostatin in the DRG, spinal cord, or both DRG and spinal cord establish that it is an important player in modulating pruritic responses.

Title: Characterisation of a novel population of spinal superficial dorsal horn neurons in the Thy1-GFP mice

Authors: *B. A. GRAHAM[1], K. M. SMITH[2], M. A. GRADWELL[1], R. J. CALLISTER[1], D. I. HUGHES[3], F. R. WALKER[1];
[1]The Univ. of Newcastle, Callaghan, Australia; [2]The Univ. of Newcastle, Callghan, Australia; [3]Inst. of Neurosci. Psychology, Col. of Medical, Vet. & Life Sci., Univ. of Glasgow, Glasgow, United Kingdom

Abstract: The superficial dorsal horn (SDH) of the spinal cord plays a critical role in processing and relaying sensory information from the periphery to higher brain centres. Signals carrying nociceptive, thermal, itch and light touch related information terminate in the SDH, and are processed by a heterogeneous population of neurons before they are relayed along the neuroaxis to finally shape perception. Several groups have undertaken the task of dissecting heterogeneity in this region by analyzing transgenic mice that express green fluorescent protein (GFP) in discrete SDH neuron subpopulations. In this study we report on a small population of SDH

neurons expressing GFP controlled by a neural-specific promoter for a protein referred to as Thy1. These mice have been used widely in neuroscience because they selectively label projection neurons in the neocortex, hippocampus and other brain regions. Previous work has reported that GFP positive neurons also exist in the SDH of Thy1GFP mouse (Porrero 2010 Brain Res 1345:59) and therefore we have undertaken an initial electrophysiological and morphological characterization of these neurons. Adult mice (n = 14, 2-6 months old, both sexes) were deeply anaesthetized with ketamine (100 mg/kg, i.p.) and decapitated. Parasagittal spinal cord slices were prepared from the lumbar cord. Whole cell patch clamp recordings were made from targeted GFP+ neurons and unidentified GFP- neurons in the same region using a K-gluconate-based recording solution. GFP-expressing (Thy1+) neurons (n=28) had similar input resistances (397 ± 31 MΩ vs. 452 ± 57 MΩ) but more depolarized RMPs (-55 ± 1 mV vs. -60 ± 2 mV) than unidentified recordings (n=21). Action potential discharge patterns evoked by depolarisaing current steps (1s, 20pA increments) also differed between recordings. Tonic firing dominated in GFP+ recordings (22/26), with few neurons exhibiting initial busting (2/26) or delayed firing (2/26). Discharge was more variable in the unidentified sample with tonic firing (4/22), initial bursting (7/22), delayed firing (7/22), and single spiking (2/22) all represented in the sample. We also assessed the responsiveness of GFP+ neurons to somatostatin, which selectively evokes outward currents in some inhibitory SDH populations. All GFP+ neurons tested exhibited somatostatin responses (6/6), reinforcing the likelihood that Thy1+ SDH neurons are inhibitory. Finally, neurobiotin filled GFP+ neurons did not conform to the routinely described morphological classes described in the SDH. Together these findings suggest that Thy1+ neurons represent a novel inhibitory interneuron subclass in the SDH.

Title: Intrinsic excitability of spinal projection neurons is enhanced by a Na^+ leak conductance activated by substance P

Authors: *N. C. FORD, M. L. BACCEI;
Anesthesiol., Univ. of Cincinnati Dept. of Anesthesiol., Cincinnati, OH

Abstract: Lamina I projection neurons (PNs) represent a major output of spinal nociceptive circuits, and serve as the conduit by which noxious stimuli detected in the periphery are transmitted to higher brain regions. While PNs exhibit high levels of spontaneous activity during the neonatal period, which may contribute to the proper formation of central pain networks, the underlying ionic mechanisms are poorly understood. Specifically, the voltage-independent (i.e. "leak") channels that regulate the intrinsic membrane excitability of this neuronal population, and how these channels respond to neuromodulators, remain unclear. The present study investigated the contribution of the non-selective Na^+ leak channel NALCN to the intrinsic excitability of identified spino-parabrachial (PB) neurons during early life. PNs were back-labeled by DiI injection into the PB at postnatal day 1 (P1). Whole-cell patch clamp recordings were obtained from spino-PB neurons using an in vitro, intact spinal cord preparation on P3-P5. Decreasing extracellular Na^+ levels to 15 mM evoked a positive shift in holding current and robust membrane hyperpolarization, thus demonstrating the presence of a Na^+-dependent leak conductance in immature PNs. Bath application of $GdCl_3$ (10-100 μM) prevented the effects of the low Na^+ bath on both the holding current and resting membrane potential (RMP), which is consistent with its ability to block the recently identified Na^+ leak channel NALCN. Importantly, the bath application of Gd^{3+} significantly hyperpolarized the RMP, decreased spontaneous activity, and increased rheobase levels in spino-PB neurons, suggesting that NALCN-like channels facilitate action potential discharge in neonatal PNs. In addition, NK1R activation by substance P (SP; 5 μM) significantly enhanced the NALCN conductance in a Gd^{3+}-sensitive manner. Finally, SP activation of NALCN channels was suppressed by the Src kinase inhibitor PP2 (30 μM) delivered via the patch electrode. We conclude that NALCN channels are functionally expressed in spino-PB projection neurons and are modulated by NK1R-dependent Src kinase signaling. The overall effect of this Na^+ leak conductance is to enhance the intrinsic excitability of spino-PB neurons and thereby increase the output of the spinal nociceptive network. As a result, age-related or neuropeptide-evoked changes in NALCN channel activity could profoundly alter the ascending flow of nociceptive transmission to the developing brain.

Title: Subcellular distribution of Sigma-1 receptor in Dorsal Root Ganglion of rodents

Authors: *T. A. MAVLYUTOV[1], M. L. EPSTEIN[2], J. YANG[1];
[1]Anesthesiol., [2]Neurosci., Univ. of Wisconsin, Madison, WI

Abstract: Sigma-1 receptor (S1R) is a widely found signaling modulator and a promising target for treatment of a number of neurological diseases. Intrathecal administration of S1R specific antagonists has been shown to attenuate pain as shown by changes in behavior of rodents in both inflammatory and neuropathic pain models. Since primary afferents are the major component in the pain pathway, we examined the mouse and rat DRGs for the presence of the S1R. At both mRNA and protein levels, Western blots and qRT-PCR confirmed that the DRG contains significantly greater S1R expression in comparison to liver, spinal cord, or cortex. Using a custom-made highly specific antibody, we demonstrate the presence of a strong S1R immuno-fluorescence in all rat and mouse DRG neurons that colocalize with the NSE marker, but little or no signal in terminal neural processes, in GFAP-containing or glial satellite cells, or in dorsal horn neurons. Moreover, S1R was absent in afferent terminals in the skin and in the dorsal horn of the spinal cord. Using immuno-electron microscopy, we detected S1R in the nuclear envelope and endoplasmic reticulum of DRG neurons. In contrast to other cells, S1R is uniquely located directly at the plasma membrane of the DRG neurons. The presence of S1R in the nuclear envelope of all DRG neurons suggests a potential role of S1R as a regulator of neuronal nuclear activities and/or gene expression, a possibility which may provide insight towards new molecular targets for modulating nociception at the level of primary afferent neurons.

Abstract: Spinal lamina I is a key element of the pain processing system which integrates primary afferent input and relays it to supraspinal areas. Intrinsic network of lamina I, to more than 90%, consists of interneurons whose roles in the signal processing are poorly understood. We used whole-cell patch-clamp recordings in an isolated spinal cord preparation with attached dorsal roots to examine morphological features and physiological properties of lamina I small interneurons (n=47). Successfully filled with biocytin neurons (n=17) had fusiform (n=10), flattened (n=4) and multipolar (n=3) somatodendritic morphology and their axons branched intensively terminating in laminae I-III. Small interneurons showed diverse firing patterns. In addition to standard tonic (n=16), adapting (n=7) and delayed firing (n=6), we also found interneurons generating intrinsic rhythmic discharges (n=6) and plateau potentials (n=10), the latter were suppressed by the L-type Ca^{2+}-channel blocker nifedipine. Small interneurons in lamina I received monosynaptic primary afferent inputs from Aδ and C fiber afferents, and some of them could generate bursts of spikes upon the root stimulation. In addition, interneurons (n=6) received monosynaptic inputs from the low-threshold Aβ afferents, which could be picked up by the ventrally protruding dendrites reaching lamina III. Small interneurons also received disynaptic inhibitory inputs driven by the Aβ, Aδ or C afferents. Thus, our results indicate that small lamina I interneurons show diverse firing properties, can generate rhythmic discharges and plateau potentials, and receive primary afferent inputs from Aβ, Aδ and C afferents. These properties are important for processing diverse modalities of nociceptive inputs in lamina I.

Title: Postsynaptic and presynaptic inhibition revealed by optogenetic activation of spinal cord dorsal horn parvalbumin interneurons

Authors: *M. A. GRADWELL[1], R. J. CALLISTER[1], D. I. HUGHES[2], B. A. GRAHAM[1]; [1]Biomed. Sci. and Pharm., Univ. of Newcastle, Callaghan, Australia; [2]Vet. and Life Sci., Univ. of Glasgow, Glasgow, United Kingdom

Abstract: The dorsal horn (DH) of the spinal cord is essential for the appropriate encoding of sensory signals. The role of inhibitory interneurons in segregating nociceptive and tactile inputs within the spinal cord is critical to this sensory encoding. We have previously described a population of inhibitory parvalbumin-positive interneurons (PVINs) with functional properties and connectivity that would enable them to segregate tactile and nociceptive information (Hughes, 2012 J Physiol 16:3927). Furthermore, recent findings demonstrate PV^+INs are necessary for normal sensory processing and their loss produces allodynia (Petitjean, 2015 Cell rep 13:1246). The circuitry underlying these findings, however, remains unclear. To better understand the connectivity underlying the role of PV^+INs in sensory encoding we have taken an optogenetic approach, using transgenic mice that express Channelrhodopsin-2 in PV^+INs. Adult mice (2-12 months old, both sexes) were deeply anaesthetized with ketamine (100 mg/kg, i.p.) and decapitated. Parasagittal spinal cord slices were prepared from the lumbar cord. Whole cell patch clamp recordings were made from targeted PVINs and unidentified (PV-negative) neurons and slices photostimulated using brief whole-field illumination (488nm, 1ms). Synaptic responses and photocurrents were recorded using a range of pipette solutions including CsCl- and CsMSF-based internal (inhibitory responses), and K-gluc (excitatory responses). During inhibitory recordings, photostimulation evoked short latency mixed GABA/Glycine inhibitory postsynaptic currents (ie, bicuculline and strychnine sensitive) in 96% of PVINs and 74% of unidentified interneurons. Thus, PVINs are a highly interconnected network and provide postsynaptic inhibition to other DH populations. During excitatory recordings photostimulation evoked short latency excitatory postsynaptic currents (EPSCs - blocked by CNQX) in 54% of recordings (38/70), presumably arising from a small population of previously described excitatory PVINs. In other recordings (36%, 22/70), photostimulation evoked longer latency EPSCs that could be blocked by CNQX, but also bicuculline. This pharmacology suggests a polysynaptic circuit mediated by inhibitory PVINs. Under these conditions the observed EPSC likely results from primary afferent depolarisation, reflecting the role of PVINs in presynaptic inhibition. Together our findings indicate PV^+INs regulate a wide range of SDH circuits that regulate both incoming sensory signals and local interneurons. It is likely that modulation of PV^+IN function contributes to aberrant sensory experience in pathological pain states.

Title: Markovian analysis of spontaneous spinal cord dorsum potentials reveals non random dynamic adaptive changes in the configuration of the functional connectivity between segmental populations of dorsal horn neurons in response to acute nociceptive stimulation.

Authors: *P. RUDOMIN[1,2], M. MARTIN[3], E. CONTRERAS-HERNANDEZ[1], J. BEJAR[3], G. ESPOSITO[3], D. CHAVEZ[1], U. CORTES[3,4], S. GLUSMAN[1];

Abstract: We used a Markovian approach to examine the changes produced by the intradermic injection of capsaicin on the *state* of functional connectivity between the segmental populations of dorsal horn neurons involved in the generation of spontaneous cord dorsum potentials (CDPs) as well as the extent to which these changes could be reverted by therapeutic approaches clinically known to reduce neuropathic pain. In anesthetized, paralyzed and artificially ventilated cats we placed a 12 silver ball electrode array to record the spontaneous CDPs generated along the L4-L7 spinal segments (see Contreras *et al*. *J Physiol* 10, 23: 43-63, 2015 for details in Methods). A machine learning procedure was used to select from continuous recordings made throughout the whole experiment spontaneous CDPs with similar shapes and amplitudes and group them in specific classes (see Martin *et al*., *Front Neuroinform* 26: 9-21, 2015). Analysis of the sequence of classes of CDPs recorded during non-overlapping periods of 10 min allowed us to build, for each segment *i* and time period *t,* a Markovian model $M_{i,t}$ of transition probabilities between the different classes of the recorded CDPs. Finally, we generated a *consensus similarity graph* of Markovian behaviour of the whole network of dorsal horn neurons in different time periods by combining models from all segments in the same time period *t.* Clustering of the similarity graph revealed significant differences between groups of models obtained before and

after the injection of capsaicin, each expressing a particular state of functional neuronal connectivity. The capsaicin-induced changes in functional state could be temporarily reverted to their pre-capsaicin (control) state by the slow systemic injection of clinically relevant doses of lidocaine (5mg/kg). Our observations indicate that the ensemble of dorsal horn neurons involved in the generation of the spontaneous CDPs may acquire specific structured (non-random) patterns of functional connectivity as an adaptive response to the capsaicin-induced nociceptive stimulation. A Markovian approach is presently being used to address the question on whether the same or different structured changes in the state of functional connectivity between the dorsal horn neurones are induced by other types of nociceptive stimulation.

Title: Activation of spinal STAT6 signaling in M2 like microglia suppressed neuropathic pain

Authors: H. OKUTANI[1], H. YAMANAKA[1], K. KOBAYASHI[1], M. OKUBO[1], M. HIROSE[2], *K. NOGUCHI[3];

Abstract: An inflammatory process that is mediated by the activated spinal microglia has been considered as an important factor in neuronal sensitization in a neuropathic pain state. Similar to macrophages, microglia adopt two different activation phenotypes, the classical (M1) and alternative activation (M2). In this study we examined the expression of phosphorylation of signal transducer and activator of transcription 6 (STAT6) in order to evaluate M2 responses of spinal microglia, and investigated possible involvement of interleukin 4 signals in the endogenous anti inflammatory responses.
Sprague-Dawley rats, weighing 200-250 g received tibial and common peroneal nerve ligation (spared nerve injury model; SNI) were used in this study. Expression of phosphorylated STAT6 was examined by immunohistochemistry using specific antibody for STAT6. IL4 and IL4 receptor (IL4-R) mRNAs were examined by RT-PCR and in situ hybridization (ISH). The effect of intrathecal IL4 was assessed by the withdrawal threshold of mechanical stimuli to the hind-paw of SNI rats.

We detected injury-induced phosphorylated STAT6 in the spinal cord of SNI model rats. Phosphorylated STAT6 signals were specifically detected in microglia. RT-PCR revealed that peripheral nerve injury increased the expression of IL4-R mRNA in spinal cord. The increase of the IL4-R mRNA began from 12 hours, peaked at 48 hours and continued for at least 14 days after nerve injury. In the double labeling analysis, we observed IL4-R mRNA positive signals exclusively in the Iba1 immunolabeled microglia in the dorsal horn of SNI rats. In contrast, we could not detect expression of IL4 mRNA both in dorsal root ganglia and spinal cord. Intrathecal administration of IL4 up-regulated phosphorylated STAT6 in the spinal microglia and suppressed mechanical hypersensitivity of SNI model rats.
These results suggest that adaptive responses of microglia to nerve injury has an anti-inflammatory signals such as IL4-R and phosphorylated STAT6. Activation of STAT6 signals in spinal microglia has a potential to reduce neuropathic pain. Utilizing these anti-nociceptive mechanisms may provide novel therapeutic strategy for neuropathic pain.

Title: The VGF-derived neuropeptide TLQP-62 induces neuroplasticity in the dorsal horn

Authors: *A. G. SKORPUT[1], H. TRUONG[1], W.-J. LIN[2], J. J. WAATAJA[1], S. R. SALTON[2], L. VULCHANOVA[1];

Abstract: Maladaptive neuroplasticity in the dorsal horn following peripheral nerve damage spurs the transition from acute to chronic pain. While BDNF signaling is heavily implicated in the induction of such plasticity, regulation of its involvement is less well understood. The neurosecretory protein VGF (non-acronymic) is rapidly and robustly upregulated following nerve injury and is proteolytically processed to yield bioactive neuropeptides, including the C-terminal peptide TLQP-62, which has been demonstrated to induce BDNF dependent neuroplasticity in the hippocampus. Therefore, we hypothesized that TLQP-62 may play a

similar role in the dorsal horn following nerve injury. Multiphoton imaging of Ca^{2+} responses in the superficial dorsal horn demonstrated limited direct activation of Flou-4 labeled cells by TLQP-62, yet consistent positive modulation of submaximal glutamate responses, which was blocked by the kinase inhibitor K252a. Further, treatment of spinal cord slices with 500nM TLQP62 increased the ratio of pTrkB/TrkB suggesting induction of BDNF signaling. We are studying the function of TLQP-62 in this context to better understand BDNF induced plasticity in pain, and elucidate regulators of its involvement for targeted pharmacologic intervention.

Title: Acyloxyacyl hydrolase modulates pelvic pain severity

Authors: *W. YANG[1], R. E. YAGGIE[1], M. JIANG[2], C. N. RUDICK[1], C. J. HECKMAN[2], J. DONE[1], A. J. SCHAEFFER[1], D. J. KLUMPP[1];

Abstract: Chronic pelvic pain causes significant morbidity to patients and is a bane to clinicians. Using a murine neurogenic cystititis model that recapitulates key aspects of interstitial cystitis/bladder pain syndrome (IC), we recently showed that pseudorabies virus (PRV) induces severe pelvic allodynia BALB/c mice, relative to C57BL/6 mice. Here, we report that a quantitative trait locus (QTL) analysis of PRV-induced allodynia in F_{2CxB} progeny identified a polymorphism on chromosome 13, rs6314295, significantly associated with allodynia (LOD=3.11). The mouse gene for acyloxyacyl hydrolase (*Aoah*), encoded near rs6314295, was induced in the sacral spinal cord of PRV-infected mice. AOAH-deficient mice exhibited increased vesicomoter reflex consistent with spontaneous bladder hypersensitivity in response to bladder distension and increased pelvic allodynia both in neurogenic cystitis and post-bacterial chronic pain models. AOAH deficiency resulted in greater bladder pathology and TNF production in PRV neurogenic cystitis, consistent with increased bladder mast cell activation.

AOAH immunoreactivity was detectable along the bladder-brain axis, including in brain sites previously correlated with chronic pelvic pain in humans. Finally, AOAH-deficient mice had significantly higher levels of urinary and bladder VEGF, an emerging marker of chronic pelvic pain in humans. These findings indicate that AOAH modulates pelvic pain severity and suggest that allelic variation in *Aoah* influences pelvic pain in IC.

Title: Alteration of neurovascular coupling in the rat spinal cord by systemic blood pressure changes evoked by nociceptive stimulation

Authors: *T. PAQUETTE[1], H. LEBLOND[2,4], M. PICHÉ[3,4];
[1]Dept. de biologie médicale, [2]Dept. d'anatomie, [3]Dept. de chiropratique, Univ. Du Québec À Trois-Rivieres, Trois-Rivières, QC, Canada; [4]Groupe de Recherche CogNAC (Cognition, Neurosciences, Affect et Comportement), Univ. du Québec à Trois-Rivières, Trois-Rivières, QC, Canada

Abstract: Neurovascular coupling is a physiological process involving a local hemodynamic response associated with surrounding neuronal activity. Functional magnetic resonance imaging (fMRI) uses this relation to infer neuronal activity by measuring magnetic signals related to changes in deoxyhemoglobin concentration. In general, this neurovascular coupling is relatively stable. However, in the rat primary somatosensory cortex, it is altered during nociceptive processing associated with increases in systemic blood pressure. The objective of this study was to examine neurovascular coupling in the rat spinal cord during nociceptive processing and to determine whether it is affected by systemic blood pressure, as in the primary somatosensory

cortex.
All experimental procedures were approved by the Université du Québec à Trois-Rivières animal care committee, and were in accordance with the guidelines of the Canadian Council on Animal Care. Ten male Wistar rats were anesthetized using isoflurane (1.2-1.5 %). Local field potentials (LFP) and spinal cord blood flow (SCBF) were recorded concurrently in the lumbosacral enlargement, where activity was evoked by sciatic nerve stimulation. The mean arterial pressure (MAP) was recorded continuously with a pressure transducer connected to a cannula inserted in the right carotid artery. Electrical stimulation was applied on the sciatic nerve as constant current at 11 intensities ranging between 0.01 and 9.6 mA. Physiological responses to electrical stimulation were recorded twice, once in intact conditions and once after a spinal transection at the C1 cervical segment of the spinal cord. Spinal transection at C1 was used to abolish MAP changes associated with the nociceptive stimulation in order to test the effect of MAP on neurovascular coupling.
In intact conditions, stimulation between 2.4 and 9.6 mA produced linear MAP changes that were paralleled by similar changes in SCBF, while LFP amplitude followed a similar trend at lower intensities but not at high stimulus intensities, for which it decreased. As expected, spinal transection almost abolished MAP changes. In these conditions, SCBF and LFP amplitude were strongly coupled.
These results imply that in studies involving nociceptive stimulation, estimation of neuronal activity in the spinal cord from the associated hemodynamic changes might lead to inaccurate results due to the influence of MAP on SCBF. This further implies that results from fMRI studies on pain should be interpreted with caution. Future studies should develop methods to control for MAP changes or alternative measures unaffected by MAP.

Title: Resting-state connectivity in the human spinal cord

Authors: *F. EIPPERT[1], Y. KONG[1], J. BROOKS[2], I. TRACEY[1];
[1]Univ. of Oxford, Oxford, United Kingdom; [2]Univ. of Bristol, Bristol, United Kingdom

Abstract: Spontaneous fluctuations in the functional magnetic resonance imaging (fMRI) signal have been extensively investigated in the human brain. Recently, this has been extended to the

human spinal cord (Barry et al., 2014; Kong et al., 2014), where the organization of these resting state signals has been characterized both spatially and temporally. Here, we aim to further this characterization by investigating resting-state connectivity both within and across spinal cord segments.
We acquired resting-state fMRI data of the cervical spinal cord from 20 healthy participants on a 3 Tesla MRI-scanner for 7.5 minutes. Initial data processing consisted of slice-wise motion correction, smoothing, physiological noise correction, high-pass filtering, and warping to standard space. Next, we extracted time-courses from spinal cord grey matter voxels and averaged these for each dorsal and ventral horn at each segmental level. Finally, we computed time-course correlations 1) within each spinal level between the dorsal and ventral horns and 2) across the different spinal levels and assessed their significance using non-parametric permutation testing.
We observed highly significant positive correlations between the ventral horns, as well as between the dorsal horns, although ventral horn correlations tended to be stronger. Connectivity between ventral and dorsal horns was significantly weaker, both within each hemi-cord and across. Regarding between-segment connectivity, we observed that correlations became significantly weaker the further two segments were apart. Importantly though, this distance-specific loss of connectivity differed between ventral and dorsal horns: dorsal horns showed significantly stronger inter-segmental connectivity than ventral horns – this effect persisted for a distance of three segments and only then vanished.
Our results replicate a previous observation of ventral horn and dorsal horn connectivity (Barry et al., 2014) – but while this previous finding relied on the advantages of ultra-high field (7 Tesla) data acquisition, we here show that it is possible to observe this connectivity profile also at the clinically relevant field-strength of 3 Tesla. Building on earlier resting-state spinal cord studies (Barry et al., 2014; Kong et al., 2014) we also investigated inter-segmental connectivity, and observed a distance-dependent reduction of functional connectivity that differed between ventral and dorsal horns. It will be interesting to investigate whether the integrity of inter-segmental connectivity can be harnessed in a clinical situation, e.g. when investigating recovery after spinal cord injury.

Title: Utilizing mouse glabrous skin-specific tactile behavior assays to dissect innocuous touch circuits of the spinal cord dorsal horn

Authors: *A. TOLIVER, L. L. OREFICE, V. ABRAIRA, D. GINTY;
Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Innocuous touch is detected and processed by neural circuits involving specialized dorsal root ganglion neurons and their respective post-synaptic partners in the spinal cord dorsal horn, comprised of an array of local interneurons as well as long-range projection neuron populations. An obstacle in understanding innocuous touch circuitry is a lack of behavioral assays specific to innocuous touch that may be used for genetic circuit dissection in mice. To this end, we have utilized a battery of behavioral paradigms that enables assessment of the contributions of glabrous skin innervating sensory neurons to tactile behaviors. The tactile assays consist of Von Frey and the brush test, which we use to assess responsivity to non-painful, innocuous touch stimuli. We also assayed the contribution of glabrous skin-innervating sensory neurons using sensorimotor paradigms, including rotarod, balance beam, wire hang, Treadscan gait analysis, and the horizontal ladder test. Nociceptive and thermoreceptive control tests, including Hargreaves and the hot plate test, were used for comparison.
To determine baseline dependency on sensory innervation of glabrous skin using these behavioral measures, we topically applied 20 microliters of 5% lidocaine to the glabrous skin, 20 minutes prior to each behavioral assay. The use of topical lidocaine allows us to determine the cutaneous sensory neuron dependence of the different measures of somatosensory function. This approach will inform us of the utility of tactile and sensorimotor behavioral paradigms for measuring glabrous skin somatosensory functioning. Preliminary findings using the Von Frey and brush tests indicate hyposensitivity following topical lidocaine application to the paws, compared to a control saline gel application. Gait analysis revealed a decrease in stride time following topical lidocaine application to the paws.
Current studies are focused on assessing the contribution of spinal cord interneurons to tactile-based behaviors. We are employing intersectional Cre/Flp genetic tools and a dual recombinase tetanus toxin line, to specifically silence lineages of RorB and CCK expressing interneurons exclusively in the spinal cord. These animals are then tested on the aforementioned battery of behavioral assays in order to determine the effect of silencing various spinal cord interneuron subtypes on somatosensory behaviors. Utilizing multiple behavioral assays will enable a quantitative assessment of the contributions of glabrous skin-innervating sensory neurons to innocuous touch perception and may reveal spinal cord interneuron subtype-specific roles for somatosensory-related behaviors.

Title: Synapse specificity in peripheral sensory neurons

Authors: *B. A. COPITS, K. C. MCKENZIE, K. M. WILSON, S. K. VOGT, J. P. GOLDEN, R. W. GEREAU, IV;
Pain Center, Dept of Anesthesiol., Washington Univ. Sch. of Med., Saint Louis, MO

Abstract: Rapid processing and integration of sensory information is critical for the survival of an organism, and permits the discrimination of a tremendous variety of external inputs. Noxious stimuli must be separated from less offensive sensations to ensure potentially dangerous environmental conditions are avoided. However these sensory circuits can become activated in the absence of noxious events following nerve trauma or inflammation, leading to chronic pain states. While we have learned a great deal about the plasticity of nociceptive transmission, we possess a limited understanding of the underlying molecular mechanisms which orchestrate the formation of these neural circuits, and the synaptic adaptations that lead to states of altered sensory perception.

Transsynaptic interactions between presynaptic neurexins (Nrxns) and postsynaptic neuroligins (Nlgns) have been suggested to impart a combinatorial code for neural connectivity. In the peripheral nervous system, sensory neurons are unable to form synapses with each other in culture, suggesting that they lack key signals involved in determining appropriate synaptic partners. To understand the mechanisms governing synaptic connectivity in the somatosensory system, we co-cultured fibroblasts expressing a variety of cell adhesion molecules with both mouse and human sensory neurons. We found that expression of postsynaptic Nlgn isoforms strongly promoted functional hemi-synapse formation, while neurexins were ineffective at inducing presynaptic contacts. Overexpression of Nrxns or Nlgns was unable to induce autaptic connections in these neurons, suggesting that both attractive and repulsive mechanisms exist to specify synapse formation.

