Title: Combined Zinc plus N-acetyl-L-cysteine supplement increases adult hippocampal neurogenesis

Authors: *D. HONG[1], B. CHOI[1], B. LEE[1], S. LEE[1], A. KHO[1], S. LEE[1], J. JEONG[1], M. SOHN[2], S. SUH[1];

Abstract: Adult hippocampal neurogenesis (AHN) occurs in the subgranular zone (SGZ) of the dentate gyrus (DG), where high levels of vesicular zinc are localized. Zinc is an essential trace element involved in numerous biological functions, including DNA synthesis, hormone control, enzymatic activity, and cell proliferation. Recent studies, including those from our lab, have demonstrated that Zn^{2+} plays an important role in regulating AHN. In addition, several antioxidants such as flavonoids, vitamin E, curcumin, and N-acetyl-L-cysteine (NAC) increase neurogenesis in the rodent brain. Thus, in the present study, we evaluated the effect of Zn^{2+}-NAC complex ($Zn(NAC)_2$) on hippocampal neurogenesis in adult mice. C57BL/6 male mice (8 weeks old), were divided into four groups: Vehicle, $ZnCl_2$, NAC and $Zn(NAC)_2$ treated groups. The mice were given intraperitoneal injections of $ZnCl_2$ (5 mg/kg), NAC (25 mg/kg) or $Zn(NAC)_2$ (30 mg/kg) once daily for 2 weeks. Vehicle-treated mice were injected on the same schedule with saline. To confirm the proliferative identity of cells, BrdU was intraperitoneally injected twice daily for 4 consecutive days before sacrifice. Neurogenesis was evaluated by immunohistochemistry for BrdU, Ki67 and doublecortin (DCX). Mice receiving 5 mg/kg $ZnCl_2$ alone, showed no differences in the number of progenitor cells and neuroblasts, compared with vehicle-treated mice. However, NAC-treated mice showed a significant increase in the number of progenitor cells and neuroblasts. Furthermore, $Zn(NAC)_2$-treated mice showed an even greater increase in the number of progenitor cells and neuroblasts. The present study demonstrates the additive and synergistic effects of $Zn(NAC)_2$ on progenitor cell proliferation and neuroblast production, respectively. These findings suggest that $Zn(NAC)_2$ may promote the regenerative capacity of the adult brain as a potent enhancer of hippocampal neurogenesis. Keywords : zinc, n-acetly-l-cysteine, $Zn(NAC)_2$, neurogenesis, hippocampus

Title: Overexpressed APPL2 result a depressive- and anxiety- like behaviors, which associated with impaired hippocampal neurogenesis

Authors: *G. CHONG[1], X. CHEN[1], A. XU[2], J. SHEN[1];
[1]Sch. of Chinese Medicine, LKS Fac. of Med., The Univ. of Hong Kong, Hong Kong SAR, Hong Kong; [2]Dept. of Med., The Univ. of Hong Kong, Hong Kong, SAR, Hong Kong

Abstract: Adult hippocampal neurogenesis plays important roles in animals' mood and cognitive regulation. Impaired growth and differentiation of neural stem cells (NSCs) usually associates with many types of neurodegenerative or psychiatric disease. Relationship between neurogenesis and depression disorder is nowadays most popularized studied not only because that depression is nowadays a common and serious psychiatric disorder affects people's daily life, but it also because that increased neurogenesis can truly buffer the stress induced mood disorder. Daptor protein, phosphotyrosine interaction, PH domain and leucine zipper containing (APPL) appears to play a critical role in cell growth and metabolism modulation. In two isoforms of APPLs protein, APPL1 was reported to associate with the regulation of insulin sensitivity by facilitating the binding of IRS1/2 to the insulin receptor. APPL2, the other isoform of APPLs, participate in the glucose uptake in skeletal muscle. However, whether APPLs participate with the neurogenesis regulation remains unexplored. In this study, we obtained APPL2-Tg mice with overexpressed APPL2 protein. We found APPL2-Tg mice presented a spontaneous depressive- and anxiety- like symptoms though different types of behavioral tests. Furthermore, our immunofluorescence indicated that overexpressed APPL2 limited the production of new neurons and the proliferation of the radial glia-like stem cells (RGLs) in hippocampus. The *in vivo* clone analysis also indicated that APPL2 overexpression decreased the intermediate progenitor cell (IPC) fate choice of the RGLs. And we found the maturation process of the young neurons was also delayed in APPL2-Tg mice. Combine these lines of evidence together; we can conclude that APPL2 might acts in the animal mood regulation and antidepressant behaviors that associated with its functions in neurogenic modulation.

Title: Directed differentiation of neural progenitors in dentate gyrus in naïve and epileptic rats.

Authors: ***E. MELIN**[1], X. XIAN[2,3], N.-B. WOODS[2,3], T. RAMOS-MORENO[3,4], M. KOKAIA[4];
[1]Lunds Universitet, LUND, Sweden; [2]Div. of Mol. Med. and Gene Therapy, Lund, Sweden; [3]Stem Cell Ctr., Lund, Sweden; [4]Epilepsy Ctr., Lund, Sweden

Abstract: Neural progenitors (**NP**) in the adult *dentate gyrus* (**DG**) continuously produce new functional granule cells. It is well known that epileptic environment in the hippocampus promotes neurogenesis in an early stage of the disease and could be considered to be a different niche than in the healthy hippocampus. Here we study *in vivo* directed differentiation of the neural progenitors in the adult DG in naïve and epileptic animals. We generate *status epilepticus* (**SE**) animals by injecting a sub cutaneous dose of kainic acid, and target neural progenitors with a retroviral vector coding for Ascl1 and/or Dlx2 transcription factors, both being expressed by GABAergic cells during different stages of development. Our results show that different glia and neuronal populations are generated from the infected NP in both naïve and epileptic environments. For example, after retroviral infection coding for Ascl1 in epileptic rats, immunohistochemical analysis reveals that one majority cell population is positive for neuro/glial antigen 2 (NG2), a marker for oligodendrocytic progenitor cells (OPCs) and another population expresses NeuN, a marker for mature neurons. These results shows for the first time that overexpression of a single transcription factor in an epileptic environment is able to direct differentiation of NP, which has implications for treatment of pharmacoresistant epilepsy, memory formation and neurological affections.

Title: Efficient isolation of viable primary neural cells from adult murine brain tissue based on a novel automated tissue dissociation protocol

Authors: H. ZHANG[1], S. REIß[1], S. TOMIUK[1], S. RÜBERG[1], R. FEKETE[2], M. JUNGBLUT[1], *A. BOSIO[1];
[1]Miltenyi Biotec, Bergisch Gladbach, Germany; [2]Fluidigm Corp., South San Francisco, CA

Abstract: Tissue dissociation and preparation of single-cell suspensions with high cell viability and a minimum of cell debris is the prerequisite for cellular analysis, cell culture, and cell separation. As dissociation of adult brain requires sophisticated mechanical and enzymatic treatment to successfully disaggregate the tightly connected neural cells, cell analyses is often restricted to embryonic or neonatal murine tissue. We have set up a new technology for dissociation of neonatal brain by combining automated mechanical dissociation using the gentleMACS™ Octo Dissociator (Miltenyi Biotec) with an optimized enzymatic treatment. To extend the analyses to adult neural cells we have further optimized the automated dissociation process and included a novel protocol for removal of debris, which is crucial for successful cell isolation and culture. The new process increased the number of viable cells and yielded 3-5x10E6 total living cells per adult mouse brain. Subsequently, astrocytes, oligodendrocytes, neurons, microglia, or endothelial cells were separated from dissociated adult murine brain tissue by magnetic cell sorting (MACS). Astrocytes were isolated using Anti-ACSA-2 (astrocyte cell surface antigen-2) MicroBeads. The process yielded 4.0x10E5 ± 0.7x10E5 astrocytes with a viability of 69.1 ± 10.3% and a purity of 93.9 ± 5%. In case of neurons, non-target cells were depleted using a mixture of non-neuronal cell markers. 2.0x10E5 ± 0.25x10E5 neurons with a viability rate of 72.0 ± 7.1% and a purity of 92.2 ± 1.1% were acquired per adult mouse brain. Likewise, 1.2x10E5 ± 0.25x10E5 oligodendrocytes with a viability of 76.7 ± 10.3% and a purity of 90.0 ± 6.7% were separated using Anti-O4 MicroBeads, mouse and rat. Purified Microglia were gained by using CD11b MicroBeads, mouse or CD11b/c MicroBeads, rat, respectively. A purity of 97-99% and a viability of 94.7% ± 4.2% was obtained. In case of astrocytes, highly purified cells were further subjected to a single-cell mRNA sequencing analysis in order to characterize neonatal and adult astrocyte diversity. Therefore, the C1 Single-Cell Auto Prep System (Fluidigm) was used for single-cell capturing of highly purified neonatal and adult astrocytes (98.5-99%) and preparation of cDNA libraries. Single-cell transcriptome analyses

revealed a highly diverse expression profile of neonatal and adult astrocytes with distinct subgroups within each population. In summary, we present a novel standardized technology to generate highly purified and viable adult neural cells that extends the analysis from neonatal to adult murine brain tissue and facilitates sophisticated cellular and molecular analyses.

Title: Region-specific transcript profiles of the lncRNA Sox2ot in adult rat brain: correlation with Sox2 enhancers and Sox2 expression.

Authors: *D. A. CARTER[1], S. YULE[2];
[2]Sch. of Biosci., [1]Cardiff Univ., Cardiff, United Kingdom

Abstract: Sox2 is a transcription factor gene with numerous, partially defined, roles in neural development. Recent studies have identified multiple novel enhancer sequences that span 200kb of the Sox2 locus, and act to confer brain region-, and embryonic stage-specific expression (and activity) of Sox2 (Okamoto et al [2015] Develop. Growth Differ. 57, 24-39). We are investigating the molecular mechanisms that underlie an unusual pattern of adult Sox2 expression in the adult ventral diencephalon, including neurons of the suprachiasmatic nucleus (SCN). One class of potential regulators are long non-coding (lnc) RNAs; in addition to the string of genomic enhancers across the Sox2 locus, this region is also spanned by a multi-exon lncRNA, Sox2ot (Sox2-overlapping transcript), that may contribute to cell-type-specific Sox2 expression. In the current study, we investigated the expression of Sox2ot isoforms in the SCN, and correlated transcripts with Sox2 enhancer sequences that confer specificity for distinct brain regions, including the ventral diencephalon ('U6' enhancer). In order to identify potential SCN-specific expression of Sox2ot isoforms, expression was compared with olfactory bulb (OB) and somatosensory cortex (COR). Sox2ot sequences were amplified using PCR primers directed against known (rat/ mouse/human) exons/EST sequences of both Sox2ot, and also Sox2dot, a group of isoforms that include distal (more than 500kb upstream of Sox2) exons. We found that

both Sox2ot and Sox2dot transcripts are abundantly expressed in rat brain, and the relative abundance of specific isoforms is brain region-specific. For Sox2dot, transcripts are expressed across OB/SCN/COR but the pattern of isoform expression is markedly distinct in COR, compared with OB and SCN. This result is consistent with a similar (immature) transcript profile in OB and SCN. However, for Sox2ot, the transcript profiles are similar in SCN and COR, and distinct from OB. These findings concur with the well-known cell-type specificity of lncRNA expression, and evidence distinct Sox2ot transcript profiles across OB/SCN/COR. Expressed Sox2ot/dot exons closely align with Okamoto enhancers (3/4, and 2/5, respectively), and a common 5' Sox2dot exon also aligns with a VISTA forebrain enhancer (hs192). However, we found no evidence that Sox2ot/dot incorporate U6 sequence, and could not amplify U6 independently of Sox2ot/dot exons. Our results indicate two classes of Sox2 enhancer: (1) transcribed within Sox2ot/dot in adult brain, and (2) non-transcribed. Differential use of these enhancer/ lncRNA(+/-) units may contribute to cell-type specific Sox2 expression, including that in the adult SCN.

Title: Unique regional and sex-dependent properties of adult endogenous neural stem cells to chronic alcohol and cocaine co-adminstration.

Authors: *E. L. MCGRATH[1], J. GAO[2], T. DUNN[2], A. GRANT[2], J. ALLENDE-LABASTIDA[2], K. DINELEY[3], B. KAPHALIA[4], K. CUNNINGHAM[5], P. WU[2]; [1]UTMB, Galveston, TX; [2]Neurosci. and Cell Biol., [3]Neurol., [4]Pathology, [5]Pharmacol. and Toxicology, Univ. of Texas Med. Br., Galveston, TX

Abstract: Cocaine and alcohol are two of the most commonly co-absued substances, and the third most fatal drug combination. Efforts in drug addiction research primarily focus on preventing or stoping abuse, however little work is being done to reverse brain damage incurred by chronic drug abuse. Neural stem cells are a promising target to stimulate brain recovery,

however little is known about the effect of long term co-abuse of alcohol and cocaine on this cell population. Additionally, sex differences in NSC behavior following chronic drug abuse have yet to be evaluated. This is the first study to evaluate regional and sex differences of endogenous adult neural stem cells to chronic treatment with alcohol and cocaine. We sought to elucidate the response of adult endogenous NSCs to chronic alcohol and cocaine treatment using a inducible lineage tracing mouse model. Adult mice were randomly divided into 1 of 4 groups: control, cocaine, ethanol, or combination treatment. Daily i.p. injections of cocaine were administered and ethanol was provided in a complete nutrient liquid diet to appropriate groups. Brain tissue was analyzed for markers of NSC survival and differentiation. The subventricular zone of lateral ventricle (SVZ) subgranular zone of dentate gyrus (SGZ) and tanycyte layer of third ventricle (TL) were evaluated. KEY FINDINGS: We found that NSCs have a unique response to drug depending on the regional location and sex of the animal. Females had more robust decreases in neural stem cell (NSC) survival in SVZ compared to males. SGZ neurogenesis was reduced in combination group. The TL showed the greatest variation in astroglial marker (glial fibrillary acidic protein) among both sexes and treatment groups.

Title: The effects of high-fat diet on adult neurogenesis in the hippocampus

Authors: ***F. NASRI**, M. WOJTOWICZ;
Dept. of Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: High-fat diet (HFD) is associated with poor cognitive health and exacerbation of neurodegenerative diseases. Some of the effects of HFD have been attributed to impairments in neurogenesis and cognitive functions of the hippocampus, a brain area important for learning and memory. However, how the specific attributes of the diet such as the diet length and fat percentage affect hippocampal neurogenesis is not fully understood. This study examines the effects of a 4-week or 8-week period of HFD (45% of total energy contributed by saturated fatty

acids) on the levels of adult hippocampal neurogenesis. 12 male Long-Evans rats (4 weeks old) were used for each of the two studies. In the 4-week HFD study, the animals were fed either HFD (n=6) or regular chow diet (n=6) for 4 weeks, and for the 8-week HFD study, the animals were fed either HFD (n=6) or regular chow diet (n=6) for 8 weeks. The food consumption and caloric intake of the animals were measured every week over the study period. The HFD-fed animals consumed less food but their caloric intake was higher than the chow-fed animals (as each gram of the HFD was more energy-dense than one gram of regular chow). This suggests that the HFD-fed animals may have been trying to compensate for the energy-dense HFD by eating less food although the results do not show a complete compensation. Furthermore, only the HFD-fed animals in the 8-week experiment underwent a significantly higher weight gain compared to the chow-fed animals. After the end of the diet period the animals were sacrificed. Hippocampal sections were stained for doublecortin (DCX; marker for young neurons) and NeuN (marker for mature neurons) to examine the levels of neuronal differentiation and maturation respectively. Cell numbers expressing DCX and NeuN were quantified per section in the dorsal, medial and ventral regions of the hippocampus or per dentate gyrus. There was no significant difference in DCX or NeuN expression between the HFD- and chow-fed animals in either of the two studies. This lack of effect may be due to these specific HFD periods (i.e. 4 weeks and 8 weeks) not being long enough to show changes in neurogenesis. Longer periods of HFD may result in higher levels of inflammation, higher percentages of weight gain and/or lower levels of physical activity that could in turn result in significantly reduced levels of neurogenesis. Additionally, it may take a longer time after the end of the diet period for changes in neurogenesis to show. Therefore, an increased period of high-fat diet exposure or prolongation of the monitoring period after the exposure may be required to show effects.

Title: Matrix metalloproteinase-12 regulates the establishment of the subventricular zone neural stem cell niche

Authors: *X. SHAN, Q. YANG, H. A. COLOGNATO;
Pharmacol. Sci., Stony Brook Univ., Stony Brook, NY

Abstract: The subventricular zone (SVZ) houses the largest neural stem cell niche in the mammalian brain. In this niche, molecular cues from special cellular and extracellular structures tightly regulate stem cell proliferation and differentiation. Apical surfaces of SVZ neural stem cells are encircled by multiciliated ependymal cells, forming a pinwheel-shaped cellular arrangement. Ependymal cells arise postnatally from neural stem cells, and the movement of their motile cilia directs the flow of cerebrospinal fluid, ensuring proper neurogenesis. The planar cell polarity of ependymal cells coordinates the orientation of this ciliary movement.
The adult apical SVZ contains a distinctive extracellular matrix (ECM), which we have recently found to develop concurrently with the formation of niche pinwheels. While this niche ECM is diffuse at birth, by adulthood it becomes highly polarized to discrete regions in niche pinwheel centers, which we have termed “ECM hubs”.
Since a dramatic remodeling of both cells and ECM occurs during postnatal SVZ development, we hypothesized that matrix metalloproteinases (MMPs), a family of extracellular endopeptidases that regulate ECM spatial organization in many tissues, may play a role in niche reorganization. Here we report that MMP-12 expression in particular is highly upregulated during ependymal cell maturation, and that MMP-12 knockout mice have an abnormal SVZ niche structure, characterized by aberrant numbers of stem cells per pinwheel, and reductions in the number and size of ECM hubs. Furthermore, the establishment of planar cell polarity in niche ependymal cells is significantly disrupted in MMP-12 knockout mice.
Surprisingly, we found that lentivirus- or neonatal ventricle electroporation-mediated acute knockdown of MMP-12 impeded ciliogenesis in ependymal cells, which was not observed in MMP-12 knockout mice. We found that in MMP-12 knockout ependymal cells, a truncated MMP-12 mRNA is still expressed and can be translated into a shorter, intracellular isoform of MMP-12. Intracellular MMP-12 has been recently reported to act as a novel transcription factor that can enhance the transcription of IκBα, a negative regulator of NFκB signaling. As inappropriate NFκB pathway activation has recently been linked to a ciliogenic defect in ependymal cells, our data suggests a model in which aberrant NFκB activation upon MMP-12 knockdown leads to a ciliogenic defect in ependymal cells. Together, these findings indicate that both secreted and intracellular MMP-12 may regulate the establishment of cellular and extracellular structures of the SVZ neural stem cell niche.

Title: Primary cilia modulate TLR4-mediated NF-kB signaling in hippocampal neurons

Authors: H. BAEK[1], J.-J. KIM[2], J. PARK[1], C.-S. KIM[1], *D. KIM[3];
[1]Physiol., [2]Anat., Chungnam Natl. Univ. Sch. of Med., Daejeon, Korea, Republic of; [3]Chungnam Natl. Univ., Daejeon, Korea, Republic of

Abstract: The primary cilium is an organelle that can act as a master regulator of cellular signaling. Despite the presence of primary cilia in hippocampal neurons, their function is not fully understood. Recent studies have demonstrated that the primary cilium influences interleukin (IL)-1β-induced NF-κB signaling, ultimately mediating the inflammatory response. We, therefore, investigated ciliary function and NF-κB signaling in lipopolysaccharide (LPS)-induced neuroinflammation in conjunction with ciliary length analysis. Primary ciliary length decreased in hippocampal pyramidal neurons after intracerebroventricular injection of LPS, whereas it increased in TLR4-/- mice. Next, to exclude the effects of microglial TLR4, we utilized HT22 hippocampal neuronal cells. LPS treatment decreased primary ciliary length, activated NF-κB signaling, and increased Cox2 and iNOS levels in HT22 hippocampal neurons. In contrast, silencing Kif3a, a key protein component of cilia, increased ciliary protein levels and suppressed NF-κB signaling and expression of inflammatory mediators. These data suggest that LPS-induced NF-κB signaling and inflammatory mediator expression are modulated by cilia, and that blockade of primary cilium formation by si_Kif3a regulates TLR4-induced NF-κB signaling. We propose that primary cilia are critical for regulating NF-κB signaling events in neuroinflammation and in the innate immune response.

Title: The atypical RhoGTPase Rnd2 is critical for newly generated neurons in the adult hippocampus

Authors: *T. KERLOCH[1], A. GORON[1], F. GUILLEMOT[2], N. D. ABROUS[1], E. PACARY[1];
[1]Neurogenesis and Physiopathology, Neurocentre Magendie, Bordeaux, France; [2]Div. of Mol. Neurobio., Natl. Inst. for Med. Res., London, United Kingdom

Abstract: Adult-born hippocampal neurons go through distinct developmental steps, from a dividing neurogenic progenitor to a synaptically integrated mature neuron and this requires an extensive and dynamic remodeling of the cytoskeleton at each step of the process. Nevertheless, few studies have explored the role of the RhoGTPases, which are well-known regulators of the actin cytoskeleton, in the regulation of adult hippocampal neurogenesis. In this context, we have focused our attention on relatively newly characterized members of this family: the Rnd proteins and in particular on Rnd2. Rnd2 plays a critical role during embryonic neurogenesis in the cerebral cortex and is expressed in the adult dentate gyrus. However the implication of Rnd2 in the process of adult hippocampal neurogenesis is still unknown.
To address this role, we have implemented two strategies of loss of function. First, we used retroviruses expressing Cre together with GFP to delete *Rnd2* expression in newborn neurons of the dentate gyrus of $Rnd2^{flox/flox}$ mice. With this strategy, we show that *Rnd2* deletion affects the survival of newborn neurons and induces an ectopic migration as well as an acceleration of the dendritic maturation in the surviving new neurons. Second, we have generated $NestinCreER^{T2}/Rnd2^{flox}/AI6$ mice to study the impact of *Rnd*2 deletion on the functions sustained by hippocampal adult-born neurons in particular spatial navigation and pattern separation. We are now analyzing these mice to confirm the effects observed with the retroviral strategy.
Our preliminary data reveal a novel function for Rnd2 in the adult brain and provide mechanistic insights into the critical aspect of adult neurogenesis regulation.

Title: The expression of Gas1 is regulated by proneural factors Neurogenin (Ngn2) and NeuroD via distal E-boxes

Authors: *M. A. QUEZADA, J. SEGOVIA;
Physiol., CINVESTAV, Mexico, Mexico

Abstract: Gas1 is a membrane GPI-linked protein that inhibits cell proliferation by blocking the PI3K-Akt transduction signal when overexpressed. We have taken advantage of this

characteristic for pre-clinical gene therapy assays directed at treating glioblastoma. However, the physiological role of Gas1 is more complex than previously considered and genetic studies have indicated that it is an important regulator of central nervous system development acting as a co-receptor for Sonic Hedgehog (Shh) during the establishment of neuronal progenitor cells in spinal cord and granular cells of cerebellum. Recently we observed the expression of Gas1 in embryonic proliferating progenitor cells of cortex and hippocampus indicating that Gas1 fulfills a relevant function during brain development. On the other hand, although several studies have been published about Gas1 gene regulation little is known about the mechanisms that govern its pattern of expression during the development of the nervous system (specifically in neuronal cell linages) an aspect that is key, to understand the role of Gas1 in neurogenesis. As a first step to reach this objective we analyzed the promoter sequence of the mouse Gas1 gene by comparative genomics searching for transcription factor binding sites that could explain the expression pattern of Gas1 in the nervous tissue. Interestingly, the screening of the mouse Gas1 promoter revealed the presence of at least three highly conserved E-boxes with the consensus sequence CANNTG that can bind the proneural basic-helix loop helix (bHLH) transcription factors Neurogenin 2 (Ngn2) and NeuroD. These proneural factors are known to regulate different stages of neurogenesis, including the specification of neuronal progenitor cells, the differentiation and the establishment of neuronal subtypes. We cloned a fragment of the mouse Gas1 promoter and performed luciferase reporter assays in the N1E-115 neuroblastoma cell line. By deletion and mutagenesis assays we demonstrated that two distal E-boxes motifs, located -1699 and -1940 relative to the transcription start site of Gas1, mediate its activation by potentially binding to Ngn2, NeuroD and NeuroD2 proteins. This is the first time, to our knowledge, that a relationship between Gas1 and basic proneural signals that induce neuronal fate is observed.

Title: mTORC1 regulates retinal development via the immune proteasome

Authors: *J.-H. CHOI;
KAIST, Taejon-City, Korea, Republic of

Abstract: The growth and development of mouse retina are regulated by cellular mechanisms that couple neurogenesis to the proliferation of retinal progenitor cells (RPCs). In this study,

mammalian target of rapamycin complex 1 (mTORC1) pathway was determined to be explored in connection with retinal development. We identified a regulatory role of mTORC1 in retinal development, showing that it facilitates both the synthesis and degradation of cyclin proteins to accelerate the cell cycle progression of RPCs and consequently the retinal neurogenesis. Interestingly, it has also revealed that the level of immune proteasome subunit β-9 (Psmb9) highly correlated with mTORC1 activity in developing mouse retina, and concomitant loss of Psmb9 decelerated cell cycle progression in *Tsc1*-deficient mouse RPCs and normalized retinal development. These results together support the hypothesis that mTORC1 may coordinates protein synthesis and degradation during retinal development process through a mechanism involved by immune proteasome.

Title: *In vitro* model for characterizing migration and differentiation of primary cranial and trunk neural crest cells isolated from Sox9-cre/EYFP mouse embryos

Authors: *M. R. REPLOGLE[1], K. R. SVOBODA[2], A. J. UDVADIA[1];

Abstract: Neural crest cells (NCCs) are a transient population of embryonic stem-like cells that have the potential to differentiate into neurons and glia of the peripheral nervous system, as well as a variety of other non-neural derivatives including the skeletal elements of the vertebrate head. We are interested in investigating epigenetic modulation of genes regulating NCC migration and differentiation, and the potential disruption of this modulation by genetic and environmental insults. In order to obtain cell numbers sufficient for biochemical analyses of protein-protein and protein-gene interactions in developing NCCs we have optimized conditions for expanding and differentiating murine NCCs *in vitro*. Specifically we have isolated cranial and trunk NCCs from E9.5 *Sox9-cre/EYFP* mouse embryos. These cells can be expanded in culture for several passages while maintaining mesenchymal morphology, and expression of neural crest and stem cell-like markers. Using this *in vitro* model we have found that undifferentiated murine NCCs

stain positive for choline acetyltransferase, and thus have the potential to produce cholinergic signals prior to differentiation as observed previously in chick and quail. In addition, undifferentiated murine NCCs may also possess the capacity to respond to cholinergic signals based on their expression of nicotinic acetylcholine receptor subunits. Here we present a detailed characterization of these cholinergic properties, as well as the morphology and migratory behavior of *Sox9*-expressing NCCs in culture under proliferative conditions and during different stages of neuronal, glial, and chondrocytic differentiation.

Title: Expression of glycoprotein non-metastatic melanoma B in the developing rat brain

Authors: *S. YOKOYAMA;
Kanazawa Univ., Kanazawa, Japan

Abstract: The glycoprotein non-metastatic melanoma B (Gpnmb) is a type-I transmembrane protein that is produced by various types of normal cells including melanocytes, osteoclasts, osteoblasts, and dendritic cells in peripheral blood, as well as by various carcinoma cells. An increasing number of studies have described that Gpnmb is abundantly expressed in invasive glioblastomas, suggesting its contribution to tumor progression and metastasis. We have reported that Gpnmb is produced by macrophages and microglia in the normal and central nervous system of adult rats (Huang *et al.*, Brain and Behavior 2, 85-96, 2012). In this study, we further examined whether Gpnmb was expressed in the developing rat brain. Gpnmb mRNA was detected by reverse transcription-polymerase chain reaction analysis in postnatal day 1 (P1) brain at roughly the same level as in the adult brain. Immunoperoxidase staining detected intense Gpnmb-immunoreactivity (IR) in choroid plexus, leptomeninges, and ependyma through the postnatal period. In the cerebral cortex, Gpnmb-positive cells were distributed diffusely in all layers at P1; some of the cells were positive for OX42, a microglia/macrophage marker. After P7, Gpnmb-positive cells became more prevalent in cortical layers II-IV, as shown in adult rats. In addition to cell bodies, the Gpnmb-IR was also detectable in process-like structures. In the hippocampus, Gpnmb-IR became more intense in the dentate gyrus after P7. In the cerebellum, as in the cerebrum, Gpnmb-positive cells were observed in all layers at P1. At P15 and P30, Gpnmb-IR was steadily detectable in Bergmann glial cells, with cell bodies adjacent to Purkinje

cells, as previously demonstrated in adult rats. Additionally, in the both cerebrum and cerebellum, Gpnmb-positive cells were detected in the white matter and inner layers most frequently at P7 and P15, suggesting involvement in myelin formation. These results suggest that Gpnmb plays multiple roles in the development of postnatal rat brain.

Title: Nek2A phosphorylates and stabilizes SuFu: a new strategy of Gli2-Hedgehog signaling regulatory

Authors: *S. LUO[1], Y. WANG[2], Y. LI[2], G. HU[2], H. RAO[3], Q. LU[4];
[2]Ctr. for Exptl. Med., [1]The First Affiliated Hospital, Nanchang Univ., Jiangxi, China; [3]Dept. of Mol. Med., Univ. of Texas Hlth. Sci. Ctr., San Antonio, TX; [4]Dept. of Biostatistics & Epidemiology, Sch. of Publ. Health, Nanchang Univ., Jiangxi, China

Abstract: The Hedgehog (Hh) signaling pathway plays pivotal roles in normal embryonic development and postnatal homeostasis. Suppressor of Fused (SuFu), one of the key negative regulators of Hh signaling and Gli activities, is indispensable in vertebrates, as ablation of SuFu in mouse embryos leads to widespread activation of the Hh pathway and causes early embryonic lethality with cephalic and neural defects. Despite the central importance of SuFu in the Hh pathway, little is known about its regulation. Here, we performed a GAL4-based yeast two-hybrid screen using human SuFu as bait, and identified NIMA-related expressed kinase 2A (Nek2A) as a new SuFu-interacting protein, which was also confirmed by Glutathione-S-transferase pull-down and co-immunoprecipitation assays. Intriguingly, Nek2A is found to stabilize SuFu at least partly depending on its kinase activity, thereby triggering phosphorylation of the SuFu protein. Moreover, the phosphorylated SuFu inhibits the nuclear localization and transcriptional activity of Gli2. These findings reveal a new mechanism of mammalian SuFu regulation, and offers novel insights into Hh signaling regulation in development and human disease.

Title: Bone morphogenetic protein-7 and the development of the peripheral pain pathway

Authors: ***C. A. WEBBER**[1], T. FRIEDMAN[2], P. SABIRI[2], T. JOY[2], V. ZOUVELOU[4], D. GRAF[3];
[1]Div. of Anat., [3]Dent., [2]Univ. of Alberta, Edmonton, AB, Canada; [4]Univ. Hosp. Agia Sofia, Athens, Greece

Abstract: Neuropathic pain (NP) is a priority health issue that affects up to 10% of all adults worldwide. Medical interventions are often inadequate and can lead to drug tolerance or addiction. An understanding of the development of the pain pathways may provide essential clues to develop novel treatments for NP. Bone Morphogenetic Proteins (BMPs) are evolutionarily conserved, secreted, highly regulated signaling molecules with pleiotropic functions. Loss of Bmp7 affects multiple neural crest-derived craniofacial structures including a significantly delayed outgrowth of the trigeminal nerve. As Bmp7 has been implicated in neural development and regeneration of the peripheral nerves, we sought to investigate whether loss of Bmp7 affects development and function of peripheral sensory neurons. Bmp7-lacZ reporter mice revealed that in E9.5 embryos *Bmp7* is expressed in newly formed neural crest cells. At E11.5 *Bmp7* was detected in a mottled pattern in migrating dorsal root ganglion neurons (DRGN) suggesting it is expressed in a subpopulation. Lineage tracing for neural crest-derived cells using the Rosa26lacZ allele and wnt1-Cre revealed that at E15.5 *Bmp7*-deficient mice have noticeably fewer spinal nerve axons and a decrease in size of DRGs. To assess potential functional consequences (and to overcome perinatal lethality), we deleted *Bmp7* in all neural crest-derived cells using a conditional *Bmp7* allele (*Bmp7fl*) and wnt1-Cre. Behavioral analysis (Von Frey filament test) in adult *Bmp7*fl:wnt1Cre mutant mice revealed a significant allodynia. Histological

analysis of corresponding DRGs demonstrated a decrease in calcitonin gene related protein (CGRP)-expressing neurons found in a subpopulation of both Aδ (primarily sharp pain) and C fibers (dull ache/inflammatory pain) (12.8% ± 0.6 and 21.7% ± 0.2% of CGRP expressing DRGN in control and *Bmp7*fl:wnt1Cre mutant mice respectively ($p<0.05$)). Conversely in C-fibers there was an increase in isolectin B4 (IB4)-expressing DRGN from 33.0% ± 0.07% in control mice to 45.7% ± 0.16 in the *Bmp7*fl:wnt1Cre mutant mice respectively ($p < 0.05$). In summary, our data reveal for the first time a role of Bmp signaling in pain fiber sub-specification and regulation of physiological pain responses. In future work we will explore this lead to identify molecular networks involved in pain fiber sub-specification, which might lead to novel targets for therapeutic intervention in neuropathic pain.

Title: The effect of electrical stimulation on muscle reinnervation and axon elongation in a mouse model of Val66Met

Authors: *C. MCGREGOR[1], A. ENGLISH[2];
[1]Cell Biol., Emory Univ., Decatur, GA; [2]Cell Biol., Emory Univ., Atlanta, GA

Abstract: A single nucleotide polymorphism (SNP), Val66Met, results in abnormal regulated release of brain derived neurotrophic factor (BDNF) from neurons. The presence of this SNP could impact the translational capacity of activity-dependent treatments which enhance nerve regeneration after injury through a BDNF-dependent mechanism. We tested the effects of 1 hour of 20 Hz ES on muscle reinnervation in wild type (WT) C578/6 mice and mice of the same background strain in which the native BDNF gene was replaced by one containing the Val66Met SNP. Sciatic nerves were cut and repaired with end-to-end anastomosis, and 4 weeks later motor unit number estimation (MUNE) was performed using EMG recordings from lateral gastrocnemius. Motor endplate reoccupation was evaluated using histological sections of lateral and medial gastrocnemius. To measure axon regeneration, Val66Met mice were crossed with SLICK (Single neuron Labeling with Inducible Cre mediated Knockout) mice, which express

yellow fluorescent protein (YFP) in a subset of neurons, and nerve transection was repaired with acellular allografts from WT mice. Axon profile lengths of YFP+ neurons were measured two weeks post-repair. From all three outcome measures, our preliminary data indicate that untreated mice expressing the Val66Met SNP have superior regeneration than WT mice after injury, but that treatment with ES does not further enhance their regeneration. The enhancement of regeneration in the untreated Val66Met mice may be a result of compensatory mechanisms other than BDNF that are unaffected by ES.

Title: Realizing the potential of adult human skin-derived Schwann cells for transplantation therapy

Authors: *J. A. STRATTON[1,2], R. KUMAR[2], P. SHAH[2,1], M. STYKEL[2], R. MIDHA[1,3], J. BIERNASKIE[2];
[1]Hotchkiss Brain Inst., Calgary, AB, Canada; [2]Dept of Comparative Biol. and Exptl. Med., [3]Dept Clin. Neurosciences, Univ. of Calgary, Calgary, AB, Canada

Abstract: Nerve injury causes significant long-term disability. With this in mind, we believe that supplementing the injured nerve with autologous Schwann cells (SCs), a glia cell type that can be harvested directly from injured patients, and that has potential to rejuvenate the injury environment, will improve functional outcomes. Although promising, Schwann cell collection procedures for autologous transplant, currently under clinical trial, require invasive surgery for collection, causing additional discomfort. As such, for over a decade now several laboratories have been developing protocols to derive SCs from the easily accessible skin. Using rodent skin-derived SCs (SkSCs), it has been shown that SkSCs can improve anatomical measures, ultimately supporting improved behavioral outcomes following CNS and PNS injury. Because most of the convincing research pertaining to SkSC potential has been demonstrated using neonatal rodent cells, it is paramount that similar experiments are perform using adult human

SkSCs before they can be seriously considered as a replacement for current treatment options. Here we describe the purification and characterization of SCs from adult human skin of 4 male donors (27-46 years old). Within 2 weeks of isolating and culturing adherent mixed skin cells in serum-free SC media, colonies of bipolar shaped cells were sporadically detectable. Within 2-4 weeks of growth, we selected these colonies using cloning cylinders, and re-plated these colonies. By 5 weeks, we obtained 3-5 million purified SCs - a cell number appropriate for transplantation in the clinic. Using a battery of Schwann cell lineage-specific markers, we demonstrated that SkSCs are phenotypically indistinguishable from nerve-derived SCs (nSCs). Namely, SC associated genes were highly expressed in both nSCs and SkSC cultures compared to dermal fibroblast cultures. This included genes such as SOX10, SOX9, AP2A1, CDH19, EGR1, ETV5, PAX3, SOX2, CX32, DHH, NECL4, NFATC4, POU3F1, S100B and YY1. Using immunocytochemistry we demonstrated that the percentage of cells in nSC and SkSC cultures expressing Sox10 were 89.3±6.3% and 77.3±6.2%, respectively (P=0.2). Following transplantation into nerve injury in immune-deficient mice, the majority of transplanted SCs maintained Sox10 immunoreactivity in both nSCs and SkSC transplant conditions, and also expressed the promyelinating factor, POU3F1, in 60.85±2.21% and 50.85±1.87% of cells, respectively (P=0.09). In addition, subsets of these cells were associated with myelin (MBP, Pzero or fluoromyelin+), aligned on neurofilament+ axons. Such findings suggest that SkSCs should be considered for clinical application.

Title: Androgen receptor signaling is required for activity-dependent somatic motoneuron axon regeneration

Authors: ***P. J. WARD**[1], J. D. ZAJAC[2], A. W. ENGLISH, 30306[1];
[1]Emory Univ. Dept. of Cell Biol., Atlanta, GA; [2]Univ. of Melbourne, Heidelberg, Australia

Abstract: Systemic treatment with flutamide, an anti-androgen, blocks the enhancement of axon regeneration produced either by brief electrical stimulation (ES) or moderate treadmill exercise following peripheral nerve injury. The specific cellular target sites of the required androgen receptor (AR) signaling are unknown. Here, we used mouse genetics to investigate whether the requirement for AR signaling was in somatic motoneurons whose axons are regenerating. Two weeks following sciatic nerve transection and repair by end-to-end anastomosis, sciatic nerves were soaked in fluorescent retrograde tracer applied 4 mm distal to the repair. In SLICK (Single neuron Labeling with Inducible Cre mediated Knockout) mice, which express YFP in a subset of motoneurons, one hour of 20 Hz ES applied just prior to nerve repair resulted in a greater number of retrogradely-labeled and double-labeled (YFP+ and retrograde labeled) motoneurons than SLICK mice that underwent transection and repair alone (untreated). When SLICK:AR floxed mice are tamoxifen treated, the DNA binding portion of the AR is knocked out selectively in the YFP+ motoneurons. In male mice with this inducible AR knock-out, ES failed to promote axon regeneration in the knock-out (YFP+) motoneurons (fewer double-labeled motoneurons), but enhanced axon regeneration in the wild type (YFP-) motoneurons. In females, sciatic nerves in these same genotypes were cut and repaired using non-fluorescent nerve grafts. Lengths of YFP+ regenerating axon profiles were measured in confocal images two weeks later. Brief ES enhanced the median lengths of YFP+ axons in SLICK:AR floxed mice with motoneuron-specific AR signaling knock-out. Activity-enhanced axon regeneration of motoneurons is dependent on the transcriptional cascades resulting from AR signaling in motoneurons in males but not females. ES does not enhance motor axon regeneration via motoneuron ARs in a transcription-dependent manner in females.

Title: A novel local FK506 delivery system for the treatment of peripheral nerve injury.

Authors: *K. TAJDARAN[1,2], T. GORDON[3], G. H. BORSCHEL[1,2];
[1]Univ. of Toronto/Sickkids Hosp., Toronto, ON, Canada; [2]Inst. of Biomaterial and Biomed. Engin., Toronto, ON, Canada; [3]SickKids Res. Inst., Toronto, ON, Canada

Abstract: Purpose: Many challenges exist in improving outcomes following peripheral nerve injuries, specifically in cases with delayed nerve repair and with large nerve defects. This study

focused on investigating a new method to improve axon regeneration after surgical repair of a severely injured nerve. FK506, an FDA approved immunosuppressant, promotes functional recovery and reinnervation following peripheral nerve injury. However, FK506 has not been widely adopted for treating nerve injuries because the systemically delivered drug causes undesirable immunosuppression. We investigated a novel local delivery system for FK506 which utilizes fibrin gel as a biodegradable drug reservoir that could be placed at a site of nerve injury.
Methods: FK506 was incorporated into fibrin gel in solubilized, particulated and poly(lactic-*co*-glycolic) acid (PLGA) microspheres-encapsulated forms. In order to analyze the effectiveness of the delivery systems in enhancing nerve regeneration, a rat nerve transection model was used, where the proximal tibial nerve stump was cross-sutured to the distal stump of a cut common peroneal nerve. Rats in the negative control groups either did not receive any delivery system treatment or received fibrin gel with empty microspheres (without any FK506). The experimental groups included rats treated with fibrin gel loaded with solubilized, particulated, or PLGA microspheres encapsulated FK506. 3 weeks after repair, nerve regeneration was assessed using retrograde labeling and collecting nerve samples 7 mm distal to the repair site for histomorphometric analysis.
Results: Rats in experimental groups receiving FK506-loaded microspheres and the particulate form of FK506 doubled the number of motoneurons regenerating their axons after injury and allowing *all* the tibial motoneurons to regenerate their axons successfully. The number of the motor and sensory neurons that regenerated their axons for the FK506 microspheres treated group and the particulated FK506 treated group were significantly higher than the number in all the groups, including the solubilized FK506 treated group and negative control groups. Histomorphometric analysis indicated increased numbers of myelinated axons following particulated FK506 and FK506 microspheres treatment compared to the native control groups.
Conclusion: The local application of FK506 via our proposed delivery systems resulted in excellent axon regeneration while preventing the toxicity of systemic FK506 that has prevented clinicians from using FK506 routinely for treating severe cases of peripheral nerve injuries.

Title: Luminopsin mediated attenuation of exercise induced functional improvements after sciatic nerve injury

Authors: *P. B. JAISWAL[1], J. K. TUNG[2], R. E. GROSS[2], A. W. ENGLISH[1];
[1]Cell Biol., [2]Neurosurg., Emory Univ., Atlanta, GA

Abstract: Inhibitory luminopsins (iLMOs) integrate opto- and chemo-genetic approaches and allow for cell-type specific inhibition of neuronal activity. iLMOs are fusion proteins with a light- emitting, Renilla luciferase (RLuc), and a light-sensing inhibitory opsin, Halorhodopsin (NpHR). A small molecule substrate, coelenterazine (CTZ), binds to RLuc and is converted into photons that activate the NpHR channel to hyperpolarize cells expressing the iLMOs. Moderate daily exercise following peripheral nerve injuries (PNI) results in enhanced axon regeneration. An interval treadmill-training (IT) regimen is effective in female mice. We hypothesized that iLMO mediated inhibition of motoneuronal activity during exercise would attenuate the associated improvements in functional outcomes after sciatic nerve injury. Utilizing Cre-lox technology and viral vector delivery methods we expressed iLMOs in motoneurons. Unilateral intramuscular injections of AAV9-EF1a-DIO-iLMO2 (~8.5x1013 vg/ml) were made in young female ChAT-Cre mice. Four-six weeks were allowed for retrograde viral transduction of motoneurons after which a unilateral sciatic nerve transection (Tx) and repair was performed. Animals were randomized into four groups: IT with CTZ treatment, CTZ treatment only, IT only, and untreated (UT). Three days after Tx-repair, IT and/ or CTZ treatments were administered every day, five days a week for two weeks. Evoked M- response recovery was measured at three weeks post Tx-repair. The maximal M- response amplitude recorded from the reinnervated muscles of the IT only group was significantly greater than that in UT mice, confirming that this exercise regimen was effective in promoting axon regeneration and muscle reinnervation. Inhibiting motoneuronal activity during exercise in the IT+CTZ group resulted in a significant attenuation of the maximum M-response in this group, compared to the IT only group. The maximum M response amplitude in the CTZ only group was smaller than that found in UT mice at this survival time, indicating that inhibiting the activity of axotomized motoneurons impeded the regeneration of their axons. We conclude that neuronal activity may be required for successful motor axon regeneration and its enhancement by exercise.

Title: Rat slow and fast nerves regenerate into appropriate endoneurial tubes to reinnervate tibialis anterior (TA) muscles after common peroneal (CP) nerve transection and surgical repair but, size-dependent branching occurs more distally within intramuscular sheaths

Authors: *T. GORDON[1], J. E. TOTOSY DE ZEPETNEK[2];
[1]Dept of Surgery, Div. of Plastic Reconstructive Surgery, Hosp. for Sick Children, Toronto, ON, Canada; [2]Univ. of Alberta, Edmonton, AB, Canada

Abstract: Muscle fibers innervated by one nerve, a muscle unit (MU), may be identified with periodic acid staining (PAS) after repetitive on-off fatiguing tetanic contractions of isolated and physiologically characterised MUs. MU muscle fibers are located within defined MU territories that normally occupy 21 $\pm$ 2 % (n=20) of the cross-sectional area of TA muscles. These MU territories, that link the outermost muscle fibers, provide an indirect image of the extent of intramuscular nerve branching (Rafuse and Gordon, *J Neurophysiol 75:282-297, 1996*). MU contractile forces and muscle fiber numbers increase with size of their innervating nerves in normal and reinnervated muscles (Gordon and Stein, *J Neurophysiol 48: 1175-1190, 1982*; Totosy de Zepetnek and Gordon, *J Neurophysiol 67: 1385-1403, 1992*). It follows that extent of nerve branching, as measured by the size of MU territories, and electrophysiological parameters of motor nerve size must also correlate. Here we asked 1) Is this prediction accurate in normal and reinnervated TA muscles? 2) If and how does the pattern of MU nerve branching within intramuscular nerve sheaths change after the known random axon regeneration into distal nerve stumps after CP nerve transection and surgical repair?; and 3) Is the normal preference of slow nerves to reinnervate muscle fibers in the deep portions of skeletal muscles, slow muscle fiber regionalization, demonstrated during nerve regeneration? The answers were 1) Yes. MU territories that were significantly reduced in size, demonstrated the same size-dependent relationship between the size of the motor nerve and the extent of the intramuscular branching of the nerve prior to formation of functional nerve-muscle contacts, as in normal TA muscles; 2) Yes. The pattern of single motor nerve branching *was* altered with significantly more MU fibers adjacent to one another in reinnervated muscles as compared to the typical mosaic distribution with few adjacent MU muscle fibers, in normally innervated muscles. The more distal nerve branching within the denervated intramuscular nerve sheathes restored the normal size relationships in reinnervated muscles despite the altered branching patterns; and 3) Slow motor nerves demonstrated a preferential reinnervation of denervated endoneurial tubes that had formerly contained these nerves. With thanks to the CIHR for their financial support.

Title: A randomized controlled trial on electrical stimulation to accelerate axon regeneration and functional recovery following cubital tunnel surgery

Authors: *K. CHAN[1], H. A. POWER[2], M. J. MORHART[2], J. L. OLSON[2];
[2]Plastic Surgery, [1]Univ. Alberta, Edmonton, AB, Canada

Abstract: Introduction
Brief post-surgical electrical stimulation (ES) enhances motor and sensory axonal regeneration in animal models following axotomy and crush injury. The ulnar nerve that innervates the majority of hand muscles makes a vital contribution to hand strength. In this study, we investigated the hypothesis that ES following cubital tunnel surgery in patients with severe ulnar nerve injury would result in significantly better muscle reinnervation and functional recovery compared to surgery alone.
Methods
Patients with severe axonal loss from ulnar nerve compression at the elbow were randomly assigned to the treatment or control group in a 2:1 ratio. Those in the control group received cubital tunnel surgery and sham stimulation, while patients in the treatment group received 1 hour of 20Hz ES following surgery. Stimulation was delivered via two stainless electrodes placed adjacent to the ulnar nerve intraoperatively. Patients were followed yearly for 3 years. At each visit, axonal regeneration was quantified using motor unit number estimation (MUNE) and functional recovery was evaluated using grip strength and key pinch strength. Statistical analysis was performed using non-parametric tests, with statistical significance set at $p<0.05$.
Results
Twenty-four patients were enrolled in the study: 8 received surgery alone and 16 received surgery and ES. There was no significant difference in demographics between the two groups. At three years following surgery, MUNE was significantly higher in the treatment group (182±25, mean±sd) compared to controls (93±14, $p<0.05$). In terms of functional recovery, grip strength was significantly improved in the treatment group (43±3kg) at 3 years post-operatively compared to controls (39±3kg, $p<0.05$). Key pinch strength was also significantly better in the treatment group (5.2±0.5kg) compared to controls (4.4±0.8kg, $p<0.05$).
Conclusions
These results suggest that post-surgical ES enhances axonal regeneration, muscle reinnervation

and functional recovery following cubital tunnel surgery in humans. We propose that ES may be a clinically useful adjunct to surgical release for severe ulnar nerve injuries where functional recovery with conventional treatment is poor.

Title: Satellite glial cell renewal in dorsal root ganglia after peripheral nerve injury involves self renewal and intrinsic reprogramming of non-glial cells

Authors: *A. KRISHNAN[1], C. CHENG[2], D. W. ZOCHODNE[1];
[1]Dept. of Med., Univ. of Alberta, Edmonton, AB, Canada; [2]Clin. Neurosciences, Univ. of Calgary, Calgary, AB, Canada

Abstract: The generation of new satellite glial cells (SGC) in dorsal root ganglia (DRG) after peripheral nerve injury has previously been described but how they appear is not well understood. In this work we examined proliferative events within rat dorsal root ganglia, three days after sciatic nerve axotomy, to understand overall cellular dynamics. We encountered five main perineuronal cell types relevant to this question: (i) $GFAP^+$ $sox2^+$, (ii) $sox2^+$ $ki67^+$, (iii) $GFAP^+$ $ki67^+$, (iv) $ki67^+$ $GFAP^-$ $sox2^-$, and (v) $sox2^+$ $ki67^-$ $GFAP^-$. Population (i) potentially indicates activation ($GFAP^+$) and dedifferentiation ($sox2^+$) of existing SGCs while, (ii) &(iii) represent proliferation ($ki67^+$) of these de-differentiated ($sox2^+$) SGCs ($GFAP^+$) for self renewal. Interestingly, the population (iv), indicates proliferation of cell types other than SGCs while (v), potentially indicates reprogramming of these unknown cell types. Vimentin positivity in population (iv) & (v) indicate that these cells are of mesenchymal origin. Among all the cell types, population (iv) was seen also in the nerve roots suggesting local proliferation at that site with potential follow up migration of non-glial cells from distant territories to DRGs. We also marked the proliferating cells with Brdu and encountered results supporting the above conclusions. Overall, our observations suggest that SGC generation in response to peripheral

nerve injury involves self renewal of existing SGCs and *in vivo* reprogramming of non-glial mesenchymal cells. The intrinsic reprogramming potential of cell populations in the DRG and nerve roots may shed light on other possibilities such as the potential for generation of new sensory neurons. Title: Repeated application of 20 Hz electrical stimulation after peripheral nerve injury promotes motor axon regeneration and retention of exaggerated H reflexes.

Authors: S. PARK, *A. W. ENGLISH;
Dept Cell Biol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: A single treatment with one hour of 20 Hz continuous electrical stimulation promotes the regeneration of axons in cut peripheral nerves. This enhanced axon regeneration is the result of a transient increase in neuronal expression of BDNF and its trkB receptor (Al-Majed et al, Eur J Neurosci, 2000. 12:4381-4390). A slightly more robust enhancement of peripheral axon regeneration is achieved by two weeks of daily treadmill exercise, also in a BDNF/trkB-dependent manner. We tested the hypothesis that repeated application of brief electrical stimulation (rES) would be more effective in promoting functional muscle reinnervation than a single application (sES). Sciatic nerves of C57B6 mice were cut and repaired by end-to-end anastomosis. At the time of nerve repair and every third day for the following two weeks, the proximal segment of the cut nerve was stimulated continuously for one hour at 20 Hz. In control groups used for comparison, nerves were cut and repaired and mice were either untreated (UT) or treated with a single application of electrical stimulation (sES) at the time of nerve repair. Beginning two weeks later, functional muscle fiber reinnervation was assayed using stimulus evoked EMG activity from the gastrocnemius and tibialis anterior muscles. Direct muscle (M) responses and monosynaptic H reflexes produced in response to sciatic nerve stimulation above the injury site were studied in awake animals. The amplitude of M responses recorded from reinnervated muscles increased progressively over the 14 week post transection study period. In the rES animals, this increase was more rapid than sES or UT mice. In rES mice, the amplitude

of H reflexes recorded from reinnervated muscles increased more rapidly than found in either UT or sES mice, reaching a peak at six weeks after nerve injury. The H reflexes in the rES animals were maintained at more than twice the amplitude of the same reflexes recorded prior to injury for the remaining eight weeks studied. Repeated ES does enhance motor axon regeneration and functional muscle reinnervation, and this enhancement is more robust than a single ES treatment, but rES also results in the retention of exaggerated H reflexes.

Title: A growth suppressive role for major urinary protein (MUP) expression in diabetic and nondiabetic adult sensory neurons

Authors: *D. W. ZOCHODNE[1,2], V. SINGH[3], A. CHANDRASEKHAR[1,2], T. POITRAS[2], J. A. MARTINEZ[3];

Abstract: In an array analysis of gene expression in dorsal root ganglia (DRGs) of mice we encountered an unexpected upregulation of major urinary proteins (MUPs 1,2) in chronic experimental diabetes. MUPs were initially identified as secretory proteins in urine with a potential role as pheromones, among other possibilities. Mice with chronic experimental diabetes provide a model that exhibits key features of human diabetic polyneuropathy with electrophysiological abnormalities (motor and sensory conduction slowing) and behavioural changes (loss of thermal sensation). Here, we confirmed the prominent and widespread cytosolic expression of MUPs in both mouse and rat sensory neurons and in DRG glial cells. Moreover, MUPs were expressed in sciatic axons, Schwann cells and distal sensory branches within the skin dermis of the footpad. In a chronic diabetes model, knockdown of MUP2 through intranasal nonviral siRNA delivery had an impact on downstream axonal function, improving motor and sensory conduction abnormalities. Anticipating that MUP may have a functional impact on

overall growth plasticity of sensory neurons, we also examined the impact of its knockdown on neurite outgrowth of dissociated and preinjured rat DRG sensory neurons. MUP1,2 knockdown was associated with a significant rise in neurite outgrowth compared to neurons exposed to control scrambled siRNA sequences. Moreover, this impact was confirmed separately in adult mouse neurons. Taken together, our findings suggest unique and functional roles for MUPs in sensory axons that may differ from their potential pheromone actions. Overall, MUPs appear to restrain growth in adult neurons. Their upregulation in experimental diabetes may contribute, along with other abnormalities of sensory gene expression, to the complex phenotype of this disorder. [Supported by CIHR, CDA]

Title: AlphaB-crystallin modulates immune responses and lipid metabolism in an age dependent matter in the uninjured and damaged peripheral nervous system.

Authors: E.-M. LIM[1], *S. S. OUSMAN[2];
[1]Neurosci., [2]Clin. Neurosciences and Cell Biol. & Anat., Hotchkiss Brain Institute, Univ. of Calgary, Calgary, AB, Canada

Abstract: As the peripheral nervous system (PNS) ages, immune responses and oxidative stress are enhanced while lipid metabolism is reduced. Further, Wallerian degeneration is delayed in an age dependent manner following PNS injury. To determine what underlies the aging-related deficits in the undamaged and injured PNS, we noted that a small heat shock protein called alphaB-crystallin (αBC), which is expressed by PNS axons and Schwann cells, is significantly reduced with age. To evaluate whether αBC contributes to PNS aging related processes, we assessed for presence of macrophages (Iba1 staining), and for markers of lipid metabolism

(SQLE staining) and oxidative stress (CHOP immunohistochemistry). We found that naïve and 28d injured αBC null mice exhibited increased Iba1+ profiles at 3 and 12 months of age compared to WT counterparts. This augmented immune response correlated with enhanced levels of chemokines at particular time points after injury in the knockout animals. With respect to lipid metabolism and oxidative stress, the number of SQLE profiles was markedly decreased in 12 month old null mice while the counts for CHOP remained unchanged. Altogether, these data demonstrate that the reduced levels of αBC in sciatic nerves with age correlated with a deficit in lipid metabolism and, an exuberant macrophage presence.

Title: Chronic electrical muscle stimulation (EMS) following nerve injury and repair in Sprague Dawley rats does not lead to preferential reinnervation of target muscles

Authors: *M. WILLAND[1], J. CATAPANO[1], J. BURGUET[2], P. ANDREY[2], G. H. BORSCHEL[1], T. GORDON[1];
[1]Div. of Plastic Reconstructive Surgery, The Hosp. For Sick Children, Toronto, ON, Canada;
[2]Inst. Jean-Pierre Bourgin, Versailles, France

Abstract: Regenerating motor nerves randomly reinnervate target muscles resulting in synkinesis. The efficacy of chronic EMS on nerve regeneration is controversial. In a canine model of laryngeal nerve injury, EMS of reinnervating muscles promotes selective and appropriate reinnervation of muscles. This evidence is largely based on functional measurements. We provide direct evidence through retrograde labeling and spatial analysis of neuronal populations that EMS does not preferentially reinnervate target muscles.
The soleus and lateral gastrocnemius (LG) muscles in two groups of rats were used as the target muscles. Soleus muscles were injected with True Blue (TB) fluorescent tracer to label the original soleus motoneuron pool. One week later, bipolar stainless steel wire electrodes were implanted into the soleus muscle. The lateral gastrocnemius soleus (LGS) nerve was then transected and immediately repaired using one epineurial suture (11-0). The experimental group of rats underwent EMS of the soleus muscle with 12 hrs of EMS per day at 20 Hz (10 sec on, 20 sec off, 400 μs pulse width) followed by 12 hrs of intermittent stimulation (10 sec on, 1 hr off) performed 7 days per week. Two months following nerve injury and repair the soleus nerve was

retrogradely labelled with Fluoro-Ruby (FR). The contralateral uninjured side was also labelled to assess the distribution of normal motoneuron pools. Labeled motoneurons were counted, and where possible, spatially normalized models were created to analyze and compare the spatial distributions between groups. In a subset of rats in which the motoneuron pools could not be spatially normalized, the nearest-neighbour distance distribution function was used for analysis. The number of motoneurons that labeled with both TB and FR were not different whether or not the soleus muscle was stimulated demonstrating that EMS did not promote preferential reinnervation of the muscle. However, retrograde labeling via intramuscular injection only labeled ~75% of the soleus motoneurons. Spatial statistics were used to provide a more detailed examination of the segregation of the soleus and LG motoneuron pools. The pools show a clear segregation in the dorsal-ventral plane in uninjured rats. However, nearest-neighbour analysis demonstrated that the reinnervated motoneuron pools were highly segregated as compared to the original soleus motoneuron pools *and* the EMS did not affect the degree of segregation.
Our findings here demonstrate that chronic EMS of reinnervating muscle does not promote preferential reinnervation of target muscles but, importantly, it does not prevent muscles from being reinnervated by regenerating nerves.

Title: Expression of the monocyte chemokine CCL2 in regenerating peripheral nerve is rapidly elevated in response to brief electrical nerve stimulation

Authors: J. M. JOHNSTON, R. ZHAI, N. A. MCLEAN, J. R. NADEAU, *V. M. VERGE; Anat. & Cell Biol., Univ. Saskatchewan-CMSNRC, Saskatoon, SK, Canada

Abstract: The neural immune axis plays a critical role in peripheral nerve regeneration, with previous studies linking overexpression of CCL2/MCP-1 to an enhanced regenerative capacity akin to a conditioning lesion (Kwon et al., 2015 J Neurosci 35(48):15934; Niemi et al, 2016 Exp

Neurol 275(1):25-37). We and others have shown that electrical nerve stimulation (ES) is an effective adjunct therapy to enhance nerve regeneration in manner akin to a conditioning lesion (reviewed in Gordon and Borschel 2016 Exp Neurol). What is not known is whether this is linked to an impact on the neural immune axis with respect to regulation of CCL2 expression and monocyte recruitment. To examine this, we conducted a time course analysis on adult male Wistar rats subjected to a unilateral mid thigh sciatic nerve crush with 1 hour continuous electrical nerve stimulation at 20 Hz at the time of nerve injury. Injury only and injury + ES with lidocaine block served as controls. Preliminary data reveals a rapid response to ES with respect to CCL2 expression as early as 3 hours post-ES, when a discernible increase in CCL2 expression was evident in the Schwann cells of the regenerating nerve proximal to injury with a more robust increase observed at the level of the dorsal root ganglion (DRG) in sensory neurons and axons. By 2 days post-injury the nerves subjected to ES had even higher levels of CCL2 expression relative to the non-stimulated nerves in both axons and Schwann cells, the former suggesting anterograde transport of CCL2 in the sensory axons to the regenerating front. Further, there was also a corresponding increase in the numbers of macrophages observed in the injury zone of the stimulated nerve. As with the 3 hr timepoint, the 2 day ES-associated increases in CCL2 expression was even higher in the corresponding DRG neurons and axons. Analysis of the additional timepoints will reveal how long this response is sustained. Collectively, these results demonstrate an impact of ES on an aspect of the neural immune response known to benefit axon regeneration.

Title: Global knockout of Toll-like Receptors 2 and 4 does not hinder Wallerian degeneration but does somewhat impair regeneration after sciatic nerve injury

Authors: *J. LINDBORG, O. SHELTON, R. ZIGMOND;
Neurosciences, Case Western Reserve Univ., Cleveland, OH

Abstract: Peripheral neurons can regenerate after a nerve injury. The axon distal to the site of injury degenerates and the debris is cleared by macrophages (mφs) and Schwann cells (a process called Wallerian degeneration), which allows regenerating axons to extend from the proximal nerve segment. Mφs accumulate after nerve injury in the distal nerve segment and near the cell bodies. Although it has been shown that without mφ accumulation there is hindered degeneration and regeneration, the mechanisms by which mφs are able to accumulate and aid in these processes are incompletely understood. It has been proposed that Schwann cells, neurons and satellite glial cells induce the release of the chemokine CCL2 after nerve injury via the activation of the Toll-like receptors (TLRs) 2 and 4, which results in the accumulation of mφs at the cell body and distal to the site of injury. We have investigated the importance of these receptors in mφ accumulation, myelin clearance and regeneration in dorsal root ganglia (DRG), superior cervical ganglia (SCG), and sciatic nerves after injury in wildtype (WT) and TLR 2/4 double knockout (DKO) mice. Our results show variable accumulation of mφs in all tissues depending on the specific marker used. $CD68^+$ mφ accumulation is unchanged between genotypes in all tissues 7d following axotomy. However, accumulation is decreased in all tissues in DKO mice when using CD11b to label mφs. $Iba1^+$ mφ accumulation is comparable between genotypes in the sciatic nerve, but is significantly decreased in DKO DRG compared to WT DRG. At present, we do not know the significance of the differential expression of mφ markers. While myelin clearance is comparable between genotypes 7d after axotomy, L5 DRG explants of DKO mice show a small but significant decrease in neurite outgrowth relative to WT DRG after 48h in culture. Interestingly, the loss of TLRs 2 and 4 has no effect on CCL2 mRNA expression at 24 or 48h after injury in all three tissues of DKO mice, except in the sciatic nerve at 24h post-injury where we observe a significant decrease compared to WT mice. In the DRG and SCG 24h after axotomy, we observed no differences between genotypes in mRNA expression of Csf1, GFAP, c-Jun, or CX3CL1. c-Jun expression at 24h after injury was significantly increased in WT sciatic nerve compared to DKO mice, although no difference was observed at 48h. c-Jun expression at 48h post-injury was significantly increased in DKO DRG compared to WT DRG, but the converse was found in SCG. In conclusion, TLR 2/4 signaling has no effect on myelin clearance after injury, but exerts a small yet significant effect on nerve regeneration. (Supported by DK097223, EY11373, and 2R25GM075207)

Title: Classification of macrophage activation state in dorsal root ganglia after peripheral nerve injury

Authors: M. HOWARTH[1], *A. DEFRANCESCO-LISOWITZ[2], J. P. NIEMI[3], C. MOORE[4], R. E. ZIGMOND[3];
[1]Hathaway Brown Sch., Shaker Heights, OH; [2]Neurosci., [3]Neurosciences, [4]Med. Physiol., Case Western Reserve Univ., Cleveland, OH

Abstract: Understanding the complex process by which peripheral neurons regenerate plays an integral role in the ability to develop therapies for injury both to the peripheral nervous system and to the normally non-regenerating central nervous system. Previous research conducted by our laboratory suggested that the regenerative process is dependent on post-axotomy macrophage accumulation not only in the segment of the nerve distal to the site of injury, as previously established, but also around the neuronal cell bodies, located in peripheral ganglia. However, the exact method by which these macrophages assist in regeneration is unknown due to a poor understanding of their properties, including whether they behave in a pro- or anti-inflammatory manner. Thus, to obtain a better understanding of the function of these macrophages, we performed a phenotypic analysis of macrophages in the lumbar level 5 dorsal root ganglion (DRG) after sciatic nerve transection. Real-time PCR analysis was used to determine the time course of pro- and anti-inflammatory macrophage markers in DRG after injury. Interestingly, a significant increase in the anti-inflammatory markers CD206, Ym1, and Arginase 1 occurred only at 7 days after injury compared to the early upregulation of the pro-inflammatory markers CD86 and iNOS occurring at 3 days post-injury. These data raise the possibility that macrophages are not polarized to an anti-inflammatory activation state when they first accumulate in the DRG but rather shift their activation over time. To specifically localize these markers to macrophages, immunohistochemistry was performed to label macrophages, using antibodies to CD11b and CD68, and antibodies to markers expressed by anti-inflammatory macrophages, using CD206, and pro-inflammatory macrophages, using iNOS, in the DRG at various times after injury. Our analysis suggests that macrophages in the DRG 7 days after

injury, but not at earlier time points, highly colocalize with the anti-inflammatory phenotypic marker, CD206. Staining was also carried out in the CCR2 knockout mouse, a mouse that has a significantly diminished macrophage response to injury. CCR2 knockout mice displayed a significant reduction in CD206 expression, as a result of the reduced macrophage population within the ganglia. Taken together, these data suggest that macrophages accumulating in axotomized peripheral ganglion tend towards an anti-inflammatory phenotype at 7 days. Title: Macrophage stimulation of peripheral axon regeneration requires CCL2 and pSTAT3

Authors: ***J. P. NIEMI**[1], A. DEFRANCESCO[1], C. MOORE[2], R. E. ZIGMOND[1]; [1]Neurosciences, [2]Med. Physiol., Case Western Reserve Univ., Cleveland, OH

Abstract: Neuroinflammation plays a critical role in the regeneration of peripheral nerves following axotomy. An injury to the sciatic nerve leads to significant macrophage accumulation in the L5 DRG, an effect not seen when the dorsal root is injured. Recent evidence showed that macrophage accumulation around axotomized cell bodies is necessary for a peripheral conditioning lesion response. In response to an axonal injury, DRG neurons upregulate and release CCL2, a macrophage chemokine which acts on the receptor CCR2. In a CCR2 knockout mouse (CCR2-/-), CD11b+ macrophage accumulation was inhibited in the distal sciatic nerve and in the axotomized DRG after injury. Increased outgrowth was seen in previously lesioned DRGs from wild type but not CCR2-/- mice. These data suggest a relationship between macrophage accumulation near neuronal cell bodies and the regenerative capacity of neurons as well as highlighting the role CCL2/CCR2 signaling plays in mediating macrophage entry into DRGs. We asked whether overexpression of CCL2 specifically by DRG neurons of uninjured

mice is sufficient to cause macrophage entry and enhanced regeneration, or whether other injury-derived signals are necessary. We found that CCL2 could be significantly overexpressed in DRG neurons by utilizing an adeno-associated virus (AAV) encoding for CCL2 driven by the EF1α promoter injected intrathecally. The injection led to a time dependent increase in CCL2 expression and in macrophage accumulation in the L5 DRG compared to controls injected with virus expressing YFP. CCL2 overexpression and subsequent macrophage accumulation led to a conditioning-like increase in neurite outgrowth of DRG neurons in explant and dissociated culture. An AAV-CCL2 injection resulted in increased LIF mRNA in the DRG and increased neuronal phospho-STAT3. Blockade of STAT3 activation, through the administration of STAT3 phosphorylation inhibitors, AG490 or Stattic, reduced or completely ablated, respectively, the CCL2 overexpression-induced increase in axonal outgrowth. To demonstrate the necessity of macrophage accumulation in stimulating the increased axonal regeneration observed after CCL2 overexpression, a CSF-1 receptor inhibitor will be employed to prevent macrophage accumulation in the DRG. Further studies into the necessity of neuronal expression of CCL2 after injury are also being carried out using a DRG sensory neuron specific knockout of CCL2. Together, these data indicate that neuronal CCL2 expression and macrophage accumulation within the DRG are both necessary and sufficient for peripheral axonal regeneration to occur. Title: Oncomodulin is not essential for a conditioning lesion effect in mouse dorsal root ganglia

Authors: A. DEFRANCESCO[1], A. J. HORNAK[2], D. D. SIMMONS[2], *R. E. ZIGMOND[3]; [1]Neurosciences, Case Western Reserve Univ., Cleveland, OH; [2]Integrative Biol. and Physiol., UCLA, Los Angeles, CA; [3]Case Western Res. Univ. Sch. Med., Cleveland, OH

Abstract: A conditioning lesion (CL) of the sciatic nerve increases neurite outgrowth measured subsequently in explant and dissociated cultures of L4 and L5 dorsal root ganglia (DRGs), effects that are dependent on macrophage accumulation in these DRGs (for review see DeFrancesco-Lisowitz et al., Neuroscience 302:174, 2015). The molecule secreted by macrophages that is responsible for triggering the CL effect has not been identified. Oncomodulin has been proposed to account for the beneficial effect of neuroinflammation on axonal growth by retinal ganglion cells and to be secreted by macrophages and neutrophils (for review see Benowitz et al., Exp Neurol 2016 in press). Oncomodulin is also expressed in DRGs after axotomy and is required for the increased outgrowth in cultured neurons produced by conditioned medium from macrophage-neuron co-cultures treated with dibutyryl-cAMP (Kwon et al., J Neurosci 33:15095, 2013). Since it is unknown whether oncomodulin plays a role in the CL effect, we examined this effect in oncomodulin knockout (KO) and wild type (WT) mice (Tong et al., J Neurosci 36: 1631, 2016). Seven days after unilateral sciatic nerve transection, L4 and L5 DRGs were removed. L4 ganglia were dissociated and cultured for 24 h in the absence of added growth factors. The neurons were then stained for βIII tubulin and outgrowth determined. The length of the longest neurite per neuron was measured as well as the total neurite outgrowth. For both measures, a CL increased outgrowth in both KO and WT ganglia, though the effect was somewhat smaller in the KO mice. The ratio of the mean length of the longest neurite in neurons from axotomized DRGs to that in neurons from sham-operated ganglia was 3.2 for WT tissues and 2.5 for KO tissues ($p<0.01$; all statistics reflect differences between genotypes). The ratio of the total neurite outgrowth in axotomized compared to sham-operated neurons was 4.1 for WT ganglia and 3.3 for KO ganglia ($p<0.05$). L5 ganglia were placed in explant cultures in Matrigel, and neurite outgrowth was measured at 24 and 48 h under phase microscopy. Again, a CL effect was seen in DRGs from both genotypes, but the effect was somewhat smaller in the KO DRGs (mean length of 20 longest neurites at 48 h: WT=0.93 mm and KO=0.72 mm; $p<0.01$). Since macrophages also play an important role in Wallerian degeneration, we asked whether oncomodulin is involved in myelin clearance but found no significant difference in clearance in the distal sciatic nerve between genotypes. In conclusion, our results indicate that oncomodulin plays only a small, though significant, role in the CL effect in DRGs. [Supported by grants DK097223 (REZ) and K18 DC013304 (DDS)]

Title: Axonal regeneration requires activation of Sonic hedgehog signaling pathway in peripheral nerve injury

Authors: *Y. YAMADA[1], T. MAEDA[2], A. OHAZAMA[3], K. SEO[1];
[1]Dent. Anesthesiol., Grad. Sch. of Niigata Univ., Niigata, Japan; [2]Ctr. for Advanced Oral Sci., [3]Oral anatomy, Niigata Univ. Grad. Sch. of Med. and, Niigata, Japan

Abstract: [Introduction] When the peripheral nerve is transected completely, their transected nerve ends can meet together to reconnection. However, its mechanism remains unclear. Sonic hedgehog (Shh) signaling pathway plays critical roles in axonal guidance (Charron et al. Cell 2003) in addition to determining the proximal and distal direction during organogenesis. Our previous report has demonstrated the peripheral nerve injury induces the expression of Shh and its receptor (Patched1) in the distal and proximal neve ends of , respectively (Annual meeting Sfn 2015), suggesting a possible involvement of Shh signaling in nerve regeneration. Aim This study aims to clarify the expression pattern of Shh signaling pathway during neural regeneration in a nerve injury model. [Materials and methods] Male C57BL6 mice (7-8 weeks old) were used in this study. Transgenic mice expressing GFP under the control of Gli1 (the transcription factor) promoter (Gli1-GFP) were also used to identify which cell type induces Gli1 expression after nerve injury. Under an anesthesia, the inferior alveolar nerve (IAN) was exposed and completely transected in both kinds of mice. They were sacrificed at 1, 3, 7 and 14 days post-surgery. In some mice, cyclopamine, an inhibitor of Shh signaling pathway was local administrated at every 24 hours for 14 days. This study examined 1) the chronological changes in expression pattern of Shh and Patched1 during regeneration of injured IAN by in situ hybridization, 2) compared Gli1 expression with neuronal and non-neuronal markers molecules by immunohistochemistry, and 3) assessed the nerve regeneration process in mice with cyclopamine by immunohistochemistry for PGP9.5. [Results] 1) The distal stamp of transected IAN showed the expressions of Shh in contrast to Patched1 expression at proximal stump at 1day after surgery. This expression pattern reduced at 7days after surgery. 2) We found a co-localization of Gli1-GFP and p75-reactions. 3) Sprouting axons neuron from distal and proximal stumps were found in random directions in cyclopamine group. [Conclusion] The Shh signaling pathway is involved in reconnection of transected axonal ends and regrowth of axon during the early stages of regeneration.