Both *Nrxns* and *Nlgns* are subject to extensive alternative splicing, generating thousands of different isoforms, which can specify interactions with various transsynaptic adhesion molecules. Alternative splicing of *Nrxns* at one site in particular, SS4, shifts binding affinities between Nlgns and other postsynaptic partners including leucine-rich repeat transmembrane proteins (LRRTMs) and cerebellins in cortical and cerebellar neurons. We found that the alternative

splicing of all *Nrxn* isoforms is markedly different in spinal and sensory neurons from both mice and humans, compared to those in the cortex. This suggests that the somatosensory system may use these adhesion molecules in functionally distinct ways to specify synaptic connectivity. We are currently focusing on how these interactions might influence synaptic transmission in the spinal cord and regulate sensory behaviors.

Title: Characterization of Zic2+ dorsal spinal neurons as potential integrators of sensory and motor circuits

Authors: *S. PAIXAO, A. ESCALANTE, R. KLEIN;
Max Planck Inst. of Neurobio., Martinsried, Germany

Abstract: The dorsal spinal cord is the integrative center that processes and transmits a variety of somatosensory modalities such as touch, pain, temperature and itch. It is also becoming clear that the integration of spinal microcircuits, sensory feedback and supraspinal descending circuits necessary for accurate motor performance occurs in the dorsal spinal cord. Nevertheless, the molecular identity and specific function of individual interneuron classes in this circuit is largely unknown.
In our previous work, we identified a population of dorsal spinal neurons marked by the co-expression of EphA4 and the transcription factor Zic2, which we suggested represents a subpopulation of postsynaptic dorsal column (PSDC) neurons (Paixao *et al*., Neuron, 2013). We have recently developed an inducible Zic2-Cre line to genetically target these neurons. Zic2+ neurons reside in laminae III-V in a medial position surrounding the dorsal funiculus, where they partially colocalize with the recently described markers of lamina V interneurons Tcfap2β and SatB1/2. Contrary to what was described for these two populations, Zic2 neurons seem to be exclusively excitatory. Intraspinal cord trans-synaptic rabies virus experiments have confirmed that Zic2 neurons receive sensory input primarily from cutaneous afferents. Preliminary retrograde tracing experiments, indicate that at least a subset of Zic2 neurons send projections to the cuneate nucleus in the medulla, suggesting that Zic2 likely represents a molecular marker of PSDC neurons and could be involved in discriminative touch sensation.

Furthermore, rabies virus experiments have also highlighted that Zic2 neurons receive inputs from ventral spinal cord interneurons and several descending brain centers involved in motor control, like the motor cortex and numerous brainstem nuclei, raising the interesting possibility that Zic2 dorsal spinal neurons could play a role in the integration of sensory and motor spinal circuits.
Ongoing efforts are aimed at investigating the *in vivo* activity of Zic2+ spinal cord neurons during somatosensory stimulation and their requirement for specific motor outputs.

Title: Somatosensory enhancement of the lips size increases tactile acuity

Authors: *E. AMBRON[1], M. COYLE[2], H. B. COSLETT[2];
[1]Univ. of Pennsylvania Sch. of Med., Philadelphia, PA; [2]Perelman Sch. of Med. at the Univ. of Pennsylvania, Philadelphia, PA

Abstract: Magnifying the view of a body part is known to improve tactile acuity. For the fist time, we tested the effect of somatosensory magnification of a body part on tactile accuracy by applying an anesthetic cream on participants' lips. Tactile discrimination markedly improved after the application of the cream and decreased when the cream was removed. This effect was observed only in participants who perceived an increase of the lips size with the application of the cream. The magnification of body part has beneficial effect on tactile discrimination, not only if it is induced by vision but also in the somatosensory modality.

Title: Neural signatures of vibrotactile stimulation at 7T MRI and links to autism traits

Authors: *L. K. BRYANT[1], L. CHEN[2], A. MISHRA[2], C. J. CASCIO[3], M. T. WALLACE[4]; [2]Radiology, [3]Psychiatry, [4]Hearing & Speech Sci., [1]Vanderbilt Univ., Nashville, TN

Abstract: It is well known that individuals with autism spectrum disorders (ASD) can display sensory sensitivities across modalities, yet the majority of sensory research in ASD focuses on vision and audition. The sense of touch is comparatively understudied in ASD, despite its central role in early social development and strong links between aberrant tactile processing and clinical symptoms of autism (Foss-Feig et al., 2011). However, the neural basis of such aberrations is not understood. Atypical tactile sensory responsiveness may arise from deviations in sensory cortical organization, as suggested by a magnetoencephelopgraphy (MEG) study of cortical representations of the thumb, lip, and index finger in the primary somatosensory cortex (S1) (Marco et al., 2012). However, MEG lacks the precise millimeter spatial resolution afforded by high-field, 7-Tesla functional magnetic resonance imaging (7T fMRI) to localize aberrant somatotopy to functionally distinct S1 subregions. Such resolution could reveal previously undetected relations between tactile perception, somatotopic organization, and social-communication abilities affected by ASD. Using a combination of psychophysics and high resolution fMRI, we first examined vibrotactile detection ability at the fingertip in neurotypical adults, and then delivered high intensity (200 Hz, 400um) vibrotactile stimulation randomly to the left digits 2-4 during 7T fMRI. Preliminary results suggest the ability to replicate single digit separation (Stringer et al., 2014) using a novel method of vibrotactile stimulation. In addition to quantifying inter-digit distance, ongoing work includes the correlation of psychophysical data with self-report questionnaires targeting behavioral patterns of sensory responsiveness (Sensory Profile (Dunn, 1999)) and subclinical autism traits in daily life (Social Responsiveness Scale-2 (Constantino, 2012)). Emerging relations suggest that increased dynamic range of vibrotactile detection is associated with increased sensation seeking, and with decreased social motivation, in daily life. The ultimate goal of this research is to strengthen our understanding of how the brain

processes tactile information and provide an empirical basis for advancing the treatment of sensory-based symptoms in autism.

Title: Transcranial oscillatory stimulation at individual somatosensory alpha frequency specifically decreases network centrality of S1

Authors: C. GUNDLACH[1], T. NIERHAUS[3], P. RAGERT[2], M. MUELLER[1], A. VILLRINGER[3], *B. S. SEHM[3];
[1]Psychology, [2]Inst. for Gen. Kinesiology and Exercise Sci., Univ. of Leipzig, Leipzig, Germany; [3]Max Planck Inst. For Human Cognitive and Brain Sci., Leipzig, Germany

Abstract: Ongoing alpha oscillations might reflect aspects of functional specific perceptual inhibition. In a previous study we found that transcranial alternating current stimulation applied at an individual somatosensory mu alpha frequency (mu-tACS) induces a phasic decrease of somatosensory perception, suggesting a causal interference with somatosensory processing. Here, we aimed at investigating underlying functional brain changes on a whole brain level by concurrent mu-tACS and resting-state functional MRI. Based on the suggested inhibitory nature of alpha, we hypothesized that mu-tACS decreases functional connectivity of the primary somatosensory cortex.
In a randomized single-blind crossover design, 20 healthy subjects underwent 2 separate sessions of functional magnetic resonance imaging during either 6 minutes of mu-tACS applied over the somatosensory cortex or sham stimulation. Eigenvector centrality mapping (ECM) was used to investigate mu-tACS-induced changes (as compared to sham stimulation) in functional connectivity across the whole brain.
In line with our hypothesis, our results demonstrate that mu-tACS induces a specific decrease in whole-brain centrality of the left primary somatosensory cortex (whole brain analysis, $p<.05$, cluster corrected, voxelwise threshold: $z>2.576$, cluster size: 59 voxels).
These findings (i) add causal evidence to previous correlative findings and underline the inhibitory nature of functional relevant alpha rhythms, and (ii) demonstrate the potential of

transcranial stimulation methods to specifically modulate brain function when adjusting the stimulation to intrinsic oscillatory frequencies.

Title: The event-related somatosensory responses to long lasting gentle touch measured with magnetoencephalography

Authors: *E. J. ERIKSSON[1], D. LUNDQVIST[2], J. SCHNEIDERMAN[3], V. JOUSMÄKI[4,2], J. WESSBERG[1];
[1]Inst. of Neurosci. and Physiol., Sahlgrenska Academy, Univ. of Gothenburg, Gothenburg, Sweden; [2]NatMEG, Dept. of Clin. Neuroscience, Karolinska Institutet, Solna, Sweden; [3]MedTech West and the Inst. of Neurosci. and Physiol., Sahlgrenska Academy, Univ. of Gothenburg, Gothenburg, Sweden; [4]Aalto NeuroImaging, Dept. of Neurosci. and Biomed. Engineering, Aalto Univ., Espoo, Finland

Abstract: The sense of touch is conveyed from the skin to the brain via fast myelinated Aβ afferents and slow unmyelinated C tactile (CT) afferents. Aβs signal discriminative properties of tactile input whereas CTs are believed to code for pleasantness of touch. CTs only exist in hairy skin and single unit recordings show that CT firing is highest when a soft object, e.g., a brush, strokes the skin at a velocity of 3 cm/s. Functional magnetic resonance imaging (fMRI) studies show that CTs project to the insula but not to primary or secondary somatosensory cortices. Nevertheless, how CTs contribute to pleasantness of touch is currently not known. Touch to the hairy skin activates both the fast Aβs and slow CTs; hence tactile sensory perception requires the integration of both types of mechanosensation.
In this study, combined MEG and electroencephalography (EEG) was recorded in 19 healthy volunteers (22-45 years) with an Elekta Neuromag® TRIUX system during 200 ~3 cm/s brush

strokes using a custom-made MEG-compatible brush robot that provided precise and replicable timing, length, and velocity of brush stroke stimuli. A multifilament fiber-optic sensor was attached alongside the bristles of the brush, marking the timing of brush contact with the skin, and a load cell was used to measure the pressure applied on the skin.
Two conditions were performed. In the first condition, brush strokes were delivered to the left upper arm proximal to the elbow. In the second condition, brush strokes were delivered to the left forearm proximal to the wrist. Based on previous EEG work we expected that CT-related brain activity should have a very late onset (>400 ms post stimulation) due to slow peripheral conduction velocity. Altering the stimulation sites i.e., brushing on the upper arm vs the forearm should give rise to a time-delay of CT-related brain activity with approximately 200 ms between the two conditions.
Preliminary results show clear and consistent somatosensory evoked fields (SEFs) to the onset and offset of the brush strokes i.e., contact with the skin, and time-frequency analyses show patterns of early-onset beta and alpha de-synchronization that are most prominent over parietal areas. These patterns reflect the signalling from fast Aβ afferents. Moreover, there are indications of a very late (onset >400 ms post stimulation) CT-related SEF and alpha synchronization over midline parietal sensors, but the postulated time shift between the two conditions is not consistent over subjects.

Title: Dynamic cortical network processing of a somesthetic stimulus as revealed by magnetoencephalography (MEG)

Authors: *A. C. LEUTHOLD, C. CHORN, A. P. GEORGOPOULOS;
Dept Neurosci, Univ. Minnesota, Minneapolis, MN

Abstract: The dynamic interactions among cortical areas involved in processing somesthetic stimuli over time are not well understood. In this study we used MEG to explore the time-evolving neural interactions following the application of a single stimulus on the right finger.

Healthy participants lay supine with eyes closed, and the right arm to the side and angled slightly away from the body. The palm was up and the stimulus delivered to the right index finger near the tip. The stimulus was an air driven membrane in contact with the skin. The Somatosensory Stimulus Generator (4D Neuroimaging, San Diego, CA) was set to a pressure of 100 kPa and a duration of 20 ms, which produced a reliably perceived stimulus. The stimulus was repeated 100 times with a long (relative to the duration of the stimulus) interstimulus interval (ISI) of 10 seconds. Data were collected with a Magnes 3600 MEG instrument (4D Neuroimaging, San Diego, CA). The system has 248 channels using 1st order axial gradiometers detection coils, with an on-center separation of just under one inch. The MEG signals was recorded continuously with a bandwidth 0.1 to 400 Hz and a sampling rate of 1017.25 Hz (i.e. every 0.974 s). The resulting data file consisted of 248 (sensor) columns and ~10000 rows (every 0.974 s, for 10 s). For each stimulus, MEG time series were prewhitened using a (50,1,3) ARIMA model that we have found most appropriate for such data (Mahan et al., Proc 14th Python In Science Conference, Scipy, Austin, TX, 2015). Next, the crosscorrelation function (CCF; ± 50 lags, corresponding to ± 48.7 ms) was computed for all 30628 sensor pairs and analyzed as a function of sensor location and distance between pairs. The analysis revealed a systematic variation in the values of crosscorrelations at different lags, reflecting lag-dependent strength and polarity of neural interactions following a single stimulus. Results from the 100 independent single stimulus presentations were compared among themselves and summary statistics computed to derive an expected average, time-evolving, dynamic cortical processing network, including strength, polarity and timing of interactions among its elements.

Title: fMRI representation of erotic vs non-erotic genital self-stimulation; attenuation during the post-orgasmic refractory period in men

Authors: *K. ALLEN[1,2], B. KOMISARUK[3];
[1]PWP, Princeton Univ., Princeton, NJ; [2]Psychology, [3]Rutgers, Newark, NJ

Abstract: The neural mechanism underlying the inability of men to have rapid, consecutive orgasms (the "refractory period") is unknown. While prior studies have analyzed neural responses to erotic stimuli, none has compared erotic and prosaic touch, or *imagined* erotic and prosaic touch before/after orgasm. Thus the present study (in healthy men), mapped fMRI responses to genital self-stimulation, self-patterned to feel "erotic" versus "prosaic", prior to orgasm and during the post-orgasmic "refractory" period. Prior to orgasm, a number of brain regions were more active during "erotic" than "prosaic" self-stimulation including the operculum (SII), anterior cingulate, and insula, and we confirmed our previous finding that genital self-stimulation activated the paracentral lobule (i.e., the "genital sensory cortex" of the "Penfield homunculus"). Just "imagining" genital stimulation prior to orgasm also activated the paracentral lobule. By contrast, during the post-orgasmic refractory period, neither the physical nor imagined genital self-stimulation significantly activated the paracentral lobule, whereas the fMRI response to a finger tapping control, was not affected. Moreover, during the refractory period (compared to the orgasm phase), we observed a significant increase in activity of the rostral temporal cortex and the septum. *Conclusion*: As lesions of the rostral temporal lobe induce the Kluver-Bucy "hypersexuality" syndrome, and lesions of the septum have been described as disinhibiting sexual responses in humans and animals*, the activation of these two regions during the refractory period, combined with the attenuation of genital sensory responses in the paracentral lobule during the refractory period, suggest the existence of an active neural inhibitory mechanism underlying the refractory period.

Title: Neural activity in the secondary somatosensory cortex during the tactile working memory delay period

Authors: *Y. YU[1], J. YANG[1], H. SHIGEMASU[2], H. KADOTA[2], K. NAKAHARA[2], H. YAMAMOTO[3], Y. EJIMA[1], J. WU[1];
[1]Okayama Univ., Okayama, Japan; [2]Kochi Univ. of Technol., Kochi, Japan; [3]Kyoto Univ., Kyoto, Japan

Abstract: The human secondary somatosensory cortex (SII) is a cytoarchitectonic region located in the bilateral parietal operculum. Previous non-human primate studies indicated that the SII has sensory-related functions involved in receiving and integrating somatosensory information and mnemonic-related functions linked to the processing of tactile working memory (TWM). However, the mnemonic-related functions of the human SII in the context of TWM processing remain unclear. In the present study, we used delayed tactile orientation-matching tasks (separated by up to 16-s delays) to determine whether the human SII delay period activity reflects the retention of sensory information or the rehearsal of memory traces in TWM. Twenty-six healthy, right-handed subjects (21 males and 5 females; mean age 22.6 years) participated in the fMRI experiment. Participants were asked to memorize a first grating orientation (GO1) pressed onto their right or left middle finger and then to judge whether this was the same as or different from a second tactile grating orientation (GO2) after a random delay interval between 2 s and 16 s. To confirm the activation tendency in the bilateral SII during each delay period, we conducted ROI analysis in the bilateral SII and used the SPM12 to extract BOLD signals from whole anatomical areas of the bilateral OP1 and to calculate percent signal changes. The results showed that the bilateral SII regions were significantly activated by both the GO1 and GO2 phases and that the positive activation related to GO1 extended to the earliest delay period (i.e., the first 2 s). However, the activity of SII differed from other memory retention related areas, such as the persistent delay activity in dorsal prefrontal cortex, which is thought to reflect the sustained internal representations of information in the WM. By contrast, the bilateral SII showed an initial increase in activity followed by decreased activation during the delay period (peak at 12-s temporal interval). As mentioned above, memory retention is often assumed to depend on the persistent neural activity, but recent evidences suggest that the constantly changing delay neural activity seems to reflect the attention-based rehearsal of memory traces. The present result suggests that tactile memory traces are initially sustained in the SII and are subsequently transferred to areas of the prefrontal and parietal areas for sustained memory processing. Therefore, the SII may be linked to the sustained engagement of an attention-based rehearsal mechanisms occurring during the delay period.

Title: A new simple objective method to evaluate haptic perception

Authors: *Y.-T. TSENG[1], N. ELANGOVAN[2], J. KONCZAK[2];
[1]Human Sensorimotor Control Lab, Sch. of Kinesiology, [2]Sch. of Kinesiology, Univ. of Minnesota Twin Cities, Minneapolis, MN

Abstract: Haptic perception refers to the ability to perceive an object's shape and texture by active touch, typically by exploring its surfaces by our hands. Existing haptic perceptual assessment techniques often either require specialized laboratory equipment and/or provide not very precise and reliable measurements. Psychophysical somatosensory evaluation has been proven to yield reliable and precise for proprioception but not has been extensively utilized in haptic assessments. This proof-of-concept study evaluated haptic acuity for perceiving object curvature in healthy young adults. The portable assessment tool consisted of 28 small objects of curvature ranging from 0 to 6.6 x 10^{-3} mm^{-1} (lateral deviation (LD): 0 - 34 mm). Using a 2-forced-choice paradigm, 11 healthy young adults (Age, mean ± SD: 23.2 ± 3.1 years) performed two tasks that tested the abilities to 1) detect curvature (*detection task*), and 2) discriminate between two curved surfaces (*discrimination task*). In both the tasks, participants moved the index finger of their dominant hand over the curved surface of a test block with vision occluded. Detection involved identifying whether a block was curved. Discrimination required the exploration of two blocks (standard had LD = 20 mm) and to identify which block was more curved. During testing subsequent stimuli were selected using an adaptive algorithm (Ψ-marginal method) to reduce testing time. After testing, psychophysical thresholds were obtained by fitting a logistic Weibull function to the response data. Test duration for the detection task ranged from 4-6 mins, while the discrimination task required 8-10 mins. Mean haptic threshold for detecting curvature from a straight surface (LD = 0 mm) was 3.72 ± 1.43 mm (Range: 1.76 - 5.97mm). Mean haptic discrimination threshold was 2.85 ± 0.47 mm (Range: 2.06 - 3.77mm). CONCLUSION: The results establish the feasibility and practicality of this novel method to objectively assess haptic perception function. A larger sample size is necessary to establish a normative database against which clinical populations can be compared. Once these steps are completed, the test has the potential to be used in clinical practice

Title: H-coil rTMS to S2 and insula affects only S2; alters touch intensity but not pleasantness

Authors: L. K. CASE[1], E. A. RICHARDS[1], C. M. LAUBACHER[1], H. OLAUSSON[2], P. A. SPAGNOLO[3], B. WANG[1], *M. C. BUSHNELL[1];
[1]NCCIH/NIH, Bethesda, MD; [2]Linköping Universiy, Linköping, Sweden; [3]NIAAA/NIH, Bethesda, MD

Abstract: Numerous studies point to divergence in the neural processing of touch discrimination and affect. In line with this, we recently reported that repetitive transcranial magnetic stimulation (rTMS) inhibition of S1 decreased tactile discrimination and increased touch intensity but had no effect on touch pleasantness (Case et al., 2016). In contrast, the posterior insula (pINS) has been implicated in affective touch, in part because it receives projections from c-tactile fibers, sensory afferents whose firing rate correlates with the perceived pleasantness of gentle touch (e.g. Löken et al., 2009).

In the current study, we probed the causal role of S2 and pINS in perception of touch intensity and pleasantness. We used an H-coil designed for deep brain stimulation to target pINS with 1-Hz inhibitory rTMS. Because S2 lies superficially above pINS, S2 and pINS were necessarily stimulated together. We hypothesized that S2-pINS stimulation would decrease perceived touch intensity and touch pleasantness but would not affect sensory discrimination.

Nineteen healthy adults (8 male) completed two 20-minute sessions of 1-Hz rTMS on separate days. One session targeted right hemisphere S2-pINS and the other targeted the vertex (control). Before and after rTMS, subjects rated the intensity and pleasantness of gentle touch (3 and 30 cm/s; palm and dorsum of left hand) and performed a 2-point discrimination task (dorsum). Subjects also completed an fMRI scan while receiving gentle touch to validate H-coil inhibition of S2-pINS.

As predicted, rTMS to S2-pINS decreased ratings of touch intensity (compared to the vertex; $F(1, 132.3 = 2.89)$, one-tailed $p = 0.046$). However, rTMS did not alter ratings of touch pleasantness *(*$F(1, 132.6 = 0.90)$, $p = 0.34$) or affect sensory discrimination ($F(1, 196 = 0.00)$, $p = 1.00$). A whole-brain analysis ($N = 16$) showed no differences in BOLD response to brushing between rTMS sessions, but a region of interest analysis found reduced S2 response to brushing after S2-pINS rTMS (compared with vertex; $t(16) = 1.89$, one-tailed $p = 0.04$). Neither pINS nor the untargeted right hemisphere S1 showed any effect of rTMS ($t(16) = 0.60$, $p = 0.56$; $t(16) = 0.78$, $p = 0.45$).

Our study is one of the first attempts to target the insula with an H-coil. Together, our behavioral and fMRI results suggest that 1-Hz rTMS to S2-pINS reduced activity in S2 and decreased perceived touch intensity, demonstrating the causal role of S2 in touch intensity perception. In contrast, we were unable to detect any effect of rTMS on pINS or on touch pleasantness. This study confirms the role of S2 in touch intensity but not touch discrimination, and it highlights the challenges of reaching the insula with rTMS.

Title: Spinal projection pathways of human C-tactile afferents

Authors: *A. MARSHALL[1,2,3], M. SHARMA[4], K. MARLEY[5], F. MCGLONE[2];
[1]Salford Royal Hosp. Fndn. Trust, Salford, United Kingdom; [2]Liverpool John Moores Univ., Liverpool, United Kingdom; [3]Univ. of Manchester, Manchester, United Kingdom; [4]The Walton Ctr., Liverpool, United Kingdom; [5]Univ. Hosp. Aintree, Liverpool, United Kingdom

Abstract: Introduction: Microneurographic and psychophysical studies have established the existence of a system of low threshold mechanosensitive C-fibres, so called C-Tactile (CT) afferents, in human hairy skin. CT afferents show velocity dependent spiking in response to gentle stroking touch and are hypothesised to encode the pleasant nature of touch. Currently the CT ascending spinal projection pathways in humans are unknown. Whilst their putative homeostatic function and likely primary cortical target (posterior insula) suggest spinothalamic transmission there is in rodents also evidence of significant integration of primary mechanosensitive information across all nerve classes in the dorsal horn. To address this we assessed for alterations in pleasant touch following therapeutic spinothalamic tract ablation.Methods: Nine patients with intractable unilateral cancer related pain underwent assessment of discriminative and affective touch before and after anterolateral C1/C2 cordotomy. Stroking at velocities optimal (3cm/s) and sub-optimal (0.3 and 30cm/s) for CT afferent activation were performed on the dorsal aspect of the right and left forearm. Patients were asked to rate the pleasantness of touch. Absolute pleasantness ratings and the CT preference index ([rating for 3cm/s x 2 - ratings for 0.3cm/s + 30cm/s] / 2) were calculated. Discriminative touch was assessed using two-point discrimination, tactile detection thresholds and graphesthesia. Results: Ablation of the spinothalamic tract was confirmed by total or sub-total loss of cold and warm sensation contralateral to the cordotomy as well as the complete or partial abolishment of the cancer related pain. Discriminative touch showed no significant difference between lesioned and non-lesioned sides and was unaltered by cordotomy. Pleasantness ratings for CT optimal touch were significantly higher across all conditions ($p<0.005$). A small but significant ($p<0.05$) reduction in CT preferred touch was seen following cordotomy on the side contralateral to lesioning. There was a significant reduction in CT preference index ($p<0.005$) on the side contralateral to cordotomy. No change was seen on the side ipsilateral to lesioning. Conclusion: The alterations in the perception of CT optimal touch contralateral to cordotomy lend support to hypothesis that information salient to affective touch is transmitted in the spinothalamic tract. However, unlike the dramatic changes in temperature and nociception, the effects are relatively

subtle which could reflect spinal integration, incomplete ablation of spinothalamic pathways or top-down processing of dorsal column cortical input.

Title: Is ineffective processing of sensory information linked to rewired pathways for sensory-motor input? A functional connectivity study on Nerve Growth Factor Beta mutation carriers.

Authors: *H. VAN ETTINGER-VEENSTRA, I. PERINI, I. MORRISON;
Linköping Univ., Linköping, Sweden

Abstract: Deficits in stimulus-appropriate behavioral responses to pain and affective touch caused by a reduction in thin-diameter sensory afferents (C nociceptors and C-tactile afferents) are linked to a rare mutation (R221W) of the human nerve growth factor beta (NGFB). Mutation carriers show more pain and pleasant touch indifference compared to controls, with high individual variability [1,2]. Following findings of [2,3] suggesting a vital executive role for midcingulate cortex (MCC) in context-sensitive behavioral responses to pain, we investigated functional connectivity differences in heterozygous carriers of the R221W mutation. **Methods**: Resting state fMRI of 10 min on 12 R221W carriers and 12 controls at a Philips 3T Ingenia, SENSE head coil, single-shot EPI gradient echo, TR/TE/FA/resolution = 2s/30ms/30°/3.4mm^3, whole-brain coverage. Preprocessing in SPM12 for realigned, normalized and smoothed images (8mm FWHM). ROI-to-ROI functional connectivity analysis (in CONN-toolbox; atlas-based and a 10mm radius sphere at MCC) at $p<0.05$ FDR corrected. For 6 R221W carriers, a quantification of C-fiber density was obtained using corneal confocal microscopy. **Results**: R221W carriers showed increased connectivity between nucleus accumbens (NAc) and left temporal fusiform gyrus compared to controls. In the R221W group, lower C afferent density was associated with increased connectivity between MCC and sensorimotor cortices on the pre- and postcentral gyri. Carriers, but not controls also showed increased connectivity between MCC and putamen, left temporal fusiform and right lingual gyrus. **Discussion:** NAc is suggested to integrate cognitive and affective information to engage in action selection [4]. Fusiform gyrus contains a multisensory input region [5] modulating emotional responses [6]. Interestingly, no altered

functional activation in NAc was found during pain for the R221W group (post-hoc analysis, see [2] for dataset). The R221W carriers may have a functional rewiring involving basal ganglia, sensorimotor regions and MCC, and fusiform gyrus. As a compensatory mechanism, MCC and sensorimotor connections might be increased as an effect of lack of reduced sensory afferent input, and reflected in compensatory functional connectivity between other affective modulatory regions, as well as and altered behavioral responses to pain [2]. **References:** [1] Morrison et al. Title: The influence of testosterone on pain perception differences between males and females exposed to the cold pressor test

Authors: M. ARCHEY[1], S. GARDON[1], E. CROCKETT[3], K. GOLDEY[1], *J. A. BOYETTE-DAVIS[2], *J. A. BOYETTE-DAVIS[2];

Abstract: Pain is a complex and demanding sensation that affects millions every year and represents one of the leading causes for health care intervention and costs. Research indicates that women are more susceptible to pain than men, both in acute and chronic forms. While the reasons for these sex differences are not well defined, it is thought that hormones may have a modulating effect. Indeed, several lines of literature indicate that estrogen and progesterone are especially important in female pain responding. Interestingly, testosterone has not received adequate consideration in this literature, despite the fact that females have lower levels than males. In the present study, saliva samples were collected from males and females completing a cold pressor test (CPT) and analyzed for testosterone concentration levels. The CPT is a common tool used for experimentally inducing pain, in which healthy participants place their hand in a container of very cold water (2^0 C) and report the level of pain perceived using a visual analog scale. Fifty-six participants (16 males, 40 females) completed the CPT and provided saliva that was later analyzed with hormone immunoassay kits. The results support previous findings that females have lower pain thresholds than males which can be explained in terms of gender

differences in salivary testosterone levels. This study therefore adds to the body of literature investigating the mechanisms of pain, and has interesting implications for possible treatments for pain.

Title: Neural correlates of distorted body representations underlying tactile distance perception

Authors: *L. TAMÈ[1], M. I. SERENO[2], R. SADIBOLOVA[1], M. R. LONGO[1];
[1]Dept. of Psychological Sci., Birkbeck, Univ. of London, London, United Kingdom; [2]Univ. Col. London/Birkbeck, Univ. of London, London, United Kingdom

Abstract: Tactile distance perception is believed to require that immediate afferent signals be referenced to a stored representation of body size and shape (the *body model*). For this ability, recent studies have reported that the stored body representations involved are highly distorted, at least in the case of the hand, with the hand dorsum represented as wider and squatter than it actually is. Here, we investigated whether we can elicit the same type of distortions by using an MR-compatible system for somatosensory stimulation (airpuff) and in turn define the neural basis of this phenomenon. In each trial, participants received sequential tactile stimulations via airpuff on two out of nine points on a square grid (5x5cm) on the dorsum of their hand. In a behavioural experiment (Exp. 1) they estimated the distance between the two points by adjusting the length of a visually-presented line on the screen. The technique of multidensional scaling (MDS) was used to reconstruct a perceptual map of tactile space. Analysis of spatial distortion using Procrustes alignment showed that maps were stretched in the mediolateral hand axis. These behavioural results are consistent with previous studies, in which there were clear biases to overestimate distances oriented along the mediolateral axis of the hand compared to the proximodistal axis. In order to determine the neural correlates of these body distortions, we performed an fMRI study (Exp. 2) - functional scans in a random block design and a tactile localiser - in which the same nine points were this time individually stimulated. For each participant, we measured the response pattern generated by each stimulated point by contrasting

each stimulation condition (e.g., repeated stimulation of point 1, 2, etc) against baseline. In order to relate the representations between the different points and to computational models, we compare response-pattern dissimilarity matrices in several regions of interests (ROIs). ROIs were defined using both anatomical (i.e., probabilistic map) and functional (i.e., functional localiser) criteria at individual level. Similar to the behavioural experiment, we used MDS to reconstruct maps of the neural representation of tactile space using the values from the dissimilarities matrices. We expect to find a similar pattern of results (i.e., distortions) in the brain areas, of the tactile representation processing, that generate the distorted body representations we found in the behavioural experiment.

Title: Functional MRI responses in monkey somatosensory cortex during grasp and touch observation.

Authors: S. SHARMA, *K. NELISSEN;
Dept. of Neurosciences, KU Leuven, Leuven, Belgium

Abstract: Background: Numerous studies in human and non-human primates have shown that merely observing other's actions can modulate activity in the observer's motor cortices. Similar automatic responses have also been suggested in human somatosensory cortices when actions involving touch are observed, with some studies suggesting an involvement of primary S1 (Pihko et al., 2010) and/or secondary S2 somatosensory regions (Keysers et al., 2004), while others emphasize the involvement of more posterior parietal regions (Chan and Baker, 2015). Methods: Here we investigated brain responses during grasp or mere touch observation using contrast-enhanced functional MRI (Siemens 3 Tesla) in monkeys. We first localized hand representations of S1 and S2 in three macaques (male, 4-6 kg) by stimulating the hand region with a brush in anaesthetized fMRI scans. In subsequent awake experiments, we scanned these monkeys while they observed videos of various actions displaying different instances of touch (grasping or

simple touching of objects or hands). Control videos depicted the same actors performing reaching movements towards the same objects/hands without interacting with them. In an additional experiment, videos of different actions (grasp and touch) towards a hand displaying obvious skin displacements (Ferri et al., 2015) were also presented. Results: A region-of-interest analysis of S1 and S2 hand regions responding during passive tactile stimulation did not yield significant fMRI signal increases during either grasp or touch observation (compared to controls), nor did observing actions showing obvious skin displacements. Posterior parietal regions, including AIP and PFG, as well as premotor F5, in addition to early visual and STS regions, showed significant responses during observation of both grasp and mere touch (compared to controls). Interestingly, a more anterior S2 sector, that mainly responds during monkeys' active hand manipulation tasks like grasp execution (Nelissen and Vanduffel., 2011; Ishida et al., 2013), showed consistent responses during touch observation, particular those actions involving a grasp. Conclusion: Our results suggest that somatosensory sectors of monkey S1 and S2 that respond significantly during passive tactile stimulation do not show modulations during grasp and touch observation. However, a more anterior portion of S2 responds during touch observation. These observations are in line with recent evidence of single-cell responses in macaque S2 during human action observation (Hihara et al., 2015).

Title: Unravelling somatotopy in time

Authors: ***P. AVANZINI**[1,3], F. CARUANA[2,3], V. PELLICCIA[4], L. TASSI[4], G. LO RUSSO[4], G. A. ORBAN[1], G. RIZZOLATTI[2,3];
[2]Dept. of Neurosci., [1]Univ. of Parma, Parma, Italy; [3]Neurosci. Inst., Natl. Res. Council, Parma, Italy; [4]Niguarda Hosp., Milan, Italy

Abstract: We recently reported that a number of cortical areas respond to median nerve stimulation, far beyond the primary (SI) and secondary (SII) somatosensory areas, describing also their temporal pattern of activity. Whether these areas are somatotopically arranged or not is still a matter of debate. In this study, we examined the intracerebral recordings collected in 104

hemispheres (L=49, R=55) of 96 patients during the electrical stimulation of three peripheral nerves, namely the median, tibial and trigeminal (mandibularis branch, V3) nerves. Over 11680 leads exploring grey matter (L=5678, R=6002), we identified 381 responding for tibial (L=178, R=203), 1089 for median (L=489, R=600) and 258 for trigeminal (L=82, R=176) stimulation. Outside SI, we report a clear somatotopical arrangement of primary motor and dorsal premotor cortex, as well as a partial somatotopy for supplementary motor areas and anterior parietal operculum (PR). The comparison of the three maps highlighted several areas housing multiple nerve representations, and two regions responding to all three stimulations: the first included OP1, OP2 and insular long gyri, bilaterally, while the second was located in the hand area of right primary motor cortex. The comparison between left and right hemispheres revealed no lateralization for tibial nerve representation, a greater responsiveness of right premotor cortex for median nerve representation and, notably, a large right-sided bias in the whole motor system for trigeminal nerve. To examine the time course of the responsive areas, we clustered all responsive leads on the basis of their time course, separately for each stimulation dataset. Results showed prototypical patterns for the three nerves, with 3 phasic clusters (strong, middle and weak), a prolonged activity peaking later with respect to the strong phasic response and a tonic cluster. The backmapping of these clusters on the cortical sheet showed that the strong phasic maps yield a precise somatotopical organization of primary somatosensory cortex, that the leads with delayed activity are mainly exploring the dorsal motor and premotor cortices and, finally, that the tonic activity is generated by a peri-sylvian network including mostly OP1, OP2, human PR and posterior insular cortex. The different time course of afferents from hand and mouth in the hand-part of motor cortex may subserve hand-mouth interactions, giving a functional meaning to the so-called imprecisions of somatotopy. Abstract: Homeostasis depends not only upon knowledge of the external environment provided by *exteroceptive* senses (the traditional five senses) but also upon awareness of the state of the body. Such *interoceptive* awareness is likely to be of great importance in the experience of medical symptoms, the majority of which arise from internal or visceral sensation. Despite its biological and clinical importance, interoceptive awareness is understudied and poorly understood, particularly with respect to higher levels of cognition. We used rectal electrosensation in healthy human participants (n=51) to establish the first psychophysically-controlled study of interoceptive awareness. This allowed us to explore not only basic interoceptive perceptual processes (such as stimulus detection or magnitude estimation) but also the higher order cognitive process of awareness of basic task performance, known as "metacognition". We show that exteroceptive and interoceptive metacognitive abilities are dissociable, and that poorer interoceptive metacognition is associated with a greater burden of subjective-health complaints. This implies that the study of metacognitive processes is an important avenue for developing new mechanistic and diagnostic insights into the expression of medical symptoms, including many challenging clinical disorders where symptoms are reported in the absence of objective markers of illness.

Title: Interaction of attention, instructions, and proprioception in a joint matching and N-Back task

Authors: *A. FORREST[1], B.-C. LEE[2], A. THRASHER[2], R. KABBALIGERE[2], C. LAYNE[2]; [1]Kinesiology, Ouachita Baptist Univ., Arkadelphia, AR; [2]Hlth. & Human Perofrmance, Univ. of Houston, Houston, TX

Abstract: *Background*
Application of vibration to the muscle tendon is understood to produce an illusion of movement at the joint, but not in all people at all times. Thus it is possible that this phenomenon is not purely a physiological response, but instead may be influenced by factors such as attention and comprehension of instructions.
Purpose
The purpose of this study was to examine the influence of investigator provided instructions, locus of attention, and distraction on a joint matching task during tendon vibration.
Methods
10 healthy, young adults between the ages of 20-32 were asked to continuously match the position of their elbows for 10 seconds while vibration was applied to the biceps tendon of their dominant arm while their vision was blocked. The following conditions were tested 1) no instructions about the direction or magnitude of the anticipated illusion 2) correct instructions and 3) false instructions; 4) direction to an external focus of attention 5) direction to an internal focus of attention and 6) a simultaneous N-back task. The N-back task requires the participant to repeat the previous word, every time a new word is provided. The maximum absolute difference between the two elbow joints was recorded and the absolute error (AE) as a measure of the magnitude of the illusion and variable error (VE) as a measure of the variability of participant responses between trials was calculated. The percent of correct responses and reaction time during the N-back task alone and during the joint matching task was also obtained.
Results
A repeated measures MANOVA and subsequent univariate analysis confirmed a significant effect of instruction type on both AE and VE. The condition of providing No Instructions lead to the least VE and the greatest AE of all instruction conditions. Instructions to an external focus of attention lead to the least AE. The distraction task did not have an effect on either AE or VE. However, participants reported significantly more correct responses when simultaneously performing both the N-Back task and the joint matching task than the N-Back task alone.
Conclusion
The results of this study suggest that illusions induced by tendon vibration are influenced by instructions and are likely not a purely physiological response. However, it is probable that directed attention toward the perception of vibration is not required. The data suggest that investigators should carefully select the language provided in their instructions and maintain consistency across participants when investigating human responses to tendon vibration.

Title: Gender differences in kinesthesia

Authors: *Y. ACOSTA-SOJO[1], D. E. ADAMO[2], B. J. MARTIN[1];
[1]Univ. of Michigan, Ann Arbor, MI; [2]Wayne State Univ., Detroit, MI

Abstract: Vibration-induced movement illusions are widely used to investigate the role(s) of proprioceptive information. In a recent study we showed that a dominant non dominant asymmetry in movement perception asymmetry was gender dependent and females appeared to be more sensitive than males Hence, the aim of the study was to determine whether these asymmetries/symmetries and sensitivity could be frequency dependent and use this data as baseline for further comparison with stroke patients. Our hypothesis is that the effect of frequency would significantly differ between stroke patients and healthy participants. Six strongly right handed young adults (3 males, 3 females, aged matched), free from any neurological disorders, participated in this pilot study. Vibration-induced Illusions of elbow flexion were matched concurrently with the opposite arm for 40, 60, 80, 120 or 150 Hz frequencies with a constant displacement amplitude of 100 μm. Vibration was applied for 10 seconds or less when the matching forearm flexion reached the torso. The preliminary results indicate as expected an increase in velocity of the matching movement as a function of the vibration frequency. In addition, a gender difference was also observed at all vibration frequencies. Asymmetries between dominant and non-dominant hand could not be clearly assessed. These results confirm a difference in proprioceptive sensitivity between females and males and may also strengthen our previous hypothesis proposing a feed forward control of matching movements.

Title: Synaptic or intrinsic, that is the question; parsing out synaptic currents in mapping the auditory corticocollicular inputs with glutamate uncaging

Authors: *B. SLATER[1], S. K. SONS[2], D. A. LLANO[2];
[1]Neurosci., Univ. of Illinois Syst., Urbana, IL; [2]Mol. and Integrative Physiol., Univ. of Illinois, Urbana, IL

Abstract: In the auditory cortex, a subset of neurons in layers 5 and 6 project to the inferior colliculus. These projections have been shown to have a wide variety of effects when stimulated *in vivo*. Very little is currently known about nature of the inputs from the rest of the auditory cortex onto these cells. To investigate these inputs, we use laser photo-uncaging of glutamate to stimulate the cells that synapse onto the layer 5 and layer 6 corticocollicular cells in brain slices taken from adult mice. Pre-identified cells were recorded in a whole cell patch configuration then stimulated with a larger grid covering the area from the white matter to the pia. In this preparation we use a low calcium artificial cerebral spinal fluid method to isolate synaptic responses, and contrast this method with the more commonly used time window method. In identified layer 5 and layer 6 corticocollicular recordings, cells show spatial differences in their respective input maps with layer 5 having inputs coming from various layers compared to layer 6 which almost exclusively receives input from layer 6. Previously, layer 5 and layer 6 have been shown to have different electrophysiological properties and we find evidence that they differ in the nature of their inputs. Differences in these properties will likely then play different roles in modifying ascending information at the IC. These differences may explain the varied results seen in the inferior colliculus during *in vivo* stimulation of the auditory cortex.

Title: Nmda receptor-dependent temporal processing plasticity in the developing auditory cortex requires $gaba_b$ receptor-mediated inhibition

Authors: D. CAI, R. HAN, M. LIU, F. XIE, L. YOU, Y. WANG, Y. YUE, *K. YUAN; Tsinghua Univ., Beijing City, China

Abstract: Faithful tracking of rapidly successive acoustic signals in the primary auditory cortex (A1) is vital to processing of temporal information and perception of natural sounds such as human speech and animal vocalizations. However, how cortical stimulus-tracking capacity developmentally emerges remains poorly understood. Using *in vivo* whole-cell recordings, we found that inhibition in the developing rat A1 was initially prolonged and strong, leading to cortical responses with considerably poor temporal resolution. Unexpectedly, exposure to repeated acoustic stimulation produced significant and long-lasting shortening of inhibition duration, resulting in strongly improved periodicity of cortical responses. Selective interruption of the signaling pathway of postsynaptic $GABA_B$ receptors shortened inhibition duration, prevented exposure-induced plasticity and improved cortical stimulus-tracking ability. Furthermore, the blockade of NMDA receptors abolished exposure effect. These results identified $GABA_B$ receptor as a key player in NMDA receptor-dependent , non-map plasticity of temporal processing in the developing cortex.

Title: Modular innervation of primary auditory cortex (A1) by morphologically diverse thalamocortical axons

Authors: *E. E. DIEL[1], S. KUROKI[2], S. ITOHARA[2], T. K. HENSCH[1,2,3];
[1]Mol. and Cell. Biol., Harvard Univ., Cambridge, MA; [2]RIKEN Brain Sci. Inst., Wako-shi, Saitama, Japan; [3]Dept Neurol, Boston Children's Hosp., Boston, MA

Abstract: Primary auditory cortex (A1) reflects the tonotopic layout of sound frequency within the peripheral organ of corti relayed by thalamocortical (TC) projections originating in the ventral medial geniculate body (MGBv) and terminating within cortical layer IV. While roughly topographic, TC axonal anatomy has not been fully characterized, especially in the context of their contributions to the tonotopic map. Here, we describe a strategy to label TC axons by targeted injection of AAV-Brainbow into mice expressing Cre recombinase in thalamic nuclei. We find that MGBv projections to A1 are non-uniformly distributed across the extent of the tonotopic axis, giving rise to domains of axonal innervation. This modular structure is recapitulated in functional connectivity using voltage sensitive dye (VSD) imaging of an acute TC slice preparation. Upon stimulation of MGBv, cortical responses best correlated with ΔF/F in thalamus are non-homogeneously distributed across the horizontal tonotopic axis in layer IV, revealing a modular pattern reminiscent of TC axonal labeling. Further leveraging the multi-colored Brainbow labeling to partially reconstruct several TC axons spanning these domains, we reveal a wide morphological diversity of branching patterns with respect to macroscopic modules. Many axons run along vertical trajectories between layers in largely columnar fashion, restricting branches within a domain to send collaterals into both layers IV and I. Other axons instead extend horizontal branches within layer IV to span axonal domains. These two TC axon subtypes, ‘columnar’ and ‘horizontal’, may differ in their contribution to domains and tuning properties in A1 or MGB subdivision of origin. Single arbor tracing by combined AAV-Brainbow and dilute AAV-Cre injection in C57Bl6/J mice, as well as various sound-rearing paradigms to alter tonotopy may offer further insight. Together, these results describe an unanticipated modular structure and the underlying contribution of individual axons to the auditory TC axon map.

Title: Laminar distribution of calcium binding proteins in macaque auditory cortex.

Authors: *L. A. DE LA MOTHE[1], C. R. CAMALIER[2], H. CANSLER[3], S. M. HUBBARD[1], T. A. HACKETT[4];
[1]Psychology, Tennessee State Univ., Nashville, TN; [2]Lab. of Neuropsychology, Natl. Insitute of Mental Hlth., Bethesda, MD; [3]Neurosci., Univ. of Texas Southwestern, Dallas, TX; [4]Hearing and Speech Sci., Vanderbilt Univ., Nashville, TN

Abstract: Inhibitory interneurons play an important role in cortical computation, and characterizing their histochemical diversity and laminar distribution in cortex is key to understanding computational differences between areas and species. One major family are the GABA-ergic interneurons that express calcium binding proteins (CBP) parvalbumin (PV), calbindin (CB), and calretinin (CR). Though these groups of neurons have received attention in some species and cortical areas (Cruikshank et al., 2001; Kawaguchi and Kubota, 1997; Markram et al., 2004), their distributions remain to be fully characterized in primate auditory cortex, an important model for human communication. To address this, cortical depth distributions were examined for each CBP in the primary core region of macaque auditory cortex. Preliminary data suggests that PV neurons have comparable cell expression in both supragranular and infragranular layers, whereas CB and CR expression is located predominantly in the supragranular layers. In addition, these distributions were compared to depth distributions of fast and regular-spiking neurons classified from extracellular waveforms recorded in the same region. Interestingly, fast-spiking neurons exhibit similar distribution patterns as the PV expression, consistent with the identification of fast-spiking as a marker for PV cells in sensory cortex. Multi-fluorescent immunohistochemistry revealed that CBP were found to express largely distinct patterns of expression with limited incidence of co-localization.

Title: Imbalanced excitation and inhibition in pyramidal cells in awake mouse auditory cortex.

Authors: *H. K. KATO, J. S. ISAACSON;
UCSD Sch. of Med., La Jolla, CA

Abstract: In the primary auditory cortex (A1), sound representations in principal pyramidal cells are shaped by inhibitory inputs provided by a variety of inhibitory neuron subtypes. Revealing the interplay between excitation and inhibition in individual neurons is of critical importance in order to understand how sound is encoded in the brain. Studies in anesthetized mice suggest that approximately balanced inhibition counteracts excitation to sharpen the tuning properties of pyramidal cells. While both parvalbumin-expressing neurons (PV cells) and somatostatin-expressing neurons (SOM cells) are thought to contribute to sound-evoked inhibition, the tuning properties of these interneuron subtypes are a matter of debate.
Here, we use cell type-specific large-scale calcium imaging to reevaluate the excitatory and inhibitory receptive fields in major neuronal subtypes in A1 of awake mice. We found that a large fraction of pyramidal cells show either purely inhibitory receptive fields or mixed excitatory/inhibitory receptive fields, suggesting an imbalance between excitation and inhibition in individual cells. In contrast to the coarse alignment of excitatory receptive fields to the A1 global tonotopic axis, inhibitory receptive fields showed high spatial heterogeneity, further suggesting a mismatch between excitation and inhibition. Furthermore, we observed stronger and broader excitation in SOM cells compared to PV cells or pyramidal cells. The broad tuning properties of SOM cells make them well poised to provide untuned inhibitory input onto pyramidal cells. Currently, we are investigating how inputs from distinct inhibitory neuron subtypes differentially shape tuning properties of pyramidal cells.

Title: Avalanche dynamics during spontaneous and sound evoked activity in the auditory cortex of awake mice

Authors: *D. E. WINKOWSKI[1], Z. BOWEN[2], S. SESHADRI[3], T. RIBEIRO[3], D. PLENZ[3], P. O. KANOLD[2];
[2]Biol., [1]Univ. of Maryland, College Park, MD; [3]NIMH, NIH, Bethesda, MD

Abstract: In sensory cortical areas, thalamic afferents synapse primarily on mid-cortical layer neurons (L4) which in turn project to neurons in upper (L2/3) and lower (L5/6) cortical laminae. Within L2/3, neurons incorporate ongoing cortical activity, usually in the form of reverberating activity from within or distant cortical regions that reflect the state and behavioral context of the animal. These features, among others, may contribute to the heterogeneous organization of stimulus preference in L2/3. A well-established hypothesis is that cortical activity, especially in L2/3, reflects a complex system operating at or near criticality in order to maintain network stability while optimizing information processing. Prior studies have shown that spatiotemporal patterns of spontaneous neuronal activity organize into neuronal avalanches that exhibit signatures of critical dynamics; that is, the probability distribution of avalanche sizes can be fit with a power law of specific parameters. Here we study neuronal avalanche dynamics preceding as well as during sensory stimulation in primary sensory cortex. We investigate neuronal avalanches using in vivo 2-photon Ca^{2+} imaging of ongoing and sound evoked activity of primary auditory cortex (A1) in awake mice using GCaMP6s. We explore the relationship between properties of sensory stimuli, single cell responses, and population responses with respect to avalanches. We investigate the spectral tuning properties of neurons participating in avalanches in order to probe the relationship between criticality and sensory coding. On the single cell level, many neurons were tuned to a particular sound frequency but responded unreliably. On the population level, we found that avalanche statistics varied depending on the stimulus frequency and intensity of the presented sound. We speculate that stimulus frequency and intensity dependence reflected in avalanche size suggests that stimuli are encoded in distinct local subpopulations; not just single neurons. Furthermore, stimulus-evoked avalanches often contained neurons that are not overtly tuned to the presented stimulus. The role of these neurons in sensory coding is unclear. Our investigation provides insight into how neural networks

containing differing populations of neurons with varying firing rates stably encode information about sensory stimuli in the context of self-organized criticality.

Title: Control of cortical network activity by somatostatin- and parvalbumin-positive interneurons

Authors: *B. M. KRAUSE[1], D. J. UHLRICH[2], M. I. BANKS[1];
[1]Dept. of Anesthesiol., [2]Dept. of Neurosci., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Experiments *in vivo* and in brain slices suggest that that the vast majority of spiking in auditory cortex in response to feedforward inputs occurs in the context of network bursts corresponding to synchronous, brief UP states in cortical neurons. Previous work also has shown that subtypes of inhibitory interneurons participate in this network activity to different degrees, and their involvement varies between distinct cortical regions. However, the degree to which these subtypes control the occurrence and magnitude of these network events, and the timing of pyramidal cell spikes within UP states, remains unclear. Here, we studied two types of cortical interneurons in slices of mouse auditory cortex, parvalbumin (PV+) and somatostatin (SOM+) interneurons. We found that both PV+ and SOM+ interneurons fired considerably more than pyramidal cells, but differed in timing: PV+ cells fired earlier in UP states, whereas SOM+ cells

were active later. PV+ cells were more precise and reliable relative to thalamocortical stimuli, whereas individual pyramidal cells were more precise relative to network activity; SOM+ cells were precise in neither sense. Although optogenetic suppression of either interneuron population increased overall population activity, suppression of PV+ cells reduced the onset latency and threshold of network bursts, whereas suppression of SOM+ cells increased burst duration. Surprisingly, the precision of spiking in pyramidal cells did not deteriorate upon suppressing either interneuron population. These data suggest that spike timing in auditory cortex is not tightly controlled by interneurons during network events, when cortical activity is at its highest level in the column.

Title: A role for Martinotti cells in auditory cortex dynamics: A modeling study

Authors: *D. BEEMAN, L. NATALE;
Univ. of Colorado Boulder, Boulder, CO

Abstract: The importance of the role of inhibitory neurons in cortical dynamics and in auditory processing has long been recognized and has been the subject of many modeling studies. The ACnet2 model (genesis-sim.org/GENESIS) is a simple model of primary auditory cortex layer with 2304 multi-compartmental spiking pyramidal cells coupled to 576 inhibitory basket cells and tonotopically arranged thalamic inputs. The use of structurally realistic cell models provides proper dendritic locations of synapses and allows modeling of field potentials in auditory evoked potential simulations.
Martinotti cells are the next most common cortical inhibitory interneuron after basket cells and have significantly different properties that could affect cortical dynamics. They fire at low thresholds and produce adapting rather than tonic fast spiking spike trains. Their excitatory synapses are strongly facilitating, rather than depressing. Their axons contact pyramidal cell dendrites on different locations.
To study the effect of including Martinotti cells in the ACnet2 model, an 8 compartment model was created with GENESIS 2.4. The elongated bitufted morphology was based on published cell

images. Passive cell parameters and ion channel parameter fits were based on published electrophysiology data.
As a first step, a simple circuit was modeled consisting of a pyramidal, basket, and Martinotti cell, each receiving a 20 Hz spike train, and with the latter two inhibiting the pyramidal cell. The figure shows how the depressing synapses on the basket cells and the facilitating ones on the Martinotti cells affect their firing and that of the inhibited pyramidal cell during the three periods of separate and overlapping inhibition. This suggests a behavior that will broaden the spectra calculated from field potentials in the ACnet2 network.