Title: Over-expression of muscarinic acetylcholine type 1 receptor causes cytoskeletal abnormalities and impairs mitochondrial trafficking in adult sensory neurons.

Authors: *M. G. SABBIR[1], P. FERNYHOUGH[2,3];
[1]St. Boniface Res. Ctr., Winnipeg, MB, Canada; [2]1Division of Neurodegenerative Disorders, St. Boniface Hosp. Res. Ctr., Winnipeg, MB, Canada; [3]Dept of Pharmacol. & Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Muscarinic acetylcholine receptors are a subfamily of G protein-coupled receptor that regulate numerous fundamental biological pathways in the central and peripheral nervous systems. It has been shown in a non-mammalian system that neurotransmitters such as acetylcholine can direct axonal growth during development. Modulation of these cholinergic pathways could be therapeutically useful for neurodegenerative diseases such as peripheral neuropathy in which sensory nerve terminals are gradually depleted. Recently, we have shown that selective or specific muscarinic acetylcholine type 1 receptor (M1R) antagonists can induce a dose-dependent elevation in neurite outgrowth. The exact mechanism of M1R-antagonist driven neurite outgrowth is not understood. In order to understand the biological function of M1R in peripheral neurons, we have overexpressed M1R in primary adult dorsal root ganglion (DRG) sensory neurons and studied the physiological as well as molecular effects. Interestingly, we have found M1R overexpression caused significant ($p<0.005$) depletion of functional mitochondria at the growth cone and a subsequent decrease in neurite outgrowth ($p<0.0001$). The diminished abundance of mitochondria in axons was associated with discontinuity in the β-tubulin cytoskeleton structure that, in turn, suppressed mitochondrial trafficking. The tubulin associated cytoskeletal defect was corrected by treatment with muscarinic antagonists pirenzepine (PZ) and muscarininc toxin 7 (MT7) which mediated recruitment of G proteins and increased Ca^{2+} signaling in the neurites. In accordance with this finding, we observed significant increase in neurite outgrowth in rat sensory neurons when treated with 100nM MT7 or 1μM PZ, respectively. Our findings suggest a novel mechanism in which modulation of M1R influences mitochondrial distribution in nerve terminals and controls axonal growth and regeneration.

Title: Electrospun polymer-polyvalent hydrogel composite fiber scaffolds with encapsulated neurons and glia for neural repair

Authors: ***J. M. COREY**[1,2], C. CHAN[3,2], C. M. WHITE[3,2], A. RASTOGI[3,2], A. M. GRANT[3,2], R. J. MILLER[3], R. K. DUNCAN[3];
[1]Dept Neurol, Univ. of Michigan Dept. of Neurol., Ann Arbor, MI; [2]VA Ann Arbor Healthcare Syst., Ann Arbor, MI; [3]The Univ. of Michigan, Ann Arbor, MI

Abstract: Aligned polymer nanofibers made by electrospinning provide powerful topographical guidance cues in nerve guidance channels and other tissue engineering applications. Seeding these biomimetic scaffolds with transplanted Schwann cells or stem cells seems straightforward, but small pores inherent in electrospun fiber scaffolds limit depth of cell penetration to only 1-2 cell diameters. One potential solution is to construct electrospun fibers scaffolds to include polyvalent hydrogel (PVH) fibers in which cells can be encapsulated so that cells can be released and contact the polymer fibers for topographic guidance. While recent work has shown that endothelial and other cell types can be encapsulated by PVH, cells from the nervous system can

be much more sensitive to insult in culture and artificial biomaterials. Therefore we sought to test the suitability of PVH microfibers with cells from the nervous system. We hypothesized that primary neurons would have a more difficult time surviving in PVH than fibroblasts or glia. Aligned poly-L-lactide nanofibers were electrospun on to substrates. L929 fibroblasts, primary astrocytes, or primary cortical neurons were mixed into a 2.5% alginate solution. PVH fibers were constructed by justaposing a large drop of this solution with 2% chitosan in 0.2M acetic acid and manually pulling the interface. The PVH fiber was guided on nanofiber substrates attached to a rotating mandrel. Substrates were cultured for 30 m, 4 h, 1 d, and 7 d, prior to staining with a Calcein-AM viability assay. We found that all cell types survived well outside PVH fibers, ranging from 86±0.8% for cortical neurons to 97±0.02% for L929 fibroblasts. In PVH fibers, survival of L929 fibroblasts was lowest at 30 m (61±17%) and steadily increased to a high of 88±05% at 1 d, and falling slightly to 87±12% at 7 d. Astrocytes viability was somewhat less at 47±8% at 30 m but climbing steadily to 74±10% at 7 d. The increase in cell number over the 7 d time window of both astrocytes and L929 cells suggests that cell proliferation may be occurring inside the hydrogels. Cortical neuron viability was worse, ranging from 12±13% at 30 m to a low of 6.3±4% at 4h. These data are consistent with our hypothesis that primary neurons, being a very sensitive cell type, would fare poorest. These experiments may be the first to encapsulate cells from the CNS into PVH fibers. To encapsulate primary neurons at useful survival percentages, PVH fibers will likely require modification by adjusting pH or addition of growth factors. Further work will center on studying the release of cells from the PVH fibers and attraction to and interaction with the electrospun nanofibers.

Title: Outcomes of muscle reinnervation with direct nerve implantation into the native motor zone of the target muscle

Authors: ***S. SOBOTKA**[1,2], J. CHEN[1], T. NYIRENDA[1], L. MU[1];
[1]Dept. of Res., Hackensack Univ. Med. Ctr., Hackensack, NJ; [2]Dept. of Neurosurg., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Our recent work has demonstrated that the native motor zone (NMZ) within a given skeletal muscle is the best site for muscle reinnervation. This study was designed to investigate the efficacy of direct nerve implantation (DNI) into the NMZ of denervated sternomastoid (SM) muscle in a rat model. The right SM muscle was experimentally denervated by transecting its innervating nerve at its entrance to the muscle (motor point). The proximal stump of the severed SM nerve was immediately buried into a small muscle slit made in the NMZ of the target muscle. The implanted nerve was then secured with an epineurial suture of 10-0. At the end of the 3-month recovery period, all experimental animals underwent postoperative evaluations to assess surgical outcomes of the DNI-NMZ procedure. Functional recovery and muscle reinnervation were evaluated using electrophysiological and histochemical techniques, respectively. Maximum tetanic force was measured from the treated and contralateral control SM muscles in each animal. The degree of functional recovery was determined by comparing the muscle force of the reinnervated SM muscle with that of the contralateral control muscle. Averaged maximal muscle force at the operated side was 0.763 N, whereas 1.200 N at the contralateral control side. The DNI-NMZ reinnervated SM muscles produced 63.6% of the maximal tetanic force of the control muscles. The difference was statistically significant ($p = 0.0013$). Muscle analyses showed that the treated SM muscle recovered morphologically and histologically as indicated by a good preservation of muscle mass and abundant regenerated axons. Specifically, DNI-NMZ reinnervated SM muscles weighed 71% of the weight of contralateral control muscles. The treated muscles exhibited slight-to-moderate fiber atrophy as compared with the controls. Quantitative analysis showed that the mean number and area of the regenerated axons in the treated muscles was 62% and 51% of the contralateral controls, respectively. The findings from this study suggest that DNI-NMZ holds promise in the treatment of muscle paralysis. For optimal outcome, further studies are needed to promote the efficacy of this technique by further refining surgical procedure and using additional approaches to accelerate axonal regeneration.

Title: Phosphoproteomics identifies a phosphorylation site of GAP-43 in the peripheral nerve regeneration

Authors: *M. OKADA[1,2,3], A. KAWASAKI[2], Y. YOSHIDA[4], Y. FUJI[3], M. IGARASHI[1];
[1]Dept. of Neurochemistry and Mol. Cell Biol., [2]Ctr. for Transdisciplinary Res., Niigata Univ., Niigata, Japan; [3]Dept. of Neurosurg., Brain Res. Inst., Niigata, Japan; [4]Dept. of Structural Pathology, Inst. of Nephrology, Niigata university, Niigata, Japan

Abstract: Growth-associated protein 43 (GAP-43) is believed as a classical molecular marker for axon growth/regeneration, since this protein is known to be high expressed and intensively undergoes anterograde transport in the regenerating axon after injury. In our previous study, phosphoproteomic analysis using neonatal rat brains revealed several novel phosphorylation sites of GAP-43. We then successfully generated specific antibody (pGAP-43 Ab) against one of those sites (Kawasaki, Okada, Igarashi *et al.*, submitted).
To test whether this phosphorylation is induced in the axon regeneration, we tried both the immunohistochemistry and the phosphoproteomics using the sciatic nerve injury of adult C57B6N mice (9-weeks-old or later). The crushed nerves (day 3 after injury) and the uninjured control nerves were assessed by western blotting and immunohistochemistry using pGAP-43 Ab. For quantitative evaluation of regeneration, we used the confocal micrographs along the longitudinal nerve section and calculated "Regeneration Index", which is defined by the distance between the crush site (point A) and the site at which the intensity level of pGAP-43 Ab is half of that at point A (*Shin J.E. et al. Neuron 74(2012)*). Immunohistochemistry revealed the very low staining of pGAP-43 Ab in the control nerve. Regeneration Index with the pGAP-43 Ab labeling could be used to measure the extent of Axon regeneration. The signal intensity of bands of pGAP-43 Ab on western blotting was detected higher in the the crushed nerve than that in the control nerve. For mass spectrometric analysis, the protein extracts prepared from the defined portions of either single crushed or uninjured sciatic nerves, underwent phosphoproteomics directly by LC-MS/MS. As results, we succeeded in unambiguously detecting GAP-43-derived peptides containing this phosphorylated site exclusively in the regenerating axon. Taken together, we concluded that this site is the major phosphorylation residue of GAP-43 in the regenerating axon, and the pGAP-43 Ab which quantitatively detected the phosphorylation of GAP-43 could be a novel probe for the axonal regeneration *in vivo*.

Title: Muscle reinnervation: modified nerve-muscle-endplate band grafting technique

Authors: *L. MU[1], S. SOBOTKA[1,2], J. CHEN[1], T. NYIRENDA[1];
[1]Dept. of Res., Hackensack Univ. Med. Ctr., Hackensack, NJ; [2]Dept. of Neurosurg., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: Neural regeneration and functional recovery of the paralyzed skeletal muscle caused by peripheral nerve injuries are major challenges in rehabilitation medicine. This study was designed to modify our recently developed nerve-muscle-endplate band grafting (NMEG) for promoting the efficacy of this muscle reinnervation technique in a rat model. The right sternomastoid (SM) muscle was denervated by resecting a 5-mm segment of its innervating nerve and immediately reinnervated with NMEG. Specifically, a NMEG pedicle was harvested from the native motor zone (NMZ) of the right sternohyoid (SH) muscle and implanted into the NMZ of the ipsilateral experimentally denervated SM muscle. A NMEG contained a muscle block (6 x 6 x 3 mm), a nerve branch with nerve terminals, and a motor endplate band with numerous neuromuscular junctions. A muscular defect (recipient bed) with the same dimensions as the NMEG pedicle was made in the NMZ of the right denervated SM muscle. The well-prepared NMEG was embedded in the SM muscle defect and sutured with four to six 10-0 nylon microsutures. Three months after surgery, maximum tetanic force was measured from both SM muscles in each rat. The removed SM muscles were immunostained to detect regenerated axons and reinnervated and non-reinnervated motor endplates. The axon density was assessed using ImageJ software. Muscle force measurement demonstrated that NMEG-NMZ technique resulted in more optimal force recovery (82% of the control) as compared with the original NMEG procedure (67% of the control), in which the NMEG pedicle was implanted into the caudal endplate-free area of the target muscle. The mean muscle weight of the NME-NMZ reinnervated muscles was 89% of the contralateral control muscles. The mean count and area of the regenerated axons in the treated muscles were 76.8% and 75.6% of the contralateral controls, respectively. Double fluorescence staining showed that the regenerated axons from the implanted NMEG grew across the NMZ to innervate the denervated motor endplates in the target muscle. The majority (80%) of the denervated motor endplates in the target muscle regained motor innervation. Axonal sprouts and newly formed small endplates were also identified in the reinnervated muscles. Our results suggest that the NMZ of the target muscle is the best site for

NMEG implantation to obtain optimal axon-endplate connections and functional recovery and that NMEG-NMZ technique may become a viable means of muscle reinnervation in certain clinical situations.

Title: An evolutionarily conserved mechanism for cAMP elicited axonal regeneration involves direct activation of the dual leucine zipper kinase DLK

Authors: ***Y. HAO**[1], E. FREY[3], H. WONG[4], C. YOON[2], R. GIGER[2], L. HOLZMAN[4], A. DIANTONIO[3], C. COLLINS[1];

Abstract: A broadly known method to stimulate the growth potential of axons is to elevate intracellular levels of cAMP, however the cellular pathway(s) that mediate this are not known. Here we identify the Dual Leucine-zipper Kinase (DLK, Wnd in *Drosophila*) as a critical target and effector of cAMP in injured axons. DLK/Wnd is thought to function as an injury 'sensor', as it becomes activated after axonal damage. Our findings in both *Drosophila* and mammalian neurons indicate that the cAMP effector kinase PKA is a conserved and direct upstream activator of Wnd/DLK. PKA is required for the induction of Wnd signaling in injured axons, and DLK is essential for the regenerative effects of cAMP in mammalian DRG neurons. PKA stimulates DLK by directly phosphorylating its activation loop and this regulation is independent of downstream JNK signaling. These findings link two important mediators of responses to axonal injury, DLK/Wnd with cAMP/PKA, into a unified and evolutionarily conserved molecular pathway for stimulating the regenerative potential of injured axons. Previous studies have implicated a role for DLK/Wnd is regulating the structure and arborization of presynaptic terminals. The addition of cAMP and PKA into this regulatory pathway suggests a mechanism that may be widely utilized to orchestrate structural changes at synapses.

Title: The interaction of regenerating sensory and motor axons

Authors: ***T. M. BRUSHART**[1], F. KEBAISCH[2], R. WOLINSKY[2], R. SKOLASKY[2];
[1]Dept Orthopaedic Surgery, [2]Orthopaedics, Johns Hopkins, Baltimore, MD

Abstract: Preferential motor reinnervation (PMR) is the tendency for motor axons regenerating in mixed nerve to reinnervate muscle nerve and/or muscle. We have shown previously that PMR is enhanced when afferent axons are eliminated from the regenerate (Redett et al., 2005). We now use our organotypic model of nerve repair in vitro (Vyas et al., 2010) to explore interactions of regenerating sensory and motor axons that may underlie these findings.
Spinal cord slices in which motoneurons express YFP (thy1-YFP-H) and DRG explants from mice expressing RFP (ROSA mT/mG) were used to populate cultured segments of mouse femoral nerve with fluorescent axons. Nerves contained either green motor axons alone (motor group [M]; n=7) or both green motor and red sensory axons (sensory-motor group [SM]; n=6). These nerves were then transected and their axons grown out on unstructured collagen/laminin mats. After 5 days, axons were counted at each 0.25 mm increment from the nerve end. In the SM group we also quantified the length of each motor axon that was in direct contact with a sensory axon.
Significantly fewer motor axons regenerated to each distance interval from 0.25mm to 1.0 mm when these axons were accompanied by sensory axons (SM) than when they regenerated alone (M). Mean axon counts were: 0.25mm, SM=27, M=77, p=0.0; at 0.5mm, SM=10, M=70, p=0.0; at 0.75mm, SM=4, M=51, p=0.0002; at 1mm, SM=1, M=29, p=0.0016. To compare sensory and motor axon outgrowth within the SM group, counts were converted to percentages using the counts at 0.25 mm as 100%. The percentage of axons counted at 0.25mm that reached the 0.50, 0.75, and 1.0 mm levels was significantly higher for sensory axons (s) than for motor axons (m). At 0.5mm, s=84%, m=34%, p=0.0042; at 0.75mm: s=71%, m=12%, p=0.0012; at 1mm: s=43%,

m=2%, p=0.0005. Quantification of sensory and motor axon contact revealed that a mean of 81% of total motor axon length was in direct contact with sensory axons. These experiments quantify, for the first time, the interaction of two distinct populations of regenerating axon. They reveal that sensory axons extend more rapidly than motor axons, and thus precede them during the early stages of regeneration. Furthermore, motor axons adhere to sensory axons throughout most of their length. As a result of this previously unappreciated interaction, sensory axons inhibit motor axon growth. These findings suggest that defining and blocking the negative effects of sensory axons on their motor partners could enhance PMR.

Title: Neural dependence of fin regeneration in zebrafish

Authors: *N. W. KLECKNER[1], R. DOBBIN[2], H. LOEB[2], A. ESTRELLA[2], S. HOLMES[2]; [1]Biology/Neuroscience, [2]Neurosci., Bates Col., Lewiston, ME

Abstract: Most organisms have the ability to regenerate certain body parts. However, some vertebrates have a particularly extensive regenerative capacity. For example, some amphibian limbs and teleost fins can be regrown when lost, and both of these processes are well characterized. In both cases regeneration has been found to be dependent on the presence of nerves; once denervated, a limb loses its ability to regenerate following an amputation. In salamanders this dependence may be due to the release of anterior gradient proteins (nAg, in salamanders) by Schwann cells. While zebrafish (*Danio rerio)* tail regeneration is phenotypically well characterized, the molecular basis of the neural dependence of regeneration has not been adequately explored. The purpose of this study was to compare methods of denervation of the zebrafish caudal fin to assess the role of molecular factors that might play a role in fin regeneration. We explored *agr2* (a nAg orthologue), myelin basic protein and vascular endothelial growth factor expression in caudal fins that were denervated either manually or by

exposure to metronidazole or the ErbB (and Schwann cell) inhibitor AG-1478, and then amputated in 3-6 month old Nacre zebrafish. Denervation was verified by comparing anti-acetylated tubulin antibody labeling of caudal fin axons from treated and control fish. We found that the expression of *agr2* was upregulated in the caudal fin during regeneration in metronidazole treated fish, although not specifically in the blastema. Additionally, while mechanical denervations did not consistently remove neural input, exposure of fish to 5 mM metronidazole reduced axon density. Unexpectedly, metronidazole enhanced regeneration, suggesting that it changes expression of regenerative factors that are independent of neural input. These findings provide additional information on the identity of molecular factors involved in neural (or Schwann cell) dependence of fin regeneration. Conserved or contrasting pathways between regeneration of amphibian limbs and teleost fins may highlight why most vertebrates have such a limited ability to regenerate.

Title: Nerve regeneration in Octopus vulgaris: possible involvement of stem progenitor cells and epigenetic regulation

Authors: *P. IMPERADORE[1], G. FIORITO[2];
[1]Assn. For Cephalopod Res. - Cephres, Napoli, Italy; [2]Biol. and Evolution of Marine Organisms, Stazione Zoologica Anton Dohrn, Napoli, Italy

Abstract: Aims
Octopus vulgaris, an invertebrate, is known since antiquities for remarkable regenerative abilities of body parts and tissues including arms and nervous tissue. A striking example of regeneration in this species is given by the pallial nerve, which is involved in the control of mantle muscle contraction facilitating breathing and of body patterning. After complete transection of this nerve, full recover of functions is observed and nerve regeneration achieved in relatively short time. Here we provide the first description of the biological machinery involved in the pallial nerve regeneration in the octopus, including the involvement of cellular types helping the process

and epigenetics regulation.

Methods and Results

Octopus pallial nerve (right side) is exposed and transected while the contralateral nerve served as control. After surgery, animals are recovered and behavior observed for 3, 7 and 14 days before humane-killing. Nerve samples are analyzed for gene and protein expression by qRT-PCR and immunohistochemistry.

After injury scar tissue forms between the two stumps of the injured nerve. Hemocytes contribute to the formation of the scar and remain highly proliferative during the whole process. The scar does not represent an inhibitory environment to regrowth, and fibers of the proximal stump start regenerating across it and toward the distal stump maintaining a disorganized orientation. Two weeks after injury a spike-like protrusion appears in this stump with connective tissue enwrapping the new forming axons. Degeneration is observed at the level of the distal stump. However, fourteen days post-surgery fibers organized in bundles are found in advanced regeneration.

Dedifferentiation of the connective tissue cells of the nerve is also observed in both stumps, particularly 7 days post lesion. Marked up-regulation in the expression of 'factors' controlling epigenetic modifications, such as Polycomb group proteins and DNA methyltransferases, is also observed.

Conclusions

Active role of octopus hemocytes in the pallial nerve regeneration is found such as in scar tissue formation, debris removal and axonal regrowth. In addition, cells of the connective tissue drive nerve fibers regeneration facilitating their correct orientation; these also appear to dedifferentiate to a neural progenitor/stem cell state during the process.

Epigenetic factors have been identified for the first time in the *O. vulgaris* and up-regulation of their expression has been highlighted during the regenerative process compared to control nerves.

Title: Involvement of Na^+/K^+-ATPase in peripheral nerve regeneration via lactate signaling in sciatic nerve transection-regeneration model

Authors: N. H. TU[1], *S. ITO[2], M. SHINJI[1], K. TAYO[1], P. MINH VUONG[1];
[1]Dept. of Med. Chem., Kansai Med. Univ., Hirakatashi - Osaka, Japan; [2]Med. Chem., Kansai Med. Univ., Hirakata-shi, Osaka, Japan

Abstract: Peripheral nerve is not always regenerated fully after injury. Incomplete regeneration causes functional loss and persistent pain. To prevent these consequences, elucidation of mechanisms for nerve regeneration is crucial. We previously established a sciatic nerve transection-regeneration model and demonstrated that functional recovery was delayed in mice lacking Nax, a Na^+ concentration-sensitive Na^+ channel. Endothelin receptor type B functionally coupled with Na_x and increased sodium influx to Schwann cells, which in return enhanced lactate release. The released lactate was then uptaken to axons to accelerate nerve regeneration (Unezaki et al., Eur. J. Neurosci. 39:720-729, 2014). Nax is known to interact with Na^+/K^+-ATPase leading to lactate production in the brain. In this work, we investigated the role of Na^+/K^+-ATPase in peripheral nerve regeneration in our model and applied ouabain, a Na^+/K^+-ATPase inhibitor, to the cutting site of the sciatic nerve for 4 weeks with an osmotic mini-pump. While functional recovery started at the 5th week after nerve transection and completed by the 7th week, ouabain delayed the functional recovery by 1 week as compared to the vehicle control. Lactate reversed the inhibitory effect of ouabain and a monocarboxylate transporter (MCT) inhibitor, significantly delayed functional recovery. Using primary DRG cell culture, we tested the effect of ouabain, lactate, and MCT inhibitor on neurite outgrowth enhanced by nerve growth factor (NGF). NGF accelerated neurite outgrowth by 1.9 times as compared with the vehicle, but ouabain reversed the stimulatory effect of NGF in a concentration-dependent manner. Lactate itself also increased neurite outgrowth 2 times as compared to the control, but inhibition of lactate transport by MCT 4 inhibitor suppressed neurite outgrowth. Collectively, Na^+/K^+-ATPase has a role in peripheral nerve regeneration via lactate signaling.

Title: Nerve growth factor induces mitochondrial fission which is required for axon branching

Authors: *L. ARMIJO WEINGART, A. KETSCHEK, R. SAINATH, A. PACHECO, G. GALLO;
Temple Univ., Philadelphia, PA

Abstract: Nerve Growth Factor (NGF) induces branching through activation of phosphoinositide 3-kinase (PI3K). Recently, mitochondria have emerged as major determinants of the sites of axon branching. NGF treatment decreased the length and increased the number of axonal mitochondria labeled with mitotracker green after 15 min of acute treatment, indicative of fission. Consistently, live imaging of mitochondria following 5 minutes of NGF treatment revealed mitochondria fission. Direct activation of PI3K using a cell permeable peptide in the absence of NGF copied the effects of NGF. Conversely, inhibition of PI3K using LY294002 blocked the effects of NGF on mitochondria. Pharmacological and peptide-mediated inhibition of dynamin related protein 1 (Drp1), a required component of mitochondria fission, blocked NGF induced axon branching. Live imaging of axons in the presence of NGF revealed that EYFP-Drp1 accumulated at sites of mitochondria fission and endogenous Drp1 was detected in axons through immunocytochemistry. NGF promoted phosphorylation of Drp1 at the activating site S616 trough ERK activation independently of the PI3K pathway. Additionally, inhibition of ERK signaling blocked the effect of NGF in mitochondria fission and Drp1 accumulation along the mitochondria. Inhibition of actin polymerization using Latrunculin-A also blocked the effect of NGF in mitochondria fission and Drp1 accumulation. Furthermore, live imaging of axons indicates that actin patches strongly co-localize with sites of mitochondria fission. Finally, we found that Brain-derived neurotrophic factor and Neurotrophin-3 also decrease the length and increase the number of mitochondria. Collectively, these observations indicate that NGF mediates phosphorylation of Drp1 through ERK signaling, and drives mitochondria fission through the activation of both the ERK and PI3K pathways. As PI3K signaling is not involved in Drp1 phosphorylation, PI3K might contribute to fission through regulation of the actin cytoskeleton independently of changes in Drp1 activity.

Title: Chondroitin sulfate proteoglycans inhibit axon branching by impairing the mitochondria-dependent local regulation of actin cytoskeletal dynamics and axonal protein synthesis

Authors: *R. SAINATH, A. KETSCHEK, L. GRANDI, G. GALLO;
Shriners Hosp. Pediatric Res. Ctr., Temple Univ., Philadelphia, PA

Abstract: Chondroitin sulfate proteoglycans (CSPGs) are extracellular matrix components that regulate aspects of axon development and regeneration. CSPGs inhibit the formation of axon collateral branches. Branching requires the regulation of the axonal cytoskeleton and mitochondria are important components of this mechanism of branching. Here we report that CSPGs depolarize the membrane potential of axonal mitochondria, which impairs the dynamics of the axonal actin cytoskeleton (e.g., axonal actin patches) and decreases the formation and duration of axonal filopodia, the first step in the mechanism of branching. The effects of CSPGs on actin cytoskeletal dynamics are specific to axon segments populated by mitochondria. In contrast, CSPGs do not affect the microtubule content of axons, or the localization of microtubules into axonal filopodia, a required step in the mechanism of branch formation. We also report that CSPGs decrease the mitochondria-dependent axonal translation of cortactin, an actin associated protein involved in branching. Finally, the inhibitory effects of CSPGs on axon branching, actin cytoskeletal dynamics and the axonal translation of cortactin were reversed by culturing neurons with acetyl-L-carnitine, which promotes mitochondrial respiration. Collectively these data indicate that CSPGs impair mitochondrial function in embryonic sensory axons, an effect which contributes to the inhibition of axon branching.

Title: αII-spectrin-dependent cytoskeletons are essential for axon function, domain assembly and integrity

Authors: *Y. HUANG[1], C. ZHANG[1], D. ZOLLINGER[2], J. LALONDE[1], C. LETERRIER[3], J. NOEBELS[1], M. RASBAND[1];
[1]Baylor Col. of Med., Houston, TX; [2]UCSF, San Francisco, CA; [3]Aix Marseille Univ., Marseille, France

Abstract: Spectrins are a family of cytoskeletal proteins that provide structural support of the cell membrane, link membrane-associated proteins to actin and serve as platforms for cell signaling. Spectrins consist of α and β subunits, forming heterotetramers to function as a complex. Among the spectrins, αII-spectrin is the only α-spectrin expressed in the nervous system. αII-spectrin is also implicated in a variety of neurological disorders. Recently, we found that αII-spectrin forms a periodic cytoskeleton and interacts with βIV-spectrin at axon initial segments (AIS) and nodes of Ranvier. To investigate the functions of αII-spectrin-dependent cytoskeletons, we generated conditional knockout (cko) mice. Loss of αII-spectrin in the central nervous system (CNS) causes profound neurological phenotypes including seizures, aberrant cortical lamination, AIS fragmentation, massive neurodegeneration and perinatal lethality. To more specifically interrogate spectrin functions in axons, we generated peripheral sensory neuron specific αII-spectrin cko mice using *advillin-cre.* We found that large diameter axons preferentially degenerate. By immunostaining, the injury marker ATF3 is observed in dorsal root ganglia (DRG) neurons in cko mice beginning at P10 and increasing with age. Consistent with EM results, $ATF3^+$ neurons are mostly large diameter neurons. The preferential degeneration of large diameter neurons caused ataxia due to deficits in proprioception, while nociception remains unaffected. Mutant mice have fewer nodes of Ranvier and sodium channel intensity at nodes is significantly decreased. Paranodal junctions are extensively disrupted. Axon degeneration and disrupted nodes of Ranvier caused decreased nerve conduction velocity in cko mice. Thus, neuronal αII-spectrin is crucial for proper axon function, node of Ranvier assembly and axon integrity. **Support:** This reseach is funded by NIH grant NS044916, NS069688 and the Adelson medical research foundation.

Title: Identifying signaling cascades involved in growth and cell clustering of functional, non-prenylatable RhoA and Rac1

Authors: *N. G. RAUT, J. M. REDDY, D. L. HYNDS;
Biol., Texas Women's Univ., Denton, TX

Abstract: The Rho guanine triphosphatase (GTPase) are highly characterized and GTPase proteins that act as molecular switches operating between an active GTP-bound state and an inactive GDP-bound state. These proteins play a pivotal role in neuronal differentiation and affect neurite outgrowth, axonal guidance, cell migration, cytokinesis and endocytosis. RhoA promotes assembly of focal adhesion complexes and formation of stress fibers. RhoA regulates the organization of actin cytoskeleton and several other cellular functions in response to the extracellular signals. On the other hand, Rac1 stimulates assembly of multimolecular focal complexes at plasma membrane, induces the peripheral actin accumulations, regulates membrane protrusions, membrane ruffling and formation of lamellipodia and filopodia. The interaction between RhoA and Rac1 is not well explored, though they are thought to be antagonist to each other. Both require prenylation for membrane localization, though active forms of both have been found in other cellular compartments (GTP-bound Rac1 in the cytosol and GTP-RhoA primarily in the cytosol and nucleus). We designed non-prenylatable Rac1 and RhoA constructs to test how inhibiting prenylation affects signaling cascades involved in neurite outgrowth. Western blot analysis after transfection with the wild-type RhoA decreased cofilin in the cytosol compared to that associated with membranes. ERK and JNK phosphorylation was increased in cytosol when cells were transfected with non-prenylatable RhoA or Rac1. We have found transfection of these constructs in rat cortical neurons increase neurite outgrowth (for non-prenylatable RhoA) and neurite formation (for non-prenylatable Rac1). Both retained the ability to be made active independent of membrane targeting by prenylation. With emerging evidence of differential activation of these Rho GTPases based on their subcellular localization, elucidating the signaling cascades of the active GTPases may identify the distinct functions of these GTPases in the cytosol and can be used as novel targets to facilitate axon regeneration in traumatic or degenerative neurological conditions. This research was supported by the TWU Department of Biology and grants from the TWU Research Enhancement Program.

Title: RacGAP α-chimaerin is required to establish spinal midline barrier for proper corticospinal projection

Authors: *S. KATORI[1], S. ITOHARA[2], T. IWASATO[1,3];
[1]Natl. Inst. of Genet., Mishima, Shizuoka, Japan; [2]RIKEN Brain Sci. Inst., Wako, Saitama, Japan; [3]Dept. of Genet., SOKENDAI (The Grad. Univ. for Advanced Studies), Mishima, Shizuoka, Japan

Abstract: In the developing central nervous system, "midline barrier (MB)", which consists of radial glia and their processes expressing repulsive guidance molecules, plays a pivotal role for midline axon guidance. However, mechanisms for MB formation have remained obscure. We here describe that Rac-specific GTPase activating protein (RacGAP) α-chimaerin, which we and others previously identified as a key downstream effector of EphA4 forward signaling, is required for MB establishment. We generated spinal cord-specific α-chimaerin knockout mice and found that these mice had numerous “cracks” in dorsal spinal cord MB, which expresses ephrinB3 to prevent EphA4(+) axons from midline crossing. Through these cracks, corticospinal axons expressing EphA4 aberrantly crossed the midline. During embryonic development of normal mice, EphA4(+) cells are localized in the vicinity of, but not within, the spinal cord midline. In contrast, in α-chimaerin knockout mice, extensive midline accumulation of spinal EphA4(+) cells was observed, and MB cracks emerged around these cells. We found similar phenotypes in EphA4-deficient mice. Our results suggest that spinal cord α-chimaerin repeals juxta-midline EphA4(+) cells from ephrinB3(+) MB in the spinal cord and plays a critical role

for establishing intact spinal MB. Here we shed light on an MB establishment mechanism, in which ephrinB3-EphA4-α-chimaerin signaling-mediated cell repulsion could be involved.

Title: RACK1 regulates point contacts and local translation in growth cones

Authors: *L. J. KERSHNER[1], K. WELSHHANS[2];
[1]Dept. of Biol. Sci., [2]Dept. of Biol. Sciences, Sch. of Biomed. Sci., Kent State Univ., Kent, OH

Abstract: In the developing nervous system, select mRNAs are transported to and locally translated within growth cones. Formation of appropriate connectivity in the developing nervous system is dependent on local translation within axonal growth cones, but the specific locations and molecular mechanisms underlying this process are not well understood. We have previously shown that local translation of β-actin mRNA within growth cones is necessary for appropriate axon guidance and is dependent on receptor for activated C kinase (RACK1). RACK1 is a multi-functional ribosomal scaffolding protein that can interact with a number of signaling molecules concurrently through its 7WD repeats. In response to stimulation with brain-derived neurotrophic factor (BDNF), phosphorylation of RACK1 facilitates the local translation of β-actin mRNA. We recently found that RACK1 is localized to point contacts, suggesting that local translation may be regulated at point contacts, adhesion sites important for axonal pathfinding. Thus, here we investigate whether local translation occurs at point contacts and examine the role of RACK1 in the regulation of point contact dynamics. First, we examined the location of components of the local translation complex relative to point contacts under both basal and growth factor stimulated conditions in cortical neurons of embryonic day 17 C57BL/6J mice. Indeed, both β-actin mRNA and RACK1 colocalize with point contacts, and this colocalization increases following BDNF stimulation. This suggests that local translation is regulated at point contacts. Additionally, RACK1 is necessary for point contact formation, and the density of point contacts within growth cones increases following BDNF stimulation in a RACK1 dependent manner. Phosphorylation of

RACK1 is also required for the BDNF-induced increase in point contact density. Furthermore, live cell experiments using total internal reflection fluorescence (TIRF) microscopy demonstrate a role for RACK1 in the regulation of point contact dynamics. Finally, we demonstrate that RACK1 is vital for functional aspects of neuronal development. Axonal growth and growth cone spreading require both RACK1 expression and phosphorylation. Taken together, these data suggest that point contacts are a targeted site of local translation within growth cones, and that RACK1 is critical to the formation of point contacts, the local translation process, and appropriate neuronal development. These data provide further insight into how and where local translation is regulated within growth cones, and thereby leads to appropriate connectivity formation in the developing nervous system.

Title: Kinesin-1 is required for cannabinoid-induced axonal development through the axonal transport of CB1 receptor.

Authors: *T. M. SAEZ[1,2], M. OTERO[1], G. OUBIÑA[2], L. E. CROMBERG[1], M. ALLOATTI[1], V. M. POZO DEVOTO[1], D. GELMAN[2], T. L. FALZONE[1,2];

Abstract: During development, axonal navigation through the intricate architecture of the brain depends on the proper presentation and positioning of guidance receptors, which allow for the correct reading of external clues. Receptors for axonal growth and guidance are shifted to axons and localized in growth cones, where they are activated by attractive or repulsive guidance cues resulting in axonal pathfinding decisions. However, little is known about the crucial mechanisms controlling the proper trafficking of these receptors involved in neural circuits wiring. The endocannabinoid (eCB) system has been identified as an important regulator of axonal outgrowth and pathfinding. eCBs mediate the motility and directional turning of axons by activating type 1 cannabinoid receptor (CB1R) in the axonal growth cone. Although cargo delivery mediated by molecular motors is essential in developing neurons, the mechanism underlying the directional axonal transport of CB1R remains basically unknown. To test the hypothesis that CB1R delivery to the growth cone depends on kinesin-1 mediated axonal transport, we used mice lacking the

kinesin light chain 1 (*klc1*) subunit of the anterograde motor kinesin-1. We performed L1-NCAM staining and axon-tracing experiments in developing *klc1*-/- brains and found pathfinding defects in corticothalamic and thalamocortical axonal tracts, which resemble those in CB1R knockout mice. Using live imaging of fluorescent CB1R tagged vesicles in wildtype and *klc1*-/- neurons, we revealed the dependency of Kinesin-1 in CB1R transport towards the axonal growth cone. Next, to assess the role of kinesin-1 on CB1R-mediated axonal development, primary cortical cultures of wildtype and *klc1*-/- neurons were treated with pharmacologic modulators of the CB1R (WIN55-212,22, ACEA and AM251). We demonstrated that kinesin-1 is required for the correct axonal growth cone remodeling and outgrowth-induced by CB1R agonist and antagonist. Altogether, our results suggest that kinesin-1-mediated axonal transport of CB1R is required for a normal eCB signaling and is also required for proper axonal pathfinding.

Title: DCLK1 phosphorylates the microtubule-associated protein MAP7D1 to promote axon elongation in cortical neurons

Authors: *H. KOIZUMI[1], K. TOGASHI[1], J. GLEESON[2,3], K. EMOTO[1];
[1]Dept. of Biol. Sci., The Univ. of Tokyo, Tokyo, Japan; [2]Lab. of Pediatric Brain Dis., The Rockefeller Univ., New York, NY; [3]Howard Hughes Med. Inst., New York, NY

Abstract: Doublecortin-like kinase 1 (DCLK1) is a neuronal serine-threonine protein kinase that is a closely related family protein of Doublecortin (DCX) originally identified as a causative gene product of human cortical malformation. DCLK1 contains the microtubule-binding domain at N-terminus that has 75% amino acid identity to DCX and the protein kinase domain at C-terminus. In mice, targeted disruption of both *Dclk1* and *Dcx* results in severe defects in cortical

lamination and the formation of axonal projections. Thus DCLK1 functions together with DCX in multiple stages of neural circuit formation including neuronal migration and axon growth. DCLK1 is suggested to play these roles in part through its kinase activity, yet the kinase substrates of DCLK1 remain largely unknown. Here we have identified mouse MAP7D1 (microtubule-associated protein 7 domain containing 1) as a novel substrate of DCLK1. miRNA-mediated knockdown of MAP7D1 in cortical layer 2/3 pyramidal cells resulted in impaired callosal axon elongation. We have further identified MAP7D1 serine 315 (Ser 315) as a DCLK1-induced phosphorylation site, and the expression of a phosphomimetic mutant of MAP7D1 fully rescues the impaired callosal axon elongation caused by *Dclk1* knockdown. These data suggest that DCLK1 phosphorylates MAP7D1 on Ser 315 to facilitate axon elongation of cortical neurons.

Title: A dynein-based mechanism, repurposed from neuronal migration, establishes and preserves microtubule organization in the axon

Authors: *A. RAO[1], M. BLACK[2], E. CRAIG[3], K. MYERS[4], P. BAAS[1];
[1]Drexel Univ., Philadelphia, PA; [2]Anat. and Cell Biol., Temple Univ. Sch. of Med., Philadelphia, PA; [3]Physics, Central Washington Univ., Ellensburg, WA; [4]Dept. of Biol. Sci., Univ. of the Sci., Philadelphia, PA

Abstract: We propose that dynein-driven forces manifest in different ways at different stages of neuronal life, depending on the capacity of the MTs to slide. MT sliding is limited by the attachment of MTs to the centrosome, as well as their length, with longer MTs being less able to slide. In migratory neurons, it has long been believed that all functionally relevant MTs are attached to the centrosome, which would render them unable to slide relative to one another. However, we were able to document a limited amount of MT sliding in the leading process of cultured cerebellar migratory neurons, with treatment with a drug that inhibits MT sliding resulting in an impairment of the trajectory of migration. By knocking down in cultured rat cerebellar granule neurons the expression of ninein, a centrosomal protein responsible for

anchoring MTs to the centrosome, we increased the number of centrosome-unattached MTs and observed an increase in MT sliding. Concomitantly, migration was severely compromised and the leading process became longer, reminiscent of the phenotype of an axon-bearing post-migratory neuron. Next, we pursued the idea that in a bona fide axon where MTs appear in a variety of lengths that dynein-based forces are repurposed to establish and preserve the nearly uniform plus-end-out polarity pattern of the MT array. Exposure of cultured rat sympathetic neurons to the Ciliobrevin D, a small molecule dynein inhibitor, for various windows of time resulted in a dose-dependent appearance of greater numbers of minus-end-distal MTs in the axon. In addition, MT transport events were reduced in frequency in both the anterograde and retrograde directions. The MT movements that did occur in the presence of the drug showed an increase in abrupt pausing of movements and directional changes in the movements, as well as abnormal transport rates. These effects are consistent with a mechanism whereby dynein-based forces propel MTs with plus-end-out anterogradely down the axon, while clearing MTs with minus-end-out back to the cell body. These two sets of data, on neurons of different stages of development, demonstrate how dynein-driven forces on MTs can be repurposed to orchestrate different neuronal phenotypes.

Abstract: The actin related protein (Arp) 2/3 complex is a seven subunit complex that is required for the nucleation of branched actin filaments for the development of neurons. Within a cell, several proteins tightly regulate the activity of this complex but how these proteins

modulate the activity of the Arp 2/3 complex is still unclear on a structural basis. Structural modeling identified several mutations that are important in maintaining the active structure of the Arp 2/3 complex. We constructed these mutant and are using them as tools to decipher the structure-based functional relationships governing Arp 2/3 mediated nucleation of actin. The current work involves understanding the effect of different regulators (rac1 inhibitor, arp 2/3 complex inhibitor, and profilin) on actin polymerization activity of constitutively active Arp3 mutant in neuroblastoma cells. The results from this study will help in understanding the structural regulation of Arp3 protein in the development of neurons and, hence, in the regeneration of the neuronal network at the site of spinal cord injury.

Title: Axonal mRNA dynamics in live hippocampal neurons

Authors: *B. LEE[1], S. BANG[2], S. LEE[2], N. JEON[2], H. PARK[1];
[1]Physics and Astronomy, Seoul Natl. Univ., Seoul/Gwanak-gu, Korea, Republic of; [2]Inst. of Advanced Machinery and Design Seoul Natl. Univ., Div. of WCU (World Class University) Multiscale Mechanical Design Sch. of Mechanical and Aerospace Engin., Seoul, Korea, Republic of

Abstract: Localization of mRNA and protein synthesis is critical for axonal guidance and regeneration. Yet it is not clearly understood how mRNA localization is regulated in axons. Using a transgenic mouse that expresses fluorescently labeled beta-actin mRNA (Park, Lim et al. 2014) , we investigated the dynamics of endogenous beta-actin mRNA in axons. By culturing hippocampal neurons in a microfluidic device which allows separation of axons from cell bodies, it is possible to track β-actin mRNA motions in live axons. We observed high-frequency random oscillating movements of β-actin mRNA, which were clearly different from the movements in the dendrites. In addition, we found several mRNAs localized at axonal varicosities where synapses typically occur. We modeled mRNA dynamics in axons using a theoretical random walk model, Orstein-Uhlenbeck process that has a specific destination. This study suggests a

biophysical mechanism of mRNA transport and localization in axons, which will have important implications for axon regeneration.

Abstract: Characteristic neuronal changes occur following Traumatic Brain Injury (TBI) including axonal injury which is comprised of axonal swelling, degeneration and the loss of synapses, alterations in dendrites (reduction in dendritic spine density) and ultimately neuronal cell death. We speculate that changes in transport rate and deterministic axonal growth are altered following mechanical injury induced cell trauma. Advances in quantitative phase imaging (QPI) techniques allow unlabeled live biological specimens to be imaged with sub-nanometer sensitivity and diffraction limited resolution. The recently developed technique called Spatial Light Interference Microscopy (SLIM) has been useful in discovering the emergent behavior in human neuronal networks and the intercellular dynamics and SLIM has proven its potential to be used in neuroscience [Z. Wang et al., Opt. Exp., 19, 1016 (2011) & M. Mir et al., Sci. Rep., 4, 4414 (2014)]. This technique, which allows for a wide-field imaging of live neuronal activities, therefore, can be used for a measurement of dynamic structural changes over long time scales. We use this imaging technique to measure changes in axon growth cone dynamics (sprouting and extension), neuronal extension transport rates, deterministic motility and we provide 3D cellular topography maps at high-resolution, in live cortical neurons over time, following mechanical cell trauma induced by a fluid percussion injury device.

Title: Mechanistic study of neurite outgrowth stimulated by the amyloid precursor protein interactor FE65

Authors: *W. LI, H. CHEUNG, K.-F. LAU;
Sch. of Life Sci., The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Alzheimer's disease is a devastating neurodegenerative disorder that affecting millions of people worldwide. Severe neurite degeneration is observed in Alzheimer's disease which is suggested to be associated with cognitive decline in the disease. FE65 is a brain-enriched multi-domain adaptor protein which is shown to interact with the Alzheimer's disease amyloid precursor protein (APP) and to alter APP metabolism. Moreover, recent evidence reveals that FE65 is also involved in other neurophysiological processes including neurite development. However, the mechanism(s) by which FE65 stimulates neurite outgrowth is still largely unknown. As an adaptor protein, FE65 functions in recruiting various interactors to form biological complexes. Hence, identification of the full complement of FE65 interacting proteins is an important step for improving our understanding of FE65 in various processes including neurite development. In this project, we have identified several small GTPases interact with FE65 including ARF6 and Rac1 and their corresponding regulators. ARF6-Rac1 signaling has been implicated in neurite outgrowth via regulation of cytoskeleton remodeling. In fact, FE65 stimulates neurite outgrowth in primary neurons via activation of ARF6 and its downstream GTPase Rac1. Additionally, we also found that the regulators of ARF6 and Rac1 are required for FE65-mediated neurite extension. Our work suggests that FE65 functions as an adaptor to recruit

various small GTPase and their regulators to form functional complexes to regulate neurite outgrowth. Since neurite degeneration is observed in Alzheimer's disease, strategies that attenuate neurite loss and/or stimulate neurite outgrowth may represent a promising direction for therapeutic development for the disease. Our work shed important light on the role of FE65 in neurite outgrowth.

Medicine, Johannes-gutenberg-University, Mainz, Germany

Abstract: Precise connection of thalamic barreloids with their corresponding cortical barrels is critical for processing of vibrissal sensory information. Here, we show that the phospholipid interacting molecule PRG-2 plays an important role in thalamocortical axon guidance. Developing PRG-2$^{-/-}$ thalamocortical fibers prematurely entered the cortical plate eventually innervating non-corresponding barrels. This misrouting was due to lost axonal sensitivity towards lysophosphatidic acid (LPA), which failed to repel PRG-2-deficient thalamocortical fibers. PRG-2 electroporation in the PRG-2$^{-/-}$ thalamus was able to restore the aberrant cortical

innervation. We identified radixin (RDX) as a PRG-2 interaction partner in thalamocortical fibers, and showed that RDX accumulation in axon growth cones and its phosphorylation upon LPA stimulation was dependent on PRG-2. *In vivo* recordings and whisker-specific behavior tests demonstrated sensory discrimination deficits in PRG-2$^{-/-}$ animals. Our data show that bioactive phospholipids and PRG-2 are critical for axon guidance of thalamic fibers to their proper cortical termination field.

Title: Cyclic gmp dependent protein kinase 1 guides axonal regeneration after sciatic nerve injury

Authors: ***L. VALEK**[1], A. HÄUSSLER[1], S. DRÖSE[2], K. SCHRÖDER[3], I. TEGEDER[1]; [1]Clin. Pharmacol., [2]Anaesthesiology, [3]Cardiovasc. Physiol., Univ. Hosp. Frankfurt, Frankfurt, Germany

Abstract: Cyclic GMP-dependent protein kinase 1 (PKG1) essentially contributes to nociceptive long-term potentiation in the spinal cord, and consequently, PKG inhibition or knockout in sensory neurons of the dorsal root ganglia (SNS-PKG1$^{-/-}$) reduces inflammatory nociception in mice, but unexpectedly, PKG1 deficiency in SNS-PKG1$^{-/-}$ mice provided no protection against nerve injury evoked neuropathic nociception. The result suggested specific repair functions of PKG1 that are necessary for regeneration and indeed, these functions were impaired after nerve injury because PKG1 transcription, redox-sensitive dimerization/auto-activation and axonal transport were reduced or blocked. Primary neurons of adult SNS-PKG1$^{-/-}$ mice showed enhanced branching and outgrowth due to a reduction of growth cone collapse evoked by oxidation events that occur physiologically at the growth cones and branching points in response to repulsion cues. Consequently, PKG1 deficient outgrowing axons *in vivo* failed to find the path

through a nerve lesion. At the molecular level, PKG1 deficiency impaired cofilin phosphorylation and hence actin dynamics essential for growth cone collapse evoked e.g. by semaphorin 3a. Enhanced outgrowth but defective path-finding may increase aberrant sprouting thereby outweighing spinal mechanisms of pain attenuation provided by PKG1-deficiency in inflammatory conditions and PKG1 inhibition after nerve injury may therefore impair endogenous repair mechanisms.

Title: BIG1 is required for the survival of deep layer neurons and the thalamocortical connectivity in developing brain.

Authors: ***J.-J. TEOH**[1], T. IWANO[2], M. KUNII[1], A. HARADA[1];
[1]Grad. Sch. of Med., Osaka Univ., Suita-Shi, Japan; [2]Grad. Sch. of Med. and Engin., Univ. of Yamanashi, Yamanashi, Japan

Abstract: As embryonic neocortex develop, radial glial cells in ventricular zone (VZ) start to produce postmitotic neurons around embryonic day 11.5 (E11.5) to form deep layer (Layer VI) in neocortex. As the development continue, the new neuroblasts migrate through and form a new layer above the existing layer. Prenatal neurogenesis continues until all layers are formed. Deep layer neurons, in particular, from various regions of neocortex start extending axons into respective thalamic region.
BIG1, a brefeldin A-inhibited guanine nucleotide-exchange protein, coded by Arfgef1 gene, have a Sec7 domain that activates Arf1 and Arf3 by replacing bound GDP with bound GTP, and thus, involves in vesicular trafficking in various cell types. In addition, BIG1 has also been found to regulate neurite outgrowth and maturation in vitro.
Using a BIG1 knockout ($BIG1^{-/-}$) mice model, the role of BIG1 in neocortex development and axonal connectivity was examined. Indeed, BIG1 knockout caused morphological defects in neocortex and pallial/subpallial boundary (PSPB). In BIG1 knockout neocortex, apoptosis occurred in early-born deep layer neurons and reached a peak soon after deep layer neuron differentiation at E15.5. Immunofluorescense staining using axonal or dendritic marker showed that the neuronal connectivity defects were observable only after E15.5. At E17.5, in BIG1

knockout brain, the corticothalamic axons from primary somatosensory cortex (S1) extended into dorsal lateral geniculate nucleus (dLGN) instead of ventrobasal complex (VB). The thalamocortical axons were unable to cross internal capsule (IC). Primary hippocampus neuron culture at 9 days-in-vitro (DIV) showed abnormal accumulation of NCKX2, a calcium channel protein that is a cargo for axonal motor protein Kif21a, at plasma membrane of dendrites. This might suggest that the loss of BIG1 lead to abnormal trafficking of NCKX2 through Kif21a, whose cargo binding site can also bind to BIG1 in wild type neurons.
This study showed the role of BIG1 in maintaining deep layer neuron survival and subsequent neuronal connectivity in developing embryonic brain. BIG1 may also function as a mediator for selective NCKX2 distribution at axon surface.

Title: Actin/spectrin periodicity at synapses and nodes of Ranvier reveald by STED microscopy

Authors: ***E. DESTE**[1], D. KAMIN[1], S. SIDENSTEIN[1], C. VELTE[2], M. SIMONS[2], S. HELL[1]; [1]Max Planck Inst. For Biophysical Chem., Goettingen, Germany; [2]Max Planck Inst. of Exptl. Med., Goettingen, Germany

Abstract: A ~190 nm periodic subcortical cytoskeleton lattice consisting of actin, spectrin, and other proteins was recently discovered underneath the membrane of hippocampal neurons and at nodes of Ranvier. By performing three-color STED nanoscopy, we show that this lattice is present in thick spine necks but is absent from post-synaptic sites, identified by Homer co-staining. Similarly, the lattice is discontinued at pre-synaptic sites, identified by Bassoon co-staining.
Whether the periodic cytoskeleton lattice is a structural feature of all neurons and how it is modified when axons are ensheathed by myelin-forming glial cells is not known. Therefore, we first confirmed the presence of the actin/spectrin lattice in different excitatory and inhibitory neuron types from both the central nervous system (cortical neurons, striatal neurons, cerebellar granule cells, retinal bipolar cells) and the peripheral nervous system (dissociated dorsal root ganglion cells). The lattice was also revealed in myelinating cells, specifically in cultured oligodendrocyte precursors, indicating that it is not a unique neuronal feature. The actin/spectrin lattice arrangement was found underneath the myelin coat at both internodes and paranodes of

sciatic nerve fibers *ex-vivo*. Co-staining of betaII and betaIV spectrin shows a continuity of this structure between paranodes and nodes, without any interruption. Consistent with the finding on oligodendrocyte precursor cells, at paranodes also glial cells exhibit a periodic arrangement of cytoskeletal and related proteins (Ankyrin B and Neurofascin 155).
In conclusion, we show that the subcortical actin/spectrin lattice is ubiquitous throughout the nervous system, being present in a variety of neuronal cell types. Our results suggest the existence of mechanisms that allow a fine-tuning of this substructure and open up many questions regarding both synaptic plasticity and de-myelination diseases.

Title: Molecular mechanisms underlying polarized mitochondria structure and function in cortical neurons

Authors: *T. LEWIS, JR[1], S.-K. KWON[1], R. SHAW[2], F. POLLEUX[1];
[1]Dept. of Neurosci., Columbia Univ. Med. Ctr., New York, NY; [2]Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: The importance of mitochondria for neuronal function is evident by the large number of neurodegenerative diseases (ALS, Alzheimer's disease, Parkinson's disease, Friedreich ataxia) which have been associated with a disruption of mitochondrial function or transport (Chen & Chan, 2009). Mitochondria are essential for multiple physiological functions as a result of their

ability to produce ATP through oxidative phosphorylation, buffer cytoplasmic calcium, regulate lipid biosynthesis and trigger apoptosis through cytochrome c release (Schon & Przedborski, 2011). In non-neuronal cells, mitochondria are highly dynamic as a result of mitochondrial biogenesis, fission, fusion, transport and removal via mitophagy. In neurons, mitochondria structure differs strikingly between the axon and dendrites: in axons, mitochondria are small (on average ~1 microns length) and often localized presynaptically whereas in dendrites, they form long, tubular networks covering almost the entire dendritic arbor. Therefore, we hypothesized that mitochondrial fission must be dominant over fusion in axons and vice versa in dendrites. These observations suggest highly polarized molecular mechanisms controlling mitochondria dynamics and function in axons vs. dendrites, however, at this point, the molecular mechanisms underlying compartmentalized mitochondrial fission/fusion in neurons are currently unknown. Recently, we have identified that Mitochondrial Fission Factor (MFF) activation (one of four known Drp1 'receptors'), controls mitochondrial size in both cell lines and neuronal dendrites in an AMPK-dependent manner (Toyama, Herzig et al, *Science* 2016). We will present results demonstrating that mitochondrial fission is regulated differentially by MFF in axons compared to the somatodendritic domain. We provide evidence that MFF-dependent mitochondrial fission is dominant in the axon, and that knockdown of MFF (but not Fis1) results in elongated, fused mitochondria along the axon without affecting dendritic mitochondrial morphology. Finally, disruption of mitochondrial fission in the axon results in changes to mitochondrial presynaptic localization resulting in changes to axonal morphology and mitochondrial-dependent calcium buffering function.

Title: Bilaterian giant ankyrins have a common evolutionary origin and a conserved role in axon initial segment organization

Authors: ***T. J. JEGLA**[1], M. M. NGUYEN[2], D. J. GOETSCHIUS[2], E. LUNA[2], D. B. VAN ROSSUM[2], B. KAMEL[2], A. PISUPATI[2], E. S. MILNER[2], M. M. ROLLS[2];

Abstract: In vertebrate neurons, the axon initial segment (AIS) is specialized for action potential initiation. It is organized by a giant 480 Kd variant of ankyrin G (AnkG) that serves as an anchor for ion channels and is required for a plasma membrane diffusion barrier that excludes somatodendritic proteins from the axon. An unusually long exon required to encode this 480Kd variant is thought to have been inserted only recently during vertebrate evolution, so the giant ankyrin-based AIS scaffold has been viewed as a vertebrate adaptation for fast, precise signaling. We re-examined AIS evolution through phylogenomic analysis of ankyrins and by testing the role of ankyrins in proximal axon organization in a model multipolar *Drosophila* neuron (ddaE). We find giant isoforms of ankyrin in all major bilaterian phyla, and present evidence in favor of a single common origin for giant ankyrins and the corresponding long exon in a bilaterian ancestor. This finding raises the question of whether giant ankyrin isoforms play a conserved role in AIS organization throughout the Bilateria. We examined this possibility by looking for conserved ankyrin-dependent AIS features in *Drosophila* ddaE neurons via live imaging. We found that ddaE neurons have a diffusion barrier in the proximal axon that requires a giant isoform of the neuronal ankyrin Ank2. Our results indicate that the giant ankyrin-based cytoskeleton of the AIS may have evolved prior to the radiation of extant bilaterian lineages, much earlier than previously thought.

Abstract: Axonal fragmentation is a regulated process that uses a growing set of receptors, signaling molecules, proteases and other regulators to disintegrate the axonal compartment. Little is known about the changes (and possible role) of the axonal cytoskeleton during degeneration. In this study we aimed at describing cytoskeletal changes associated with axonal degeneration induced by of trophic factor (NGF) withdrawal (TFW) or injury in cultured DRG neurons. We first focused our attention in the actin-rich growth cone and found that growth cone collapse (GCC) is an early event observed in TFW and injured axons. Live-imaging shows that GCC is almost complete by 30 minutes after TFW, which is well before the 18-24 hours needed to observe axon fragmentation. Accompanying increased filopodia dynamics at the axonal tip suggest that GCC is caused by a sudden increase in F-actin dynamics. To our surprise, drugs (Nicotinamide Adenine Dinucleotide, EGTA, go6976, N-Acetyl Cysteine) or gene deletions (Caspase-3 -/-) known to prevent axonal fragmentation do not prevent GCC. Growth cone collapse does not represent a point of no return towards axonal fragmentation since re-adding NGF after GCC (6-12 hours) prevents axonal fragmentation and growth cones are re-form. Total F-actin staining decreases in every cell compartment during degeneration. On the other hand, axonal microtubules form tight bundles and we observed an early and marked microtubule de-bundling in degenerating axons and microtubules curves at the tip of axons where growth cones collapsed. These previously unnoticed early changes in the cytoskeleton suggest an instructive role for the cytoskeleton during axon fragmentation.

Title: Weakening of GABAergic connections from somatostatin interneurons to pyramidal neurons after eye-opening in layer 2/3 of visual cortex

Authors: *W. GUAN, J.-W. CAO, Y. FU, Y.-C. YU;
Inst. of Brain Sci., Fudan Univ., Shanghai City, China

Abstract: A precise cortical GABAergic network is critical for the normal sensory coding and perception. However, how cortical GABAergic circuits are developmentally assembled and regulated in the early postnatal period is far from fully understood. Eye opening is a timed event critical for the maturation of cortical circuits, yet our knowledge of the relationship between eye-opening and the maturation of specific GABAergic connections is incomplete. Here we report first time that, 1-2 days after eye-opening, the IPSC amplitude from somatostatin interneurons to pyramidal neurons abruptly decrease by about 50% in layer 2/3 of the visual cortex. Similar results were not found in connections from somatstatin interneurons to other interneurons subtypes. What's more, the reduction of IPSC amplitude is impared by the disruption of normal visual input, suggesting that the developmental change after eye-opening is regulated by early visual experience. Our work revealed a novel early developmental pattern of GABAergic circuits around the time eye opens and indicated that early visual experience is critical for the maturation of somatostatin interneuons GABAergic circuits in visual cortex.

Title: Function of early generated interneurons in the developing neocortex of neonatal mouse

Authors: ***C. WANG**, S. JIANG, J. MA, L. ZHANG, Z. YUAN, X. MAO, Y. YU;
Inst. of Brain Sci., Fudan Univ., Shanghai, China

Abstract: The generation of neocortex interneurons approximately starts from E9.5 and ends at E18.5. Previous studies have revealed that a portion of early generated interneurons (EGIns) in the hippocampus can act as hub neurons which may modulate the synchronized activity of the hippocampus network. However, the functional significance of EGIns in neocortex is not well understood. In this study, combining fast multi-scale calcium imaging (fMCI) with whole cell recording, we found that some EGIns in the neocortex also have hub function. On the basis of electrophysiological and morphological data, we observed that EGIns have a higher connectivity level than ordinary generated interneurons (OGIns) which were born around the peak of neurogenesis. Nevertheless, this advantage of EGIns almost only occurs in the first postnatal week and disappears later when the neocortex gets more mature. Our results implied that EGIns have a stronger regulatory function in the developing neocortex at early postnatal stage when vast cortical synaptic network begin to establish.

Title: Distinct roles for presynaptic and postsynaptic nmdars in visual circuit development

Authors: ***P. M. KESNER**, E. C. WARREN, F. MA, E. S. RUTHAZER;
Neurol. and Neurosurg., Montreal Neurolog. Inst., Montreal, QC, Canada

Abstract: The N-methyl-D-aspartate type glutamate receptor (NMDAR) has been strongly implicated as playing a role in retinotectal projection refinement, arbor stabilization, and plasticity during development. Chronic receptor blockade experiments have demonstrated that NMDARs in the optic tectum play a key role in retinotectal axon remodeling and refinement. Once thought to be exclusively postsynaptic, more recent work has revealed the existence of presynaptic NMDARs (preNMDARs) that may also contribute to synaptic function and plasticity. We have therefore undertaken a set of experiments to specifically assess the relative contributions to synaptic plasticity and circuit refinement of pre- versus postsynaptic NMDARs (postNMDARs). To do so, we have developed a novel model system in which we inject an antisense Morpholino oligonucleotide (MO) against the obligate GluN1 subunit of the NMDAR into just one cell at the two-cell stage of development. This results in the NMDAR being effectively knocked-down in half the embryo. Because the retinal ganglion cells (RGC) cross the midline to project to the optic tectum, these hemimorphant animals lack NMDARs in all the RGC inputs to their wildtype contralateral hemisphere and in all the tectal neurons (with wildtype RGC inputs) in the other hemisphere. Preliminary findings suggest complementary contributions to axon complexity and dynamics for pre- and postNMDARs as well as alterations in visual response properties. These early findings set the groundwork for a more comprehensive investigation of the specific roles of pre- and postsynaptic NMDARs in neural circuit development, plasticity, and visual processing.

Title: Optical imaging of widely-spreading wave activity in the embryonic chick forebrain induced by olfactory nerve stimulation

Authors: *K. SATO[1], Y. MOMOSE-SATO[2];
[1]Dept. of Hlth. and Nutr. Sci., Komazawa Women's Univ, Fac. of Human Hlth., Tokyo, Japan;
[2]Dept. of Nutr. and Dietetics, Kanto Gakuin Univ., Col. of Nutr., Yokohama, Japan

Abstract: We have applied multiple-site optical recording with a voltage-sensitive dye to the olfactory nerve (N.I)-olfactory bulb-forebrain preparation of the chick embryo, and pursued functional development of the olfactory system. In our previous studies, we showed that optical responses in the olfactory bulb induced by N.I stimulation consisted of three components, viz., a fast spike-like signal, a delayed long-lasting slow signal, and an oscillation. The fast spike-like signal corresponded to the sodium-dependent action potential, and the slow signal included the glutamatergic excitatory postsynaptic potential. Functional synaptic transmission in the olfactory bulb was expressed at the embryonic 6-7-day stage, while the oscillation was detected from the embryonic 9-day stage. In the present study, we found that the slow signal spread into the forebrain as a wave-like activity and distributed widely in the cortex in some conditions. This wave-like activity was elicited from the embryonic 9-day stage in normal physiological solution and the 8-day stage in the Mg^{2+}-free solution. We examined fundamental characteristics of the wave-like activity and their developmental dynamics.

Title: *In vivo* 2-photon imaging of neuronal activity in layer 4 of the neonatal barrel cortex

Authors: *H. MIZUNO[1,2], T. SATO[1], T. IWASATO[1,2];
[1]Natl. Inst. of Genet., Mishima / Shizuoka, Japan; [2]Genet., SOKENDAI, Mishima / Shizuoka, Japan

Abstract: Establishment of precise neuronal circuits in the mammalian neocortex relies on activity-dependent circuit reorganization during postnatal development; however, the nature of cortical activity that could underlie the circuit refinement remains largely unknown. We addressed this question using the mouse somatosensory cortex. In the mouse somatosensory cortex layer 4, the arrangement of whiskers on the face is topographically represented as "barrels", which are discrete modules of layer 4 neurons. Thalamocortical (TC) axon termini that correspond to a whisker are clustered in the center of a single barrel, and dendrites of a layer 4 neuron are mostly restricted to a single barrel. These highly organized TC circuits are established during neonatal stages, in which neuronal activity via thalamus plays a critical role. We first developed a method to analyze activity of layer 4 neurons with respect to the TC axon projection patterns: To observe the arrangement of barrels (TC axon terminus clusters) in vivo, we generated transgenic mice expressing RFP in TC axons (TCA-RFP mice). We expressed genetically encoded calcium indicator GCaMP in a sparse population of layer 4 neurons in these mice. Sparse cell labeling was achieved by using the Supernova system, which we recently reported (Mizuno et al., Neuron 2014). We then monitored neuronal activity in the somatosensory cortical layer 4 during neonatal stages, and analyzed features of the activity with

respect to the TC input patterns. The properties of cortical activity during early postnatal period that may be involved in circuit refinement will be discussed.

[1]Ophthalmology, Univ. of California San Francisco, San Francisco, CA; [2]Psychiatry, Douglas Mental Hlth. Res. Center, McGill Univ., Montreal, QC, Canada

Abstract: During early postnatal development in mouse retinorecipient areas, retinal projections are broad and diffuse, exemplified by the highly overlapping eye-specific (ipsi- vs. contralateral) retinal projections in the dorsal lateral geniculate nucleus (dLGN). A Hebbian mechanism was hypothesized to orchestrate the large-scale refinement of these eye-specific circuits, resulting in a highly segregated organization of eye-specific connectivity. Previously, we explored the role of glutamate release in the refinement of eye-specific inputs to the dLGN, concluding that glutamate release from ipsilateral fibers is important for the removal of contralateral fibers in the territory destined to be ipsilateral, whereas the maintenance and refinement of ipsilateral fibers does not require normal levels of glutamate release. We sought to uncover the molecular signal that conveys this latter aspect of retinogeniculate refinement through examination of serotonin release. The model of serotonin's role in refinement of the retinogeniculate synapse had long been thought to be inhibitory onto contralateral inputs via release from ipsilateral inputs. However, using conditional genetic deletion of serotonin's vesicular transporter (VMAT2) in ipsilaterally-projecting retinal ganglion cells (ipsi-RGCs), we found that loss of serotonin release from ipsi-RGC unexpectedly accelerates refinement leading to early and complete refinement of inputs. Furthermore, genetic disruptions of both glutamate and serotonin release surprisingly rescued the retinogeniculate refinement phenotype observed after disrupted glutamate or

sertotonin release alone. These results suggest an antagonistic role of glutamate and serotonin release from ipsi-RGCs and furthermore demonstrate that normal developmental circuit refinement is capable after reduction of both transmitters. These results update our current understanding of the role of serotonin and glutamate signaling over neural circuit refinement during development.