Title: L5 corticocollicular and L6 corticothalamic neurons support a parallel and complementary analysis of auditory stimulus features

Authors: *R. S. WILLIAMSON[1,2], D. B. POLLEY[1,3];
[1]Eaton Peabody Labs., Massachusetts Eye and Ear Infirmary, Boston, MA; [2]Ctr. for Computat. Neurosci. and Neural Technol., Boston Univ., Boston, MA; [3]Dept. of Otolaryngology, Harvard Med. Sch., Boston, MA

Abstract: Neurons in layers (L) 5 and 6 of the auditory cortex (ACtx) give rise to a massive subcortical projection that innervates all levels of the central auditory pathway as well as non-auditory areas including the amygdala, striatum, and basal ganglia. L5 and L6 neurons feature distinct morphology, connection patterns, intrinsic membrane properties and synaptic properties, yet little is known about how these differences relate to sensory selectivity *in vivo*. Here, we focused on two distinct ACtx L5 and L6 projection neurons; L5 corticocollicular neurons (L5CCol), and L6 corticothalamic neurons (L6CT).
We developed a dual-channel antidromic optogenetic "phototagging" strategy to isolate single L5CCol and L6CT units from extracellular recordings in awake, head-fixed mice. We injected two adeno-associated viral constructs (AAV) into ACtx of Ntsr1-Cre transgenic mice, in which Cre-recombinase is expressed only in L6CT neurons. One Cre-dependent AAV encoded Chrimson (a red-shifted channelrhodopsin) and a second non-specific AAV encoded hChR2. One optic fiber was then implanted near the surface of the inferior colliculus and a second near the medial geniculate body. By evoking antidromic spikes from L5CCol neurons with blue light and L6CT neurons with red light, we could simultaneously isolate and characterize both types of projection neurons with a single multi-channel recording probe in ACtx.
L5CCol neurons exhibited shorter response latencies and broader frequency tuning than L6CT neurons. Linear spectrotemporal receptive field (STRF) fits were able to explain a higher percentage of response variance in L5CCol neurons, indicating a higher degree of linearity in their responses when compared to L6CT units. Finally, we used a closed-loop evolutionary stimulus optimization strategy to identify the best stimulus for L5CCol and L6CT neurons across a 4-dimensional stimulus manifold. The evolutionary search strategy manipulated the modulation frequency, level, spectral bandwidth, and center frequency of noise tokens in real time based on spike feedback to identify an optimal stimulus. We found that L5CCol neurons featured a lower multi-dimensional sparseness index, indicating a reduced stimulus selectivity and a broader response distribution than L6CT neurons. These findings suggest a functional dichotomy in the form of stimulus-related modulation imposed by L5 and L6 neurons to subcortical targets. Future work will entail recording from these projection neurons during task engagement to establish how these functional differences are adaptively used in service of goal-directed behavior.

Title: Anesthetic induced changes in cortical spike timing across awareness states

Authors: *N. S. MORAN[1,2], J. KAKES[1], S. M. GRADY[1], M. I. BANKS[1];
[1]UW Madison, Dept. of Anesthesiol., Madison, WI; [2]Neurosci. Training Program, Univ. of Wisconsin Madison, Madison, WI

Abstract: Introduction: The mechanisms of loss of consciousness (LOC) under anesthesia are poorly understood. Theoretical and experimental evidence indicates that network connectivity, and especially cortical feedback connectivity, is impaired upon LOC. However, anesthetics also affect stimulus representation in cortex. Anesthetics impair temporal representations in the ascending auditory pathway, but have also been reported to improve spike precision and decrease response variability. Here, we tested the effects of anesthesia LOC on spontaneous and stimulus-evoked spiking activity in auditory cortex. We chose three anesthetics with distinct molecular targets: Isoflurane (iso), which acts at multiple pre- and postsynaptic loci, propofol (pro), which acts primarily on $GABA_A$ receptors, and dexmedetomidine (dex), an α_2 adrenergic agonist. **Methods:** Spontaneous and click train-evoked (3-100Hz) multiunit activity was recorded from auditory cortex in rats chronically implanted with 16 channel microwire arrays under four conditions: waking (ctrl), sub-LOC and just-LOC doses of iso, pro and dex, and recovery. Spike timing precision and reliability was evaluated using the Spike Time Tiling Coefficient (STTC; Cutts & Eglen 2014 J. Neurosci 34:14288). This method was used to evaluate consistency across trials of single channel click train responses (within channel STTC), and the similarity (i.e. connectivity), during spontaneous activity, of spike trains on different channels (across channel STTC). **Results:** STTC peaked at click frequencies of 10-20Hz. All anesthetics caused a reversible decrease in within channel STTC. For iso and pro, the majority of this effect occurred at sub-LOC doses (STTC ctrl - just-LOC = 0.045 and 0.047, iso and pro respectively; $p < 0.03$). For dex, the decrease in STTC was only significant at the just-LOC dose (STTC ctrl - sub-LOC = 0.042, $p = 0.17$; ctrl - just-LOC =0.085, $p =0.007$). Although anesthesia decreased the STTC at all click frequencies, 10-20Hz clicks responses were preferentially impaired. In ctrl, between channel STTC decreased with increased distance between recording sites, but there were no

consistent effects of anesthetics on this measure. All three agents caused reversible increases in first spike latency (just-LOC - ctrl = 0.70, 3.5 and 5.3 ms for iso, pro and dex, respectively). **Conclusions:** All anesthetic agents had profound effects on the encoding of temporal information in auditory cortical responses, but these effects appear to be unrelated to LOC. Agent-specific effects likely arise due to diverse mechanisms of action. There was little effect on millisecond-scale spike precision in spontaneous activity.

Title: Dopaminergic modulation of vocalization-selective neurons in the inferior colliculus acts via D2-like receptors

Authors: *J. M. HOYT[1], R. A. FELIX, II[1], D. J. PERKEL[2], C. V. PORTFORS[1];
[1]Integrative Physiol. and Neurosci., Washington State Univ. Vancouver, Vancouver, WA; [2]Univ. of Washington, Seattle, WA

Abstract: Background: The ability to understand speech relies on the accurate processing of these sounds by the auditory system. A variety of factors may impede accurate representation, including disorders associated with neuromodulatory systems. For example, individuals with Parkinson's disease suffer from deficits in speech perception, suggesting that dopamine may be involved in the normal encoding of behaviorally relevant sounds. The inferior colliculus (IC) receives inputs from multiple auditory and non-auditory sources and is rich in both dopaminergic terminals and D2-like receptors. Recent studies in our lab demonstrated that dopamine heterogeneously modulates responses of individual neurons to tones and noise in the IC of mice. However, it is currently unknown which type(s) of dopamine receptors is/are involved in such alteration of neuronal responses to auditory stimuli, and whether dopamine affects neuronal responses to communication sounds. In this study, we tested the following hypotheses: dopamine acts via D2-like receptors to alter auditory evoked neuronal responses in the IC; dopamine alters neuronal responses to conspecific vocalizations in the IC.
Methods: We recorded extracellular responses of single neurons in the IC of awake mice. We compared neuronal responses to tones and mouse vocalizations before and after iontophoretic

application of dopamine and D1- or D2-like agonists or antagonists. We quantified how activating or blocking dopamine receptors changed the rate and timing of action potential spikes.
Results: We found that the effects of both dopamine and a D2-like agonist on spiking rate in IC neurons were heterogeneous as both similarly increased or decreased auditory-evoked responses to pure tones, while a D2-like antagonist reversed the effects of dopamine. Moreover, both dopamine and a D2-like agonist similarly affected responses of IC neurons to vocalizations in the same relative direction as responses to tones, while a D2-like antagonist reversed the effects of dopamine.
Conclusions: Our study increases the understanding of neurophysiological mechanisms underlying hearing and auditory-based communication. We found that dopaminergic neuromodulation in the IC acts on responses to behaviorally relevant sounds, and that such modulation occurs via D2-like receptors. Understanding how dopamine modulates auditory processing will ultimately provide insight into mechanisms underlying specific communication- and auditory-based neurological disorders.

Title: Functional properties in the secondary auditory field are derived from structural organization of primary auditory thalamus and thalamocortical projections in mice

Authors: *H. TSUKANO[1], K. SHIBUKI[2];
[1]Brain Res. Institute, Niigata Univ., Niigata-Shi, Niigata-Ken, Japan; [2]Dept of Neurophysiol, Brain Res. Inst, Niigata Univ., Niigata, Japan

Abstract: Optical imaging studies revealed multi-frequency organization in the mouse auditory cortex. A higher-order auditory field, the secondary auditory field (AII), is also tonotopically

arranged. Frequency organization of the auditory cortex reflects cochleotopy that generates in the ears and is kept through the course of the auditory ascending pathway. In a prevailing dogma, fundamental tonal information is relayed to the primary auditory cortex (AI) via the primary thalamus, the ventral division of the medial geniculate body (MGv, MGB). In contrast, the AII is believed to receive thalamic inputs from the higher-order thalamus, the dorsal division of the MGB (MGd), although the MGd is not tonotopically arranged. To reconcile the presence of tonotopy in the AII and the absence of tonotopy in the MGd, we precisely investigated distribution of thalamic neurons projecting to the functionally identified AII using a retrograde tracer, Alexa Fluor-conjugated CTB. Contrary to our expectation, the AII received dense projections from the caudal part of the MGv, and only a small number of neurons in the MGd gave rise to projections to the AII. In addition, triple injection of fluorescent tracers along the frequency gradient of the AII revealed topological organization in the caudal part of the MGv that run ventrodorsally. We noticed that MGv neurons labeled by injection to a particular site in the AII were distributed wider than MGv neurons labeled by similar injection to the AI. We conducted double injection of fluorescent CTB into a low or high frequency area of the AI and AII, and found that two neuronal groups projecting to a low or high frequency area of the AII were not clearly separated compared with neurons projecting to a low or high frequency area of the AI. These data suggest that an AII neuron receives a wider range of tonal information from the MGv compared with an AI neuron. To validate this, we used two-photon calcium imaging and observed tonal responses of neurons in cortical input layers stained with Cal520. As expected, band width of neurons in layer 4 was broader in the AII than that in the AI, and tonotopic arrangement of layer 4 in the AII was less ordered than that in the AI. Furthermore, we found a possibility that the mouse MGd is also tonotopically arranged, albeit only weakly. Although MGd neurons projecting to a low, middle, or high frequency area of the AII were highly intermingled, the average coordinate of each neuronal group was slightly but significantly shifted. These findings suggest that functional properties of the AII are largely determined by the thalamocortical projections from the MGv, but not those from the MGd.

Title: Activation of auditory cortex induces excitatory postsynaptic potential in midbrain neurons

Authors: J. QI, *J. YAN;
Physiol. & Pharmacol., Univ. of Calgary Fac. of Med., Calgary, AB, Canada

Abstract: Neuroanatomical studies reveal a great amount of descending (corticofugal) projections from the primary auditory cortex (AI) to all subcortical regions such as the central nucleus of the inferior colliculus (ICc). In the past 20 years, physiological studies show that corticofugal system implements a highly specific modulation of the sound information processing in the ascending auditory system. In the frequency domain, for example, focal electrical stimulation of the AI (ES_{AI}) facilitates subcortical neurons when the best frequency (BF) of subcortical neurons is identical to the BF of cortical neurons (physiologically matched). In contrast, ES_{AI} suppresses subcortical neurons when their BFs are different (unmatched). In addition, ES_{AI} shifts the frequency tunings (e.g., BFs) of unmatched subcortical neurons towards the BF of the stimulated AI neurons. It is noted that all previous physiological findings are achieved by extracellular recording. To date, little is known about the cellular mechanism of corticofugal modulation. An immediate question raised here is if the postsynaptic membrane potential is depolarized or hyperpolarized following focal cortical stimulation. Since the inactivation of the entire auditory cortex reduces tone-evoked spike number of ICc neurons by 30-50%, our hypothesis is that ES_{AI} should primarily induce excitatory postsynaptic potential (EPSP) in the ICc neurons. We used the C57 mouse as animal model. The membrane potential of ICc neurons was recorded by in vivo whole cell patch current-clamp. We found that ES_{AI} induced EPSP of ICc neurons. The range of the threshold current was from 8 to 64 μA, with an average of 34.38 ± 18.94 μA for inducing ICc EPSPs. Further analysis indicated that the ES_{AI}-induced ICc EPSP was related to the BF difference of stimulated AI and recorded ICc neurons; at the 64 μA level, ES_{AI} induced ICc EPSP was larger in matched neurons than in unmatched neurons. Our data suggests that corticocollicular synapses are excitatory. Additionally, corticofugal synaptic strength relies heavily on the frequency tuning relationship between the stimulated AI and recorded ICc neurons.

Title: Cortical network activity in posterior parietal cortex following feedforward and feedback afferent stimulation

Authors: *C. MURPHY, R. D. SANDERS, B. K. KRAUSE, M. I. BANKS;
Dept. of Anesthesiol., Univ. of Wisconsin, Madison, WI

Abstract: Introduction:
Evidence suggests that information flow in neocortex relies on coordinated activity within local ensembles, and that this activity arises on the platform of depolarization synchronized across cells in the network (UP states). However, little is known about the contribution of feedforward (FF) versus feedback (FB) pathways in triggering network activity. Posterior parietal cortex (PPC) integrates information from primary sensory and higher order cortical areas. Because activity in PPC is specifically linked to awareness, understanding the integration of FF and FB inputs has important implications for elucidating the neural basis of consciousness and its disorders. We investigated properties of FF- and FB-induced UP states in PPC.
Methods:
Coronal slices (500 μm) containing primary somatosensory (S1), PPC, and retrosplenial (RSC) cortices were prepared from mice (4-10 weeks old). Multiunit activity (MUA) signals were recorded from PPC using 16-channel electrode arrays oriented orthogonally to the cortical laminae. Electrical stimuli were applied to supragranular (SG) layers of S1 and infragranular (IG) layers of RSC using bipolar tungsten electrodes. UP states were defined as positive-going excursions of the MUA signal above a pre-stimulus baseline. Previous results indicate that UP state activity in SG & IG layers is distinct, and thus properties of UP states were compared between SG & IG layers.
Results:
Stimulation of both FF (S1) and FB (RSC) afferents to PPC induced UP states. Increasing stimulus intensity led to monotonic decreases in latency, and increases in magnitude and duration, for UP states induced by S1 stimulation; UP states induced by RSC stimulation were more variable. S1-induced UP states occurred with higher probability and were of shorter latency

and greater duration, amplitude, and integral compared to RSC- induced. Differences in UP state properties between SG and IG layers were also evident, especially for S1-induced UP states: UP states occurred with higher probability in IG layers, and were shorter latency and greater duration, amplitude, and integral than those in SG layers.
Conclusions:
These data support a model in which propagation of information across the cortical hierarchy via coordinated network activity is more efficacious in the FF compared to FB direction. That FF stimulation results in less variable, more robust UP states suggests that FF connections may be responsible for driving the network into an active, highly synchronous state, while FB connections are more apt to modulate the receptivity of the network to these inputs.

Title: A computational modelling study of cortical network activity

Authors: *A. RAMAMOORTHY[1,2], N. MORAN[3], B. KRAUSE[2], M. I. BANKS[2];
[2]Dept. of Anaesthesiology, [3]Neurosci. Training Program, [1]Univ. of Wisconsin-Madison, Madison, WI

Abstract: Introduction: Auditory cortical networks exhibit periods of coordinated network activity (50-200 ms), both spontaneously and in response to acoustic stimuli, similar to brief UP-states, that impact sensory responses. Previously, we examined the cellular and circuit-level mechanisms of UP-state generation *in vitro* and observed their occurrence *in vivo* in chronically implanted animals. Here, we developed a computational model aimed at simulating UP-states in an artificial cortical circuit. **Methods:** A model representing L2/3, L4 and L5 of rodent auditory cortex was set up using the Brian2 simulator for spiking neural networks. Each layer consisted of excitatory and inhibitory units, modelled as conductance-based leaky-integrate and fire neurons. Excitatory connections were all-to-all, with connection strength decreasing as a function of

distance. Inhibitory connections were confined to the layer of origin. Non-zero mean white noise generated and sustained spontaneous network activity. Network activity was also driven via simulated thalamic synaptic input. We compared network activity in the model to data from 1x16 laminar probe recordings in rat auditory cortex. Spike-trains were analyzed to determine interval statistics and the presence and properties of network bursts. Burst-detection analysis was performed using the logISI method described in Pasquale et al. (J Comput Neurosci 29:213, 2010). **Results:** The model reproduces the firing patterns observed in both spontaneous and stimulus-driven recorded data. More specifically, the network, in the absence of an extrinsic stimulus, generates coordinated bursts confined to the granular and infragranular layers, as well as bursts that encompass the entire column. Over a wide range of simulated stimulation intensities, model responses to stimuli correspond to all-or-none network bursts. Increasing stimulus strength increases burst response probability. The inter-spike-interval histograms from the data and the model deviate from an exponential distribution in a similar fashion, suggesting the presence of bursts and pauses. Burst detection analysis on the units in the network suggests that bursts typically range from 50-220 ms. **Conclusions:** The overarching goal of this computational modelling effort is to test presumptive mechanisms of anaesthesia with a specific focus on how global activity in cortical networks is mediated by depth of anaesthesia. The model described above reproduces typical activity profiles observed in cortical networks of interest (murine auditory cortex) and is a suitable theoretical tool for the intended purpose.

Title: Stimulus-specific adaptation in distinct inhibitory populations in auditory cortex

Authors: *T. S. YARDEN, A. MIZRAHI, I. NELKEN;
Hebrew Univ., Jerusalem, Israel

Abstract: Neurons in primary auditory cortex exhibit stimulus-specific adaptation (SSA), the decrease in responses to a common (standard) stimulus that does not generalize fully to another,

rare stimulus (deviant). Here we use *in vivo* two-photon targeted loose-patch recordings in mice to investigate how inhibitory populations shape SSA. We recorded in primary auditory cortex from identified neurons of the three main inhibitory populations, parvalbumin- (PV), somatostatin- (SST) and vasointestinal polypeptide-(VIP) positive neurons. PV neurons, which form the major inhibitory population in the cortex, exhibited early-onset SSA with responses that terminated about 30 ms after stimulus onset. Responses of VIP neurons lasted up to 150 ms following stimulus onset, i.e. substantially beyond stimulus offset, maintaining SSA for nearly the whole time. SST neurons were less responsive to sound stimuli. Those that did respond to pure tones showed SSA, but with somewhat weak deviant responses. Our findings of SSA in all inhibitory populations suggest that the temporal dynamics of inhibitory responses are important in shaping the dependence of cortical responses on stimulus history. In particular, different populations of interneurons can control deviance sensitivity during different temporal windows following stimulus onset. In addition, as inhibitory neurons are a main locus of top-down and neuromodulatory regulation, modulation of their deviant responses can be a means for controlling the level of deviance detection according to the behavioral state.

Title: Anaesthetic choice modulates basic auditory processing: A combined EEG/LFP study in guinea pigs

Authors: *O. WOOLNOUGH, J. I. BERGER, B. COOMBER, M. N. WALLACE, A. R. PALMER, C. J. SUMNER;
MRC Inst. of Hearing Res., Nottingham, United Kingdom

Abstract: Anaesthesia is widely used in *in vivo* studies of sensory neural processing. Previous studies of the effects of general anaesthesia on neurons in the auditory cortex have shown significant changes to frequency tuning and responses to basic features within the stimulus such as onsets and offsets. Studies of this nature have typically used a single anaesthetic agent, comparing awake and anaesthetised states, and it remains unclear to what extent the choice of anaesthetic agent will affect basic response properties of cortical neurons to sensory stimulation. Electrophysiological recordings were made with chronically implanted, extradural electrodes, positioned over auditory and visual cortices, and penetrating electrodes in auditory cortex.

Recordings were made both while awake and under a range of anaesthetic regimes including opiates, NMDA antagonists and GABA potentiators. Recordings of spontaneous oscillations replicate the results of previous human studies, showing a rapid increase in power of low-frequency (<10Hz) oscillations at loss of consciousness, suppression of high frequency activity and a shift toward criticality, with a higher proportion of unstable oscillatory modes being observed - effects which appear mostly independent of anaesthetic regime. Responses to a range of basic sensory stimuli, such as auditory clicks and tones, display substantive differences in population level processing of even basic auditory stimuli between anaesthetic regimes. These modulations range from -20% to +50% changes in onset response amplitude, up to 25ms peak latency shifts and up to 600% increases in offset response amplitudes. Neural responses to visual flashes demonstrated universal suppression of visually evoked potentials under all anaesthetics and we also observed, under all anaesthetics tested, near total abolishment of auditory-visual cross-modal interactions. Adapter-probe stimuli were also tested showing substantial modulation of adaptation recovery time constants, with diazepam slowing the release from adaptation and ketamine allowing faster recovery than when awake. Local field potentials were used to isolate changes occurring in primary auditory cortex, helping to explain the phenomena seen in the EEG recordings and show changes in frequency tuning resulting from each anaesthetic. In conclusion, we have demonstrated that anaesthesia has significant effects on systems level sensory processing and that the choice of anaesthetic used for recording can have grossly different effects on the response to even simple sensory stimuli.

Abstract: Cortical sensory maps are remodeled throughout life to adapt to a changing environment. Both sensory and neuromodulatory signals are important in sculpting these maps, but how these inputs converge within thalamocortical circuits to trigger plasticity remains unknown. Here, we reveal that a layer (L) 1 map within mouse primary auditory cortex (A1) is a site of convergence of neuromodulatory and topographically-organized thalamic inputs. Surprisingly, we found that L1 cells receive strong, monosynaptic connections from the auditory thalamus (ventral division of the medial geniculate body; MGBv). Electrical stimulation of the MGBv in thalamocortical slices evoked minimum- and maximum- evoked excitatory postsynaptic potentials (EPSPs) in L1 cells as large as those recorded in L4 pyramidal cells. Anatomical studies using targeted AAV-Brainbow injections into mice expressing Cre recombinase in thalamic nuclei revealed abundant MGB axonal projections up to L1. Furthermore, voltage-sensitive dye imaging in thalamocortical slices to examine functional connectivity between MGBv and A1 confirmed a topographic map in L1 along the tonotopic rostro-caudal axis that mirrored the map in L4. L1 cells were also robustly activated by serotonergic and cholinergic input, suggesting that L1 integrates precise sensory information with neuromodulatory state. Functional and anatomical studies further demonstrate developmental and experience-dependent changes in this L1 map. Both MGBv and neuromodulatory activation of L1 are enhanced during an early critical period when passive sound exposure robustly restructures A1 tonotopic maps. Interestingly, L1 and L4 exhibit distinct topographic alterations following early tone exposure, suggesting that the MGBv connections onto L1 cells may be mediated by specific plasticity mechanisms. Together, our studies reveal an unexpected function of L1 cells within the auditory thalamocortical circuit. Namely, L1 cells are activated by both neuromodulatory tone and temporally- and spatially-precise sensory signals. Such inputs to L1 cells may evolve over postnatal development and in response to sensory experience, controlling the manner in which these cells orchestrate activity and plasticity in the cortical layers below.

Title: Corticothalamic neurons control modes of cortical processing and perception by entraining columnar oscillations

Authors: *W. GUO[1], A. R. CLAUSE[1], A. N. BARTH-MARON[2], B. G. SHINN-CUNNINGHAM[3], D. B. POLLEY[1];
[1]Eaton Peabody Lab., Massachusetts Eye and Ear Infirmary, Boston, MA; [2]Dept. Neurobio., Harvard Med. Sch., Boston, MA; [3]Ctr. for Computat. Neurosci. and Neural Technol., Boston Univ., Boston, MA

Abstract: The cortical column is the canonical unit of information processing in the cerebral cortex. Until recently, the neural circuitry that imposes real-time modulation on columnar sensory processing has remained obscure. Here, we characterize thalamocortical response dynamics by activating a subtype of layer 6 (L6) neuron that makes a massive projection to the thalamus and also has abundant connections within the local column. We used a cre-dependent viral construct to selectively express ChR2 in L6 of primary auditory cortex (A1) of Ntsr1-cre transgenic mice. We explored the modulatory effects of L6 activation on thalamocortical sound processing by simultaneously recording from the ventral subdivision of the medial geniculate body (MGBv) and all layers of A1 in awake, head-fixed mice while optogenetically activating L6 corticothalamic (L6CT) neurons. In current source density (CSD) traces, photoactivating L6CT neurons induced robust gamma oscillations in deep layers (at 100-120 Hz) and superficial layers (at 40-50 Hz). Cessation of L6CT activation induced a delta-theta oscillation (2-6 Hz) that persisted for hundreds of milliseconds. The delta-theta offset oscillation exhibited a stereotypical spatial-temporal pattern such that CSDs in each layer were reset to the same phase, independent of the duration or amplitude of laser power. Sound responses across the column were modulated with either divisive or multiplicative gain, depending on the phase of the oscillation, which enhanced either discrimination or detection behavior of mice in a perceptual task. Granger causality analysis revealed that delta-theta oscillations did not originate from L6, but from L4 and L5, suggesting that L6CT neurons do not influence columnar neural activity directly, but rather engage distributed networks of excitatory and inhibitory neurons throughout the cortical column that could dynamically transform afferent sensory traces. By analyzing spontaneous spiking activity in relation with the CSDs, we identified a group of neurons that were linked with columnar CSD resetting, including fast-spiking (FS) neurons and regular-spiking (RS) neurons in cortical L4 and L5, as well as neurons in MGBv. We found that L6CT neurons strongly activated the cortical FS resetter neurons, whose activity persisted for an extra 10-20 milliseconds post L6CT activation, inducing the observed columnar CSD phase reset. In sum, by driving cortical FS neurons that entrains columnar CSDs, L6CT neurons can dynamically and bi-directionally modulate sound processing and perception, providing a powerful tool for analyzing time-varying stimuli in complex auditory scenes.

Title: Rewiring the deafferented cortical neurons to the remaining auditory inputs: A model for treatment of tinnitus patients

Authors: *P. JENDRICHOVSKY, J. FENG, J. HE;
Dept. of Biomed. Sci., City Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Tinnitus is an auditory phantom sensation when no external sound is present. Our working theory is that tinnitus is caused by the positive feedback oscillation in the thalamo-cortical circuit [1] that becomes hypersensitive and causes tinnitus after hearing loss [2]. Cholecystokinin (CCK) has plasticity enabling properties towards cortical neurons [3]. In the present study, we aim to rewire weak connections from the remaining inputs towards the deaff erented ones. We hypothesize that this will suppress the hypersensitivity and therefore silence tinnitus permanently. The first main objective was to verify whether the auditory cortical neurons could be changed to retune to other frequency in the presence of CCK. The rat was chronically implanted with recording electrodes and injection cannula for CCK delivery in the auditory cortex. After successful pairing of a previously low-responsive or non-responsive sound stimulus with cortical stimulation after CCK infusion, the neuron shows higher firing rates to the paired sound. The second objective is to establish appropriate hearing loss and tinnitus model. Our results so far indicated that neural network could be rewired in the presence of CCK.

Title: Reafference integration in an escape circuit.

Authors: *C. R. VON REYN[1], G. M. CARD[2];
[1]Sch. of Biomed. Engineering, Sci. and Hlth. Systems, Drexel Univ., Philadelphia, PA; [2]Janelia Res. Campus, HHMI, Ashburn, VA

Abstract: Reafferent signals, sensory cues generated by an animal's motor actions, are indistinguishable from externally generated sensory signals at the first stage of sensory processing. Nonetheless, nervous systems have devised ways to identify and properly integrate reafferent signals to avoid ambiguity and saturation of sensory pathways, to determine whether a performed motor action produced intended consequences, and to guide future motor actions. Substantial evidence supports the necessity for reafference integration in sensory processing and motor coordination, however we still know little about the neural circuits that underlie these computations. Here, we provide evidence for reafference integration within the Giant Fiber (GF) escape circuit of the fruit fly *Drosophila melanogaster*. Voluntary leg motion, like that experienced during walking, significantly increased GF EPSPs and spikelets recorded in whole-cell, current-clamp mode in behaving animals. Since passive antennal deflections have been observed during walking behaviors, we hypothesized that the increase in GF activity occurred through stretch activation of mechanosensory neurons located in the Johnston's Organ of the antenna that make direct synapses onto the GFs. We found that antennal ablation significantly reduced EPSPs and spikelets during leg movements, supporting that the GFs receive reafference from the antenna during self-motion. Antenna ablation additionally uncovered a significant hyperpolarization within the GFs, also synchronized to leg motion. Our data suggest that the GF circuit is organized to recognize and diminish reafferent signals, avoiding an energetically

unfavorable self-stimulation of an escape pathway. This work establishes the GF circuit as a model for dissecting the neural architecture behind reafference integration using the neuroengineering toolkit of *Drosophila melanogaster*.