Title: Supernova: Extensible vector systems that enable high intensity single-cell labeling and labeled cell-specific gene knockout and editing *In vivo*

Authors: *S. NAKAZAWA[1,2], W. LUO[1,2], R. IWATA[1,2], H. MIZUNO[1,2], T. IWASATO[1,2]; [1]Natl. Inst. of Genet., Mishima, Shizuoka, Japan; [2]Dept. of Genet., SOKENDAI (The Grad. Univ. for Advanced Studies), Mishima, Shizuoka, Japan

Abstract: The mammalian brain, a complex organ, comprises numerous cells (neurons) densely packed and interconnected with each other to form intricate neural circuits responsible for higher brain function. To understand the precise cellular and molecular mechanisms of the neural circuit development and function, single-cell analyses that dissect connectivity of individual cells and molecular machinery operating in these cells are indispensable. For this purpose, we developed “Supernova” series of vector systems. In Supernova, sparse labeling relies on rare TRE leakage.

In a small population of cells with over-threshold leakage, initial tTA-independent weak expression is enhanced by tTA/TRE-positive feedback along with a site-specific recombination system (e.g., Cre/loxP, Flpe/FRT). Sparse and bright labeling by Supernova with little background enables the visualization of the morphological details of individual neurons in densely packed brain areas such as the cortex and hippocampus, both during development and in adulthood. Sparseness levels are adjustable. Labeled cell-specific gene knockout was accomplished by introducing Cre/loxP-based Supernova vectors into floxed mice. Furthermore, by combining with RNAi, TALEN, and CRISPR/Cas9 technologies, Supernova achieved labeled cell-specific gene knockdown and editing/knockout without requiring genetically altered mice. Thus, Supernova system is highly extensible and widely applicable for single-cell analyses in complex organs, such as the mammalian brain.

Title: Layer specific developmental changes of excitatory and inhibitory balance in pyramidal neurons of rat primary visual cortex

Authors: *R. TATTI, A. MAFFEI;
Stony Brook Univ., Stony Brook, NY

Abstract: Neural circuits are highly sensitive to changes in environmental inputs, especially early in life when windows of heightened plasticity have been reported. These developmental windows are known as “critical periods”. In rat primary visual cortex (V1) the best studied of the critical periods was shown to open at postnatal day 21 (P21) and peak by the end of the fourth week. In addition, a second window of plasticity was also identified. It is known as pre-critical period, starts at eye opening and extends to P21. In these two developmental windows the circuit

in V1 appears to have different sensitivity to patterned stimulation. For example, the same pattern of activity can induce completely different forms of plasticity if applied in the pre-critical or in the critical period, suggesting that the local circuit may be in different states of excitability. Here, we recorded spontaneous excitatory and inhibitory currents from pyramidal neurons (Pyr) in different layers of V1 at eye opening and the peak of the critical period. Our data show that there are laminar differences in the balance between excitation and inhibition (E/I) in V1 Pyr neurons recorded at these two developmental stages. At eye opening (P14) spontaneous activity was dominated by excitation in layer L4 (E/I ratio in L4 =1.29 ± 0.14, *n*=12 Pyr neurons) while inhibition was dominant in L2/3, L5 and L6 (E/I ratios: L2/3=0.39 ± 0.06, L5=0.72±0.2, L6=0.81±0.1 respectively, *n*=12 neurons for each layer). At the peak of the critical period inhibition was dominant throughout the cortical mantle (L2/3=0.1±0.02, L4=0.2±0.02, L5=0.2±0.02, L6=0.1±0.01). Our results indicate that from eye opening and the peak of the critical period there is a progressive shift toward inhibition becoming dominant in all cortical layers. This transition is likely to contribute to the maturation of the response properties and to the changes in capacity for plasticity of neurons in V1.

Title: Convergent tectal inputs drive circuit plasticity and visuomotor behavior via changes in excitatory to inhibitory balance

Authors: *A. C. GAMBRILL[1], R. L. FAULKNER[2], H. CLINE[2];
[1]The Scripps Res. Inst., La Jolla, CA; [2]The Scripps Res. Inst., San Diego, CA

Abstract: Communication between tecta/colliculi is thought to be required for sensorimotor behaviors by comparing input across the midline, however the role of visual experience in the

function and plasticity of developing intertectal (IT) connections in unclear. Using in vivo time-lapse imaging, electrophysiology, and visuomotor behavior experiments in *Xenopus* tadpoles, we examine the experience-dependent plasticity and function of intertectal inputs. We find that intertectal neurons provide convergent excitatory and inhibitory input onto retinorecipient tectal neurons, and that these intertectal inputs are required for visuomotor behavior. We show that spike-timing dependent plasticity of intertectal inputs and experience-dependent structural plasticity in presynaptic excitatory and inhibitory IT boutons change the balance of excitation to inhibition (E:I) of intertectal input to tectal neurons. Intertectal inputs are required for visual avoidance behavior and exposing tadpoles to unilateral patterned visual input impairs behavior and disrupts E:I balance. These results demonstrate that visual experience induces plasticity in IT synapses and that discordant retinal inputs shift the E:I ratio of IT input onto tectal neurons, which is sufficient to transiently disrupt the integration of visual information and motor output in the tectal circuit and to disrupt visuomotor behavior. Title: Store-operated calcium entry in pupal *Drosophila* neurons regulates flight through Ral expression and vesicular release

Authors: ***S. RICHHARIYA**[1], S. JAYAKUMAR[1,2], K. ABRUZZI[3], M. ROSBASH[4], G. HASAN[1];
[1]NCBS, TIFR, Bangalore, India; [2]Manipal Univ., Manipal, India; [3]Brandeis Univ., Waltham, MA; [4]HHMI, Brandeis Univ., Waltham, MA

Abstract: Transcriptional regulation by Store-operated Calcium Entry (SOCE) is well studied in non-excitable cells. However, the role of SOCE has been poorly documented in neuronal cells with heterogeneous calcium dynamics. We study the role of SOCE in the developing nervous

system of *Drosophila*. Previous reports demonstrated a requirement for SOCE in *Drosophila* flight circuit neurons. We refine this requirement temporally to the early pupal stage and use RNA sequencing to identify SOCE mediated gene expression changes in the developing *Drosophila* pupal nervous system. Down regulation of *dStim*, the endoplasmic reticular calcium sensor and a principal component of SOCE in the nervous system, altered the expression of 131 genes including *Ral*, a small GTPase. Disruption of Ral function in neurons impaired flight, whereas ectopic expression of *Ral* in SOCE compromised neurons restored flight. We demonstrate, by live imaging of cultured pupal neurons, a role for SOCE dependent *Ral* expression in regulating vesicular exocytosis. Compromising vesicle release in early pupal neurons alone, hampers flight, supporting the functional significance of *Ral* expression at this developmental stage. These results identify neuronal SOCE as a mechanism that regulates *Ral* expression and consequently neural function and behaviour. They also demonstrate the relevance of SOCE regulated gene expression for neuronal circuit maturation.We also profiled the pupal transcriptome of Dopaminergic and Glutamatergic, two known neuronal domains where SOCE has been implicated in flight, under conditions of impaired dSTIM function to study the role of SOCE in these neurons. Interestingly, we find SOCE to differentially regulate a set of genes in these two subsets.

Title: Role of early activity in the development of the *Caenorhabditis elegans* egg laying behavior circuit

Authors: *B. RAVI, K. M. COLLINS;
Biol., Univ. of Miami, Miami, FL

Abstract: Early activity has been shown to be important for the proper development and assembly of neural circuits. Activity is also required to form coordinated patterns in mature neural circuits that drive efficient behaviors. We are interested in studying the functional importance of early activity using the developing egg-laying behavior circuit in the nematode

Caenorhabditis elegans. The *C. elegans* egg laying circuit is a simple, well characterized neural circuit which drives a two-state behavior in which adult animals alternate between an inactive state and an active state when eggs are laid. The circuit comprises two types of motor neurons: the Hermaphrodite Specific Neurons (HSNs) and Ventral Type C motor neurons (VC) that innervate the vulval muscles which contact to lay eggs. During the L4 larval stage, the cells of the circuit undergo morphological maturation and establish synaptic connections. We are using GCaMP calcium imaging in freely behaving animals to record activity in cells of the egg laying circuit at the late L4 larval stage and in adults after development. We found the HSN neurons have rhythmic Ca^{2+} transients at the late L4 larval stage at intervals of about 55s even before eggs are produced. HSN Ca^{2+} transients are also observed at the mid-L4 stage, but are less frequent than during late-L4 (1hr post mid-L4). HSN activity in late-L4 animals lacked the characteristic burst-firing pattern at intervals of about 20s in adults during egg laying. Developing vulval muscles have Ca^{2+} activity during the transition from mid-L4 to late-L4 and after the L4 molt is complete. Vulval muscle L4 Ca^{2+} transients are uncoordinated at the mid-L4 stage, where we see asynchronous Ca^{2+} transients at either the anterior or posterior muscle cells. At the end of the L4 stage, coordinated muscle transients appear, which resembles the activity seen in adult muscles that allows efficient egg release. In order to understand the functional consequences of circuit connectivity, we are analyzing how the observed activity correlates with morphological changes observed during circuit development. We are also analyzing the role of early activity in regulating other behaviors that change during the L4 stage, including locomotion and pharyngeal pumping. We hope to test how acute and/or developmental perturbations in cell activity drive functional and behavioral plasticity. Together, these results will help us to understand how normal patterns of cell activity allow for proper development of neural circuits that drive robust, stable behaviors.

Title: Development of spontaneous activity in the larval zebrafish tectum

Authors: *L. AVITAN[1], Z. PUJIC[1], B. SUN[1], E. K. SCOTT[2], G. J. GOODHILL[1,3];
[1]Queensland Brain Inst., The Univ. of Queensland, Brisbane, Australia; [2]The Univ. of

Queensland,, Sch. of Biomed. Sci., Brisbane, Australia; [3]The Univ. of Queensland, Sch. of Mathematics and Physics, Brisbane, Australia

Abstract: Spontaneous patterns of activity in the developing visual system may play an important role in shaping the brain to optimally reflect the statistics of the visual environment. During the period 4-9 dpf (days post-fertilization) larval zebrafish learn to hunt prey, a behaviour critically dependent on the optic tectum. However whether and how spontaneous activity in the tectum evolves over this period is unknown. To address this we performed 2-photon calcium imaging of GCaMP6s unanesthetised, unparalysed zebrafish larvae in the dark for 1 hour at ages 4-9 dpf. We recorded spontaneous activity of ~600 active tectal cells per age (n = 48 fish, an average of 8 fish per age), and found significant changes in activity characteristics over development. From 4 to 5 dpf the frequency of spontaneous activity events in the PVL (periventricular layer) increased, and remained elevated until 8 dpf, when it returned to the same level as 4 dpf. Cells within the neuropil (n=410 total over all ages) segregated both functionally and spatially into two groups with different spontaneous activity profiles. PVL activity took the form of structured assemblies, whose spatial and temporal characteristics also changed over development. Preliminary results indicate a strong role for retinal input in shaping this tectal spontaneous activity, since fish with one eye enucleated showed substantially reduced activity in the enucleated vs normal tectum. Together these findings show that spontaneous activity characteristics in the zebrafish tectum change rapidly over the period in which the animal is learning to process visual stimuli and hunt prey, and that visual experience may play a role in driving these changes.

Title: Role of histone deacetylase 2 (HDAC2) in PV cell circuit development

Authors: *M. LAVERTU JOLIN, T. BADRA, G. DI CRISTO;
CHU Sainte-Justine / Univ. De Montréal, Montreal, QC, Canada

Abstract: Cortical parvalbumin-positive, basket cells (PV cells), a subtype of GABAergic interneurons, innervate hundreds of postsynaptic targets with multiple synapses clustered around the cell body and proximal dendrites. These cells are thought to be particularly important for the generation of gamma oscillations, which in turn regulate many cognitive functions, and for the regulation of developmental cortical plasticity. Although the function of PV cells within cortical networks is being explored extensively, the mechanisms that control the development and plasticity of their extensive arborization and synaptic contacts have not been entirely resolved. Molecular mechanisms involved in synapse formation and strengthening include the activation and repression of specific genes or subsets of genes by stable epigenetic modifications that do not change the genetic code itself. Chromatin remodeling, especially through histone-tail acetylation, which alters the compact chromatin structure and changes the accessibility of DNA to regulatory proteins, is emerging as a fundamental mechanism for regulating gene expression. In particular, Histones Deacetylase 2 (HDAC2) has been shown to regulate excitatory synapse formation and plasticity, and memory formation. Whether HDAC2 affects PV cell synapse development is unknown. Here, we show that HDAC2 is expressed by PV neurons. To dissect the role of HDAC2 in PV cell development *in vivo*, we generated conditional knockout mice by breeding $HDAC2^{lox}$ with PV-Cre mice, which express Cre selectively in PV cells after the second postnatal week. We found that PV expression levels and PV cell perisomatic boutons density is significantly reduced in both the cortex and basal lateral amygdala by P60. We are currently characterizing the cognitive behavior of these mice.

Title: Intrinsic spontaneous network activity in the neonatal mouse olfactory bulb is required for dendrite pruning of mitral cells.

Authors: *M. N. LEIWE[1], S. FUJIMOTO[1], Y. MUROYAMA[2], R. KOBAYAKAWA[3], K. KOBAYAKAWA[3], T. SAITO[2], T. IMAI[1];
[1]Ctr. for Developmental Biol., RIKEN, Kobe, Japan; [2]Dept. of Developmental Biol., Chiba Univ., Chiba, Japan; [3]Inst. of Biomed. Sci., Kansai Med. Univ., Osaka, Japan

Abstract: The correct formation of neural circuits is vital for the function of the brain, and is achieved by both the correct outgrowth and pruning of neurites. In the mouse olfactory bulb (OB), mitral and tufted cells (M/T cells) are the principal output neurons, receiving input from olfactory sensory neurons (OSNs) in the glomerular layer of the OB, and projecting axons to the olfactory cortex. During postnatal development, M/T cells refine their dendrites from connecting to multiple glomeruli (Postnatal days 0-3/4) to a single primary dendrite connecting to a single glomerulus ≥P5). However, the mechanisms of this selective pruning remain unclear.
Our genetic experiments uncovered a critical role for non-sensory (spontaneous) activity in shaping this refinement. Notably, hyperpolarising mitral cells through the expression of the inward rectifying potassium channel Kir2.1 caused mitral cells to retain multiple primary dendrites well beyond the typical pruning period (>P28). Naris occlusion or altering odour sensitivity genetically resulted in no or only a slight delay in refinement.
Although the role of spontaneous activity in circuit refinement is established in visual and auditory circuit development, the nature of spontaneous activity in the olfactory system is unknown. To directly record spontaneous activity in the neonatal mouse OB, we performed two-photon *in vivo* imaging with genetically encoded calcium indicators (GCaMP3/6f) expressed either in M/T cells or OSNs across the early postnatal development (≤P10). Spontaneous activity was present in M/T cells in awake mice, but not in OSNs, suggesting that it is intrinsic to the OB, consistent with our genetic experiments. We also found a significant shift from synchronous to asynchronous firing during postnatal development. Using correlation analyses, we demonstrated synchronous firing at earlier stages (P0-2, stage I), and desynchronized and seemingly random firing at later stages (stage II). Pharmacological experiments on ex-vivo explants revealed that synchronicity is dependent on both synaptic and gap junction connectivity for stage I spontaneous activity, while stage II activity requires GABAergic inhibition. We have also begun to analyse the activity patterns of mutant mice in which dendritic pruning is delayed.
This shift in spontaneous activity patterns occurs prior to dendritic pruning, suggesting that the stage II pattern of intrinsic OB spontaneous activity may be important to initiate the pruning of primary dendrites. Formation of discrete microcircuits by emergent network activity may be an important principle in the formation of mammalian central nervous system.

Title: Major vault protein, a candidate gene in 16p11.2 microdeletion syndrome, is required for homeostatic regulation of cortical plasticity

Authors: *P. IP[1], I. NAGAKURA[1], J. PETRAVICZ[1], J. BENOIT[1], E. A. C. WIEMER[2], M. SUR[1];
[1]Picower Inst. for Learning and Memory, MIT, Cambridge, MA; [2]Inst. of Hematology, Erasmus Univ. Rotterdam, Rotterdam, Netherlands

Abstract: Microdeletion of a region in the chromosome 16p11.2 increases susceptibility to autism and accounts for up to 1% of this population. Although this region contains 29 genes, disrupting only a small piece of this region, which spans 5 genes, is sufficient to cause autistic traits. One candidate gene in this region is the major vault protein (MVP), which has been implicated in the regulation of several cellular processes including transport mechanisms and multidrug resistance. We found that MVP expression levels in MVP Het mice closely phenocopy those of 16p11.2 mice, suggesting MVP Het mice may serve as a model of MVP function in 16p11.2 microdeletion. However, the function of MVP in the central nervous system, in particular its role in brain function and plasticity, has not been investigated. To determine the role of MVP in experience-dependent synaptic and circuit plasticity, we first measured ocular dominance plasticity (ODP) in primary visual cortex (V1). We found that MVP Het mice show impairment in strengthening of open eye responses in V1 after 7 days monocular deprivation (MD), resulting in reduced overall plasticity. Furthermore, electrophysiology experiments showed that the frequency of mEPSCs was decreased in MVP Het mice after 7 days MD, suggesting a decrease in the number of functional synapses, which may underlie the reduced plasticity in MVP Het mice. By a biotin-labeling assay, we found impaired homeostatic upregulation of surface GluA1 in MVP Het mice after longer term MD. To investigate the underlying molecular mechanism, we measured intracellular signaling in MVP WT and MVP Het mice and found ERK activation was significantly increased in MVP MVP Het mice, while activation of other signals such as Akt and JAK were normal. STAT1 is a downstream molecule of JAK signaling and reported to be inhibited by MVP. We found a tendency towards increased

expression of STAT1 in MVP Het mice, suggesting the possibility of MVP inhibition on STAT1. We have previously examined ODP in STAT1 KO mice and shown that they have an accelerated increase in open eye responses and enhanced plasticity after 4 days of MD. These results suggest that MVP may interact with STAT1 to regulate plasticity, and one function of MVP may be to negatively regulate STAT1. Collectively, we find a highly specific role for MVP as a critical molecule in the homeostatic or response-restoring component of activity-dependent synaptic plasticity. Thus, this study helps reveal a new mechanism for an autism-related gene in brain function, and suggests a broader role for neuro-immune interactions in circuit level plasticity.

Abstract: The specificity of synaptic connections is fundamental for proper neural circuit function. Here we show that cortical excitatory neurons that arise from the same neural stem cell and reside within the same layer preferentially establish reciprocal synaptic connections, guided by molecular cues predetermined by epigenetic regulation during embryonic development. We observed a transient increase in synaptic connections between clonal but not nonclonal neuron pairs postnatally, followed by selective stabilization of the reciprocal connections between clonal neuron pairs. This lineage-dependent connective reciprocity was abolished in clonal cells lacking DNA methyltransferase 3b (Dnmt3b), which determines DNA-methylation patterns of genes in stem cells during early corticogenesis. A similar abolishment of reciprocity was observed in clonal neurons lacking clustered protocadherin (cPcdh), adhesion molecules involved in cell-cell

interactions. Dnmt3b regulated the postnatal expression of cPcdh isoforms. Our findings suggest that the Dnmt3b-mediated epigenetic regulation of cPcdh expression enables clonal neurons to establish cell-lineage-specific reciprocal connections.

Title: The regulatory roles of perineuronal semaphorin 3A and chondroitin sulfates on the developing vestibular circuitry

Authors: *D. K.-Y. SHUM[1,2], P. Y. KWAN[1], C. W. MA[1], Y. S. CHAN[1,2];
[1]Sch. of Biomedic. Sci., Fac. Med., Univ. Hong Kong, Hong Kong, China; [2]Res. Ctr. of Heart, Brain, Hormone and Healthy Aging, Fac. Med., Univ. Hong Kong, Hong Kong, China

Abstract: Perineuronal nets (PN) are crucial for restricting neuronal plasticity during development. Our study of the central vestibular nucleus (VN) found consolidation of PN around GABAergic interneurons as from postnatal day (P)9 of Sprague Dawley (SD) rats. This was accompanied by progressive localization of semaphorin 3A (Sema3A) to chondroitin sulphate moieties (CS) of PN. We hypothesized that PN-CS binding of Sema3A limits the action of Sema3A as a plasticity-inducing factor in the VN. We tested for structural plasticity in VN explant cultures (P3+up to 31DIV) following treatment with chondroitinase ABC (ChABC) and/or Sema3A. Parallel cultures were fixed for assessment of neurite arborization and growth. Compared with null treatment controls, increase in these parameters suggested involvement of CS and Sema3A in controlling structural plasticity of VN neurons. To study the impact of PN-CS/Sema3A at the circuit level, the rats were assessed for the emergence of negative geotaxis as a read-out for maturation of the circuit for graviception. We observed negative geotaxis as early as P9, in correlation with consolidation of PN around GABAergic neurons in the VN. ChABC/Sema3A-treated rats showed delayed display of negative geotaxis, similar to effects of bicuculline but contrasting those of muscimol. The delay also correlated with postponed formation of PN after ChABC treatment, revealing that disturbance of PN consolidation

interfered with maturation of the vestibular circuitry for graviception. We further performed whole-cell patch-clamp recordings of miniature excitatory post-synaptic current (mEPSC) from VN interneurons of P7/P9 rats, control versusthose treated with ChABC and Sema3A. We found increase in frequency of mEPSCs, suggesting strengthening of presynaptic signals along extended lengths of dendrites of interneurons in the ChABC/Sema3A-treated VN circuit. Our results provide evidence for the role of PN-CS-Sema3A in controlling structural and circuit plasticity at the interneuron level with impacts on the developmental display of graviceptive behaviour. Title: Differential effects of decreasing excitatory inputs on excitatory and inhibitory neurons

Authors: *H. HE[1], W. SHEN[2], H. CLINE[1];
[1]The Scripps Res. Inst., LA Jolla, CA; [2]Inst. of Developmental and Regenerative Biology, Col. of Life and Envrn. Sci., Hangzhou Normal Univ., Hangzhou, China

Abstract: AMPARs are the major receptors mediating fast excitatory synaptic transmission in the CNS. Trafficking of AMPARs to and from synapses plays pivotal roles in the excitatory neural transmission, thus affecting synaptic plasticity, structural plasticity, circuit function and behavior. Here, we studied the role of AMPAR-mediated fast excitatory synaptic transmission by expressing peptides corresponding to the C-terminus of GluA1 or GluA2 subunits (called GluA1 and GluA2 CTPs) in optic tectal neurons in Xenopus laevis tadpoles. In contrast to the effect of the disruption of inhibitory inputs, which significantly disrupts the E/I of visually-evoked synaptic inputs onto the postsynaptic neurons (Shen et al., 2011), GluA CTPs decreased both spontaneous and visually-evoked EPSC and IPSC onto tectal neurons. As a result, the E/I balance was unchanged. Nonetheless, the neuronal receptive field properties and the visually-guided avoidance behavior of the animals were all affected by the expression of GluA-CTPs. To

dissect the effect of disruption of excitatory inputs on excitatory versus inhibitory neurons respectively, we used time-lapse in vivo imaging to evaluate the effects of GluA CTP expression on dendritic arbor growth and experience-dependent structural plasticity in tectal neurons combined with posthoc GABA immunostaining to determine the identity (excitatory or inhibitory) of imaged neurons. The dendritic arbor structures of excitatory and inhibitory neurons were differentially affected by the disruption of excitatory inputs and demonstrated distinctive changes in experience-dependent structural plasticity as assayed by a two-part visual manipulation paradigm (4hrs of dark vs. 4hrs of enhanced visual stimulation). In particular, the excitatory neurons showed decreased dendritic branch density and mostly abolished their response to experience-potentiated dendritic arbor growth as results of expression of either GluA1-CTP or GluA2-CTP. On the other hand, inhibitory neurons did not exhibit significant change in the overall dendritic arbor morphometric parameters to expression of GluA1-CTP, while expression of GluA2 CTP modestly increased the total dendritic length and total branch tip number without changing branch density. Importantly, the bi-modal experience-dependent plasticity that has been observed in tectal inhibitory neurons (He et al., 2016) were disrupted by the disruption of excitatory inputs. These studies suggested differential effects of decreasing AMPAR-mediated fast excitatory synaptic transmission on structural plasticity in inhibitory and excitatory neurons.

Title: The NuRD chromatin remodeling complex drives neural circuit development *In vivo*

Authors: ***K. K. HILL**[1], Y. YANG[1], T. YAMADA[2,1], T. E. HOLY[1], A. BONNI[1];
[1]Washington Univ. Sch. of Med., Saint Louis, MO; [2]Univ. of Tsukuba, Tsukuba, Japan

Abstract: Chromatin remodeling enzymes are thought to play key roles in brain development, but their relevance to in vivo neural circuit function remains poorly understood. We have

identified a role for the nucleosome remodeling and deacetylase (NuRD) chromatin remodeling complex in dendrite morphogenesis in granule neurons of the mouse cerebellar cortex. Conditional knockout of the core NuRD subunit, Chd4, impairs granule neuron dendrite pruning in vivo. To uncover the function of the NuRD complex in neural circuit function, we developed a technique for in vivo imaging of awake behaving mouse pups. Two-photon calcium imaging of head-fixed juvenile mice walking on a motorized treadmill reveals a sub-population of cerebellar granule neurons that is stimulus-responsive. Remarkably, conditional knockout of Chd4 results in hyperresponsivity of granule neurons to the sensorimotor treadmill stimulus. Our findings suggest the NuRD chromatin remodeling complex drives dendrite morphogenesis and sparse sensorimotor encoding in the cerebellum.

Title: Developmental switch in striatal adaptation to cortical hyperactivity

Authors: *R. PEIXOTO, W. WANG, J. LEVASSEUR, B. SABATINI;
Harvard Med. Sch., Boston, MA

Abstract: Despite the implication of basal ganglia (BG) dysfunction in multiple neurodevelopmental disorders the rules underlying the maturation of BG circuits remain poorly understood. Our previous work has shown that afferent activity is a major driver of glutamatergic synaptogenesis in striatal spiny projection neurons (SPNs) suggesting that perturbations of cortical activity during early postnatal stages can alter the normal development of corticostriatal circuits. Indeed, mice lacking Shank3 isoforms ($Shank3B^{-/-}$) exhibit increased corticostriatal network activity during the second postnatal week resulting in accelerated maturation of excitatory synapse development in SPNs. However, this early phenotype is opposite to the one observed in adult animals that exhibit depressed corticostriatal connectivity instead. To explore the causes underlying these phenotypic differences we tested how SPNs respond to increased

cortical activity during different stages of development and manipulated cortical activity by silencing cortical interneuron output via Cre-dependent deletion of the vesicular GABA transporter (vGAT). Interestingly, we found that chronic elevation of cortical activity from early postnatal stages recapitulates the phenotype found in Shank3B$^{-/-}$ animals, with increased connectivity early on and a subsequent reduction in adult stages. Moreover, elevation of cortical activity during adulthood for one week (P53-P60) was sufficient to depress corticostriatal connectivity whereas activation of the Gi-coupled DREADD hM4Di in layer 5 cortical neurons of adult Shank3B$^{-/-}$ mice partially rescued the corticostriatal depression found in adulthood. Together these results reveal distinct and dynamic adaptations of SPNs to cortical hyperactivity during different developmental stages and suggest that the abnormal developmental trajectory of corticostriatal connectivity caused by loss of Shank3 is caused by persistent cortical hyperactivity.

Title: Exploring the role of p75NTR signaling pathway on GABAergic circuit maturation following neonatal hypoxia induced seizure

Authors: B. CHATTOPADHYAYA, M. BERRYER, D. DUFOUR-BERGERON, N. SANON, C. BOSOI, L. CARMANT, *G. DI CRISTO;
Res. Ctr., CHU Ste.justine-University of Montreal, Montreal, QC, Canada

Abstract: Perinatal hypoxic-ischemic encephalopathy is the most important cause of acute mortality and morbidity in newborns. The most common acute effect of hypoxic-ischemic encephalopathy is neonatal seizures, which are very often refractory to conventional seizure medications. Hypoxia-induced seizures (HIS) are associated with a high incidence of epilepsy as well as cognitive disabilities later in life. Despite the significant long-term morbidity of HIS in the neonates, there is currently no specific treatment. Further, our understanding of how HIS

changes the developmental trajectory of neuronal circuit development, and ultimately results in cognitive dysfunction, is still mostly unknown. Understanding the precise mechanisms by which HIS affects brain development, and how its effects can be ameliorated, can help us in designing the appropriate therapeutic approaches towards preventing the consequences of neonatal hypoxia.
Using a combination of molecular tools, electrophysiological recordings and imaging techniques, we studied the affects of HIS particularly on inhibitory GABAergic synapse development in rodent neocortex. We determined that HIS affects the maturation of distinct GABAergic interneuron populations, parvalbumin (PV)-positive and somatostatin (SOM)-positive interneurons differentially in the neocortex and in the hippocampus. In particular, we show that PV expressing interneurons in the neocortex remain immature. This correlates with a reduction in gamma oscillation power during exploration, and with impaired working memory and social novelty recognition. We are currently investigating the molecular mechanisms involved, specifically looking at the role of neurotrophin receptor (p75NTR) mediated signaling pathways in ameliorating the deficits induced by HIS on GABAergic circuit development.
All together, the knowledge we will gain from these experiments will pave the way for developing novel, targeted pharmacological interventions to prevent the severe and lasting consequences of perinatal HIS.

Title: T-cadherin/Cdh13 expressed by hippocampal interneuron populations affects synaptic activity and memory

Authors: *J. LIU[1], H. BADIE-MAHDAVI[2], A. ROBERTS[3], J. SANES[4], B. RANSCHT[2]; [1]Sanford Burnham Prebys Med. Discovery Inst., LA Jolla, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., La Jolla, CA; [3]The Scripps Res. Inst., La Jolla, CA; [4]Harvard Univ., Cambridge, MA

Abstract: A growing body of evidence implicates cell surface glycoproteins in regulating synapse formation, stability and function in the central nervous system (CNS). Glycosylphosphatidylinositol-linked T-cadherin (T for truncated; also Cadherin-13; *Cdh13*) is prominent in diverse structures of the CNS. Variations in the human *CDH13* gene have been associated with neuropsychiatric disorders, including addiction, bipolar-, autism spectrum- and attention deficit hyperactivity disorders. Mice generated to systemically lack Cdh13 gene expression show no overt neurological phenotypes under baseline conditions but display alterations in cue-based memory. In the hippocampus, T-cadherin immunoreactivity delineated pyramidal cell dendritic fields in stratum radiatum and lacunosum moleculare and the dendritic fields of dentate granule neurons. This pattern was reiterated in $Cdh13^{Cre};Rosa26^{LSL\text{-}tdTomato}$ reporter mice expressing the red fluorescent protein by recombination with Cre expressed in place of the first *Cdh13* coding exon. The tamoxifen-inducible reporter strain was used to determine the neuron populations expressing T-cadherin during hippocampal development. At all stages examined, reporter fluorescence was induced in $GAD67^{+}$ and $VGAT^{+}$ interneurons while neurons classified as excitatory did not show the red fluorescent protein marker. Sub-populations of interneurons expressing T-cadherin were further classified. In adult mice, $Cdh13^{Cre};Rosa26^{LSL\text{-}tdTomato}$ fluorescence was observed in interneurons expressing somatostatin $(SST)^{+}$ and vasoactive intestinal polypeptide (VIP), but not in major populations of other interneuron types. We could not discern $Cdh13^{Cre};Rosa26^{LSL\text{-}tdTomato}$ expression in association with CA1 pyramidal neurons at any postnatal stage examined. In acutely prepared brain slices from mice systemically lacking T-cadherin, CA1 pyramidal cell dendritic spines were reduced in number, and fewer spines reached maturity. This correlated with significant reductions in synaptic transmission and CA1 long-term potentiation. Our data suggest that T-cadherin regulates maturation/function of interneuron populations intrinsic to the hippocampus and thereby modulates pyramidal neuron synaptic activity associated with aspects of hippocampal-based memory formation, processing or retrieval.

Title: Gap junctions in early postnatal excitatory neurons regulate spine density and maturation of response reliability

Authors: *K. HAYASHI, K. OHKI;
The Univ. of Tokyo, Tokyo, Japan

Abstract: Gap junctions in neocortex excitatory neurons have been demonstrated to interconnect the cells only during the development stage and enable propagation of electrical activity and small molecules and are suggested to have essential roles in the development of neuronal circuits. However, the roles of gap junctions in the development of neuronal circuits have remained to be elucidated, mainly due to technical difficulties in regulating the expression of gap junctions without affecting migration of neurons to the cortical plate.
Here we achieved Tet-inducible knockdown (KD) of connexin-43 only during the early postnatal stage to avoid the effect of connexin-43 KD on the migration of neurons. The KD vector was transfected to V1 by *in utero* electroporation at E15.5 to induce the shRNA expression in layer 2/3 excitatory cells, and the mice were administered with Dox to repress the expression of the shRNA with an exception of a developing period from P2 to P14. We found that connexin-43 KD significantly decreased spine density of KD neurons. Further, we examined visual functions of connexin-43 KD neurons by using *in vivo* two photon calcium imaging. We found that connexin-43 KD resulted in sharper orientation selectivity. Furthermore, we found that reliability of the visual response was decreased by the KD. The higher visual selectivity and the lower response reliability in connexin-43 KD neurons may be attributable to a decrease in spine density. These results suggest that connexin-43 before visual experiences is essential for neuronal circuitry development and regulates the spine density for reliable computation.

Title: A role of presenilin in the developing visual circuit of Xenopus tadpole

Authors: *Z. LIU[1], A. M. THAKAR[2], K. G. PRATT[2];
[2]Zoology and Physiology, Program in Neurosci., [1]Univ. of Wyoming, Laramie, WY

Abstract: Presenilin (PS) is an interesting molecule that was first identified, and named, in the context of Alzheimer's disease, but is now known to carry out a myriad of functions that are important during development. As the catalytic component of γ-secretase, PS is responsible for cleaving a wide range of substrates that are crucial for many phases of nervous system development, including neurogenesis, differentiation, and axon guidance. This suggests a global and multifaceted role for this molecule in the development of neural circuits. Here, to provide a comprehensive understanding of the roles PS plays in circuit development we use the Xenopus tadpole retinotectal projection as our model. This projection is the major component of the amphibian visual system. This model system allows for the function of a protein to be characterized across all stages of neural circuit development at the cell, circuit, and behavioral levels. First, western blot studies confirmed that PS is expressed in the tadpole optic tectum during the time when the retinotectal circuit is forming. To test the role of PS during the development of this circuit, PS function was inhibited globally by adding the PS blocker L685,458 (5μM) to the tadpoles' rearing solution during development, or by electroporating a PS morpholino into the tectum to knock down PS expression specifically in the postsynaptic tectal neurons. We found that blocking PS function using either of these approaches significantly compromised visual avoidance behavior, which was quantified using an established moving dot test (control: 65.6% ± 5.9%, n=25; PS morpholino: 33.3% ± 4.9%, n=30). This suggests deficits in visual system function. To further identify the underlying pathology at the circuit level, we performed in-vivo whole cell electrophysiological recordings from PS-inhibited neurons. We found that PS morpholino-transfected neurons displayed significantly decreased peak current amplitudes in response to light-activated RGC input (control: 72.07 ± 11.01 pA, n=15; PS morpholino: 28.87±3.43 pA, n=16) while passive electrical properties such as resting membrane potential, input resistance, and capacitance were unchanged compared to control. This indicates that the decreased light responses could be due to compromised synaptic transmission. Preliminary data shows a modest yet significant increase in paired-pulse facilitation at the retinotectal synapse, indicating decreased probability of presynaptic transmitter release. Thus far, our results suggest a role for PS in the normal development and function of the tadpole visual system.

Title: Cortical layer 6b neurons selectively innervate higher order nuclei in the thalamus

Authors: A. HOERDER-SUABEDISSEN[1], *A. L. UPTON[1], E. L. GRANT[1], K. V. KORRELL[1], S. VISWANATHAN[2,3], P. O. KANOLD[2], Y. KIM[4], Z. MOLNAR[1];

Abstract: We studied the targeting of layer 6b projections to the thalamus by using a transgenic mouse line (Drd1a-Cre). The cortical Cre expression is selective to layer 6b and starts from early postnatal ages and continues to adulthood. The labelled cortical neurons in the Drd1a-Cre::tdTomato line show an antero-posterior and medio-lateral gradient of expression level. 15%±7 (mean±s.d.) of NeuN expressing neurons in layer 6b is labelled by Drd1a-Cre::tdTomato in S1 at P8. The labelled neurons are immunoreactive for Ctgf, neuroserpin and Cplx3. They do not co-localise with Lpar1-eGFP labelled subplate cells in triple transgenic mice. Using the Drd1a-Cre::tdTomato mouse we studied the targeting of the layer 6b projections from the entire cortical mantle to the thalamus and established that these projections selectively innervate the higher order thalamic nuclei (including PO, LP). This is similar to layer 5 thalamic projections, and in contrast to layer 6a. No labelled projections were found contributing to the corpus callosum. Using Cre-dependent eYFP expressing AAV virus tracing from S1 revealed that layer 6b neurons from this region project to PO, whereas those from M1 do not. We used serial two-photon tomography based whole brain imaging in cellular resolution and quantified axonal projection pattern in the entire brain. The morphology and size of the terminals was compared

with 6a and layer 5 thalamic terminals. The layer 6b subcortical projections do not form branches in thalamic reticular nucleus, similar to layer 5 projections. Our finding that layer6b projections selectively target higher order thalamic nuclei and develop a similar thalamic innervation pattern to layer 5 is an unexpected and novel discovery that has to be integrated into the current schemes of thalamocortical communication systems. Title: Roles of Celsr3 in central projections of dorsal root ganglion neurons

Authors: ***W. FEIFEI**[1], L. ZHOU[2];
[1]Guangdong-hongkong-Macau Inst. of CNS Regene, Guangdong, China; [2]Guangdong-Hongkong-Macau Inst. of CNS Regeneration,Jinan Univ., Guangzhou, China

Abstract: Dorsal root ganglion (DRG) neurons relay nociceptive and thermoceptive, mechanoreceptive, and proprioceptive information to the central nervous system via different afferent axons. Different central projections establish interactions with different targets in the spinal cord, such as large proprioceptice fibers transiently synapse with the spinal motoneuorns at early development. Atypical cadherein *Celsr3* plays a critical role in brain wiring including forebrain, hippocampus and spinal cord. *Celsr3* mRNA is highly expressed in the DRGs, but its function in the central projections of DRGs is still not known. Here we study this issue by inactivating *Celsr3* in DRGs with *Wnt1-Cre*. Using *Celsr3-GFP* transgenic mice, *Celsr3* is identified to be expressed in different DRG cells. Upon Wnt1-Cre activation, *Celsr3* is conditionally removed in DRG cells and some sensory neurons in the dosal spinal cord. In *Wnt1-Cre;Celsr3*$^{f/-}$ mutants, the sensory process is abnormal; the distribution of central projections of DRG neurons is studied using DiI tracing and immunostaining and showed different from the control samples. Furthermore, Transient synapses between Ia afferent fibers and spinal

motoneurons behave somewhat abnormalities in the mutant. In conclusion, *Celsr3* is involved in axonal targeting of the DRGs in mice.

Title: Early GABAergic microcircuits and cortical dynamics

Authors: *L. MODOL VIDAL[1], V. SOUSA[2], A. MALVACHE[2], T. TRESSARD[2], A. BAUDE[2], R. COSSART[2];
[1]INMED, INSERM U901, marseille, France; [2]INMED, Inserm, Marseille, France

Abstract: The onset of electrical activity in a developing neural network is characterized by the acquisition of spontaneous oscillatory coordinated activity between large numbers of maturing neurons. Such coordinated neuronal activities play a pivotal role in the assembly of neuronal circuits and are characteristic of most developing neural systems as they have been observed in a wide array of peripheral and central tissues. Therefore, to understand how neural circuits form in the normal and pathological brain it is essential to understand the molecular and cellular mechanisms of synchronization in maturing cortical networks. Functional maturation of GABAergic neurons has been described to shape cortical dynamics, plasticity and synaptic wiring during the course of pre- and -postnatal development. For instance, the emergence of Giant Depolarizing Potentials (GDPs) has been shown to be driven by GABAergic transmission . Although GDP appearance has been described to depend on long-range GABA ‘‘hub’’ neurons (high functional connected neurons) in the hippocampus and to be responsible to orchestrate synchrony of hippocampal development nothing is known concerning their role in the maturation of the neocortex. This is an important issue given that both structures share common developmental programs including a similar sequence for the emergence of population coherence, but also since recent evidence indicates important differences especially regarding the origin of GABAergic neuron diversity. Therefore, understanding the function of these GABA hub neurons and their origin is a hallmark to elucidate mechanisms underlying cortical

maturation. To this aim, we have applied a multidisciplinary strategy to our experiments including functional multineuron calcium imaging *in vitro* and *in vivo*, online computational analysis and electrophysiology, as well as mouse genetics in order to approach and to analyse the changes in cortical activity during the maturation of mammalian cortical networks.

Title: Genetic and epigenetic regulation of the cortical phenotype: The effects of early bilateral enucleation on epigenetic and genetic modifications in developing neocortex

Authors: K. FOREMAN[1], D. RAMAMURTHY[2], C. WELLER[2], L. A. KRUBITZER[2], *D. S. STOLZENBERG[1];
[1]Psychology, [2]Ctr. for Neurosci., Univ. of California Davis, Davis, CA

Abstract: Early experience plays a critical role in the development of the nervous system, particularly the neocortex. For example, early exposure to persistent sensory stimuli, or loss of sensory inputs critically impacts cortical map formation and connectivity of cortical fields. While the types of modifications to the neocortex that occur when sensory input is altered during development have been well described, the underlying mechanisms that give rise to these changes are not well understood. In the current investigation we utilized a unique animal model, the small South American short-tailed opossum (*Monodelphis domestica*), to examine how early and complete loss of vision alters the expression pattern of genes involved in the formation of cortical fields and cortical connections. Importantly, the opossum is born extremely immature, so that bilateral enucleations can be made well before the retinal ganglion cells have reached the diencephalon and before thalamocortical axons have reached their targets in the neocortex. Thus, using this model organism we can examine how this very early loss of vision alters the expression of key genes involved in axonal guidance, cortical arealization, and cortical

connectivity within primary somatosensory and visual cortices at several key developmental stages. In these studies, *Monodelphis domestica* were bilaterally enucleated at P4 (equivalent to embryonic day 15 in mice) and the effects of this manipulation were examined just after eye opening (P36). The expression of several genes (*Ephrin A5, COUP-TF1, RZRβ, ID2, Cad8,* and *EphA7*) was measured by real-time qPCR from microdissected primary somatosensory and visual cortical tissue. All microdissections were histologically verified. As a first step toward understanding the mechanisms through which early sensory experience helps construct the developing cortex, we also examine epigenetic modifications that may function to program the expression of these genes involved in directing cortical development and connectivity.

Title: Comparison of postnatal cortical development between primary auditory and somatosensory cortexes in the mouse

Authors: *M. CHANG, S. ISHIZAWA, H. D. KAWAI;
Dept. of Bioinformatics, Soka Univ., Hachioji, Tokyo, Japan

Abstract: Sensory cortices are considered to possess similar laminar architecture, however earlier studies by Andersen et al. (*Brain Res*., 1252, 130-142, 2009) had suggested that primary auditory cortex (A1) might differ from primary somatosensory and visual cortexes (S1 and V1) based on the staining pattern observed using cytochrome oxidase and acetylcholinesterase. In the past, we lacked information that could help us define each layer and neuronal subtypes using specific genetic markers. However, today, such information is available for some of the genes (Molyneaux et al., *Nat. Rev. Neurosci.*, 8, 427-437, 2007).
In this experiment, we used different specific lamina markers to study the lamination between A1 and S1 during postnatal development. We used antibodies against Cut-like homeobox 1 (Cux1), COUP-TF-interacting protein 2 (Ctip2), and Forkhead-box protein 2 (Foxp2) to identify layers 2-4, 5, and layer 6, respectively. The results show that the lamination between the two cortices were significantly different. At postnatal day (PD) 5, the cortical proportion of layer 5 and that of layer 6 were ~15% wider and ~10% narrower in presumed A1 compared to presumed S1, respectively. This contrasting proportional difference remained throughout development until

the adulthood. Thus, from PD 10 through PD 60, layer 5 proportion was ~13% wider in A1 compared to S1. The difference in layer 6 proportion became slightly smaller with ~7% narrower laminar thickness in A1 than S1. The proportion of layers 2-4 was ~10% narrower in A1 compared to S1.
Ctip-2 immunopositive cells, which are reportedly subcortical projecting neurons, were distributed sparsely in A1 at any ages, while they distributed more homogeneously in the lower portion of layer 5 in S1. Retrograde labeling of neurons projecting to contralateral A1 (cA1) and ipsilateral inferior colliculus (iIC) indicated that the labeled neurons were intermingled in layer 5 of A1. Some of the commisural A1 projection neurons were also present in FoxP2-defined layer 6. iIC projection neurons were located in layer 5 with Ctip2-positive neurons below the upper layers defined by Cux1 and above layer 6 defined by Foxp2.
Our studies suggest that laminar thickness and projection neuron distributions in A1 differ from those in S1.

Title: Anatomical, molecular and functional characterization of rhombomere 4-derived sensorimotor sub-circuits in the mouse brainstem

Authors: ***M. DI BONITO**, E. SETTI, M. STUDER;
iBV Inst. de Biologie Valrose, CNRS UMR7277, Inserm U1091, UNS Univ. Nice Sophia Antipolis, Nice, France

Abstract: Neuronal networks relay sensory information and process motor responses to control vital functions. The sensorimotor circuits are established during development and depend on spatially- and temporally-ordered sequence of neuronal specification, migration and connectivity. Cell lineage studies have started to correlate early rhombomeric subdivisions to adult neuronal connectivity maps in the brainstem demonstrating that regional patterning along the anteroposterior (AP) axis and neuronal subtype specification along the dorsoventral (DV) axis intersect to specify neuronal fates. *Hox* genes, besides conferring AP identity during hindbrain segmentation, regulate the specification, the stereotypic neuronal migration and axon

pathfinding as well as topographic connectivity of different sensorimotor neurons along the DV axis in a rhombomere-specific manner. We have used a *b1r4-Cre* mouse line to genetically label rhombomere 4 (r4) and followed all r4-derived neuronal populations and axonal tracts at different stages from their embryonic origin to the adult final location and targets. We have demonstrated that a rhombomere-specific *Hox* code controls the assembly of distinct functionally segregated sub-circuits in the developing auditory brainstem. R4 contributes to the majority of the auditory nuclei required for sound transmission and amplification, and to the establishment of two efferent feedback sub-circuits involved in the protection from acoustic overstimulation. In the vestibular system, r4 gives rise mainly to the vestibulospinal projection neurons and in particular to the lateral vestibulospinal tract, the principal pathway that conveys vestibular information to limb-related spinal motor circuits. Moreover, r4 contributes to the specific topographic trigeminal pathway to the thalamus associated with the r4-derived spinal trigeminal oral sub-nucleus. In this study, we use a novel *r4-Flippase* mouse and several subtype-specific *Cre-recombinase* lines of different DV domains to characterize by intersectional fate mapping the specific contribution of r4 sub-domains to distinct sensorimotor systems. The intersectional genetic strategy will enable to label and capture selected neuronal populations and to identify, through genomic approaches, novel factors of single rhombomere-specific DV domains. Our overall aim is to dissect the molecular and cellular mechanisms allowing proper cell fate specification, migration and connectivity of sensorimotor neurons originating from rhombomere 4.

Title: Dynamic changes in brain network activation during emotional face processing in the developing brain

Authors: ***C. STAMOULIS**[1], P. DINARDO[3], A. WESTERLUND[3], C. A. NELSON, III[2]; [2]Developmental Med., [1]Harvard Med. Sch., Boston, MA; [3]Developmental Med., Boston Children's Hosp., Boston, MA

Abstract: There is substantial evidence that adult brains are organized into parsimonious and optimally connected small-world and scale-free networks, which facilitate efficient processing of sensory information and cognitive performance. In contrast, little is known about the dynamic development of these networks in early life, their progressive optimization and neural computation across incompletely myelinated and redundantly connected circuits. Furthermore, there is limited systematic evidence that core networks, which are involved in cognitive function that is critical for survival, may develop at distinct rates from those involved in higher-level function. Using longitudinally acquired electrophysiological (EEG) data measured at <12 months and 36 months from 58 typically developing infants, this study investigated changes in the organization of distributed functional network activation in response to emotionally salient faces (happy, angry, fearful and neutral (only at 36 months)) during early development. A significant increase in network connectivity in response to fearful faces (compared to happy and angry faces) was estimated both at <12 months ($p<0.001$) and 36 months ($p<0.01$) across neural oscillations. This indicates that the mechanisms underlying network activation in response to fear may be in place at birth or the first few months of life. However, differential clustering in connectivity was also estimated in oscillation-specific networks, including higher connectivity in frontal areas in the gamma network and higher connectivity in parieto-occipital areas in the alpha network. A significant decrease in the number of network connections was estimated from <12 to 36 months across oscillations ($p<0.001$). Finally the lowest number of network connections was estimated in response to neutral faces ($p<0.0001$). These findings suggest that differential network activation in response to fearful faces occurs as early as 5 months and persists consistently during the first 3 years of life, although functional network topologies change dynamically during this period becoming increasingly sparse and clustered in a frequency-specific manner.

Title: Theoretical models of visual map alignment in the superior colliculus.

Authors: *R. A. TIKIDJI-HAMBURYAN[1], T. EL-GHAZAWI[2], J. W. TRIPLETT[3];
[1]Inst. of Massively Parallel Application and Computer Technology, Sch. of E, [2]Sch. of Engin. and Applied Sci., George Washington Univ., Washington, DC; [3]Ctr. for Neurosci. Res., Children's Natl. Hlth. Syst., Washington, DC

Abstract: In the visual system, neuronal connections are organized topographically to preserve the spatial order of the visual scene. In associative visual centers, topographic projections from multiple areas must be aligned to facilitate integration. However, the mechanisms by which alignment is achieved remain poorly understood. The superior colliculus (SC) integrates visual inputs from retinal ganglion cells (RGCs) and Layer 5 neurons of the primary visual cortex (L5-V1), each of which are organized topographically and in register with one another. Previous studies suggest that RGCs instruct L5-V1 alignment in a manner dependent on spontaneous retinal activity, however, the underlying mechanism of activity-dependent instruction remains unclear. To explore possible mechanisms and generate testable hypothesis, we have developed novel computational framework to describe visual map alignment in the SC. Similar to existing models of retinocollicular map formation, our model of alignment consists of three major components: chemoaffinity (interaction between Ephin-A/B and Eph-A/B), axon competition and activity dependent plasticity. We were able to adopt existing chemoaffinity and axon competition components with subtle changes to replicate *in vivo* organization of L5-V1 inputs. To explore the mechanism of activity-dependent alignment, we developed two models, each of which are able to replicate *in vivo* experimental findings. The first model is based on assumption that spiking activity of SC neurons is driven exclusively by RGC inputs, with no contribution from V1 axon activity. This model effectively simulates map alignment under wild type (WT) conditions, as well as under conditions in which the retinal map is duplicated, as in *Islet2-EphA3* knock-in mice ($Isl2^{EphA3}$) and disruption of retinal activity, as in mice lacking the beta2 subunit of the nicotinic acetylcholine receptor ($\beta2^{-/-}$). However, this model fails to replicate *in vivo* findings in combination $Isl2^{EphA3}/\beta2^{-/-}$ mice unless the spatial correlation parameter is increased 7-fold over reported values in the retina. In a second model, we assumed that SC neurons are driven by both RGCs and V1 inputs, but RGCs inputs significantly stronger. Remarkably, this model is able to simulate L5-V1 projection patterns in the SC of WT, $Isl2^{EphA3}$, $\beta2^{-/-}$ and $Isl2^{EphA3}/\beta2^{-/-}$ mice with minimum additional assumptions. We then used embarrassingly parallel computing on 1048 cores cluster to study robustness of both models. These novel computational models of visual map alignment in the SC suggest an activity-dependent mechanism of map alignment in which V1 inputs contribute to SC spiking activity during development.

Title: Distinct developmental patterns in attentional selection and suppression

Authors: *E. WANG[1], M. SUN[1], Y. TAO[1], J. HUANG[1], L. SUN[2], Y. SONG[1];
[1]State Key Lab. of Cognitive Neurosci. and Learning, Beijing Normal Univ., Beijing, China;
[2]Peking Univ. Sixth Hosp. / Inst. of Mental Hlth., Beijing, China

Abstract: Searching through a visual scene requires a number of complex processes, such as covert spatial attention, which must be utilized to enhance processing of the attended items while simultaneously irrelevant items must be ignored. Although covert visual spatial attention is very important in many everyday situations, little is known about whether and how covert spatial attention differs in children compared to adults. The current study sought to identify the neurophysiological bases of development in covert spatial attention, focusing on electroencephalographic (EEG) markers of attentional selection (N2pc) and suppression (P_D). EEG data were collected from healthy young adults (aged 20-28 years) and typically developing children (ages 9-15 years), while they searched for a shape singleton target either with the absence (Experiment 1) or presence (Experiment 2) of a task-irrelevant color singleton distractor. The results showed that the shape target elicited a prolonged and smaller N2pc in children (n = 25) compared to adults (n = 28) in Experiment 1, and the N2pc delay might be caused by the early P1 component. Moreover, the target-elicited N2pc was followed by a similar positivity in both children and adults. In Experiment 2, we replicate the reduced target-elicited N2pc in children. Counterintuitively, the salient-but-irrelevant color distractor elicit a larger P_D in children (n = 22) than in adults (n = 31). We found no evidence for a correlation between the reduced target-elicited N2pc and the increased distractor-elicit P_D in children. Our results provide neurophysiological evidence that covert spatial attention in children of 9-15 years old is still undergoing significant development. Compared to adults, children deploy insufficient attention resources to the targets and use more attentional suppression to resist to the silent-but-irrelevant distractors. However, the development of target selection and distractor suppression might depend on distinct cognitive mechanisms.

Title: Calibration of visual map through bimodal NMDAR signal

Authors: *M. HIRAMOTO[1], H. CLINE[2];
[1]Mol. & Cell. Neurosci., [2]The Scripps Res. Inst., San Diego, CA

Abstract: The optical axis in the eyes varies between individuals, however, the anteroposterior axis of the visual field map in the brain precisely matches the spatial axis of the outer world. It suggests that sensory experience calibrates the antero-posterial axis of the visual field map. The anteroposterior perception is a feature of the bilaterally-symmetric animals. It predicts that the anteroposterior axis in the visual field map is calibrated utilizing some features of the bilaterally-symmetric animals. We previously found that the forward-directed optic flow, unique to the bilaterally-symmetric, calibrates the anteroposterior organization in the visual field map. In the mechanism, the retinal ganglion axons (RGCs) activated earlier are connected to the cells in the brain that perceive anterior vision. Thus, the anterior-posterior axis in the space is transformed into the sequential order of RGC activities, which is further transformed into the sequential projection of RGC axons, in a Spatial-Temporal-Spatial (STS) transformation manner. This temporo-spatial linkage reflects the natural situation in which objects in the optic flow move in the anterior to posterior direction Hiramoto & Cline, 2014). NMDARs are a key molecule that converts the sequential order of synaptic transmission into the directionality of synaptic plasticity through its bimodal properties, suggesting that NMDAR activity is a core event that links the sequential order of retinotectal synaptic transmission with the directionality of RGC axon movement. To test this, we stimulated two groups of RGC axons in a sequence and analyzed the retinotectal axon branch tip shifts in the tectum while manipulating NMDAR activity. We found that attenuating NMDAR inverts the directionality of branch shift induced by temporally ordered convergent inputs. This shows the role of NMDAR in the transformation of the sequential order of afferent activity in the temporal domain into the sequential spatial organization of the visual field map and the potential to change the transformation rule through the attenuation of NMDAR activity in other circuits.

Abstract: Ligand-gated ion channel *N*-methyl-*D*-aspartate receptors (NMDARs) are major excitatory neurotransmitter receptors in the mammalian brain. Mutations in the genes encoding NMDAR subtypes GluN2A/2B (*GRIN2A*/*2B*) are implicated in neurological diseases including epilepsy and intellectual disability. NMDARs have critical developmental and functional roles in the central nervous system. We have investigated the mechanisms by which NMDAR function, structure, and expression are altered by 25 missense mutations or rare (less than 1%) variants in the GluN2A and GluN2B agonist binding domains, which also include 3 unpublished mutations. Most of the mutations in *GRIN2A* were identified in patients with epilepsy or seizure disorders. When these missense mutations were introduced into recombinant human NMDAR subunits, they caused significant decreases in receptor expression and/or function. Furthermore, several

mutations in both *GRIN2A* and *GRIN2B* increased functional properties of NMDARs but reduced cell surface expression, which in the absence of homeostatic compensatory mechanisms might cause an overall reduction in NMDAR activity. It is important to note here that *GRIN2A* and *GRIN2B* mutations affected NMDARs through related mechanisms, but were associated with different neurological disorders and had different response to NMDAR modulators. Taken together, this study elucidates mechanisms by which mutations in both GluN2A and GluN2B alter the agonist binding domain and could be relevant for the different disorders observed in patients with *GRIN2A* vs *GRIN2B* mutations.

Title: A redefined critical period for visual acuity

Authors: *M. F. DAVIS[1], D. X. FIGUEROA VELEZ, 92697[2], S. P. GANDHI[2];
[1]Neurobio. & Behavior, [2]Neurobio. and Behvaior, UC Irvine, Irvine, CA

Abstract: It is known that early visual deprivation leads to impaired vision in adulthood. It has also been shown extensively that monocular deprivation during a defined developmental critical period in visual cortex results in a phenomenon known as ocular dominance (OD) plasticity. Until now OD plasticity has been assumed to be synonymous with the critical period for the development of visual acuity. Here we show that although related, the critical period for visual acuity is distinct from the critical period for ocular dominance plasticity. The critical period for visual acuity occurs much earlier than previously thought. Brief monocular deprivation before the onset of OD plasticity (about 1 week after eye opening) produces an unexpected, long-lasting reduction in cortical acuity, whereas equivalent deprivation during OD plasticity has no persistent effect. Thus the well-studied critical period for OD plasticity is not coincident with the critical period for acuity development. We also show that enhancement of intracortical inhibition at this early time point, previously shown to activate precocious OD plasticity, disturbs the development of acuity. Further, early visual deprivation also altered subsequent OD plasticity, making it resemble adult plasticity. Thus although distinct, the acuity critical period and the OD plasticity critical period are clearly linked. Taken together, these results show that the critical period for visual acuity occurs earlier than previously thought, but is important for the subsequent development of normal OD critical period plasticity. Other developmental disorders of the brain may also involve early periods of vulnerability that precede the expression of measuable plasticity and overt disorganization of neural function.

Title: CPEB3-regulated megf10 expression controls retinal mosaic spacing of starburst amacrine cells

Authors: *Y.-S. HUANG, Y.-P. CHEN, K.-S. BAI;
Academia Sinica/Institute of Biomed. Sci., Taipei, Taiwan

Abstract: Cytoplasmic polyadenylation element binding protein 3 (CPEB3) regulates target RNA translation in neurons. Here, we examined CPEB3 distribution and function in the retina.

CPEB3 is expressed in retinal neurons, including those located in the inner nuclear layer (INL) and ganglion cell layer (GCL), but not in photoreceptors and retinal pigment epithelia. Retinal neurons display spatial arrangements in order. Many individual subtypes are organized non-randomly in patterns called mosaics. Among them, CPEB3 was detected in cholinergic starburst amacrine cells (SACs) and calbindin-positive horizontal cells (HCs). Despite the presence of CPEB3 in both populations of SACs, OFF SACs in the INL and ON SACs in the GCL, CPEB3-knockout (KO) retina showed aberrant mosaic spacing only in ON SACs. Molecular characterizations identified that translation of multiple epidermal growth factor 10 (*Megf10*) RNA was suppressed by CPEB3 during the first week of postnatal development when MEGF10 is restrictedly expressed in SACs and mediates homotypic repulsive interactions for mosaic arrangement. Thus, elevated MEGF10 expression in the absence of repressor CPEB3 likely accounts for defective spatial organization of ON SACs.

Title: Postnatal refinement of feedforward projections in ferret visual cortex.

Authors: *R. KHALIL[1], V. C. RAMIREZ[2], J. B. LEVITT[2];
[1]BCE department, American Univ. of Sharjah, Sharjah, United Arab Emirates; [2]Biol. Dept., The City Col. of New York, New York, NY

Abstract: Visual cortical areas in the adult mammalian brain are linked by a network of interareal feedforward (FF) and feedback (FB) circuits that refine from an immature state. We

studied the postnatal refinement of FF projections from ferret primary visual cortex (V1) to multiple cortical targets during the period from just before eye opening (4 weeks) to 10 weeks. Our aim was to determine (a) whether the developmental refinement of FF projections parallels that of FB cortical circuits, and (b) whether FF pathways from V1 to different target areas refine with a similar rate. We injected the bidirectional tracer CTb into V1 of juvenile ferrets, and visualized the distribution and pattern of orthogradely labeled axon terminals in extrastriate cortex. We analyzed the refinement of FF terminals in each target area by quantifying the density of labeled synaptic boutons and axonal processes, and interbouton intervals along individual labeled axons. As early as 4 weeks of age, orthogradely labeled FF axon terminals were found in areas 18, 19, 21, and (Suprasylvian cortex) Ssy. Orthogradely labeled axons and retrogradely labeled FB cells were organized into overlapped clusters, indicating reciprocal FF and FB connections of each extrastriate area with V1 (though FB label was always more extensive). Bouton density of FF projections to target areas 18, 19, and 21 declined steadily from 4 to 8 weeks postnatal. However, in area Ssy this decline was delayed somewhat, not occurring until after 6 weeks of age. Mean interbouton intervals along individual FF axons to all visual areas increased over the same postnatal period (6-8 weeks). Similarly, we observed a concomitant moderate decrease in axon density in areas 18, 21, and Ssy during this postnatal period. Thus the decline in bouton density is partly attributable to a reduction in axon density (pruning of supernumerary axon collaterals) as well as a loss of boutons along individual axons (leading to larger interbouton intervals). These data suggest that FF circuits from V1 to its main extrastriate target areas remodel largely synchronously in the weeks following eye opening. Furthermore, both FF and FB cortical circuits share a broadly similar developmental timecourse in the weeks following eye-opening; this suggests that postnatal visual experience is critical for the refinement of both FF and FB cortical circuits. However, the refinement of FF projections from V1 to its targets appears to be delayed 1-2 weeks relative to the refinement of FB projections from those targets to V1.

Title: Developmental changes of spontaneous and sensory evoked activity of the habenular circuits in zebrafish

Authors: *S. L. FORE[1], S. K. JETTI[2], C. V. DIAZ[1], M. HOFFMANN[3], E. BARTOSZEK[1], E. YAKSI[1];
[1]Med., Kavli Inst. for Systems Neurosci. - CNC, Trondheim, Norway; [2]MIT, Cambridge, MA; [3]Charite, Berlin, Germany

Abstract: The Habenula (Hb) is an evolutionary conserved brain structure, subdivided into different nuclei, that is shown to play an important role in associative learning, stress, mood disorders as well as in social interactions such as aggression. Our laboratory has recently highlighted the presence of highly structured spontaneous activity in the habenular neurons. This activity might have a potential role in processing sensory stimuli and comparing this information with the animals' internal behavioral states (such as fear, arousal, stress etc.). The behavioral repertoire of animals evolves and maturates throughout development. For example, it was recently shown that complex social interactions progress during zebrafish development. Similar studies in the past also provide evidence for increased performance at associative learning tasks across different developmental stages in zebrafish.
In this project we aimed to study how spontaneous and sensory driven activity changes throughout development, what mechanisms are underlying these changes and what would be the consequence of these changes with respect to neural computations. In order to achieve this, we measured the activity of habenular neurons at several developmental stages. Our preliminary results suggest a strong change in firing rates of habenular neurons as well as a prominent reorganization in the spatio-temporal patterning of habenular activity. We are currently further investigating transformations in habenular architecture that could underlie these functional changes and how this might link to the changing behavioral repertoire of developing zebrafish.

Title: Roles of neuronal activity in the establishment of neocortical neuron identity.

Authors: *T.-C. WANG, C. HANASHIMA;
Ctr. For Developmental Biology, RIKEN, Kobe / Hyogo, Japan

Abstract: The mammalian neocortex comprises of diverse neurons that can be classified into six major layers according to their gene expression profiles, connectivity, and dendritic patterns. These neurons are generated from progenitor cells that reside in the ventricular zone in a fixed temporal order. Lineage tracing experiments of early cortical progenitors have shown that a single progenitor cell can contribute to neurons of multiple layers [Eckler *et al*., 2015]. Furthermore, reports have also demonstrated that upper-layer neurons can be reprogrammed to deep-layer neuron identity after they migrate into the cortical plate [De la Rossa *et al.*, 2013], raising the possibility that neuronal identity also utilize cues during the post-mitotic stages. In addition to transcriptional regulation, layer IV neurons require thalamocortical inputs for dendritic development and cellular rearrangements, but the relationship between genetic codes and neuronal activity, as well as the critical time window for layer IV neuron specification remain largely elusive. To assess the contribution of intrinsic and extrinsic mechanisms in neocortical neuron development, we inhibited neuronal activity during the early stage of neocortical layer IV neuron differentiation. Our results indicate that the reduction of neuronal excitability affects both the integration and dendritic maturation of layer IV neurons. We further elucidate the crosstalk between intrinsic and extrinsic cues for layer IV neuron maturation.

Title: Quasi-regular structure of ON and OFF retinal mosaics provides a common organizing principle of functional maps in V1

Authors: *J. JANG[1], C. LEE[1], S.-B. PAIK[1,2];
[1]Dept. of Bio and Brain Engin., [2]Program of Brain and Cognitive Engin., KAIST, Daejeon, Korea, Republic of

Abstract: Primary visual cortex (V1) is organized into functional maps that represent specific features of visual stimulus such as preferred orientation and spatial frequency. Recent studies reported that the structure of a cortical functional map is strongly correlated to the local organization of ON and OFF afferents from the retina and thalamus (Lee et al., 2016; Kremkow et al., 2016). In addition, another study suggested that the geometry of these functional maps in the same cortical area may be correlated to each other, as in the case between the preferred orientation and spatial frequency maps (Nauhaus et al., 2012). Here, we suggest an idea that the quasi-regular structure of ON and OFF retinal ganglion cell (RGC) mosaics seeds various functional maps in V1, in a way that their geometries are systematically correlated to each other as observed in previous studies. Using computer simulations of model retinal mosaics and visual cortex, we could successfully reconstruct the systematic organizations of orientation, direction and spatial frequency maps in V1 with an identical set of ON and OFF RGC mosaics, and could explain geometrical relationships between different maps.
A previous model proposed that orientation map can be seeded by moiré interference between ON and OFF RGC mosaics (Paik & Ringach, 2011). The model assumed that the preferred orientation is determined by the alignment of an ON-OFF dipole—a pair of neighboring ON and OFF RGCs. Based on this model, we showed that the preferred direction and spatial frequency of a V1 neuron can be determined by the direction and size of a dipole. In the moiré interference pattern, we observed the dipole properties - alignment, direction and size - were spatially correlated, and this originated correlation between the functional maps. First, the direction of dipole flips at the center of iso-orientation domain, resulted in the subdivision of the domain into two opposite direction domains as previously reported (Weliky et al., 1996). Next, the spatial gradation of the alignment and the size of dipole were correlated orthogonal to each other in moiré interference, and this induced the perpendicular intersection between the contours of orientation and spatial frequency maps as observed (Nauhaus et al., 2012). These results indicate that the moiré interference of retinal mosaics may seed various functional maps in V1 and correlate them systematically.
Our model, for the first time, offers a common developmental mechanism for the various functional maps in V1 and explains their structural correlations. This suggests that the structure of periphery in sensory system may determine the basic framework of cortical functional circuits**.**

Title: NMDA-dependent competition drives subcellular topography of multisensory inputs in the tadpole tectum

Authors: A. S. HAMODI, 82072, *K. G. PRATT;
Dept. of Zoology and Physiol., Univ. of Wyoming, Laramie, WY

Abstract: The development of topographic maps is known to require both molecular cues and activity-dependent mechanisms. In addition to the topographic map, there is an additional level of subcellular topography involving different sets of axons targeting specific regions of an individual dendrite. However, the mechanism that guides different axonal inputs to different regions of the dendrite is not clear. Here, We address this in the tadpole optic tectum, where tectal neurons receive both visual and non-visual inputs. The visual inputs consistently innervate the distal region of the tectal dendrite, while the non-visual inputs that enter the tectum via the hindbrain (HB) target the proximal region. Field-potential recordings from the tectal neuropil at stage 49 combined with axon imaging studies show that exposing tadpoles to the NMDA receptor antagonist MK 801 (25uM) at the stage when retinal ganglion cell (RGC) and HB axons arrive to the tectum (stage 39) disrupts lamina-specific targeting of RGC and HB axons, whereas blocking action potentials with the sodium channel blocker TTX (1uM) did not. Furthermore, rearing tadpoles in MK 801 after the circuit has formed (stage 45) did not disrupt the normal spatial pattern of RGC and HB inputs along the tectal neuropil. These results indicate that the formation of subcellular dendritic topography of multisensory inputs, but not their maintenance, depends on NMDAR activation. The requirement of NMDAR activation for subcellular topography suggests that this process is competition-dependent. To test this, we disrupted axon competition by monocular enucleation at stage 34. Monocular enucleation experiments revealed that mechanosensory axons are less focused in space and extend into the vacant dendritic region that is normally occupied by RGC axons, thus confirming the role of competition between two sensory inputs for dendritic real estate.

Title: The effect of omega-3 fatty acids on murine visual function and plasticity

Authors: *E. CENTOFANTE[1], L. ANEZ-BUSTILLOS[2], M. A. BAKER[2], N. HODGSON[1], T. K. HENSCH[1,3], M. PUDER[2], M. FAGIOLINI[1];

Abstract: Omega-3 fatty acids (O3FA), including docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), play a critical role in the maturation and stability of neuronal circuits throughout life stages. O3FA are essential structural components of membranes and serve major functions in synaptic function. Here we investigated how O3FA-enriched diet affects visual system function and its plasticity in mice. Pregnant female mice from C57BL/6 background were fed either O3FA-enriched or standard rodent chow diet starting approximately from embryonic date E10.5 and throughout the lifespan. When compared to 6-8 week-old control mice, O3FA-fed animals showed significantly higher contents of DHA and EPA in brain tissue. Interestingly, EPA is not supplemented in the experimental diets yet significantly higher in the O3FA-fed mice compared to controls. These differences were present even in aging animals (postnatal day (P) 500). No differences were detected across feeding paradigms in the general health and weight of the mice suggesting no detrimental effects of a chronic exposure to an O3FA-enriched diet. Visual evoked potentials (VEP) were then evaluated. VEP were first recorded from anesthetized animals at the peak of the critical period for visual cortex (P24-34). No significant differences were revealed in the response to low spatial frequency stimulus and spatial visual resolution across the two feeding paradigms. The effects of O3FA-enriched diet were assessed on the expression of ocular dominance plasticity by short term monocular deprivation (MD, 4 days) at P24-P28. Surprisingly, O3FA-fed mice did not show a depression in the response of the deprived eye to the low spatial frequency stimuli despite exhibiting a significant loss in spatial acuity. Cortical inhibition mediated by parvalbumin interneurons (PV) enwrapped by specialized extracellular matrix, perineuronal nets (PNN), control the expression of ocular dominance plasticity. Immunohistochemistry analysis revealed a significant decreased in PV intensity after MD in chow- but not in O3FA-fed mice. Visual function was then analyzed in adult (P150-200) and aging (>P500) mice. There was an age-dependent decrease in VEP response in chow-fed mice that was prevented by the O3FA-enriched diet. VEP amplitude was significantly increased in response to all spatial frequencies, resulting in a higher visual acuity in the aging O3FA-fed mice. Interestingly, the PV and PNN circuits in aged mice had a significant increase in PV and PNN intensity in O3FA-fed mice compared to age matched chow-fed mice. Overall, these results suggest a possible neuroprotective effect of O3FA-enriched diet on visual function.