Title: Mapping auditory information flow in primate cortex

Authors: *B. H. SCOTT[1], Y. KIKUCHI[2], K. S. SALEEM[1], M. FUKUSHIMA[1,3], M. MISHKIN[1], R. C. SAUNDERS[1];
[1]Lab. Neuropsychol, NIMH, Bethesda, MD; [2]Inst. of Neurosci., Newcastle Univ. Med. Sch., Newcastle Upon Tyne, United Kingdom; [3]Lab. for Marmoset Neural Architecture, RIKEN Brain Sci. Inst., Saitama, Japan

Abstract: The flow of information in the primate auditory cortex follows a hierarchical processing scheme, with projections in the medial-lateral dimension from core, to belt, to parabelt. We recently showed that rostral auditory cortex in the rhesus monkey receives input via stepwise serial projections in the caudal to rostral dimension: through the primary, rostral, and rostrotemporal core areas (AI, R, and RT) on the supratemporal plane (STP), continuing to the rostrotemporal polar area RTp (Scott et al., *Cerebral Cortex* 2015). In addition to this serial cascade of corticocortical connections, every region of auditory cortex receives parallel thalamocortical projections from the medial geniculate nucleus (MGN), with the caudal core (AI and R) being the primary recipient of input from the ventral division (MGv, i.e. the lemniscal auditory pathway). Because few studies have placed tracer injections into the rostral STP beyond AI and R, we injected anterograde and retrograde anatomical tracers into AI, R, RT, and RTp to quantify the thalamic inputs to these areas and address several outstanding questions about the organization of auditory cortex. Whereas AI and R both receive nearly 90% of their thalamic inputs from the MGv, RT receives only ~45% from MGv, and an equal share from the dorsal subdivision, MGd (Fig. 1). Area RTp receives ~25% of its inputs from MGv, but ~30% of its thalamic inputs arise from multisensory areas outside the MGN (e.g., medial pulvinar). In accord with the laminar patterns evident in corticocortical connections in the same cases, these

thalamocortical connections support a model in which AI and R lie at the same hierarchical level, but RT and RTp lie at a higher level, perhaps between that of the core and belt (Fig. 1). These results will be presented in the context of an expanded hierarchical model that aims to capture the complexity of the primate's ventral *auditory* stream, which may well exceed the complexity of the primate's ventral *visual* stream.

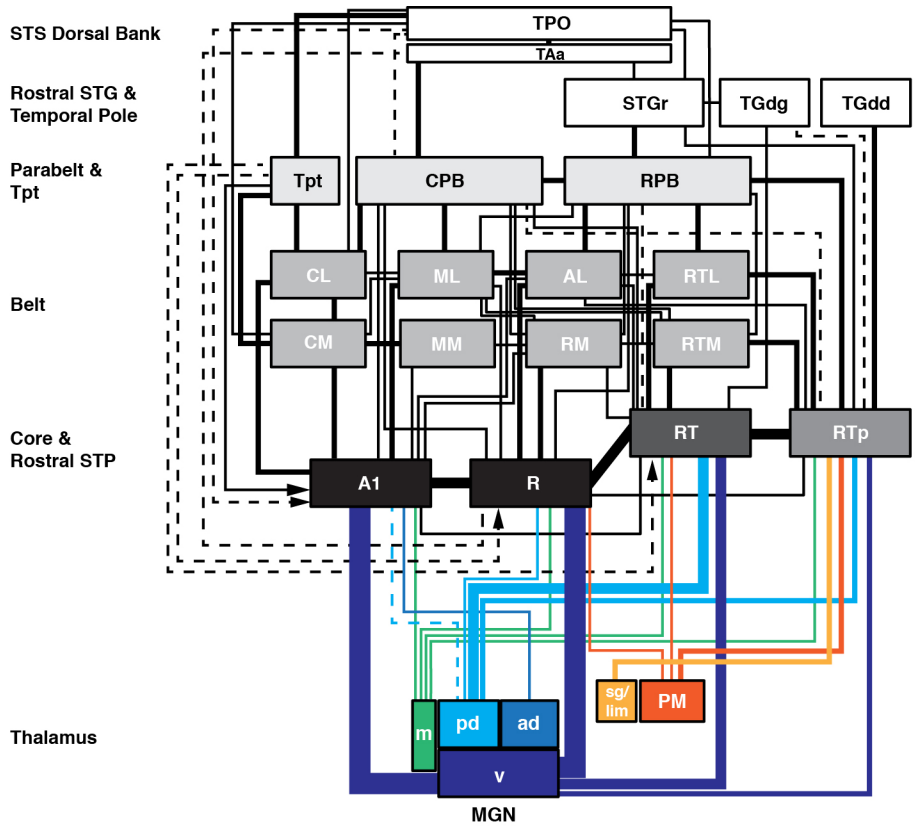

Figure 1: *Connections of the auditory thalamus and temporal cortex. Line weight reflects connection strength. Only thalamocortical connections to AI, R, RT, and RTp are shown.*

Title: Thalamic inactivation does not prevent auditory cortical plasticity induced by intracortical stimulation

Authors: *L. KONG, S. WANG, X. LIU, J. YAN;
Dept. of Physiol. and Pharmacology, Cumming Sch. of Med., Hotchkiss Brain Institute, Univ. of Calgary, Calgary, AB, Canada

Abstract: Auditory learning induces frequency-specific plasticity in the auditory cortex. However, the role of the intracortical circuitry for the development of the cortical plasticity remains unclear until the potential contribution of the corticothalamic and thalamocortical loop is excluded. Here, we examine the frequency-specific plasticity in the primary auditory cortex (AI) by electrical stimulation of AI (ES_{AI}) with and without inactivation of the auditory thalamus. We found that ES_{AI} induced cortical frequency-specific plasticity in the control condition when the auditory thalamus was not inactivated. Similar pattern of cortical plasticity was induced by ES_{AI} even when the auditory thalamus was inactivated during the ES_{AI}. The best frequencies (BFs) of the recorded cortical neurons shifted towards the BFs of the electrically stimulated ones. In addition, the BF shifts were linearly correlated to the BF differences between the recorded and stimulated cortical neurons. More importantly, the ratio of the linear function with thalamic inactivation was nearly the same as the ratio of the linear function in the control condition. Our data suggest that the induction of frequency-specific plasticity in auditory cortex does not rely on the corticothalamic and thalamocortical loop, thus the intracortical circuitry appears to independently underlie the cortical frequency-specific plasticity.

Title: Opposing shifts in the transcription of AMPA and GABAA receptor subunit genes support homeostatic gain adjustments in the auditory cortex and midbrain following cochlear denervation

Authors: *P. BALARAM[1], D. B. POLLEY[1,2];
[1]Eaton-Peabody Labs., Massachusetts Eye and Ear Infirmary, Boston, MA; [2]Dept. of Otology and Laryngology, Harvard Med. Sch., Boston, MA

Abstract: A loss of cochlear hair cells or afferent synapses induces a host of intracellular changes at every stage of the central auditory pathway. These changes are often compensatory, allowing central auditory neurons to recover threshold sensitivity and support robust sound perception despite a loss of inputs from the inner ear. One common compensatory response involves a homeostatic 'rescaling' of excitatory and inhibitory neurotransmission. Under normal conditions, neurons maintain a stable ratio of excitatory and inhibitory synaptic transmission (E/I balance) that allows them to preserve a set point of activity in the face of large drops or surges in afferent drive. Following the loss of auditory nerve afferent fibers or inner hair cells, sound-evoked activity is reduced in the auditory nerve and brainstem nuclei. However, recordings at higher stages of the auditory pathway, including the midbrain, thalamus, and auditory cortex, show significant increases in sound-evoked activity despite diminished input from the periphery. This increase in central gain points toward a shift in the underlying E/I balance in these structures, which could provide greater sensitivity toward spared inputs that remain following peripheral insult.
Here, we describe transcriptional changes that contribute to altered E/I balance following unilateral round window application of ouabain, a Na+/K+ ATPase inhibitor that lesions Type 1 afferent fibers in the auditory nerve. Selective denervation of afferent fibers without hair cell dysfunction was confirmed with ABR and DPOAE measurements. Several weeks following cochlear denervation, neurons in the auditory cortex, medial geniculate body and inferior colliculus all showed increased mRNA expression of the GluR2 AMPA receptor subunit (*Gria2)* and decreased expression of the GABAα1 receptor subunit (*Gabra1).* Using high-sensitivity fluorescence *in situ* hybridization, we compared *Gria2* and *Gabra1* counts in individual neurons, and conclude that more pronounced changes in E/I were found in auditory cortex than in subcortical areas. These changes may support the persistence of rudimentary sound perception in the face of extreme afferent loss but may also underlie auditory pathologies typified by hyperexcitability, such as tinnitus and hyperacusis.

Title: Influence of sensory activity on the development of subplate neuron circuits

Authors: *X. MENG[1], P. O. KANOLD[2];
[1]Dept. of Biol., [2]Biol., Univ. of Maryland, College Park, MD

Abstract: Subplate neurons (SPNs) are among the earliest generated neuronal population in the cerebral cortex. They provide a transient excitatory relay of thalamic information to layer 4. Ablation studies have shown that SPNs play an instrumental role in the establishment and refinement of early thalamocortical and intracortical circuits.
Sensory experience, esp. sensory deprivation, has a profound influence on cortical development. Since SPNs are the first cells to receive sensory activity, sensory deprivations could alter SPN function. This altered SPN function could influence the cortical circuit, and thereby cortical development, even past the duration of the sensory disruption. Thus we here test if sensory experience influences SPN function. We use genetic deafness model (TMC1,2 double-knockout mice) and investigate if synaptic circuits associated with SPNs in the auditory cortex (ACX) are disrupted.
To investigate synaptic circuits we use laser-scanning photostimulation (LSPS) in thalamocortical slices of ACX at postnatal days 6-14. We compare the spatial pattern of excitatory inputs to SPNs in cells from genetically deaf mice with those in normal controls. The analysis of a limited sample of cells suggests that the pattern of excitatory inputs to SPNs in cells from genetically deaf mice. These results indicate that early sensory experience might sculpt SPN circuits and thereby potentially alter subsequent development.
Since in humans the effects of deafness on SPNs would happen in utero before deafness can be diagnosed even at the earliest possible diagnosis cortical circuits could have already been affected by deafness.

Title: $GABA_A$ and $GABA_B$ mediated inhibition display distinct critical periods in auditory cortex.

Authors: *T. M. MOWERY[1], J. DIMIDSCHSTEIN[2], G. FISHELL[2], V. KOTAK[1], D. SANES[1]; [2]Langone Med. Ctr., [1]New York Univ., New York, NY

Abstract: Introduction
Sensory deprivation can induce profound changes to central processing during developmental critical periods (CPs). For example, loss of visual or auditory function during development commonly leads to reduced $GABA_A$ receptor-mediated inhibitory synaptic responses in cortex. However, the effect of hearing loss on $GABA_B$ receptor-mediated inhibition is not known. Here, we used a novel recombinant adeno-associated virus (rAAV) that restricts channelrhodopsin expression to telencephalic GABAergic interneurons, permitting us to optogenetically activate only inhibitory interneurons while recording from pyramidal cells. Using this approach, we investigated whether auditory cortex $GABA_A$ and $GABA_B$ receptor function was differentially altered by a period of developmental hearing loss.
Methods
Bilateral earplugs were inserted in gerbils (*Meriones unguiculatus*) on postnatal day 11, and were subsequently removed at successively later ages (P13, P17, or P18). On P48, auditory cortex was injected with rAAV-mDlx-ChR2-mCherry (50 nl). Adult thalamocortical brain slices were generated and whole-cell current clamp recordings were obtained from unlabeled L2/3 pyramidal cells. Inhibitory postsynaptic potentials (IPSPs) were evoked by stimulating with 1 ms pulses of blue light (470 nm).
Results
Light stimulation reliably evoked IPSPs that were composed of a short latency $GABA_A$ and a long latency $GABA_B$ receptor-mediated component. In a subset of experiments, each component was validated with selective antagonists to either $GABA_A$ (bicuculline) or $GABA_B$ (SCH-50911) receptors. When hearing loss was reversed at P13, both $GABA_A$ receptor amplitude components were normal in adulthood ($p's > 0.1$). When hearing loss was reversed at P17, $GABA_A$ergic IPSPs were smaller in adults (mean mV ± SEM: Ctrl – 9.4 ± 0.9 vs. EP11 to 17 – 6.0 ± 0.4, $p < 0.01$). In contrast, $GABA_B$ receptor amplitude was normal (mean mV ± SEM: Ctrl – 5.8 ± 0.9 vs. EP11 to 17 – 6.1 ± 0.5, $p > 0.1$). Finally, when hearing loss was reversed at P18, then both

$GABA_A$ (mean mV ± SEM: Ctrl – 9.4 ± 0.9 vs. EP 11 to 23 – 3.9 ± 0.4, $p < .001$), and $GABA_B$ receptor-mediated IPSPs were significantly diminished (mean mV ± SEM: Ctrl – 5.8 ± 0.9 vs. EP 11 to 23 – 1.9 ± 0.2, $p < .001$).

Conclusion

Our results support the concept that a brief period of sensory deprivation during developmental CPs has a long-lasting effect on synaptic inhibition. However, the two major classes of GABAergic transmission display unique CPs. Specifically, the effect of hearing loss on $GABA_B$ergic transmission requires a longer period of auditory deprivation.

Title: Mice with reduced alpha7 nicotinic receptors demonstrate auditory processing EEG abnormalities relevant to schizophrenia

Authors: *A. M. PATINO[1], D. J. GRAZIANO[1], D. FEUERBACH[2], M. M. SIDOR[1]; [1]Novartis, Cambridge, MA; [2]Novartis, Basel, Switzerland

Abstract: Recent studies have associated the α7 nicotinic acetylcholine receptor (nAChR) subunit gene, CHRNA7, with the pathophysiology of schizophrenia. In addition to abnormalities in cognition and mood, individuals with schizophrenia show robust deficits in inhibiting or suppressing incoming sensory input, termed sensory gating. Sensory gating is a normal physiological response observed across species and is measurable using electroencephalography (EEG). Such event-related potentials have been used to examine both normal and disease states, making them robust translatable biomarkers between humans and rodents. Understanding how these deficits in processing environmental stimuli arise may yield insight into the underlying circuit abnormalities in schizophrenia.

Heterozygous mice with a null mutation in the α7 nAChR gene have a ~ 50% reduction in nAChRs. Here, we systematically phenotype α7 heterozygous mice (α7 mice) through a battery of EEG-based auditory sensory paradigms, including auditory gating, mismatch negativity and

the auditory steady-state response. EEG recordings were performed with male α7 mice (B6.129S7-Chrna7<tm1Bay>/J , n=10) and age-matched wild type (WT) controls (C57BL/6J , n=10) using the Data Sciences International wireless telemetry system with skull screws implanted over the hippocampus for signal and cerebellum for reference. For auditory gating, paired 10kHz tones (10ms pulse width, 500ms interstimulus interval, 10s trial length) were presented for a total of 180 trials. The amplitude of the response to the first tone stimulus (S1) was compared to that of the second tone stimulus (S2). Gating was calculated as the S2/S1 ratio. We observed a significant deficit in auditory gating in α7 mice relative to WT controls. This deficit was primarily driven by reduced S1 P20 (most positive deflection between 10-30ms) and N40 amplitudes (most negative deflection between 35-65ms); no differences in S2 amplitudes were detected. This suggests that α7 nicotinic receptors primarily modulate the S1 response. To determine if gating deficits were due to reduced α7 receptors, nicotine was used to increase receptor activity. In both groups, nicotine (2.3mg/kg, sc) increased the P20 amplitude while decreasing N40 amplitudes, resulting in no overall S1 response change. However, nicotine decreased the S2 response, thus reversing the gating deficit in α7 mice to WT levels. Subtle deficits in the auditory steady-state response were also observed in α7 mice, suggesting broad network impairment. No abnormalities were observed in resting-state EEG. This work gives insight into the potential cortical circuit abnormalities involved in schizophrenia.

Title: An inhibitory corticostriatal circuit

Authors: *C. ROCK, H. ZURITA, C. WILSON, A. APICELLA;
Biol., Univ. of Texas at San Antonio, San Antonio, TX

Abstract: It is very well established that cortical neurons regulate the activity of spiny projection neurons (SPNs) in the striatum through long-range glutamatergic/excitatory projections, while inhibition is thought to be mediated by local feed-forward and feed-back circuits. Striatal neuronal activity has been shown to be involved in movement, learning, and goal-directed behavior, therefore it is crucial to understand the cortical connectivity pattern and dynamics that shape the flow of information in the striatum. Although anatomical and physiological studies have led to the assumption that the dorsal striatum receives exclusively excitatory afferents from

the cortex, here we demonstrate that the dorsal striatum also receives GABAergic projections from the cortex. We addressed this by taking advantage of optogenetics and directly examining the functional effects of cortical GABAergic inputs to SPNs from the mouse auditory and motor cortex. We found that the cortex, via corticostriatal somatostatin neurons (CS-SOM), has a direct inhibitory influence on the output of the striatal SPNs. Our results describe a previously unknown corticostriatal long-range inhibitory circuit (CS-SOM inhibitory projections → striatal SPNs) underlying the control of spike timing/generation in SPNs and attributes a specific function to a genetically defined type of cortical interneuron in corticostriatal communication. These findings may suggest that the timing and ratio of excitation and inhibition, two opposing forces in the mammalian cerebral cortex, can dynamically affect the output of the dorsal striatum, providing a general mechanism for motor control driven by sensory stimuli.

Title: Isoflurane anesthesia attenuates cortical responses to sounds in rats

Authors: M. M. HOLDFORD[1], Z. R. HOLLOWAY[1], J. J. SABLE[1,2], F. ANDRASIK[1], *H. J. SABLE[1];
[1]Dept. of Psychology, Univ. of Memphis, Memphis, TN; [2]Dept. of Behavioral Sci., Christian Brothers Univ., Memphis, TN

Abstract: The N100 component of the auditory event-related brain potential (ERP) represents the initial negative peak occurring approximately 80-120 ms after the onset of sound. The N100 is generated during sleep, but it is delayed. Anesthesia reduces the amplitude of the N100, but research examining anesthesia-related effects on N100 amplitude and latency is limited. In this study, we used subdermal needle electrodes in Wistar rats to examine isoflurane effects on auditory N100 amplitude and latency over a 20-minute session. The stimuli were pairs of 50-ms complex tones, presented with onset-to-onset intervals of 500 ms. The inter-pair interval (IPI) was randomized between 1 and 5 seconds. The isoflurane was then discontinued, and subjects were allowed to fully awaken, at which point the recording procedure to the tone pairs was repeated. Peak-to-peak amplitude of the N100 was reduced by isoflurane. These results confirm that the characteristics of the N100 are modified by anesthesia. Other ERPs were similarly

affected. Thus, measuring the N100 for diagnostic purposes in anesthetized patients is not advisable, but may provide information about optimal levels of sedation/anesthesia.

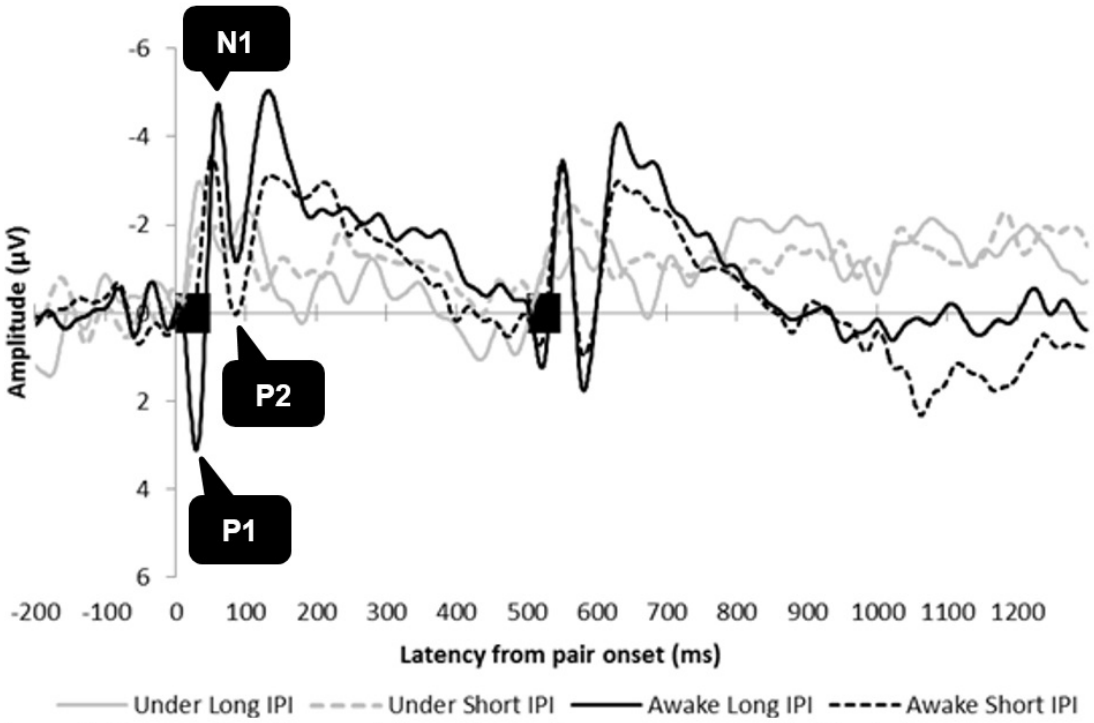

Figure 1. Event-related potentials to the auditory two-tone task. Black boxes represent the presentation of each tone in the pair. The short interpulse interval (IPI) was 1 second, while the long IPI was 5 seconds.

Title: Omissions of expected phonemes generate stimulus specific predictions in superior temporal gyrus, an ecog study

Authors: *Y. M. FONKEN[1], A. MUKERJI[2], P. BRUNNER[3,4], G. SCHALK[3,5], R. T. KNIGHT[2,6];
[1]Knight Lab. - Univ. of California, Berkeley, Berkeley, CA; [2]Helen Wills Neurosci. Inst., Univ. of California, Berkeley, CA; [3]Dept. of Neurol., Albany Med. Col., Albany, NY; [4]Natl. Ctr. for Adaptive Neurotechnologies, Wadsworth Center, New York state department of health, Albany, NY; [5]Natl. Ctr. for Adaptive Neurotechnologies, Wadsworth Center, New York state department of health, Albany,, NY; [6]Psychology, Univ. of California, Berkeley, Berkeley, CA

Abstract: Recent evidence suggests that higher-level predictions inform perception at the level of early sensory processing. The underlying mechanism of how predictions influence sensory processing is unknown. Studying omissions of expected sounds provides a unique way of isolating top-down prediction effects on auditory cortex. Evidence from electroencephalography (EEG) has revealed early (< 100ms) responses to unexpectedly omitted stimuli. In the current study we aimed to 1) establish whether auditory cortex responds to omitted stimuli by delineating the source of early activation and 2) define if this response is specific to the content of the prediction of the sound that was expected. We investigated these questions by recording electrocorticography (ECoG), while subjects listened to a sequence of phonemes in a regular pattern La-La-Ba; La-La-Ga, in which two of the phonemes ('Ba' and 'Ga') were infrequently omitted. To determine if an omission response was stimulus-specific, a binary classifier was applied to distinguish which phoneme was omitted. In one subject with a high-density grid (3mm; 250 channels) located over superior- and middle temporal gyrus (STG and MTG respectively), we found an early positivity (< 100ms) in the event-related potential (ERP) over the MTG in response to omitted stimuli, as well as a high-gamma band (70-150Hz) response in the STG (100-500ms). A logistic regression classifier trained on high-gamma in phoneme responsive electrodes successfully predicted (61.4%, compared to null distribution; 95% C.I. at 58.3%) which stimulus was omitted based on high-gamma band traces from 0-400ms relative to the omission 'onset' (i.e. when the omitted sound was expected). This study isolates a pure top-down influence on auditory cortex when an omission of a predicted event occurs. Our results localize previously reported omission positivity observed in EEG to auditory cortex. In addition, we confirm that expectation activates a representation of the expected stimulus in STG. In summary, our results suggest that the brain is generating higher-order predictions that influence auditory processing.

Title: Can transcranial direct current stimulation (tDCS) modulate auditory cortical oscillations? Simultaneous acquisition of tDCS and magnetoencephalography (MEG)

Authors: *M. HOLDING[1], P. ADJAMIAN[1], N. WEISZ[2], G. DEMARCHI[2], D. HALL[3]; [1]MRC Inst. of Hearing Res., Nottingham, United Kingdom; [2]Ctr. for Cognitive Neurosci., Univ. of Salzburg, Salzburg, Austria; [3]Nottingham Biomed. Res. Unit, Nottingham, United Kingdom

Abstract: Abnormal neural oscillations in the auditory cortex have been implicated in the generation of tinnitus. This has been shown several times in both magento- and electro-encephalography (MEG/EEG) studies. Given the problems that people with tinnitus face such as increased anxiety and depression, and the lack of treatments and therapies, anything that could be capable of helping tinnitus should be considered of importance. tDCS has been shown to be able to proactively modulate certain neuronal oscillations. However, those oscillatory frequencies studied were not the same as the ones implicated in tinnitus. When combined with residual inhibition (the temporary suppression of tinnitus following presentation of a masking noise) tDCS has been found to have the potential to increase the suppression of tinnitus. However, it is unclear what neural effects the tDCS and white noise combination is having. Both tDCS and masking noise devices are becoming increasingly available to consumers so it is imperative to fully understand what effects tDCS is having on neuronal oscillations. This study aimed to investigate the effects of tDCS on auditory cortical oscillations using MEG. We carried out a combined tDCS and MEG experiment on 13 non-tinnitus participants. Participants were stimulated using either a sham tDCS or anodal stimulation on alternating trials in conjunction with a white noise masker known to induce residual inhibition. MEG data was recorded during this process using an Elekta Neuromag 306 channel system. The data presented are the results of this investigation, and show modulations in alpha and delta frequency oscillations. This would indicate that tDCS is capable of modulation oscillatory frequencies implicated in the generation of tinnitus. Further work is needed to assess how this would convert to a tinnitus population, but offers a promising avenue of exploration.

Title: Entrainment of EEG during the music listening

Authors: Y. KUMAGAI, *T. TANAKA;
Dept. of Electrical and Electronic Engin., Tokyo Univ. of Agr. and Technol., Koganei-shi, Japan

Abstract: Introduction: It has been reported that music perception has an important role in developments of human cognitive functions such as intelligence, language, and memory (Schellenberg et al., 2005). Recently, the relationship between music and cortical activities have been well investigated. Nozaradan et al. reported that cortical entrainment to periodic tone (Nozaradan et al., 2012). Meltzer et al. showed cortical entrainment to periodic rhythm of music (Meltzer et al., 2015). However, it is unclear whether or not the celebral cortex entrains to natural music, aperiodic stimuli. Meltzer et al. also demonstrated that the cerebral cortex more strongly responded to the periodic rhythm of unfamiliar music than to that of familiar music. On the other hand, Jacobsen et al. reported that a deviant sound among a sequence of familiar sounds enhanced the mismatch negativity (MMN) compared to that among a sequence of unfamiliar sounds (Jacobsen et al., 2005). Therefore, it remains unclear how the familiarity of music affects the cerebral cortex. To better understand the mechanism of music perception, we investigated by using electroencephalogram (EEG) the cortical entrainment to natural music, and the relationship between cortical response and familiarity of music.
Methods: Eight subjects in their twenties participated in the experiment. All subjects were healthy and had normal or correctedtonormal vision. They were given an informed consent, and the study was approved by the research ethics committee of Tokyo University of Agriculture and Technology. We prepared single-tone melody as simple and natural music, and recorded EEG while a subject was listening to them. The experiment consisted of 30 trials, each of 32 seconds in length, while listening to one of the music stimulus. After each trial, subjects were instructed to answer whether the listened music was familiar or not. Each music was labeled with either “familiar” and “unfamiliar” according to the answers of subjects. The cross-correlation function was calculated between filtered EEG (2-8 Hz) and envelope of music for each label, based on the

finding that perception low-frequency is important for music perception (Farbood et al., 2013). Results: The cross-correlation function averaged across trials, channels, and subjects showed a peak at time lags around 150 ms. Moreover, the value of cross-correlation function at the peak while listening to unfamiliar music was larger than listening to familiar music. These findings suggest that at a low-frequency band, the EEG is entrained to natural aperiodic music, and the response to the music is stronger to unfamiliar music than to familiar music.

Title: Different cortical oscillation patterns effectively distinguish auditory selective and non-selective attention in multi-talker speech perception

Authors: *Y. GAO, L. LI;
Dept. of Psychology, Peking Univ., Beijing City, China

Abstract: Human listeners are able to selectively attend to the target speech in the noisy natural environment. The current study focuses on different cortical oscillation pattern of internal speech representation, long-term neural activities and cortical causal connections between selective and non-selective attention. The Event-Related Potentials (ERPs) signals were recorded from participants listening to multi-talker speech under selective or non-selective attention states. The results show that selective attention enhances the causalities from temporal area in alpha band oscillation and also enhances both causalities to right motor area and internal target speech representation in beta band oscillation, but non-selective attention improves both causality from motor area to frontal area long-term neural activities in gamma band oscillation. The findings suggest that different frequency bands of neural recording distinguish selective and non-selective attention by different cognitive processing.

Title: Neural noise in the human electroencephalogram predicts perceptual decisions

Authors: *L. WASCHKE, M. WÖSTMANN, J. OBLESER;
Dept. Of Psychology, Univ. of Lübeck, Luebeck, Germany

Abstract: Perceptual decisions close to threshold are error-prone and unstable. With less Information to base a decision on, the impact of spontaneous variations in brain activity increases. This is taken to extremes when discriminative information is absent altogether: When comparing two identical stimuli, pre-stimulus differences in brain activity and varying post-stimulus neural responses to the stimuli (together referred to as “neural noise”) must be driving the ensuing decision. Evidence from both modeling and experimental work on the discrimination of identical stimuli suggests that neural noise could indeed lead to varying percepts. Here, we investigated the potency of different indicators of neural noise in the electroencephalogram (EEG) to predict the later perceptual decision. We recorded the 24-electrode scalp EEG while human subjects (n = 16; age 19-74) discriminated two identical, consecutively presented pure tones (SOA = 900ms, 650 Hz) and reported whether the first or second tone was higher in pitch. Since evoked responses did not differ between decisions, we pursued two routes of analysis to address trial-by-trial variations of pre-stimulus noise and systematic differences in the neural post-stimulus response. First, we analyzed trial-wise Weighted Permutation Entropy (WPE) of the broadband EEG signal (1-100 Hz), an information-theoretic measure quantifying the regularity of time series data. WPE around presentation of the first tone allowed classification whether participants would later report the first versus the second tone to be higher in pitch (above-chance classification in 12 out of 16 subjects). Second, Theta band (6-9 Hz) Inter-Trial Phase Coherence (ITPC) as a measure of stimulus-evoked activity around the presentation of the first tone was higher over central electrodes when this first tone was later chosen as compared to trials of the opposite decision. Lastly, we quantified differences in phase concentration around tone onset with a phase bifurcation index. Higher phase concentration (i.e., lower neural noise) in the Delta- (1- 4 Hz, before onset of the first tone) and Theta-Band (at onset of the first tone) at fronto-central sensors marked decisions for the first tone. In sum, both time-domain, information-theoretic measures and time-frequency, phase-coherence measures suggest that auditory decisions in the absence of physical stimulus evidence can serve as a proxy for the

degrees to which neural noise is involved in varying percepts and to which neural noise can promote perceptual learning.

Title: Neural representation and hierarchical processing of Chinese phonemes in temporal cortex revealed by intracranial EEG

Authors: *C. SONG[1], R. XU[2], B. HONG[2];
[1]Tsinghua Univ., Beijing City, China; [2]Tsinghua Univ., Beijing, China

Abstract: An important procedure in human speech recognition is to recognize the segmental units, e.g. phonemes and syllables, from the continuous speech sound stream. In English, these segmental units, especially phonemes and their acoustic features were represented in temporal cortex (Mesgarani, 2014). In this study, we used intracranial EEG signal from both surface and depth electrodes on human cortex to explore the representation of segmental units in Chinese, e.g. phonemes and combination of phonemes, which are supposed to be fundamental units in previous phonological studies. Subjects were instructed to listen to short stories. Chinese rhymes, which are defined to be composed of 3 phonemes named glide, nucleus and coda in phonology (Lee, 2003; Duanmu, 2000), were manually segmented from the stories. High gamma responses showed clear selectivity to Chinese rhymes on some electrodes throughout auditory pathway such as Heschl's gyri (HG), superior temporal gyri (STG) and superior temporal sulci (STS). To further explore the hierarchies along auditory pathway, we constructed both acoustic model and identity model for the Chinese rhymes. In the acoustic model, features for the rhymes were derived from principal components of their spectrograms. These models showed significantly different explained variance along the auditory pathway, which clearly dissociate the low level areas (HG) and high level areas (STG, STS). High level areas also showed stronger speaker invariance in their selective response. In short, the representation of speech units clearly exists in continuous speech perception, and distinct features of speech were processed along the

hierarchies of auditory pathway, with high level representation biased to the identity of rhymes rather than acoustic features.

Title: Effects of L-dopa on the benefit from attention to memory

Authors: *S.-J. LIM[1,2], C. THIEL[3], B. SEHM[2], L. DESERNO[2], J. LEPSIEN[2], J. OBLESER[1,2]; [1]Dept. of Psychology, Univ. of Luebeck, Luebeck, Germany; [2]Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany; [3]Dept. of Psychology, Univ. of Oldenburg, Oldenburg, Germany

Abstract: Selective attention to working memory (i.e., retrospective attention) is known to facilitate recall performance. We previously showed that retrospective attention to syllable objects in auditory working memory improves representational quality of the attended object. However, the extent to which multiple attention-related top-down brain networks and sensory (i.e., auditory) cortical regions are modulated by auditory retrospective attention is relatively unknown. Furthermore, dopamine is known to enhance working memory and cognitive flexibility. Yet, it is still unclear whether increased level of dopamine modulates neural activity that underlies retrospective attentional benefits. By using functional magnetic resonance imaging (fMRI) and pharmacological manipulation, we investigated the neural basis of auditory retrospective attention benefits in respect to dopaminergic modulation. Human participants (N=22, aged 25-35) underwent two separate scanning sessions, each with either 150 mg of L-dopa (Madopar) or placebo, while performing a syllable pitch-discrimination task. On each trial, participants encoded and maintained two sequentially presented syllables. During maintenance, a valid or neutral visual retro-cue was presented to guide participants' attention to a to-be-probed syllable in memory. Behaviourally, directing attention to the to-be-probed syllable via exogenous valid retro-cues led to faster and more precise detection of pitch change occurred at probe. However, under L-dopa the response-time benefit from valid retro-cues was reduced as L-dopa

increased the speed of response even in the uninformative neutral cue trials. Neurally, during the cue and maintenance period the primary auditory cortical regions were suppressed regardless of cue conditions. Overall, retrospective attention to a specific syllable led to enhanced activations in language-related networks, such as left inferior frontal gyrus and left posterior superior temporal regions as well as top-down attentional control networks, such as fronto-parietal and cingulo-opercular networks. However, L-dopa attenuated the extent of neural modulation in attentional networks, especially in the right dorsolateral prefrontal cortex and right insula by enhancing neural activity in the neutral cue trials. Overall, our results suggest that retrospective attention to auditory working memory engages top-down networks to actively select and maintain attended objects in memory, but increased dopamine level generally reduces attentional benefits from the exogenous cue to direct attention to memory.

Title: Investigating decay in human auditory sensory memory with direct intracranial recordings

Authors: *A. WILSCH[1], A. RHONE[2], K. V. NOURSKI[2], C. S. HERRMANN[3], J. OBLESER[4]; [1]Univ. of Oldenburg, Oldenburg, Germany; [2]Dept. of Neurosurg., The Univ. of Iowa, Iowa City, IA; [3]Exptl. Psychology lab, Universitiy of Oldenburg, Oldenburg, Germany; [4]Dept. of Psychology, Univ. of Lübeck, Lübeck, Germany

Abstract: Working memory is characterized by two limitations: First, the amount of information that can be retained in memory (i.e., memory load) and second, the duration of retention (i.e.,

memory decay). Neural oscillations in the alpha frequency range (8-13 Hz) have been shown to increase in power with increasing memory load during memory retention (e.g. Jensen et al., Cereb Cortex. 2002, 12:877-882). However, it is unclear whether alpha power plays a more direct role in sensory memory decay and in potential counteracting factors, such as temporal expectations during sensory encoding. This study sought to characterize the degree to which neural oscillatory responses in human superior temporal cortex and its vicinity co-vary with sensory memory decay, and whether oscillatory decay would be modulated by temporal expectations. Subjects were neurosurgical patients undergoing chronic invasive electrocorticographic (ECoG) monitoring for remediation of medically refractory epilepsy. In an auditory delayed matching-to-sample task temporal expectations were manipulated (fixed vs. jittered cue-stimulus time interval) for a pair of pure tone sequences (S1-S2) embedded in white noise. Memory decay was manipulated with variable S1-S2 delays (1, 2, 4 s). ECoG data were simultaneously recorded from Heschl's gyrus (HG) and perisylvian cortex including supramarginal gyrus (SMG) using depth and subdural grid electrodes, respectively. Time-frequency analysis of neural responses focused on activity during the delay phase. Linear mixed models on the factors temporal expectations and memory decay revealed that alpha power increased with increasing delay phase duration at HG, independent of temporal expectations. Additionally, there was an interaction of temporal expectations and memory decay on left SMG indicating that alpha power increased with delay phase duration when S1 was temporally expected and decreased when S1 was not expected. Notably, the expected event-related high gamma power (80-150 Hz) increase at stimulus presentation was only present at the very onset of a trial but not during encoding of S1 and S2, most likely due to the ongoing noise masker. These findings imply that alpha power in auditory cortex (HG) serves as a neural marker of the inhibitory or protective processes required for sensory memory. This supports a domain-general interpretation of alpha as a modulatory top-down signal. Moreover, alpha power in SMG, a region relevant for pitch memory, indicates facilitated stimulus retention during memory decay for temporally expected sensory events.

Title: Ongoing dynamics of frequency-specific large-scale brain networks predict the speed of auditory decisions

Authors: *M. ALAVASH[1,2], C. DAUBE[2], M. WÖSTMANN[1,2], A. BRANDMEYER[2], J. OBLESER[1,2];
[1]Auditory Cognition Group, Inst. of Psychology I, Luebeck, Germany; [2]Max Planck Res. Group "Auditory Cognition", Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany

Abstract: Combining human magnetoencephalography (MEG) and source localization with large-scale network analyses allows us to explore the dependence of perception and cognition on frequency-specific brain network states. It is unknown to what degree the neural implementation of perceptual decisions relies on the brain functional connectivity networks that process the information available, for example from the auditory modality. Here, we investigate how ongoing brain network states relate to listeners' perceptual decisions in two distinct yet challenging auditory tasks. We measured MEG signals in human listeners (N = 20, age 20-38) who judged brief (400-ms) acoustic textures along one of two distinct dimensions. The acoustic textures consisted of densely layered tone sweeps and varied in the proportion of coherent tones in terms of sweep rate (upwards or downwards; local feature), as well as their overall pitch (global feature). Oscillatory power of the MEG source signals were derived within -0.5-1.5 sec relative to stimulus onset for the frequencies 1,2,4 Hz, together with the alpha and beta bands (8-32 Hz). To assess neural interactions in terms of graph-theoretical measures, Pearson's correlations between the power of all pairs of sources were computed per trial. Binary brain graphs were built at 10% of density, from which graph metrics were extracted per trial. To predict trial-by-trial decision speed from the ongoing brain network states, we used a general linear model approach, controlling the effects of the acoustic features (i.e. coherence and pitch). The standardized regression weights obtained from this model were averaged over subjects and compared with a null distribution. On the whole-brain level and for both tasks, faster decisions were correlated with lower global integration and higher segregation of dynamic brain networks. This effect was found prominently in the beta band (peaking at 21 Hz; false coverage-statement rate corrected). Interestingly, on the regional level we also found task-specific effects: Higher local efficiency in the vicinity of right supramarginal gyrus correlated with faster decisions in the pitch task. In contrast, higher local efficiency within the right anterior cingulate and left middle frontal gyrus correlated with faster decisions in the coherence task. Our results suggest that higher segregation of brain functional connectivity networks in mainly extra-temporal cortices speeds up auditory decisions. This might be due to more efficient local communication within the task-relevant networks. Depending on the task, this network configuration can emerge in distinct areas within the parietal and frontal cortices.

Title: Scalp EEG predicts listener's attentional focus and attentional demands under continuously varying signal-to-noise ratio

Authors: *L. FIEDLER[1,2], M. WÖSTMANN[2], S. HERBST[2], C. GRAVERSEN[3], T. LUNNER[3], J. OBLESER[2];
[1]Auditory Cognition, Univ. of Luebeck, Luebeck, Germany; [2]Dept. of Psychology, Univ. of Lübeck, Lübeck, Germany; [3]Oticon A/S, Eriksholm Res. Ctr., Snekkersten, Denmark

Abstract: In natural auditory scenes, the sound pressure level of the many sound sources varies over time. If a listener attends to one sound source (i.e., the signal) and ignores the other sound sources (i.e., the noise), the time-varying signal-to-noise ratio (SNR) can be extracted. In concurrent-speaker paradigms, the low-frequency oscillatory responses (~1-5 Hz) in the magneto- and electroencephalogram (M/EEG) phase-lock to the slow amplitude fluctuations (i.e., the temporal envelope) of speech. Importantly, this neural phase-locking is enhanced for attended versus ignored speech and furthermore for higher versus lower signal-to-noise ratios. In addition, the power of neural alpha oscillations (~10 Hz) correlates with the top-down demands of effortful listening and might indicate the inhibition of task-irrelevant perceptual input and neural processes. However, it is unclear in how far listening depends on the interplay of low-frequency phase and alpha power in time.
In order to extract the time courses of low-frequency phase-locking and alpha power in an approximated real-life listening scenario, four human subjects (aged 23-47) were asked to listen to one of two simultaneously presented audiobooks while the EEG was recorded. Over time, the two audiobooks followed two uncorrelated level time courses, yielding a highly variable underlying SNR time course varying between -6 and +6 dB. We employed regularized regression to predict (i.e., to forward-model) the EEG responses from the acoustic input signals. In detail, first, spectro-temporal profiles of attended and unattended speech were used to predict low-frequency phase-locking. Second, the underlying SNR time course was used to predict the power of induced alpha oscillations.
Under these continuously varying listening conditions, the attended speaker could be identified with an accuracy significantly above chance in all individuals by predicting the low-frequency phase-locking both of the attended and unattended speaker from the spectro-temporal representations. Best prediction of the listener's attentional focus was found at fronto-central

scalp channels. Furthermore, a fronto-central alpha power enhancement followed increases in the SNR with a temporal delay of several seconds.
These data pose a new approach to identifying a listener's attentional focus from EEG data applying a combined model for the prediction of low-frequency phase and alpha power. In this respect, our results suggest that low-frequency phase and alpha power reflect the enhanced neural encoding of attended acoustic input and the ensuing deployment of attentional control to overcome listening demands, respectively.

Title: Imagined rhythm can be decoded from EEG

Authors: *H. OKAWA, K. SUEFUSA, T. TANAKA;
Tokyo Univ. of Agr. and Technol., Koganei-Shi / Tokyo, Japan

Abstract: Introduction : The neural mechanisms of rhythm perception have been studied for many years. A related work reported that rhythm imagery elicits a periodic electroencephalogram (EEG) response tuned to the imagined rhythm frequency (Nozaradan et al., 2011). They recorded EEG while subjects listened to periodic sounds and imagined rhythm. Their study revealed the neuronal entrainment to imagined rhythm by investigating neural responses to auditory rhythmic stimulus. However, brain activity during rhythm imagery without any auditory stimulus has not been revealed. Therefore, in this study, we recorded EEG while subjects imagined beat and meter under the condition that they were not presented any auditory stimulus, and investigated neuronal entrainment to imagined beat and meter by analyzing amplitude spectra of EEG. Methods : Nine subjects in their twenties participated in the experiment. All subjects were healthy and had normal or corrected-to-normal vision. They were given an informed consent, and the study was approved by the research ethics committee of Tokyo University of Agriculture and Technology. Subjects were asked to perform a no imagery task and three types of rhythm imagery tasks. In the rhythm imagery tasks, subjects were asked

to imagine beat by imaging tones at regular intervals and imagine the meter by changing strength of imaging tones. To give subjects a reference tempo for rhythm imagery, we used a movie like a rhythm game. In the no imagery task, subjects were asked to watch the movie without thinking about anything. This task was performed to compare the results with the rhythm imagery tasks. The EEG was recorded using 30 Ag/AgCl active electrodes located on the scalp following the international 10-10 system. We analyzed EEG epochs lasting 10 s during tasks as follows. Firstly, EEG epochs were filtered using the third-order Butterworth bandpass filter with a passband of 0.5-15 Hz. Secondly, EEG epochs were segmented into four epochs lasting 2.5 s, and then, they were averaged. Thirdly, for each subject and task, averaged EEG epochs lasting 2.5 s were averaged across trials. Finally, the trial-averaged EEG epochs were transformed into the frequency domain using the discrete Fourier transform. Results : EEG amplitude at imagined rhythm frequency clearly increased in each of the rhythm imagery tasks. We found that EEG amplitudes at imagined rhythm frequency in each of the rhythm imagery tasks were significantly greater than that in the no imagery task. Conclusions : We investigated neuronal entrainment to rhythm which was imagined without any auditory stimulus. We found that rhythm imagery elicited a periodic EEG response at imagined rhythm frequency.

Abstract: In a previous study (Selezneva et al, 2013), neuronal responses from the macaque primary auditory cortex had sensitivity to the type of isochronous sequence being presented. We defined isochrony as the occurrence of all tones with a strict periodicity, in our study 400ms apart. Stimuli consisted of complex tones of either 50 or 200 ms (also referred to as “short” and “long” respectively). Short and long tones were presented either in regular sequences of short-

short-long triplets or in irregular sequences in which they were randomly permuted (scrambled). The modulation of neuronal responses was in particular evident in a higher firing rate during the long tone in the regular isochronous sequence.
§
In this experiment we parametrically varied isochrony and regularity to determine whether either or both factors were important in the facilitation of neuronal responses by the rhythmical sequences. We presented 6 types of sequences with regular isochronous, regular partially isochronous and regular non-isochronous tone sequences, as well as irregular sequences where the long tones were randomly permuted among the short tones. The macaques were passively listening to these sequences and were not required to make a behavioural response.
§
A total of 101 multiunits with excitatory responses were analysed from two monkeys. A repeated measures ANOVA with 2 fixed factors, isochrony and regularity (i.e. whether the stimuli were arranged in short-short-long triplets or were randomly scrambled) was carried out. Both factors were significant in modulating the response of the population of neurons to the long tone. The responses to the 200ms stimuli were highest in the two regular isochronous sequences without scrambling.
§
We conclude that neural activity in the auditory cortex was modulated by regularities in a sound sequence. The modulation led to higher network excitation during the regular isochronous and partially isochronous sequences, the most rhythmical sequences with the highest degree of temporal predictability.
§

Title: Subconscious detection of the pitch change direction

Authors: *K. SAITO[1,2], M. MATSUHASHI[1,4], T. AWAYA[2], T. KATO[2], T. MIMA[1,5], A. IKEDA[3], H. FUKUYAMA[1,4], T. HEIKE[2];

Sch. of Core Ethics and Frontier Sci., Ritsumeikan Univ., Kyoto, Japan

Abstract: [Introduction] The ability to discriminate emotion is so primitive that infants before speaking words are partly able to recognize emotions of the speaker. A distinction of emotion is sometimes represented by an alteration of pitch change direction of prosody. So we hypothesized that alterations of pitch change direction were detected in an early stage in perception. To clarify this hypothesis, we recorded mismatch fields of pitch change directions in unattended condition. [Method] Subjects were 20 healthy volunteers, age 19 - 26, without history of neurological or audiological diseases. Auditory multi-feature odd-ball paradigm with one standard and two types of deviants were performed. Each sound stimulus consisted of a common 600 ms tone-burst and a successive 200 ms that had different pitch from the preceding part, and presented with a 1200 ms stimulus onset asynchrony. The direction of pitch change of the latter 200 ms part of deviant 1 sound was the same as standard sound but with larger difference, and that of deviant 2 sound was opposite to standard sound but the same difference. Mismatch fields were recorded by 306 ch whole head magnetoencephalography (MEG). Source dipoles of deviant 1 and deviant 2 over left and right temporal areas were estimated from respective averaged waveforms in the time window of 75 ms to 225 ms from the beginning of the change of pitch, then mismatch responses were calculated as the largest differences between source activities of deviant stimuli and those of standard-like stimuli, which consisted of only the corresponding deviant sound presented with a 1200 ms stimulus onset asynchrony. After the MEG recording, behavioral tests to detect dissimilarity of stimuli pairs were performed with similar sound stimulus sets used in MEG. [Results] Two subjects were excluded from MEG analysis because of large and poorly controlled artifacts. ANOVA of the mismatch responses revealed a main effect of the pitch change direction ($p = 0.0002$), and the mismatch responses of deviant 2 (opposite direction) were larger than that of deviant 1(same direction). Behavioral study of 19 subjects excluding one subject because of lack of understanding showed that the pitch change directions significantly affected accuracy ($p < 2.2 \times 10^{-16}$) and response time ($p = 2.3 \times 10^{-9}$), and the accuracy was higher and the response time was shorter when the pitch change directions of the paired stimuli were opposite to each other. [Discussions] The results show that discrimination of pitch change direction is processed in the early, subconscious stage. This explains the result of behavioral data that it is easier to discriminate the pitch changes with a alteration of direction.

Title: Cyborgs have problems too: measuring the cognitive cost of assistive technologies for the deaf

Authors: ***H. WILLIS**, S. ROSEN, D. VICKERS;
Speech, Hearing and Phonetic Sci., Univ. Col. London, London, United Kingdom

Abstract: In this century, those with hearing impairment have become cyborgs: their physiological functioning is dependent upon, or aided by, an electronic device. It is often assumed that, because many of these technologies are able to significantly improve speech perception, the negative impact of the disability has been ameliorated too. However, it must be borne in mind that none of these assistive technologies are able to restore perfect hearing, meaning that extra cognitive processing is required to compensate. This additional cognitive load has been specifically identified as listening effort. Alarmingly, listening effort has recently been discovered to have a direct and negative impact on physical and mental health. Yet, despite these acknowledged health consequences, there is no clinical test available to quantify and monitor this pernicious phenomenon. This study piloted a prototype of the first clinical test of listening effort on 6 normal hearing controls listening to simulations of the cochlear implant, as well as 4 experienced cochlear implant users. This cohort of deaf individuals were selected because cochlear implant users are often deemed to be the closest to being cured of their disability. This prototype was based on a novel dual task paradigm comprising of a primary task of auditory recall (in either quiet or in noise) that was to be simultaneously executed alongside a secondary task of visual recall. The intention was that secondary task performance will become the index of listening effort in the cochlear implant user. To validate the sensitivity and reliability of this listening effort index, a physiological process known to be intimately related to listening effort was measured: the pupil dilation response. In addition, a thorough assay of cognitive, executive,

intellectual and hearing function was performed to separate out any confounding variables. Results showed that normal hearing controls exhibited a decrease in secondary visual recall when listening to cochlear implant simulations compared to normal speech, suggesting increased listening effort. However, the cochlear implant users were unable to perform in noise (i.e. signal-to-noise ratio of -5dB SPL), despite being exemplary users of the cochlear implant. The pupil dilation response indicated that the cochlear implant users were overwhelmed by the auditory stimulation, with pupil constriction being exhibited instead of the predicted dilation. Therefore, there are indications that: 1) listening effort is being detected by this prototype clinical test; and 2) cochlear implant users are particularly vulnerable to excessive listening effort levels.

Title: Electrophysiology of the human superior temporal sulcus during speech and language processing

Authors: *M. STEINSCHNEIDER[1], K. V. NOURSKI[2], A. E. RHONE[2], H. KAWASAKI[2], M. A. HOWARD, III[2];

Abstract: The superior temporal sulcus (STS) is a crucial hub in the cortical system subserving speech perception. To date, this area has been primarily examined with non-invasive functional neuroimaging (e.g. fMRI). Electrocorticography (ECoG) offers a unique opportunity to study this region with both high spatial and temporal resolution. Here, we examined ECoG activity evoked in the STS by a variety of stimulus classes under multiple task conditions. Our goal was to identify fundamental electrophysiological properties of this region. Subjects were neurosurgical patients undergoing chronic invasive monitoring for medically intractable epilepsy. All procedures were approved by the University of Iowa Institutional Review Board and NIH, and all subjects gave informed consent for this study. Direct recordings from middle and anterior portions of the STS were made using multicontact depth electrodes that targeted mesial temporal lobe structures (amygdala and hippocampus). ECoG data were simultaneously acquired from the auditory cortex in Heschl's gyrus (HG) and lateral superior temporal gyrus (STG) using penetrating depth and subdural grid electrodes, respectively. Stimuli were non-speech and speech sounds, presented in passive-listening and target detection tasks. Additional data were acquired during performance of the Mini Mental State Exam (MMSE; Folstein et al., J Psychiatr Res, 1975, 12:189-98) and other cognitive tasks. ECoG frequencies between 4 and 150 Hz were examined. The STS exhibited response profiles distinct from those in auditory cortex. The STS was less responsive to non-speech stimuli compared to speech. Prominent activity occurred in low gamma (30-70 Hz) and beta (14-30 Hz) bands. Responses had longer onset latencies than those in HG and on STG, except its most anterior portion. Activity within the STS preceded subjects' behavioral responses during active tasks. In a minority of sites, activity preferentially increased to target stimuli, including complex tones. Responses increased with intelligibility when speech was manipulated using a noise vocoder. Comparable degrees of activity were elicited in the language-dominant and non-dominant hemispheres. Finally, a conversation-based paradigm (MMSE) revealed sites in STS that preferentially responded to the subject's own speech over that of the interviewer's, reflecting their possible involvement in the dorsal audiomotor processing pathway. We conclude that human STS can be effectively probed with ECoG, offering unique insights into its response properties and the transformations that occur from earlier processing stages in auditory cortex.

Title: Biological motion sensitivity in deaf adults:an fMRI study

Authors: *M. SIMON[1], L. LAZZOUNI[1], E. CAMPBELL[1], F. CHAMPOUX[2], A. NEWMAN[3], F. LEPORE[1];
[1]Psychology, [2]Audiol., Univ. De Montreal, Outremont, QC, Canada; [3]Dalhousie Univ., Halifax, NB, Canada

Abstract: BACKGROUND: After an auditory privation, plasticity changes occur in the brain that make reference to a cross-modal reorganization. For individuals who use sign language as their primary means of communication, it is necessary to be more sensitive to the different types of motions (communicative *vs* non-communicative). Recently, research with deaf adult signers has uncovered an enhancement for visual motion detection. Also, the neural substrates for sign language requires activations of neuronal regions used in the processing of spoken language. However, it is not strictly identical as structural and hemispheric distinctions are noticeable on deaf subjects. OBJECTIVE: The aim of this study is to explore the influence of these processes (linguistic and visual detection) on the acute sensitivity of deaf subjects to detect and identify communicative *vs* non-communicative motions. METHOD: Functional MRI data were acquired on normal hearing and deaf signer participants. The task consisted of identifying the type of motion (communicative sign for "eat"), non-communicative ("playing piano") and scrambled (random motion) represented by point-light animations. Lasting approximately six minutes, the task was completed twice by each participant in a randomized order. RESULTS: Group differences were found between deaf and normal hearing participants in all conditions. More activity in temporal and frontal regions is found in deaf participants. Normal hearing participants were significantly less sensitive and slower to the presentation of communicative gestures than to the presentation of non-communicative movements, whereas deaf signers were equally sensitive and prompt to both types of motion. DISCUSSION: Consistent with previous research, these findings suggest that deaf and normal hearing participants use different systems for processing motion that may be result of an adaptative brain plasticity.