Title: Loss of autism-associated gene Cntnap2 has broad effects on neuropsychiatric features in juvenile rats

Authors: *D. CONNOLLY, S. VEERARAGAVAN, S. SORIANO, A. J. LIANG, L. YUVA, R. PAYLOR, R. C. SAMACO;
Baylor Col. of Med., Houston, TX

Abstract: Mutations in the *CNTNAP2* gene have been associated with a wide spectrum of neurobehavioral outcomes and a number of neuropsychiatric disorders. Behavioral phenotypes have been characterized in *Cntnap2*-NULL mice, but the complete loss of CNTNAP2 in mice may not fully model the consequences of heterozygous deficiency of the gene as observed in humans. Disease-related features reported in adult mice raise the question of whether similar findings would manifest during early stages of life. In addition, sex-specific differences due to the loss of *Cntnap2* in rodents are poorly understood. Given the availability of a novel *Cntnap2* loss-of-function rat model, we set out to characterize behavioral phenotypes in juvenile male and female rats with either the loss of one (HET) or both (NULL) copies of *Cntnap2*. We found that juvenile *Cntnap2*-HET and -NULL rats display multiple neurobehavioral deficits, including increased obsessive compulsive-like behaviors, increased play behavior, hyperactivity, and an increased acoustic startle response. In some cases, behavioral impairments appeared to manifest only in rats that completely lacked CNTNAP2. Furthermore, sex-specific differences were observed only in the number of ultrasonic vocalizations emitted during play behavior. In comparison with reported findings in the *Cntnap2* mouse model, our study indicates that *Cntnap2* deficiency in the rat results in different behavioral outcomes with the exception of hyperactivity. Taken together, these findings provide insight into the consequences of *Cntnap2* deficiency in a complementary, evolutionarily divergent rodent species and suggest common *Cntnap2*-mediated behavioral phenotypes among genetic rodent models may be useful behavioral outcome measures in preclinical studies.

Title: TBCK-encephalopathy, a novel syndrome associated with mTOR over inhibition and mitochondrial dysfunction

Authors: ***X. R. ORTIZ-GONZALEZ**, J. A. TINTOS-HERNANDEZ, *D. C. WALLACE; CMEM, Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Over-activation of mTOR signaling has been implicated in pediatric neurologic disorders as well as in adult neurodegenerative disease. However, very little is known about the effects of chronic mTOR inhibition in the brain. We have recently discovered a novel pediatric intellectual disability syndrome, TBCK-associated encephalopathy, uniquely characterized by mTOR over-inhibition. Our cohort of patients with homozygous null TBCK mutations present with progressive central and peripheral neurodegenerative features. Intriguingly, they also exhibit mitochondrial dysfunction, including mtDNA (mitochondrial DNA) depletion. Given that TBCK knockdown leads to downregulation of mTORC1, which is known to regulate oxidative phosphorylation, mitochondrial biogenesis, and mitophagy, we hypothesize that TBCK deficiency causes a severe neurodegenerative phenotype due to chronic mTORC1 inhibition resulting in progressive mitochondrial dysfunction. Specifically, our preliminary data show downregulation of mitochondrial biogenesis via PGC1-alpha, decreased mtDNA copy number, and upregulation of mitophagy in *TBCK*$^{-/-}$ fibroblasts. Therefore we propose to further characterize the mitochondrial defects in *TBCK*$^{-/-}$ fibroblasts and the effects of mTOR modulators. We then propose to generate TBCK$^{-/-}$ IPSC-derived neurons and test the effects of mTOR and mitochondrial targeted therapeutic interventions. This work could elucidate a fundamental disease mechanism in neurodegeneration, where mTOR dysregulation and mitochondrial defects are almost invariably found.

Abstract: Regulation of chromatin structure and DNA packaging plays a critical role in gene expression. Recent exome sequencing of aAutism trios has revealed that coding mutations in the gene encoding the chromodomain helicase DNA binding protein protein 8 (CHD8) results in macrocephaly, aberrant craniofacial morphology, mild-to-severe cognitive impairment, seizures, gastrointestinal problems and autism. The macrocephaly phenotype has been recapitulated in zebrafish. However, the molecular mechanisms underlying how loss of CHD8 results in macrocephaly, intellectual disability and autism are unclear. Toward this end, we generated a ChdD8 mutant mouse using the Cas9/CRISPR system at a position 5' of the majority of human mutations identified in autism exome sequencing studies. Similar to previously reported, homozygous deletion of ChdD8 is embryonic lethal in mouse. To uncover how haploinsufficiency of ChdD8 results in aberrant brain development we profiled forebrain gene expression patterns of ChdD8 heterozygotes (ChdD8+/-) and wild-type littermates during neurodevelopment by isolating forebrain at embryonic day (e)12.5, e14.5, e17.5, p0 and adults. We found significant changes in expression of early neurodevelopmental and differentiation genes in ChdD8+/- forebrain, including genes for RNA processing and chromatin organization. We further identified changes in genes that are low in expression early in development and that gradually increase during neuronal differentiation, including genes involved in synaptic transmission that are hallmarks of more mature neurons. Consistent with an altered expression of early neurodevelopmental genes, we found that ChdD8+/- mice have an increase in neuronal

proliferation in the ventricular zone in at the peak of neurogenesis, at e13.5 by performing EdU incorporation. We observed increase at P7 in cortical length and cortical thickness utilizing whole mount imaging and Nissl staining. Cursory examination of cortical lamination reveal no obvious differences in layer specification in at postnatal day 1. Adult ChdD8+/- mice have no difference in interneuron cell types or interneuron counts. This study revealed transcriptional and neurodevelopmental mechanisms by which loss of ChdD8 results in macrocephaly, and suggests significant changes neurogenesis and synaptic processes that may underlie behavioral deficits.

Title: Migration of cortical interneurons is modulated by MTOR signaling in the LgDel model of 22q11.2 DS

Authors: *T. M. MAYNARD[1], E. M. PARONETT[2], D. W. MEECHAN[2];
[1]Pharmacol. and Physiol., [2]GW Inst. for Neurosci., George Washington Univ., Washington, DC

Abstract: Interneurons are essential for the proper function of the neuronal circuitry of the cerebral cortex, and disruptions in interneurons have been identified as a key pathological target in several behavioral disorders, including autism and schizophrenia. We have previously shown in a mouse model of 22q11.2 Deletion Syndrome (22q11.2 DS), a neurodevelopmental syndrome strongly associated with autism and schizophrenia, that the migration of interneurons into the cortex is delayed and disrupted, leading to an aberrant distribution of interneurons in the cortex. This disruption in interneuron migration is due to dysregulated signaling via the Cxcr4 cytokine receptor, which has been shown to act via modulation of the mammalian target of rapamycin (MTOR) signaling pathway in several models of cell motility. We have used a conditional genetic approach to disrupt MTOR signaling in both *LgDel* and WT mice, by using a Dlx5/6-Cre line to specifically ablate either the MTOR-repressor *Tsc2*, or *Mtor* itself, specifically in interneuron precursors. We found that heterozygous loss of *Mtor* appears to amplify the

migration defects normally observed in the *LgDel* cortex, with compound *LgDel*;*Mtor*$^{+/-}$ interneurons showing disorganized distributions; while the compound LgDel;*Tsc2*$^{+/-}$ cortex shows that few interneurons enter the cortex at E14. Thus, genetic complementation reveals that MTOR signaling appears to be disrupted in the *LgDel* cortex. MTOR signaling is itself implicated in behavioral disorders such as autism, and multiple genetic syndromes with autism-like behavioral consequences have been described that involve *Mtor* and its interacting partners. Thus, it is possible that this signaling mechanism may be a point of convergence between 22q11.2 DS and other, genetically distinct forms of syndromic behavioral disorders.

Title: Treatment with novel ERK inhibitor rescues ASD pathophysiology in 16p11.2 deletion mouse model.

Authors: *J. PUCILOWSKA[1], C. KELLY[2], J. KARLO[2], A. GOZZI[3], R. BRAMBILLA[4], G. E. LANDRETH[2];
[1]Neurosci., [2]Neurosciences, Case Western Reserve Univ., Cleveland, OH; [3]Inst. Italiano di Tecnologia, Rovereto, Italy; [4]Cardiff Univ., Cardiff, United Kingdom

Abstract: Autism Spectrum Disorders (ASDs) are complex, highly heritable neurodevelopmental disorders affecting 1 in 100 children. Our research delineates the contribution of the ERK MAP kinase pathway to the pathogenesis of autism associated with copy number variation (CNV) of human chromosomal region *16p11.2*. CNVs of the *16p11.2* region are genetically linked to 1% of all ASDs. The *16p11.2* locus contains 27 genes, including the ERK1 gene (*MAPK3*). Mutations in upstream elements regulating the ERK pathway are genetically linked to autism and other disorders of cognition including the neuro-cardio-facial cutaneous syndromes (NCFC). ERK1 and its homolog ERK2 are central elements of the MAP kinase pathway governing neural development and synaptic plasticity. We provide direct evidence connecting the ERK kinases to the developmental abnormalities and behavioral deficits observed in the 16p11.2del mouse and show that treatment with novel ERK inhibitor rescues the aberrant pathophysiology in these mice.

We report that the *16p11.2del* murine model exhibits a reduction in brain and body size and perturbations in cortical cytoarchitecture similar to those observed in ERK KO mice. Importantly, we observed a paradoxical increase in ERK signaling in the *16p11.2del* mice, which is coincident with the development of aberrant cortical cytoarchitecture. The *16p11.2del* mice exhibit many abnormal behaviors including anxiety, hyperactivity and impaired memory. Since the aberrant ERK upregulation may be amenable to pharmacological intervention, we treated the *16p11.2del* mice with a novel, brain permeant ERK inhibitor. We employed two treatment paradigms: 1) prenatal, where pregnant dames were treated for 5 consecutive days starting at E10.5; 2) adult, where adult mice were treated for 5 consecutive days starting at P90. We report that prenatal treatment with the ERK inhibitor rescued developmental deficits in neurogenesis and cortical cytoarchitecture as well as aberrant behaviors in the *16p11.2del* mice, whereas adult treated mice showed restoration of some behavioral deficits (e.g. hyperactivity). Importantly, these data suggest that dysregulation of ERK activity can be rescued by two mechanisms, developmentally (through the rescue of cell cycle regulators downstream of ERKs) and in adult mice, presumably due to its synaptic actions.
Our findings provide strong evidence connecting the ERK MAP kinases to the developmental abnormalities in the *16p11.2* deletion. Based on the reversal of the anatomical and behavioral deficits in the *16p11.2del* mouse model, we suggest that treatment with ERK inhibitors can lead to therapeutic interventions in patients with 16p11.2 CNVs.

Abstract: Neuroligins (NLs) are postsynaptic cell adhesion molecules that are related with autism spectrum disorders (ASDs). The neuroligin-3 (NL3) amino acid substitution (R451C) mutation was found in two brothers with ASDs in a Swedish family, and caused social novelty deficits in the specific mutation knock-in mice. The medial prefrontal cortex (mPFC), a brain region that is closely associated with neuropsychiatric disorders including autism. However, little is known about the roles of NL3 during the development of glutamatergic and GABAergic circuitry in mPFC, particularly the roles of NL3 that associated with fast-spiking (FS) interneurons. Here, our electrophysiology data demonstrated decreased N-methyl-D-aspartate receptors (NMDA receptors) function of pyramidal neurons and declined excitability of fast-spiking (FS) interneurons in NL3 R451C knock-in (KI) mice. Additionally, the development and maturity of GABAergic synapses on pyramidal neurons and glutamatergic synapses on FS cells were abnormal in NL3 R451C KI mice compared with WT mice. Together, our findings suggest that the mPFC microcircuit dysfunction may contribute to the ASD-like phenotypes in NL3 R451C KI mice.

Abstract: In the human brain, there are two major functional domains. One has been conserved in all mammals through evolution and governs fundamental functions such as reward, emotion and memory; the other is unique to primates, and is acquired through the enlargement of the

cerebral cortex governing special functions such as tool use, language, and self-consciousness. Thus, to properly understand these brain functions, we need appropriate animal models for studying each function. Animal models that are used to analyze brain functions are different in each case. In the former, a reductive approach is adopted based on gene manipulation using models such as genetically-modified fish and rodents, while in the latter, the main approach is psychological and involves complex behavior analysis using non-human primates such as macaque monkeys. Many researchers believed that the complementary nature of genetic engineering technologies in rodent and fish models and cognitive neuroscience techniques in primate research would lead to progress in this research field. However, due to lack of appropriate animal models that can be analyzed in both aspects of the brain's functions, contact points between these two approaches have been limited.
The development of genetically engineered non-human primates has attracted attention for its potential to connect the two research fields. Recently, we succeeded in creating the world's first transgenic primate using marmosets. This technological breakthrough provides a potential paradigm shift by enabling researchers to analyze both the brain functional domains using various model marmosets.
Currently, we are developing a technique for creating knockout marmosets using zinc finger nuclease (ZFN) technology. By combining this technique with the development of cognitive information for marmoset brain analysis, innovative MRI imaging technology and marmoset genetic analysis tools, we created and are analyzing MECP2 mutant marmosets suitable for research on Rett syndrome. MRI imaging shows that the brain size of MECP2 +/- marmoset is smaller than wild-type one by approximately 10% at 18 months of age. Use of MECP2 deficient marmoset will not only reveal pathogenesis of Rett syndrome, but also potentially contribute to future therapeutic strategies for Rett syndrome.

Title: Initial characterization of a new loss-of-function mouse model of the autism susceptibility gene Chd8

Authors: *M. PRIDE[1], I. ZDILAR[1], A. GOMPERS[1], A. VISEL[2], L. PENNACCHIO[2], D. DICKEL[2], J. L. SILVERMAN[1], J. N. CRAWLEY[1], A. S. NORD[1];
[1]UC Davis, Sacramento, CA; [2]Lawrence Berkeley Natl. Lab., Berkeley, CA

Abstract: Autism spectrum disorder (ASD) is a heterogeneous neurodevelopmental disorder in which it may be possible to stratify subtypes based on genetic mutations and behavioral profiles. Gene-based subtype identification recently discovered the chromodomain helicase DNA-binding protein 8 (*Chd8*) as a likely candidate for a specific subtype of ASD (Bernier et al., 2014, O'Roak et al., 2012, Talkowski et al., 2012 and Neale et al., 2012) with associative cognitive impairments, seen in approximately 60% of human cases with mutations in *Chd8* (Bernier et al. 2014). Genetic engineering via the Cas9/CRISPR system was employed to generate a constitutive *Chd8* mutant mouse model. Briefly, synthetic guide RNA was injected along with Cas9 mRNA to mouse oocytes, and F0s carrying mutations were genotyped and bred to expand lines that harbored a mutation. We selected a line that harbors a short deletion in the fifth exon of *Chd8* causing a frameshift resulting in a predicted loss-of-function allele. We evaluated this new line of mice with a constitutive mutation in *Chd8* on a sequence of behavioral assays relevant to the diagnostic and associated symptoms of autism. Cognitive deficits were detected in the *Chd8* heterozygotes on two distinct learning and memory tasks, novel object recognition and fear conditioning. Social scores were normal on both 3-chambered social approach and male-female reciprocal social interactions with ultrasonic vocalizations. No spontaneous motor stereotypies, repetitive self-grooming or unusual levels of marble burying were detected in either genotype. Other behavioral assays conducted included two anxiety-related tasks, elevated plus-maze and light↔dark transitions, open field exploration, hot plate nociception, acoustic startle and prepulse inhibition, and measures of general health. Our behavioral impairments suggest loss of *Chd8* is a contributing factor to the cognitive deficits seen clinically. These findings highlight the need to further examine this unique *Chd8* mouse model with extensive pathophysiology and behavioral phenotyping efforts.

Ctr., Los Angeles, CA

Abstract: Recessive truncating mutations in CNTNAP2 cause Cortical Dysplasia Focal Epilepsy (CDFE), a syndrome that is highly co-morbid with Autism Spectrum Disorder (ASD). Cntnap2/CASPR2 knock-out (KO) mice recapitulate core ASD deficits, including impaired communication and social interactions, as well as repetitive behaviors. KO mice also display seizures, decreased neuronal synchronization and neuronal migration abnormalities (Peñagarikano et al. 2011, Cell). To uncover the mechanisms underlying these phenotypes, we tested whether loss of Cntnap2 results in altered neuronal excitability, synaptic transmission, and microcircuit connectivity. We performed whole-cell in vitro slice recordings from L2/3 pyramidal (Pyr) and parvalbumin (PV) inhibitory neurons of the medial prefrontal cortex (mPFC), an area important for social behavior. Surprisingly, intrinsic neuronal excitability of both cell types was not significantly different between wild-type (WT) and KO mice. We then tested whether loss of Cntnap2 affected synaptic neurotransmission by quantifying miniature excitatory and inhibitory postsynaptic currents (mEPSCs and mIPSCs, respectively) and found a two-fold decrease in mEPSC frequency on Pyr but not PV cells, and no significant change in amplitude for any of these measures. Moreover, cortical input mapping using laser scanning photostimulation (LSPS) with glutamate uncaging further revealed a drastic decrease in both excitatory and inhibitory functional synaptic connectivity. Paired recordings from connected excitatory and PV neurons also point toward a decrease in the size of unitary evoked inhibitory currents. We also performed anatomical studies which show that, while dendritic complexity is normal in Pyr KO neurons, there is a 20% decrease in spine density. Therefore, loss of Cntnap2 affects local synaptic inputs and microcircuit connectivity in the murine mPFC and sheds light on a potential target for therapeutic interventions in the treatment of ASD.

Title: Characterization of TAO2 KO mice as an autism spectrum disorder model and the pathophysiological effects of TAO2 human genetic variants

Authors: *N. MURTAZA[1], M. RICHTER[2], S. WHITE[1], R. SCHARRENBERG[2], F. MORELLINI[2], A. NAUMANN[2], B. SCHWANKE[2], V. KWAN[1], S. WALKER[3], R. YUEN[3], S. W. SCHERER[3], F. CALDERON DE ANDA[2], K. SINGH[1];

Abstract: Atypical brain connectivity is a major factor in the pathophysiology of Autism Spectrum Disorders (ASDs). To model ASD we are studying the thousand and one amino acid kinase 2 (TAO2), known to play a role in neuron development and identified as part of a common ASD CNV region, 16p11.2. Initial studies reveal impairments in social interaction, a common finding in ASD models, and the presence of associated behavioural changes, including altered anxiety levels, impaired spatial and working memory, and alterations in contextual fear conditioning. These mice also have reduced basal level excitatory synaptic activity, corroborated by reduced dendritic arborisation and decreased dendritic spine numbers in the prefrontal cortex. Concurrently, whole genome sequencing of ASD families identified multiple *de novo* and rare-inherited variants in *TAO2*. Expression of the *de novo* variants in cortical neurons revealed altered dendrite and spine morphology, and abnormal activation of known downstream signalling pathways. The identification of multiple functionally validated *de novo* mutations in *TAO2* highlights the significant impact of disruptions in *TAO2.* Further studies will aim to delineate targetable pathways downstream of TAO2 and their role in atypical brain connectivity.

Title: Impaired hippocampus-dependent learning and synaptic plasticity in a novel animal model of autism spectrum disorders with telomerase reverse transcriptase overexpression

Authors: *K. PARK;
Biol. Sci., Konkuk Univ., Seoul, Korea, Republic of

Abstract: Recently, we have reported that animals with telomerase reverse transcriptase (TERT) overexpression exhibit reduced social interaction, decreased preference for novel social interaction and poor nest-building behaviors—symptoms that mirror those observed in autism spectrum disorders (ASD). Overexpression of TERT also alters the excitatory/inhibitory (E/I) ratio in the medial prefrontal cortex. However, the effects of TERT overexpression on hippocampal-dependent learning and synaptic efficacy have not been investigated. In the present study, we employed electrophysiological approach in combination with behavioral analysis to analyze hippocampal function of TERT transgenic (TERT-tg) mice in comparison to that of FVB controls. We found that TERT overexpression results in enhanced excitation with no changes in inhibition in the hippocampus and significantly impairs long-term synaptic plasticity. In addition, TERT-tg mice showed poor performance on the Morris water maze test, indicating disrupted hippocampal-dependent spatial learning. Interestingly, the expression levels of phosphorylated CREB and phosphorylated CaMKIIα were significantly decreased while the expression level of CaMKIIα was slightly increased in the hippocampus of TERT-overexpressing group. Our observations highlight the importance of TERT in normal synaptic function and behavior and provide additional information on a novel animal model of ASD associated with TERT overexpression.

Title: Neuroanatomical phenotypes in a novel inducible mouse model of Ube3a overexpression and chromosome 15q11.2-13 duplications

Authors: *J. L. SILVERMAN[1], N. BUSCHER[1], N. A. COPPING[1], S. CHRISTIAN[2], J. LERCH[3], S. V. DINDOT[2], J. ELLEGOOD[3];
[1]UC Davis Sch. of Med., Sacramento, CA; [2]Texas A&M, College Station, TX; [3]Mouse Imaging Ctr., Toronto, ON, Canada

Abstract: Maternally derived duplications or triplications of 15q11.2-q13 (Dup15q) are one of the most common genetic variations associated with autism spectrum disorder (ASD), detected in ~1-3% of cases. Overexpression of the ubiquitin protein ligase E3A (*UBE3A*) gene is believed to cause the symptoms observed in Dup15q, as there is a known role of *UBE3A* mutations or deletions as the causal determinant of Angelman Syndrome (AS). UBE3A expresses three isoforms with distinct amino terminal ends that exhibit differential localization and functions in neurons. Our initial neuroanatomical characterization studies focused on mouse *Ube3a* isoform 2 (*Ube3a2*), as it is highly conserved and has been shown to selectively regulate dendritic morphogenesis. An inducible (Tetracycline-Off) transgenic mouse model of *Ube3a2* (TRE-Ube3a2) was generated and crossed to the CamKIIa-tTA transgenic mouse model (Jackson Laboratory #003010), which induces expression of the TRE-transgene in excitatory neurons in the forebrain. We hypothesized that neuronal forebrain overexpression of *Ube3a2* would cause structural neuroanatomical phenotypes compared to wildtype littermate sex and aged matched controls, since neuroimaging in Dup15q patients indicated large hippocampal heterotopias and dysplasias (Boronat et al., 2015). Whole brains were harvested from the behaviorally tested mice, and structural MRI was performed to identify volume changes in different brain regions. MRI revealed that the total brain volume was decreased by (5.0%, $q<0.001$) in the TRE-*Ube3a2*-

tTA mice compared to WT. Localized decreases in absolute volume (mm^3) were found throughout the cortex, with the overall cortex decreasing by (3.8%, $q<0.01$); however the main effect of the TRE-*Ube3a2*-tTA mutation appeared to be in the subcortical gray and white matter. The amygdala ($q<0.001$), hippocampus ($q=0.001$), and striatum ($q<0.0001$) were all significantly smaller in the TRE-*Ube3a2*-tTA mice and the cerebral white matter as a whole was 7.3% smaller ($q<0.0001$) and all major white matter structures were affected. The cerebellum, on the other hand, was the one area in the brain that was largely unaffected by the TRE-*Ube3a2*-tTA mutation. To date, there has been no neuroanatomical analysis of preclinical models that overexpress *Ube3a* in an isoform specific manner. This information is essential to understand how dysregulated expression of UBE3A in the brain results in multiple neurodevelopmental disorders, such as Dup15q, AS and ASD.

Title: Identifying potentially haploinsufficient genes in 22q13 deletion syndrome

Authors: *A. R. MITZ[1], A. SHCHEGLOVITOV[2], L. BOCCUTO[3,4], A. THURM[5];
[1]Lab. of Neuropsychology, NIH, Bethesda, MD; [2]Dept. of Neurobio. & Anat., Univ. of Utah, Salt Lake City, UT; [3]JC Self Res. Inst. of the Greenwood Genet. Ctr., Greenwood, SC; [4]Clemson Univ. Sch. of Hlth. Res., Clemson, SC; [5]Pediatrics and Developmental Neuropsychiatry Br., Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Large-scale GWAS studies of CNVs or SNPs have been valuable tools for studying mutation load associated with major neuropsychiatric disease (e.g., schizophrenia, autism).

However, haploinsufficiency from gene loss, not mutation, is usually the primary mechanism in chromosomal deletion syndromes. Multiple methods for predicting haploinsufficiency have been reported. Cody et al. (Am J Med Genet C Semin Med Genet, 2015) used gene dosage estimation based on published studies of specific genes. Other groups have developed computational approaches that combine gene co-expression and genetic variation estimates (Huang et al., PLoS Genet, 2010; Petrovski et al., PLoS Genet, 2013; Steinberg et al., Nucleic Acids Res, 2015). We used these two approaches to identify potentially haploinsufficient genes in 22q13 region deleted in patients with 22q13 deletion syndrome (Phelan-McDermid syndrome). 22q13 deletion syndrome is characterized by intellectual disability and paucity of speech, but patients manifest many problems from the involvement of 100 or more genes, depending upon the size and location of the deletion. Clinical cases of this syndrome occur independently of any one locus, ruling out the possibility of a single gene cause. There are also too few clinical cases to otherwise assess the impact of any single deleted gene without confounds of nearby genes implicated in CNS pathology (Sarasua et al., Hum Genet, 2014). To uncover evidence for individual gene haploinsufficiency, gene dosage estimates were compiled for the distal 100 genes in 22q13 through literature review, and dosage predictions were taken from the published algorithm-based haploinsufficiency scores. Gene expression was measured using quantitative real-time PCR in cultured iPSC neurons derived from patients. Based on gene dosage from the literature, 6% (6/100) genes were identified as potentially haploinsufficient and 3% (3/100) were judged conditionally haploinsufficient. However, over half of the genes (55/100) lacked sufficient information to make a determination. Although the *SHANK3* gene is most commonly associated with 22q13 deletion syndrome, the algorithm-based search for potentially haploinsufficient genes identified at least 18 other genes with a higher likelihood for haploinsufficiency. We tested the expression of potentially haploinsufficient genes in iPSC-derived neurons from patients. Our results indicate that several genes in the 22q13 region show evidence for contributing to the clinical features seen in these patients.

Title: Generation and preliminary characterization of artificial transcription factors (ATFs) for the regulation of Shank3 in a preclinical model of Phelan McDermid Syndrome and Autism

Authors: C. REN[1], B. R. PYLES[1], M. C. PRIDE[2], N. BUSHCER[2], N. A. COPPING[2], H. O'GEEN[1], *M. YANG[2], D. J. SEGAL[1], J. L. SILVERMAN[2];

Abstract: Mutations in SHANK have been observed in ~1% of individuals with ASD. Mouse models with targeted mutations in *Shank3* exhibit well-characterized, reproducible, ASD-relevant behavioral phenotypes. Manipulating gene expression in rodent models is critical to understanding gene functions. We developed an artificial transcription factor (ATF) protein that can be injected intraperitoneally or subcutaneously, crossed the blood-brain barrier, and increased expression of endogenous genes, such as *Ube3a* (Bailus et al., 2016). Herein, animals were given doses of (2mg/ inj., 3x weekly, s.c.) of full length ATF protein designed, cloned and purified to be specific to *Shank3,* for two weeks. Minimal to no toxicity stress was observed with this dosing regimen. Minimal to no toxicity stress was observed with this dosing regimen. RT PCR for RNA and Westerns protein analysis of Shank3 in the brain tissue showed elevated expression levels. Following dose optimization, we performed a custom designed series of assays aimed to assess cognitive dysfunction using simple and complex learning tasks, as previously described (Silverman et al., 2010). We utilized the innovative, operant touchscreen system to evaluate complex, hippocampal and cortical-dependent learning and memory, as well as behavioral flexibility (Silverman et al., 2015; Leach et al., 2016). In addition, we measured endpoints of motor abilities and ASD relevant behavioral phenotypes, such as, locomotion in an open field, balance beam walking and repetitive motor behaviors. Improvements in motor activity, cognitive function or ASD-relevant behavioral phenotypes have important translational value. Phelan McDermid Syndrome, the genetic disorder caused by terminal deletions in 22q13.3 (a region that encompasses the *SHANK3* gene), is associated with a number of motor problems, including generalized developmental delay, neonatal hypotonia, low energy and muscle/motor weakness --- symptoms not commonly found in ASD cases unrelated to *SHANK3* mutations (Phelan and McDermid, 2012, Harony-Nicolas et al., 2015; Mieses et al., 2016.). Our data corroborate the *Shank3B* mouse model (Peca et al., 2011) by recapitulation of motor symptoms and cognitive deficits in PMS. The effect of increased *Shank3* expression by ATF on behavioral outcomes adds to our knowledge of *Shank3* biology, while demonstrating the utility of ATFs as a novel tool for neurodevelopmental disorders.

Title: Selective neuronal forebrain overexpression of Ube3a isoform 2 causes behavioral phenotypes relevant to chromosome 15q11.2-13 duplications

Authors: *N. COPPING[1], S. CHRISTIAN[2], N. BUSCHER[1], M. S. ISLAM[1], M. C. PRIDE[1], J. M. LASALLE[1], S. V. DINDOT[2], J. L. SILVERMAN[1];
[1]UC Davis, Sch. of Med., Sacramento, CA; [2]Texas A&M Univ., College Station, TX

Abstract: Maternally derived duplications or triplications of 15q11.2-q13 (Dup15q) are one of the most common genetic variations associated with autism spectrum disorder (ASD) detected in ~1-3% of cases. Overexpression of the ubiquitin protein ligase E3A (UBE3A) gene is believed to cause symptoms observed in Dup15q and ASD. UBE3A expresses three isoforms with distinct amino terminal ends that exhibit differential localization in neurons. We hypothesize that the overexpression of a single isoform can alter functional behavioral phenotypes. In this study, we have characterized neuronal forebrain overexpression of Ube3a isoform 2 (*Ube3a2*), to discover if this single isoform is sufficient to cause impairments relevant to Dup15q and ASD. An inducible (Tetracycline-Off) transgenic mouse model of Ube3a2 (TRE-Ube3a2) was generated and crossed to the CamK2a-tTA transgenic mouse model (Jackson Laboratory #003010), which induces expression of the TRE-transgene in excitatory neurons located in the prefrontal cortex and hippocampus. The TRE-*Ube3a2* transgene was expressed in cortex at levels approximately 2.5-fold higher than endogenous Ube3a in CamK2a-tTA/TRE-*Ube3a* (TRE-*Ube3a2*-tTA) double transgenic mice compared to wildtype littermate sex and aged matched controls. A battery of behavioral assays relevant to Dup15q and ASD, as well as numerous control assays to detect confounds in physical health or ability to evaluate complex behaviors were conducted as previously described (Crawley et al., 2007; Silverman et al., 2010, 2012). TRE-*Ube3a*2-tTA offspring showed cytoplasm-specific expression of Ube3a2 in forebrain neurons above level of endogenous Ube3a expression. Robust anxiety-like behaviors were observed in two gold standard conflict anxiety assays. As compared to wildtype, TRE-*Ube3a2*-tTA mice exhibited

high anxiety-like phenotypes. A tertiary anxiety-like measurement, the stress-induced hyperthermia assay, corroborated our findings. ASD-relevant behavioral phenotyping identified normal sociability and elevated repetitive, restricted behavior in TRE-*Ube3a*2-tTA offspring. In this first characterization, of a Ube3a isoform-specific transgenic mouse, we confirmed the genetic construct and detected significant functional outcomes in anxiety-like and repetitive behaviors. However, social behaviors were normal. These studies reveal for the first time a strong functional role for Ube3a2, specifically. Importantly, these data suggest Ube3a2 to be a causative determining factor for at least some of the major phenotypic impairments underlying Dup15q.

Title: Investigating the neuronal function of dock4, a autism/dyslexia related gene

Authors: *D. GUO, Y. PENG, C. LIANG, L. SHI;
Jinan Univ., Guangzhou City, China

Abstract: Rho GTPase regulators are key modulators of actin cytoskeleton, which essentially controls neuronal morphogenesis and synapse plasticity. Dock 4, a guanine nucleotide exchange factor (GEF) that activates Rac1, has recently been found in multiple studies as a risk gene in neurodevelopmental disorders such as autism and dyslexia. Previous studies by others and us using in vitro models showed that Dock4 is important for normal neurite outgrowth and spine morphogenesis, but its in vivo function has not been revealed so far. By generating a knockout mice line of DOCK4, we characterized autism-related behaviors and learning and memory abilities when DOCK4 expression is lacking. In particular, we assessed sociability, stereotype

and repetitive behaviors, anxiety, spatial learning and recognition memory, and DOCK4 KO mice showed some features of ASD-like behaviors. Moreover, neuroanatomical analysis of these mice and molecular mechanism regulated Dock4 were characterized. Results from this work will be presented and discussed.

Title: The role of hormones in male-specific social and behavioral deficits in the protocadherin 10 (Pcdh10) mouse model of autism

Authors: ***S. L. FERRI**[1], M. R. BRUCE[4], H. C. DOW[2], C. C. ANGELAKOS[1], W. T. O'BRIEN[3], H. SCHOCH[5], S. HIRANO[6], R. T. SCHULTZ[7], E. S. BRODKIN[2], T. ABEL[1]; [1]Biol., [2]Psychiatry, [3]Neurosci., Univ. of Pennsylvania, Philadelphia, PA; [4]Temple Univ., Philadelphia, PA; [5]Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA; [6]Cell Biol., Kansai Med. Univ., Osaka, Japan; [7]Ctr. for Autism Res., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Autism spectrum disorder (ASD) is a neurodevelopmental disability that affects nearly five times as many males as females, but the basis of this male bias is unknown. ASD has been linked to a number of genes that encode synaptic proteins, one of which is protocadherin 10 (PCDH10), an activity-dependent cell adhesion molecule expressed primarily in the amygdala

and striatum. Utilizing mice heterozygous for *Pcdh10* (Pcdh10+/- mice), we previously reported male-specific deficits in juvenile social behavior and fear conditioning, as well as changes in the basolateral amygdala including increased dendritic spine density and decreased NMDA receptor expression, as well as decreased BLA gamma band power in response to lateral amygdala stimulation. New preliminary data indicates that Pcdh10+/- mice emit significantly more ultrasonic vocalizations than their wildtype littermates at postnatal day 6 when separated from their mother, a deficit that has been reported in other mouse models of autism. In addition, males but not females lacking one copy of *Pcdh10* exhibit deficits on a high speed rotarod and hypoactivity during the dark phase in their home cages. In order to investigate the sex specificity of the behavioral deficits, we gonadectomized male mice prior to puberty and found that gonadectomy increased social approach behavior to wildtype levels in the Pcdh10+/- males but did not affect the performance of the wildtype males. Future studies will investigate the effect of gonadectomy on other male-specific behavioral deficits, adult testosterone levels, and the role of neonatal versus pubertal hormones.

Title: Cognitive phenotypes in a novel model of chromosome 15q11.2-13 duplication

Authors: *N. BUSCHER[1], S. CHRISTIAN[2], N. A. COPPING[1], D. RITTER[2,1], S. V. DINDOT[2], J. L. SILVERMAN[1];
[1]UC Davis, Sacramento, CA; [2]Texas A&M Univ., College Station, TX

Abstract: Maternally derived duplications or triplications of 15q11.2-q13 (Dup15q) are one of the most common genetic variations associated with autism spectrum disorder, detected in ~1-3% of cases. Overexpression of the ubiquitin protein ligase E3A (*UBE3A*) gene, which is located at the telomeric end of the 15q11.2-q13 region, is believed to cause the symptoms observed in Dup15q. *Ube3a* expresses three isoforms with distinct amino terminal ends that exhibit differential localization in the cell, and that display different functions in neurons. The initial characterization studies focused on *Ube3a* mouse isoform 2 (*Ube3a2*), as it is conserved among vertebrate species and has been shown to regulate dendritic morphogenesis in pyramidal neurons (Miao et al., 2013). We hypothesized that overexpression of *Ube3a2* disrupts cognitive and behavioral phenotypes. An inducible (Tetracycline-Off) transgenic mouse model of *Ube3a2* (TRE-*Ube3a2*) was generated and crossed to the CamK2a-tTA transgenic mouse model, which induces expression of the TRE-transgene in excitatory neurons located in the prefrontal cortex and hippocampus. The TRE-*Ube3a2* transgene was expressed in cortex at levels approximately 2.5-fold higher than endogenous *Ube3a* in CamK2a-tTA/TRE-*Ube3a* (TRE-*Ube3a2*-tTA) double transgenic mice. Expression of the transgene was limited to excitatory neurons in the cortex and hippocampus and responsive to doxycycline. Breeding pairs of TRE-*Ube3a2* transgenic mice were donated by the Dindot laboratory (Texas A&M). Breeding pairs of B6;CBA-Tg(Camk2a-tTA)1Mmay/J (tTA) were purchased from the Jackson laboratory (#003010). PCR genotyping and Western blotting were done to confirm TRE-*Ube3a2*-tTA overexpression. We designed a custom series of assays aimed to assess cognitive dysfunction using simple and complex learning tasks as previously described (Silverman et al., 2010). Traditional novel object recognition and pavlovian context and cued conditioning were tested. To corroborate and extend, we utilized the innovative operant touchscreen system, evaluating complex, hippocampal and cortical-dependent learning and memory (Silverman et al., 2010, 2015). TRE-*Ube3a2*-tTA subjects exhibited learning and memory impairments in contextual and cued fear conditioning but did not show deficits in novel object recognition, compared to wildtype age and sex matched littermates. In addition, our study measured latencies to criterion in the visual touchscreen based assays. These studies are impactful because they are the first to show that *Ube3a* isoforms play a substantial role in cognitive function.

Abstract: Autism is a pervasive neurodevelopmental disorder characterized by abnormal social behavior and communication and by various cognitive abnormalities, including hyper-focusing on specific brain processes and difficulties in attention switching and redirection. While marked heterogeneity characterizes autism landmarks both in human patients and in mouse models of the disease, a consistent involvement of the cerebellum has been highlighted. In order to address the cerebellar microcircuit dysfunction in autism pathophysiology, we have analyzed single-neuron and microcircuit activity in the cerebellar cortex of IB2 knock-out (KO) mice (Giza et al., 2010), which carry the same mutation revealed in the familial form of autism known as Phelan-McDermid syndrome. By using patch-clamp electrophysiology and voltage-sensitive dye imaging (VSDi) we observed severe alterations in neural processing in the granular layer microcircuit of IB2 KO mice compared to age and background strain matched wild-type mice. Granule cells showed increased NMDA receptor-mediated currents and intrinsic excitability, while GABAergic inhibition was reduced, bringing about a raise in the excitatory/inhibitory balance (E/I ratio, WT 1.02±0.13 vs KO 1.44±0.13, n=4 for both, $p<0.05$). Moreover, the magnitude of long-term potentiation was almost quadrupled (LTP; WT 35.64±10.64% n=13 vs KO 120.59±49.27% n=12; $p<0.05$) and it spatial extent triplicated (LTP area KO/WT 3.1±0.3, both n=6, $p<0.003$). Both in IB2 KO and in WT mice, the granular layer response was organized in center-surround. Interestingly, IB2 KO mice responses showed larger centers of excitation (29.5±4.9μm vs. 12.9±1.7μm in WT, both n=5, $p<0.01$) and thinner inhibitory surrounds, demonstrating the shift from a "mexican-hat" to a "stove-pipe" profile predicted by Casanova (2003, 2006) on theoretical grounds. Taken together, our results reveal a critical damage in granular layer microcircuit functions that could seriously alter the signals transmitted to the cerebral cortex, thereby altering functions like attention switching and thought coordination, that are believed to be regulated by the cerebellum, and contributing to the pathogenesis of autistic symptoms.

Title: Autism-associated missense mutations in SCN2A impair $Na_V1.2$ sodium channel function

Authors: *R. BEN-SHALOM[1], C. M. KEESHEN[1], J.-Y. AN[2], K. BERRIOS[3], S. SANDERS[2], K. J. BENDER[1];
[1]Neurol., [2]Psychiatry, UCSF, San Francisco, CA; [3]Chem., Univ. of Puerto Rico, Rio piedras, Puerto Rico

Abstract: Heterozygous mutations in *SCN2A,* identified by exome sequencing of 5,563 autism spectrum disorder (ASD) cases in the Simons Simplex Consortium (Iossifov et al., 2014) and Autism Sequencing Consortium (De Rubeis et al., 2014) demonstrate strong ASD association (Sanders et al., 2015). *SCN2A* encodes the alpha subunit of $Na_V1.2$, a voltage-gated sodium channel that is involved in action potential generation at the axon initial segment of glutamatergic neurons. Along with four *de novo* loss of function (LoF) mutations, *SCN2A* is the only gene in the genome with a clear excess of *de novo* missense mutations in ASD. The eight missense mutations, many of which are clustered near the ion selectivity pore, represent a 36-fold increase over expectation ($p = 1x10^{-10}$, binomial distribution). Whether these missense mutations alter the function of translated NaV1.2 channels remains unclear. Here, we used heterologous expression to examine electrophysiological properties of NaV1.2 channels mutated to contain ASD-associated LoF and missense mutations. Further, channel expression and membrane association were assessed by visualizing immunostained NaV1.2 channels using confocal and total internal reflectance (TIRF) microscopy. HEK293 cells were transfected with plasmids that allowed for expression of the wild type or mutated alpha subunit, GFP, and accessory beta subunits. Interestingly 5/8 ASD-associated missense mutations resulted in a complete loss of channel conductance, despite normal membrane association. Mutations in two other sites reduced peak current amplitude, and we are currently working to determine the biophysical basis for these changes. Based on these results, we are developing compartmental models that incorporate LoF and missense mutations to determine how ASD-associated changes in NaV1.2 function affect neuronal excitability. This work therefore identifies SCN2A as having the most mutations and strongest evidence of ASD association of any gene observed in the exome.

Title: The role of PAK signaling in the regulation of synaptic plasticity and social memory

Authors: ***C. LEUNG**[1,2], F. CAO[1,2], Z. P. JIA[1,2];
[1]Neurosciences and Mental Hlth., Hosp. For Sick Children, Toronto, ON, Canada; [2]Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Neurodevelopmental disorders including Autism spectrum disorders (ASD) and intellectual disability (ID) are characterized by social impairments that impact adaptive functioning. PAKs (p21-activated kinase) are a family of serine/ threonine protein kinases that are central regulators of actin cytoskeleton reorganization and neuronal morphology, and are involved in synaptic and behavioural plasticity. Recent genetic screening and post-mortem studies have implicated mutations in the PAK gene in ASD and ID, but whether and how PAKs are involved in social behavior remains unclear. To directly address this question, we have generated a novel transgenic mouse model using the tetracycline operator system (tet-off) where the expression of a dominant negative PAK mutation can be inducibly controlled. We find that the transgenic mice showed specific deficits in social memory but normal sociability and novelty recognition. These mice also exhibited impairments in synaptic transmission and plasticity. The deficits were fully rescued through the administration of a tetracycline analog, doxycycline. Together, these results suggest a critical role of PAK signaling in social behavior in mice. Supported by CIHR and NSERC.

Title: Functional Assessment of ASD-associated variants in the PTEN gene

Authors: *K. POST, B. P. YOUNG, B. CALLAGHAN, M. BELMADANI, S. ROGIC, C. RANKIN, S. BAMJI, T. O'CONNOR, D. ALLAN, P. PAVLIDIS, C. LOEWEN, K. HAAS; Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Although progress has been made in identifying genes associated with autism spectrum disorder (ASD), the underlying mechanism of this disorder remains unknown. Recently, several exome-sequencing studies of thousands of patients and their families have been completed yielding hundreds of genes loosely linked to ASD, and a smaller subset repeatedly found to be mutated in ASD probands, indicating their likely association with this disorder. The research community is now faced with the daunting task of determining how multiple genes give rise to the disease. To address this problem, a two-stage strategy was used to capitalize on rigorous bioinformatics and high-throughput biological systems to screen for gene mutations most likely to provide strong phenotypes in a secondary slower throughput assay. The gene PTEN (phosphatase and tension homolog) was selected as the first gene to screen in these assays due to its rank as a high confidence candidate gene for ASD. PTEN and its variants, selected based on rigorous bioinformatics, were expressed in high-throughput assays in yeast. Using the synthetic gene array assay, genetic interaction profiles were analyzed to understand altered molecular function. This will inform how variants disrupt protein function and identify mutations producing the strongest phenotypes. The effect of a reduced set of variants on experience-driven growth, synaptogenesis, and neural encoding in vivo in awake, transparent *Xenopus laevis* tadpoles was analyzed. This powerful vertebrate system provides sensitive measures of precisely how ASD gene variants alter brain circuit development. This strategy provides insight into underlying molecular pathways mediating pathophysiology, neuronal and neural circuit development.

Title: Deficits in cerebellar synapse and circuit function in an autism mouse model for the human 15q11-13 duplication

Authors: *D. H. SIMMONS[1], C. PIOCHON[2], T. TAKUMI[3], C. HANSEL[4];
[1]Dept. of Neurobio., Univ. of Chicago Dept. of Neurobio., Chicago, IL; [2]Dept. of Physiol., Northwestern Univ., Chicago, IL; [3]RIKEN Brain Sci. Inst., Wako, Japan; [4]Dept. of Neurobio., Univ. of Chicago, Chicago, IL

Abstract: Autism Spectrum Disorder (ASD) is characterized by two hallmark symptoms: impaired social interaction and increased repetitive behaviors. While ASD is typically regarded as a social disorder, about 80% of patients also display motor learning deficits, suggesting involvement of the cerebellum in ASD pathology. We studied cerebellar physiology in the 15q11-13 copy number variation mouse model, which is the most frequent and penetrant genetic aberration seen in ASD. In these mice, genetic imprinting determines whether offspring will show pathology associated with the autistic-like phenotype. A mouse receiving the 15q11-13 duplication paternally (patDp/+), but not maternally (matDp/+), will show ASD-resembling behaviors (Nakatani et al., *Cell* 137, 2009). To investigate cerebellar abnormalities associated with this phenotype, including the known impairment of LTD-induction at parallel fiber (PF) – Purkinje cell synapses in patDp/+ mice (Piochon et al., *Nat. Commun*. 5, 2014), we studied

climbing fiber (CF) – Purkinje cell and PF – Purkinje cell synaptic transmission. patDp/+ mice showed abnormally large amplitude CF-evoked excitatory postsynaptic currents, which led us to look for altered synaptic density between CFs and Purkinje cells. Immunohistochemistry with VGluT2, a marker for CF terminals, indicated that patDp/+ mice displayed increased density of CF terminals on both large-caliber and fine Purkinje cell dendrites, the latter of which are ordinarily considered PF input territory. We next examined calcium transients in spines, fine dendrites, and large-caliber dendrites, evoked by paired stimulation of PF 100Hz with a single CF stimulation, a single CF stimulation, or PF 100Hz stimulation. Although the CF-evoked calcium transient was unaltered in patDp/+ and matDp/+ mice, our calcium imaging results revealed abnormally small amplitude calcium transients in response to paired stimulation and PF 100Hz stimulation in patDp/+ spines and fine branches. These data suggest that the underlying cause of the known LTD-induction impairment in patDp/+ mice may be due to weak, abnormally small calcium signaling at PF-Purkinje cell spines. It is possible that PFs, even with paired CF-stimulation, do not provide a sufficient calcium signal to induce LTD. The result of increased CF-Purkinje cell synapse density with reduced PF calcium transients raises the possibility that CF synapses are too abundant on Purkinje cell fine dendrites, and thereby invade territory typically reserved for PF-Purkinje cell synapses. Taken together, our findings highlight cerebellar physiological abnormalities that contribute to motor deficits in a mouse model of ASD.

Title: Altered connectivity of neonatal subplate and layer 4 neurons in primary auditory cortex in a mouse model of autism

Authors: *D. NAGODE[1], P. O. KANOLD[2];
[1]Biol., College Park, MD; [2]Biol., Univ. of Maryland Col. Park, College Park, MD

Abstract: Autism Specturm Disorder (ASD) is thought to be of neurodevelopmental origin, though the causes are unclear. Recent brain imaging studies have revealed significant abnormalities in the way that autistic individuals process speech and sound. Specifically,

temporal (including auditory) cortical areas exhibit different patterns of activation compared with typically developed individuals, suggesting that improper “wiring” in areas during development might contribute to problems in speech perception or interpretation. One potential cause for autism is in utero insults. For example prenatal exposure to the antiepileptic drug valproic acid (VPA), increases the incidence of ASD in humans and fetal VPA exposure also results in autistic phenotypes in rodents. The peak vulnerability for VPA in rodents is in the second gestational week thus the neural circuits affected are those present at this time. In the fetal cortex, the first functional circuits are formed by subplate neurons (SPNs). SPNs are crucially involved in key steps of cortical maturation, particularly processes in layer 4 (L4) such as the functional maturation of thalamocortical and intracortical wiring and in critical period plasticity. The vulnerability window for VPA to cause autistic symptoms coincides with the peak generation window of SPNs, thus SPN disruption after VPA might lead to later cortical dysfunction. We investigated in vitro the functional connectivity of SPNs and L4 neurons in neonatal and adult auditory thalamocortical slices using whole-cell patch clamp electrophysiology and laser scanning photostimulation (LSPS) of caged glutamate. VPA, at a dose of 500 mg/kg, resulted in altered excitatory and inhibitory connecions in subplate neurons and L4 neurons. Thus, prenatal exposure to VPA causes disruptions in early SPN circuits that are later reflected in permanent deficits in both excitatory and inhibitory connectivity in L4. Our results provide direct evidence that the earliest cortical auditory circuits are already disrupted in rodent models of autism, and suggest that dysfunction in transient SPN circuits in the developing brain might play a key role in the etiology of ASD.

Title: Cntnap2 -/- autism model mice display deficits in tonic and phasic inhibition in primary visual cortex

Authors: *M. BRIDI, S. PARK, S. HUANG;
Neurosci., Hussman Inst. For Autism, Baltimore, MD

Abstract: Investigations into the genetics of autism in human patients strongly suggest that changes in synaptic function are a common factor in autism pathophysiology. Evidence from studies in both humans and animal models suggest that this synaptic dysfunction leads to

excitatory/inhibitory (E/I) imbalance in the form of reduced inhibition and/or over-excitation, and that neuronal inhibition may be impacted by both pre- and post-synaptic changes. *Cntnap2* -/- mice are a well-established model of ASD. Numerous reports have found that these mice exhibit autism-like behaviors including reduced social interaction, hyperactivity, and repetitive/stereotyped behavior. In addition, *Cntnap2* -/- mice exhibit aberrant neuronal migration, reduced interneuron numbers, seizure activity, and alterations in synaptic spines. Here, we examined tonic and phasic inhibition in L2/3 pyramidal cells in primary visual cortex (V1) of *Cntnap2* -/- mice compared to wild-type (WT) controls, in two different age groups, 3-4 weeks and 6-8 weeks of age. We found that L2/3 pyramidal cells from 6-8 week old *Cntnap2* -/- mice exhibited significant smaller inhibitory tonic conductance. In 3-4 week old mice we found no significant effect of genotype on tonic inhibition. We also analyzed sIPSCs in both genotypes and age groups. While no differences were seen in sIPSC amplitude, frequency, or kinetics in 3-4 week old mice, we found an age-dependent effect of genotype in 6-8 week old animals, with lower sIPSC frequency in *Cntnap2* -/- mice. We did not observe an effect of age or genotype on resting potential or intrinsic excitability of L2/3 pyramidal cells in area V1. These data indicate that network-level GABAergic activity is disturbed in *Cntnap2* -/- autism model mice, which dovetails with previous reports of reduced interneuron numbers, altered network activity, and seizure susceptibility. Our findings suggest that reduced tonic inhibition could underlie autism-like behaviors, and future studies should investigate cellular/molecular mechanisms of reduced tonic inhibition as well as the effects of diminished inhibition on cortical function *in vivo*.

Title: Comparative expression analysis of autism-associated cadherin superfamily members

Authors: *J. A. FREI, G. J. BLATT, Y.-C. LIN;
Neurosci., Hussman Inst. For Autism, Baltimore, MD

Abstract: Cell adhesion molecules (CAMs) play crucial roles in neural circuit formation. The cadherin superfamily is one of the largest families of CAMs containing more than one hundred molecules, including classical cadherins type I and II, protocadherins, and atypical cadherins.

Cadherins share a similar structure consisting of multiple EC-cadherin domains in the extracellular region to mediate Ca^{2+}-dependent adhesion. The cytosolic tail of cadherins interacts with catenins and small Rho GTPases to regulate actin dynamics. The type I classical cadherin N-cadherin is the most well-studied member to-date. N-cadherin functions throughout the development of the nervous system and is essential for synapse formation, spine morphogenesis, synaptic signaling and plasticity. In contrast to N-cadherin, little is known about the function of other cadherins. A genome wide association study performed by the Hussman Institute for Human Genomics identified the classical cadherin type II CDH8, CDH9 and CDH11; the protocadherin family member PCDH9; the atypical cadherin FAT1 and the α-catenin CTNNA3 (αT-catenin) as candidate risk genes. This suggests that cadherin signaling pathways could be disrupted and may display increased vulnerability in autism. Here, we investigate how cadherins across the different subfamilies, as well as components of the cadherin signaling pathway, play a role in brain development. The findings provide insights toward understanding the etiology of autism.

To investigate the importance of cadherin signaling in autism, we analyzed the spatial and temporal expression patterns of different autism-associated cadherin family members in different brain areas, as well as their subcellular localization in neurons. Temporal expression analysis in the developing mouse brain revealed increased cadherin protein expression from P0 to P7. For some of the cadherins analyzed, elevated expression persisted throughout stages P14 and P21. An increased expression from P7 to P21 is consistent with the proposed functions in dendritogenesis and synaptogenesis. Furthermore, cadherins from differing subfamilies showed distinct but partially overlapping expression patterns in various brain areas implicated in autism. Taken together, our results show that cadherins from different subfamilies could potentially converge into common signaling pathways to regulate neural circuit formation. Perturbation of these pathways might result in disrupted dendrite formation, spine morphogenesis and synapse function, cellular phenotypes that have been linked to autism.

Abstract: The Shank3 protein is a scaffold protein that is located in the postsynaptic density (PSD) of excitatory synapses and is crucial for synapse development and plasticity. *SHANK3* genetic haploinsufficiency is thought to be the major cause of neuropsychiatric symptoms in Phelan-McDermid syndrome (PMS). In this study, we investigated the molecular mechanisms associated with the ASD-like behaviors observed in *Shank3Δ11*$^{-/-}$ mice in which exon 11 has been deleted. Our results indicate that Shank3 is essential to mediating mGlu5 receptor signaling by recruiting Homer1b/c to the PSD, specifically in the striatum and cortex. Moreover, augmenting mGlu5 receptor activity by administering the mGlu5 PAMs ameliorated the functional and behavioral defects that were observed in *Shank3Δ11*$^{-/-}$ mice, suggesting that pharmaceutical treatments that increase mGlu5 activity may represent a new approach for treating patients that are affected by PMS and *SHANK3* mutations.

Title: The number of parvalbumin-expressing chandelier and basket cells are differentially decreased in medial prefrontal cortex in autism

Authors: *V. MARTINEZ-CERDENO;
Pathology, UC Davis, Sacramento, CA

Abstract: Cortical interneurons have been linked with the altered balance of excitation / inhibition in the cerebral cortex that is present in autism. However, a specific subtype of interneuron had not been correlated with autism until we discovered that the number of parvalbumin (PV) expressing interneurons was decreased in the prefrontal cortex in autism. There are two PV+ interneuron subtypes: Basket (Bsk) cells and Chandellier (Ch) cells. Bsk cells innervate the soma and proximal dendrites of pyramidal neurons, while Ch cells innervate the initial segment of pyramidal neuron axon. Both Bsk and Ch cells are fast-spiking neurons that innervate a large number of pyramidal neurons, and therefore even a small decrease in Ch or Bsk cell number could critically impair pyramidal neuron output and regional cortical function. These cells account for only 1% of total neurons in the cerebral cortex, with Bsk cells more numerous than Ch cells. A specific marker that differentiates Bsk from Ch cells has not been devised. However, we have designed a method that allows us to discern between these two cell types. Our method is based on the differential expression of *Vicia villosa* lectin (VVA) by Bsk and Ch cells. VVA lectin is present in the perineuronal net surrounding Bsk cells. While the vast majority of Bsk cells can be labeled using VVA, Ch cells do not express VVA. We used PV and VVA double labeling, and based on exclusion distinguished Ch cells from Bsk cells in cortical slices of prefrontal cortex in autism and control groups. We then quantified the number of each cell type (PV+/VVA+; PV+AVV-) present in each Brodmann area in our tissue samples and compared data between autism and control groups. We found that PV+ Ch cells (VVA-) are decreased in prefrontal BA46, BA47, and BA9. PV+ BsK cells may be also decreased but to a lesser degree in these areas. The changes in PV+ Ch and PV+ Bsk cells reported here may reflect altered information processing within the PFC and could contribute to the cognitive impairments seen in autism.

Title: Human tuberous sclerosis (TSC) 2 (-/-) genome-edited neural stem cells and neurones exhibit inhibited autophagy which is restored following mTORC1 inhibition

Authors: *L. STEWARD, N. ANASTASI, A. MARCUZ, N. BE, M. GURIDI ORMAZABAL; Roche Innovation Ctr. Basel, Neurosci. Discov, Basel, Switzerland

Abstract: mTORC1 regulates autophagy and in some neurodevelopmental disorders, such as tuberous sclerosis (TSC), mTORC1 hyperactivity leads to reduced autophagy which likely contributes to disease pathology. This is supported by evidence of impaired autophagy in tuberous sclerosis (TSC) patient cortical tuber tissue, as well as from rodent TSC knockdown studies (e.g. Di Nardo et al., 2014; McMahon et al., 2012) where p62 (a marker of protein build up and impaired autophagy) are increased when compared to control tissues. Although the TSC patient genotype is heterozygous TSC2 (+/-), an additional somatic TSC mutation can result in a knockout. We generated human TSC2 genome-edited neural stem cells (TSC2 NSCs) (+/+) wild type, (-/-) knockout and (+/-) heterozygote cells. These cells have many of the characteristics of patient cortical tubers (Costa et al., 2016). In this study we examined p62 levels and the effect of rapalog treatment in the TSC2-NSCs and their derived neurones, using western blots (WB) and a novel immunocytochemistry (ICC) assay using high content image analysis (HCS; Operetta). Preliminary studies confirmed mTORC1 hyperactivity, as rapamycin sensitive phospho-S6 was increased in TSC2 (-/-) NSCs and 1, 2, 3 and 4 wk old neurones, whereas TSC (+/-) neurones were similar to WT. P62 was significantly increased in TSC2 (-/-) NSCs and neurones compared to WT, whereas TSC (+/-) NSCs and neurones were not altered in WB or ICC HCS studies. In the ICC studies, it was apparent that there was a high level of diffuse P62 in the cytoplasm of the TSC2 (-/-) NSCs and neurones, which was decreased after 24h or 1 wk of rapamycin or everolimus treatment. Bafilomycin decreased the diffuse P62 and increased punctate p62 form (likely indicative of translocation from cytoplasm to autophagosomes and accumulation because of inhibited lysosomal degradation). This punctate P62 was further increased when combined with everolimus or rapamycin, indicating a treatment related increased autophagic flux after mTORC1 inhibition. Overall the data indicated that the TSC2 (-/-) NSCs and neurones are a good model for the human TSC patient cortical tubers, in that they mimic many aspects of the disease phenotype and specifically in this study, show similar mTORC1 dependent markers of dysfunction observed in patient cortical tubers.

Title: Contributions of Cadherin-8 to establishing corticostriatal networks

Authors: *R. E. MESIAS, L. G. FRIEDMAN, D. L. BENSON, G. W. HUNTLEY;
Icahn Sch. of Med. At Mount Sinai, New York, NY

Abstract: Motor and executive tasks are supported by the development of functional corticostriatal networks. Nevertheless, little is known about the molecular mechanisms that control the establishment and function of these connections. Recently, we demonstrated that Cadherin-8 (Cdh8), a type II classic cadherin, was highly expressed in prefrontal cortex and dorsal striatum during an early postnatal period when cortical axons are growing into the striatum. Furthermore, using *in situ* hybridization techniques, we showed that Cdh8 is enriched in striatally-projecting pyramidal neurons in the medial prefrontal cortex and in striatal spiny projection neurons (SPNs). Knockdown of Cdh8 by RNA silencing in cultured cortical neurons or in SPNs *in vivo* significantly alters dendritic arborization and dendrite self-avoidance. Additionally, the temporal and spatial distribution patterns of expression strongly point toward a role for Cdh8 in development of corticostriatal synapses. We generated a conditional mutant mouse in order to selectively delete *Cdh8* from particular cell types. The effects of postsynaptic *Cdh8* deletion on synaptic transmission and plasticity were examined in SPNs using whole-cell voltage clamp recordings from wild-type and AAV-cre injected $Cdh8^{fl/fl}$ mice. These data reveal multifaceted roles of Cdh8 in regulating development of corticostriatal circuits. Elucidating the role of Cdh8 in circuit formation is essential as microdeletions in chromosome 16 have implicated *CDH8* in autism and learning disabilities.

Title: The basal ganglia has altered inhibitory receptor expression in autism: implications for cortico-striatal dysfunction

Authors: *K. SUBRAMANIAN, C. BRANDENBURG, G. J. BLATT;
Neurosci., Hussman Inst. for Autism, Baltimore, MD

Abstract: The basal ganglia (BG) is a collection of highly interconnected sub-cortical nuclei that contain mainly inhibitory GABAergic medium spiny neurons (MSN's). The BG is connected to the cerebral cortex via the thalamus and the cerebellar cortex via the subthalamic nucleus (STN). Specific regions of the BG are implicated in stereotypy, cognitive behavior, motor, speech and language disorders. Thus, the BG is an ideal region of interest to examine the neurochemical basis of repetitive, stereotyped behavior and social communication difficulties observed in autism. This study examined changes to GABAA receptor expression in the BG of post-mortem brain tissue. Specifically, the dorsal striatum consisting of the caudate and putamen, and the ventral striatum including the core and shell territories of the nucleus accumbens (NAcc) and the subthalamic nucleus (STN) were quantified. Sampled regions in the dorsal striatum included projections from the dorsal anterior cingulate cortex (dACC), dorsolateral pre-frontal cortex (dlPFC), pre-motor, motor cortical areas and STN. Sampled regions in the ventral striatum included projections from ventromedial pre-frontal cortex vmPFC and orbitofrontal cortex (OFC) to the NAcc, areas that play a critical role in reward related and stereotypic behaviors. An autoradiographic assay with the ligand [^{3}H]-flunitrazepam was used to label benzodiazepine binding sites on GABAA receptors. There was a significant increase ($p<0.0001$) in GABAA receptor binding, measured in fmol/mg of protein, expressed as (mean ± sem) in age-matched control vs autism cases in dorsal striatum (57.63 ± 1.67, n=17 vs 92.80 ± 2.27, n=19), ventral striatum (98.98 ± 5.10, n=8 vs 161.21± 4.58, n=11) and a significant decrease ($p<0.0001$) in GABAA receptor binding in STN (12.56 ± 0.66, n=9 vs 7.48 ± 0.41, n=8). This initial GABAA receptor binding study suggests that there are significant increases in the expression of inhibitory receptors in the GABAergic regions of BG in autism. Conversely, a significant decrease of GABAA receptor binding was found in the glutamatergic STN region of BG. Taken together, this altered receptor expression pattern indicates a region-specific excitatory-inhibitory imbalance (E/I) in the BG in the autism cohort suggesting a dysregulation of key intrinsic BG circuits. It is unknown whether these changes are due to primary alterations in development or

compensatory due to the E/I imbalance. Further studies are underway to examine specific regions within the BG to better elucidate the extent of changes in cortical - BG connectivity and functions.

Title: Loss of KIDLIA/KIAA2022 causes alterations in synaptic function, gene transcription and autistic behaviors in a novel autism mouse model

Authors: *J. P. GILBERT, H.-Y. MAN;
Biol., Boston Univ., Boston, MA

Abstract: Autism spectrum disorders (ASD) are characterized by impaired social activity, diminished communication and repetitive behavior. We have previously shown that loss of the ASD gene, KIDLIA/KIAA2022, impaired dendritic and axonal outgrowth *via* a disruption of N-cadherin/δ-catenin signaling. To further investigate the role of KIDLIA in neural development, we found that loss of KIDLIA expression resulted in a dramatic decrease in synapse formation and synaptic transmission, accompanied with a shift in the excitation/inhibition balance. RNA sequencing demonstrated that knockdown of KIDLIA altered the transcription of a large number of genes including those involved in synaptogenesis, synaptic plasticity and excitability. To further investigate the role of KIDLIA *in vivo*, we generated and characterized the first KIDLIA knockout mouse. The knockout mice showed significant impairments in social interactions, increased repetitive behaviors and deficits in learning and memory. The mice also demonstrated seizure activity and elevated anxiety. Therefore this new KIDLIA knockout mouse will be a valuable new model for autism research.

Title: Verification of abnormality of postnatal synapse formation/pruning in a primate model of ASD

Authors: *T. SASAKI[1,2], T. SANAGI[1], K. NAKAGAKI[1], T. MANABE[1], N. ICHINOHE[1]; [1]Dept. of Ultrastructural Research, Natl. Inst. of Neurosci., Natl. Ctr. of Neurol. and Psychiatry, Kodaira, Japan; [2]Lab. for Mol. Analysis of Higher Brain Function, Brain Sci. Institute, RIKEN, Wako, Japan

Abstract: The majority of excitatory synapses in the mammalian cerebral cortex occur at small protrusions, or spines, on the dendrites. In primates, the number of dendritic spines rapidly increases after birth, reaches a peak at around the early infancy or mid-childhood period, and then decreases towards the adult level. This characteristic “overshoot-type” profile is assumed to result from pruning of existing spines in excess of the generation of new spines in the later periods. Abnormalities of the processes of spinogenesis and pruning are implicated in several psychiatric disorders, such as autism spectrum disorder (ASD), schizophrenia, and Rett’s syndrome. In ASD, excess spine formation or incomplete pruning may occur, which leads to increased spine numbers.

We investigated the normal processes of spine formation/pruning in the cerebral cortex of the common marmoset (*Callithrix jacchus*) as a primate model. Our previous studies showed similarities and differences of developmental profiles of basal dendrites and spines of layer-III pyramidal cells among the six cortical areas (V1, TE, area 12, area 9, area 14r, area 24), and reported that all cortical areas showed overshoot-type spine formation with peaked at 2-3 month old (Oga *et al*., 2013, Sasaki *et al*., 2015).

We have developed ASD model of the marmoset by expose to valproic acid (VPA) during gestation period. The VPA marmoset has a deficit in communication and perseveration, which

are core features of ASD (Yasue *et al*., 2015). In this study, we measured the thickness of cortices, the density of cortical neurons, microglia, and the analyzed the processes of spine formation/pruning in the six cortical areas of the model animals. On 2, 3, and 6 month old, the thickness of gray matter was found to be increased in the VPA-exposed animals compared to that in unexposed (UE) animals. The density of cortical neurons and microglia was lower in the model animals than that in the UE animals. Layer-III pyramidal cells in the areas were intracellularly injected with Lucifer Yellow in lightly fixed slices, and reacted for Diaminobenzidine. Basal dendrites of more than 150 cells were reconstructed, and their morphological features were analyzed. In the prefrontal cortical areas, we found that insufficient spine pruning of the ASD model compared with UE animal. Search for the molecular mechanisms that underlie the developmental changes will provide further clues for an understanding of pathogenesis of ASD.

Title: The autism associated gene cntnap3 is a critical cell-adhesion molecule in neurite and synapse development

Authors: *D. TONG;
Inst. of Neurosci., Shanghai City, China

Abstract: Autism spectrum disorders (ASD) is one kind of heterogeneous neurodevelopmental syndrome. These years, more and more genes have been reported to be predisposed to ASD, and many of them transcribe cell-adhesion molecules, such as *contactin associated protein-like* (*CNTNAP*), a superfamily of *neurexin* (*NRXN*). Here, we constructed a mouse model which *CNTNAP3* gene was knockout. The *CNTNAP3* KO mice showed deficits in social interaction and displayed abnormal learning and memory. The *in vitro* experiments revealed that *CNTNAP3* was required for the establishment of neural networks. RNAi-mediated knockdown of *CNTNAP3* induced the decrease of axon and dendrite length. We also constructed *CNTNAP3* KO rats which showed decreased spine density in CA1 pyramidal neurons and increased GABAergic interneuron density specifically in CA1 zone. Otherwise, the *CNTNAP3* KO rats also manifested the deficits in E/I balance. Our data suggest that *CNTNAP3* is a critical gene for neurite and

synapse development and provide another important model for investigating the mechanisms and therapeutic strategies of ASD.

Title: Autism-associated mutations in cep290 disrupt cell proliferation process

Authors: *M. B. KILANDER, Y.-C. LIN;
Neurosci., Hussman Inst. For Autism, Baltimore, MD

Abstract: Autism is classified as a neurodevelopmental condition, but the defined spatiotemporal molecular mechanisms contributing to the altered neurophysiology observed in individuals with autism are still largely unknown. In large-scale genetic analysis for autism risk genes, CEP290, a centrosomal protein has been identified as one of the candidate genes. Mutations in the *CEP290* gene are common in ciliopathies; severe multi-organ disorders caused by primary cilia dysfunction. The primary cilium is a microtubule rich cell protrusion crucial for normal cell migration, polarity and division. Moreover, the primary cilium serves as the confined compartment for selective cell signaling and for cell-environment communication. Sonic Hedgehog (Shh) signaling, a biological pathway necessary for proper tissue development and maintenance, is preferentially localized to the primary cilium and is essential for proliferation of granule cell progenitors (GCP) during cerebellar development. Interestingly, defects in cerebellar development occur frequently in CEP290 associated ciliopathies. However, how mutations of CEP290 may contribute to autism phenotypes is still unknown. Here, we test the hypothesis that autism-associated mutations in CEP290 alter the primary cilium in cerebellar GCPs and affect their proliferation during development.
First, the temporal and spatial expression of CEP290 in mouse brains was determined. CEP290 protein levels increase during normal postnatal development and it is highly expressed in the cerebellum compared to other brain regions. In Neuro-2a cells and cultured cerebellar GCPs, CEP290 is observed at the primary cilium and in the cytosol, displaying a dynamic, cell cycle-dependent, re-distribution pattern. Overexpression of CEP290 increased the rate of cell proliferation while CEP290 knockdown resulted in delayed cell population growth. Additionally,

alteration of the CEP290 level reduced neurite complexity in Neuro-2a cells. Furthermore, following the introduction of autism-associated CEP290 mutant constructs, the cell proliferation process was perturbed resulting in slower rate of cell division possibly due to disruption of primary cilium function ultimately leading to reduced Shh-mediated cell signaling events. In summary, CEP290 regulates cell proliferation, with additional effects on neurite complexity. Autism-associated mutations of CEP290 reduce cell proliferation. Our present investigation into the cellular functions of CEP290 offers novel insight into the role of the primary cilium in neurodevelopmental conditions including autism.

Title: Oxytocin fails to enhance serotoninergic neurotransmission in autistic patients

Authors: *A. Q. LEFEVRE[1,2], R. MOTTOLESE[2], J. REDOUTÉ[3], N. COSTES[3], D. LE BARS[3], M.-M. GEOFFRAY[2], M. LEBOYER[4], A. SIRIGU[2];

Abstract: A lot of efforts are currently made to evaluate the efficiency of oxytocin, a neuropeptide that can improve social behavior in Autism Spectrum Disorders (ASD). However, behavioral effects are often small and it is unclear how this molecule acts in the patients' brain. Some of oxytocin actions on social behavior are known to happen through an interaction with serotonin neurotransmission in animals and healthy humans. Critically, both oxytocinergic and serotonergic systems are suspected to be altered in ASD patients. We investigated oxytocin-serotonin interaction in 18 high functioning autistic male patients and 24 healthy controls (HC) using PET scan. With the radiotracer [18F]MPPF, a selective serotonin 1A receptor (5-HT_{1A}R) antagonist, we compared [18F]MPPF binding potential in both groups at baseline and after a spray containing placebo or oxytocin (24IU). Blood samples were also collected to evaluate the impact of oxytocin on peripheral serotonin.

Results showed no differences of [18F]MPPF binding potential at basal levels between patients and HC. In contrast, while oxytocin increased [18F]MPPF binding potential and serotonin peripheral levels in HC, we found no oxytocin effects in ASD patients. Our findings suggest that 5-HT_{1A}R density is normal in autistic patients, but their functioning might be disrupted, and thus oxytocin-serotonin interaction cannot occur in this pathology. This is in line with results from recent clinical trials showing moderate effects of oxytocin and suggests that therapeutic impact of this molecule alone may be limited. Our results thus open ways to investigate combined oxytocin-serotonin treatments.

Title: Neuronal overexpression of β-catenin results in severe intellectual disabilities and autism

Authors: *J. ALEXANDER, S.-X. JIN, L. FEIG, M. H. JACOB;
Neurosci., Tufts Univ., Boston, MA

Abstract: Intellectual disabilities (ID) and autism spectrum disorders (ASD) are prevalent in the general population. Treatments are lacking because these disorders are molecularly ill-defined. Recent advances suggest that the hundreds of human ASD and ID-linked genes converge on a few key biological processes in neurons that predispose to disease. Our studies focus on the role of the β-catenin (β-cat)/ canonical Wnt signal transduction pathway in cognition and social behaviors. β-cat functions in both cadherin synaptic adhesion complexes and canonical Wnt target gene expression; these pathways modulate synaptic density, maturation, and plasticity, and are essential for proper brain function. Several human ID- and ASD-linked genes are predicted to cause either loss- or gain-of-function of the β-cat/ canonical Wnt pathway. However, direct tests that β-cat malfunction can cause these disorders, and knowledge of the underlying pathophysiological changes, are largely lacking. Our recent studies show that targeted deletion in mouse neurons of adenomatous polyposis coli protein (APC), a major negative regulator of β-cat levels, leads to elevated β-cat, altered synaptic density and function, cognitive deficits and autism-like behaviors (reduced social interest, increased repetitive behaviors). We propose that

among the downstream effects of APC loss, excessive β-cat is the major cause of these phenotypes. To test this, we have created a mouse that has targeted deletion of the degradation domain of β-cat, resulting in a stabilized protein product even in the presence of APC. Our new β-cat overexpressor mouse shows elevated β-cat levels in the brain, comparable to that of APC cKOs, and similar autism-like behaviors. However, β-cat overexpressor mice show more severe cognitive deficits, drastically reduced synaptic plasticity, severe reductions in AMPAR and NMDAR receptor levels, and an unanticipated upregulation of APC. We are identifying several, novel molecular and plasticity changes caused by aberrant β-cat levels in neurons. Our findings suggest new molecular etiologies that can cause cognitive deficits of different severities and autistic disabilities.

Title: Decreased parvalbumin mRNA levels in Purkinje cells in cerebellar Crus II in autism: implications for altered excitatory/inhibitory balance in fronto-cerebellar circuitry

Authors: *G. J. BLATT[1], S. REPRAKASH[2], K. ZHANG[2], J.-J. SOGHOMONIAN[2]; [1]Hussman Inst. For Autism, Baltimore, MD; [2]Anat. and Neurobio., Boston Univ. Sch. of Med., Boston, MA

Abstract: The most consistent neuropathological finding in postmortem brains from individuals with autism is decreased numbers of GABAergic cerebellar Purkinje cells (PCs), most pronounced in the posterior lobe lateral hemispheric region. The Crus II area, located immediately inferior to the horizontal fissure, has strong connections with prefrontal cortical areas that participate in high order cognitive tasks. A previous study from our laboratory reported that the remaining PCs in the Crus II region had significantly decreased GAD67 mRNA levels, the key synthesizing enzyme for GABA (Yip et al., Acta Neuropathol., 2007, 113(5):559-68). Most PCs also express the calcium-binding protein parvalbumin (PV). Physiologically, PV-containing neurons are fast spiking and exert powerful inhibitory effects on the soma and initial axon segment of their target neurons. For Crus II PCs, the main target neurons are those in the dentate nuclei that contain both excitatory and possibly inhibitory projection neurons, as well as

inhibitory interneurons. The current study further examined PV mRNA levels in Crus II area of control and autistic brains using radioisotopic in situ hybridization histochemistry and quantification of labeling at the single cell level. Results indicate that PV mRNA levels are significantly decreased in autism compared to control cases (mean (±SEM) and was respectively 114.7±14.48 vs. 191.6±32.13; n=10). mRNA values were not correlated with age at death or post-mortem interval in either group. In addition, there were no significant differences in PV mRNA levels between autism cases with reported seizures or not (respectively 148.7±49.51 vs. 127.5±27.62; n=5). A decrease in the number of PV neurons has been recently documented in prefrontal cortex of autistic brains (Hashemi et al., Cereb. Cortex. 2016). Results in our study provide new evidence that altered PV expression could contribute to the pathophysiology of the cerebellum and possibly to the pathophysiology of cerebellar-prefrontal circuits in autism. A role of PV in autism is consistent with a recent animal study showing that brain-wide metabolic dysfunction of PV neurons leads to impaired sensory gating and social ability in the mouse (Inan et al., Neurobiol Dis., 2016, 93:35-46). We are currently investigating the possibility that a deficit in PV expression affects other brain regions in autism.

Title: Changes to microglial but not oligodendrocyte density in the posterior parietal cortex of autistic individuals

Authors: *M. S. MANIERKA, J. J. HUTSLER;
Integrative Program in Neurosci., Univ. of Nevada Reno, Reno, NV

Abstract: A variety of cortical changes associated with autism spectrum disorders (ASD) indicate disruptions to cellular patterning during neurodevelopment, including evidence of altered laminar structure, abnormal cortical minicolumns and possible deficits in synaptic pruning. Microglia play a variety of developmental roles, including; supporting neuronal health, synaptic growth, and synaptic pruning, in addition to acting as the primary immune defenders of the central nervous system. Given their importance in neurodevelopment and the prevalence of immune disturbances comorbid with ASD, it has been suggested that microglia may be critical to the etiology of this disorder. Previous research has found support for an increase in immune-

activated microglia in the prefrontal cortex and increased density of microglia in ASD grey matter (Morgan, JT, et al. 2010). However, the ionized calcium binding antigen that has been used as a microglia marker in previous research is heterogeneously expressed across microglial morphologies and is most strongly expressed in activated microglia. Staining methods relying on this marker may therefore have an inherent bias towards labeling of activated microglia. Thus, it is possible that previous reports of increased microglial density indicate increased conversion to an activated state rather than increased proliferation.
To explore this possibility, we compared cortical densities of microglia and oligodendrocytes in the supragranular layers (layers II and III) of posterior parietal cortex (Brodmann area 7) in four autistic males and five age- and sex-matched neurotypical controls. Tissue blocks were sectioned at 25µm across the cortical layers and stained with thionin to label Nissl bodies. In order to estimate cell population densities, counts were acquired from multiple tissue sections taken from each block using the optical dissector method (Stereologer, SRC Inc.). Microglial density was significantly increased within the ASD sample. Our findings support a possible general increase in microglial proliferation and density in the ASD cortex, which extends beyond microglial subtype and is not found in oligodendrocytes. Disturbances of microglial cell populations appear widespread in the ASD cortex, suggesting that altered microglial density may contribute to changes in synaptic and cellular patterning during cortical development.

Col. of Med., Seoul, Korea, Republic of

Abstract: Autism-spectrum-disorders (ASD) are neurodevelopmental disease entities primarily defined by deficits in social interaction and repetitive behaviour. In addition, individuals with autism often suffer from motor skill deficiencies, many of which manifest early in the disease. The aetiology of ASD is complex with reported pathophysiological alterations encompassing multiple brain regions, including the cerebellum. Cerebellum-related motor symptoms of ASD patients have been observed by impairments in eyeblink conditioning, eye movement abnormalities, general motor learning deficits as well as balance and postural difficulties. Loss-of-function mutations in the gene encoding the postsynaptic scaffolding protein SHANK2 are a highly penetrant cause of autism-spectrum-disorders (ASD) including cerebellum-related motor problems. Recent studies have implicated cerebellar pathology in the etiology of ASD. Using a KO mouse model we evaluated the possibility that cerebellar Purkinje cells represent a critical locus of ASD pathophysiology in SHANK2-related ASD. Absence of Shank2 impaired both Purkinje cell intrinsic plasticity and induction of long-term potentiation at the parallel fiber to Purkinje cell synapse. Moreover, inhibitory input onto Purkinje cells was significantly enhanced, most prominently in the posterior lobe where simple spike regularity was most affected. Using Purkinje cell-specific Shank2-knockout mice, we confirmed the in vivo alterations of simple spike regularity and the cerebellar-dependence of ASD-like behavioural phenotypes in motor learning and social interaction. These data highlight the importance of SHANK2 for Purkinje cell function, and support a model by which cerebellar pathology functions prominently in certain forms of ASD.

Title: DNA methylation, hydroxymethylation and formylation in human frontal cortex of autistic and schizophrenic subjects

Authors: *R. C. DETH[1], M. S. TRIVEDI[2], Y. ZHANG[3], H. ABDOLMALEKY[4];
[1]Pharmaceut. Sci., Nova Southeastern Univ., Davie, FL; [2]Nova Southeastern Univ., Fort Lauderdale, FL; [3]Northeastern Univ., Boston, MA; [4]Boston Univ., Boston, MA

Abstract: Epigenetic regulation provides a molecular mechanism for long-lasting, activity-dependent changes in gene expression. In the brain, increased neuronal activity can translate into changes in DNA and histone methylation with epigenetic consequences, contributing to neuroplasticity and memory formation. The folate and vitamin B12-dependent enzyme methionine synthase (MS) controls methylation and is sensitive to redox status, linking aerobic metabolism to epigenetic regulation. In previous postmortem brain studies we showed that MS expression in frontal cortex decreases dramatically with age (500-fold), while levels of the MS cofactor methylB12 (methylcobalamin; MeCbl) decrease more than 10-fold across the lifespan. Furthermore, in autistic subjects MS expression and MeCbl levels were significantly lower than age-matched controls, in association with decreased levels of the methyl donor S-adenosylmethionine (SAM). MeCbl levels were also decreased in schizophrenia subjects. To determine whether these abnormal metabolic conditions are associated with epigenetic manifestations, we measured global levels of 5-methylcystosine (5mCyt), 5-hydroxymethylcytosine (5hmCyt) and 5-formylcytosine (5fCyt) in DNA from Brodmann areas 10/11 and 44/45 in frontal cortex. Levels of 5mCyt and 5hmCyt were higher in autistic subjects (4-11 yrs) vs. age-matched subjects (5-13 yrs), while levels of 5fCyt were lower. In schizophrenic subjects (36-49 yrs), levels of 5mCyt were lower than age-matched controls (36-50 yrs), while levels of 5hmCyt and 5fCyt were higher. A comparison of young vs. middle-age control subjects revealed significantly lower levels of 5mCyt and 5fCyt, while levels of 5hmCyt were higher in the older subjects. These findings confirm that abnormally decreased MS expression and MeCbl levels in frontal cortex of autistic and schizophrenic subjects are associated with differential 5mCyt, 5hmCyt and 5fCyt status, suggesting that epigenetic dysregulation may contribute to neurodevelopmental and neuropsychiatric disorders.

Abstract: Autism Spectrum Disorders (ASDs) comprise a heterogeneous group of neurodevelopmental disorders characterized by a complex genetic etiology and impairments in social skills, communication and repetitive behavior. Mutations in the human *APBA2*/*MINT2* gene that encodes for a neuronal adaptor protein have been genetically-linked to autism. Interestingly, the PDZ domain of Mint2 interacts directly with neurexin I, an ASD gene, as part of a multi-protein complex that acts as a facilitator of neurotransmitter release. Since Mints are multi-domain proteins and bind to several synaptic proteins, this raises the question whether Mint2 ASD mutants alter the binding and function to any of its interacting partners and affect Mint2 function. Here, we found the autism-linked Mint2 N723S mutation located within the second PDZ domain effectively binds neurexin I, but leads to reduce neurexin I protein stabilization and defective trafficking to the membrane in HEK293T cells. To determine the direct effects of Mint2 N723S mutant in synapse formation in primary neurons, we examined the heterozygous Mint2 N723S mutation phenotype in a Mint knockout background based on redundancy of Mint proteins. We found neurons expressing Mint2 N723S mutant blocked heterologous synapse formation induced by neuroligin-1 which correlated with decrease in miniature event frequency in excitatory synapses. In addition, we performed live imaging of GFP-tagged Mint2 wild type and Mint2 N723S mutant in primary neurons and observed the N723S mutant was less mobile which may alter the surface mobility of neurexins to the plasma membrane. Together, our results suggest that sequence N723S variant in Mint2 lead to dysfunction in synaptic formation, in part due to alterations in intracellular neurexin trafficking and altered synaptic function of Mint2 as potential mechanisms that contributes to ASD pathogenesis.

Title: Understanding mechanisms of susceptibility genes implicated in autism spectrum disorders

Authors: *K. R. BARBER[1], A. M. BUCKLEY[1], J. TANQUARY[1], M. WOODSON[2], M. B. SHERMAN[2], Y. P. WAIRKAR[1];

Abstract: Autism spectrum disorders (ASD) are a heterogeneous group of neurodevelopmental disorders affecting one in every 68 children under the age of three. It is generally accepted that ASDs have a genetic component and many large-scale screens have identified several susceptibility genes involved in synapse development. However, the relationship between ASDs and synaptic dysfunction is poorly understood. In order to explore this relationship, we selected genes from the SFARI database that had not been strongly correlated with ASD and asked whether these genes might disrupt synaptic structure/function. For this, we utilized the *Drosophila* neuromuscular junction, which is a model of synapse development. Furthermore, Drosophila allows for powerful genetic manipulations, high-resolution single synapse studies and electrophysiological characterization that can be performed with relative ease. We found that some of these genes may disrupt axonal transport of synaptic proteins. These deficits in axonal transport could lead to improper development and malfunction of synapses, thereby affecting their normal neuronal function. These data will be further discussed during the conference.

Title: Altered responses of synaptic strength and intrinsic excitability to homeostatic challenges in Timothy Syndrome

Authors: *S. D. SUN[1,2], B. S. SUUTARI[1,2], B. LI[2], R. W. TSIEN[2];
[1]Ctr. for Neural Sci., New York Univ., New York, NY; [2]Neurosci. Inst., New York Univ. Med. Ctr., New York, NY

Abstract: Dysfunctional homeostasis has been suggested as a potential pathogenic mechanism underlying autism spectrum disorders (ASD). To explore this possibility, we have studied homeostatic regulation of synaptic transmission and intrinsic excitability in a mouse model (TS2-neo) of a monogenic form of ASD, Timothy Syndrome (TS). TS arises from mutations in the pore /forming subunit of the $Ca_V1.2$ calcium channel and recapitulates ASD behaviors.
We characterized differences between wild-type (WT) and the TS2-neo mouse model of TS with regard to homeostatic regulation of unitary neurotransmission and spike firing. We investigated changes in homeostatic synaptic plasticity by measuring miniature postsynaptic currents (mEPSCs) in dissociated primary cultures from cortices of heterozygous TS2-neo and WT siblings. Between 12-14 days *in vitro* (DIV), TS2-neo pyramidal neurons exhibited a lower basal frequency of events no difference in mEPSC amplitude compared to WT. After 24 h of action potential (AP) blockade by chronic tetrodotoxin (TTX) treatment, mEPSC amplitude increased in both TS2 and WT pyramidal neurons. Relative to WT, the TS2-neo pyramidal cells exhibited a significantly larger rightward shift in their amplitude distribution curve after TTX treatment, whereas mEPSC frequency was not different.
We also assessed homeostatic regulation of intrinsic excitability in pyramidal neurons, both in primary cortical cultures and *ex vivo* slices, by monitoring the alternative splicing of BK channels, a pivotal regulator for AP duration. As we describe elsewhere, chronic TTX treatment resulted in a prolongation in action potential attributed to the reduction in the inclusion of exon 29 (E29) in BK channel mRNA. Strikingly, the effect of inactivity was accentuated in TS2-neo neurons, just as for synaptic strength; in these neurons, E29 inclusion was significantly less than in WT E29 inclusion, both in cultures treated with TTX and in pyramidal neurons in contralateral visual cortex after 5 d monocular deprivation (MD) *in vivo*. We also observed electrophysiological differences (AP prolongation, increased excitability) in layer 2/3 pyramidal

neurons recorded *ex vivo* from MD animals.
These data reveal intriguing alterations in the homeostatic responses of TS2-neo pyramidal neurons, both *in vitro* and *in vivo.* The general pattern is that responses to homeostatic challenges are exaggerated in the mutant genetic context, both for synaptic events and neuronal properties. Our results encourage further investigation of homeostatic regulation in neuropsychiatric diseases and the hypothesis that dysfunctional homeostasis may contribute to ASD.

Title: Increased spontaneous activity and seizure susceptibility in a mouse model of Timothy Syndrome

Authors: *A. SALAH[1], O. DEVINSKY[2], D. M. TALOS[3], R. W. TSIEN[1];
[1]NYU Neurosci. Inst., [2]Comprehensive Epilepsy Ctr., New York Univ. Sch. Med., New York, NY; [3]Perelman Sch. of Medicine-Neurology, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Timothy syndrome (TS) is a rare multisystem genetic disorder caused by mutations in the L-type calcium channel Cav1.2 and manifesting with cardiac arrhythmia, autism and epilepsy. We focused on an established TS mouse model (TS2-neo mice; Bader et al. 2011) that recapitulates critical autistic features of the human disease. These mice develop an autism phenotype prior to 3 months of age, but the nature and time course of abnormal electrical brain activity is not known. Accordingly, we investigated their spontaneous activity and seizure susceptibility under Kainic acid (KA) by performing long-term (6 h to 2 weeks) video-electroencephalography (V-EEG).
Methods: 3-6 month old mice under Isoflurane anesthesia were implanted with 6 epidural electrodes. In search of spontaneous activity, each animal was subjected to recordings for 60 h at 3 different points (20 h per session). For seizure susceptibility, animals were recorded for 2 h at baseline before KA administration (25mg/kg; i.p); after the injection mice were recorded for an additional 4 h to determine seizure latency (n=6 for each phenotype). Behavioral scoring for

seizure intensity after KA injections was performed with the Schauwecker and Steward Scale (1997). Seizure latency was determined along with the time spent to reach the first stage stage (S1) and the first tonic-clonic seizure (S4).
Results: Spontaneous activity was increased in the TS mice compared to controls as seen in the mean number of single spikes ($p<0.0005$), repetitive spikes ($p<0.02$), and runs of spikes ($p<0.0005$) over a 30 min period. Over 90 min, highly significant differences were found for all three conditions ($p<0.0001$) ($n=6$ for each phenotype). After KA injections, seizure susceptibility was greater in autistic mice compared to controls ($p<0.012$). Also, TS mice required less time to reach the first state (S1) ($p<0.0004$) or the first tonic-clonic seizure (S4) ($p<0.015$).
Conclusions: Our results support the relevance of the TS mouse for studying the mechanistic link between epilepsy and autism, and its possible usefulness as a model system for the testing of new therapeutics.

Title: Maternal immune activation leads to impairments in behavioral flexibility, repetitive grooming, and social approach deficits

Authors: ***D. A. AMODEO**, S. B. POWELL;
Univ. of California San Diego, San Diego, CA

Abstract: Epidemiological studies suggest that the risk of developing autism spectrum disorder (ASD) is increased by prenatal exposure to viral or bacterial infection during pregnancy. Individuals diagnosed with ASD have impairments in behavioral flexibility as evidenced by a probabilistic reversal learning deficit. Here we investigated how maternal immune activation (MIA) may impact behavioral inflexibility in mice in a spatial discrimination task using an 80/20 probabilistic reinforcement procedure. We hypothesized that MIA would lead to impaired probabilistic reversal learning, social approach deficits, and repetitive grooming which is associated with lower order repetitive behaviors expressed in ASD. MIA was initiated by

injecting pregnant C57BL/6J dams with 20 mg/kg polyriboinosinic-polyribocytidilic acid (poly I:C) in saline on gestational day 12.5. Control females were injected with saline. Both male and female pups born to poly I:C- or vehicle-treated dams were subsequently tested for ASD-relevant behavioral phenotypes, including social approach, repetitive grooming, and probabilistic reversal learning. Male and female offspring of MIA or control dams demonstrated comparable learning for the initial probabilistic discrimination. MIA led to impaired probabilistic reversal learning compared to controls in male mice but not female mice. Similarly, male MIA mice exhibited decreased social approach and elevated repetitive grooming compared to saline-treated control mice, while MIA females did not exhibit these phenotypes. These findings suggest that MIA during late gestation can lead to impairments in behavioral flexibility in male mice similar to that exhibited in ASD individuals. These findings provide a model for examining novel treatments for disorders such as autism that may be triggered by prenatal immune challenges.

Title: Early neurodevelopmental consequences of maternal immune activation in male and female Wistar rats.

Authors: *J. NEILL[1], M. EDYE, MP13 9PT[2], K. MURRAY[3], M. HARTE[2], J. DENNISON[2], I. KNUESEL[4], E. PRINSSEN[4];

Abstract: Maternal immune activation (mIA) through administration of the viral-mimetic polyriboinosinic-polyribocytidylic acid (poly-I:C) is a key model for neurodevelopmental disorders such as schizophrenia (see Knuesel et al. 2014 for review). Gestational and early postnatal day neurodevelopmental changes in the offspring of poly I:C treated mothers have yet to be fully explored in rats. Our study aimed to establish an mIA model in rats and investigate early neurobiological markers in male and female offspring from poly I:C-treated rat dams. MIA was induced in pregnant Wistar rats with 10mg/kg poly I:C at gestational day (GD)15. Blood

samples were taken at 3h following poly I:C administration and changes in IL-6 expression measured in the plasma by ELISA. Offspring development was assessed in males and females at GD21 and postnatal day (PD)21. Brains were harvested for quantitative RT-PCR to measure changes in expression associated with neuronal development (myelin basic protein, MBP; myocyte enhancer factor-2, Mef2; major facilitator superfamily domain 2a, Mfsd2a; semaphorin 3a, Sema3a; shank3), glial cells (glial fibrillary acidic protein, GFAP; olfactomedin-like 3, Olfml3). Microglia in 30um hippocampal slices from male offspring were stained using Iba1. Values are means of multiple counting frames for 6 slices per brain. Counting areas were randomly placed over the hippocampus. Counting was performed by an experimenter blind to treatment. Number of total microglial cells counted classed as resting (A), intermediate (B) or ameboid (C) was calculated. Poly I:C at 10mg/kg on GD15 induced mIA without affecting litter numbers or maternal weight. However, at GD21, pups of poly I:C-treated dams displayed reduced weight, length, head circumference and placenta weight and this reduction in body weight was maintained in both genders at PD21. Elevated expression of Mef2 and Sema3a was observed in the frontal cortex of offspring of poly I:C-treated dams at both GD21 and PD21, whereas MBP expression was reduced at GD21 but elevated at PD21 and Mfsd2a expression reduced at GD21 only. We also observed significantly elevated levels of ameboid microglia in hippocampus on PD21. We have established a robust model of mIA in rats and used this to identify early neurodevelopmental changes. Poly I:C-induced mIA resulted in pup and placenta growth restriction alongside changes in markers suggesting delayed myelination and development of the blood-brain barrier but accelerated synaptic pruning and axonal guidance and activation of microglia. This work supports existing data in mice and further provides a model to study behavioural changes in rats alongside neuroimaging read-outs.

Title: Prenatal allergen exposure effects on microglia, dendritic spines in the prefrontal cortex, and cognitive flexibility

Authors: *K. M. LENZ[1], A. KRUG[2], A. JOSHI[2], A. GALAN[2];
[1]Psychology, Ohio State Univ. Dept. of Psychology, Columbus, OH; [2]The Ohio State Univ., Columbus, OH

Abstract: Perinatal inflammation increases risk for neurodevelopmental disorders, including autism, schizophrenia and ADHD, and both autism and ADHD are four times more common in males than females. Maternal allergic conditions during pregnancy increase the risk for ADHD and autism in children and allergic conditions are highly co-morbid with both ADHD and autism, but little is known about how allergic inflammation may alter brain development to increase risk for these neurodevelopmental disorders. In these experiments, we sought to determine whether prenatal allergic immune challenge shapes a.) innate immune cell number or activity in the developing brain, b.) locomotion, anxiety, cognitive flexibility, and social behavior and c.) dendritic spine density in the prefrontal cortex of male and female offspring. Adult female rats were sensitized to ovalbumin (OVA) via two injections with alum adjuvant, and then bred. On embryonic day 15 dams were challenged with intranasal OVA, which induced significant increases in maternal serum levels of IgE. On embryonic day 16 or the day of birth, brains of pups were assessed for innate immune cell numbers, both microglia (immunostained for the marker Iba1) and mast cells (stained with toluidine blue). Prenatal allergen exposure led to significant increases in microglial and mast cell number and activation in brains of both male and female offspring. A second cohort of OVA-exposed pups was grown to adulthood for behavioral testing and dendritic spine analysis. On the open field test, OVA offspring showed decreased anxiety and increased locomotor behavior. In juvenile social play testing, OVA challenged males showed decreases in sociality. Animals were then tested for cognitive flexibility and working memory on the attentional set shifting task, which is dependent on the prefrontal cortex. OVA-exposed offspring showed no deficits in simple discrimination, but showed significant deficits in reversal and extra-dimensional shifting, indicative of attentional deficits or cognitive inflexibility. Following behavioral testing, animals were sacrificed and their brains processed for Golgi-Cox staining and dendritic spine density assessed using Neurolucida software. Preliminary data shows that OVA exposure led to significant decreases in dendritic spine density in males, and significant increases in dendritic spine density in females. Together, these studies show that prenatal allergen exposure alters brain development and function and may be an underappreciated contributor to neurodevelopmental disorders.

Title: Placental group B Streptococcus infection: sex specific inflammatory response and autistic-like traits in male offspring

Authors: *M.-J. ALLARD[1], J. BERGERON[2], M. DESCOTEAUX[2], L. TREMBLAY[2], M. LEPAGE[2], L.-C. FORTIER[2], G. SÉBIRE[1,2];
[1]McGill Univ., Montreal, QC, Canada; [2]Univ. de Sherbrooke, Sherbrooke, QC, Canada

Abstract: Introduction: Group B *Streptococcus* (GBS) is infecting 15-30% of pregnant women, and is one of the major causes of chorioamnionitis, which is associated with preterm births and perinatal brain injuries leading to neurobehavioral impairments such as autism spectrum disorder (ASD). Our hypothesis is that end-gestational GBS infection of the dams impacts the placenta through an interleukin-1β (IL-1β)-driven inflammatory response, and that IL-1 driven chorioamnionitis leads to critical ASD network injuries. Using a rat model, our goal was to study the consequences of GBS infection on the placenta, and the subsequent neurodevelopmental effects in the offspring.
Methods: Lewis dams were inoculated intraperitoneally on gestational day (G) 19 with live serotype Ia GBS (10^8 CFU). Caesarian-sections were performed at multiple time points following the infection to collect placentas, and maternal and fetal blood samples. The maternofetal inflammatory response was studied by ELISA and immunohistochemistry. Behavioral tests were performed from postnatal day (P)7 to P40 to assess ASD-like behaviors. Brains were collected at P40 for histological studies. Magnetic resonance imaging and diffusion weighted imaging were performed on young adult rats.
Results: GBS placentas were infected, but did not result in pups' infection. Male offspring from GBS-exposed dams presented developmental impairments characterized by ASD-like behaviors with defective: communication, social interactions, and sensory integration. GBS-exposed dams displayed chorioamnionitis characterized by a higher infiltration of polymorphonuclear cells in male than female. Following GBS infection, increased titers of IL-1β were detected in maternal blood, male placentas, and male fetuses' blood, vs control tissues. At P40, GBS-exposed males showed a reduced thickness of the external capsule, of the frontal neocortex and of the corpus callosum, with a decreased mean fractional anisotropy in the anterior part of the corpus callosum. An increased thickness of the cingulum were observed in GBS-exposed males. None of these differences were observed in GBS-exposed females. Placental inflammation and forebrain

injuries will be further characterized by ongoing studies.
Discussion: Exposure to live GBS induces maternofetal immune activation resulting in neurodevelopmental abnormalities recapitulating those of human ASD, including sex dichotomy and behavioral phenotype. The results of the present study provide new evidence in favor of the role of a common and modifiable infectious/inflammatory environmental factor in human ASD pathophysiology.

Labs, Tampa, FL; [3]Anat. & Neurobio., Univ. of Kentucky, Lexington, KY; [4]Col. of Arts & Sci., [5]The Honors Col., Univ. of South Florida, Tampa, FL; [6]Ctr. for Infection & Immunity, Columbia University, Mailman Sch. of Publ. Hlth., New York, NY

Abstract: There is much concern surrounding the neuropathological sequelae of gestational Zika virus infection in man. Here, we examined the effects of another neurotropic RNA virus, the Bornavirus, on the developing brain of rat pups. Information regarding the impact of this viral infection on developing neurons and neural circuitry would lend additional insight (and could raise red flags) regarding the potential neurodevelopmental consequences of other related fetal or neonatal viral infections. Neonatal Lewis rats were infected with Borna Disease Virus (BDV) by innoculation into the right cerebral hemisphere (N=6). Controls (N=6) received PBS. Three week-old rats were sacrificed and brains stained using Rapid Golgi (hemispheres) or Golgi-Cox

(cerebellum) procedures. Dendritic branching and spines were quantitated from coded slides. BDV-infected rat brains tended to show widespread dysmorphic changes in neurons characterized by reduced branching of the dendritic arbor and loss of complexity of the tree, and of dendritic spine loss, often accompanied by dendritic branch varicosities Significant effects of the viral infection were seen in all regions evaluated. The most salient reductions were found were found in: (1) *Cerebellar Purkinje cells:* branching area (-21%), spines (-16%); (2) *Hippocampal CA1s:* basilar branching (-20%), spines (-9%); (3) *Dentate Gyrus Granule cells*: branching (-29%), spines (-25%, thin spines); (4) *Parietal Cortex Layer V pyramids*: basilar branching (-19%), spines (-12%). These findings suggest that early exposure to a neurotropic RNA virus can disrupt maturation of normal dendritic parameters, impair neuroplasticity, and damage brain circuitry. As such, these virus-related dysmorphic changes may represent an underlying neurostructural basis for the pathogenesis of subsequent cognitive impairment and/or developmental disorders.

Title: The role of the peripheral immunophenotype in behaviour

Authors: ***S. L. THOMPSON**[1], C. MORI[2], S. PAVALAGANTHARAJAH[2], D. M. E. BOWDISH[3], J. A. FOSTER[1];
[1]Psychiatry and Behavioural Neurosci., [3]Pathology and Mol. Med., [2]McMaster Univ., Hamilton, ON, Canada

Abstract: Recent behavioural studies in our laboratory revealed decreased anxiety-like behaviour in T cell deficient mice. Specifically, mice lacking the β and δ chains of the T cell receptor (*TCRβ-/-δ-/-*) showed reduced anxiety-like behaviour in several approach/avoidance

behavioural tests including the elevated plus maze (EPM), open field test, and light/dark box test in adulthood. Research from our laboratory also indicates the relevance of early life immune function to later behavioural outcomes, as mice challenged with lipopolysaccharide in the first week of life demonstrated sex-specific alteration in both the temporal emergence and phenotypic expression of anxiety-related and exploratory behaviours. This study examines peripheral immune cells and behaviour in adolescence and adulthood in wild type (WT) and *TCRβ-/-δ-/-* mice. Behaviour was assessed using the EPM at postnatal day 28 (P28, pre-puberty in mice), marble burying at P42, open field at P56, novel object at week 10 and 14, and fear conditioning at week 16. Both male and female *TCRβ-/-δ-/-* mice showed increased exploratory behaviour measured by time spent in the intersection zone of the EPM and reduced anxiety-like behaviour measured by increased number of open arm entries. Interestingly, male *TCRβ-/-δ-/-* mice showed increased risk assessment behaviours measured by head dips while on the open arm that was not observed in female *TCRβ-/-δ-/-* mice. No difference was observed in marble burying. Increased locomotor activity was observed in the open field. The behavioural differences observed in T cell deficient mice pre-puberty mirror previous findings in adult mice, suggesting that T cells influence the central nervous system early in development. Genotype and sex-by-genotype effects were observed in both cued and contextual fear conditioning in *TCR β-/-δ-/-* mice. Analysis of novel object is ongoing. Results of FACS analysis at P28 shows increased neutrophil numbers in both male and female *TCR β-/-δ-/-* mice that was significantly associated with behaviour. While additional analysis is ongoing, these initial findings suggest that changes in the profile of immune cells influences anxiety-like behaviour.

Title: Maternal high fat diet affects microglial function in prepubertal immune challenged offspring: Implications for neurodevelopmental disorders

Authors: *M. BORDELEAU[1], M.-E. TREMBLAY[2], G. N. LUHESHI[1];
[1]Douglas Mental Hlth. Univ. Institute, McGill, Verdun, QC, Canada; [2]CRCHUQ Univ. Laval, Québec, QC, Canada

Abstract: Background. Neuropsychiatric disorders, like schizophrenia (SCZ), represent an important burden for the individual and the society. Understandably, a considerable research effort aims to unravel the underlying pathological mechanisms. Recent research showed that the synergistic effects of prenatal and peripubertal stressors lead to behavioral anomalies reminiscent of schizophrenia. This "double hit" model suggests that a prenatal stress could induce brain vulnerability to subsequent stressors. Considering the dramatic increase of high fat diet (HFD) consumption in the West, it is crucial to investigate the repercussions of this biological stressor. HFD consumption is known to increase pro-inflammatory cytokines and, during pregnancy, leads to microglial activation in the offspring. Microglia are involved in synaptic pruning during development suggesting that their abnormal activation could result in neuronal circuit miswiring, leading to abnormal schizophrenia-like behaviors. Objective. Our aim is to understand the effect of maternal HFD, as a prenatal biological stressor, rendering the developing brain vulnerable to subsequent stressors that may lead to SCZ-like pathology through aberrant synaptic pruning. Methods. To test this hypothesis, we used a "double hit" mouse model where maternal high saturated fat diet was used as a prenatal stressor combined with administration of lipopolysaccharide at postnatal day 30 in the offspring, to mimic bacterial infections occurring at puberty. Behavioral paradigms were performed to assess resulting changes in anxiety, stereotyped behaviors, as well as impairment of learning, memory, and social interactions. Microglial function, neuronal connections and neuron-microglia interactions were evaluated in the adult brain (P80) of these offspring using immunohistochemical staining, quantitative-PCR and western blot. Results. Animals from the "double hit" group presented more pronounced behavioral anomalies during adulthood compared to the control and "single hit" groups. These behavioral changes were associated with changes in some of the molecular signals involved in microglial pruning. Conclusion. Our study provides new insights into the mechanisms underlying brain vulnerability to common biological stressors and their deleterious effects on microglial function. In the long-term, it could lead to the development of new therapeutic targets for schizophrenia, as well as new nutritional guidelines for pregnant and nursing women aimed at preventing brain developmental disorders such as SCZ.

Title: NF-κB p50 knock-out mice as animal model of maternal immune activation linked to neurodevelopmental disorders

Authors: *S. A. BONINI, A. MASTINU, M. PREMOLI, G. MACCARINELLI, G. FERRARI-TONINELLI, M. MEMO;
Dept. of Mol. and Translational Med., Univ. of Brescia, Brescia, Italy

Abstract: Introduction: Recently, increasing research has focused on the connections between the immune system and the nervous system, including its possible role in the onset of several neurodevelopmental disorders (NDDs). The hypothesis is that aberrant immune activity during vulnerable and critical periods of neurodevelopment could participate in the generation of neurological dysfunction characteristic of several NDDs, including autism, schizophrenia, and epilepsy. Numerous epidemiological studies have shown an association between maternal infections and the risk of NDDs; animal models of Maternal Immune Activation (MIA) have confirmed this dangerous association. **Aims:** One of the pathway with a main role both in neuron plasticity and immune system regulation is nuclear factor-κB (NF-κB). In this study, we evaluated whether mice lacking the NF-κB p50 subunit ($p50^{-/-}$) represent a new model of MIA and if they present alterations in cortical structure, with consequent behavioural impairments. **Methods:** $p50^{-/-}$ and wild type mice were analyzed, in terms of inflammation, cortical structure and behavioural abnormalities, to clarify the role of a biological mechanism (NF-κB pathway) in the pathophysiology of NDDs and to study possible ways of therapeutic intervention. Experiments were conducted on both male and female mice. **Results:** $p50^{-/-}$ mice have been reported to show multifocal defects in immune responses and we found that they display a chronic inflammation phenotype. Indeed, we observed increased brain gliosis in the cortex and altered cytokines levels in the serum of $p50^{-/-}$ mice. Looking at structural brain alterations, we found that $p50^{-/-}$ mice at post-natal day 2 present an increase in radial glial cells, an in Reelin protein expression levels, other than a specific alteration in the cortical layering. Moreover, adult $p50^{-/-}$ mice display abnormal columnar organization in the somatosensory cortex, a specific decrease in somatostatin- and parvalbumin-expressing interneurons, altered neurite orientation and a concomitant decrease in Synapsin I protein levels. Concerning behaviour, $p50^{-/-}$ mice, other than an increase in locomotor and exploratory activity, present impairments in social behaviours, with a reduction in social interaction, and impaired communication. Finally, we found that Risperidone treatment decreased hyperactivity in $p50^{-/-}$ mice. **Conclusions:** Together, these data provide new insight on the possibility of a link between altered function of NF-κB and the pathogenesis of NDDs. We propose NF-kB $p50^{-/-}$ mice as a new mouse model of MIA leading to NDDs with social impairment.

Title: Poly(I:C) immune response is dependent on length: Implications for preclinical maternal immune activation models

Authors: *M. D. BAUMAN[1], M. CAREAGA[2], C. CHANG[2], A. CHIANG[2], K. KU[2], R. F. BERMAN[2];

Abstract: The Polyinosinic-polycytidylic acid (PolyIC) model, which mimics the acute phase of a viral infection, has become one of the most widely used models in maternal immune activation (MIA) research, particularly for research in the fields of schizophrenia and autism. PolyIC consists of a chain of double stranded inosine (I) and cytidine (C), and as a result of its manufacture the chain length and therefore molecular weight can vary dramatically. Recent studies have shown that *in vitro*, the ability of PolyIC to stimulate an immune response can vary greatly depending on molecular weight. The present studies were carried in order to determine the relationship between molecular weight, immune system activation and sickness behavior. This information is critical for further development of the MIA. Females rats were treated with either saline, low molecular weight PolyIC (LMW-PolyIC), or high molecular weight PolyIC (HMW-PolyIC). Levels of the proinflammatory cytokine IL-6 were measured at 3, 4.5, and 6 hours after injection. Sickness behavior, including core temperature, activity and basal metabolism, was monitored for 24-hours post injection. Mean serum IL-6 was significantly elevated three hours after injection in animals receiving LMW-PolyIC compared with those receiving saline alone ($p < 0.01$). Animals receiving HMW-PolyIC had significantly higher IL-6 levels compared to saline controls ($p < 0.001$), and significantly higher levels over LMW-PolyIC ($p = 0.02$). Similarly, at both 4.5 ($p = 0.006$) and 6 ($p = 0.002$) hours after injection animals receiving HMW-PolyIC had significantly higher levels compared with animals receiving LMW-PolyIC. PolyIC of varying molecular weights can induce significantly different IL-6 responses *in vivo*. This has major implications for the MIA model and highlights the need to validate the reagents used, and to interpret of the results of previous studies with these results in mind.

Title: Toll-like receptor-selective placental vulnerability, fetal brain impairment and post-natal behavioral deficits in models of neurodevelopmental disorder

Authors: *B. A. BABINEAU[1], H. M. MOON[1], A. R. NARAYAN[1], K. M. CORREA[1], V. SARAVANAPANDIAN[1], G. SUBRAMANYAM[3], T. CISNEROS[2], M. RIVERA[1], T. D. PALMER[1];

Abstract: Neurodevelopmental disorders (NDD), such as autism and schizophrenia have a diverse and multi-faceted etiology that is poorly understood, though epidemiological studies suggest that environmental risks such as prenatal infections or other gestational immune events correlate with increased NDD risk. Innate immune responses are evoked by toll-like receptor (TLR)-dependent signaling pathways. Both bacterial- (TLR4 selective) and viral- (TLR3-selective) mimetic-mediated maternal immune challenges have been shown to result in brain and behavioral changes (as reviewed by Meyer 2014), however, differences in methodologies prevent the direct comparison of the TLR- selective effects. Previously, we demonstrated that a TLR4-selective insult at E12.5 has adverse effects on fetal and placental health, proliferation of radial glial cells, altered cortical laminar patterning in the adult and behavioral deficits (Carpentier et. al 2013). Here, we aim to directly determine the differential effects of TLR3- and TLR4-selective agonists on a similar set of assays. Placental pathology and pregnancy outcomes were evaluated by quantifying tissue necrosis and fetal survival, respectively. Neocortical alterations in the developing fetuses were examined via immunohistochemistry for markers of cell proliferation and neural progenitor cell populations. Finally, behavioral outcomes were measured using tasks that evaluate behaviors analogous to the symptoms of NDDs, including pup vocalizations, social approach and pre-pulse inhibition. Our results indicate that bacterial and viral immune insults differentially affect placental health, fetal viability and early embryonic

brain development. Post-natal behaviour outcomes also appear divergent with the bacterial insult leading to an earlier onset and more severe phenotype of behavioural alterations. These findings suggest that specific immune events create differential outcomes for the health of the placenta and fetus and lead to distinct changes in cortical patterning which can ultimately manifest as unique behavioural symptoms. Our results have implications for understanding how similar environmental insults may lead to distinct developmental disorders or contribute to the heterogeneity of a specific condition.

Title: Gene by environment interactions in a maternal allergic asthma model of Autism Spectrum Disorders.

Authors: ***F. J. EMERSON**, M. L. BERKOWITZ-CERASANO, J. J. SCHWARTZER; Neurosci. and Behavior, Mount Holyoke Col., South Hadley, MA

Abstract: Autism Spectrum Disorders (ASD) are a class of neurodevelopmental disorders that currently affect around 1 in 68 children in the U.S. While genetics are key factors in the development of ASD, environmental factors such as perturbations *in utero* are believed to play a crucial role. Recent reports suggest an association between maternal allergic asthma (MAA) and a heightened risk of having a child later diagnosed with ASD. However, these studies are limited in identifying causal mechanisms and are unable to control for genetic susceptibility. Mouse strains afford the unique opportunity for exploring how maternal immune alterations may interact with genetic background to exacerbate environmental insults. For example, while both C57 and FVB mice show high social approach behaviors, FVB mice exhibit an enhanced immunological response to allergic asthma exposure compared to C57 mice. Therefore, it was hypothesized that MAA exposure in FVB dams would result in exacerbated ASD-like behavioral responses in offspring compared to C57 mice. To test this, we utilized a novel MAA mouse model in which female mice were sensitized and exposed to repeated allergic asthma inductions

throughout pregnancy. Male and female C57 and FVB offspring were tested for autism-associated behavioral deficits following developmental exposure to maternal allergic asthma. Our findings indicate an interaction between mouse strain and MAA exposure on sociability measures. Interestingly, while C57 mice showed no changes in sociability between treatment conditions, FVB offspring showed altered social approach and reciprocal social interaction when born to MAA-exposed dams, indicating a gene by environment interaction. These findings support a link between maternal allergic priming and altered social development in offspring.

Title: ASD-like behavioral deficits in a mouse model of gestational exposure to concentrated ambient particulate matter.

Authors: *M. A. COBURN[1], M. E. JOHNSON[1], P. B. TIJERINA[2], J. ZELIKOFF[2], J. SCHWARTZER[1];

Abstract: Exposure to city-level pollution, especially fine-sized particulate matter (<2.5 microns in diameter; $PM_{2.5}$), can have adverse neurodevelopmental effects. For example, epidemiological studies indicate that living in close proximity to a highway is associated with an increased risk of having a child who is later diagnosed with autism or other neurodevelopmental disorders. Mouse models offer a unique opportunity to directly test the biological and behavioral consequences of air pollution and identify which specific constituents produce neurodevelopmental deficits. Pregnant female $B_6C_3F_1$ mice underwent whole-body exposure to Concentrated Ambient $PM_{2.5}$ (CAPs) or Filtered Air (FA) for 6 hours per day throughout gestation followed by additional exposures 2 hours per day for 10 days postpartum. Adult offspring were then tested for autism-associated behavioral changes including reciprocal social interaction, social approach and recognition, and repetitive grooming behavior. Results revealed significant impairments in social behavior and increased repetitive grooming in male mice exposed to CAPs throughout development. These data support the link between environmental air pollution and increased risk of neurodevelopmental disorders.

Title: Deleterious impact of hyperoxia on the development of hippocampus in a mouse model of premature birth injury

Authors: ***C.-M. VACHER**[1,2], J. ABBAH[1], L.-J. CHEW[1], V. GALLO[1];
[1]Children's Natl. Med. Ctr., Washington, DC; [2]Paris Saclay Inst. of Neurosci., Orsay, France

Abstract: At birth, the newborn is exposed to a sudden transition from low oxygen *in utero* to relatively high oxygen tension in the extrauterine environment. With an already underdeveloped antioxidant defense system, coupled with high frequency of oxygen ventilation for lung complications, the preterm infant becomes particularly vulnerable to oxidative stress from reactive oxygen species (ROS). This can lead to cerebral damage and neurological sequelae, including learning difficulties. Adolescents born preterm show spatial memory deficits correlated with a smaller hippocampus[1], a brain structure important for cognitive processing. Disrupted hippocampal development is implicated, but the effects of high oxygen levels on ROS production and its consequences in developing hippocampal neurons have not been established. This study aims to evaluate 1/ the impact of hyperoxia (HO) on ROS production and its consequences in developing hippocampal neurons in a mouse model of neurodevelopmental injury, and 2/ the benefits of a pharmacological intervention by inhibiting GSK3β, a pro-apoptotic and anti-proliferative kinase.
Using a hyperoxia model of perinatal brain injury[2,3], which consists of exposing mice to high oxygen tension (80%) from postnatal day (P) 6 to 8, we have shown that HO induces a significant production of ROS (as evidenced by injecting pups with di-hydroethidium, a cellular superoxide indicator) in all subfields of the hippocampus (CA1-3 and dentate gyrus). This was associated with exacerbated cell death and reduced cell proliferation. By P60, HO mice exhibited a significant loss of interneurons in the whole hippocampus, and the dendritic arborization of remaining interneurons was significantly less complex than room air controls. Furthermore, GSK3β, a kinase known to increase apoptosis and to decrease neurogenesis and neuritogenesis, was more active in the hippocampus following HO. Finally, the HO-induced cellular alterations

observed at P8 and P60 were entirely prevented by GSK3β inhibitor administration during HO exposure.
In conclusion, our data show that early-life exposure to HO leads to increased hippocampal levels of ROS and the activated form of GSK3β. This is accompanied by a decline in neurogenesis and a disrupted development of the local inhibitory network. Taken together, these modifications may account for the diminished learning ability observed in our mouse model as well as in humans. Notably, the inhibition of GSK3β could represent a potential therapeutic intervention against the neurological outcomes of preterm birth.

Title: Long-term cognitive dysfunction associated with isoflurane/nitrous oxide-induced general anesthesia in neonatal nonhuman primates is greatly diminished by prophylactic administration of acetyl-l-carnitine

Authors: ***M. G. PAULE**[1], M. LI[1], S. LIU[1], X. ZHANG[1], J. P. HANIG[2], W. SLIKKER, Jr.[1], C. WANG[1];
[1]Div. of Neurotoxicology, FDA's Natl. Ctr. For Toxicological Res., Jefferson, AR; [2]Office of Testing and Res., Ctr. for Drug Evaluation and Res., Silver Spring, MD

Abstract: In proof-of-concept studies in rhesus monkeys it was shown that 24 hours of ketamine-induced general anesthesia during the first week of life caused significant neuronal cell death and seemingly permanent cognitive deficits in rhesus monkeys. In subsequent studies similar effects were noted after only 8 hours of general anesthesia induced by isoflurane (ISO, 1%) plus nitrous oxide (N2O, 70%). In both cases, subjects began training at 7 months of age to perform cognitive function tasks as part of the National Center for Toxicological Research Operant Test Battery (OTB): these included tasks for assessing learning, motivation, color

discrimination, and short-term memory. Subjects responded for food pellets by pressing response levers and press-plates during daily (M-F) test sessions (50 min). Training scores were assigned based upon their individual task performance. Beginning as early as 8 months of age—and continuing throughout prolonged testing (>2 years) typically with no indication of recovery—exposed animals earned fewer reinforcers in a task assessing appetitive motivation, completed less of a task designed to assess daily learning, and performed a visual discrimination tasks less efficiently than controls. Acetyl-l-carnitine, an anti-oxidant and mitochondrial membrane stabilizer, when given prophylactically was able to prevent many of the adverse functional effects of the ISO plus N2O anesthesia. These data suggest that specific behavioral phenotypes are associated with general anesthetic exposures that occur during a sensitive period of brain development and that certain agents will be able to ameliorate at least some of the developmental neurotoxicity associated with general anesthesia.

Title: Ketamine anesthesia during the first week of life can cause permanent cognitive deficits in rhesus monkeys

Authors: *J. C. TALPOS, III, J. CHELONIS, M. LI, M. P. GILLAM, C. WANG, W. SLIKKER, M. G. PAULE;
Natl. Ctr. for Toxicological Res., FDA, Jefferson, AR

Abstract: As a result of advances in medical practice more children born pre-term or with birth complications are surviving to adulthood. An unintended consequence of this is that more children are being exposed to various anesthetic and sedative agents at increasingly younger ages. The developmental consequences of these exposures on cognitive function are largely unknown because it is difficult to evaluate the safety of these agents directly in a pediatric population. In this circumstance nonhuman primates serve as necessary alternatives to estimating the neurotoxicological risk associated with perinatal drug exposure in very young children. In an attempt to model human pediatric anesthetic use, we exposed rhesus monkeys on post-natal day 5 or 6 to intravenous ketamine-induced general anesthesia (24h). When these monkeys reached 7 months of age, we started training them on the National Center for Toxicological Research

(NCTR) Operant Test Battery (OTB) to determine potential effects on cognitive ability. The OTB is designed to measure various aspects of complex brain function including color and position discrimination, working memory, motivation, and temporal discrimination / impulsivity and learning. We previously reported that after nearly 3 years of training animals exposed to ketamine performed worse on a color and position discrimination task and on a progressive ratio (PR) motivation task. These animals, now adults 9-10 years old, continue to show a similar pattern of impairment when compared to a control group (n=6). The ketamine group (n=6) consistently performs worse on an incremental repeated acquisition task (spatial discrimination learning task), earns fewer rewards in a temporal response discrimination (timing) task and a PR task and responds more slowly. Over the last 100 sessions the ketamine group has on average performed 1 standard deviation below the control group on these measures, suggesting that these impairments are permanent in the absence of a remediation program. Yet some areas of function appear to be preserved: no impairment was observed in the ability to learn a visual conditioned place response *after* response contingencies were reversed. These data indicate that 24h of ketamine anesthesia on postnatal day 5 or 6 is capable of causing permanent changes in cognitive performance in the rhesus monkey and suggest that a similar ketamine general anesthetic regimen would likely have detrimental consequences in very young human infants. Additional work is underway to determine if this effect is specific to ketamine, or a more general consequence of neonatal anesthesia.

Title: Prenatal valproic acid exposure induces sex specific autism-related behavioral phenotypes in prairie voles

Authors: *L. L. ELVIR[1], H. WANG[2], F. DUCLOT[1], Y. LIU[2], Z. WANG[2], M. KABBAJ[1]; [1]Biomed. Sci., [2]Psychology, Florida State Univ., Tallahassee, FL

Abstract: Previous studies have shown that rats and mice prenatally treated with sodium valproate (valproic acid, VPA) exhibit deficits in social behaviors that resemble some aspects of autism spectrum disorders. Although significant discoveries on the embryopathology of VPA have been proposed, not one study has assessed its effects on social bonding, a complex behavior not exhibited by rats and mice. In this study, we aimed at validating the socially monogamous prairie vole (*Microtus ochrogaster*) model for the study of the effects of prenatal VPA exposure. Male and female control and VPA-prenatally exposed subjects were assessed on a battery of behavioral tests to evaluate the VPA-induced social deficits and anxiety-like behavior. VPA-pretreated voles engaged in fewer play behaviors and had reduced social interaction with novel conspecifics of the same age, compared to control animals. An interesting sex difference is found: VPA-pretreated male, but not female, subjects showed enhanced anxiety-like behavior and did not develop partner preference during adulthood, in the absence of mating. We are now in the process of examining if partner preference formation is disrupted following cohabitation with mating in response to prenatal exposure to VPA. We are also examining, in the prefrontal cortex, mRNA and protein expression of genes that modulate social bonding in prairie voles, such as the oxytocin and vasopressin receptors, as well as genes largely implicated in neurodevelopmental disorders and involved in synaptic formation and signaling, such as Shank3, Nlgn3, and MeCP2.

Title: Chronically elevated prenatal cytokine exposure as a translational model for ADHD and ASD. Rodent behavior and resting state connectivity MRI

Authors: *B. D. MILLS[1], A. SHUMNMUGAVEL[2], A. GONCHAROVA[2], C. PIZZIMENTI[2], M. LATTAL[2], S. MITCHELL[2], D. FAIR[2];
[1]Oregon Hlth. & Sci. Univ., Portland, OR; [2]Behavioral Neurosci., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Attention deficit hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) have been linked to prenatal risk factors including maternal obesity, stress, and viral infections during pregnancy. These risk factors share a common mechanism, elevated inflammatory cytokines and in particular elevated interlukin-6 (IL-6). Resting state functional connectivity (rs-fcMRI) abnormalities have been identified in both ADHD and ASD and have similarly been identified in infants whose mothers had elevated IL-6 blood levels. The current work uses a rodent model to test the causal mechanisms of IL-6 exposure and behavioral and neural phenotypes associated with these developmental disorders. Sprague-Dawley rats were implanted with osmotic pumps delivering either saline or a daily dose 4.98 ug/kg IL-6 over the course of 40 days. This dose was designed to mimic chronic inflammatory states throughout pregnancy. Offspring were given a battery of behavioral tests and rsfc-MRI imaging both early (PD25) and late (PD50) in development. Here, we find that IL-6 exposed offspring show a robust anxiety phenotype on both the open field and light dark behavioral tests. We also found that IL-6 animals more readily acquired fear, as measured by increased freezing to three .5 mv footshocks. No differences in social approach behavior was found. Finally, to serve a translational tool, we discuss atypical network structure, default mode network connectivity in IL-6 exposed animals, developmental change in rs-fcMRI, and the relationship of these findings to connectivity structure seen in developmental disorders. Overall, this work sheds light on the underlying mechanisms associated maternal inflammation and the role of IL-6 as risk factor for developing phenotypes seen in ASD and ADHD.

Title: Developing a ferret model of newborn brain injury and cortical dismaturation

Authors: A. MIKHAILOVA[1], J. K. ELLIS[2], *P. S. MCQUILLEN[3];
[1]Pediatrics, [2]Regeneration Med., [3]Pediatrics and Neurol., Univ. of California San Francisco, San Francisco, CA

Abstract: Background: Existing small animal models fail to reproduce permanent dysmyelination that is the hallmark of brain injury in the preterm human newborn. Furthermore, it is unclear how closely these models recapitulate human developmental pathways because rodents have a lisencephalic cortex. Despite being a small animal (0.5-1kg), ferrets have gyrencephalic cortex with radial cortical organization. Objective: We aim to develop an improved translational small animal model that reproduces cerebral cortical dysmaturation that may contribute to adverse neurodevelopment following human newborn brain injury. Our specific focus is glial development in the outer subventricular zone and late cortical migratory pathways of neuronal precursors. Methods: Using a previously described method of chronic sublethal hypoxia (Tao et al Pediatric Research (2012) 71, 192-198), jill and kits are exposed to 10% oxygen from P10-20. Some kits are examined at P20, while the rest are reared in normoxia until sacrifice. Age matched controls are reared in normoxia. Results: (1) Consistent with published findings, following exposure to hypoxia, myelin basic protein expression decreases and glial fibrillary protein expression increases at P20 and P30. We evaluated the persistence of these changes into later ages - at P40, GFAP is still upregulated in white matter, and MBP doesn't extend out into lower cortical layers like in control (normoxic) animals. Studies are in progress to determine the permanency of changes and evaluate functional myelination (e.g. electron microscopy). (2) Using cell proliferation markers we find decreased density of ki67 positive cells at P20 following hypoxia vs age matched control, but ki67 density is greater at P30 following hypoxia than age matched control. We are using neural cell lineage-specific markers to determine which cells undergo changes in proliferation and potential associated maturation arrest. (3) Hypoxia during this period (P10-20) also influences newly identified postnatal neuronal migration streams, which are most active at P40. Following hypoxia, the transcription factor Sp8 is increased in the white matter and its laminar organization is affected in the cortex. Future analysis will look at younger ages (P20, P30) to evaluate the progression of Sp8 expression. Lastly, we are using lineage tracing techniques to track the postnatal neuronal migration in normal development and following hypoxia. Conclusion: A ferret model of human preterm brain injury may provide insight into important cerebral cortical developmental pathways that are perturbed with preterm birth, birth asphyxia and congenital heart disease in human newborns.

Title: Postnatal fluoxetine treatment evokes persistent alterations in perineuronal nets within the hippocampus

Authors: S. MUKHOPADHYAY[1], A. SOOD[1], *V. A. VAIDYA[2];
[1]Tata Inst. Fundamental Res., Mumbai, India; [2]Tata Inst. Fundamental Rese, Mumbai, India

Abstract: Major depressive disorder is a complex and widespread psychiatric disorder. Studies have indicated that early life events have a powerful role in modulating the development of emotional neurocircuitry, and that fine tuning of these circuits is greatly influenced by serotonergic signaling in this period. Increasing availability of synaptic serotonin in an early postnatal window in rats using a Selective Serotonin Reuptake Inhibitor (SSRI) - Fluoxetine, results in the emergence of depressive- and anxiety-like behaviours in adulthood. We used this postnatal Fluoxetine model of depression (PNFLX) and investigated the acute and long lasting consequences of PNFLX treatment on cellular architecture in key neurocircuits implicated in emotional regulation, focusing on GABAergic interneurons. We studied three non-overlapping subtypes of GABAergic interneurons characterized by the presence of Parvalbumin (PV), Somatostatin (SST) and Calretinin (CR) in the hippocampus and the prefrontal cortex (PFC). Numbers of GABAergic neurons have been shown to be altered in different models of psychopathology, and are especially vulnerable to early life interventions since they continue to migrate and integrate into circuits in this postnatal period. Our results indicate no striking differences in the numbers of PV, SST and CR positive interneurons, in either the hippocampus or the PFC, between the Vehicle treated and PNFLX treated animals in adulthood or immediately after the drug treatment is ceased at postnatal day 21. Further, we studied perineuronal nets (PNNs), which are ECM-associated structures found around fast spiking PV positive interneurons, and play an important role in circuit maturation and stabilization. We observed a reduction in the number of PNNs in the hippocampal subfields of adult animals with a history of PNFLX. This may imply a circuit maturation defect in these PNFLX treated animals arising due to altered serotonergic signaling in a critical window important for the sculpting of emotional neurocircuitry. At least one study has reported that prenatal fluoxetine exposure can hamper formation of hippocampal PNNs, and Fluoxetine administration is known to reopen critical window-like neuronal plasticity in adulthood. We thus hypothesize that increased serotonergic drive as a result of Fluoxetine exposure during an early postnatal window leads to a

defect in the initiation, regulation or closure of the maturation process of emotional neurocircuitry, and that this may underlie at least some of the behavioural deficits observed in this model of early life pharmacological perturbation leading to development of depression and anxiety like behaviours.

Title: Early changes in behavior and brain metabolism in socially isolated rats

Authors: *J. HERNANDEZ-FALCON[1], M. PORRAS-VILLALOBOS[2], E. AGUIRRE-BENÍTEZ[2], L. PARRA-GÁMEZ[2], J. GONZÁLEZ-RÍOS[2], M. AVILA-RODRÍGUEZ[2], D. ALBORES-GARCÍA[2], K. MENDOZA-ANGELES[2], A. MELO[3];

Abstract: Social and sensory experience is vital for a harmonic development, maturation and whole individual organization. Development involves the coordinated growth and functioning of cardiovascular, nervous and endocrine systems, among others. In altricial species, maternal care, immediately after birth and until weaning, determines a well growth in pupae. Social interaction of the cub with its mother and littermates seems determinant for a successful development, such that early social isolation impairs postnatal development.
The main goal of this work was to analyze the effects of social isolation in young artificially reared rats upon behavior, brain glucose metabolism, and astrocyte population in the brain. Three day-old male pups were artificially reared in isolation. Sensory stimulation during artificial rearing was provided each 4 hours. After weaning, we tested animals in the open field paradigm and measured brain use of 18-fluoro-glucose (through micro-PET). After sacrifice, we analyzed astrocyte population in different brain areas.
Results show an erratic behavior in experimental animals: long lasting periods in the open field combined with an increased tendency to bury themselves; higher levels of aggressiveness in the presence of littermates, and increased grooming. PET images showed decreased capture of 18-fluoro-glucose in amygdala and brain cortex. This decrease was more evident during social

interaction with littermates. Astrocytic distribution was also different in experimental animals. In them, we detected a greater number of astrocytes in the same regions. These results indicate that social isolation disturbs brain metabolism and development which is reflected in an altered behavior.

Title: Effect of developmental sleep fragmentation on social behavior and parvalbumin expression in prairie voles

Authors: ***M. M. LIM**[1,2,3], E. A. D. HAMMOCK[4], J. QUINTANA[4], R. D. CHAMPAIGNE[1], R. A. OPEL[1], D. L. COCKING[1], R. C. DRIESSEN[1];

Abstract: Consolidated sleep periods during development, especially rapid eye movement (REM) sleep, are critical for parvalbumin inhibitory interneuron expression in basic brain circuits (such as the visual system). Parvalbumin expression is significantly decreased in brains of human subjects with autism spectrum disorder. It is unknown whether REM sleep plays a role in the maturation of more complex circuits for social behavior, such as those relevant to autism. Prairie voles (*Microtus ochrogaster*) are a highly social rodent species and form lifelong pair

bonds with other individuals, thus providing an ideal model organism to study the role of sleep in shaping social behavior. We selectively suppressed REM sleep in prairie vole pups during a sensitive post-natal period of development from P14 to P21. Following developmental sleep fragmentation, voles underwent tests for social behavior as juveniles, and again as adults. At 5 weeks of age, there were no significant differences in social behavior between groups. At 12 weeks of age, male prairie voles showed hyperactive approach behavior towards juveniles, where as females showed decrease approach behaviors. Social memory as assessed by a habituation-dishabituation paradigm did not seem to be affected by sleep fragmentation. However, sleep-fragmented male prairie voles showed profoundly impaired pair bond formation as assessed by the partner preference test. Sleep-fragmented females showed mildly decreased partner preference but significantly increased aggression towards strange males. Locomotor activity assays and wheel running showed that sleep-fragmented males were more hyperactive than controls. Parvalbumin immunohistochemistry was performed to determine if sleep fragmentation disrupted parvalbumin immunoreactive cell counts in the neocortex, and if effects of sleep fragmentation on parvalbumin interneuron are sex or age dependent.
Our data suggest that sleep fragmentation during the third post-natal week profoundly impairs social development. Studies utilizing this unique animal model will enhance our understanding of modifiable risk factors, such as sleep, that may contribute to atypical development of the brain and social behavior.

Title: Effects of exposure during adolescence to different PCB aroclors and doses on hyperactivity and impulsiveness in male and female rats

Authors: *J. P. LOMBARDO[1], J. A. PECK[1], D. F. BERGER[2], P. M. JEFFERS[3];
[2]Psychology, [3]Chem., [1]SUNY Col, Cortland, Cortland, NY

Abstract: Previous studies of PCB-induced hyperactivity and impulsiveness in rats suggest that exposure to PCBs have different effects on males and females. To further investigate this possible sex difference, two studies were conducted to examine the effects ingested polychlorinated biphenyls (PCBs) would have on the operant behavior of water deprived

Sprague-Dawley rats. All animals were dipper - trained to bar press for water. All animals were deprived of water for 22-hr prior to test days. In Experiment 1 the diet of adolescent male and female rats was augmented with 0.5 µg/g Aroclor 1248 for 30 days. In Experiment 2, groups of male and female adolescent rats had their diets augmented with 1.5 or 4.0 µg/g Aroclor 1248 for 30 days. Other groups of adolescent male and female rats had their diets augmented with 1.5 or 4.0 µg/g of a 1:1 mixture of Aroclors 1254/1260. In both experiments animals were tested in a mult 120-s FI- 5 min extinction procedure. Exposure to PCBs, in all rats, took place between PND 35-64. On test days, operant lever responding was reinforced with water. In Experiment 1 ingestion of Aroclor 1248 did not produce hyperactivity or impulsiveness in the female rats, but did produce both behaviors in males. Results of Experiment 2 revealed a similar pattern: ingestion of both Aroclor mixtures did not produce hyperactivity in females, but male rats exposed to either Aroclors showed hyperactive and impulsive behavior. Females in Experiment 2 that were exposed either 1.5 or 4.0 µg/g of Aroclor 1248 or the 1254/1266 mixture were *hypoactive* relative to their controls.

Title: The impact of preconception paternal experience on offspring neurodevelopment and behavior

Authors: *A. F. HARKER[1], R. DOMBOWSKY[1], B. KOLB[2], R. GIBB[2];
[2]Neurosci., [1]Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: A rich literature has been amassed demonstrating the impact of early life events on the structure and function of the developing brain. While a plethora of research has shown that maternal experience during the prenatal period of life has the ability to alter neurodevelopment and behavioural outcomes of offspring, far less in understood regarding the impact of preconception paternal experience on developing brain architecture. The goal of this research

was to examine the effect of two independent preconception paternal experiences on subsequent neurodevelopment and behaviour of male and female offspring. Research has shown that stress during the prenatal period can alter brain morphology in the developing brain, and is thought to be a factor in the development of some adult psychopathologies. Our first experiment examined the impact of preconception paternal stress on offspring brain and behaviour. Our hypothesis was that paternal stress in the preconception period would negatively impact brain development in offspring, leading to behavioural abnormalities. While stress and environmental enrichment have been shown to have opposing effects on brain architecture and behavioural outcomes in offspring, we decided to explore the impact of environmental enrichment provided to fathers during the preconception period. We hypothesized that preconception paternal enrichment would alter brain development and positively impact behaviour of offspring. Both experiments followed the same experimental design. Male Long Evans rats were exposed to either a stressing paradigm or a complex environment for 27 days prior to mating. Developmental assays, anatomical measurements, and brain morphology analyses were conducted throughout offspring lifespan.

Title: Transgenerational effects of prenatal ethanol exposure in a mouse model

Authors: ***D. J. ROHAC**[1], R. NAIR[2], K. J. HUFFMAN[1];
[1]Psychology, [2]Col. of Natural and Agr. Sci., Univ. of California Riverside, Riverside, CA

Abstract: Fetal Alcohol Spectrum Disorders (FASD) describe a range of phenotypes in children whose mothers consumed alcohol during pregnancy. Recent work by our laboratory suggests that prenatal ethanol exposure, or PrEE, alters DNA methylation, one of the main pathways involved with epigenetic inheritance, in the offspring. Thus, we have proposed that some of the hallmark phenotypes of FASD may be heritable to non-exposed generations. To explore how PrEE may induce heritable, transgenerational effects on neocortical anatomy and behavior, we used a murine FASD model in CD-1 mice. Our initial studies on the first filial (F1) generation of PrEE mice found disruptions in the intraneocortical network, changes to the anatomy of the neocortex and altered behavior (El Shawa et al., 2013). In this study, we extend the anatomical and

behavioral analyses in F1 PrEE mice to F2 and F3 generations. If changes are seen in the F3 generation, we can deduce that an epigenetic pathway has been altered and the changes are not caused by direct exposure. Analyses in F2 and F3 PrEE mice were performed on the day of birth (P0) and 20 days later, at normal weaning age (P20). Assessments at P0 included structural thickness measurements in different cortical regions including frontal cortex and the corpus callosum as well as intraneocortical connectivity. We found differences in anatomical structures that persist through the third generation after PrEE and found that results from behavioral assays, measured at P20, demonstrated a heritable phenotype. Specifically: F2 and F3 PrEE mice showed ectopic connections in frontal cortex, altered cortical thickness measures at P0 as well as reduced sensorimotor integration, motor coordination and increased anxiety when assessed on the Suok test at P20. Along with the changes to DNA methylation (Abbott et al., in preparation), these data point to a strong heritable effect of prenatal ethanol exposure that is transmitted via an epigenetic pathway.