Title: Listening to music increases motor evoked potential amplitude in healthy older adults

Authors: *P. IZBICKI[1], S. ANDERSON[1], E. STEGEMOLLER[2];
[1]Neurosci., [2]Kinesiology, Iowa State Univ., Ames, IA

Abstract: Music has the ability to evoke various emotions as well as physical movement. However, there is only anecdotal experience that suggests that music influences the intent to produce a movement. Previous results from our lab using EEG have shown an increase of power in the upper Beta and lower Gamma band when moving in time with music. Moreover, there was a differential effect of style of music on the sensorimotor cortical activity when moving at fast rates. The use of transcranial magnetic stimulation (TMS) may provide further insight into these findings. Thus, the aim of this study was to examine motor evoked potential (MEP) amplitude induced by TMS in healthy young adults listening to different styles of music. Participants were exposed to three listening conditions during TMS: no music, relaxing music, and activating music. Twenty single pulses of TMS were applied over the hand area in the primary motor cortex approximately every 8 seconds at 120% resting motor threshold intensity for each condition. MEPs were recorded from the first dorsal interossieous muscle (FDI) using bipolar surface electromyography (EMG) (Delsys). Mean MEP amplitude was obtained for each condition. Repeated measures ANOVA was completed to compare MEP amplitude between the music and non-music conditions. Results thus far have revealed no statistically significant differences. However, mean MEP amplitude was greater for both music conditions compared to rest, suggesting that music listening may increase motor cortical excitability. Increasing the number of participants may reveal significant differences between music conditions.

Title: A neural signature of segregation of tone sequences, independent of the attended stream

Authors: *A. J. BILLIG[1,2], M. H. DAVIS[2], R. P. CARLYON[2];
[1]Brain and Mind Inst., London, ON, Canada; [2]MRC Cognition and Brain Sci. Unit, Cambridge, United Kingdom

Abstract: Repeated ABA- triplets of pure tones are often initially heard as arising from a single source but after several seconds split into two streams, each containing tones of one frequency. The percept then alternates between “integrated” and “segregated” forms. Characterising the neural response associated with these contrasting percepts is valuable for two reasons. First, it may reveal the loci and timing of mechanisms underlying perceptual organisation. Second, it provides an objective signature that can be used to probe how segregation is affected by cognitive factors, such as intention. Scalp recordings of evoked electric and magnetic fields have revealed percept-related differences in phase-locked activity between the B and final A tone of each triplet (Gutschalk et al., J Neurosci, 2005; Hill et al., Front Hum Neurosci, 2012; Szalárdy et al., Bio Psychol, 2013). However, whether this reflects modulation of native components (P1/N1), perhaps due to attention, or instead represents a new streaming component remains unclear. Divergent results may be due in part to different recording modalities and signal processing approaches. Here, 24 participants with normal hearing listened to 150-second ABA- sequences (A tones four or six semitones higher than B tones, 600-ms between-triplet onset asynchrony) while continuously reporting their percept. Cortical activity was recorded with concurrent EEG and MEG. In some sequences participants listened neutrally, while in others they attempted to bias their perception (by attending to the whole pattern, or to the A or B tones exclusively). The 20 sensors with the highest signal-to-noise ratio (for power at the triplet repetition rate, 1.67 Hz) in each recording modality were selected for each participant, and a weighted average evoked response calculated for each condition over 600-ms epochs. The continuous presentation of stimuli does not allow for an activity-free baseline period, so various alternative high-pass filters and baselines were applied to emphasise activity on different timescales. Percept differences in the neutral condition were revealed more strongly in magnetic than electric fields, and their timing depended on the signal processing. In general, segregation was reflected in an extended positivity beginning around 90 ms after the B tone, and distinct

from the canonical P1/N1 responses. Importantly, this signature persisted when comparing "attempt segregation" to "attempt integration" trials, and did not depend on whether the A or B tones were the focus of attention during attempts to segregate. This suggests the signature is truly one of streaming, and that listeners can influence their percept.

Title: Direct human electrical recordings demonstrating fundamental bases for auditory figure-ground analysis

Authors: *P. E. GANDER[1], S. KUMAR[2,3], K. V. NOURSKI[1], H. OYA[1], H. KAWASAKI[1], M. A. HOWARD, III[1], T. D. GRIFFITHS[2,3];
[1]Dept. of Neurosurg., Univ. of Iowa, Iowa City, IA; [2]Inst. of Neurosci., Newcastle Univ., Newcastle Upon Tyne, United Kingdom; [3]Wellcome Trust Ctr. for Neuroimaging, Univ. Col. London, London, United Kingdom

Abstract: The ability to detect a relevant sound by filtering out irrelevant sounds in the environment is crucial in day-to-day listening. This ability requires that the features of the relevant sound be grouped together as a single source (figure) and segregated from the features (background) of other competing sounds in the environment. How the auditory system performs this task is not completely understood. In the current experiment we recorded local field potentials (LFPs) from human subjects undergoing invasive ECoG monitoring for pre-surgical localization of their epileptic foci while they were listening to a stimulus in which the salience of the figure was varied systematically against a background. The subjects were implanted with depth electrodes in auditory cortex along the axis of Heschl's Gyrus (HG) and subdural grids covering the superior temporal gyrus (STG).
The subjects listened to a stimulus in which the salience of the figure was varied systematically against a background. We used a stochastic-figure-ground (SFG) stimulus developed in our lab that has been previously characterized using psychophysics and modelling. The SFG consisted of

a sequence of simultaneously presented tones that were randomly distributed in log frequency space and varied from one 25 ms time frame to the next. During one time segment, a certain proportion of the tones remained the same over several consecutive time frames. This causes a figure to emerge from the background in which the salience is determined by number of tones kept fixed (the coherence) and the number of time frames over which this occurred (duration). In the current experiment, the first part (700ms) of the stimulus consisted of only the background with no figure, and in the second part the coherence of the figure was varied across trials (between 0, 2, 4 and 8). The overall duration of the figure was 28 individual 25ms time frames (700ms).
We measured event-related potentials (ERPs) and carried out single-trial time-frequency analysis using a wavelet transform. In HG responses to the figure when compared to the acoustically matched background were minimal or non-existent. In contrast, we observed a power change in the high gamma band (60-120 Hz) that peaked 200-300 ms and varied with the coherence of the stimulus on STG for all tested subjects.
The data demonstrate a neural correlate of auditory figure-ground segregation in the form of high-frequency local oscillations in human non-primary auditory cortex.

Title: Cortical mechanisms of auditory streaming in humans: An intracranial electrophysiology study

Authors: *X. WANG[1], R. CURTU[1], B. BRUNTON[2], K. NOURSKI[1];
[1]The Univ. of Iowa, Iowa City, IA; [2]Univ. of Washington, Seattle, WA

Abstract: Grouping and segregation of sounds within an auditory scene into coherent "streams" is a key component of auditory perception. To date, the neural mechanisms of auditory streaming in humans have been primarily investigated with non-invasive functional neuroimaging (e.g. EEG, MEG and fMRI). This study utilized electrocorticography (ECoG), which offers a unique opportunity to study auditory cortical processing in humans with high spatial and temporal resolution. ECoG activity was recorded during an auditory streaming paradigm, including stimuli that support auditory perceptual bistability, to characterize the transformation of acoustic stimulus attributes into auditory percepts. Subjects were neurosurgical patients undergoing chronic invasive monitoring for medically intractable epilepsy. Stimuli were 5-minute sequences of pure tones, presented in a classical ABA_ auditory streaming paradigm, where A and B are pure tones with a frequency difference ΔF, and "_" is a silent pause. Triplets presented with 2 and 12 semitone ΔF were used as control conditions to elicit stable 1- and 2-stream percepts, respectively. Triplets presented with 6 and 8 semitone ΔF were used as perceptually bistable stimuli. Subjects reported perceptual switches between 1 and 2 streams using a button press. ECoG recordings were made simultaneously from depth electrodes implanted in Heschl's gyrus (HG) and subdural grid electrodes implanted over perisylvian cortex, including superior and middle temporal gyrus (STG, MTG). Auditory cortical activity was characterized in the time domain as averaged evoked potentials (AEPs). In HG, responses to tone B were both positively correlated with stimulus acoustic attributes (ΔF) and, for perceptually bistable stimuli, were significantly larger to triplets reported as 2-stream vs. 1-stream. In contrast, no consistent correlation between responses to B-tones and ΔF was observed on STG and MTG, yet these areas exhibited a significant effect of percept (larger AEPs to 2-stream vs. 1-stream percept). The maximum difference between 2-stream and 1-stream percepts occurred at 60-100 ms after tone B onset in HG and at 100-140 ms in STG and MTG. The present findings confirm the results and expand the understanding of previous human functional neuroimaging studies. Effects of acoustic and perceptual stimulus attributes on cortical responses and their latency demonstrate differential contributions of hierarchically organized auditory and auditory-related cortical areas to auditory scene analysis. This work lays the foundation for further studies addressing the influence of top-down mechanisms such as attention on auditory scene analysis.

Title: Cortical encoding of speech intonation on human superior temporal gyrus

Authors: *C. TANG, L. S. HAMILTON, E. F. CHANG;
Univ. of California, San Francisco, San Francisco, CA

Abstract: Speech intonation plays a crucial role in vocal communication, conveying linguistic information that is not explicit in word choice or syntax. For example, in English, rising pitch can turn a statement into a question and local changes in pitch can change sentence semantics through emphasis. Despite the importance of intonation in language comprehension, it is not known how different intonation contours are represented in human auditory cortex or how intonation affects the neural encoding of phonetic content. To investigate these questions, we created a set of sentences with linguistically distinct pitch contours and manipulated baseline pitch and formant values for each to create three speakers (two female, one male). Using electrocorticography, we recorded neural activity (high-gamma, 70-150Hz, analytic amplitude of the local field potential) from the cortical surface of human participants as they listened to these sentences. We found that local neural populations on the superior temporal gyrus (STG) showed activity that differentiated intonation contours regardless of phonetic content or speaker identity. These populations were spatially distinct from regions that encoded phonetic content or speaker identity. In addition, intonation did not affect the representation of phonetic features, such that phonetically selective electrodes had the same response to phonetically identical sentences with different intonation contours. Because neural activity patterns on intonation electrodes were similar in response to speakers with different baseline pitch values, the results cannot be attributed solely to differences in absolute pitch level between intonation conditions. However, they could still be explained by encoding of relative pitch, a measure of pitch which is normalized by speaker. Using a separate speech corpus (TIMIT) containing sentences spoken by hundreds of male and female speakers, we fit temporal receptive field models that predicted neural activity from absolute and relative pitch values simultaneously. We found that neural discriminability of intonation contours on single electrodes was significantly correlated with relative pitch encoding, while discriminability of speakers was associated with absolute pitch encoding. Our results indicate that the cortical representation of speech intonation is locally encoded in STG, is phoneme and speaker invariant, and is associated with the encoding of relative pitch, a more abstract feature than absolute pitch.

Title: The contribution of cognition in speech-in-noise perception in younger and older normal hearing listeners

Authors: *A. DRYDEN[1,2], H. A. ALLEN[1], H. HENSHAW[1,3], A. HEINRICH[1,2];
[1]Univ. of Nottingham, Nottingham, United Kingdom; [2]MRC Insitute of Hearing Res., Nottingham, United Kingdom; [3]NIHR Nottingham Hearing BRU, Nottingham, United Kingdom

Abstract: This study aimed to investigate the contributions of cognition in Speech-in-Noise (SiN) perception in a systematic way for a range of speech situations in a cross-section of younger and older adult listeners with age-normal hearing.
We hypothesised the strength of associations between intelligibility and cognition to vary depending on the choice of fore- and background sounds. For instance, sentences and words invoke semantic processing for intelligibility to different extents, and therefore might be expected to differ in their engagement of cognition. A similar reasoning may apply to informational and energetic maskers. Finally, by examining younger and older adults, we can investigate how cognitive contributions to speech perception change with age and hearing loss.
In the SiN tests, the target speech consisted of semantically low- and high-predicable (LP/HP) sentences, and of single words. Background noise was either speech-modulated noise or 3-talker babble. The speech conditions were chosen to vary the extent of semantic processing (words versus LP/HP sentences); the background noise was chosen to invoke more energetic (speech-modulated noise) or informational masking (3-tallker babble).
Cognitive assessments were selected to reflect the components of Baddeley's model of working memory: The central executive (Test of Everyday Attention subtests 1, 6 and 7, the Stroop test, reading span test, letter-number sequencing and digit span backward); the visual-spatial sketchpad (Corsi blocks forward and reverse); the episodic buffer (digit span forward and word list recall), and the phonological loop (two versions of a rhyme verification task).
Using principal component analyses, cognitive measures were reduced to four latent variables corresponding to the four sub-domains of the Baddeley model. Individual differences in latent variable scores were then related to each SiN condition using linear mixed models.
Young adults showed no predictive effect of central executive processing for any SiN measures, but did show an overall predictive effect of phonological loop processing. They also showed a predictive effect for visuo-spatial sketchpad as a main effect and in interaction with masker type, and for the episodic buffer component in interaction with masker type. Data collection for the older participant group is ongoing, results will be available in the poster presentation.

For normal hearing younger adults the results indicate that non-executive cognitive processes are more important in speech-in-noise perception, and that underlying cognitive processes may differ between listening in energetic and informational masking.

Title: How to create the intelligible speech perception by cochlear nerve stimulation?

Authors: *Y. TAMAI, S. HIRYU, K. I. KOBAYASI;
Grad. Sch. of Life and Med. Sci., Doshisha Univ., Kyoto, Japan

Abstract: For compensating the hearing sense in a deaf person, a cochlear implant is generally used. While, the method has surgical invasiveness and infection risk. Stimulating cochlear nerves by a probe (an electrode, glass fibers, etc.) placed outside of the cochlea has been investigated as one possible solution for the problem. Most of these methods, however, has limited capacity to differentially stimulate auditory nerves comparing to a cochlear implant, and is virtually same as a single channel stimulation. The purpose of this study was to investigate whether the single channel stimulation enable the subjects to perceive speech sounds. Because mono channel stimulation evokes action potentials from several cochlear nerves simultaneously, the stimulation may create the perception that resemble the sensation evoked by a click sound. Therefore, click vocoded speech sounds were synthesized. The sounds were repetitive click, whose pitch (repetition rate) and amplitude followed formant frequency and amplitude envelope transition of an original speech sound respectively. Peak frequencies of first and second formant were extracted every 15 msec and amplitude envelope was extracted using half-wave rectification and low pass filter. Four-mora Japanese words with high familiarity (FW03: Japanese voice data set of familiarity-controlled word lists made by NTT speech resources consortium) were used as original sound; fifty words were randomly selected. Each stimulus was calibrated to 60 dB SPL. Five Japanese native speakers participated in the experiment as subjects. Tow session were conducted. In first session, subjects listened click vocoded speech sounds and answered what they perceived from four alternative choices. In second session, they wrote down their perception in the Roman alphabet. Consequently, the percentage of correct answers was significantly higher

than chance level in both the alternative choice test and the writing test. The result demonstrated that click vocoded sounds were at least partially intelligible as speech sound. In conclusion, with our speech coding algorithm, mono channel stimulation may enable the subjects to comprehend speech.

Title: Auditory-motor integration in the dorsal stream of the early blind

Authors: *J. PHILLIPS-SILVER[1], J. P. RAUSCHECKER[2];
[2]Neurosci., [1]Georgetown Univ. Med. Ctr., Washington, DC

Abstract: The dorsal auditory stream is crucial for sensorimotor control and integration (Rauschecker, 2011), auditory spatial localization and motion in space (Rauschecker & Tian, 2010), and musical anticipation, auditory and motor sequential processing (Leaver et al., 2009; Rauschecker, 2014). The ultimate expression of auditory-motor integration in humans is musical rhythm, using hierarchical temporal processing from auditory and motor channels and their interaction (Chen et al., 2007; Phillips-Silver & Trainor, 2005). Using fMRI we investigate the role of the dorsal stream in sensorimotor integration during the multisensory experience of 'feeling the beat' of music. We examine activation of the dorsal pathway in sighted and early blind populations, as the latter exhibit sensorimotor plasticity in auditory, motor and spatial processing (Fiehler & Rösler, 2010; Renier et al., 2010). Early blind and sighted individuals were trained to 'feel the beat' of an ambiguous drum rhythm pattern, by bending their knees on every second or third beat (from Phillips-Silver & Trainor, 2007). Following training, subjects entered the scanner and completed a beat recognition task, listening to paired renditions of the rhythm pattern with acoustic strong beats on every second or third beat. Patterns were played on varying percussion timbres; subjects identifed the rendition with the familiar strong beat based on their movement training. In a control task, subjects determined whether the pairs of stimuli were played on instruments of identical or different timbres. We predicted that the beat recognition task would recruit the auditory dorsal stream and other areas for musical beat processing (Merchant et al., 2014) in the sighted and blind. In contrast, we predicted that the timbre

discrimination task would recruit areas of the ventral stream in both groups. Preliminary data analyses in sighted (N=10) and blind (N=5) groups reveal predicted activations: dorsal stream areas (posterior auditory cortex, inferior parietal lobule, premotor and dorsal prefrontal areas including supplementary motor areas), as well as subcortical beat processing regions (cerebellum, thalamus and putamen), for the beat task; ventral areas light up during the timbre task. Findings from this study will illuminate sensory cortical organization and functional specialization in the dorsal stream of the early blind, and identify the neural circuitry for auditory-motor integration that is necessary and sufficient for musical anticipation, temporal processing and action.

Title: Cortical plasticity for own and partner material after short- term musical duet training

Authors: *C. LAPPE, S. BODECK, M. LAPPE, C. PANTEV;
Univ. Muenster, Muenster, Germany

Abstract: Predictive mechanisms in the human brain can be investigated using markers for prediction violations like the mismatch negativity. Short-term piano training increases the mismatch negativity for melodic and rhythmic deviations in the training material. This increase occurs only when the material is actually played, not when it is only perceived through listening, suggesting that learning predictions about upcoming musical events are derived from motor involvement. However, music is often performed in concert with others. In this case, predictions about upcoming actions from a partner are a crucial part of the performance. In the present MEG experiment we trained non-musician subjects in a piano-duet task and measured mismatch components elicited by melodic and rhythmic errors within the pianist's own and the partner's material before and after training. The training exercise was a short piano piece based on the C-major chord progression. Training sessions were scheduled for each pair separately on 8 days over the course of three weeks and lasted 30 min each. For the pre- and post-training mismatch negativity measurement in the MEG, the intro of the piano exercise was used. To generate a melodically elicited mismatch negativity within the primo and secundo musical material, 80

deviant sequences were altered by lowering the sixth tone, which was part of the primo training material, by a minor third. In the remaining 80 deviant sequences of that run the eighth tone was lowered by a minor third. This tone was part of the secundo training material. To generate a mismatch negativity to a rhythmic change, the sixth (primo part) and eighth tones (secundo part) were presented 70 ms earlier. ERP results revealed that the mismatch negativity increased significantly both for own and partner material suggesting a neural representation of the partner's part in a duet situation. Source analysis using beamforming revealed common activations in auditory, inferior frontal and parietal areas, similar to previous results for single players but also a pronounced contribution from the cerebellum. In addition, activation of the precuneus and the medial frontal cortex was observed, presumably related to the need to distinguish between own and partner material.

Title: Auditory aversion in subjects with absolute pitch

Authors: *L. ROGENMOSER, H. LI, G. SCHLAUG;
Beth Israel Deaconess Med. Ctr., Harvard Med. Sch., Boston, MA

Abstract: Musicians with absolute pitch (AP) have the advantageous ability of correctly identifying or producing pitches without making use of reference tones. However, they are known to become unusually disturbed when hearing tones out of tune, this possibly disadvantaging their adaptability during group performance. This study aimed at empirically confirming an AP-specific auditory aversion. In order to measure aversive experiences, we recorded EEG in a sample of AP possessors and a sample of matched control musicians without AP while letting them perform an affective priming task. According to this paradigm, subjects were instructed to judge valenced pictures (selected from the International Affective Picture System) as quickly and accurately as possible while musical primes preceded these targets. These primes were bimodal, simultaneously presented as tones (i.e., auditory) and notes (i.e., visual) that either matched or mismatched (i.e., sharp or mistuned). Compared to controls, subjects with AP judged the targets less accurately and with greater delay when the preceding

musical primes were mismatched. In line with these behavioral findings, the N400 component peaked stronger in the mistuned conditions in subjects with AP. In addition, AP subjects exhibited increased P200 amplitudes in response to the primes. These findings (i.e., behavioral priming effect, N400 response) suggest that subjects with AP respond more aversively to tones when they are out-of-tune than control subjects do. Furthermore, the P200 responses indicate an early (undirected) affective integration, for which AP subjects appear to be accelerated. Taken together, these findings support an AP-specific auditory aversion and further suggest overall altered emotional responding to musical stimuli in subjects with AP.

Title: Investigating the effect of perceptual enhancement on the cortical representation of speech using source space analysis with MEG

Authors: *G. M. DI LIBERTO[1], R. E. MILLMAN[2], E. C. LALOR[1];
[1]Trinity Ctr. for Bioengineering, Trinity Col., Dublin, Ireland; [2]Univ. of Manchester, Manchester, United Kingdom

Abstract: It has been suggested that speech perception in humans is underpinned by a hierarchical cortical system which constantly attempts to match incoming sensory inputs with top-down predictions (Friston & Kiebel 2009; Peelle et al., 2010; Clark, 2013). In this context, perception depends on both "external" sensory inputs and "internal" predictive mechanisms. A number of recent studies have identified effects consistent with this view by measuring cortical activation while modulating these internal predictions by providing prior-knowledge of an upcoming stimulus. In particular, enhanced cortical activation has been linked with perceived intelligibility (post. STG/MTG) while cortical suppression has been associated with repeated stimuli (ant. STG/STS; Tuennerhoff & Noppeney, 2016). Importantly, the timing of cortical activations has been shown to be crucial. Specifically, areas involved in higher order functions have been shown to be activated at very short latencies when prior-knowledge is available, while

suppression of lower level cortical areas emerged at longer latencies (Sohoglu et al., 2012). These findings advanced our current understanding of speech perception, however it has been suggested that counteracting effects may co-occur in particular cortical areas (Tuennerhoff & Noppeney, 2016). A recent EEG study derived a measure of speech encoding at the phonemic level that is sensitive to differences in the recognition of degraded speech stimuli (Di Liberto et al., in press). However the cortical areas involved in this phenomenon remain unclear.
Here, we used magnetoencephalography (MEG) to study the effect of perceptual enhancement on both cortical activation and entrainment measures in response to speech. Beamforming-based analysis was used to estimate cortical activity in brains areas of interest. Participants were presented with tone-vocoded speech sentences, which were unintelligible in the first part of the experiment. Subsequently, priming was used to enhance the perceived intelligibility of the same degraded sentences. The "pop-out" condition was compared with a control condition where no prime was provided. The effect of perceptual enhancement on cortical activation was consistent with previous findings. Additionally, cortical entrainment to the speech envelope revealed significant variations in STS and MTG in the pop-out condition.

Title: Decoding cocktail party attention using EEG signatures of hierarchical speech processing

Authors: *E. TEOH, E. C. LALOR;
Trinity Col. Dublin, Dublin, Ireland

Abstract: The cocktail party problem is a phenomenon that refers to the remarkable ability of humans to selectively focus on a single speaker in noisy environments. Exactly how the auditory system performs this feat remains incompletely understood. Recently, progress has been made with the realisation that cortical activity entrains to the amplitude envelope of speech. By employing a stimulus-reconstruction approach where neural activity is mapped back to the envelope, it has been shown that attentional selection can be decoded to a high degree of accuracy, even from single-trial (~60 s) electroencephalography (EEG) data (O'Sullivan et al., 2014).

While this approach has opened up new opportunities for studying cocktail party attention, the reliance on the amplitude envelope as the representation of speech is almost certainly suboptimal. This is because speech is processed by a hierarchical cortical network with multiple stages performing specialized, but interrelated roles. Thus, a mapping of EEG to the speech envelope may be to conflate the multi-stage processing of many speech features into a single aggregate measure. Indeed, recent research has shown that EEG responses to natural speech are best predicted when that speech is represented in terms of both its low-level spectrotemporal acoustics and a higher-level categorical labelling of phonetic features, rather than simply as its envelope (Di Liberto et al., 2015).
Here, we sought to explore the efficacy of decoding attentional selection when relating cortical activity to different low- and high-level representations of natural speech. EEG data were collected as subjects engaged in a listening task where they were cued to attend to a story in one ear whilst ignoring a different story in the other ear. We perform stimulus-reconstruction with speech represented in the form of a so-called AI-gram, which reflects the spectrotemporal features of speech necessary for articulation and intelligibility, as well as in terms of word categories and sentences. Finally, we leverage the complementary information provided by these various representations to further improve the decoding of attentional selection.

Title: Scenereader: a high-level visual prosthesis

Authors: *Y. LIU, M. MEISTER;
Caltech, Pasadena, CA

Abstract: To achieve the goal of helping blind people to navigate, we translate information about the surrounding scene into sounds, using simple and intuitive rules that require minimal training. This technology may lead to non-invasive, cost-effective visual prostheses, as well as augmented reality for normally sighted subjects.
There are tens of millions of visually impaired people worldwide. Several approaches are being developed to directly restore visual function, but most are surgically invasive and not yet available for clinical use. As a noninvasive alternative, sensory substitution methods deliver visual information through other sensory modalities, such as sound (“sonification”). Current

devices in this domain encode low-level scene features, such as the distance to an obstacle, or the intensity pattern in a static image, and have met with limited success. We propose to take advantage of modern computer vision technology to extract high-level knowledge about the surrounding scene. For example, driverless cars already combine GPS, radar and real-time computer vision into a rich, high-level and actionable representation of the environment. Here we focus on the remaining challenge, namely to efficiently communicate this high-level knowledge to blind subjects.
We have created an experimental platform with which diverse sensory substitution methods can be implemented and compared, using sighted or blind human subjects. The subject wears virtual reality goggles and navigates in a 3D virtual environment, which provides visual experience as well as a sonification of the scene. After training we remove the visual input and the subject navigates based on acoustic signals alone. Any given method of sonification can be assessed by the subject's final performance and training time required. As an example, we have developed a strategy called SceneReader that describes the scene in natural language. It calls out the names of selected actionable objects with natural sound localization cues so that the user experiences the sound as coming from the object's location. Obstacles to be avoided emit a generic noise signal. Sighted naive subjects have learned to use SceneReader in minutes and successfully navigate in some common urban environments with ease. In ongoing studies we are also recruiting blind subjects to perform the same tasks.
Future directions for this project include support for the blind in tasks other than navigation, such as social encounters, as well as augmented reality benefits for sighted subjects. The system also serves as a valuable research tool into crossmodal perception, owing to the ease with which multisensory relationships can be manipulated.

Title: Assessment of the effects of Schisandrin-B on apoptosis in the pde6c Zebrafish mutant retina

Authors: *P. VENKATRAMAN[1], Y. LEUNG[2];
[1]Biol. Sci., [2]Purdue Univ., West Lafayette, IN

Abstract: Loss of photoreceptors (PRs), rods and/or cones, in eye diseases such as retinitis pigmentosa, expedites loss of vision in humans. However, no proper chemical treatment has been developed to tackle PRs degeneration so far. In our lab we wish to address this by identifying naturally extracted compounds as potential therapeutic targets. One of the compounds we are currently testing is Schisandrin-B (SchB), which is one of the active components of a fruit used in traditional Chinese medicine for many years. We recently showed that that SchB treatment reduced the size of the abnormally enlarged rods found in *pde6c* mutants. We also observed an improvement in vision-mediated behavior in the SchB-treated mutant larvae when compared with the untreated mutants. Based on these results, ***we hypothesized that SchB could be interfering with the apoptosis of rods thus exerting a preserving effect on the degenerating rods in pde6c mutants.*** To test this hypothesis, I performed TUNEL staining to assess the level of apoptosis in the *pde6c* mutants. Taking together these results and our previous work, we observe cell death in the *pde6c* mutants. This will be corroborated with immunohistochemical (IHC) analysis of activated-caspase-3 labeling for apoptotic pathway combined with co-labelling of antibody markers for rods and cones. I will present some preliminary data on this work by comparing the cell death in untreated *pde6c* mutants SchB-treated *pde6c* mutants. Following IHC, I will quantify the number of apoptotic cells in both experimental conditions. I expect that the SchB-treated *pde6c* retinas will show fewer or delayed apoptosis in rods. This will give us more information about the pathway which the drug (SchB) is targeting.

Title: Determine the development basis of retina-SCN functional connectone

Authors: *P.-S. CHIN[1], Y. CHANG[2], S.-K. CHEN[2];
[1]Dept. of Life Sci., [2]Natl. Taiwan Univ., Taipei, Taiwan

Abstract: In mammals, suprachiasmatic nucleus (SCN) located at the hypothalamus is the master clock to control daily activity pattern and influence many physiological functions. In mammalian retina, intrinsically photosensitive retinal ganglion cell (ipRGC) contributes to many light-induced non-image forming functions. They directly project to suprachiasmatic nuclei (SCN) for circadian photoentrainment. The SCN can be separated into several regions, such as the ventral lateral SCN (vlSCN), which contains VIP and GRP expressing neuron, and the dorsal

medial SCN, which contains AVP neurons. Previous studies suggests that light input is only transmitted to VIP and GRP expressing neuron in the vlSCN, while the AVP expressing neurons in the dmSCN provide output from the SCN. However, our single cell tracing study indicated that ipRGCs innervate to whole SCN and make putative synaptic contact with VIP, GRP and AVP neuron. Furthermore, we found that each ipRGC preferentially innervates to a specific region of the SCN. In the retina, ipRGCs projecting to ventral part of the SCN are clustered together. To determine whether a specific chemo-attractive or repulsive cue is expressed in the SCN, we used immune-histochemistry method to stain axon guidance molecular in SCN coronal sections.

Title: Possible role of zinc dyshomeostasis in matrix metalloproteinase-2, 9, endoplasmic reticulum stress, and photoreceptor cell death in experimental retinal detachment

Authors: *J. CHOI[1], Y. KIM[2], B.-R. SEO[1], J.-Y. KOH[1,3], Y. YOON[2];
[1]Neural Injury Res. Ctr., Asan Inst. For Life Sci., SEOUL, Korea, Republic of; [2]Ophthalmology, Asan Med. Center, Univ. of Ulsan Col. of Med., SEOUL, Korea, Republic of; [3]Neurol., Asan Med. Center, Univ. of Ulsan Col. of Med., Seoul, Korea, Republic of

Abstract: Purpose: To investigate the possibility that zinc dyshomeostasis has a role in activation of matrix metalloproteinase (MMP), induction of endoplasmic reticulum (ER) stress, and photoreceptor cell death in the retinal detachment (RD).
Methods: In order to induce retinal detachment in mice, we created by injecting 3 µl of 1% sodium hyaluronate through self-sealing scleral incision. Pathological endpoints examined in vivo included photoreceptor cell death, intracellular zinc level, ER stress induction, and MMP-2, 9 expressions in RD mice at 30minutes, 1 day, 3 days, and 7 days post RD. In addition, we examined whether expressions of ER stress markers and the degree of apoptotic cell deaths may change by modulating extracellular zinc concentration or MMP activation in subretinal fluid.
Results:. We observed that the intracellular zinc was markedly decreased after 30 min of RD induction. Concurrently, activities of MMP-2 and 9 increased in RD mouse retinal tissue,

followed by photoreceptor cell death. Photoreceptor cell death was peaked on day 3. Immunostaining for the ER stress marker GRP78 Bip, revealed that ER stress was also induced in our RD model. We examined that subretinal injection of CaEDTA reduced ER stress markers and photoreceptor cell death in RD eyes. Additionally, we observed that ER stress markers and photoreceptor cell death were decreased by treated with GM6001 (MMP inhibitor).
Conclusions: Our work showed that redistribution of zinc in retinal tissues may be a contributing factor in MMP activation, ER stress, and photoreceptor cell death in RD. Since MMP inhibition protected against ER stress in and death of photoreceptor cells, MMPs may be a reasonable target for cytoprotection in case of RD.

Title: Characterisation of a mouse model for testing the efficacy of transplanted human RPE cells

Authors: *A. LYNCH, M. SEMO, J. ASLAN, A. VUGLER;
ORBIT, UCL Inst. of Ophthalmology, London, United Kingdom

Abstract: Introduction: The RCS dystrophic rat has been used to test efficacy of human retinal pigment epithelium (RPE) cells for the treatment of dry age-related macular degeneration (AMD). However, unlike dry AMD, where geographic atrophy denudes Bruch's membrane of RPE, the dysfunctional RPE cells of RCS rats fail to degenerate. An alternative approach uses sodium iodate ($NaIO_3$) to selectively kill the host RPE, a procedure that facilitates survival of polarised human RPE cells along Bruch's membrane in mice (Carido et al., 2014). However, despite RPE phagocytosis of outer segments, no evidence of functional recovery could be found by electroretinography (ERG), possibly due to insufficient delivery of visual chromophore by the grafted cells. Here we characterise the functional and anatomical consequences of administering sodium iodate to mice and test whether the complete restoration of retinal chromophore supply by systemic 9-cis-retinal supplementation can restore retinal function to $NaIO_3$-treated mice.

Methods: Adult C57 mice received a single intravenous injection of $NaIO_3$ (40mg/Kg) and photoreceptor function was then assessed by ERG at 3 days, 7 days and 1-month post-$NaIO_3$ treatment. Mice were dark adapted and received intraperitoneal injections of 9-cis-retinal (1mg/mouse) or saline 16h prior to ERG recordings. Photoreceptor function was also assessed in $NaIO_3$-treated mice by measuring the pupillary light reflex (PLR) at 1 month post-injection. Mice were sacrificed after functional testing and Immunohistochemistry was performed in order to assess RPE ablation and photoreceptor integrity.
Results: In the absence of systemic chromophore, the ERG was flat or negative at all time points studied. Functional recovery of the ERG in $NaIO_3$-treated mice (restoration of A and B waves) could be produced following systemic delivery of 9-cis-retinal. However, this effect only occurred in 50% of animals at 3 days post-$NaIO_3$-treatment and at 7 days post-treatment the ERG was unrecoverable. The sensitivity of the PLR in $NaIO_3$-treated mice was reduced but appeared largely intact at high irradiances. Immunohistochemistry confirmed focal RPE degeneration, disruption to the outer nuclear layer and the persistence of melanopsin expression in $NaIO_3$-treated mice.
Conclusion: The ability of systemic chromophore supplementation to recover ERG function in $NaIO_3$-treated mice is lost between 3 and 7 days post-treatment. This suggests that photoreceptors may be irreversibly damaged by $NaIO_3$-treatment and may help to explain the failure of others to correlate functional improvement by ERG with the presence of grafted human RPE (Carido et al 2014).

Title: Effects of prolonged treatment with uv-a radiations in arpe19 cells: expression of early and late cellular damage markers.

Authors: *G. TRINGALI[1], B. SAMPAOLESE[2], M. CLEMENTI[2];
[2]CNR-ICRM-Catholic Univ. Sch. Med., Roma, Italy, [1]Catholic Univ. Sch. Med., Roma, Italy

Abstract: Exposure to solar radiation has been implicated in many ocular pathologies and in particular in the macular degeneration: UV radiations can induce the production of reactive oxygen species (ROS), mitochondrial dysfunction, DNA damage, and an increasing of apoptotic activity. However the underlying mechanisms of UV-mediated retinal pigment epithelium (RPE)

cell death are controversial and remain unclear. Two hypotheses are the most accredited in literature: i) exposure to UV radiation causes the production of ROS, which may damage RPE cells through apoptotic mechanisms activation; ii) UV radiation stimulates an elevated production of ROS which can lead to an irreversible cellular necrosis. Within this framework, to better understand both molecular basis and temporal sequence of the degenerative processes underlain to RPE dead after UV radiation exposition, we investigated cell viability, ROS production and the expression of principal apoptotic genes (Bax, Bcl2, Caspase-3) on Arpe-19 cells after UV-A radiation for consecutive times (5/7 hours). We found that UV-A prolonged exposure induced: i) cell death: the decrease of cell viability was time-dependent and reached statistical significance after three hours; ii) a significant and substantial increase in ROS levels that remained constant for the duration of the experiment: this increase was a statistically significant result from one hour of exposure; iii) an activation of apoptotic genes (Bax and Caspase 3) after 1 h of treatment, which it is accompanied by a decrease of Bcl2, anti-apoptotic gene; iv) a loss of apoptotic signals and a rapid decrease in the cellular availability after three hours of consecutive treatment; these processes could trigger the necrosis observed in morphological traits of cells treated consecutively for five hours. To the best of our knowledge, this is the first report that describes the sequence of molecular events that occur after continuous exposure to UV-A radiation: it starts with ROS levels increase, which lead before to activation of apoptotic events and then to an irreversible cellular necrosis. These interesting findings, even if preliminary, may be useful for improving our understanding about oxidative damage which is underlain various UV-induced ocular cell damage.

Title: Dim light at night influence gut microbe and metabolic status through melanopsin

Authors: *C.-C. LEE[1], Y.-F. ZOU[1], S.-K. CHEN[1,2];
[1]Dept. of Life Sci., Natl. Taiwan Univ., Taipei, Taiwan; [2]Genome and Systems Biol. Degree Program, Natl. Taiwan Univ. and Academia Sinica, Taipei, Taiwan

Abstract: In 20 th century, the invention of artificial light source has dramatically change the human society. In addition to sun light during the day time, artificial light prolongs the light exposure time at the night time. Furthermore, increasing number of shift workers are working at the night time with bright light exposure. Recent human studies suggested that exposure to the artificial light during nighttime (LAN) is strongly associated with obesity, which could lead to cardiovascular disease. In addition, studies in mice indicated that the LAN exposure induces metabolic disorder such as obesity and hyperglycemia independent of the total caloric intake. Therefore, it is likely that light exposure could have direct influence on metabolic function in both diurnal and nocturnal aniamls. However, the exact mechanism for LAN induced metabolic disorders remains unclear. It has been shown that intrinsically photosensitive retina ganglion cells (ipRGCs), which expressed novel photo pigments melanopsin, transmit the light signal to control many non-image forming physiological functions. Thus, we hypothesize that melanopsin photo-detection system is involved in the LAN induced metabolic disorders. Using genetic mouse model and metagenomics analysis, here we showed that dim light at night induced obesity, hyperglycemia and insulin resistance through melanopsin. Moreover, the LAN induced metabolic disorders are partially blocked by antibiotics treatment which eliminated gut microbiota. Together our data suggests that aberrant light dark cycle could modulate gut microbiota and affect the energy metabolism in mice through melanopsin photo detection pathway.

Title: Photoreceptor-glial signaling during neurovascular coupling underlying functional retinal imaging.

Authors: *M. BEGUM, D. Y. TS'O;
Neurosurg., SUNY Upstate Med. Univ., Syracuse, NY

Abstract: Light-evoked reflectance decreases in the retina, seen using intrinsic signal optical imaging, are likely to be of an outer retinal origin. Other studies have shown that such reflectance changes are dominated by hemodynamics. We have sought to dissect the role of several prospective signaling pathways in the observed stimulus-evoked neurovascular responses in vivo through intravitreal injections of selected agonists, antagonists and blockers. Of particular

interest are the possible mechanisms by which the light response that is transduced in the photoreceptors is then transmitted into neighboring Muller cells to ultimately effect a neurovascular response.
Adult cats were anesthetized and positioned in a stereotaxic. Using a modified fundus camera, the retina was stimulated with visible (550nm) patterned stimuli and illuminated in the near-infrared (700-900nm), while intrinsic optical signals were recorded with a CCD camera. Previous retinal imaging studies using intravitreal injections of blockers of inner retinal function (e.g. TTX, PDA, APB) yielded little impact on the retinal imaging signals. Those studies also indicate no role of glutamate receptors in the observed response. Among the pathways by which photoreceptors might signal Muller cells without the involvement of the inner retina, we considered 1) changes in K^+ concentration, 2) adenosine/ATP signaling, 3) glutamate via transporters (e.g. GLAST). We have therefore employed injections of Ba^{+2}, adenosine agonists and antagonists, and GLAST blockers, performing functional retinal imaging before and after these intravitreal injections. Each agent exhibited a profound impact on the observed light-evoked retinal imaging signals. In some cases, the sign of the observed retinal imaging signal changed from negative (vasodilation) to positive (vasoconstriction). Injections of Ba^{+2} abolished the imaging signal completely, while GLAST blockers inverted the sign of the reflectance change. Adenosine agonist and antagonists exhibited multiple effects with differing time courses, suggesting actions at several sites/receptors. These studies help establish the chain of retinal events from light absorption to observed changes in retinal reflectance in vivo.

Title: Transcriptomic and epigenetic profiling of cone photoreceptor generation from a restricted retinal progenitor population

Authors: *D. F. BUENAVENTURA[1], M. EMERSON[2];
[2]Biol., [1]City Col. of New York, New York, NY

Abstract: Every cell type in the retina is derived from multipotent retinal progenitor cells (RPCs). Current evidence suggests that some RPCs are molecularly restricted to produce only

certain cell types. Recently, a specific cis-regulatory module of the early cone photoreceptor marker Thrb was identified. The ThrbCRM1 regulatory element drives reporter expression in cells that normally express the thrb gene, including a subset of RPCs. Our data indicates that these RPCs are fate-restricted and preferentially generate cones and horizontal cells. Additionally, Onecut1 (OC1) is present in these RPCs, necessary for activation of the ThrbCRM1 element, and sufficient to induce early cone photoreceptor gene expression. We have used differential transcriptomic and epigenomic profiling of the ThrbCRM1 cell population to investigate the transcription factor networks and intergenic regulatory regions that are active during this phase of cone photoreceptor development. To further dissect the role of OC1, transcriptional changes will be identified through similar profiling and testing after the introduction of a OC1 dominant-negative construct. Currently, ex-vivo/in-vivo electroporations in chicken retinas are being used to functionally assess the roles of identified genes and cis-regulatory regions in cone fate determination. Finally, analysis of the ThrbCRM1-negative retinal population at this developmental stage led to the identification of a regulatory element that our current evidence suggests is active in the multipotent progenitor population. Together, these studies will investigate the gene regulatory events underlying the formation of restricted RPCs and the generation of cone photoreceptors.

Title: Photoreceptor shape variation does not account for perceptual threshold variation in single cones

Authors: M. DEFENDERFER[1], A. MEADWAY[1], K. S. BRUCE[1], *L. C. SINCICH[2];
[2]Vision Sci., [1]Univ. of Alabama Birmingham, Birmingham, AL

Abstract: To perceive a spot of light at photopic threshold, a minimum number of photons must be absorbed by cone photopigments. The threshold depends on many factors, such as background luminance and distance from the fovea. Less well appreciated are two additional factors operating at the cellular scale: the waveguide properties of photoreceptors and their individual variation in synaptic weighting. We reported previously that thresholds for stimuli delivered to single cones can vary widely; neighboring cones differ in threshold by up to 80% (Bruce et al. 2015). Because the efficiency of light absorption depends on photoreceptor size and shape, we investigated whether variation in these dimensions explains the threshold variation found with adaptive optics (AO) microstimulation. To estimate how waveguiding contributes to threshold, the interaction of diffraction-limited light in cones was modeled using a finite difference beam propagation method which quantifies light coupling efficiency in idealized cones. Human and macaque cones located at retinal eccentricities matching sites studied psychophysically were measured from wholemount histological material. Image processing was used to fit an ellipse to the cone inner segments when viewed axially along the normal light path. These fits were used in the cone model to estimate light coupling efficiency in the outer segment. For the model, the initial electric field was for an unaberrated eye with a power of 59.9 D at wavelength=543 nm. Light coupling was compared to luminance increment thresholds from cone-targeted stimulation measured in humans using AO-based microstimulation. For these data, a ~3.6 micron square of 543±11 nm light was flashed for 130 microsec per trial on single cones at various intensities. Thresholds were found by a staircase procedure from subject responses. Measured from local patches of retina, cone inner segment dimensions varied by 6% SD, with a mean anisotropy ratio (major/minor axis) of 1.1±0.05. To see how this shape variation compared to the distribution of relative threshold increments observed perceptually, we used a Monte Carlo method to calculate the likely distribution of relative light coupling from randomly selected pairs of nearby cones. We found that the estimated light coupling in human and macaque cones varied by a factor of 10 less than the threshold variation observed psychophysically. Because shape differences yielded such minor variation in light coupling between cones, our results suggest that synaptic weighting is likely to account for most of the variation in perceptual thresholds to cone-targeted microstimulation.

Title: C-terminal phosphorylation of mouse melanopsin plays a crucial role in the kinetics of non-image forming visual behavior

Authors: P. SOMASUNDARAM[1], D. FERNANDEZ[2], A. RUPP[2], T. BADEA[3], Z. WU[4], R. BROWN[5], S. HATTAR[2], *P. ROBINSON[1];

Abstract: The melanopsin photopigment is expressed in intrinsically photosensitive retinal ganglion cells (ipRGCs) of the mammalian retina, which are specialized for functions such as circadian photo-entrainment, pupillary light reflex, and certain visual functions. Melanopsin's role in a broad spectrum of functions calls for a deeper understanding of the regulation of its activity. Melanopsin resembles visual pigments found in rhabdomeric photoreceptors and *in vitro* data suggest that its activity is terminated by light-dependent phosphorylation by a G-protein coupled receptor kinase (GRK). The working hypothesis of this study is that GRK mediated melanopsin phosphorylation controls the lifetime of the activated visual pigment by initiating deactivation of the receptor. In order to test the impact of this phosphorylation on non-image forming behavior and physiology, a phosphorylation-deficient melanopsin, in which putative GRK phosphorylation sites on the carboxy-terminal tail were mutated to alanines (phosphonull), were expressed in mice through a cre-dependent AAV2 gene delivery method. These mice show successful viral transduction as seen by the expression of reporter gene in their retinas. Behavioral analyses indicate that mice expressing the phosphonull mutant of melanopsin exhibit a prolonged constriction of pupillary light reflex following a 30 second stimulus of high intensity blue light. The AAV2 gene delivery approach was also used to transduce ipRGCs in melanopsin knockout mice (MKO) with wild type melanopsin gene. This method of re-introducing melanopsin into MKOs restored non-image forming behavioral deficits that have previously been reported in these animals. In this study, an AAV2 transduction method has been successfully used to generate targeted mutations in melanopsin. The data indicate that putative GRK phosphorylation sites on melanopsin C-terminus play a vital role in pupillary light reflex behavior.

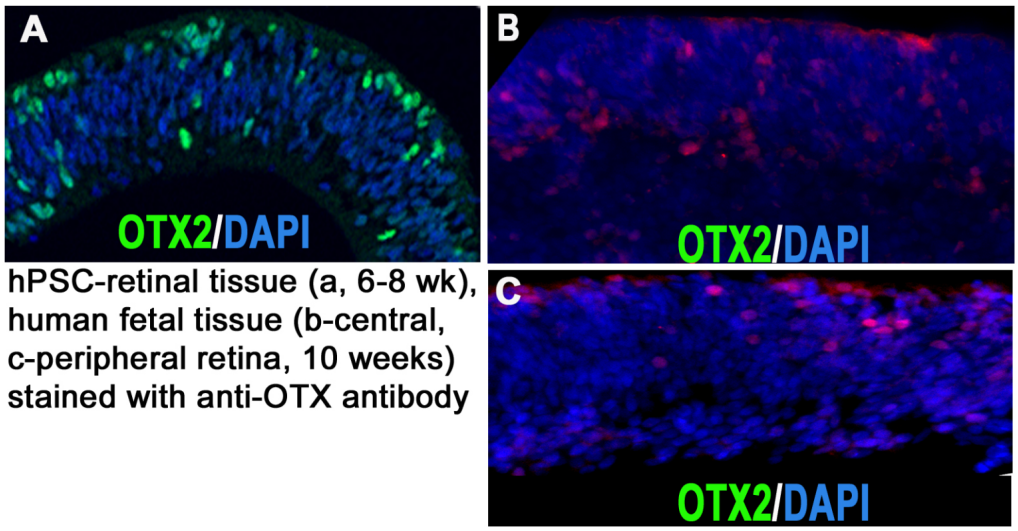
Title: Comparison of developmental dynamics in human fetal retina and human stem cell-derived retinal tissue

Authors: R. K. SINGH, H. STERNBERG, O. CUZZANI, M. D. WEST, *I. O. NASONKIN; Biotime, Inc., Alameda, CA

Abstract: Retinal degenerative diseases such as age-related macular degeneration (AMD) and retinitis pigmentosa (RP) are incurable blinding conditions, severely impacting quality of life and affecting millions of people. Finding efficient treatment for these devastating diseases is among the greatest unmet clinical needs. Retinal replacement strategy can bring a piece of healthy mutation-free human retina into a patient's eye to replace fully degenerated retinal tissue. The only donor tissue, which was demonstrated to work in animals with retinal degeneration as well as in RP patients is human fetal retinal tissue age 8-17 weeks, which cannot be used for routine therapies. 3D retinal tissue (retinal organoids) derived from human pluripotent stem cells (hPSCs) shares many similarities with human fetal retina and may be an excellent replacement of fetal retinal tissue in retinal transplantation experiments. To evaluate the optimal developmental point of hPSC-3D retinal tissue, which may replicate successful survival and differentiation of human fetal retina in subretinal grafts (Seiler, M.J., et al., Eur J Neurosci, 2010, **31**[3]: p. 508), we are characterizing a set (8-16 week old) of human embryonic and fetal retinal tissue samples. We are mapping RPE, retinal stem, progenitor and retinal cell fate markers in these samples to hPSC-3D retinal tissue (Singh et al., Stem Cells Dev. 2015 Dec 1;24[23]:2778) using histology, immunohistochemistry and RNA-seq methods. We present data on similarities and differences in distribution and expression of molecular markers in human developing embryonic and fetal retina and in hPSC-3D retinal tissue and suggest the optimal range of time points in hPSC-3D retinal tissue development, which may engraft successfully and develop into laminated human retina in subretinal grafts. The data will streamline the development of hPSC-3D retinal tissue (retinal organoid) technologies aimed at repairing and replacing human retina affected by degeneration and causing irreversible blindness.



hPSC-retinal tissue (a, 6-8 wk), human fetal tissue (b-central, c-peripheral retina, 10 weeks) stained with anti-OTX antibody

Title: A neural circuit uses distinct mechanisms to support transient and sustained pupil constriction

Authors: *W. T. KEENAN[1], A. C. RUPP[1], P. SOMASUNDARAM[2], S. HIRIYANNA[3], Z. WU[3], T. C. BADEA[3], P. R. ROBINSON[2], S. HATTAR[1];

Abstract: The fundamental goal of neuroscience is to understand how neural circuits drive behavior. Here, we investigated the neural circuit centered on intrinsically photosensitive retinal ganglion cells (ipRGCs), critical relays for light's effects on sleep, circadian rhythms, and pupil size. ipRGCs receive photosensory input from 3 sources (rods, cones, and melanopsin), and are

thought to transmit information to the brain with 2 neurotransmitters: glutamate and the neuropeptide PACAP. However, the functional contribution of each of these circuit components remains unclear. By measuring pupil size while silencing each ipRGC circuit component—photoreceptive inputs or neurotransmitters outputs—we show that transient and sustained behavioral responses are mediated by distinct inputs and outputs. Transient responses utilize input from rod photoreceptors and output by glutamate. In contrast, sustained responses are dominated by non-conventional signaling mechanisms: melanopsin phototransduction in ipRGCs and the neuropeptide PACAP. These results reveal a novel role for a neuropeptide in visual function and highlight a neuronal circuit transition that supports behavioral responses over time.

Title: Circuits in the retina: A deep learning framework for algorithmic modeling.

Authors: *D. BAGHERIAN, M. MEISTER;
BBE, Caltech, Pasadena, CA

Abstract: Retinal circuits, which take light stimuli as input and produce retinal ganglion cell (RGC) spike trains as output, are often modeled as layered networks of linear spatiotemporal filters and static nonlinearities, or “cascade models” (Meister and Berry, 1999). Such a model provides both a quantitative formulation of what a given RGC reports about the visual scene and a biologically interpretable hypothesis for the circuit mechanisms that implement the computation.
The network structure of the cascade is often selected based on the researcher’s intuition, but many networks may approximate a given RGC computation equally well, and the space of all such models is large and high dimensional. We develop a modeling paradigm that searches through this space comprehensively to produce a range of circuit models that are suitablecandidates for further circuit dissection experiments.

To solve this system identification problem, we employ feedforward convolutional neural networks (CNNs), which are mathematically equivalent to cascade models. In this machine learning setting, there is a direct mapping from CNN nodes and connections to biological neurons and synapses. Trains of action potentials are recorded from an RGC in response to a broad set of visual stimuli. Then, a CNN is used to fit this stimulus response relationship. We initialize a large, over connected CNN with a layered structure generally consistent with anatomy of the retina. Then we use backpropagation and gradient descent with L1 regularization to "prune" the network. Due to the highly degenerate nature of the model space, after many such initialization and training instances, the end result is often a family of candidate circuit mechanisms.
As a proof of concept for this method of circuit inference, we apply it to a canonical computation in the retina: direction selectivity. First, we simulate the neural circuitry that leads to the ON/OFF direction selective ganglion cell (DSGC) to produce large sets of stimulus response data (Vaney et al. 2012) . After training a deep learning model on these data, we find that the model can replicate the direction selective visual responses, but the learned circuit structure is somewhat dependent on the initialization and training parameters of the CNN. Second, we apply the same learning model to neural recordings from genetically targeted real DSGCs, We expect that this method for inferring neural circuits will serve to generate new hypotheses for circuit mechanisms beyond those currently considered that can then be evaluated with directed anatomical and physiological studies.

Title: ATP vesicular pools present in VNUT expressing zebrafish horizontal cells

Authors: *D. S. MCDEVITT, S. L. STELLA, Jr;
Neural and Behavioral Sci., Pennsylvania State Univ. Col. of Med., Hershey, PA

Abstract: The discovery of a vesicular nucleotide transporter (VNUT) has established that ATP can be concentrated and stored in neuronal vesicles. VNUT expression has been localized to horizontal cells in the outer retina. Therefore, we hypothesize that an ATP pool is present in horizontal cells and contributes to ATP release which can serve as a precursor to adenosine during nocturnal conditions. Experiments were performed on both intact retinas and isolated horizontal cells from zebrafish retina. Confocal live cell imaging of quinacrine and molecules to label ATP stores in horizontal cells were used to monitor ATP levels and release. Immunohistochemical analysis using confocal microscopy of zebrafish retina was performed on vertical sections and wholemounts. Live cell imaging of vesicle cycling was monitored using a VNUT antibody targeted to the luminal face of the protein conjugated to CF488 or CF568 in order to characterize vesicle turnover in horizontal cells. Vesicles containing ATP labeled stores co-localized with VNUT in horizontal cells. VNUT labeled both horizontal cells and Muller cells in the zebrafish retina. Antibodies targeted to the luminal face of VNUT transporters labelled cycling vesicles within horizontal cell processes. Uptake was stimulation and Ca^{2+}-dependent arguing in favor of a vesicular mechanism, and reduced in the absence of Ca^{2+} and Ca^{2+} channel blockers. Synaptic vesicle recycling and retrieval was demonstrated with sequential Ca^{2+} labeling of vesicles with fluorescently labelled VNUT antibody followed by a secondary antibody targeted to the VNUT antibody. These findings support the hypothesis that horizontal cells contain a competent compartment containing VNUT expressing vesicles that have the capacity to release ATP from horizontal cells in the outer retina. Thus, during nocturnal conditions it is possible that outer retinal adenosine is derived from ATP present in horizontal cells.