Title: Negative synergism between prenatal alcohol exposure and chorioamnionitis: a preclinical investigation

Authors: *J. MAXWELL, S. DAVIES, D. SAVAGE, L. JANTZIE, PhD;
Univ. of New Mexico Hosp., Albuquerque, NM

Abstract: To identify and refine targets for new therapeutic interventions, a clearer understanding of how *in utero* insults cause impaired neurodevelopment is imperative. Prenatal alcohol exposure (PAE) and placental insufficiency are clinically related, but the mechanisms leading to subsequent brain injury have not been studied in validated animal models. Women who abuse alcohol during pregnancy have a five-fold increased rate of chorioamnionitis, the chief placental abnormality associated with preterm birth and encephalopathy of prematurity. Indeed, numerous structural and diffusion cerebral abnormalities are seen in children with prenatal alcohol exposure. Here, we hypothesized that PAE would exacerbate chorioamnionitis worsening brain injury, including significant deficits in myelination and white matter

microstructure. To this end, pregnant Long-Evans rats were allowed to drink 5% ethanol or saccharin until embryonic day 17 (E17) to mimic moderate PAE. Subsequently, on E19 a laparotomy was performed and the uterine arteries were clamped for 30 minutes to induce placental insufficiency and transient systemic hypoxia-ischemia (TSHI). Lipopolysaccharide (LPS, 4μg) was then injected in to each amniotic sac. The laparotomy was closed and pups born at E22. Pups matured with their dams until postnatal day 15 (P15) and P28 at which time brain tissue was collected. PAE+TSHI+LPS resulted in a severe injury concomitant with significantly increased fetal mortality and reduced postnatal survival ($p<0.05$). Specifically, the combination resulted in 95% fetal mortality and death of live born offspring by P2 (n=5 dams). This fetal and postnatal mortality was significantly greater than that observed in either PAE (3% mortality; n=4 dams) or TSHI+LPS (57% mortality; n=5 dams) alone. Animals with TSHI+LPS alone had reduced white matter fractional anisotropy and impaired axial and radial diffusion compared to sham ($p<0.05$). This is the first report that the combination of prenatal alcohol exposure and chorioamnionitis results in a severe in utero insult consistent with spontaneous abortion in rodents and injury incompatible postnatal life. Future studies will dissect the mechanisms of increased mortality with specific focus on the maternal-placental axis and developing brain. Preclinical models recapitulating prenatal alcohol exposure in the setting of chorioamnionitis will aid in the identification of interventions that may be used to reduce brain injury and chronic neurologic disabilities in children.

Title: Differential spatial extinction behavior in male and female rats prenatally exposed to moderate levels of ethanol

Authors: ***C. M. MAGCALAS**[1], J. L. WAGNER[2], S. DAVIES[2], D. D. SAVAGE[2], D. A. HAMILTON[3];
[2]Neurosciences, [3]Psychology and Neurosciences, [1]Univ. of New Mexico, Albuquerque, NM

Abstract: Prenatal alcohol exposure (PAE) is associated with structural and physiological changes that impact the central nervous system and can result in persistent negative consequences in a broad spectrum of cognitive and behavioral domains including deficits in motor behavior, social behavior, and behavioral flexibility. Previous studies have characterized the influence of PAE on spatial navigation acquisition and extinction through various behavioral paradigms including the Morris water task (MWT). The current study focuses on examining the behavioral consequences of PAE on spatial extinction behavior through the use of the MWT. Pregnant rat dams voluntarily consumed saccharin (SAC) water containing 0% or 5% ethanol (EtOH) for 4 hours per day during the entire gestational period. Male and female pups matured and were tested in the MWT in adulthood (>90 days old). In order to assess extinction behavior the animals were tested in a 5-day hidden platform protocol. Days 1-4 of the hidden protocol consisted of 12 training trials. At the end of day 4, the animals were tested in 3 consecutive no-platform probe trials to assess extinction behavior. Day 5 began with one no-platform probe trial to assess spontaneous recovery followed by 12 retraining trials. All of the animals successfully learned the hidden platform goal location during the initial training period. All of the male animals (PAE and controls) failed to extinguish, which was evident by the consistent short latency to reach the learned target location. The control females successfully extinguished, but the ethanol exposed females failed to extinguish the learned behavior. These outcomes suggest that animals exposed to moderate levels of ethanol during gestation have intact spatial acquisition abilities, but may have distinct extinction behaviors that may be sex specific and can be influenced by PAE. [Supported by grant AA019462 to DH].

Title: Microstructural connectivity of the corpus callosum after moderate prenatal alcohol exposure in the adult rat.

Authors: *C. I. RODRIGUEZ[1], G. LIEBERMAN[1], S. DAVIES[2], D. SAVAGE[2], D. HAMILTON[1];
[1]Psychology, [2]Neurosciences, The Univ. of New Mexico, Albuquerque, NM

Abstract: Previous research revealed microstructural abnormalities in the corpus callosum of individuals exposed to prenatal alcohol (PAE). Subsequent research conducted in a preclinical models of PAE demonstrated similar alterations in several white matter structures including the corpus callosum. However, the effects of moderate exposure on microstructural connectivity of the corpus callosum have not been thoroughly examined. Here, we assessed the effects of moderate PAE on measures of fractional anisotropy (FA), diffusivity, and size of the rat corpus callosum.

Long-Evans rats were exposed to 5% ethanol or saccharin throughout gestation. In adulthood, rats were anesthetized and placed in a 4.7T Bruker Biospin magnetic resonance scanner for the acquisition of diffusion weighted images.

Following image preprocessing, measures of FA, axial diffusivity (AD), radial diffusivity (RD), mean diffusivity (AD), and area were gathered and compared across sex and prenatal treatment conditions by a two-way univariate analysis of variance. No significant interactions for measures of FA, AD, RD, MD, and total sampled area were detected. Significant sex differences for FA, RD, and MD were observed. A significance trend for axial diffusivity was observed for sex. Strong effect sizes were observed for sex differences in measures of FA, RD, and MD. No significant effect of total area sampled for males or females was detected. No significant differences in prenatal treatment condition separated by sex were found when comparing measures of FA, MD, RD, AD, and sampled area.

In contrast to previous research conducted on children and adults with documented PAE, these results suggest that moderate PAE does not negatively impact axonal organization of the corpus callosum in a preclinical model of PAE. Additional reports of FA in preclinical models are mixed and implicate FA as an unreliable marker for PAE. Consistent with these findings, is a report that points to deficits in white matter myelination, but intact axonal integrity, after a single binge-like exposure to alcohol on gestational day (GD) 7. Moreover, measures of anisotropy, diffusivity, and area were limited to the whole coronal sections of corpus callosum as opposed to sagittal sections that have revealed regional differences in posterior regions of the corpus callosum. As a result, additional work is needed to examine regional differences in the corpus callosum. Additional methods that are more sensitive to white matter myelination merit strong consideration. The present findings add to the body of literature emphasizing functional and behavioral consequences of PAE may occur in the absence of structural abnormalities.

Title: Differential impact of exercise and environmental complexity on hippocampal Bdnf DNA methylation, gene expression, and dendritic complexity in a rat model of FASD

Authors: *A. Y. KLINTSOVA, K. E. BOSCHEN, T. L. ROTH;
Psychological and Brain Sci., Univ. of Delaware, Newark, DE

Abstract: Exposure to ethanol *in utero* in humans results in neuroanatomical, cognitive, behavioral, and physiological deficits collectively known as Fetal Alcohol Spectrum Disorders (FASD). Third trimester-equivalent (postnatal days [PD] 4-9) alcohol exposure (AE) in a rat model negatively impacts hippocampal neuroplasticity, increases apoptosis, and impairs adult neurogenesis and LTP. The current study investigates Brain-derived Neurotrophic Factor (*Bdnf*) gene expression, *Bdnf* DNA methylation, and granule cell dendritic complexity in the adult rat hippocampus following neonatal AE. Previous work from our lab has shown that PD4-9 AE increases BDNF and TrkB protein and *Bdnf* gene expression in the PD10 hippocampus (Boschen et al., 2015). Additionally, our model of FASD alters dendritic morphology in medial prefrontal cortex on PD72. For the current study, male AE pups received 5.25 g/kg/day of alcohol on PD4-9 in a binge-like manner via intragastric intubation. Two control groups were used: sham-intubated (SI) and suckle control (SC). From PD30-72, rats were housed in one of three conditions: standard housing (SH; 3/cage), voluntary wheel running (WRWR; 3/cage), or wheel running (PD30-42) followed by housing in a complex environment (PD42-72; 9-12/cage) (WREC). Tissue from the hippocampus was collected on PD72. AE animals had decreased dendritic complexity of immature (doublecortin/DCX-positive) dentate gyrus neurons on PD72, and these alterations to dendritic morphology were rescued by WREC and WRWR. No baseline *Bdnf* gene expression changes were found at PD72 between neonatal conditions. Interestingly, WRWR significantly increased gene expression in all three neonatal treatment groups, however WREC did not alter levels of *Bdnf* mRNA. For *Bdnf* DNA methylation, preliminary data suggests no changes to steady-state methylation status in AE animals, and lower methylation following access to WRWR. Overall, these data indicate that while neonatal alcohol exposure has pronounced effects on *Bdnf* gene expression shortly following exposure (Boschen et al., 2015), these alterations become more subtle across the lifespan. In addition, this work shows that our model of FASD negatively impacts granule cell dendritic complexity independent of

hippocampus-wide alterations to basal *Bdnf* expression. Finally, our data support the further investigation of WREC and WRWR as therapeutic interventions for the alcohol-damaged brain.

Title: A canonical Wnt-Frizzled pathway regulates epithelial mesenchymal transition in prolactin-secreting tumors in the pituitary of fetal alcohol exposed rats

Authors: S. JABBAR[1], W. BELDEN[2], J. PARK[2], *D. K. SARKAR[2];
[1]Animal Sci., Rutgers Univ., New Brunswick, NJ; [2]Rutgers, SUNJ, New Brunswick, NJ

Abstract: Prolactin-secreting pituitary tumors (prolactinomas) are the most common pituitary tumors in humans. Majority of prolactinomas are adenomas and benign and slow growing, but in some cases, they are locally aggressive and invasive. We have recently shown that alcohol abuse during pregnancy result in fetal programming of the pituitary gland to produce aggressive prolactin-producing tumors in the offspring. In this study, we employed RNA-seq to identify putative genes responsible for tumor aggressiveness in alcohol-programmed pituitaries. Pregnant Fischer 344 rats were fed between gestational days 7 and 21 with a liquid diet containing 6.7 % alcohol (AF), pair-fed with isocaloric liquid diet (PF), or fed ad libitum with rat chow (AD). At 60 days of age, female offspring rats were ovariectomized and received a subcutaneous estradiol implant. These rats were sacrificed at 3 months after the estradiol implants. We found that pituitary spheres from fetal alcohol exposed rat, express progenitor mesenchymal cell markers such as (OCT4, SOX2, KLF4, NANOG, CD133, Nestin and CD34). The gene ontology (GO) analyses of RNA-seq data of pituitary tumors from AF and AD reveal that most of the genes in AF animals are related to the mesenchymal characterization. We found that the Wnt5a and Wnt5b ligands, along with their cognate receptor Fzd, are generally overexpressed in pituitary tumor tissue of alcohol-exposed animals as compared to those in control animals. In addition, we found increased nuclear β-catenin (likely due to loss of E-cadherin), transcriptional activity of T cell factor (TCF), and several other growth factors including TGFβ, EGF, and FGF in the AF rat pituitaries. These data provide evidence for aggressive prolactinoma development due to overexpression of EMT factors involving Wnt/Frizzled signaling in the pituitary after estrogen

treatment in fetal alcohol exposed female rats. However, further studies need to be done to evaluate whether fetal alcohol exposure directly upregulates EMT pathway through Wnt/Frizzled signaling to increase aggressiveness in the pituitary gland. (This work is supported by a National Institute of Health grant R01 AA11591).

Title: Desformylflustrabromine, a positive allosteric modulator of the α4β2 nicotinic receptor, acts as an inhibitor of other heteromeric nicotinic receptor subtypes

Authors: *L. DECRISTOFANO, S. KHATRI, D. TORRES, M. SCHULTE;
Pharmaceut. Sci., Univ. of the Sci. in Philadelphia, Philadelphia, PA

Abstract: Nicotinic acetylcholine receptors are located throughout the central and peripheral nervous systems and have been implicated in many disorders including autism, depression, ADHD, and nicotine dependence. Members of the cys-loop family, nAChRs are composed of five subunits which can be assembled in a wide array of combinations that include α2-α9 and β2-β4 subunits. The α3β4 subtype of nAChR is found in the habenula and the interpeduncular nucleus where it may play a role in addiction pathways. Desformylflustrabromine (dFBr) is an established positive allosteric modulator of α4β2 nicotinic receptors and an inhibitor of α7 receptors; however, its effect on other nicotinic receptor subtypes has not been previously determined.
We examined the selectivity of dFBr on three heteromeric nicotinic receptors, α3β4, α4β4, and α3β2. Receptors were expressed in Xenopus laevis oocytes by micro injection of mRNA (300ng/µl) corresponding to the appropriate receptor subunits in α to β ratios of 1:1, 1:9, and 9:1. The effect of dFBr on each subtype was evaluated using two-electrode voltage clamp electrophysiology. Oocytes expressing nAChRs were exposed to dFbr alone to determine if it was capable of activating the receptors. Ach and dFBr were also co-applied to determine if dFBr was capable of inhibiting or modulating Ach induced activity.
Previous studies suggest that α4β2 assembles in both low sensitivity and high sensitivity isoforms. Ach dose response curves obtained from analysis of these receptors at different α/β

injection ratios supports this hypothesis. Data from these experiments also demonstrate that dFBr is an inhibitor of Ach induced responses on all three receptor subtypes. No positive allosteric modulation was observed, supporting the high selectivity of dFBr's potentiation at the α4β2 subtype. Based on these findings, we determined that both the α and β subunits contribute to dFBr's effects on different receptor subtypes.

Title: Engineered acetylcholine binding proteins for structure-guided drug design

Authors: *J. BOBANGO, S. WENSEL, I. TALLEY, T. T. TALLEY;
Dept. of Biomed. and Pharmaceut. Sci., Idaho State Univ., Meridian, ID

Abstract: Nicotinic acetylcholine receptors (nAChRs) are widely distributed throughout the CNS and periphery where they have crucial roles in physiological processes including learning, memory, and cognition. Consequently, nAChRs are potential targets for treating a variety of neurodegenerative disorders. Additionally, a number of natural products have evolved over time that target nAChRs and function for either protection or predation. Moreover, the nAChRs are the biological target of the fastest growing class of insecticides worldwide—the neonicotinoids. These pivotal roles necessitate a detailed understanding of the molecular determinates of ligand recognition and specificity for the nAChRs. The acetylcholine binding proteins (AChBPs) have been established as structural surrogates for the extracellular ligand binding domain of nAChRs and have contributed a great deal of information on the native receptor. Despite the utility of the AChBPs, they possess a distinct pharmacology to that of humans and other species of interest. To address this issue we have generated series of engineered AChBPs to evaluate potency and specificity of known and novel compounds. Furthermore, we have utilized X-ray crystallography for the direct observation of binding interactions at atomic-level resolution. Together, this allows us to contrast pertinent pharmacological information for structure-guided drug design.

Title: Chipping away at regulation of nicotinic acetylcholine receptor expression with NACHO

Authors: ***R. J. LUKAS**, J. B. EATON, L. LUCERO, P. WHITEAKER, A. A. GEORGE; Barrow Neurol Inst., Phoenix, AZ

Abstract: Nicotinic acetylcholine receptors (nAChR) are expressed extensively in all compartments of the nervous system, in skeletal muscle, and in other organs or systems such as the immune system. In these locations, nAChR play critical roles in health and have been

implicated in many disease processes and medical conditions. nAChR exist as a family of ligand-gated ion channel subtypes assembled as pentamers of different combinations of subunits encoded by a family of sixteen different genes. The law of identity (A is A) dictates that a native nAChR subtype and a heterologously expressed nAChR subtype of the same subunit composition and arrangement must have the same elemental properties. However, the local milieu can differentially influence observable properties of a given nAChR subtype. It sometimes has been a struggle to heterologously express some nAChR subtypes to facilitate comparing their properties to those of native nAChR. Examples are the failures using COS, CHO, HEK or other cells lines as hosts compared to our success in heterologously and stably expressing functional, human α7-nAChR (i.e., composed of α7 subunits) in the human epithelial cell line, SH-EP1. A multi-transmembrane domain protein has been identified recently ["NACHO" - Gu, Bredt and others, Neuron (2016) 89:1-8] that resides in the endoplasmic reticulum (ER) and promotes α7-nAChR expression, indicating importance of cell type-specific mediation of nAChR functional levels. NACHO was initially discovered, by high throughput screening, in a rare, human HEK cell variant capable of expressing functional α7-nAChR. We now demonstrate abundant expression of NACHO as mRNA in SH-EP1 cells, helping to explain the ability of those cells to stably express α7-nAChR. We also have confirmed potent facilitation of α7-nAChR functional expression in *Xenopus* oocytes also expressing NACHO, and at levels much higher than those in the presence of another chaperone, Ric-3. This occurs even for concatenated α7-nAChR, suggesting that NACHO facilitates exit of assembled receptors from the ER, although it may also promote assembly from loose subunits. Additional studies concern effects of NACHO on functional expression of other nAChR subtypes and, reciprocally, influences of nAChR functional modulation on NACHO expression. At a minimum, and as opposed to use of allosteric modulation, which alone could affect receptor properties, NACHO is a very useful research tool to "naturally" elevate functional expression of nAChR.

Title: Optogenetic activation of striatal cholinergic interneurons and D2 receptor-expressing GABAergic medium spiny neurons regulates tardive dyskinesia.

Authors: *T. BORDIA, D. ZHANG, X. A. PEREZ, M. QUIK;
Ctr. for Hlth. Sci., SRI Intl., Menlo Park, CA

Abstract: Tardive dyskinesia (TD) is a potentially irreversible drug-induced movement disorder that arises as a side effect of antipsychotics. These drugs are the mainstay of treatment for schizophrenia and bipolar disorder. They are also increasingly prescribed for major depressive disorder, autism, attention deficit hyperactivity disorder, obsessive compulsive disorder and post-traumatic stress. There is thus a need for therapies to reduce TD. Previous work showed that nicotine administration decreased haloperidol-induced vacuous chewing movements (VCMs) in a rat TD model. The present experiments demonstrate that nicotine (300 µg/ml in drinking water) also reduced antipsychotic-induced VCMs (~50%) in mice whether the antipsychotic haloperidol was given via constant infusion (subcutaneous pellet 3 mg/kg/d) or injection (1 mg/kg twice daily). To elucidate the pathways and mechanisms that underlie TD, we used optogenetics with a focus on the striatum because of the close link of this region to TD. Optical stimulation of striatal cholinergic interneurons using choline acetyltransferase (ChAT)-Cre mice expressing ChR2-eYFP decreased haloperidol-induced VCMs (~50%), with no effect in control-eYFP mice. Activation of striatal D2 medium spiny neurons using ChR2-eYFP expressing Adora2a-Cre mice also diminished antipsychotic-induced VCMs, again with no effect of stimulation in control-eYFP mice. The stimulation-induced declines in VCMs occurred via nicotinic acetylcholine receptors in both ChAT-Cre and Adora2a-Cre mice. Molecular studies indicate c-Fos activation plays a role. Overall, this work indicates that striatal cholinergic interneurons and GABAergic neurons play an important role in TD. Moreover, these studies suggest that nAChR drugs may be useful for reducing antipsychotic-induced TD.

Title: Role of the homo and heteromeric nicotinic acetylcholine receptor in mediating cytotoxicity after delayed methylmercury exposure in PC12 cells

Authors: *M. RIOS CABANILLAS[1], W. D. ATCHISON[2];
[1]Pharmacol. and Toxicology, [2]Michigan State Univ., East Lansing, MI

Abstract: Acute exposure to methylmercury (MeHg) disrupts internal calcium (Ca^{2+}) homeostasis and causes subsequent cell death. The pathways involved during the MeHg-induced increase in internal Ca^{2+} concentration ($[Ca^{2+}]_i$) and cytotoxicity are still not completely identified. Studies show that nicotinic cholinergic receptors (nAChRs) appear to contribute to MeHg-induced cytotoxicity in differentiated sympathetic neuron-like PC12 (dPC12) cells. Exposure to the nonspecific nAChR antagonist, mecamyllamine (MEC), increases cell viability after acute MeHg exposure. As different nAChR subtypes act in cell-type specific manner, and have differential Ca^{2+} affinities, we compared the role of the highly Ca^{2+}-permeable homomeric α7 subtype nAChR with other heteromeric nAChRs, to the contribution of MeHg-induced cytotoxicity. Cell viability was assayed using the calcein AM and ethidium homodimer-1 (Ethd-1). Calcein AM stains cytoplasm of live cells while Ethd-1 stains DNA of dead cells. dPC12 cells were exposed to 1, 2 or 5 μM MeHg during 1 hr in the absence or presence of the specific (α7) or nonspecific blockers: MLA (5 μM) or MEC (5 μM), respectively. Delayed viability measurements after MeHg exposure during 1 hr significantly decreases dPC12 cells viability in a concentration-dependent manner. At 2 μM MeHg, presence of either MEC or MLA treatments alone significantly increases viability by 37% and 32%, respectively. Furthermore, combination of MEC + MLA together significantly increases the protection provided by either antagonist alone by 16%. At 5 μM MeHg only MEC treatment significantly increased dPC12 cell viability by 39% from MeHg treatment alone, and the combination of MEC + MLA by 22.44%. At high MeHg concentration MLA treatment alone significantly increases cell viability by 14.28% only from the MEC group (21%) but not MeHg alone. Data suggest that the α7-subtype nAChR is not the only receptor contributing to MeHg-induced cell death but that other nAChR subtypes may also play a role. Title: Cell type-dependent TMEM35 expression and its effects on surface α7 nicotinic acetylcholine receptors

Authors: *R. H. LORING, B. GARG, H. LIN, A. REZVAYA, B. TILAK;
Pharmaceut. Sci., Northeastern Univ., Boston, MA

Abstract: Surface α7 nicotinic acetylcholine receptor (nAChR) expression depends on the cell type, possibly due to differences in endoplasmic reticulum chaperone proteins that allow folding, assembly and transport to the cell membrane. RIC3 (Resistance to inhibitors of cholinesterase 3) is a known chaperone for α7 nAChR. However, we previously found no significant RIC3 protein expression in GH4C1, a cell line derived from rat pituitary, even though these cells readily produce surface α7 receptors measured by α-bungarotoxin binding when transfected with α7 nAChR plasmid. Further, surface expression in GH4C1 cells is not changed by RIC3 shRNAs that block surface α7 expression in other cell lines that require RIC3 transfection (Koperniak et al, *J. Neurochem.* **124:** 300, 2013). Together, these data suggested that GH4C1 cells have a different α7 receptor chaperone than RIC3. Recently (3/2/2016), Gu et al. (*Neuron* **89:** 1, 2016) reported that Transmembrane Protein 35 (TMEM35, also known as NACHO) acts as another chaperone in HEK293 cells when expressed alone with α7 and also synergistically enhances RIC3 effects. We investigated how widely TMEM35 is expressed in cell lines that have little or no endogenous α7 nAChRs and compared those cells lines for surface expression of transfected α7. GH4C1 and GH3 cells readily express surface α7 when transfected, while SH-SY5Y has minor endogenous α7 expression, and SH-EP1, HEK293, RAW264.7 and H9C2 cells showed no expression when transfected. Western blots showed a rank order for TMEM35 protein expression of GH3 ≥ GH4C1 >> SH-SY5Y, with no detectable expression in other cells. These data suggest a correlation between the level of endogenous TMEM35 protein and the ability of unmodified cell lines to express surface α7 when transfected. However, preliminary binding experiments suggest that TMEM35 tagged with C terminal GFP does not significantly enhance α7 surface expression in HEK cells co-transfected with RIC3 and α7, while TMEM35 tagged with C terminal Myc-DDK antigens significantly decreases surface expression. In contrast, TMEM35-GFP permits significant surface α7 expression in H9C2 cells when transfected with α7 in the absence of RIC3. If confirmed with proper controls, these data may suggest an interaction between RIC3 and the C-terminal portion of TMEM35 that helps regulate surface α7 expression in different cell types.

Title: G protein-coupled receptor (GPCR) signaling underlies the nicotine-induced up regulation of alpha 7 (α7) nicotine acetylcholine receptors (nAChRs) expressed in Xenopus oocytes

Authors: *J. PANCHAL[1,2], K. DEBOEUF[2], M. ISLAM[2], J. FARLEY[2];
[2]Neurosci., [1]Indiana Univ., Bloomington, IN

Abstract: α7 nAChRs are widely distributed throughout the nervous system, playing important roles in learning & memory, and are also implicated in a variety of disease and neurodegenerative processes including schizophrenia, Alzheimer's and Parkinson's disease, inflammation, pain, cancer, and nicotine addiction (Thomsen et al 2010, Bencherif et al 2011, Changeux et al 2012). A variety of compounds (agonists, antagonists, PAMs) produce functional and/or numerical upregulation of α7 Rs in different cells, implicating multiple signaling pathways and mechanisms. Prolonged nicotine exposure can also upregulate α7 nAChRs, which may contribute to nicotine dependence and addiction (Govind et al 2012, Brunzell et al 2014). Previously, we found ~ 2-fold functional and numerical upregulation of murine α7 nAChRs in *Xenopus* oocytes following 12 hr of 100 μM nicotine and extensive washout. We found that nicotine-upregulation was dependent upon intracellular Ca^{2+}, being abolished by BAPTA-AM, and involved several Ca^{2+}-dependent enzymes (e.g., PP2B, PKC). But upregulation was independent of Ca^{2+} influx, being unaffected by removal of extracellular Ca^{2+}. Similar to another pentameric, Cys-loop LGIC, glycine receptor 1 (GlyR1), the α7 nAChR contains a conserved G protein-binding cluster (GPBC) in the M3-M4 loop. G-protein signaling by α7 Rs has been shown in both neurons and PC12 cells (Kabbani et al 2013). Here, we show that GPCR signaling mediates nicotine-upregulation of α7 nAChR. Mutation of α7 nAChR GPBC (RMKR to AAAA; denoted as α7 344-347A) blocks interaction of Gαq and Gβγ with the GPBC without affecting receptor expression, peak current amplitude or kinetics. However, nicotine-upregulation of α7 nAChR did not occur for α7 344-347A Rs. Conversely, 12 hr exposure to the cell-permeable, competitive antagonist Methyllycaconitine (MLA), produced ~ 2-fold upregulation of both wt and mutant (α7 344-347A) α7 Rs; and upregulation was unaffected by BAPTA-AM. Our results suggest that α7 nAChRs may function as both metabotropic and ionotropic receptors, and that GPCR-signaling is critical for nicotine-upregulation.

Title: AChRs are essential for the targeting of rapsyn to the postsynaptic membrane of NMJs in living mice

Authors: *P.-J. CHEN, I. MARTINEZ, M. AITTALEB, M. AKAABOUNE;
Mol. Cell. and Developmental Biol., Univ. of Michigan, Ann Arbor, MI

Abstract: Rapsyn, a 43 kDa scaffold protein, is required for the clustering of acetylcholine receptors (AChRs) at synaptic sites between mammalian motor neurons and muscle cells. However, the mechanism by which rapsyn is inserted and retained at postsynaptic sites at the neuromuscular junction (NMJ) *in vivo* remains largely unknown. We found that neither the N-terminal myristoylation nor the cysteine-rich RING H2 domain of rapsyn is required for its stable association with the postsynaptic membrane of NMJs. When N-myristoylation-defective rapsyn-EGFP mutant (G2A) and RING-H2 domain truncated rapsyn-EGFP were electroporated into sternomastoid muscles, a strong rapsyn fluorescent signal was selectively observed at synapses, similar to wildtype rapsyn-EGFP. The targeting of rapsyn-EGFP (wildtype and mutants) is independent of synaptic activity as they were inserted at denervated NMJs. However, when the coiled-coil domain (the AChR binding domain of rapsyn) is deleted, rapsyn fails to associate with AChRs at NMJs of living mice. In cultured myoblasts (in which AChRs are absent), myristoylated wildtype rapsyn mostly localizes to lysosomes, and is not associated with plasma membrane. However, in the presence of AChR subunits, rapsyn molecules were targeted to cell surface and formed aggregates with AChRs. The targeting of AChRs to the cell membrane, in contrast, does not require rapsyn as expressed AChRs are visible on cells membrane of rapsyn deficient myoblasts. These results provide evidence for an active role of AChRs in the targeting of rapsyn to the NMJ *in vivo*.

Title: New nicotinic acetylcholine receptor ligands using privileged scaffolds and the hybrid approach

Authors: *D. GUNDISCH, M. J. CALIBUSO-SALAZAR, I. TOMASSOLI;
Col. of Pharm. UHH, Hilo, HI

Abstract: Recently, we designed and synthesized “twin” compounds targeting nicotinic acetylcholine receptors (nAChRs) (Bioorg Med Chem, 2015, 23(15):4375-4389), and a new lead compound with high subtype selectivity for beta2-containing nAChRs has been obtained from this approach. Using a similar design approach we prepared small in silico ADME guided compound libraries based on diaza(bi)cyclic scaffolds and various established central nervous system (CNS) drugs forming so-called hybrid compounds. Diaza(bi)cyclic motifs are known to be privileged scaffolds for the interaction with various related biological targets including nicotinic acetylcholine receptors (nAChRs). This project focuses on the development of small libraries of compounds interacting with nAChRs and other biological targets which could be relevant for an improved treatment of CNS disorders like e.g. major depression, substance use disorder, and Alzheimer’s disease. For structure affinity relationship evaluation on nAChRs, compounds were tested in radioligand binding assays with [3H]epibatidine, [3H]methyllycaconitine, [3H or 125I]alpha-bungarotoxin, [3H]NS14492 and [3H]NS10743 using membrane fractions of rat brains, pig brains, pig adrenals, and Torpedo californica electroplax. A broad spectrum of affinities (Ki values: < 10 nM to > 10,000 nM) and subtype selectivity for nAChRs provided important hints for further “designing in”, “balancing”, and “designing out” strategies to obtain new active compounds for future lead candidates.

Title: Extracellular domain α4β2 nicotinic acetylcholine receptors form with specific homomeric or swapped M1 transmembrane domains

Authors: *G. B. WELLS[1], A. M. PERSON[2];
[1]Mol. & Cell. Med., [2]Mol. and Cell. Med., Texas A&M Univ. Hlth. Sci. Ctr., College Station, TX

Abstract: Background: Extracellular domain (ECD) receptors derived from α7, α4, α3, β2, and β4 nicotinic receptor subunits truncated after the first transmembrane domain (M1) have functional and structural similarity to full length nicotinic acetylcholine receptors (nAChRs). Their smaller size and reduced transmembrane sequence might have advantages for structural studies by crystallography and NMR and for understanding specific structural and functional roles of the ECD and transmembrane domains in nAChRs and other Cys-loop receptors. Chimeras of M1 suggest that M1 requires specific sequences to fulfill this role. For example, M1 from α7 or 5HT3 is an inefficient replacement for native M1 sequences in α4β2 ECD nAChRs. Important properties of M1 sequences for expressing ECD nAChRs, however, are uncertain.
Objective: To determine the efficiency of expressing α4β2 ECD nAChRs with swapped and with homomeric M1 sequences from α4 and β2. Combined with results from chimeras from M1 domains of α7 and serotonin 5HT3A subunits, these data help identify important features in M1 for expressing α4β2 ECD nAChRs and other Cys-loop subunits.
Methods: Human α4 and β2 cDNAs were truncated after M1 (α4M1 and β2M1). M1 domains were swapped between α4M1 and β2M1 subunits with site directed mutagenesis. α4β2 ECD nAChRs were expressed in *Xenopus* oocytes either with swapped M1 domains or with homomeric M1 domains. In addition, the residue juxtaposed N-terminal to M1 also was swapped (native **L** in α4M1 or native **K** in β2M1), either in isolation or along with M1. Immunoblotting and yield of [^{3}H]epibatidine binding sites assessed effects on expression.
Results: α4β2 ECD nAChRs with homomeric M1 from α4 or from β2 expressed at levels comparable to native α4β2 ECD nAChRs. α4β2 ECD nAChRs with swapped M1 domains expressed at levels comparable to native α4β2 ECD nAChRs. Placing leucine ahead of M1 in β2M1 diminished relative expression of the α4β2 ECD nAChR with this homomeric leucine site to about 5%. Placing M1 from α4 into β2M1 leading to a M1 homomer for α4 and β2 subunits did not rescue expression with this leucine. In contrast, placing lysine ahead of M1 in both α4M1 and β2M1 or swapping leucine and lysine between α4M1 and β2M1 led to good expression of α4β2 ECD nAChRs.

Conclusions: α4β2 ECD nAChRs express well with homomeric M1 from either α4 or β2 but not M1 from α7 or 5HT3A. The residue N-terminal to M1 is important for expressing α4β2 ECD nAChRs and appears to require or tolerate a positive change in either α4M1 or β2M1. Presence of a leucine in both subunits is not tolerated. These results help refine the concept of an optimally designed M1 sequence for ECD Cys-loop receptors.

Title: Studying the structure, function and interactions of the intracellular domain of Cys-loop receptors

Authors: A. PANDHARE[1], E. PIRAYESH[1], P. N. GROZDANOV[2], *M. JANSEN[1];
[1]Cell Physiol. Mol. Biophys., [2]Cell Biol. Biochem., TTUHSC, Lubbock, TX

Abstract: The intracellular domain (ICD) of metazoan Cys-loop receptor superfamily members, also known as pentameric ligand-gated ion channels (pLGICs), has been the least explored domain. Structure/function studies over decades, including recent crystal structures for mammalian pLGICs, have vastly enriched our understanding of the other two, extracellular (ECD) and transmembrane (TMD), domains. The variable lengths and amino acid sequences confer the most diversity to the ICD contrary to the highly-conserved ECD and TMD. This unique feature of being a starkly diverse domain poses its own challenges by necessitating to develop an 'individualized' approach to study structure, function and interactions of ICDs. In addition, the *a priori* assumption of the ICD being largely disordered or disorganized structurally has been prevailing in the field for decades. In our recent study, we made the surprising discovery that the 5-HT_{3A} ICD alone assembles into stable pentamers in solution (Pandhare, A. et al. *Sci. Rep.* **6**, 23921(2016)). The finding suggests a novel role for the ICD in receptor oligomerization, and significantly adds to its currently known repertoire of functions. To further expand our study across the Cys-loop receptor superfamily and, importantly, to address the huge knowledge gap pertaining to structure, function and interactions of each unique ICD, we have engineered individual chimeras comprising of ICDs of prominent pLGICs subunits. Current

studies aim at elucidating the molecular determinants of pentameric oligomerization as well as measuring affinities of self-association, investigating protein-protein interactions with non-homologous proteins, and in addition pursuing structural studies at atomic resolution and importantly determining functional contributions of the ICD.

Title: Brain α7 nicotinic acetylcholine receptor assembly requires nacho

Authors: *S. GU;
Neurosci., Janssen Res. & Development,, San Diego, CA

Abstract: Neuronal nicotinic acetylcholine receptors (nAChRs) are ligand-gated ion channels that participate in diverse physiological responses such as pain processing and cognitive functions. Alpha7 nACh receptors are homo-pentameric, and they do not oligomerize or functionally express in most all non-neuronal cell lines. Up-regulation of nAChR in brain represents a therapeutic goal and likely contributes to the pharmacology of cholinergic medicines in Alzheimer's disease and schizophrenia. Whereas some neurotransmitter receptors have auxiliary subunits that control receptor trafficking and channel gating, no essential assembly proteins have previously been identified for a mammalian neurotransmitter receptor. Using a genomic cDNA screening strategy, we identified a unique, phylogenetically conserved, four-pass transmembrane protein, NACHO, which is essential for functional α7 receptors in transfected cells. NACHO selectively promotes function of α7 and α4β2 nAChRs and does not influence a related 5-HT_3 receptor. NACHO is a neuronal, endoplasmic reticulum protein that enhances both assembly and surface trafficking of α7 receptors. Genetic disruption of NACHO completely disrupts assembly of α7 pentamers and abolishes functional α7 receptors. This work identifies NACHO as an essential, client-specific chaperone for nAChRs and has implications for physiology and disease associated with these widely-distributed neurotransmitter receptors.

Title: Toward the structure and molecular mechanisms of the human $\alpha_4\beta_2$ nicotinic acetylcholine receptor

Authors: *L. C. MORALES, C. NOVIELLO, R. HIBBS;
Neurosci., UT Southwestern Med. Ctr., Dallas, TX

Abstract: Nicotinic acetylcholine receptors mediate fast chemical neurotransmission in the central and peripheral nervous systems. The $\alpha_4\beta_2$ subtype is the most abundant nicotinic acetylcholine receptor in the human brain. The long term goals of this research project is to obtain a high-resolution structure of the $\alpha_4\beta_2$ nicotinic receptor to probe the allosteric gating, ion selectivity and ligand recognition mechanisms. Here we report biochemical and biophysical studies of a modified construct that shows an improvement in expression, homogeneity and pentameric monodispersity. We have successfully optimized our expression and purification methods to obtain milligram quantities of homogenous receptor. In addition, we have performed patch-clamp experiments and binding assays demonstrating that the modified version of the receptor is functional. To promote crystallization we have screened ligands, detergents, lipids and additives against our best construct to obtain high quality crystals. A high-resolution crystal structure will provide important insights into the molecular mechanisms of activation and selectivity of this family of ligand-gated channels.

Abstract: Nicotinic acetylcholine receptors (nAChRs) are pentameric ligand-gated ion channels where the α7 and α4β2 subtypes are the most predominant in the brain. The α4β2 nAChR is known to exist in two functional isoforms with different ACh-activation properties, namely the high sensitivity (HS) $(\alpha4)_2(\beta2)_3$ and low sensitivity (LS) $(\alpha4)_3(\beta2)_2$ receptor[1]. We and others have demonstrated that a large number of pharmacological differences between the two receptors can be attributed to the presence of an additional agonist binding site at the α4-α4 interface on $(\alpha4)_3(\beta2)_2$ receptor. MLA is natural toxic potent antagonist that competes with ACh at the same binding site. MLA is selective for α7 receptors with approximately 1000-fold greater potency than at α4β2. Identifying ligands that are selective for specific nAChR subtypes through their affinity for different binding interfaces may have significant therapeutic potential and contribute to the understanding of the physiological roles of these subtypes *in vivo*.
Previously, we have highlighted the importance of the N-succinemidoanthranilate moiety for binding at the α7 subtype[2].In this study, we propose that the AE succinimide structure of MLA has higher selectivity at the α4-α4 interface in $(\alpha4)_3(\beta2)_2$ over the α7-α7 interface. We have synthesised different MLA analogues and evaluated them by co-applying 10 μM of each compound with 1 mM ACh for $(\alpha4)_3(\beta2)_2$ and α7 and 100 μM $(\alpha4)_2(\beta2)_3$ on recombinant human α_7 and two different stochiometries of α4β2 expressed in *Xenopus* oocytes using the two-electrode voltage clamp technique.To date, we have identified three analogues (BA09, BA11 and BA12) that are able to inhibit the current at $(\alpha4)_3(\beta2)_2$ by 80%, 82% and 70% with no antagonism at the α7 subtype, when compared to 100% inhibition by 10 μM MLA at both subtypes. The same analogues on $(\alpha4)_2(\beta2)_3$, only inhibited the evoked ACh current by 35%, 30% and 33% respectively. Based on this result, we are able to design analogues that distinguish between α4β2 and α7 receptors, however further refinement of the chemical structures are required to achieve greater selectivity between the two α4β2 stochiometries.

Title: Differential pharmacology of nicotinic receptor mutations that cause Autosomal Dominant Frontal Lobe Epilepsy at two different stoichiometries

Authors: ***D. INDURTHI**[1], T. QUDAH[2], T. BALLE[1], N. L. ABSALOM[1], M. CHEBIB[1]; [1]The Univ. of Sydney, Camperdown, Australia; [2]Univ. of Sydney, Camperdown, Australia

Abstract: Introduction: Epilepsy is central nervous system (CNS) disorder characterized by recurring seizures, affecting in 1-2% of the world population. Several mutations have been identified in the α4, β2 and α2 subunits of neuronal acetylcholine receptors (nAChRs) that cause nocturnal frontal lobe epilepsy (NFLE) that is autosomal dominant in nature called ADNFLE. The α4β2 nAChR is the most abundant heteromeric nAChR in the brain, which is known to exist in two functional isoforms $(\alpha4)_2(\beta2)_3$ and $(\alpha4)_3(\beta2)_2$. We and others have extensively characterized the two isoforms and attributed pharmacological differences, to the presence of additional agonist binding site at α4-α4 interface on $(\alpha4)_3(\beta2)_2$ receptor. Very little is known on the molecular and pathophysiological mechanisms on how the ADNFLE mutations alter the native functioning of the two isoforms α4β2. **Aim:** To understand the functional changes caused by the α4 (T293I) and β2 (V287M & V287L) ADNFLE mutations that are located around extracellular domain that is in contact with the trasmembrane domain (TM2-TM3 loop). **Results and conclusion:** Using two-electrode electrophysiology and determining open probability estimates, we show that these mutants increase the efficacy of activation by the native ligand, acetylcholine (ACh), by nearly two-fold. We then studied the pharmacology of mutant receptors with several clinically-relevant ligands, including the smoking-cessation drug, varenicline, the anti-epileptic drug, carbamazepine and a selective agonist at α4β2 receptors, Sazatidine-A. Surprisingly, we observe that mutations on α and β subunits, present at the same location on the receptor have different pharmacological profiles when expressed in different stoichiometries. The increased efficacy most likely leads to the increased electrical activity in the brain that causes seizures. Understanding the pharmacology of these mutant receptors has a therapeutic potential to find a drug target to cure the disease. [1]Authors would like to acknowledge the

support by John A. Lamberton research scholarship and International postgraduate research scholarship (IPRS).

Title: α7 and α7β2 nicotinic receptor (nAChR) subtypes are differentially modulated by the endogenous membrane-associated prototoxins, lynx1 and lynx2

Authors: *A. A. GEORGE[1], J. B. EATON[1], R. J. LUKAS[1], J. M. MIWA[2], P. WHITEAKER[1]; [1]Neurobio., Barrow Neurolog. Inst., Phoenix, AZ; [2]Biol. Sci., Lehigh Univ., Bethlemhem, PA

Abstract: Nicotinic acetylcholine receptors (nAChR) exist as pentameric complexes of homologous, but genetically distinct subunits. The functional expression of nAChR mediates aspects of synaptic transmission, and nAChR dysfunction can be linked to many neurodegenerative and psychiatric diseases. The α4β2 and α7 nAChR subtypes are the most abundantly expressed subtypes in the mammalian central nervous system. α7 and α7β2 nAChR are predominantly expressed in the cortex, hippocampus, amygdala and basal ganglia. Moreover, these ligand-gated ion channels influence cellular excitability and homeostatic regulation in basal forebrain cholinergic neurons. While α7 and α7β2 nAChR mediate the cellular processes involved in many neurological processes, nAChR function can, in turn, be altered by endogenous neuropeptides. The Ly6 family of neuromodulators can influence the functional expression of many different nAChR subtypes including α7*, α4β2* and α3β4* nAChR (*indicating the presence of additional subunits). Two members of the Ly6 family, lynx1 and lynx2, have been shown to enhance desensitization and decrease sensitivity of nAChR to acetylcholine. However, the ability of lynx1 and lynx2 to interact with α7 and α7β2 nAChR is poorly understood. In the current line of investigation, we used a concatenated (i.e. linked) subunit approach to ensure consistent subunit incorporation while probing the functional modulation of α7 and α7β2 nAChR by lynx1 and lynx2. Using two-electrode voltage clamp (TEVC) electrophysiology, we

demonstrate that lynx1 attenuates macroscopic receptor peak currents for both α7 and α7β2 nAChR subtypes when expressed in *Xenopus* oocytes. Using a range of lynx1 doses, we demonstrate that significant functional blockade of both α7 and α7β2 subtypes can be achieved at a 1:1 nAChR:lynx RNA injection ratio (producing 90 ± 7.5% and 95 ± 11% reductions in maximal function, respectively). Furthermore, we demonstrate that coexpression with lynx1 fails to produce a significant shift in either α7 or α7β2 ACh concentration-response profiles. Co-expression of α7 or α7β2 nAChR with lynx2 also produced a similar reduction in macroscopic function, but the magnitude of the effect was reduced relative to that for lynx1. The current findings suggest that alterations in α7 and α7β2 nAChR function by lynx1 and/or lynx2 might be a novel and productive therapeutic strategy to mitigate cognitive decline associated with neurodegenerative disease. Title: Serine residues in the MIII-MIV intracellular loop of the α4 nAChR subunit control α4β2* nAChR expression in the neuronal surface

Authors: *C. A. ZAMBRANO[1], D. ESCOBAR[1], J. A. STITZEL[1,2];
[1]Inst. for Behavioral Genet., [2]Dept. of Integrative Physiol., Univ. of Colorado, Boulder, CO

Abstract: Chronic nicotine exposure produces an increase or upregulation of α4β2* nAChR expression in neurons. The mechanism(s) that produce α4β2* nAChR upregulation represents a pharmacological target to control its behavioral consequence. The aim of this work is to find a relationship between receptor structure and activity for the α4β2 nAChR that allow us to study mechanisms of nicotine-induced nAChR upregulation. The α4 subunit has an intracellular loop between MII-MIV transmembrane domains that contains serine residues previously described as potential phosphorylation substrates for protein kinase A and protein kinase C in heterologous expression systems. Our studies are focused on residues S336, S470 and S530. Adeno associated virus (AAV) containing the wild type mouse α4 nAChR cDNA or cDNAs for each of the three

serine to alanine point mutations S336A, S470A and S530A were produced. Primary neuronal cultures prepared from cerebral cortex, hippocampus and brainstem of α4 KO mouse embryos were infected with those vectors and chronically exposed with nicotine to measure α4β2* nAChR binding sites using [^{125}I]epibatidine. A triple HA tag was added at the C-terminal of the α4 subunit. Detection with HA antibodies revealed the formation of clusters of α4β2* nAChR that are expressed in the neuronal surface after 10 days of AAV infection. Following nicotine treatment, the α4 mutants S336A and S470A failed to show upregulation of surface receptors in hippocampal and brainstem neurons. This effect appears to be cell type specific as normal surface upregulation of the mutants as observed in cortical neurons. Data suggests that multiple mechanisms of upregulation exists for neurons obtained from different brain regions possibly due to a differential interaction with kinases or phosphatases that control surface expression of α4β2 nAChR. The mutations are also being study in vivo. AAVs containing the wild type and mutated α4 nAChR subunit cDNAs are being injected in the dorsal hippocampus of α4 KO mice, followed by chronic nicotine intravenous infusion (2 mg/kg/h). Preliminary data confirms α4-nAChR subunit re-expression in the dorsal hippocampus but also retrograde expression was observed in the entorhinal cortex. [^{125}I]epibatidine binding was detected after AAV infection confirming α4β2* nAChR expression. An increase in [^{125}I]epibatidine binding was observed in α4 wild type cDNA infected mice that received chronic nicotine infusion for 10 days compared with saline infused mice. We plan to use this model to correlate the effect of differential α4β2 nAChR upregulation with memory impairment after chronic nicotine withdrawal using the contextual fear conditioning test.

Title: Molecular determinants of α-conotoxin Vc1.1 inhibition of human α9α10 nAChR

Authors: *D. J. ADAMS[1], H.-S. TAE[1], R. YU[2];
[1]Illawara Hlth. and Med. Res. Inst. (IHMRI), Univ. of Wollongong, North Wollongong, Australia; [2]Sch. of Med. and Pharm., Ocean Univ. of China, Qingdao, China

Abstract: Nicotinic acetylcholine receptor (nAChR) α9α10 subtype mediates postsynaptic transmission in the auditory system and is expressed in sensory neurons, cancer cells, keratinocytes and immune cells. α-Conotoxin Vc1.1 a disulfide-bonded peptide from the venom of *Conus victoriae* is an antagonist of α9α10 nAChRs and a potent analgesic in rat neuropathic and chronic pain models. Two stoichiometries of the receptor, $\alpha9_2\alpha10_3$ and $\alpha9_3\alpha10_2$, have been proposed whereby at $\alpha9_3\alpha10_2$, Vc1.1 is postulated to bind at high sensitivity (HS) α9(+)α9(-) and low sensitivity (LS) α10(+)α9(-) interfaces. However, the molecular mechanism governing the interaction of Vc1.1 at α9α10 nAChR remains unclear. Given that both interfaces share the same α9(-) side, the difference in Vc1.1 sensitivity should be primarily contributed by non-conserved residues on (+) side of the subunits. We tested the hypothesis, derived from molecular modeling and computation docking of Vc1.1 at human α9α10 nAChR, that a non-conserved α9(+)N179 (previously N152) residue (G in α10(+)) is involved in Vc1.1 binding sensitivity. *Xenopus laevis* oocytes were injected with varying cRNA ratios of human α9 to α10 subunits (1:3 and 1:1) to putatively form the stoichiometries and ACh-evoked currents were recorded using two-electrode voltage clamp method. At a 1:1 ratio, the α9(+)N179G mutation reduced Vc1.1 potency due to the loss of Vc1.1-HS sites. In contrast, at 1:3 ratio favouring LS sites, Vc1.1 inhibited wild-type α9α10 nAChRs with reduced potency without affecting the sensitivity of α9(+)N179Gα10 nAChRs. In all cases, the decrease in Vc1.1 sensitivity is similar suggesting a stoichiometry of $\alpha9_3\alpha10_2$ in oocytes injected with 1:1 ratio of α9 to α10 subunits. In conclusion, the non-conserved N179 residue is essential in the formation of Vc1.1 HS binding sites at the α9(+)α9(-) interface in the postulated $\alpha9_3\alpha10_2$ stoichiometry.

Title: ion channels antibodys role in neuronal survival

Authors: ***N. AYSIT**;
neuroscience, ISTANBUL Medipol UNIVERSITY -ISTANBUL MEDIPOL UNIV, ISTANBUL, Turkey

Abstract: Neuronal excitability is finely controlled by various membranous channels and associated proteins. In the central nervous system (CNS), the rapidly inactivating voltage-gated potassium channels (Kv channels) are the major determinants of dendritic excitability. Voltage-

gated potassium channels (Kvs) play a critical role in regulating neuronal excitability and synaptic plasticity in the hippocampus. NMDA receptors, a type of Kv channel, are critical for the development of the CNS, generation of rhythms for breathing and locomotion, and the processes underlying learning, memory, and neuroplasticity. Consequently, abnormal expression levels and altered NMDAR function have been implicated in numerous neurological disorders and pathological conditions. NMDAR hypofunction can result in cognitive defects, whereas overstimulation causes excitotoxicity and subsequent neurodegeneration. Subconductance levels have been observed in virtually every type of ion channel, although the number of levels, stability, and abundance vary widely. Sublevels have been well-characterized in K channels, which are evolutionarily related to NMDARs. The aim of the study is the contribution of Kv and NMDA receptors of neuronal survival/death in hippocampal cells . Primary hippocampal cultures were prepared from the brains of newborn Bulb-c mice approximately 4 days old. The hippocampus was isolated from the brain of each mice and treated with at 4 °C. The cells were suspended in neurobasal medium and were plated at several densities 200 -1600 cells per mm2. IgG was isolated from healthy partıcıpantsand limbic patients who were NMDAR ,Kv channel pozitive. Differrent concentrations of Isolated IgG were added to the preperation at days 7v and 10. in vitro. Imagıng was performed on same days by confacal microscobe and dead cells were determined using propidium iodide. In this study T test was used for analyzes and shown that using high concentration NMDA and Kv IgG cause neuron and astrocyte death. These result showed that ion channels antibody is not only important for their function but also they regulate neuronal survival. Otherwise Neuron was deadth not only apoptozis but also necrozis.

Title: Exploring the thermosensitivity of Gustatory Receptors in *Drosophila melanogaster*

Authors: ***A. MISHRA**, A. ROBINSON, T. ZARS;
BIOLOGICAL SCIENCES- NEUROSCIENCE, UM-COLUMBIA, Columbia, MO

Abstract: The ability to detect shifts in temperature is vital for the survival of organisms. Other than the highly conserved thermosensitive Transient receptor potential (Trp) channels, little is

known about the molecules involved in temperature sensation in *Drosophila*. The Gustatory Receptor (GR) 28b-d helps flies respond to rapid changes in temperature. The discovery of temperature response properties of *GR28b-d* indicates the potential for other GRs as temperature responsive. We are studying the temperature responsiveness of the 68 GR genes in *Drosophila*, starting with *GR28* family. To test thermosensitivity, we use the heat box, which can detect the temperature preference of flies with a resolution of less than 1^{o}C. We over-expressed *GR28a* and the isoforms of *GR28b* pan-neuronally, using the *nSyb-GAL4* driver. The temperature in the heat box was increased in steps of 2^{o}C from 24-40^{o}C. At the temperature of activation of the mis-expressed gene, we expect a temporary paralysis of flies. Our preliminary results show that, out of the five isoforms of *GR28b*, only *GR28b-d* is thermosensitive in a temperature range of 34-36^{o}C. Additionally, we measured the time taken by the flies over-expressing *GR28b-d* to recover from temporary incapacitation following exposure to temperature stimulus of varying intensities. We discovered that flies that are exposed to a lower temperature stimulus (34^{o}C) recovered faster than flies that received a higher temperature stimulus (36-40^{o}C). We continue to screen the GRs for thermosensitive genes. Along with our collaborators, we are studying the molecular properties of the GRs in the *GR28b* family. Based on our results, we aim to develop novel thermogenetic tools that can act as molecular switches to enable finer temperature-dependent control of neuronal activity in different model systems.

Title: Cell swelling and SLC26A11 during simulated ischemia in neocortical brain slices

Authors: H. EL-KERDAWY, K7L 3N6, J. CARR, *R. D. ANDREW;
Queen's Univ., Kingston, ON, Canada

Abstract: During the first few minutes of ischemia, neurons swell as they undergo anoxic depolarization (AD). Water transporters energetically linked to the failing Na/K pump lose their function and neuronal water accumulates. Passive water loss is slow because neurons lack aquaporins. One proposal is that neurons swell because depolarization evokes a large increase in Na^{+} influx with Cl^{-} following via SLC26A11, a Cl^{-} channel/transporter. Water then osmotically

follows these ions into neurons. We examined in live brain slices if slice swelling during simulated ischemia (O_2/glucose deprivation, OGD) requires SLC26A11-mediated chloride influx. Neuronal and astrocytic swelling during OGD-induced AD is indirectly imaged in live coronal brain slices as a front of elevated light transmittance (LT) spreading across the neocortex. We compared swelling and its time course at 34^{o}C during AD in a) regular artificial CSF; b) low-chloride aCSF (Cl^- replaced with isethionate, methyl sulfate or proprionate); c) regular aCSF + PPQ-102 or niflumic acid, two drugs that inhibit SLC26A11 function. In low Cl^- aCSF, the propagating AD increased in LT strength and AD onset was not delayed (n=12 slices) compared to regular aCSF (n=9). Apparently the larger anions easily substituted for Cl^- influx. Pre-treatment prior to OGD with 10 uM (n=15) or 20 uM (n=11) PPQ-102 did not delay nor reduce the AD-associated LT increase compared to 25 slices without PPQ-102. Likewise 100 uM niflumic acid pre-treatment (n=16) had so significant effect on AD-associated swelling onset nor intensity compared to regular slices under OGD. Niflumic acid pre-treatment did significantly reduce the exaggerated LT increase during OGD by ~25% when proprionate was substituted for Cl^- , but swelling onset was unaffected (n=10). Two-photon microscopy of 15 live pyramidal cells containing yellow fluorescent protein (YFP) confirmed that OGD-induced neuronal swelling was not significantly reduced by PPQ-102 or niflumic acid. So in this well-established model of simulated ischemia, SLC26A11-mediated chloride influx appeared to play a minor role in acute neuronal swelling.

Abstract: In central nervous system (CNS), afterhyperpolarization (AHP) activated after single or multiple action potentials in neurons plays an important role in the modulation of neuronal excitability by limiting firing frequency and thus in the generation of spike-frequency adaptation.

We previously reported that calcium-activated AHP currents in thalamocortical (TC) neurons were mediated by multiple components including apamin-sensitive SK channels and niflumic acid-sensitive anion channels whose molecular identity was unknown. Here we investigated the calcium-activated chloride channels (CACCs) mediating AHP in TC neurons. CACCs are involved in many physiological phenomena, but the functional expression and properties of them in CNS have rarely been reported. We characterized the electrophysiological properties of CaCCs in TC neurons and investigated its molecular identity.

Title: Brain hyperpolarization-activated cyclic nucleotide-gated channels modulate methamphetamine self-administration in rats

Authors: ***R. SONG**, D.-N. CAO, S.-Z. ZHANG, N. WU, J. LI;
Beijing Insistitute of Pharmacol. and Toxicology, Beijing, China

Abstract: *Rationale* Methamphetamine addiction is believed to primarily result from increased dopamine release and the inhibition of dopamine uptake. Some evidence suggests that the hyperpolarization-activated cyclic nucleotide-gated (HCN) channels play important roles in the functional modulation of dopaminergic neurons and the pathophysiology of related diseases. However, little is known about the effects of HCN channels on methamphetamine addiction. *Objectives* The present study investigated the role of brain HCN channels in methamphetamine addiction. *Results* Acute intracerebroventricular (i.c.v.) injection or bilateral intra-accumbens microinjections of non-selective HCN channel blocker ZD7288 (0.3125 and 0.625 μg) significantly reduced both the methamphetamine (0.0125 or 0.05 mg/kg/infusion)-induced self-administration under fixed ratio 2 reinforcement and the breakpoint of methamphetamine (0.05

mg/kg/infusion) under progressive ratio reinforcement in rats. Moreover, compared with the i.c.v. injection, bilateral intra-accumbens microinjections of ZD7288 exerted stronger inhibitory effects, suggesting that the blockade of HCN channels in the nucleus accumbens reduced the reinforcing effects of and motivation for methamphetamine. We also found that ZD7288 (0.625 and 1.25 μg, i.c.v.) significantly decreased methamphetamine (1 mg/kg, intraperitoneal (i.p.))-induced hyperactivity with no effect on the spontaneous activity in rats. Finally, *in vivo* microdialysis experiments showed that the HCN channel blockade using ZD7288 (0.625 and 1.25 μg, i.c.v.) decreased the methamphetamine (1 mg/kg, i.p.)-induced elevation of extracellular dopamine levels in the nucleus accumbens. *Conclusions* These results indicate that the HCN channels in the nucleus accumbens are involved in the reinforcing properties of methamphetamine and highlight the importance of HCN channels in the regulation of dopamine neurotransmission underlying methamphetamine addiction.

Title: Postnatal development of hyperpolarization activated current h current in pyramidal neurons & parvalbumin interneurons in mouse prefrontal cortex.

Authors: *S. YANG, JR[1,2], Y.-C. LI[1], P. YU[2], W.-J. GAO[1];
[1]Drexel Univ. Sch. of Med., Philadelphia, PA; [2]Capital Normal Univ. Sch. of Educ., Beijing, China

Abstract: The hyperpolarization-activated current (h-current or Ih) is an inward current generated by the opening of hyperpolarization-activated cyclic nucleotide-gated (HCN) cation channels. In the prefrontal cortex (PFC), Ih in pyramidal neurons is proposed to maintain persistent firing for the execution of working memory function; while in GABAergic

parvalbumin (PV)-containing interneurons, Ih is mainly involved in the generation of rhythmic activity. However, despite its critical role for these featured functions of the PFC, the biophysical properties of the Ih in pyramidal neurons versus PV interneurons in the developing PFC remains uncharacterized. Here we have studied the developmental changes of physiological properties of Ih in the PFC layer V pyramidal neurons and PV interneurons. Our data show that in pyramidal neurons, the steady state current of the Ih (Iss) was significantly increased from juvenile to adolescence and adult. Whereas the Iss recorded from adolescent group of PV interneurons was significantly smaller than that in pyramidal neurons. The kinetic of Ih in PV interneurons was significantly faster than that in pyramidal neurons. Ih also contributes to the intrinsic excitability of both pyramidal neurons and PV interneurons. In pyramidal neurons, the resting membrane potentials increased along with aging. A reduction of resting membrane potential caused by blocking Ih current was observed in adolescent and adult groups but not in juvenile group. The membrane input resistance also showed aging-related changes. Application of Ih blocker ZD7288 significantly increased input resistance in adolescent and adult animals, but not in juveniles. In the adolescent group of PV interneurons, the resting membrane potential was also significantly reduced by ZD 7288, but the input resistance did not show any change. These results indicate a developmental change of Ih in the PFC pyramidal neurons. The developmental changes of Ih in PV interneurons are still under investigation but they appear to be different from those observed in pyramidal neurons.

Title: Two-photon photoswitching of optovin induces neuronal activity in rat cortex

Authors: *E. KHERADPEZHOUH[1], J. M. C. CHOY[2], V. DARIA[1], E. ARABZADEH[1]; [1]Eccels Inst. of Neurosci., [2]Australian Natl. Univ., Acton, Australia

Abstract: Photoswitch molecules provide a well-controlled method for dissecting neuronal circuitries. Here, we characterize how two-photon photoswitching of optovin (a synthetic

molecule with photoswitch capability) triggers neuronal activity in rodent cortex and demonstrate that this activation is mediated via gating the Transient Receptor Potential Ankyrin 1 (TRPA1) as previously demonstrated in zebrafish[1]. We first established the presence of TRPA1 channel in cortical cells by immunohistochemistry and showed that TRPA1 was significantly expressed in neurons and vascular structures. To determine the functional effect of TRPA1 on cortical neurons, we conducted *in vitro* two-photon Ca^{2+} imaging (with Cal-520 AM) and examined the effect of TRPA1 activator (AITC, 1 mM) and inhibitor (HC-030031, 10 μM) on the free cytoplasmic Ca^{2+} concentration in layer 5 (L5) pyramidal neurons. Introducing 1 mM AITC to the bath solution resulted in a significant increase in $\Delta F/F$ which consequently returned to baseline with 10 μM HC-030031. To further confirm this finding, we performed *in vitro* whole-cell recordings of L5 pyramidal neurons and measured the membrane potential (V_m) in the presence of TRPA1 activator and inhibitor. Application of 1 mM AITC increased the V_m significantly (depolarization, n=3, $p < 0.0001$); by replacing the AITC with 10 μM HC-030031, V_m values returned towards baseline levels. Next, we characterized the optical control of neuronal activity by focal illumination of optovin-loaded neurons using a femtosecond laser. We performed whole-cell recording of L5 pyramidal neurons using an internal solution containing optovin. Consistently across neurons, the maximum neuronal response was detected at 720-nm two-photon photoswitching of optovin (n=17). By increasing the concentration of optovin ΔV_m increased significantly resulting in action potential firing in some neurons. We further loaded neurons with different concentrations of optovin (1-20 μM) and found a systematic enhancement of neuronal activity as the optovin concentration was increased. Finally, to confirm that optovin activated these neurons via specific interaction with TRPA1, we repeated the whole-cell recordings in the presence or absence of the highly selective TRPA1 blocker, HC-030031. In the presence of HC-030031, neuronal activity was significantly reduced ($p < 0.0001$). Our results indicate that two-photon photoswitching of optovin might provide a powerful method for investigating the neuronal circuitries in the mammalian cortex. Reference: 1. Title: Regulation of mouse HCN2 channel surface expression through SUMO post-translational modification

Authors: *M. WELCH, L. A. FORSTER, A. R. PARKER, D. J. BARO;
Biol., Georgia State Univ. Dept. of Biol., Atlanta, GA

Abstract: The hyperpolarization-activated current (I_h) is a subthreshold conductance that influences a variety of intrinsic cellular properties including membrane potential, temporal summation and pacemaker activity. As such, I_h controls neuronal activity, and not surprisingly, neuronal activity regulates I_h over multiple time scales and through multiple mechanisms. In particular, activity is known to adjust the surface expression of Hyperpolarization-activated Cyclic Nucleotide-gated (HCN) ion channels that mediate I_h. Recently, the Small Ubiquitin like Modifier (SUMO) has emerged as a mechanism for regulation of ion channel surface expression. SUMO is an ~11kDa peptide that is post-translationally added to a lysine residue in a consensus sequence on target proteins. We identified several putative evolutionarily conserved SUMOylation sites on HCN channels using SUMOplot and have begun to test the hypothesis that SUMOylation mediates activity-dependent surface expression of mouse HCN2 channels. SUMOylated proteins were immunoprecipitated (IP) from adult mouse brain protein lysates and transferred to western blots that were probed with antibodies against mouse HCN2 channels. These experiments demonstrated that HCN2 channels were post-translationally modified by both SUMO1 and SUMO2 *in vivo*. Furthermore, human embryonic kidney (HEK) cells stably expressing mouse HCN2 (HEK-HCN2) showed a statistically significant roughly two-fold increase in HCN2 SUMOylation when the cell line was transiently co-transfected with plasmids encoding SUMO, its conjugating enzyme Ubc-9, and mCherry relative to transfection with mCherry alone, as determined with IPs followed by western blot experiments. Whole cell patch-clamp recordings from HEK-HCN2 cells demonstrated that I_h maximal conductance was significantly increased approximately two-fold in cells transiently transfected with SUMO, Ubc9, and mCherry relative to mCherry alone. There was no change in the voltage dependence or kinetics of activation. Biotinylation assays on HEK-HCN2 cells showed increased HCN2 surface expression in cells transiently transfected with SUMO, Ubc9, and mCherry relative to mCherry alone. We have mutated putative HCN2 SUMOylation sites that are highly conserved across species, individually and in combination, and are currently assaying the extent of HCN2 SUMOylation and I_h regulation in these mutants. Based on present data, we suggest that SUMOylation can regulate HCN2 surface expression, and future experiments will be designed to test whether or not neuronal activity can regulate HCN2 channel SUMOlyation.

Title: Dorso-ventral gradient in hyperpolarisation-activated current (I_h) in hippocampal ca1 OLM-interneurons

Authors: *M. M. HILSCHER[1,2,3], F. RATTAY[3], K. KULLANDER[2], K. E. LEÃO[1], R. N. LEÃO[1,2];
[1]Federal Univ. of Rio Grande do Norte, Brain Inst., Natal, Brazil; [2]Dept. of Neurosci., Uppsala Univ., Uppsala, Sweden; [3]Inst. for Analysis and Scientific Computing, Vienna Univ. of Technol., Vienna, Austria

Abstract: Oriens-lacunosum moleculare (OLM) cells are a class of hippocampal interneurons known to gate information arising from the entorhinal cortex and CA3 in CA1. These neurons are have been shown to express somatostatin (Som+) and the cholinergic receptor, nicotinic, alpha 2 (Chrna2+), being the latter gene the most specific OLM marker in the intermediate/ventral CA1. OLM cells are also important players in the generation of theta oscillations. These neurons show strong spike phase lock with theta oscillation and modeling studies have suggested that OLM cells can synchronize clusters of pyramidal cells and basket interneurons.
We perfomed whole-cell current- and voltage-clamp recordings in the dorsal and ventral hippocampus and show that passive and active electrophysiological properties of OLM cells differ along the dorsal to ventral axis. Dorsal OLM cells generated more hyperpolarization-activated current (I_h) than ventral OLM cells, indicating a difference in the expression of the hyperpolarization-activated cyclic nucleotide-gated (HCN) channels. Furthermore, both dorsal and ventral OLM cells showed electrical resonance at theta frequencies, with dorsal OLM cells resonating in distinct frequency bands than ventral OLM cells. The resonance frequency was extracted from the impedance amplitude profile, i.e. the voltage response to a Chirp current stimulus, which consisted of a linearly increasing (1 Hz/s) sine wave with constant amplitude. This protocol was run under the application of tetrodotoxin to block action potentials. While at near-threshold potentials I_h was not active, at hyperpolarized potentials this current contributed to theta-resonance and could be suppressed with the HCN channel blocker ZD7288.
In summary, our data suggests that dorsal OLM cells differ from ventral OLM cells through the generation of I_h and that this current contributes to the electrical resonance in OLM cells at theta frequencies.

Title: Learned fear induces a reduction in cerebellar stellate cell hyperpolarization-activated currents

Authors: ***K. L. CARZOLI**, J. LIU;
Cell Biol. and Anat., LSUHSC, New Orleans, LA

Abstract: Conditioned fear is a form of associative learning that has been shown to cause changes in the cerebellar cortex in a lobule-specific manner. To date, relatively little is known about the influence of learning on membrane excitability. Hyperpolarization activated cyclic nucleotide-regulated (HCN) channels are nonselective cation channels that activate on membrane hyperpolarization and deactivate on depolarization. Since these channels are activated close to a neuron's resting membrane potential, they play a role in determining intrinsic membrane properties. Cerebellar stellate cells are inhibitory interneurons that express HCN, an alteration of which could influence how these cells respond to input, as well as what they output onto Purkinje cells. We previously found that fear conditioning (FC) reduces hyperpolarization-activated current (I_h) amplitude, causing an increase in neuronal input resistance. Further, we observed that FC-induced changes in I_h are reversed following extinction and that they are specific to vermal lobules V/VI. In the current study, we verified that basal levels of I_h in stellate cells from naïve animals in lobule IX were similar to lobules V/VI. This was important to confirm as previous studies have shown intra-lobule variability in neuronal intrinsic membrane properties. Next, we focused on the functional consequences of modifications in I_h by evaluating the input/output relationship of cerebellar stellate cells after FC. In order to investigate this, we stimulated parallel fibers in the molecular layer at various intensities and recorded resulting extracellular stellate cell activity. Using this approach, we observed a significant difference in the threshold at which cells from FC animals responded to parallel fiber stimulation. Moreover, when comparing the response of cells to the same stimulation intensity, FC cells fired at higher frequencies than cells from naïve animals. Finally, we investigated whether FC-induced changes in I_h would enhance the integration of hyperpolarizing inputs by examining the spike frequency

response of stellate cells to a series of negative, bidirectional current ramps. In cells recorded from naïve animals, blockade of I_h resulted in a more hyperpolarized membrane potential, as well as an increase in instantaneous frequency when spiking resumed at the end of the negative current injection. Similarly, FC cells exhibited greater action potential frequency just after cessation of the hyperpolarizing ramp, and this was presumably due to a reduction in I_h. Taken together with our previous findings, these data contribute to the understanding of how fear memories are encoded in the cerebellum.

Title: An increase in somatic I_h correlates with depression-like states

Authors: *C. KIM, D. H. BRAGER, D. JOHNSTON;
The Univ. of Texas At Austin, Austin, TX

Abstract: The hippocampus is an integral brain region for affective disorders. We previously demonstrated that reduced expression of the HCN1 subunit of h-channels, and subsequent reduction in I_h, in the dorsal CA1 region leads to anxiolytic- and antidepressant-like effects. In light of this, we asked whether h-channel subunit expression and I_h are altered in an animal model of depression. Given that chronic stress can be a precipitating factor for the onset of depression, we used chronic unpredictable stress (CUS) to test the hypothesis that HCN1 protein expression and I_h are elevated following CUS. We found that HCN1 protein expression was significantly increased in the dorsal, but not ventral CA1 region following CUS. In addition, we found that somatic, but not dendritic, input resistance was lower and resonant frequency higher following CUS, consistent with higher somatic I_h. In agreement, cell-attached patch clamp recordings revealed somatic I_h was significantly higher in dorsal CA1 neurons following CUS. Surprisingly, when dorsal CA1 I_h is reduced by shRNA-HCN1, the CUS-induced depressive behavioral phenotypes (e.g. anhedonia and behavioral despair) are reversed. Our results suggest

that CUS induces a functional increase in somatic I_h in dorsal CA1 neurons and furthermore that reduction of dorsal CA1 HCN1 protein expression is sufficient to produce resiliency to CUS.

Title: Ih in CA1 pyramidal cell distal dendrites contribute to theta oscillation *In vitro*

Authors: ***M. D. LIMA**[1], S. MIKULOVIC[2], R. LEÃO[1,2];
[1]Brain Inst., UFRN, Natal, Brazil; [2]Uppsala Univ., Uppsala, Sweden

Abstract: The 4-12 Hz brain oscillation known as theta oscillation have been associated with movement when generated in the dorsal hippocampus and anxiety-like behaviours in the ventral hippocampus. We have previously shown that in horizontal hippocampus slices (from the ventral/intermediate hippocampus), OLM interneurons targeting distal dendritic compartments of CA1 pyramidal cells (PC) can modulate theta oscillations. In this work, we investigated the pyramidal cell membrane properties that facilitate theta generation by dendritic targeting interneurons. We first found that high density of Ih in distal apical dendrites of PCs produced rebound dendritic action potentials following OLM inhibition. Using pressure ejection of ZD7288 to block distal Ih, we found that OLM interneuron stimulation can no longer generate theta oscillations in slices. Taken together, our data show that an interplay between OLM interneurons and PC is crucial to theta generation. Also, we show that Ih in distal dendrites is crucial to theta rhythmogenesis.

Federal do Rio Grande do Norte, Natal, Brazil; [8]Dept. of Physiol., [9]Med. (Neurology), Univ. of Toronto, Toronto, ON, Canada

Abstract: Septohippocampal circuits generate theta rhythms that are associated with hippocampal learning. CA1 oriens lacunosum-moleculare (O-LM) cells receive robust GABAergic input from parvalbumin-positive (PV) projection neurons located in the medial septum-diagonal band of Broca (MS-DBB; Borhegyi et al., 2004). Multi-compartment computational models of O-LM cells have shown differential effects of somatic versus dendritic expression of hyperpolarization-activated cyclic nucleotide-gated (HCN) channels on output features such as back-propagating action potentials elicited by synaptic inputs (Sekulić et al., 2014, 2015). Preliminary modeling results demonstrate that driving synchronous PV MS-DBB synaptic input at theta frequency recruits HCN channels, enabling theta frequencies to be transmitted through O-LM cells via rebound spiking. Therefore, defining the subcellular distribution of HCN channels on O-LM cells is critical in understanding how O-LM cells integrate and transmit PV MS-DBB synaptic input. Previous studies employing HCN1/HCN2 double knockout mice indicated the presence HCN1-and HCN2-containing channels on O-LM cells (Matt et al., 2010). HCN2-containing channels were localized to the somata of somatostatin-positive cells in the CA1 stratum oriens (Matt et al., 2010), but the distribution of HCN2 channels on O-LM cell dendrites has neither been examined nor defined. Here, we employed Chrna2-CRE/tdTomato mice, enabling tdTomato to be visualized in all intracellular compartments of O-LM cells (Mikulović et al., 2015). In accordance with previous observations (Matt et al. 2010), HCN2 labeling was largely restricted to the somata of O-LM cells. HCN2 labeling in O-LM cell dendrites revealed a decrease in HCN2 channel expression with

decreasing distance from the soma. However, we also observed somatic labeling in CA1 pyramidal cells, with HCN2 labeling being weakest in the CA1 LM layer. Therefore, the axons of O-LM cells are unlikely to contain significant HCN2 channel densities. Moreover, given previous observations localizing HCN1 channels to the distal dendrites of CA1 pyramidal cells (Lorincz et al. 2002), HCN2 channels may have a more proximal subcellular distribution both in principal cells and interneurons. A better understanding of the subcellular localization of HCN1 and HCN2 channels will provide insight into circuit dysfunction as a consequence of their improper recruitment by altered synaptic input and the implications of such mechanisms in several neurological disorders, such as epilepsy and Alzheimer's disease.

Title: Role of Piccolo in high frequency transmission at a central auditory synapse

Authors: *T. BUTOLA[1,2], T. MOSER[1,2];
[1]Max Planck Inst. For Biophysical Chem., Goettingen, Germany; [2]Inst. for Auditory Neurosci., Goettingen, Germany

Abstract: Piccolo is a cytomatrix of the active zone (CAZ) protein involved in scaffolding and regulating neurotransmitter release at neuronal active zones. Here, we used Piccolo mutant mice to study central auditory synapses of the cochlear nucleus, which are specialized in high throughput synaptic transmission, capable of sustaining signaling frequencies of several hundreds of Hertz. We argue that even subtle deficits in the regulation of vesicle dynamics and neurotransmitter release will be revealed at synapses with such high functional demands. Moreover, the signal this synapse receives is unbiased by the mutation due to the presence of an unaffected, short isoform of Piccolo (i.e. 'Piccolino') upstream at the ribbon synapses of cochlear inner hair cells. Hence, this site of investigation provides a unique opportunity to study the implications of Piccolo deficiency on neuronal synaptic transmission. At the endbulb of Held

synapse, we observed faster rise of miniature excitatory postsynaptic currents (mEPSCs) in the mutants, while mEPSC amplitude and frequency were unchanged. Likewise, we found a faster rise of evoked EPSCs in the mutants. Moreover, when stimulated with high frequency train stimulation, the mutant responses showed faster kinetics of depression and an increased probability of vesicle release, while estimates of pool size and vesicle replenishment remained unchanged. Faster kinetics of release may be due to faster presynaptic release machinery with tighter Ca^{2+} influx and exocytosis coupling. Our hypothesis puts Piccolo as a spacer between the readily releasable pool of vesicles and Ca^{2+} channels, regulating release. Current experiments aim at revealing the contribution of postsynaptic receptor desensitization and saturation, to the observed synaptic changes. We also plan to address changes in the abundance of other CAZ proteins at the Piccolo-deficient endbulb active zones and study effects of combined manipulation of Piccolo and Bassoon.

Title: Common mechanisms of electrical synapse plasticity in invertebrates and vertebrates

Authors: ***G. WELZEL**, S. SCHUSTER;
Animal Physiol., Univ. of Bayreuth, Bayreuth, Germany

Abstract: Electrical synapses formed by gap junctions are of fundamental functional importance in the nervous system. Invertebrates form these gap junctions by using the supposedly primordial innexin proteins, whereas vertebrates use a different and unrelated protein family, the connexins. Vertebrates additionally express innexin-homologs in large quantities but only recruit connexin-based synapses for neuronal processing. These synapses have become renowned for their dynamic and use-dependent plasticity. Comparable data are lacking for innexin-based synapses so that it is unknown whether the two families differ fundamentally in how they support use-dependent plasticity. Here we directly studied the *in vivo* conductance in an innexin-based electrical synapse that is important for modulating escape behavior in the leech (*Hirudo medicinalis*). Our results show unequivocally that this innexin-based synapse shares all hallmarks of dynamic and use-dependent plasticity that are known for connexin-based synapses

of vertebrates. We show that serotonin and dopamine efficiently and rapidly modulate conductance with time constants of 14 - 18 and 48 s, respectively. Moreover, we demonstrate for the first time in any innexin-based synapse that these are capable of stable long-term potentiation (LTP) and may even share fundamental mechanisms of induction with their vertebrate counterparts. Our findings suggest that electrical synapse plasticity may be a conserved property of ancestral gap junctions that is shared by innexin- and connexin based synapses.

Title: The role of electrotonic junctions between excitatory neurons in the cortex

Authors: ***J. KILE**[1], G. KOVACIC[1], D. CAI[2];
[1]Rensselaer Polytechnic Inst., Troy, NY; [2]Courant Institute, NYU, New York, NY

Abstract: Global oscillations in the brain are linked to synchronized neuronal activity, which has been shown to contribute to cognitive processes such as perception, motor performance, learning and memory. Electric coupling through gap junctions may facilitate the emergence of synchronized oscillations, and influence their properties. Gap junctions between inhibitory neurons in the mammalian cerebral cortex have been well studied, but electrical synapses between excitatory, pyramidal neurons, or electrotonic junctions, have only recently been discovered experimentally.
In this study, we closely follow experimental data to construct a detailed, comprehensive model with both synaptic and electric coupling for both excitatory and inhibitory neurons using a modified version of the Hodgkin-Huxley equations. We have successfully replicated data for the interaction between pairs of electrically connected excitatory neurons, and pairs of electrically connected inhibitory neurons, using our mathematical model.
Our realistic, computational network model includes 25% inhibitory neurons and 75% pyramidal cells coupled both electrically and synaptically. We use a 5% coupling probability for gap junctions to occur among neighboring pyramidal cells, and a 50% coupling probability for gap junctions between interneurons less than 80μm apart, mimicking the medial prefrontal cortex, and visual cortex, of rats and ferrets.

We organize the neurons on a grid to capture the highly structured spatial properties of a network containing both synaptic and gap-junction connections, and to ensure that the probability of neurons being coupled is dependent on their location within the network. The external input to this patch of the cortex, modeling the influences of neurons from other parts of the brain, is in the form of a Poisson spike train. Using this model, we examine the dynamical regimes resulting from the inclusion of both electric and synaptic connections, with a specific interest in the emergence and properties of synchrony.
We find that the addition of gap junctions between inhibitory neurons creates oscillations in the firing pattern of the inhibitory population. Further, we show that these oscillations are strictly due to the gap junctions rather than an increased synaptic current. We also find that the pairs of electrotonic junctions serve to create specific patterning in the firing and bursting of the excitatory neurons that is linked to the timing of the inhibitory neurons' oscillations.

Title: Mechanisms of PKA-Dependent Regulation of Tomosyn

Authors: ***S. J. ZINN**[1], J. E. RICHMOND[2], D. FEATHERSTONE[2];
[2]Biol. Sci., [1]Univ. of Illinois, Chicago, Chicago, IL

Abstract: Tomosyn, a presynaptic inhibitor of neurotransmitter release, forms non-fusogenic SNARE complexes with the plasma membrane SNAREs, syntaxin and SNAP-25. In vertebrates, PKA-dependent tomosyn phosphorylation disrupts its interaction with the SNAREs *in vitro*. This has yet to be demonstrated in the intact nervous system. Our previous studies in *Drosophila* have shown that both tomosyn knockdown and forskolin application enhance neurotransmission although these effects are not additive, suggesting they act in the same pathway. Tomosyn knockdown flies also exhibit impaired PKA-dependent olfactory learning, indicating that tomosyn may be a downstream target in this modulatory pathway. However, synapsin has also been implicated in fly PKA-dependent learning. This raises the possibility that PKA-regulation of tomosyn may be a secondary consequence of synapsin phosphorylation. To address this hypothesis, we have obtained a fly line expressing beggiatoa photoactivated adenylyl cyclase (bPAC), an optogenetic tool that allows blue-light activation of cAMP. At the fly NMJ, activation of bPAC results in enhanced neurotransmitter release, translocation of tomosyn away

from the plasma membrane, and a corresponding increase in synaptic vesicle docking by EM. To test whether PKA-regulation of tomosyn is direct or indirect, we are exploring the effect of synapsin mutations on cAMP-dependent tomosyn translocation. We are also generating a tomosyn-HA line using CRISPR/Cas9 to identify physiologically relevant tomosyn phosphorylation sites by mass spectrometry. Identification and subsequent mutation of potential PKA phosphorylation sites will allow us to directly test the relevance of tomosyn PKA-phosphorylation through site directed mutagenesis.

Title: Glutamatergic & Dopaminergic neurons in the Substantia nigra of adult mouse preferentially express connexin 26 and 30

Authors: *A. HERNANDEZ SANCHEZ;
Univ. Autonoma De San Luis Potosi, San Luis Potosi, Mexico

Abstract: The mouse substantia nigra contains neurons of Dopaminergic (TH+, DAT+ or VMAT2+), Glutamatergic (VGluT2+) and GABAergic (GAD1/2+ or VGAT+) phenotypes as well as neurons of Dopaminergic/GABAergic (TH+/GAD+) and Dopaminergic/Glutamatergic (TH+/VGluT2+) double phenotype. Dopamine neurons communicate with neighbor neurons through chemical neurotransmission via the somatodendritic release of dopamine. Also, dopamine neurons synchronize during phasic electrical activity, which is modulated by electrical synapses. Interestingly, during both appetitive and aversive learning, non-dopaminergic neurons show synchronized electrical activity with dopaminergic neurons. In order to gain insight into this phenomenon, the expression profile of connexins, the building blocks of gap junctions which are responsible for fast neuronal electrical coupling, was determined in individual Dopaminergic (TH+/VGluT2-) and Glutamatergic (TH-/VGluT2+) neurons of the substantia nigra of adult (p90) mice. Single cell RT-PCR multiplex assays performed using isolated acutely-dissociated cells showed that both Dopaminergic and Glutamatergic cells can express Cx26, Cx30, Cx31.1, Cx43 and Cx45. Of them, Cx26 and Cx30 are expressed in the vast majority of these cells. Moreover, despite previous reports of the expression of Cx36 in dopamine neurons from young

mice, its expression couldn´t be detected in neurons from the adult substantia nigra. Given that Cx26 and Cx30 have the ability to form functional gap junctions either together or in combination, our results open the possibility of an electrical coupling between neurons of a different phenotype within the substantia nigra. The physiological meaning of this electrical coupling is currently under investigation in our laboratory.

Title: Tsc1 deletion in the developing thalamus synchronizes activity in relay neurons via ectopic electrical synapses

Authors: *R. MARTINEZ-GARCIA, S. R. CRANDALL, S. L. PATRICK, B. VOELCKER, M. ZERVAS, B. W. CONNORS;
Brown Univ., Providence, RI

Abstract: Tuberous Sclerosis (TSC) is a developmental genetic disorder caused by mutations in *Tsc1* and/or *Tsc2*. Neurological signs in TSC patients include epilepsy and autism, but the cellular mechanisms underpinning TSC are poorly understood. One brain region implicated in the pathology of some TSC patients is the thalamus. The laboratory previously generated a mouse model in which *Tsc1* was selectively deleted in ~70% of relay neurons on E12.5 (Normand et al., *Neuron*, 78:895, 2013). This deletion led to enlarged relay neurons with abnormal intrinsic excitability, and anomalous circuitry and synchrony in the thalamus; the deletion was also sufficient to cause aberrant repetitive grooming and seizures. One way to enhance neuronal synchrony is to interconnect cells with electrical synapses, which are comprised of neuronal gap junctions: intercellular channels that provide conductive pathways from one cell to another.

Surprisingly, we found strong but sparse electrical synapses between *Tsc1*$^{\Delta/\Delta}$ relay neurons in slices of the ventrobasal (VB) nucleus of the thalamus (*Tsc1*$^{\Delta/\Delta}$ mice: ~12% of cell pairs, *Tsc1*$^{+/+}$ mice: 0% of pairs; ages P20-P24). The laboratory has previously shown that gap junction-mediated electrical synapses are present in VB relay neurons early in development but are entirely abolished by the second postnatal week (Lee et al., *J. Physiol,* 588:2403, 2010). Electrically coupled *Tsc1*$^{\Delta/\Delta}$ relay neurons had synchronized subthreshold and spiking activity. Additionally, inhibitory inputs from the thalamic reticular nucleus to one thalamic relay neuron could, via electrical synapses, delay the activity of an adjacent neuron and briefly synchronize the activity of the cell pair afterwards. We also addressed whether *Tsc1* deletion in relay neurons alters chemical synapses. Relay cells with *Tsc1* deletions had a lower frequency of miniature excitatory postsynaptic currents, although the kinetics of these events were unaltered. Additionally, TRN inputs to *Tsc1*$^{\Delta/\Delta}$ relay neurons had slightly altered kinetics but unaffected synapse dynamics. Interestingly, *Tsc1*$^{\Delta/\Delta}$ relay neurons received more frequent feedback inhibition than control relay neurons.
Prenatal *Tsc1* deletions led to the induction ectopic electrical synapses among relay neurons as well as to changes in intrathalamic chemical synapses. These cellular changes may enhance synchrony among relay neurons and the cortex they project to, and contribute to repetitive grooming and seizures.

Title: Ankyrin and CRMP regulate gap junction dynamics through kinesin in *C. elegans*

Authors: *L. MENG[1], C.-H. CHEN[1], D. YAN[1,2];
[1]Mol. Genet. and Microbiology, [2]Neurobio., Duke Univ. Sch. of Med., Durham, NC

Abstract: The importance of gap junctions has been documented in many biological processes, but the molecular mechanisms underlying gap junction dynamics remain unclear. Here, we use *C. elegans* PLM neurons as a model to study gap junctions. In a genetic screen, we isolated two mutants, *unc-44*/ankyrin and *unc-33*/CRMP (Collapsin Response Mediator Protein) altering gap junctions. Through genetic analysis and live imaging, we found that ankyrin and CRMP function

through a kinesin (VAB-8) in regulating gap junction dynamic. Therefore, we first show a signal pathway involved ankyrin, CRMP and kinesin in regulating gap junction dynamic.

Title: Regulation of dense core vesicle trafficking and fusion at *Drosophila* synapses

Authors: ***K. G. ORMEROD**, J. T. LITTLETON;
Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: Two main classes of neurosecretory vesicles, synaptic vesicles (SVs) and dense core vesicles (DCVs), mediate regulated secretion in neurons. Fusion of SVs is a fast and highly regulated process, orchestrated by synaptic proteins that modulate docking, priming and fusion. While the molecular components driving SV fusion have been well characterized, less is understood about the molecular machinery underlying the trafficking and exocytosis of DCVs at synapses. DCVs transport, store and release proteins and neuropeptides at multiple sites, facilitating a wide range of biological processes including synaptogenesis, synaptic transmission, cell survival, and synaptic plasticity. Unlike the release of SVs, DCVs require a larger stimulus (30+ Hz stimulation) to trigger exocytosis. Given these considerable differences, we are interested in examining how the synaptic machinery that mediates trafficking and fusion of SVs and DCVs differ. We have generated tagged versions of DCV cargo and transmembrane components to investigate their trafficking at the *Drosophila* neuromuscular junction. We are also employing quantal resolution imaging of vesicle fusion at single active zones to determine how DCV containing neuromodulators regulate synaptic communication.

Title: Expression and modulation of gap junction proteins in the adrenal gland during pre and perinatal development.

Authors: *E. M. PEREZ-ARMENDARIZ[1], A. ZARZA VELA[2], L. CRUZ-MIGUEL[2]; [1]DEPARTMENT OF TISSUE AND CELL BIOLOGY, NATIONAL AUTONOMOUS UNIVERSITY OF MEXICO, Mexico City, Mexico; [2]DEPARTMENT OF TISSUE AND CELL BIOLOGY, NATIONAL AUTONOMOUS UNIVERSITY OF MEXICO, Mexico, Mexico

Abstract: It is known that connexin 36 (Cx36) and connexin Cx43 (Cx43) are expressed in the adrenal gland in adult rodents. In addition, there is evidence that stress induced by cold, in adult animals, induces changes in these connexins. Moreover, intercellular channels have been involved in the release of catecholamines (CA) by chromaffin cells (CCs) under stress induced by intermittent hypoxia during labor. However, the molecular identity, spatial distribution and ontogeny of gap junctions in the CCs during prenatal development is unknown. In addition, it is ignored whether there are gap junction changes during the perinatal period. To investigate these aspects real-time PCR studies were performed using specific probes against Cx43 and Cx36 in preparations of adrenal gland pools at 13 and 18 days post coitum (dpc) as well as 3 days postpartum (dpp). Between 13 dpc and 3 dpp, an increase in mRNA levels was found for Cx36 (1.4 fold) and Cx43 (4 fold). These transcript elevations occurred correlated with an increase in N-methyl transferase phenyl (46 fold) and 3-β-hydroxy steroid dehydrogenase (7.5 fold) and cytochrome P450 family 11 subfamily β member 1 (3.5 fold) respectively. From above, Cx43 and Cx36 are genes of early expression in the adrenal gland that are up regulated in a development and functional dependent manner. The spatial distribution of the respective proteins at these stages is presently characterized. GRANT CONACyT-SEP no. 127658, Mexico.

Title: Electrical coupling and active membrane currents support lateral inhibition and lateral excitation between Mesencephalic Trigeminal (MesV) neurons

Authors: *F. DAVOINE[1], P. MONZÓN[1], S. CURTI[2];
[1]Facultad Ingeniería, Univ. De La República, Montevideo, Uruguay; [2]Facultad Medicina, Univ. De La República, Montevideo, Uruguay

Abstract: MesV neurons are primary afferents that innervate spindles of jaw closer muscles and mechanoreceptors of the periodontal ligament. Their cell bodies lie within the CNS and form part of the networks involved in the organization of orofacial behaviors. These neurons are electrically coupled through somatic Cx36-containing gap junctions and coupling is restricted to pairs or small clusters. Instead of the classical low-pass properties, electrical transmission at these contacts behaves as a band-pass filter with a peak near 50-80 Hz. Experimental evidence indicate that this characteristic results from the interaction of the passive properties of coupled neurons with the persistent Na+ current (INap) and an A-type K+ current (IA). This frequency transfer characteristic supports synchronization and coincidence detection between these cells suggesting that sets of MesV neurons defined by electrical coupling operate as functional units. However, little is known about the specific role of the INap and the IA in frequency selectivity and how these circuits of coupled neurons contributes to the processing of relevant sensory information. To address these questions we developed a computational model of MesV neurons using NEURON and Python. The model reproduces the morphological features of these neurons and the main active membrane conductances and was adjusted to fit several experimental parameters such as input resistance, time constant, action potential shape and spiking, using evolutionary multi-objective optimization. The numerical model was used to simulate pairs of coupled neurons to study in detail the role of the active membrane currents. We found that while INap improves the gain of transmission through amplification of subthreshold signals it tends to worsen the precision of synchronization. In contrast, while the IA have the opposite effect on the gain it reduces the time difference between pre- and postsynaptic spikes improving the precision of synchronization. Therefore, these two currents seems to play opposing roles in electrical transmission and their antagonistic actions results in a compromise between gain and precision to promote neuronal synchronization. Moreover, simulations and experiments show that coupled

MesV neurons differentiate coincident and non-coincident sensorial stimuli coming from their peripheral axons. Depending on the relative delay between inputs, afferent spikes facilitates activation of coupled cells (lateral excitation) or delays it (lateral inhibition). The extent of these opposing effects and the time window over which they operate are determined by the balance between the INap and IA.

Title: A novel LTP mechanism that involves persistent self-activation of nitric oxide synthase (NOS)

Authors: A. TURCHETTI-MAIA[1], N. STERN-MENTCH[1,2], N. NESHER[1,2], T. SHOMRAT[1,2], *B. HOCHNER[1];

Abstract: The *Octopus vulgaris* vertical lobe (VL) is organized as a simple feedforward fan-out fan-in network with a robust presynaptic, NMDA-independent, activity-dependent LTP at the fan-out synaptic layer. The octopus VL and its LTP are important for the acquisition of long-term memories outside the VL, as saturating LTP or severing the VL impaired long-term memory acquisition but did not erase older memories (Young and Boycott 1955, Shomrat et al 2008). In this work we started to investigate the mechanisms underlying VL LTP. We first show that LTP induction and maintenance are likely not to involve protein synthesis, as the administration of anisomycin 20μM in VL slice preparations, before or after LTP induction, did not block LTP induction nor maintenance for at least up to 10h after LTP induction. We then investigated whether NOS, a well-known mediator of synaptic plasticity in mollusks, is involved in the long-term maintenance of LTP. Indeed, the VL neuropil is heavily stained for NOS activity (NADPH-d). We found that at least up to 8h after tetanization induced LTP, NOS

inhibitors could block LTP expression as much as bringing the facilitated synaptic LFP back to its control amplitude. A complete block of LTP expression involved a reversal of the paired-pulse facilitation ratio to the pre-induction ratio, suggesting that blocking the LTP involves reversing the probability of transmitter release to the pre-LTP level. Usually the blocking effects were reversible and washing out the inhibitors brought the response back to a full LTP level. However, we found that as the time gets longer after LTP induction, the proportion of experiments where LTP did not recover increased and, interestingly, in these cases tetanization reinduced LTP. Taken together, these results suggest a novel "molecular memory switch" mechanism whereby activity-dependent NOS activation generates NO that retrogradely mediates LTP expression in the presynaptic terminals and at the same time maintains long-term activation of NOS. We hypothesize that such a molecular and protein synthesis-independent LTP may coordinate, through the VL output, a universal protein synthesis-dependent long-term memory acquisition at brain areas outside of the VL.

Abstract: Pyramidal neurons in hippocampal area CA2 differ dramatically from neighboring CA3/CA1 pyramidal neurons in that synaptic long-term potentiation (LTP) is not as readily

induced. We previously identified Regulator of G Protein Signaling 14 (RGS14) as a critical brake on CA2 synaptic plasticity and learning and memory. RGS14 knockout (RGS14 KO) mice display a robust and nascent capacity for LTP in CA2 pyramidal neurons, which is absent in wild-type (WT) mice, and exhibit enhanced hippocampus-dependent learning and memory. However, the cellular mechanism(s) by which RGS14 suppresses LTP in CA2 remain unknown. The lack of plasticity in CA2 has been attributed to robust calcium (Ca^{2+}) buffering and extrusion mechanisms relative to CA3/CA1, but RGS14 has not been functionally linked to Ca^{2+}-activated signaling pathways critical for LTP induction. Therefore, we investigated whether RGS14 restricts LTP in hippocampal CA2 by regulating Ca^{2+}-stimulated pathways required for LTP.
To identify candidate signaling pathways through which RGS14 natively inhibits LTP in CA2, we first co-immunoprecipitated RGS14 from mouse brain. We find that RGS14 interacts with calmodulin (CaM), Ca^{2+}/CaM-dependent kinase II (CaMKII), and other members of Ca^{2+}-activated LTP signaling pathways. We validated these novel binding partners using biochemical assays and demonstrate that RGS14 directly binds CaM in a Ca^{2+}-dependent manner. Differential hydrogen/deuterium exchange (HDX) mass spectrometry reveals that Ca^{2+}/CaM binding to RGS14 causes significant conformational changes. Further, we show RGS14 binds to and is phosphorylated by CaMKII *in vitro*. We also find that viral expression of RGS14 in CA1 pyramidal neurons inhibits LTP induction, suggesting that RGS14 acts through pathways common to CA2 and CA1. Using field recordings and pharmacological inhibitors we find that the nascent CA2 LTP present in RGS14 KO mice requires NMDAR activation as well as CaMKII and PKA activity. We also demonstrate through two-photon glutamate uncaging experiments that RGS14 limits structural plasticity of dendritic spines in WT CA2 neurons whereas CA2 spines from RGS14 KO mice possess structural plasticity similar to CA1 controls. Ongoing studies using two-photon fluorescence lifetime imaging microscopy biosensors are further defining if RGS14 modulates postsynaptic Ca^{2+} levels, CaMKII activity, and other downstream signaling, to block plasticity in CA2. Together these studies provide novel mechanistic insight into the cellular regulation of synaptic plasticity in area CA2 and the key role RGS14 plays in this process.

Title: Pre- and postsynaptically expressed spike-timing-dependent plasticity contribute differentially to neural learning

Authors: *B. E. P. MIZUSAKI[1,2], S. S. Y. LI[1], R. P. COSTA[3], P. J. SJÖSTRÖM[1];
[1]Res. Inst. of MUHC, Montreal, QC, Canada; [2]Inst. de Física, Univ. Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil; [3]Univ. of Oxford, Oxford, United Kingdom

Abstract: After a long-standing debate over whether long-term plasticity is pre or postsynaptically expressed, the emerging consensus is that one or both are possible outcomes depending on factors such as age, induction protocol, and synapse type. It remains unclear, however, what specific computational impact there is to pre vs. postsynaptic expression. To address this, we systematically varied the locus of expression in a simplistic model of spike-timing-dependent plasticity (STDP) inspired by Song and Abbott (Nat Neurosci 2000 3:919; Neuron 2001 32:339): a single integrate-and-fire neuron received at least 100 excitatory inputs. Presynaptic changes were either implemented by altering the probability of release directly at a stochastic synaptic contact following a Binomial release model, or alternatively by changing short-term plasticity using the Markram-Tsodyks vesicle depletion paradigm. Postsynaptic changes were implemented by additive changes in the quantal amplitude. Synaptic weight changes were normalized to give rise to the same magnitude of change irrespective of whether probability of release or quantal amplitude was plastic. Learning was assessed as rate of convergence to a final steady state in two simple simulation frameworks testing either the coding of correlated inputs or of spiking response latencies. With the stochastic release model, plasticity of the probability of release led to faster convergence than plasticity of quantal amplitude did, irrespective of initial conditions. When modelling presynaptic expression of plasticity in terms of stochastic release, we thus found that the rate of learning was generally faster with presynaptic than with postsynaptic expression. However, with presynaptic expression implemented in terms of changes in short-term depression, the coding of correlated inputs was more rapid with postsynaptic than with presynaptic plasticity. This outcome could in part be ascribed to the details of the Song and Abbott STDP model, which is not tuned to the neurobiology of multiple spike pairings arising at high frequencies. A model biologically tuned to neocortical layer-5 pyramidal cell synapses (Costa et al, eLife 2015 4:e09457) is predicted to exhibit different properties. The vast majority of computational models rely on changing the synaptic gain to model synaptic plasticity, which corresponds to altering the quantal amplitude. This however is not a neutral choice, as it is in effect a bias toward postsynaptic expression. Here we explore key differences between pre and postsynaptic expression of STDP, demonstrating how this default assumption in modelling of plasticity may in fact affect simulation results.

Title: Binding of calcium/calmodulin to PSD-95 N-terminus mediates homeostatic scaling down

Authors: ***D. CHOWDHURY**, M. L. TURNER, T. PATRIARCHI, M. MENDEZ, J. AMES, J. W. HELL;
Univ. of California Davis, Davis, CA

Abstract: The postsynaptic density scaffold protein PSD-95 is a key organizer of excitatory synapses. Abundance of glutamate receptors at the synapse, and thereby synaptic strength, is determined largely by synaptic PSD-95 abundance which, in turn, is regulated by activity. However, the mechanisms underlying the activity-induced regulation of PSD-95 synaptic localization are not clearly understood. Previous work from our lab has shown that influx of calcium following synaptic activation induces dispersal of PSD-95 from dendritic spines via binding of Ca^{2+}/Calmodulin (CaM) to the N-terminus of PSD-95 that reduces its palmitoylation (Zhang et al., *EMBO J*, 2014). The current study elucidated the role of PSD-95-CaM interaction in mediating removal of PSD-95 from synapses that accompanies homeostatic synaptic scaling down. Using peptide screening and NMR structural analysis, we identified E17 and T19 within PSD-95 N-terminus as the critical residues interacting with CaM. We generated CaM-binding-defective mutants (E17R and T19K) to test their role in PSD-95 mobilization seen in homeostatic scaling down. Using fluorescence microscopy in cultured hippocampal neurons overexpressing recombinant PSD-95, we observed that chronic elevation of network activity with the GABA-A receptor antagonist bicuculline reduced PSD-95 spine enrichment in spines and both mutants blocked this effect. Moreover, replacement of endogenous PSD-95 with either mutant blocked reduction of surface AMPA-type glutamate receptors (AMPARs) during scaling down. Further, charge inversion mutations of the interacting residues on CaM, compensating for PSD-95 mutations, restored scaling down of AMPARs. Further work is directed to verify the role of this interaction in regulating functional AMPARs using electrophysiological analysis. Reference: Y.

Title: Plasticity of excitatory transmission onto hippocampal interneurons of the stratum lacunosum moleculare

Authors: *M. MERCIER, D. KULLMANN;
Inst. of Neurol., Univ. Col. London, London, United Kingdom

Abstract: Long-term potentiation (LTP) of excitatory transmission onto hippocampal principal cells is thought to play an important role in memory encoding. Within stratum radiatum, LTP at Schaffer collateral-CA1 pyramidal cell synapses is balanced by a complementary increase in the recruitment of feed-forward inhibitory interneurons (Lamsa *et al*., 2005). CA1 pyramidal cells also exhibit LTP at their distal synapses located in stratum lacunosum moleculare (SLM), which receive excitatory input from entorhinal cortex layer III (ECIII). Whilst this pathway recruits strong feed-forward inhibition, it is not known whether ECIII synapses onto SLM feed-forward interneurons can also be potentiated, and if so, what downstream effects this might have on pyramidal cell signaling.
Using whole-cell recordings from SLM interneurons in acute mouse hippocampal slices, we found that LTP could indeed be induced in these cells. Interestingly, this plasticity was NMDA-receptor dependent when induced by a low-frequency pairing protocol, but not when induced by a spike-timing-dependent-plasticity (STDP) protocol, and in all cases was not pathway-specific. Post-hoc anatomical characterization revealed at least a subset of LTP-expressing cells with neurogliaform cell-like morphology. Further experiments will probe the signaling pathways and mechanisms involved in this novel form of interneuron plasticity, as well as its function within the wider hippocampal network.

[1]Tokyo Univ. of Science, Fac. of Sci. and Technol., Noda, Chiba, Japan; [2]Tokyo Univ. of Pharm. and Life Sciences, Envrn. Hlth., Horinouchi, Hachioji, Tokyo, Japan

Abstract: Ca^{2+}-dependent activator protein for secretion 1 (CAPS1) regulates exocytosis of dense-core vesicles and is probably required at the priming step. Recent studies suggested its regulatory role in synaptic transmission by trafficking synaptic vesicles to the active zone. Here we report that CAPS1 also has a critical role in hippocampal plasticity. Because conventional CAPS1 knockout (KO) mice die soon after birth, we utilized forebrain-specific CAPS1 conditional knockout (cKO) mice for this purpose. In the hippocampal CA3-CA1 synapses, the amplitude and paired-pulse facilitation of the synaptic transmission was respectively reduced and increased in CAPS1 cKO. Interestingly, CAPS1 and CAPS2 (another member of the CAPS family) are widely distributed in the hippocampal formation and their major distribution areas are complementary to each other. CAPS2 KO mice is known to show reduced late-phase LTP at CA3-CA1 synapses, whereas CAPS1 cKO mice exhibited an impairment in LTP at CA3-CA1 synapse with an increased post-tetanic potentiation compared with their control littermates. In hippocampal DG-CA3 synapses, the amplitude of the synaptic transmission was respectively reduced. But paired-pulse facilitation was no significant difference, and DG-CA3 synapses are known to cause pre-synaptic LTP. These results suggest that CAPS1 plays a critical role in hippocampal presynaptic plasticity.

Title: A novel structural role for calcium/calmodulin kinase II in hippocampal pyramidal neurons

Authors: *S. INCONTRO[1], C. ASENSIO[2], R. A. NICOLL[1];
[1]UCSF, San Francisco, CA; [2]Dept. of biological sciences, Univ. of Denver, Denver, CO

Abstract: AMPA and NMDA receptors (AMPARs and NMDARs) play a key role in both basal activity and the induction of synaptic plasticity at excitatory synapses. Furthermore the trafficking and the stabilization of these receptors at the postsynaptic density (PSD) modulate synaptic strength. Long-term potentiation (LTP) in the CA1 region of the hippocampus is the primary cellular and molecular model to understanding memory. LTP induction at Schaffer collateral-CA1 synapses requires the activation of postsynaptic NMDA receptors, Ca^{2+} influx through NMDARs, and activation of Ca^{2+}/calmodulin-dependent protein kinase (CaMKII). Within 10s, this activation induces a rapid increase in the number of AMPARs at synapses. CaMKII is necessary for LTP induction and by itself enhances the efficacy of synaptic transmission. Using CRISPR to eliminate CaMKII (α and β isoforms) we have now unveiled an important structural role of CaMKII in maintaining basal synaptic transmission in CA1 pyramidal neurons. We first confirmed that the two isoforms are both important for LTP, since the elimination of both abolished LTP induction. Furthermore basal excitatory postsynaptic currents (AMPAR and NMDAR EPSCs) were strongly reduced. Surprisingly our experiments demonstrate also that CaMKII is needed for basal NMDAR participation at synapses. Molecular replacements with kinase dead forms of CaMKIIα specifically rescued NMDAR transmission uncovering a novel structural role for CaMKII in maintaining NMDARs in the PSD. Together our results uncover important roles for CaMKII in basal synaptic transmission and clarifying its fundamental role in the induction of LTP.

Title: Microglia promote post-synaptic depression of sensory relay neurons in the nucleus tractus solitarius (nTS) following acute lung injury in rats

Authors: *D. G. LITVIN[1], C. B. SMITH[1], F. J. JACONO[2];
[1]Physiol. & Biophysics, [2]Dept. of Medicine, Div. of Pulmonary, Critical Care and Sleep Med., Case Western Reserve Univ. Sch. of Med., Cleveland, OH

Abstract: Acute respiratory distress syndrome (ARDS) remains a common cause of respiratory failure, with an estimated annual U.S. mortality rate of over 40%. ARDS patients may experience neurological deficits affecting cognitive and autonomic function, which have been loosely attributed to neuroinflammatory and hypoxic episodes pursuant to the lung injury.
In an intratracheal bleomycin (BM*i*) based model of ARDS, we have previously shown that BM*i* rats displayed elevated brainstem inflammation and synaptic depression in the nTS. We hypothesized that: 1) BM*i* lung injury promotes synaptic depression through changes in post-synaptic glutamate receptor (GluR) expression, and 2) synaptic depression can be ameliorated by minocycline, a microglial/macrophage inhibitor.
7 days following intratracheal saline (S*i*) or BM*i* instillation, BM*i* rats (n=9) showed greater immunoreactivity for the GluR2 subunit of the α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor compared to control (S*i*) rats (n=8). There were no significant differences in GluR1 and GluR4 levels between groups.
In support of increased post-synaptic insertion of the GluR2 subunit, the amplitudes of spontaneous and tractus solitarii evoked excitatory post-synaptic currents (sEPSCs & TS-eEPSCs) showed reduced inhibition to the non-GluR2 inhibitor 1-Naphthyl acetyl spermine trihydrochloride (NASPM) in BM*i* (n=6) rats compared to S*i* rats (n=7). Moreover, the current rectification index of TS-eEPSCs (recorded in the presence of 0.1μm spermine at +40/-60) was significantly greater in BM*i* (n=4) compared to S*i* (n=4) rats, and the I-V relationship of TS-eEPSCs became more linear in the BM*i* group.
To determine whether microglia/macrophages contributed to the increase in post-synaptic GluR2 in the nTS following BM*i* instillation, BM*i* rats and S*i* rats were treated with intraperitoneal (*ip*) injections of minocycline (25mg/kg) or vehicle for 7 days following lung injury. BM*i* rats treated with minocycline (n=7) exhibited significantly lower GluR2 immunoreactivity in the nTS

compared to vehicle treated BM*i* rats (n=7), but was still significantly greater than *Si* rats treated with vehicle (n=5). Neurons from BM*i* rats treated with saline (n=5) had reduced amplitude and prolonged rise time of sEPSCs that were reversed in minocycline treated BM*i* rats (n=8). Increases in GluR2 expression contribute to post-synaptic depression of sEPSCs in nTS neurons following BM*i* lung-injury, and are reversed by minocycline treatment. We conclude that microglia regulate this process and that neuroinflammation may contribute to dampened autonomic function in the setting of acute lung injury.

Title: Hippocampal stratum oriens interneurons express endocannabinoid biosynthetic enzymes and undergo anandamide dependent potentiation

Authors: *L. N. FRIEND[1], R. WILLIAMSON[2], C. MERRILL[3], S. NEWTON[1], M. CHRISTENSEN[1], J. EDWARDS[1];
[1]Brigham Young Univ., Provo, UT; [2]Carnegie Mellon University, Univ. of Pittsburgh, Pittsburgh, PA; [3]UC Irvine, Irvine, CA

Abstract: The hippocampus is thought to mediate learning and memory by altering the strength of synapses within its circuitry. In many cases, this synaptic plasticity can be induced by signaling molecules. Lipid-based signaling molecules called endocannabinoids, can modulate synaptic plasticity among hippocampal pyramidal cells and stratum radiatum interneurons; however, the role of endocannabinoids in mediating synaptic plasticity among interneurons in the stratum oriens is still unclear. Using patch-clamp electrodes to extract single cells we analyzed the expression of endocannabinoid biosynthetic enzyme mRNA using RT-PCR. In this analysis, we examined cellular expression of several calcium-binding proteins and neuropeptides to determine interneuron subtype. We analyzed cellular expression of several endocannabinoid biosynthetic enzymes, including N-acyl phosphatidylethanolamine phospholipase D (NAPE-

PLD), diacylglycerol lipase alpha, and 12-lipoxygenase, as well as type 1 mGluRs. Preliminary data suggests that stratum oriens interneurons express mRNA necessary for endocannabinoid biosynthetic enzymes. To test the role of endocannabinoids in synaptic plasticity, stratum oriens interneurons were patched and glutamate currents were recorded in the presence of a fatty acid amide hydrolase inhibitor (URB597) to increase endogenous anandamide. We observed a 30% enhancement above baseline (n=7, p<.001) that was blocked by the CB1 inhibitor AM-251 (n=6, p<.001). These results demonstrate a novel endocannabinoid-mediated mechanism for synaptic plasticity in stratum oriens interneurons.

Title: ERK2 dependent phosphorylation of the immediate early protein Arc/Arg 3.1

Authors: M. S. ERIKSEN, O. NIKOLAIENKO, *T. KANHEMA, C. R. BRAMHAM; Univ. of Bergen, Bergen, Norway

Abstract: Activity-regulated cytoskeleton-associated protein, Arc, is implicated in multiple forms of synaptic plasticity. It binds to distinct sets of proteins and has functions at synapses and the nucleus. This suggests that Arc function and localization is tightly regulated. Arc transcription, postsynaptic mRNA localization, and translation are all ERK-dependent processes. We suggest that ERK is further implicated in Arc regulation by phosphorylating Arc post-translationally. Activated Erk2 phosphorylates bacterially expressed Arc *in vitro* at five sites, as confirmed by phospho-specific protein staining and subsequent LC-MS/MS analysis. Following LTP induction in the dentate gyrus of the adult rat, phosphorylated Arc was detected using a phospho-site specific antibody to probe immunoprecipitated Arc. We further demonstrate stimulus-evoked, ERK-dependent phosphorylation of Arc in neuroblastoma cell lines. Lentiviral infections of phosphomutated Arc in cultured hippocampal neurons show a time-dependent difference in cytosolic to nuclear expression compared to wildtype. In conclusion, we demonstrate ERK catalyzed phosphorylation of Arc in situ.

Title: HINT1 protein: a role in spinal neuroplasticity underlying opioid tolerance and neuropathic pain.

Authors: *C. PETERSON[1,2], R. SHAH[3], K. F. KITTO[4], C. FAIRBANKS[5,2,1], C. R. WAGNER[3], G. L. WILCOX[4,6,5];
[1]Pharmaceutics, [2]Exptl. and Clin. Pharmacol., [3]Medicinal Chem., [4]Neurosci., [5]Pharmacol., [6]Dermatol., Univ. of Minnesota, Minneapolis, MN

Abstract: Background: The interactions between the mu-opioid (MOR) and N-methyl-D-aspartate (NMDAR) receptors are an area of intense investigation due to their contribution to maladaptive neuroplasticity. Evidence suggests that their association requires the involvement of histidine triad nucleotide-binding protein (HINT1). Since it is known that spinal blockade of NMDAR prevents the development of opioid analgesic tolerance, we hypothesized that spinal inhibition of HINT1 enzyme may similarly inhibit opioid tolerance. Given the similar mechanisms underlying the development of both opioid analgesic tolerance and neuropathic pain, we reasoned that HINT1 inhibition may reduce the development of neuropathic pain, consistent with observations that antagonism of NMDAR inhibits both developments. Blockade of NMDAR is known to inhibit the development of MOR analgesic tolerance. To address these questions we evaluated HINT1 inhibitors in three models of spinal neuroplasticity: morphine-induced inhibition of NMDA-evoked behavior, endomorphin-2 induced analgesic tolerance, and spared nerve injury.
Experiments: Morphine inhibition of NMDA-induced behavior: Morphine (10 nmol, i.t.) reduced hindlimb-directed scratching and biting behaviors elicited by intrathecal NMDA (0.3 nmol, i.t.). A 5 minute pre-treatment with a HINT1 inhibitor, guanosine-5'-tryptamine carbamate (TpGc), dose-dependently inhibited the morphine-induced reduction of NMDA behavior. Pre-treatment with vehicle alone had no effect.
Endomorphin-2 Induced Analgesic Tolerance: Mice were treated with either TpGc (10 nmol, i.t.) or vehicle. Mice were then injected with endomorphin-2 (10 nmol, i.t.) to induce acute opioid tolerance. At thirty minutes post-injection, the tail flick latencies of mice returned to baseline levels and a probe dose of endomorphin-2 (10 nmol) was administered. Pre-treatment of TpGc prevented the development of endomorphin-2 tolerance.

Spared Nerve Injury: Tactile hypersensitivity was established in mice via partial ligation of the sciatic nerve. TpGc was delivered intrathecally either prior to surgery or one week following surgery, and mice were tested for their von Frey thresholds for several days following surgery. TpGc pre-treatment significantly attenuated the tactile hypersensitivity relative to vehicle-treated controls. This effect persisted through day 5 post-surgery. Additionally, delivery of TpGc one week following induction of neuropathic hyperalgesia transiently reversed tactile hypersensitivity.
Conclusion: These data suggest a role for the HINT1 enzyme in spinal neuroplasticity involving NMDA receptor mechanisms.

Title: High-frequency stimulation induces cholecystokinin release from their terminals that switches long-term potentiation in the auditory cortex

Authors: *W. XIAOYU, X. LI, Y.-T. WONG, J. HE;
City Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: In our previous studies, we found that the medial temporal lobe influences neocortical plasticity via CCK-positive cortical projection neurons in the entorhinal cortex. In the rat

auditory cortex, long-term potentiation (LTP) could be induced either by high-frequency (HF) stimulation or by only low-frequency stimulation in the presence of CCK. We hypothesized that, with two low-impedance electrodes, LTP of the connection A to B could be induced by stimulating electrode A with HF, or by stimulating electrode B with HF. We then implanted two electrodes in two hemispheres of the auditory cortex, which showed connectivity physiologically. After recording the baseline field potential responses in one hemisphere (electrode B) to the electrical stimulation in the other (electrode A), we applied HF burst stimulation at A. LTP was induced over the above baseline. We further applied HF burst stimulation at B, LTP (with A as the stimulation electrode and B as the recording electrode) was further enhanced. We further hypothesized that HF stimulation was to induce the release of CCK in the stimulation site. In the following experiment, we embedded electrodes and drug-injection needles bilaterally into the rat auditory cortex. After injection of CCK antagonist in the high-frequency stimulation side, rat showed no more LTP, whereas LTP could still be triggered when CCK antagonist was injected on the recording side. The results indicate that HF stimulation induced CCK release from their terminals and CCK strengthened the connection in the surrounding synapses. In conclusion, HF-induced LTP of the direction A to B is produced by the increased input current from A.

Title: Actin tyrosine-53 phosphorylation in rat hippocampus LTP

Authors: ***J. E. ENGLUND**[1], E. BERTLING[5], R. MINKEVICIENE[5], M. KOSKINEN[6], M. SEGERSTRÅLE[2], E. CASTREN[3], T. TAIRA[4], P. HOTULAINEN[5];

Abstract: Our objective was to study the role of actin phosphorylation in dendritic spines during plastic events. Rapid re-organization and stabilization of the actin cytoskeleton in dendritic spines enables cellular processes such as long-term potentiation (LTP). We hypothesized that phosphorylation of actin shortens the filaments, thereby increasing their dynamics (more free – and +-ends).
The common view is that actin binding proteins regulates the stability of actin filaments but in some species, like the slime mold *Dictyostelium,* actin phosphorylation has been shown to be used for this purpose. The tyrosine-53 residue of actin is highly conserved between species and this indicates that this phosphorylation site could have a functional role also in mammals. We show that actin in dendritic spines is dynamically phosphorylated at tyrosine-53 in rat hippocampal neurons.
We did fEPSP (field excitatory post-synaptic potential) recordings, induced LTP in the CA1 of acute rat hippocampal slices and used western blot to study the amount of phosphorylated actin here. The CA1 was frozen 35min after LTP induction and a pY53 (phosphotyrosine-53) specific antibody was used to show a significant increase (2.3 fold) in the amount of phosphorylated actin when compared to control slices. This shows that phosphorylation of actin occurs during LTP, probably to increase the dynamics of the actin filaments and enable the structural changes of the spine head needed for LTP formation.
To study the functional role of actin phosphorylation in LTP we expressed actin constructs modified either to mimic pY53 actin (Y53E, Tyr replaced with Glu) or to be unsuitable for phosphorylation (Y53A, Tyr replaced with Ala) and for control we used wildtype actin (wt). The constructs were conjugated with GFP to enable detection of expression. We used in vivo lenti-virus injections (under isoflurane anesthesia) during P1-4 (postnatal day) to perform transduction of the constructs. After P14 we did fEPSP recordings in CA1 and compared the size of LTP in slices expressing the different actins. Expression of the pY53 actin mimicking actin reduced the size of LTP as compared with wt and Y52A expression (22±4%, n=11 vs. 37±4%, n=22).
The conclusion is that actin is phosphorylated at tyrosine 53 during expression of LTP and that this mechanism is obstructed by the expression of pY53 mimicking actin. The idea is that if many actin filaments already are very short and dynamic, due to Y53E expression, there is a reduced number of filaments that can increase their dynamics and re-arrange as a response to the LTP induction protocol. What kinases/phosphatases that are involved in regulating actin phosphorylation is still unknown.

Title: The temporal crosstalk of NMDARs and matrix metalloproteases activity determines the magnitude of EPSP-to-spike potentiation and c-Fos expression in the CA1 hippocampal region

Authors: P. BRZDAK[1,2], J. W. MOZRZYMAS[1,2], *T. WOJTOWICZ[1];
[1]Lab.Neuroscience, Wroclaw Med. Univ., Wroclaw, Poland; [2]Lab. of Cell. Neurobiology, Dept. of Animal Mol. Physiol., Wroclaw Univ., Wroclaw, Poland

Abstract: Matrix metalloproteases (MMP) activity supports reorganization of extracellular matrix, synaptic plasticity, learning and memory. However, the functional and molecular mechanisms remain largely unknown. Recently, MMP-3 was shown to cleave NR1 subunit of NMDARs and was upregulated following hippocampus-dependent learning. NMDARs are calcium permeable channels that are necessary for induction of long-term EPSP-to-spike (E-S) potentiation and synthesis of pro-plasticity proteins via upregulation of gene expression. We hypothesized that MMP-3 activity might affect NMDAR function and downstream signaling cascades involved in neuronal plasticity but this issue has not been addressed before. We thus started with description of the temporal requirement for MMP-3 and NMDARs activity on the magnitude of E-S plasticity in CA1 hippocampal region in acute brain slices of C57BL6 adult mice. We found that E-S potentiation following high frequency stimulation (HFS, 4x100Hz, field-potentials technique) was significantly reduced when NMDAR antagonist APV (50μM) or MMP-3 inhibitor NNGH (10μM) was applied before or up to 15-30 minutes post HFS. We next analyzed immediate early gene product cFos protein expression in fixed sections of recorded slices. We found that NNGH and APV effects on E-S potentiation were temporally matched with expression of immediate early gene product cFos in CA1 pyramidal neurons. Next we asked whether exogenous recombinant MMP-3 alters NMDARs function in two models: NMDAR-mediated local field potentials evoked with glutamate puffs in acute brain slices (glutamate and D-serine in the presence of DNQX and nifedipine) and NMDA-evoked Ca^{2+} waves in cultured hippocampal neurons (measured with Fura2 Ca^{2+} indicator). We found that exogenous MMP-3 enhanced somatodendritic Ca^{2+} waves following multiple exposure to NMDA (15-20 min) in vitro and dendritic glutamate-evoked NMDAR-mediated field potentials. In conclusion, MMP-3 may modulate NMDARs function, postsynaptic Ca^{2+} entry and gene expression but this process

is time-locked vs. episode of enhanced neuronal activity. Our study also provides a new insight into mechanism of MMP-dependent hippocampal neuronal plasticity, learning and memory.

Title: Post-synaptic calcium signaling and plasticity: role of intracellular stores

Authors: ***G. MAHAJAN**, S. NADKARNI;
Biol., IISER, Pune, Pune, India

Abstract: A transient rise in calcium in the postsynaptic dendritic spine is a necessary trigger for activity-dependent synaptic potentiation/depression seen in a variety of stimulation protocols. Models for NMDAR-dependent long-term potentiation (LTP), including those for spike-timing-dependent plasticity (STDP), have traditionally attempted to link the direction and magnitude of synaptic change to the peak of the calcium elevation, or, more generally, to the time course of the calcium signal (calcium control hypothesis). In these models, NMDA-gated and voltage-gated channels provide the only sources of calcium entry into the cell. However, calcium stores in the sarco-endoplasmic reticulum (SER) can also potentially contribute to the calcium dynamics in dendrites and spines. We study how the release of calcium from intracellular stores via multiple pathways can modulate the calcium signal elicited by pre and post synaptic activation in different scenarios that span a broad range of timescales. There is growing experimental evidence implicating a role for SER calcium channels such as those coupled to ryanodine and IP3 receptors in regulation of diverse forms of plasticity. Using a computational model of a hippocampal neuron that incorporates considerable level of biophysical detail, we attempt to quantify the influence that presence of the ER machinery can have on dendritic membrane and calcium dynamics, and in turn, on the downstream signalling networks involved in LTP/LTD induction. Such an understanding will contribute to a more complete mechanistic picture of spine maintenance and plasticity. Our work should also help to better characterize how familial Alzheimer's disease-linked mutations in presenilin, a protein known to regulate calcium release from the ER, could disrupt synaptic function on the post-synaptic side.

Ctr., Greenwood, SC

Abstract: Learning depends on experience-dependent modification of synaptic efficacy and neuronal connectivity in the brain. Recycling endosomes play an essential role in regulating activity-dependent synaptic strengthening and spine morphogenesis at glutamatergic synapses *in vitro,* but the underlying molecular mechanisms involved and their role *in vivo* remains unclear. Here we provide direct evidence for physiological roles of the recycling endosome protein GRASP1 in glutamatergic synapse function and behavior. Mice lacking GRASP1 showed abnormal excitatory synapse number and synaptic plasticity. Moreover, learning-induced synaptic AMPA receptor incorporation as well as multiple forms of hippocampal-dependent learning and memory were impaired in these mice. We found that GRASP1 interacted with AMPA receptors and was recruited to synapses in an activity-dependent manner in neurons,

which may underlie experience-induced synaptic AMPA receptor delivery and synaptic strengthening necessary for subsequent learning and memory. Interestingly, we identified two GRASP1 point mutations from patients with severe intellectual disability. These GRASP1 mutations displayed altered binding to recycling endosomal proteins and impaired activity-dependent AMPA receptor recycling, suggesting a potential role for GRASP1 in the pathophysiology of human cognitive disorders.

Title: Differential roles of L-type calcium channel and NMDA receptor in early odor preference learning in mice

Authors: ***B. MUKHERJEE**[1], C. HARLEY[2], Q. YUAN[3];
[1]MEDICINE, MEMORIAL UNIVERSITY OF NEWFOUNDLAND, St John's, NL, Canada;
[2]Psychology, [3]Medicine-Biomedical Sci., Mem. Univ. of Newfoundland, St. John's, NL, Canada

Abstract: Calcium as a 2nd messenger is critical in transmitting synaptic signals to the nucleus of the neuron to initiate gene transcription required for long-term memory. Voltage-gated calcium channels such as L-type calcium channels (LTCC) and NMDA receptors (NMDARs) serve as the principle sites for calcium entry on the membrane. NMDARs permit calcium entry at the synaptic site upon coincident presynaptic activity and postsynaptic depolarization, while LTCCs have an important role in translating cytosolic calcium increases to nucleus gene expression. Using early odor preference learning in mice as a model system, we study how LTCCs and NMDARs interact to promote memory formation. Early odor preference learning is induced by pairing a novel odor with a tactile stimulation (e.g. stroking a pup with a brush). We focus on the anterior piriform cortex (aPC) which has been previously identified as a primary site for early odor preference learning. Using calcium imaging in aPC slices of postnatal 8-10 mice, we show that LTCC activation is dependent on NMDAR activation. Either D-APV (NMDAR antagonist) or nifedipine (LTCC antagonist) reduced somatic calcium transients in pyramidal cells evoked

by lateral olfactory tract (LOT) stimulation. However, nifedipine application did not result in further reduction of calcium in the presence of D-APV, while activating LTCCs directly with BayK-8644 enhanced LOT evoked calcium transients in D-APV. We next show that long-term potentiation of pyramidal cell calcium transients is dependent on both NMDARs and LTCCs. Blocking either NMDARs or LTCCs prevented the long-term calcium increase that could be otherwise induced in normal aCSF. We then studied the roles of these two channels in mediating early odor preference learning and AMPA receptor (AMPAR) trafficking to the synaptic membrane. Blocking NMDARs in the aPC prevented short-term (3h) and long-term (24h) odor preference memory, and both memories were rescued when BayK-8644 was co-infused with D-APV. Blocking LTCCs only prevented 24h memory and spared 3h memory. Synaptic AMPAR expression at 3h was elevated in the vehicle infused learning group, as well as the nifedipine group and the D-APV+BayK-8644 group. However, it was no longer elevated in the nifedipine group at 24h. The patterns of AMPAR membrane expression mirror behavioral outputs at both 3h and 24h, suggesting AMPAR insertion is critical for both 3h and 24h memories. These results suggest LTCC is not necessary for short-term odor preference memory which has been shown to be protein-synthesis independent. Further experiments will focus on the input-specificity of odor preference memory induced by NMDAR and LTCC activation.

Title: High fat diet impairs synaptic plasticity by palmitoylation and reduces trafficking of AMPA receptor GluR1 subunit

Authors: ***M. SPINELLI**, S. FUSCO, M. MAINARDI, F. SCALA, A. MATTERA, M. D'ASCENZO, C. RIPOLI, D. D. LI PUMA, C. GRASSI;
Human Physiol., Catholic Univ. of the Sacred Heart, Roma, Italy

Abstract: High-fat diet (HFD) causes metabolic alterations including dyslipidemia and insulin resistance, and impacts on hippocampal synaptic transmission and plasticity through still poorly understood molecular mechanisms. In hippocampi of mice fed with HFD for 6 weeks we found increased levels of palmitic acid and reduced long-term potentiation (LTP) at CA3-CA1 synapses (SD= 186.2 ± 19.9, HFD= 123.6 ± 8.1; n=9 for each group; $p<0.05$). Palmitic acid is the substrate for a post-translational modification called palmitoylation, that regulates trafficking and signaling pathways of many proteins involved in synaptic function. To test whether the effect of HFD on synaptic function is mediated by an altered palmitoylation of synaptic proteins, we analyzed the palmitoylation of both NMDA and AMPA receptor (AMPAR) subunits in the hippocampus of HFD-fed mice. HFD specifically increased the palmitoylation of AMPAR subunit GluR1 (+30% ± 1; n=5; $p<0.05$), that is the main effector of LTP, and reduced its phosphorylation at serine 845 (pGluR1-S845) (-35% ± 1; n=4; $p<0.05$). To deep investigate the molecular mechanism underlying the diet-dependent change of GluR1 palmitoylation we performed an *in vitro* model resembling the *in vivo* metabolic stress. Mouse hippocampal neurons treated for 24h with (20 nM) insulin and (200 μM) palmitic acid (IPA) showed: i) an alteration of GluR1 palmitoylation/S845 phosphorylation balance; ii) reduced GluR1 trafficking to the plasma membrane and lower binding with PSD-95; iii) the loss of GluR1 activation upon a chemical LTP protocol. Accordingly, autaptic hippocampal neurons exposed to IPA showed a significant reduction in amplitude of AMPAR evoked post-synaptic currents (-45% ± 1 of controls; n=20; $p<0.001$). Moreover, GluR1/PSD-95 interaction was inhibited by IPA treatment (-70% ± 2 of controls; n=4; $p<0.01$). Finally, a complete rescue of both GluR1 palmitoylation and LTP impairment was observed in organotypic brain slices exposed to the competitive inhibitor of palmitic acid, 2-bromo palmitate (5 μM for 24 h). Collectively, our data indicate that IPA affects synaptic plasticity altering both palmitoylation and trafficking of GluR1. Our findings reveal a novel molecular mechanism underlying the diet-related synaptic dysfunction.

Title: Conditional deletion of LRRTM proteins impairs long term potentiation (LTP) in hippocampal CA1 pyramidal neurons in adult mice

Authors: *M. BHOURI[1], T. J. SIDDIQUI[2,3], P. TEMKIN[1], W. MORISHITA[1], D. GOSWAMI[1], S. BOTELHO[4], T. C. SUDHOF[4], A. CRAIG[5], R. C. MALENKA[1];

Abstract: Leucine-rich repeat transmembrane (LRRTM) proteins are postsynaptic cell adhesion molecules. Like neuroligins, LRRTM proteins bind to presynaptic neurexins and form transynaptic adhesion complexes. LRRTM proteins regulate synapse formation *in vitro* and appear to influence synaptic function *in vivo*. Indeed, double knockdown (DKD) of LRRTM 1 and 2 strongly impairs LTP at both neonatal and mature Schaffer collateral-CA1 (SC-CA1) synapses but their detailed role in synaptic plasticity remains unclear.
Here we used viral-mediated knockout (KO) of LRRTM proteins *in vivo* to examine their role in long-term potentiation (LTP) and basal synaptic transmission. We performed stereotaxic injections of lentivirus expressing Cre recombinase fused to GFP in floxed LRRTM1 and floxed LRRTM2 conditional knockout (KO) mice at P21 to delete LRRTM 1 alone, LRRTM 2 alone or both LRRTM1 and 2 in CA1 pyramidal neurons. Acute hippocampal slices from these animals were prepared 10-15 days later and whole-cell recordings from CA1 pyramidal neurons were made to record excitatory postsynaptic currents (EPSCs) evoked by electrical stimulation of SCs. We find that LTP is strongly impaired in LRRTM 1 KO, LRRTM 2 KO and in LRRTM 1-2 double KO (DKO) CA1 neurons. Overexpression of LRRTM 2 alone is sufficient to restore LTP in LRRTM 2 KO and LRRTM 1/2 DKO CA1 neurons. Assays of basal synaptic transmission (i.e. AMPAR/NMDAR ratios, paired-pulse ratios, miniature EPSCs) revealed that LRRTM1/2 KO had no detectable effects on basal synaptic responses. Molecular replacement experiments using mutant forms of recombinant LRRTM2 are on-going to test the hypothesis that LRRTMs are required for the maintenance of the increased number of synaptic AMPA receptors following the induction of LTP.

Title: Dehydration lowers the threshold for CREB phosphorylation in mouse hippocampus

Authors: A. VASHISHT[1], M. MORYKWAS[1], *A. N. HEGDE[2], L. ARGENTA[1], M. MCGEE[1]; [1]Wake Forest Univ. Sch. of Med., Winston Salem, NC; [2]Dept. of Biol. & Env. Sci., Georgia Col. and State Uni, Milledgeville, GA

Abstract: Local dehydration ex-vivo was previously shown in mouse hippocampal slices to impair synaptic plasticity by preventing late-phase long-term potentiation (L-LTP) induction. There was also an increase in basal synaptic transmission upon dehydration indicating hyperexcitability of neurons. In addition, during subthreshold stimulation of L-LTP, the levels of phosphorylated cAMP response element-binding protein (pCREB) increased upon proteasome inhibition by β-lactone. Here, we examined the effect of dehydration on modulation of CREB phosphorylation by subthreshold stimulation. Controlled dehydration was achieved with inert non penetrating polymers either PEG (Polyethylene glycol-8000) or Dextran-10,000 dissolved in artificial cerebrospinal fluid (ACSF) to attain colloidosmotic pressures of 0 mmHg in control ACSF and 54 mmHg, 101 mmHg, and 196 mmHg with PEG and 109 mmHg with Dextran. This pressure range amounts to <5% of plasma osmotic pressure (~5800 mmHg).
Electrophysiological recordings were performed at 32°C. Basal synaptic responses were measured upon incremental stimuli (10-35V) at each bath pressure. To investigate the effect of dehydration on CREB phosphorylation, hippocampal slices were equilibrated at a colloid osmotic pressure of 196 mmHg for 30 min. Slices in ACSF were used as control. Thereafter, subthreshold stimulation for L-LTP induction was given as two 100-Hz trains spaced 5 min apart. Slices were fixed within 1 min, stained with anti-pCREB (Ser-133) antibody and quantified in confocal images using Image J software. For proteasome inhibition, slices were treated with β-lactone (25 μM) in both control and dehydrated slices. Experiments were reproduced in at least 6 mice.
Basal synaptic transmission increased in proportion to dehydration and the effect was reversible and independent of the polymer used to control hydration. After subthreshold stimulation, CREB phosphorylation increased in dehydrated slices but not in control slices. Upon proteasome inhibition, pCREB levels increased in both non-dehydrated and dehydrated slices to similar levels. These results indicate that dehydration, like proteasome inhibition, also increases CREB phosphorylation. This increase may be related to the observed hyperexcitability of neurons and the consequent impairment of synaptic plasticity.

Title: Cadherins mediate cocaine-induced synaptic plasticity and behavioral conditioning.

Authors: ***A. K. GLOBA**[1], F. MILLS[1], S. LIU[3], C. M. COWAN[1], A. G. PHILLIPS[2], S. L. BORGLAND[3], S. X. BAMJI[1];

Abstract: Variations in cadherin-catenin adhesion complex genes are associated with multivariate drug use, however the role of these proteins in drug-mediated synaptic plasticity has not been defined. Here we demonstrate that classical cadherins N-cadherin, R-cadherin, and cadherins -7, -8, and -11 are expressed in dopaminergic (DA) and non-dopaminergic neurons of the VTA and that N-cadherin is localized to both excitatory and inhibitory synapses being formed onto these DA neurons. Inhibiting intercellular N-cadherin interactions abolished spike-timing dependent plasticity in the VTA, indicating that cadherins are important mediators of synapse plasticity in this region. Using immuno electron microscopy we demonstrate that following cocaine-mediated conditioned place preference (CPP), cadherin and GluA1 are significantly recruited to the synaptic membrane of excitatory synapses being formed onto dopaminergic neurons. This is reversed following extinction of CPP. Moreover, stabilizing cadherin at the membrane using a transgenic mouse model significantly attenuates cocaine-mediated CPP and spike-timing dependent plasticity. These results show that cadherins play an important role in synaptic plasticity in the VTA and may be involved in structural changes at synapses caused by cocaine use.

Title: Molecular mechanisms underlying the effects of unilateral anodal transcranial direct current stimulation (tDCS) on synaptic function in the mouse hippocampus

Authors: *M. V. PODDA[1], S. COCCO[1], G. LIVRIZZI[1], S. A. BARBATI[1], C. COLUSSI[2], S. FUSCO[1], L. LEONE[1], C. RIPOLI[1], C. GRASSI[1];

Abstract: Transcranial direct current stimulation (tDCS) has been reported to enhance cognitive and motor performances in healthy subjects as well as in patients suffering from neuropsychiatric diseases. As such the molecular mechanisms underlying tDCS effects are being increasingly investigated. We recently demonstrated that a single 20-min anodal tDCS session induced long-lasting enhancement of long-term potentiation (LTP) at hippocampal CA3-CA1 synapses and improved hippocampal-dependent spatial and working memory through a mechanism involving epigenetic regulation of Bdnf gene expression (Podda et al., 2016). Here we further investigated the early molecular events triggered by anodal tDCS leading to enhanced synaptic plasticity in the hippocampus. To this aim we evaluated the involvement of Ca^{2+}-activated pathways given that increased intracellular Ca^{2+} levels likely occur following anodal tDCS-induced neuronal depolarization. We found that 3 h after stimulation, hippocampi from tDCS-mice showed increased CaMKII phosphorylation at Thr286 compared to sham-stimulated controls, as revealed by Western immunoblot analyses (+102% *vs.* controls; $P<0.05$). Additionally, immunoprecipitation assays revealed that S-nitrosylation of the histone deacetylase 2 (HDAC2) was increased in tDCS-mice compared to controls (+450%; $P<0.05$), suggesting that HDAC2 inhibition contributes to the enhanced acetylation of the Bdnf promoter we observed following tDCS. These data suggest that transient increases in intracellular Ca^{2+} levels by tDCS initiate molecular cascades leading to long-lasting chromatin remodeling of Bdnf gene. We also further investigated the molecular pathways downstream of Bdnf/TrkB signaling activated by tDCS,

focusing on glycogen synthase kinase-3β (GSK-3β). We found that anodal tDCS enhanced GSK-3β phosphorylation at Ser-9 (+155%; $P<0.005$) that inhibits the enzyme activity. Interestingly, reduced GSK-3β activity is known to enhance LTP and modulate neuronal excitability in the hippocampus. Of note, patch-clamp recordings showed that the number of action potentials elicited by depolarizing current injection (150 pA) was significantly increased in hippocampal slices obtained from tDCS-mice compared to control slices (10.4 ± 1.1 *vs.* 6.8 ± 1.0 in controls; $P<0.05$). Collectively, our findings provide further insights into the mechanisms underlying tDCS effects on synaptic function, that ground the use of tDCS for improving brain functions under physiological and pathological conditions.

Title: Chronic caffeine exposure disrupts hippocampal LTP induction but not its duration in freely behaving rats.

Authors: *J. H. BLAISE[1], J. E. PARK[2], N. J. BELLAS[3], T. M. GITCHELL[4], V. PHAN[4]; [1]Engin., [2]Biol., [3]Chem., [4]Neurosci., Trinity Col., Hartford, CT

Abstract: Caffeine is one of the most widely consumed psychoactive stimulants in the world. Its effects on neurological functions, such as increases in alertness and improvements in motor skills, have promoted its use throughout history. Although there have been many studies of the short-term cognitive benefits of caffeine intake, its long term effects have been widely debated. Despite this, it is estimated that nearly 60% of American adults consume caffeine on a daily basis, resulting in annual spending of $40 billion. In this study we examined the effects of chronic caffeine exposure on long term potentiation, a cellular model of learning and memory. Caffeine water (1.0g/L) was administered to 10-17 week-old rats at least three weeks prior to experimentation, after which these rats underwent stereotaxic surgery to chronically implant a stimulating electrode in the perforant path—a major hippocampal multimodal sensory input pathway—and a recording electrode in the dentate gyrus—the first branch of the hippocampal tri-synaptic circuit. This allowed for reliable evoked field potentials to be recorded in the dentate

gyrus and quantified by computer analysis. Following a one-week postsurgical recovery period, LTP was induced in the dentate gyrus using a standard burst tetanization protocol (100-pulse, 5-Hz theta-burst stimulation, TBS) applied to the perforant path. All experimental protocols were performed according to the United States Public Health Service's Guide for the Care and Use of Laboratory Animals and were approved by Trinity College Institutional Animal Care & Use Committee. After at least 5-7 days of post-surgical recovery, population spike amplitude measures of LTP induction were acquired in freely behaving rats using electrophysiological recording techniques. Our results indicate that rats that were exposed to caffeine (n =14) show a statistically significant ($p < 0.05$) lower level of LTP induction compared to controls (n =15). However, no statistically significant differences were found in the duration or persistence of LTP, suggesting that caffeine disrupts LTP induction but not its duration. More studies are needed to determine the exact mechanism through which caffeine alters LTP induction.

Title: A computational model of astrocyte induced modulation of synaptic plasticity and normalization

Authors: O. V. SREERAG[1], R. PHILLIPS[1], S. CHAKRAVARTHY[1], *M. SUR[2];
[1]IIT Madras, Chennai, India; [2]Dept. of Brain and Cognitive Sci., Picower Inst. for Learning and Memory, MIT, Cambridge, MA

Abstract: It has been suggested that perisynaptic astrocytic processes have a role in synaptic plasticity. Here we propose a simple model for astrocytic modulation of synaptic plasticity. The model consists of presynaptic, postsynaptic and astrocyte compartments of the tripartite synapse. Presynaptic activation initiates neurotransmitter release into the synaptic cleft. This neurotransmitter binds with NMDA receptors leading to calcium influx into the postsynaptic compartment. However, NMDAR opening is also contingent upon postsynaptic potential-

dependent magnesium blockage. The postsynaptic compartment is influenced by both the presynaptic compartment and astrocytic processes. Astrocytes release gliotransmitters including D-serine and glutamate, which in turn regulate the synaptic neurotransmitter concentration and influence the postsynaptic calcium concentration. Following the 'calcium control hypothesis,' we assume that the postsynaptic calcium controls the "synaptic strength", w, which corresponds to the strength of response of AMPA receptors to synaptic glutamate. This synaptic strength is modelled by a cubic nonlinearity exhibiting bistable dynamics.
The proposed model is comprised of a presynaptic variable (firing rate) and postsynaptic voltage (controlled by an external current), which are independently varied to display LTD and LTP. Interestingly, the model exhibits BCM-like dynamics wherein the plasticity switches from LTD to LTP at a threshold value of postsynaptic voltage. A key feature of the model is that this threshold voltage is modulated by gliotransmitter released by the astrocyte. We next simulate weight dynamics at two synapses supplied by the same astrocyte such that that the total gliotransmitter released to the two synapses is conserved. Simulations showed a mechanism of normalization of the two synaptic weights in that growth in one synapses is accompanied by attenuation in the other.
In summary, the model demonstrates: (1) astrocyte induced modulation in LTD to LTP threshold, and (2) weight normalization of multiple synapses controlled via astrocytic gliotransmitter release.

Title: Unveiling neuronal differences in chloride extrusion capacity

Authors: F. FERRINI[1], L.-E. LORENZO[2], M. COTTET[2], A. GODIN[3], N. DOYON[2], *Y. DE KONINCK[4];
[1]Univ. or Turin, Turin, Italy; [2]Laval Univ., Quebec, QC, Canada; [3]Univ. of Bordeaux, Bordeaux, France; [4]Cell. & Mol. Neurobio., Laval Univ. / IUSMQ, Quebec, QC, Canada

Abstract: The strength of synaptic inhibition in the adult neurons relies on their capacity to maintain intracellular chloride (Cl^-) concentration, and the main regulator of intracellular Cl^- concentration is the K^+-Cl^- co-transporter 2 (KCC2). As KCC2 function is not homogenous across the CNS, these differences may significantly affect the integration of inhibitory inputs. Here we combined different approaches to explore the impact of variable Cl^- extrusion capacities in nociceptive neurons of the superficial spinal dorsal horn, which includes projections neurons in lamina I and interneurons in lamina II. By imposing a Cl^- load, E_{GABA} recorded in lamina I was more depolarized than in lamina II, indicating a weaker Cl^- extrusion capacity in the former. Notably, we did not observe any difference when E_{GABA} was measured under low chloride conditions (including by gramicidin-perforate patch clamp), suggesting that a Cl^- load is required to detect apparently subtle differences. These data were replicated by performing Cl^- imaging in MQAE-loaded spinal cord slices. Indeed, when synaptic activity was completely blocked, no interlaminar differences in Cl^- concentration were detected in dorsal horn, conversely in presence of normal synaptic activity a clear gradient in Cl^- concentration was observed. The gradient was further increased by enhancing synaptic activity with capsaicin. We confirmed that the lower Cl^- extrusion capacity in lamina I neurons affects synaptic inhibition in an activity dependent manner by stimulating high frequency inhibitory activity. These experiments showed that under sustained inhibitory input, lamina I neurons accumulate Cl^- faster than lamina II. Functional experiments were mirrored by immunohistochemical analysis of KCC2 expression which confirmed a lower level of KCC2 in lamina I under the control of TrkB receptor signaling. Following nerve injury, KCC2 expression strongly decreased in both laminae, but still KCC2 in lamina I was the lowest. Our computer simulation indicated that such a low KCC2 level in lamina I of nerve injured rats fails to maintain Cl^- gradient when synaptic activity increases. Thus, constitutive differences of KCC2 activity has a strong impact on the efficiency of enhanced inhibition under both normal and pathological settings.

Title: Vanilline protects the hippocampal neuronal function from age-related deterioration

Authors: *K. ITO, S. TANIGUCHI, M. HANAFUSA, H. TSUBONE, D. YAMANAKA, M. KUWAHARA;
Univ. Tokyo, Tokyo, Japan

Abstract: Vanillin (4-hydroxy-3-methoxybenzaldehyde) belongs to the vanilloids and is widely used as an additive in food or cosmetic as a constituent of vanilla flavor. Recently, vanillin is reported to play a role in antioxidative events and antiaging. However, the effect of vanillin on age-related synaptic dysfunction is unknown so far. In this study, we investigated the chronic and acute effect of vanillin on the hippocampal Schaffer collateral - CA1 synapses using old C57BL/6J (52-weeks old). We randomly assigned the mice for the vanillin-supplemented group and the control group, and allowed them to access freely to tap water for control group and tap water including 0.17% vanillin for vanillin-supplemented group for 4 weeks, respectively. First, we recorded the field excitatory postsynaptic potential (fEPSP) slope of the vanillin-supplemented mice. The slopes of fEPSPs of vanillin-supplemented group were significantly larger than those of control group. However, we could not find the difference in the paired-pulse ratio, the representative of the short-term plasticity, between these groups. Then, we checked the long-term synaptic plasticity by determining the long-term potentiation (LTP). The degree of LTP in vanillin-supplemented group was comparable with the control group. We tested the effect of vanillin supplementation with behavioral test. Morris water maze test and Y-maze test showed that there were no significant differences in spatial memory between these groups. Next, we tested the acute effect of vanillin for the synaptic transmission and plasticity as vanillin is reported to cross the blood-brain barrier. Bath application of vanillin (1 mM) increased the slope of fEPSPs. In the same way, the degree of LTP increased under vanillin perfusion. Moreover, we conducted the biological antioxidant potential (BAP) assay for evaluation of reduction capacity which restores the oxidative level elevated in old animals. However, the BAP level in vanillin-supplemented group was comparable with that of control group. These results indicate that vanillin supplementation does not restore the age-related impairment of recognition or synaptic plasticity but it augments the synaptic transmission independently of reduction capacity. Our data about vanillin in this study is expected for improvement of neuronal function in the old animals in which the synaptic dysfunction progresses age-dependently.

Title: Acetyl-L-carnitine improves age-dependent impairment of LTP of the senescence-accelerated mouse prone 8

Authors: *S. TANIGUCHI, H. TAKIMOTO, M. HANAFUSA, H. TSUBONE, D. YAMANAKA, M. KUWAHARA, K. ITO;
Univ. of Tokyo, Tokyo, Japan

Abstract: Acetyl-L-carnitine (ALCAR) is an acetyl moiety of carnitine. The concentration of ALCAR and carnitine declines with age in skeletal muscle, cerebral cortex and hippocampus. Recently, it is reported that external addition of ALCAR improves cognitive impairment in old animals. However, little is known about the effect of ALCAR on synaptic functions in aged animals. In this study, we investigated the effect of ALCAR on the hippocampal CA1 synapses using an animal model of aging called senescence-accelerated mouse prone 8 (SAMP8) which shows not only short life-span or rapid advancement of senescence but also age-related impairments of learning and memory. We obtained the hippocampal slices from the mice and evaluated the synaptic function by filed recordings. High-frequency stimulation (HFS) evoked long-term potentiation (LTP), which is a well-established form of synaptic plasticity, in the hippocampal synapses of 6 month-old SAMR1, whereas HFS induced smaller degree of LTP in the age-matched SAMP8 synapses. However, supplementation of ALCAR (0.5 g/kg/day) for 6 weeks improved the degree of LTP in 6 month-old SAMP8 but not in SAMR1. As ALCAR is known to cross the blood-brain barrier and directly impinge on synapses, we examined the acute effect of ALCAR on LTP. Bath application of ALCAR (100 μM) did not affect the degree of LTP in 6 month-old SAMR1. On the contrary, acute application of ALCAR improved the impaired LTP of SAMP8 in a dose-dependent manner. We also investigated the effect of ALCAR with aged SAMR1, but acute application of ALCAR did not alter the degree of LTP in 2 year-old SAMR1. Furthermore, to test if ALCAR restores the elevated oxidative stress level in SAMP8, we measured the level of reactive oxygen species using reactive oxygen metabolites assay, and reduction capacity using biological antioxidant potential assay. However, these indicators revealed that ALCAR could not restore the oxidative stress level elevating in SAMP8 compared with SAMR1. These results indicate that chronic supplementation of ALCAR can improve the age-dependent impairment of long-term synaptic plasticity with the exception of the case of aged individuals, but this improvement does not require the amelioration of oxidative stress level. Although we need to study the pharmacokinetics of ALCAR in more detail, our data about ALCAR in this study is expected for prevention of age-related dysfunction of the brain including dementia.

Title: Positive modulation of GABAA receptors by allopregnanolone moderates injury-induced, but not experience-induced, potentiation in the adult visual cortex in mice

Authors: *E. G. SERGEEVA[1], C. ESPINOSA-GARCIA[1], M. T. PARDUE[2,3], D. G. STEIN[1]; [1]Emergency Med., Emory Univ., Atlanta, GA; [2]Wallace H. Coulter Dept. of Biomed. Engin., Georgia Inst. of Technol., Atlanta, GA; [3]Atlanta VA Ctr. for Visual and Neurocognitive Rehabil., Atlanta, GA

Abstract: We used selective visual stimulation to examine enhancement in visual cortical response in adult mice with unilateral optic nerve crush (ONC). To investigate the role of inhibition in the experience-dependent potentiation of visual evoked response (VEP), we administered allopregnanolone (ALLO), a positive modulator of GABAA receptors. The left optic nerves were crushed in the ONC groups, and left intact in the Sham groups. ALLO (10 mg/kg) or vehicle was injected 1 hour after ONC and then on post-injury days (dpi) 3, 8, 13, and 18. VEP to pattern stimuli were recorded before ONC (Baseline, BL) and on dpi 2, 7, 12, 17, 22 and 30. Visual spatial frequency was assessed on BL and then on dpi 2, 6, 11, 16, 21 and 29 in an optokinetic tracking system. To evaluate levels of VGlut2 and GABAAR delta subunit on dpi 30, the animals were euthanized and their brains processed for immunohistochemistry. Sham animals showed a gradual increase in responses to stimulation of the contralateral eye throughout the experiment (146±6.4% of BL; $p<0.05$). The amplitude of VEP ipsilateral to the ONC eye, induced from the contralateral, intact eye, in the ONC/Veh group was higher than in Sham animals (197±12.7% of BL; $p<0.05$). VEP amplitude increase was associated with up-regulation of VGlut2 (increased excitatory synaptic activity) and down-regulation of GABAAR delta (decreased tonic inhibition) in the left primary visual cortex, which contains projections from the intact eye. ALLO produced lasting inhibitory effects in ONC animals as shown by attenuation of VEP amplitudes on dpi 17, 22 and 30 ($p<0.0001$) as well as by down-regulated levels of VGlut2 and up-regulated levels of GABAAR delta ($p<0.05$). In Sham animals ALLO did not affect either VEP amplitudes or VGlut2 and GABAAR delta levels, demonstrating that alterations in

GABAAR-mediated inhibition exert greater effects in injury-induced than experience-dependent VEP potentiation alone. Unilateral ONC increased spatial frequency thresholds in the intact eye, and ALLO induced an even larger enhancement ($p<0.0001$). A regression analysis revealed a U-shaped relationship between VEP amplitude and visual performance (R2 change for x2=0.100, $p=0.001$). These findings indicate that an optimal level of VEP potentiation is associated with higher visual performance in animals with unilateral ONC. Together, our data suggest potential clinical applications of ALLO for modulation of injury-induced, excessive and potentially maladaptive plasticity.

Title: Neuronal activity regulates astrocyte proliferation

Authors: ***Y. CHEN**[1], C. FU[1], M. WEBER[2], H. LIN[2], H. NGU[2], J. KAMINKER[2], M. SHENG[2]; [1]IRCBC, SIOC, Chinese Acad. of Sci., Shanghai City, China; [2]Genentech Inc, South San Francisco, CA

Abstract: Astrocytes play critical roles in brain development and function, but the mechanisms that regulate astrocyte proliferation are poorly understood. We report that astrocyte proliferation is bi-directionally regulated by neuronal activity via NMDA receptor (NMDAR) signaling in neurons. Using whole genome mRNA profiling, we found that a set of cell cycle-related genes were altered by prolonged treatment of hippocampal cultures with NMDAR antagonist AP5. These cell cycle-related genes were expressed in astrocytes rather than neurons. NMDAR inhibition suppressed astrocyte proliferation *in vitro* and *in vivo*, whereas evoked neuronal activity promoted astrocyte proliferation in an NMDAR-dependent manner. Additional mechanistic studies identified Prostaglandin-endoperoxide Synthase 2 as being critical for activity-regulated astrocyte proliferation.

Title: A critical role of the E3 ubiquitin ligase IDOL in regulating synaptic strength, cortical circuit plasticity, and learning and memory

Authors: *M. MAROSI[1], J. GAO[2], C. JINKUK[2], C. PORTERA-CAILLIAU[1], P. TONTONOZ[2];
[1]UCLA Depts. of Neurol. and Neurobio., [2]Howard Hughes Med. Inst., UCLA, Los Angeles, CA

Abstract: The lipoprotein receptors like Very Low Density Lipoprotein Receptor (VLDLR), and apolipoprotein E receptor 2 (ApoER2), that bind APOE have recently been recognized as pivotal components of the neuronal signaling machinery. In addition to being receptors for ApoE, VLDLR and ApoER2 also bind the signaling protein Reelin with high affinity. The Reelin signaling pathway is essential for not only controlling neuronal positioning during brain development, but also for maintaining synaptic plasticity and enhancing learning/memory in the adult brain. Inducible Degrader of the LDL-receptor (Idol) is an E3 ubiquitin ligase that regulates cellular cholesterol levels through binding and targeting LDLR for lysosomal degradation. Here we report that Idol is highly expressed in neurons throughout the central nervous system (e.g., hippocampus, neocortex and cerebellum) where it exerts a dominant role in determining endogenous neuronal VLDLR and ApoER2 expression level. Idol knockout mice have significantly higher neuronal VLDLR and ApoER2 levels. Interestingly, Idol knockout mice showed reduced hippocampal CA1 long-term potentiation (LTP) and enhanced long-term depression (LTD), with normal synaptic transmission (53% reduction in LTP and 16% enhancement in LTD). These phenomena are associated with impaired function of learning and memory, whereby mice lacking Idol have impaired spatial learning in the Morris water maze (longer escape latency), and reduced cued fear conditioning (lower % time of freezing). To investigate the role of Idol in experience-dependent plasticity in primary somatosensory cortex, we used longitudinal optical intrinsic signal (OIS) imaging to delineate single whisker response maps in barrel cortex. Two weeks after plucking all but one of the whiskers on the contralateral snout, we found an 89 % increase in the size of the spared whisker map in young adult wild type mice. In contrast, Idol KO mice did not show an expanded map for the spared whisker. These findings demonstrated how Idol can regulate neuronal lipoprotein receptor expression and plays an important role in synaptic function, cortical plasticity, learning and memory and behavior.

Title: Activity-dependent modulation of hippocampal synaptic plasticity via PirB and endocannabinoids

Authors: *M. DJURISIC, B. K. BROTT, C. J. SHATZ;
Dept. of Biol. and Bio-X, Stanford Univ., Stanford, CA

Abstract: The threshold for Hebbian synaptic plasticity is modulated by prior patterns of activity. Endocannabinoid (eCB) signaling has been postulated to play a role in this process, but it is not well understood how prior activity engages this retrograde signaling mechanism. Here, we investigate a role for the innate immune receptor Paired Immunoglobulin-like Receptor B (PirB) in regulating use-dependent changes in LTP and LTD at CA3 to CA1 hippocampal synapses. PirB is expressed in forebrain pyramidal neurons, including hippocampus. Conditional excision of PirB (cKO) in excitatory neurons of CA3 and CA1 at P90 results in loss of synaptically induced LTD over a wide range of LTD-induction frequencies. LTP is also increased over 2 fold in cKO vs. WT at 90 min post-induction. Concomitant with the shift from LTD towards greater LTP, neurotransmitter release is also increased in cKO mice, as signaled by a change in paired-pulse ratio. Endocannabinoids are known to regulate neurotransmitter release via cannabinoid receptor type 1 (CB1R) located presynaptically; this regulation is use-dependent and modulates synaptic plasticity. In WT, blockade of CB1R with AM251 abolishes synaptically induced LTD, and also results in an enhanced LTP, thus phenocopying synaptic plasticity changes present in PirB cKO. Moreover, blockade of CB1R in cKO does not further increase the magnitude of LTP, consistent with PirB acting in the CB1R pathway. In addition to CB1R, group I mGluRs and NMDARs are all thought to be engaged in eCB-dependent signaling at adult CA3 - CA1 synapses during synaptically induced LTD. We found that NMDAR-dependent LTD induced by brief application of NMDA was also abolished in PirB cKO, while CB1R- and group I mGluR-dependent chemical LTDs were intact. Together, results suggest that PirB in

hippocampal pyramidal neurons contributes to an NMDA-dependent mechanism of endocannabinoid signaling, enabling the synapse to function across a wide range of stimulus intensities. We suggest that PirB is a part of an on-demand signaling network that dynamically regulates the threshold for Hebbian synaptic plasticity by adjusting neurotransmitter release according to prior activity.

Title: Human Neural Plasticity in a Dish

Authors: ***Y. DONG**[1], S.-C. ZHANG[2];
[1]Waisman Ctr., Univ. of Wisconsin, Madison, WI; [2]Univ. of Wisconsin-Madison, Madison, WI

Abstract: Long-term potentiation/long-term depression (LTP/LTD), inferred from analysis on the animal brain or slices, are considered the cellular processes underlying learning and memory formation. They have not so far been demonstrated in human brain or neurons and there are no model systems to assess long-term synaptic plasticity of human neurons. By expressing the light-gated cation channel, channelrhodopsin (ChR2) in human embryonic stem cell-derived cortical glutamate neurons and co-culturing them with GABA neurons, we examined synaptic plasticity in response to different regimens of stimulations. High frequency light stimulation of ChR2-expressing glutamatergic neurons increased the frequency of mEPSCs recorded in non ChR2-expressing GABA neurons, indicating a facilitating action at the presynaptic terminals. When paired with post-synaptic depolarization, it significantly increased the amplitude of light-evoked EPSC which persisted during the period, indicating LTP. In contrast, low frequency light stimulation without the pairing protocol induced LTD. These effects were blocked by NMDA receptor antagonists, suggesting that the LTP/LTD induced in human neurons are NMDA receptor dependent. Our results indicate a similar human neural plasticity. Our co-culture system may be a useful model for assessing human neural plasticity in a dish.

Title: Long-term effects of galactic cosmic radiation on neurogenesis, synaptic plasticity, learning and memory

Authors: *O. MIRY, K. R. GOPAUL, L. R. VOSE, G. SUBAH, X.-L. ZHANG, P. K. STANTON;
Cell Biol. and Anat., New York Med. Col., Valhalla, NY

Abstract: Low doses of galactic cosmic radiation (GCR), containing high atomic number and high energy (HZE) particles, have been measured and are expected during long-duration deep space missions. While research has attempted to characterize the immediate and short-term effects of GCR insults to the central nervous system, little is known about chronic, long-term sequelae which may impact cognitive function over time. In particular, given the predisposition of the hippocampus to GCR, we hypothesized that there could be chronic alterations in hippocampal adult neurogenesis, synaptic plasticity, and hippocampus-dependent learning and memory in mice following exposure to simulated GCR.
Young adult (3 month old) male and female mice received whole-body particle radiation from a ^{28}Si (300 MeV/u, 70 keV/μm) or ^{56}Fe (600 MeV/u, 180 keV/μm) source totaling 10, 50, or 100 centiGray [cGy], using the particle beam line facilities at the National Space Radiation Laboratory of Brookhaven National Laboratory, and sham irradiated mice served as controls. Effects of GCR 6-7, 12, and 20 months post ^{28}Si and ^{56}Fe exposure on synaptic plasticity were assessed by measuring the magnitude of theta-burst stimulus-induced or chemical cAMP-induced long-term potentiation (LTP) of synaptic transmission at Schaffer collateral-CA1 synapses in hippocampal slices *in vitro*.
Six, twelve, and twenty months post ^{56}Fe exposure, the magnitudes of stimulus-evoked and chemical LTP were both markedly larger in amplitude ($P < 0.05$, ANOVA). Consistent with these data, separate cohorts of ^{56}Fe-exposed mice examined 6, 12 and 20 months post-exposure exhibited faster learning acquisition in both Barnes maze and active avoidance shock platform, both hippocampus-dependent spatial memory tasks ($P < 0.05$, repeated-measures ANOVA). In contrast, stimulus-evoked, but not cAMP-induced, LTP in hippocampal slices from both male and female mice 7 months post ^{28}Si exposure was significantly smaller than sham-irradiated controls ($P < 0.05$, ANOVA). These reductions were associated with slower memory acquisition in female, but not male mice, compared to sham-irradiated controls 7 months post ^{28}Si, while

learning acquisition was faster 20 months post ^{28}Si ($P < 0.05$, repeated-measures ANOVA). Our data reveal differences in long-term cognitive effects of GCR depending upon the species of ion exposure. As advancements in technology allow for more long-term, farther reaching space explorations such as the proposed Mars swing-by, it becomes increasingly important to understand the long-term consequences of GCR exposure to critical brain functions such as learning, memory, cognition, and mood.

Br., Galveston, TX; [5]Dept. of Cell. and Mol. Med., Univ. of Ottawa, Ottawa, ON, Canada

Abstract: Mutations in the human *Large* gene result in severe intellectual disability as well as muscular dystrophy. How *Large* mutations lead to intellectual disability, however, is not clear. To address this question, we knocked *Large* gene down in the hippocampi of mice followed with behavioral and electrophysiological analyses *in vivo*. A series of learning and memory tests demonstrated that hippocampus-dependent long-term memory formation is impaired in the LARGE knockdown mice. However, their hippocampus-dependent short-term memory was intact. In the LARGE knockdown mouse, hippocampal long-term potentiation (LTP) was occluded due to the saturation of synaptic α-amino-3-hydroxy-5-methyl-4-isoxazole propionate receptors (AMPA-Rs). Consistently, our miniature excitatory postsynaptic current (mEPSC)

analyses demonstrated that LARGE downregulates synaptic targeting of the AMPA-Rs. Together, LARGE play a key role in hippocampus-dependent long-term memory formation by tuning synaptic targeting of AMPA-Rs in the hippocampus. Our study provides novel insights into the pathophysiology of intellectual disabilities in patients with muscular dystrophy.

Title: Hippocampal-prefrontal oscillations and synaptic plasticity in adult rats with early-life status epileptics

Authors: ***R. N. RUGGIERO**, D. B. MARQUES, L. S. BUENO-JUNIOR, C. LOPES-AGUIAR, J. B. DE ROSS, M. T. ROSSIGNOLI, L. KANDRATAVICIUS, J. P. LEITE; Univ. of São Paulo, Ribeirao Preto, Brazil

Abstract: Early-life seizures are frequent and associated with cognitive and psychiatric impairments later in life. We hypothesized that these behaviorally subtle dysfunctions could manifest as connectivity alterations between hippocampal CA1 and prefrontal cortex (PFC) since they are pathologically involved in the psychiatric comorbidities of adult limbic epilepsy. Thus, we induced a two-hour status epilepticus (SE) through lithium-pilocarpine in P12 rats. Once adults, they were tested for spatial working memory (radial arm maze), exploratory behavior (open field), and sensorimotor gating (prepulse inhibition of the acoustic startle, PPI). They were finally submitted to an acute electrophysiological session, with PFC field responses being recorded upon electrical pulses into CA1, both before (30 min) and after (240 min) CA1 high-frequency stimulation (HFS). Our results show that SE rats had worse radial arm maze performance, hyperlocomotion on the open field, PPI deficits, and an interestingly stronger long-term potentiation after HFS. Of note, no spontaneous seizures occurred throughout the experiment, and no changes in neuronal density were detected with NeuN immunohistochemistry. In a second experiment, adult rats with early-life SE were chronically implanted with microwire bundles into CA1 and PFC for the recording of local field potentials

and single-unit activity during a 24 h free-behavior session. Neurophysiological states were separated into active awake, resting awake, slow wave sleep and rapid eye movement sleep based on electromyogram and hippocampal theta power (4-8 Hz). Ongoing analyses compare SE and controls according to the sleep architecture, as well as hippocampal-prefrontal spectral density/coherence and cross-frequency coupling. We expect these analyses to detail the plasticity scenario outlined in the first experiment, which: (1) indicates long lasting CA1-PFC alterations independent of neuronal loss or recurrent seizures, and therefore (2) reveals unapparent neurophysiological dysfunctions in adult rats with early-life SE.

Title: NF-kappa B activation during appetitive and aversive long-term memory consolidation in the inhibitory avoidance paradigm in mice

Authors: *A. SALLES[1], M. KRAWCZYK[2], M. BOCCIA[2], M. BLAKE[2], A. ROMANO[1], R. FREUDENTHAL[1];
[1]Lab. de Neurobiologia de la memoria, IFIBYNE, CONICET, Buenos Aires, Argentina; [2]Dto. Farmacología, FFyB, UBA, Buenos Aires, Argentina

Abstract: NFkB is a transcription factor whose activation has been shown to be necessary for long-term memory consolidation in several species. NFkB is activated in the nucleus of cells in a specific temporal window during consolidation. Previous results showed that the transcription factor is also present at the synapse and is activated during consolidation at different time points than in the nucleus . Our work focuses on the mouse inhibitory avoidance learning paradigm. In

this paradigm mice are placed on an illuminated platform with an entrance to a dark compartment; the experimental group receives an electric shock when entering the dark compartment. Delay on entering the compartment is evaluated 48hrs later. The behavioral control group consists of mice who experience the same context as the experimental group but do not receive an electric shock; 48hrs later this group of mice do not show a delay to enter the compartment. Nonetheless when analyzing the activation of NFkB we found that this group of mice has elevated activation when comparing to naïve. Furthermore, animals who receive a shock without being exposed to the platform show no delay in entering the dark compartment 48hrs post training and no activation of NFkB. We argue that the mice who don't receive the shock might perceive it as a relief (an appetitive learning situation), where they associate the context with a safe place and that this information may not be discriminated by the hippocampus. This appetitive memory can be impaired with an NFkB inhibitor (Sulfasalazine) injected directly into the hippocampus. Moreover we explore the role of the amygdala in this paradigm for both the appetitive and aversive situations. This work aims to discuss these results and further investigate how appetitive and aversive memories are consolidated.

Abstract: Repeated pairing of a movement or a sensory event with vagus nerve stimulation (VNS) can reorganize cortical maps. Repeatedly pairing a tone with a brief period of VNS increases the proportion of primary auditory cortex (A1) responding to the paired tone (Engineer et al., 2011). We predicted that in addition to A1, VNS would reorganize posterior auditory field (PAF), anterior auditory field (AAF), and inferior colliculus (IC). Microelectrode maps were constructed from ten rats that had received VNS stimulation paired with a tone 300 times per day for 20 days, and 10 experimentally naïve control rats. In rats that received VNS tone pairing, a

significantly greater number of cortical neurons were tuned to frequencies near the paired tone frequency in A1, PAF, and IC compared to control rats. VNS paired rats had significantly fewer neurons tuned to the same range in AAF. This is the first study to show that VNS directed plasticity differentially alters different auditory cortex fields.

Title: Dystonia-causing mutation in the Tor1a gene does not change the number or ratio of presynaptically silent synapses of central neurons

Authors: ***N. C. HARATA**, H. KAWANO, S. IWABUCHI, Y. KAKAZU;
Dept Mol Physiol & Biophys, Univ. of Iowa, Iowa City, IA

Abstract: Dystonia is a hyperkinetic movement disorder and is characterized by sustained or intermittent muscle contractions that cause abnormal movements or postures. Patients with dystonia are subject to atypical neuronal functions in the brain, in the absence of neurodegeneration. Thus, it is generally thought that one of the main pathophysiological causes is abnormal synaptic transmission. However, it remains unclear whether dystonia is associated with an imbalance between excitatory glutamatergic and inhibitory GABAergic neurotransmitter systems. Here we report on a study testing whether the numbers of these synapses are affected in the context of dystonia. Specifically, we prepared primary cultures of hippocampal neurons from a knock-in mouse model of DYT1 dystonia, the most common form of inherited dystonia. The data obtained from heterozygous neurons were compared with those from wild-type counterparts. We evaluated the numbers of morphologically identified synapses on dendrites by

immunocytochemistry, using the glutamatergic presynaptic marker vesicular glutamate transporter 1 (VGLUT1), the GABAergic presynaptic marker vesicular GABA transporter (VGAT), and the dendritic marker microtubule-associated protein 2 (MAP2). We also evaluated the synapses for functionality by labeling nerve terminals with a marker of recycling synaptic vesicles (FM1-43). The non-recycling (non-functional) synapses are defined as presynaptically silent, and the fraction of them among the morphologically identified synapses (both functional and non-functional) has been shown to change in response to changes in neuronal network activity, in the hippocampus and cerebral cortex of wild-type animals. Comparison of the mutant neurons to wild-type controls revealed no difference in the numbers of morphologically identified glutamatergic or GABAergic synapses, or in the ratios of glutamatergic vs. GABAergic synapses in each imaged field. Moreover, the fractions of presynaptically silent synapses did not differ, for either glutamatergic or GABAergic systems. Our results demonstrate a lack of change in the fundamental parameters that define the balance between synaptic excitation and inhibition. They further indicate that potential changes in neuronal network activity might not be strong enough to induce plastic changes in presynaptically silent synapses, at least under our experimental conditions.

Title: Abnormal Retina -Specific Segregation at the dLGN of the Flailer - a myosin 5a mutant mice.

Authors: *S. PANDIAN;
McGovern Inst. for Brain Res., MIT, Cambridge, MA

Abstract: MyosinVa (MyoVA), is a widely distributed vesicular-cargo-binding actin motor known to deliver the major scaffold complex for glutamate receptors to spine synapses. In Flailer (Flr) mutant mice the cargo-binding domain of myo5a is driven by the brain specific promoter of gnb5 (Jones et al 2000). When this truncated myo5a is expressed in 1:1 ratio reproducible abnormal behaviors are seen (eg; early seizure, anxiety, repetitive whole body grooming (Pandian et al in prep). In visual cortex neurons these mice have abnormally high AMPAR

miniature current frequencies and their eAMPA/eNMDA ratio is significantly larger than in WT strain. Flr shows no LTD at the layer 4 to layer 2/3 synapses although LTP is normal (Yoshii et al 2013). In developing rodent dorsal lateral geniculate nucleus (dLGN) the ipsilateral input arrives later than the contralateral input (Godement et al., 1984) and there is a competition between the left and right eye axons (Huberman et al., 2008). We hypothesized that if the retinogeniculate pathway also lacked LTD the ipsilateral territory might be unable to terminate in its normal region because the earlier innervating projections could not undergo LTD. Here we report that when both eyes of Flr pups are differentially labeled with CTB (555, 647) they show abnormally small and displaced ipsilateral zone while the contralateral projection occupies a larger territory. Monocular enucleation before eye-specific segregation in Flr causes the contralateral projection to spread throughout the dLGN with lowest density of input in region normally occupied by the ipsilateral eye. The ipsilateral projection is abnormally large with a shift towards the medial side of the nucleus. The results are consistant with our results that NMDAR LTD is also defective in the LGN of Flr and prevents displacement of early contralateral inputs by the later arriving axons.

Title: Using CaMPARI to understand activity-dependent changes at the axon initial segment

Authors: *R. J. O'TOOLE, M. B. HOPPA;
Biol., Dartmouth Col., Hanover, NH

Abstract: The arrangement and combination of ion channels and proteins comprising the axon initial segment (AIS) define the capacity of a neuron to integrate synaptic input, set action potential threshold, and generate specific patterns and rates of firing. Research has shown that chronic depolarization or deprivation of synaptic input to neurons can lead to physical relocation or rearrangement of the AIS. This plasticity is thought to act as a homeostatic response to regulate overall neural excitability. Importantly, neurons in more physiological conditions experience less extreme changes to their synaptic input, and it is largely unknown if a similar plasticity occurs in response to functional changes in activity. In this study we examine how the AIS regulates excitability and firing patterns, and inspect how the AIS is modified by functional changes in action potential output.

Quantifying neurons across a spectrum of neural activity has posed a major technical challenge to neuroscientists. Here, we have developed a system utilizing the recently developed genetically-encoded calcium integrator, CaMPARI. This indicator undergoes a permanent shift from green to red fluorescent emission *only during the simultaneous presence of 405 nm light and neural activity*, and stands as a permanent, ratiometric marker of neural activity. Exposing primary neurons, transfected with CaMPARI, to flashes of 405 light in culture allows us to characterize the activity levels of individual neurons. Using this system, we explore how the molecular profile of the AIS is modified under physiological conditions, and whether individual neurons undergo activity-dependent changes to regulate their intrinsic excitability.

Abstract: Prefrontal circuits process input from the internal and external world and use these inputs to guide decision-making and subsequent goal-directed behavior. The ability of the medial prefrontal cortex (mPFC) to flexibly guide appropriate behaviors, including updating expectations of reward and punishment, is highly sensitive to neuromodulators such as dopamine. Therefore, cellular expression of dopamine receptors on prefrontal projection neurons will affect how dopamine can act on the prefrontal network and therefore regulate downstream behaviors.

Dopamine acts in part to regulate the activity of mPFC layer 5 (L5) principal cells via D1-family (D1/D5) or D2-family (D2/D3/D4) receptors. Recent work indicates that D1- and D2-receptors (D1R/D2R) are expressed in largely separate subclasses of L5 pyramidal cell and that these subclasses have unique electrophysiological features and projection patterns, and are modulated by dopamine via distinct mechanisms (Gee et al., 2012; Seong and Carter, 2012). How other

dopamine receptor classes are distributed in mPFC is unknown.
Here, we demonstrate that D3R-expressing (D3+) pyramidal neurons are electrophysiologically distinct from D1+ and D2+ neurons, and therefore likely represent a separate cell subclass. Further experiments reveal that though both D2R and D3R are of the same family, and are both Gi-coupled, they can have distinct roles in mPFC. First, D3Rs, but not D2Rs, act to regulate neuronal excitability by modulating calcium channels at the axon initial segment. Second, D3+ pyramidal neurons project intracortically, in contrast to the subcortically-projecting D2+ neurons (Gee et al., 2012). Thus, antipsychotic compounds with strong affinity for D2-family receptors may regulate intracortical networks via actions at the D3R.

Title: Reliable neuromodulation in variable model neurons

Authors: ***G. DRION**[1], T. O'LEARY[2], E. MARDER[3];
[1]Electrical Engin. and Computer Sci., Univ. of Liege, Liege, Belgium; [2]Univ. of Cambridge, Cambridge, United Kingdom; [3]Brandeis Univ., Waltham, MA

Abstract: Neurons and circuits are subject to significant changes in their firing activity and responsiveness to external inputs via neuromodulation (Marder, 2012). Many nervous system functions depend on reliable neuromodulation, yet the physiological properties of neurons that are targeted by neuromodulators are often highly variable (Grashow et al., 2009 ; Marder et al., 2014). In this work, we use conductance-based neuron models to investigate the mechanisms by which reliable neuromodulation can occur in populations of neurons with highly variable conductance densities. We describe how variability in neuron intrinsic properties can be classified into two types: variability in neuron passive properties vs active properties. Neuromodulation or any pharmacological manipulation that would directly affect ion channels in neurons exhibiting both these variability types is likely to be unreliable. However, we show that

a simple mechanism involving feedback interactions between the modulator receptor, a second-messenger signal and ion channel densities ensures reliability of neuromodulation even in very heterogenous populations. The ingredients for these mechanism are found in most metabotropic receptor signaling cascades.

Title: Synaptic and intrinsic mechanism of CB_{2R} mediated reduction of VTA DA neuronal excitability

Authors: *M. GAO[1], B. LARSEN[1,2], F. GAO[1], D. CHEN[1], Z. HUANG[1], H. ZHANG[3], Y. HE[3], Z. XI[3], J. WU[1];

Abstract: We have recently reported that activation of cannabinoid type 2 receptors (CB_2Rs) reduced dopamine (DA) neuron excitability in the mouse ventral tegmental area (VTA). Here, we elucidated the underlying mechanisms. Using cell-attached recording in VTA slices, bath-application of a CB_2R agonist (JWH133) inhibited VTA DA neuron firing in a concentration-

dependent manner. In addition to JWH133, five other CB_2R agonists exhibited similar inhibition. Under the patch-clamp whole-cell recording model, JWH133 (10 μM) inhibited miniature excitatory postsynaptic currents (mEPSCs) but not miniature inhibitory postsynaptic currents (mIPSCs). However, JWH133 did not inhibit evoked EPSCs or IPSCs. In freshly dissociated VTA DA neurons, JWH133 reduced the action potential (AP) firing rate, delayed AP initiation and enhanced AP after-hyperpolarization. In voltage-clamp recordings, M-type K+ currents were enhanced by JWH133. This effect was absent in $CB_2^{-/-}$ mice and abolished by co-administration of a selective CB_2R antagonist (AM630). In addition, CB_2R-mediated inhibition in VTA DA neuron firing can be mimicked by a M-curren t opener and blocked by a M-current blocker. Finally, CB_2R-cAMP signaling plays a role in modulating DA neuron excitability since enhancement of cAMP by forskolin reduced M-current and increased DA neuron firing. These results suggest that CB_2Rs modulate VTA DA neuron excitability through both synaptic and intrinsic mechanisms, including a reduction in mEPSCs and enhancement of M-currents.

Title: Effects of internal recording anion on neuronal properties and firing of a genetically identified layer 5 pyramidal cell type.

Authors: ***G. S. NEWKIRK**[1], D. PATHAK[2], N. C. DEMBROW[1,3], R. C. FOEHRING[2], W. J. SPAIN[3,1];
[1]Physiol. & Biophysics, Univ. of Washington, Seattle, WA; [2]Anat. and Neurobio., Univ. of Tennessee, Memphis, TN; [3]VA Epilepsy Ctr. of Excellence, Seattle, WA

Abstract: Intrinsic properties of neurons determine the integration of inputs from the dendrites to the soma and ultimately the output pattern of the neuron, thus understanding these properties is integral to understanding the function of neuronal circuits. Unfortunately, the most reliable methods of single-cell recordings used to measure these properties requires mimicry of the

internal composition of the cell, where physiological conditions are near impossible to reproduce. Previous work in hippocampal CA1 pyramidal cells (Kaczorowski et al. 2007: J Physiol 578: 799) examined the effects of recording stability and slow afterhyperpolarization (sAHP) plasticity with internal solutions containing either Kmethylsulfate (Kmeth) or Kgluconate (Kgluc). We used solutions based on these two anions to investigate differences in action potential firing in a subset of layer 5 pyramidal neurons in brain slices from the somatosensory and motor cortex of 4-8 wk old mice expressing *Etv*1-EGFP. Experiments were also conducted in the perforated-patch (Perf) configuration using gramicidin to gain access to the internal compartment while maintaining physiological internal solution integrity. We compared resting potential, input resistance, impedance from chirp responses, action potential and afterpolarization parameters (fAHP, mAHP, sAHP & fADP), as well as repetitive firing responses (including spike frequency adaptation) to DC current steps as well as fluctuating current steps with all three internals. Subthreshold properties and firing responses recorded with the Kgluc or Perf internal did not differ significantly whereas responses recorded with KMeth showed significant differences in afterpolarization wave forms and dramatic differences in firing (decreased steady firing rates and, and marked increase in spike frequency adaptation as well as depolarization block). During prolonged recordings (>30 min) in KMeth, the firing responses became more similar to what was observed when recording with KGluc or Perf internals. Interestingly, firing responses recorded in a different type of layer 5 pyramidal neuron that lacks a sAHP (Thy1-yfp-h) were similar with each of the recording conditions.

Title: Serotonin modulates the intrinsic electrophysiological properties of locus coeruleus neurons

Authors: *S. BREMSER[1,2], L. PAEGER[1,2], P. KLOPPENBURG[1,2];
[1]Biocenter, Inst. For Zoology, Cologne, Germany; [2]Cologne Excellence Cluster on Cell. Stress Responses in Aging-Associated Dis. (CECAD), Univ. of Cologne, Cologne, Germany

Abstract: The Locus Coeruleus (LC) contains about 50% of all noradrenergic neurons of the brain. Since these neurons have extensive projections throughout the CNS, the LC has been associated with the control of many different behavioral and cognitive functions such as arousal, stress, attention and memory processes (J. Psychopharmacol., 2013, 27(8):659-93). As an important prerequisite to unravel the physiological role of the LC, it is crucial to understand the intrinsic electrophysiological properties of the LC neurons. In previous work, certain electrophysiological properties of these neurons have been characterized. However, since the experiments have been performed in various organisms using different recording techniques the current data might not be quite comparable. Here we used perforated patch-clamp recordings, which do not disturb intracellular signaling, to comprehensively characterize LC neurons intrinsic electrophysiological properties in mice. Overall we found a homogeneous population of neurons with similar intrinsic electrophysiological properties including input resistance, excitability and action potential waveform. All LC neurons generated very regular pacemaker-like activity. Synaptic isolation did not disrupt pacemaking but significantly increased the action potential frequency in all experiments. All recorded neurons showed delayed excitation after hyperpolarization and prolonged hyperpolarization after sustained excitation.
In rodents the LC receives serotonergic projections from the dorsal raphe nucleus and LC neurons are inhibited by serotonin application. The physiological relevance of this connection is still not fully understood, hence we tested the effect of serotonin on the electrophysiological properties of LC neurons. Here we found that LC neurons in mice showed a complex response to serotonin. On the one hand serotonin caused a concentration dependent hyperpolarization accompanied by a reduction in action potential frequency, and a decrease in cell input resistance. On the other hand, the excitability in presence of serotonin was drastically increased. Together this might improve the signal to noise ratio in the LC, sharpening the noradrenergic signaling deriving from LC neurons. Our results confirm that serotonin modulates LC neurons, but also suggest that the modulatory effects are more complex than previously thought.

Title: Loss of Navβ4-mediated regulation of the resurgent and transient sodium current disrupts repetitive firing in cerebellar Purkinje neurons and impairs balance and motor coordination

Authors: *J. L. RANSDELL[1], W.-L. LO[2], P. M. ALLEN[2], J. M. NERBONNE[1];
[1]Departments of Developmental Biol. and Med., [2]Dept. of Pathology and Immunol., Washington Univ., Saint Louis, MO

Abstract: The resurgent component of the voltage-gated sodium (Nav) current, I_{NaR}, provides a depolarizing drive during the repolarization phase of action potentials and is thought to be vital in sustaining high rates of firing in many types of mammalian neurons. Previous work has linked the generation of I_{NaR} to the expression of the sodium channel beta four (Navβ4) auxiliary subunit. We used an Navβ4 'knockout' (*Scn4b*$^{-/-}$) mouse, as well as shRNA mediated acute 'knockdown' of *Scn4b*, to determine the effects of altered *Scn4b* expression on sodium currents in Purkinje neurons, as well as on the repetitive firing properties of these cells. In current-clamp experiments, we found that adult (6-8 week old) *Scn4b*$^{-/-}$ Purkinje neurons have reduced ($p<.01$) spontaneous and evoked firing rates. Acute knockdown of *Scn4b* in adult Purkinje neurons *in vivo* caused similar defects in high frequency firing. To determine if the defects in Purkinje neuron excitability impact motor performance, we used the elevated balance beam test. Here, animals were first trained to cross a narrow beam into an enclosed box and, following the training, the time it took to cross the beam and the number of foot slips along the way were measured to assess motor coordination and balance. These experiments revealed that adult *Scn4b*$^{-/-}$ animals have significant ($P<.05$) motor defects when compared to age matched WT animals. We used dynamic clamp to artificially insert I_{NaR} in mature *Scn4b*$^{-/-}$ Purkinje neurons and found that adding I_{NaR} increased spontaneous and evoked firing rates. Because of space-clamp limitations, we could not measure the magnitude of I_{NaR} in adult Purkinje neurons directly. We, therefore, measured I_{NaR} from Purkinje neurons acutely dissociated from postnatal day 12-18 (P12-P18) *Scn4b*$^{-/-}$ and WT animals. We found that I_{NaR} is significantly ($p<.05$) lower in P12-P18 *Scn4b*$^{-/-}$ Purkinje neurons, compared with WT Purkinje neurons. These voltage-clamp experiments also revealed that the peak transient sodium current density is significantly ($p<.05$) larger in P12-P18 *Scn4b*$^{-/-}$ Purkinje neurons than in WT Purkinje neurons. Interestingly, and in contrast to the attenuation in firing rate found in adult Purkinje neurons lacking *Scn4b*, repetitive firing rates in P14-P15 *Scn4b*$^{-/-}$ and WT Purkinje neurons were indistinguishable. Experiments are under way to determine the developmental expression of sodium channel alpha and beta subunits which may contribute to the observed age-dependent differences in the functional impact of the loss of *Scn4b* in cerebellar Purkinje neurons.

Title: Identifying the passive membrane properties of myelinated axons

Authors: C. C. COHEN[1,2], M. A. POPOVIC[1], J. KLOOSTER[1], *M. H. KOLE[1,2];
[1]Netherlands Inst. for Neurosci., Amsterdam, Netherlands; [2]Cell Biol., Univ. of Utrecht, Utrecht, Netherlands

Abstract: Myelination of axons by glial cells is fundamental to the rapid conduction of action potentials (APs), providing reliable and long-range signaling in the nervous system. The electrical characterization of the myelinated axon was established in the first half of the 20th century, wherein multiple layers of myelin membrane tightly wrap axons between nodes of Ranvier to create a high-resistance axo-myelin membrane combination. In this paradigm most internodal current flow is restricted to the axon core, allowing little current to leak along the internode. While some experimental studies suggest the internode is leakier than previously thought, specific membrane properties of the axo-myelin circuit for central nervous system axons remain to be identified. Here, we made multi-site whole-cell recordings of myelinated axons of large layer 5 pyramidal neurons in the somatosensory cortex and examined the properties of passive voltage attenuation between the soma and axon cut ends (up to ~800 µm distance). Together with the morphology of recorded cells we developed cable models in which the specific axon and myelin membrane parameters were constrained to the experimentally recorded voltage responses. Results show that the optimized axo-myelin transverse resistance is much lower than expected according to the classic studies (21 kΩ cm^2; n = 6 axon models). Furthermore, based on the myelin ultrastructure identified with electron microscopy of the same recorded cells, we found a low specific resistance per myelin membrane (on average 7.85 kΩ cm^2, range: 1.59-17.7 kΩ cm^2, n = 4). The optimized cable models of myelinated axons further predicted a slower rise time of fast AP-like potentials within internodes relative to adjacent nodes of Ranvier. To test this experimentally, we made high-temporal resolution voltage-calibrated optical recordings of the axolemma in nodal and internodal regions. The results confirmed that nodal AP waveforms are threefold faster than those at preceding or proceeding internodes (12 nodes of 7 axons, P < 0.003). Taken together, these preliminary data indicate that transverse axo-myelin resistance is lower than expected according to classic electrophysiological studies of the myelinated axon.

Title: Intrinsic excitability of cerebellar Purkinje cells is modulated by cholinergic inputs

Authors: G. WATKINS, *C. HANSEL;
Neurobio., Univ. of Chicago Dept. of Neurobio., Chicago, IL

Abstract: Synaptic plasticity has long been considered to be the fundamental mechanism underlying learning. Recently, however, changes in the intrinsic excitability of neurons in response to behavioral and electrophysiological stimuli have been identified as an important complementary process. In cerebellar Purkinje cells, intrinsic plasticity has been shown to be dependent on the activity of calcium-regulated potassium (SK) channels; additionally, in the hippocampus, signaling through muscarinic acetylcholine receptors (mAChRs) has been confirmed to be a regulator of SK channels. In order to identify the role of intrinsic excitability in the cerebellum, and to determine whether cholinergic signaling might have a similar function in modulating this effect, cerebellar slices were prepared from adult (P21-42) mice, and whole-cell patch-clamp recordings were performed from Purkinje cells in the vermis of the vestibular cerebellum (lobules IX/X), which contains a high concentration of mAChRs. We show that evoked spike activity is significantly increased following an induction protocol involving either somatic depolarization (SD; spike count increased to 159.3 ± 11.5% relative to baseline; n=9; $p < 0.05$) or a burst of parallel fiber synaptic input (Syn; 137.4 ± 11.6%; n=11; $p < 0.05$). While bath application of mAChR agonist oxotremorine-m in the absence of an induction protocol was also sufficient to increase Purkinje cell firing rate relative to the control (oxo-m; 115.3 ± 6.9%; n=7; $p < 0.05$), the effect was not as strong as either induction protocol on it's own. However oxo-m application significantly enhanced the response to the synaptic protocol (Syn+oxo-m; 172.1 ± 14.8%; n=6; $p < 0.05$), suggesting that mAChRs may have a function in modulating Purkinje cell excitability following synaptic input in the cerebellum. Taken together, these data indicate that intrinsic plasticity may play a role in cerebellar learning, and that cholinergic signaling may contribute to this mechanism.

Abstract: It has been shown that stimulation of the ponto-medullary junction, where serotonergic neurons originate, produces locomotion in the isolated neonatal rat brainstem-spinal cord preparation. 5-HT neurons in this region play an essential role in generating locomotion. However, the intrinsic membrane properties of these neurons remain unclear. Using ePet-EYFP mice in which EYFP was expressed in 5-HT neurons we were able to perform whole cell patch-clamp recordings on EYFP+ neurons of brainstem slices (PND 1 - PND 15). 5-HT neurons in medulla could be classified into three types: single (type 1), phasic (type 2) and tonic (type 3) firing based on their response to depolarization of step currents. Of 119 serotonergic neurons recorded from the parapyramidal region (PPR), 13% of the neurons were type 1, 9% type 2 and 78% type 3, whereas in total of 67 serotonergic neurons of the midline raphe nuclei (MRN), 18% were type 1, 6% type 2 and 76% type 3. Membrane properties measuring from 5-HT neurons in PPR (n=119) and MRN (n=67) included resting membrane potential (PPR -63.3±6 mV; MRN -65.9±6 mV), input resistance (PPR 1150.3±618 MΩ; MRN 1312.4±712 MΩ), membrane time constant (PPR 41.5±19 ms; MRN 47.5±23 ms), rheobase (PPR 30.1±23 pA; MRN 31.7±25 pA), voltage threshold (PPR -32.9±7 mV; MRN -32.6±8 mV), action potential height (PPR 38.8±9 mV; MRN 39.9±10 mV) and afterhyperpolarization depth (PPR 19.8±8 mV; MRN 21.1±10 mV). Except for resting membrane potential no significant difference was shown in the properties between the PPR and MRN 5-HT neurons. Fluorescent dying (2% cascade blue) was added into the electrodes to label the cells for morphological analysis. 5-HT neurons could be divided into oval and stellate categories according to somatic shapes or bipolar and multipolar groups based on the number of stem dendrites. Despite different from morphology 5-HT neurons were not substantially different in either membrane properties or morphological parameters (somatic diameter and spherical area). Hyperpolarization-activated inward current and persistent

inward current were found in both PPR and MRN 5-HT neurons. And furthermore, the tetrodotoxin and dihydropyridine resistant persistent inward current (TDr-PIC) was also expressed in these neurons. Bath application of 10-20 μM 5-HT enhanced the TDr-PIC or lowed the voltage or current threshold for eliciting plateau potential induced by TDr-PIC. Some neurons exhibited membrane oscillation or bursting which could be facilitated by ACh (10-30 μM). NMDA (10-30 μM) depolarized 5-HT neurons while ACh caused varying effects on them. This study provides insight into intrinsic properties of 5-HT neurons in the medulla of ePet-EYFP mice.

Title: Roles of TRPC3 channels in nigral dopamine neurons; pacemaking and activity-dependent regulation of basal firing rate

Authors: ***K. UM**[1], L. BIRNBAUMER[2], H. KIM[1], M. PARK[1];
[1]Sch. of Medicine. Sungkyunkwan Univ., Suwon-City, Korea, Republic of; [2]BIOMED, Sch. of Med. Sciences, Catholic Univ. of Argentina, Buenos Aires, Argentina

Abstract: Dopamine neurons in the substantia nigra pars compacta (SNc) are slow pacemakers that generate spontaneous action potentials (APs) regularly. Although spontaneous action potentials are essential for maintenance of background dopamine levels and proper functioning of basal ganglia, it is not clear which channels are responsible for pacemaking and determine basal firing rate in the SNc dopamine neurons. In this study, we report that TRPC3 channels drive pacemaking and regulate basal firing rate via type 1 metabotropic glutamate receptors (mGluR1) in the SNc dopamine neurons. Specific TRPC3 channel blockers, pyr10 and pyr3, stopped spontaneous firing and Ca2+ oscillations in dopamine neurons. However, spontaneous firing was conserved in dopamine neurons of TRPC3 knockout (KO) mice and there was no significant difference in spontaneous firing rates between the TRPC3 KO and wild type mice. Application of pyr10 did not affect spontaneous firing and Ca2+ oscillations in TRPC3 KO mice, suggesting that pyr10 blocked spontaneous firing by specifically blocking TRPC3 channels in normal dopamine neurons. TRPC3 channel blockade with pyr10 hyperpolarized membrane potentials, but somatic current injection regenerated pacemaker activity again, suggesting that

TRPC3 channels are constitutively active and help to maintain membrane potential depolarized within pacemaking ranges. In addition, stimulation of mGluR1 induced sustained Ca2+ influxes together with enhancement of spontaneous firing. When TRPC3 channels were blocked by pyr10, mGluR1-induced slow Ca2+ influxes were dramatically reduced. Furthermore, in TRPC3 KO mice, firing rates were not significantly enhanced by activation of mGluR1 in SNc dopamine neurons. From these experimental results, we conclude that TRPC3 channels are not only essential for pacemaking, but also determine basal firing rate in mGluR1-dependent ways in SNc dopamine neurons.

Title: Cav3.2 T-type calcium channels modulate burst firing in mature granule cells of the dentate gyrus

Authors: *J. LOPEZ-ROJAS, M. DUMÉNIEU, M. HEINE, M. R. KREUTZ, A. BIKBAEV; Leibniz Inst. for Neurobio., Magdeburg, Germany

Abstract: Mature granule cells of the dentate gyrus exhibit sparse firing of action potentials in physiological conditions. Interestingly, in the rare case of activation they show burst firing that is believed to be crucial for communication with their postsynaptic CA3 targets. The mechanisms underlying this bursting pattern in mature granule cells are not known. In the dentate gyrus T-type calcium channels contribute to a reduction of the threshold for action potential generation in immature but not in mature granule cells. We hypothesized that T-type calcium channels might have a different function in mature cells by mediating their characteristic bursting behaviour. We performed patch-clamp recordings from mature granule cells of the dentate gyrus of rats and mice and found that pharmacological blockade of T-type calcium channels indeed impaired burst

firing. We found similar results when we isolated the neurons from the network by blocking glutamatergic and GABAergic transmission showing that contribution of T-type channels to the burst firing represents an intrinsic mechanism. We also studied the contribution of axonal and dendritic calcium currents. T-type-mediated currents were observed in the axon initial segment of mature granule cells as well as in their medial-distal dendrites. From the different T-type channels subtypes, Cav3.2 shows a strong expression in the dentate gyrus and a physiological/pharmacological profile matching the observed features of mature cells bursting. We therefore assessed the consequences of the deletion of the Cav3.2 gene on bursting by using Cav3.2 constitutive knock-out mice. Interestingly, Cav3.2 knock-out mice fired mainly tonic spikes with a clear impairment in their ability to generate bursts of action potentials when compared to controls. These results show that Cav3.2 channels are strong modulators of bursting in mature granule cells of the dentate gyrus. Thus, Cav3.2 channels might be considered as a critical molecular switch that would allow mature granule cells to be effective in transmitting information to the CA3 pyramids. Modulation of these channels by experience or post-translational modifications might have important consequences to pattern separation/completion tasks as well as other dentate and CA3-mediated behaviours.

Title: Microglial activation induces the excitability plasticity in CNS neurons

Authors: *G. OHTSUKI[1], M. KIM[2];
[1]Hakubi-center / Dept. of Biophysics, Grad. Sch. of Sci., [2]Dept. of Mol. and Cell. Physiol., Kyoto Univ., Kyoto, Japan

Abstract: Microglia is the resident immune cells in the brain, which show inflammatory responses against the immune challenge caused from the bacterial infections, stroke, hypoxia,

autoimmune or neurodegenerative diseases. Activated microglia are involved in the synaptic elimination, synaptic efficacy and synaptic plasticity induction. However, whether the activated microglia alter the non-synaptic neuronal excitability plasticity remains unknown.
Here, we show activation of microglia using the bacterial endotoxin (lipopolysaccharide, LPS) modulates the neuronal excitability in two brain regions. First, in the cerebellar Purkinje neurons, exposure of LPS increased the firing frequency long-lastingly, which prevented from inducing the excitability plasticity by additional 5Hz somatic depolarization. LPS-induced firing increase was suppressed by under the existence of Apamin, the antagonist of small conductance Ca2+-activated K+ channels (SK channels), suggesting the LPS-induced firing increase was mediated through the SK2 channel down-regulation as shown that involved in the firing increase plasticity in Purkinje cells (Belmeguenai et al., 2010, JNS; Ohtsuki et al., 2012, Neuron; Grasselli et al., 2016, Cell Rep.). In contrast, the LPS decreased in firing frequency in layer 5 pyramidal neurons of the medial prefrontal cortex (mPFC). This decrease of pyramidal neurons were prevented by the intracellular application of the phosphatase inhibitor. Further, LPS-induced firing frequency decrease was in large part mediated by the up-regulation of the SK channel functions. And, we also analyzed inflammatory cytokine levels during microglial activation. Thus, these results indicated that the LPS-induced microglial activation modulates the neuronal excitability in Purkinje neurons and pyramidal neurons in opposite directions through SK channel functional changes.

Title: Sodium fluxes and cortical axonal excitability in penumbra following acute ischemic stroke

Authors: *O. STOLER[1], M. BOYKO[2], V. ZVENIGORODSKY[2], I. SHELEF[1], I. A. FLEIDERVISH[1];
[1]Dept. of Physiol. and Cell Biol., [2]Soroka Med. Ctr., Ben Gurion Univ., Baar Shava, Israel

Abstract: In the center of the cortical ischemic territory, the countdown to neuronal death starts with the onset of “anoxic depolarization” wave minutes after the onset of ischemia. The resulting

ischemic core is surrounded by the wider penumbra region where neuronal function is impaired but that is potentially salvageable with timely therapeutic intervention. Recent evidence indicates that the penumbral neurons suffer from rapid, calpain-mediated proteolysis of the axon initial segment (AIS) cytoskeleton. This stroke-induced proteolysis must have important functional implications for distribution and kinetics of the AIS channels thus affecting the ability of a neuron to generate meaningful output. Here we explored the stroke-induced changes in Na^+ fluxes and excitable properties of Layer 5 pyramidal neurons using a combination of patch-in-slice recording and high-speed fluorescence imaging of Na^+-sensitive indicator SBFI. Cortical slices including injured and contralateral hemispheres were prepared from the brains of two month old rats, 3-4 hours after focal infarction was produced by permanent middle cerebral artery occlusion. Following the surgery, animals were awakened from anesthesia to confirm neurological deficits. The boundaries of the ischemic core and of penumbra were determined using the diffusion and perfusion-weighted MRI before the animals were sacrificed. Immunohistochemical analysis revealed that ankyrin G immunoreactivity was undetectable in the AIS of neurons within the penumbra, whereas control NeuN-stained neurons in contralateral hemisphere displayed robust ankyrin G staining. The peak amplitudes of the single AP elicited Na^+ transients in the AIS of the penumbral neurons were smaller, but their times-to-peak were significantly longer than in the contralateral hemisphere, indicating that the inactivation characteristics of the underlying channels were altered. Less than 10% of the Layer 5 pyramidal neurons in control hemisphere fired bursts of action potentials (APs) in response to somatic, brief depolarizing current pulses. In the penumbra, however, the fraction of bursters increased markedly, with more than half of the neurons responded to the current pulses with more than one AP. This firing behavior was associated with increase in the size of AP afterdepolarization which could be attributed to incomplete inactivation of partially proteolyzed Na^+ channels. The changes in the firing pattern of the surviving cells of the penumbra may play an important role in development of post-stroke neurological deficits as well as in generation of spreading depolarization waves and epileptiform discharges following ischemic injury.

Title: Spontaneous emergence of highly active neurons in hippocampal primary cultures

Authors: ***M. OKADA**, C. KOBAYASHI, Y. IKEGAYA;
The Univ. of Tokyo, Tokyo, Japan

Abstract: Neurons communicate with others using spikes. In the neuron society, cells are highly heterogeneous in terms of their activity level; only a few neurons exhibit extremely high firing rates, whereas many other neurons are nearly inactive. Although highly active neurons are not dominant in numbers, their spikes contribute the majority of the total spike number in the brain, and thus, they may have a great impact on information processing, compared to those emitted by other "normal" neurons. However, little is known about how highly active neurons emerged and are maintained in neuronal networks. We optically detected highly active neurons, using Arc-dVenus transgenic mice, which express the fluorescent protein dVenus under the promoter of *arc*, an immediate early gene that is induced by neuronal activation. We prepared primary cultures of hippocampal neurons from Arc-dVenus mice and continuously observed their dVenus fluorescence for about 50 days. Under spontaneous default-mode conditions, dVenus-positive neurons started to appear on approximately 20 days in vitro and gradually increased during our observation periods. However, even on 49 days in vitro, only a few portion (less than 1%) of neurons were dVenus-positive. The number of dVenus-positive neurons increased after neuronal stimulation by a $GABA_A$ receptor antagonist. Patch-clamp recordings revealed that the dVenus-positive neurons show spontaneously higher firing rates than dVenus-negative neurons. Although a subset of dVenus-positive neurons drift over time, some neurons were dVenus-positive for a long time (up to 14 days). Moreover, there existed neurons that repeatedly expressed dVenus. These results suggest that highly active neurons are fixed over time to some extent. To investigate the spatial distribution of highly active neurons, we calculated geometric energy, a measure of spatial clustering. The geometric energy was significantly higher than randomly shuffled surrogates, suggesting that Arc-expressing neurons were not randomly distributed but rather tended to be clustered in specific loci. Our results suggest that highly active neurons constitute a functional subpopulation in the neuronal network. These fixed highly active neurons may primarily convey neural information.

Title: Calcium lowers neuronal excitability with a G-protein independent mechanism

Authors: *M. FORSBERG[1], A. BJÖREFELDT[2], H. SETH[2], E. HANSE[2];
[1]Neurosci. and Physiol., Univ. of Gothenburg, Gothenburg, Sweden; [2]Physiol., Neurosci. and Physiol., Gothenburg, Sweden

Abstract: The effect of extracellular calcium to decrease intrinsic excitability in neurons has been known since the 19th century. The dominating hypothesis to explain this phenomenon has ever since been the so-called "charge-screen effect", claiming that the positively charged calcium ion is attracted to the negatively charged cell membrane and there screens the membrane with its positive charge. Thereby the local electrical field within the membrane is shifted to a more hyperpolarized membrane potential. Thus extracellular calcium ions suppress action potential firing. Recently, other mechanisms involving the G-protein coupled calcium sensing receptor (CaSR) and a sodium leak channel (NALCN) has been proposed.
In this study we use patch-clamp recordings of rat hippocampal CA1 pyramidal neurons to explore how changes in extracellular calcium from 2 mM (the most commonly used concentration in experiments *in vitro*) to 1 mM (the concentration in cerebrospinal fluid) affect intrinsic properties. This reduction in calcium produced a hyperpolarization of the threshold for action potential firing (-47 ± 1.0 mV to -52 ± 1.1 mV, $p<0.0001$) but no depolarization but rather a slight hyperpolarization of the resting membrane potential (-55.7 ±1.9 mV to −57.2 ±2.2 mV, $p=0.016$). We also observed a decrease of the action potential amplitude (106 ± 1.0 mV to 99 ± 1.3 mV, $p<0.0001$) and a decrease of the maximum depolarization velocity (258 ± 20.3V/s to 307 ± 22.8 V/s, $p=0.0001$). The rheobase decreased to 67 ± 7% (n=10), when calcium was changed from 2 to 1 mM. Addition of the G-protein blocker GDPβS intracellularly (0.3 mM) did not significantly change this result (66 ± 9 %, n=6). We also tested a higher concentration of GDPβS (3.0 mM, n=7), but that did not significantly reduce the effect of reduced calcium on the rheobase (61 ± 4 %, $p = 0.48$).
Our results indicate that the effect of calcium on intrinsic excitability does not depend on G-proteins. The hyperpolarization of the threshold for the action potential without alteration of the resting membrane potential suggests a mechanism involving the gating properties of voltage-gated sodium currents rather than leak currents.

Title: Activity-dependent plasticity of intrinsic excitability in CA1 pyramidal neurons *In vivo*

Authors: *P. J. MORGAN, J. EPSZTEIN;
Inst. de Neurobiologie de la Méditerranée, Marseille Cedex 09, France

Abstract: On exposure to a novel environment, a subpopulation of cells in CA1 will express place fields to create a spatial map of the environment. What determines which cells will be recruited to this population is not yet known, but there is evidence to suggest intrinsic excitability could have an important role. The identity of place versus silent cells was found to be predictable from their firing pattern in response to current injections prior to exploration of a novel environment (Epsztein et al 2011): highly bursting cells tended to become place cells, whereas regular firing cells were more likely to be silent. Furthermore, small, tonic depolarisations of the membrane can be sufficient to reveal spatially modulated firing in cells that were previously silent (Lee et al. 2012).

Plasticity of intrinsic excitability in CA1 neurons has been shown following various stimulation protocols in vitro (Daoudal et al., 2002; Wang et al., 2003; Fan et al 2005, Brager & Johnston 2007, Campanac et al 2008), and could potentially regulate the availability of cells to encode a new environment, but it has yet to be demonstrated in vivo.

In this work we have examined the effect of three different stimulation protocols on the intrinsic excitability of CA1 pyramidal cells in vivo. Using whole-cell recordings in anaesthetised rats and stimulating solely via the patch pipette, we applied either 1. A theta-burst protocol previously used in vitro (Fan et al. 2005), 2. A pulse train protocol shown to modulate intrinsic excitability in the somato-sensory cortex in vivo (Mahon & Charpier 2012), or 3. A theta frequency plateau-inducing protocol, as plateaus occur at theta frequency at the centre of place fields (Epsztein et al 2011, Bittner et al 2015).

To determine intrinsic excitability we analysed the current-firing rate relationship, the membrane input resistance, the action potential threshold and the burstiness of the firing pattern. We found that the theta-burst protocol decreased intrinsic excitability, reducing the firing rate output and burstiness. These effects were accompanied by a decrease in input resistance. Similarly, the pulse

train protocol also reduced the action potential output and burstiness, however without a detectable effect on input resistance. The plateau group showed no overall differences in firing rate or burstiness, but for individual cells there were large effects in either direction, and we are exploring the possibility of differential subpopulation responses.
Our results show that single cell stimulation can induce plasticity of intrinsic excitability in CA1 pyramidal cells in vivo. Further work will investigate the role this may play in spatial coding.

Title: Differential effects of abuse solvents on the intrinsic excitability of pyramidal neurons in the medial prefrontal cortex of adolescents rats

Authors: *M. ARMENTA-RESÉNDIZ[1], S. L. CRUZ[2], E. J. GALVÁN[2];
[1]CINVESTAV Sede Sur, México, Mexico; [2]CINVESTAV, IPN Ciudad de México, Mexico

Abstract: Industrial products misused for intentional inhalation contain different solvents among which aromatic hydrocarbons such as toluene, xylene and benzene, are the most commonly found. Chronic abuse exposure to toluene produces clear behavioral effects and severe cognitive deficits, but the physiological adaptations that occur in specific brain areas are largely unknown. On the other hand, cyclohexane is another solvent, also found in commercial products which does not share behavioral effects toluene, suggesting that it may act through different mechanism. This work examines the effects of intermittent chronic exposure to toluene and cyclohexane in intrinsic excitability of pyramidal neurons of the medial prefrontal cortex (mPFC) in adolescent rats. Individual groups of male Wistar rats were exposed for 30 min in a static exposure chamber to 8000 ppm of toluene or cyclohexane twice daily for 10 days, from postnatal day 22 to 35. Pyramidal neurons in layer V were recorded using the patch-clamp technique in whole-cell mode. Neither toluene not cyclohexane changed the resting membrane potential. Toluene but not cyclohexane, decreased neuronal input resistance and rehobase

current, as well as increased the rectification phase of the curve I/V. Both solvents increased neuronal firing frequency, but, this increase was only significant in animals exposed to toluene. On the other hand, none of the solvent altered statistically the kinetics of the action potential. The increased frequency produced by toluene was related to a reduction in the after hyperpolarization current ($_{I}$AHP). In conclusion, our results show that repeated toluene exposure increases the excitability of pyramidal neurons layer V in the mPFC of adolescent rats while cyclohexane had no significant effect.

Title: Modulation of neuronal excitability in neuromorphic devices

Authors: ***A. FRANCI**[1], F. CASTAÑOS[2];
[1]Dept. de Matemáticas, Univ. Nacional Autónoma De México, Coyoacán, Mexico; [2]Dept. de Control Automático, CINVESTAV, Cd.Mx., Mexico

Abstract: The transition between different neuronal excitability types plays a fundamental role in brain functions [Lee2012]. A prototypical example is the transition between a tonic mode and a rebound/bursting mode in the thalamus associated with modulation of arousal state.
The balance between the expression of different ion channels is a key player in modulating neuronal excitability, and the involved ion channels can exhibit highly different or almost redundant properties. We have shown that, despite the high dimensionality of the ion channel conductance parameter space, modulation of neuronal excitability depends on a small number of behavioral parameters defining *dynamic input conductances* [Drion2015a]. These objects are instrumental to analyze neuronal modulation and robustness in a principled way [Drion2015b]. Here we use them in a constructive way to design simple electronic devices that exhibit the same excitability, modulation and robustness properties of biological neurons. Variations in biological parameters can be mapped into variations in the circuit parameters to reproduce the same behavioral transitions observed in experiments.
We propose this circuit as a real world analog implementation of the biological transition between excitability types and discuss its potentiality from a fundamental as well as from an

applied perspective.

Title: Hydrogen peroxide modulates neuronal excitability and membrane properties in ventral horn neurons of the rat spinal cord

Authors: M. OHASHI[1], *T. KOHNO[2], N. OHASHI[1], T. HIRANO[1], K. WATANABE[1], H. SHOJI[1], T. MIZOUCHI[1], N. ENDO[1];
[1]Niigata Univ. Sch. of Med. and Dent. Sci., Niigata City, Japan; [2]Niigata Univ. Grad Sch. Med. & Dent. Sci., Niigata, Japan

Abstract: Hydrogen peroxide (H_2O_2), a reactive oxygen species, is an important signalling molecule in synaptic and neuronal activity in the central nervous system; it is produced excessively in brain ischaemia and spinal cord injury. Although we have reported H_2O_2-mediated modulations of synaptic transmission in rat spinal ventral horn (VH) neurons, the effects of H_2O_2 on neuronal excitability and membrane properties remain poorly understood. Accordingly, these potential effects were investigated in the present study using a whole-cell patch-clamp approach in rats. We found that bath-application of H_2O_2 decreased neuronal excitability accompanied by decreased input resistance, firing frequency, and action potential amplitude and by increased rheobase. These H_2O_2-mediated changes were induced by activation of extrasynaptic, but not

synaptic, $GABA_A$ receptors. Indeed, GABAergic tonic currents were enhanced by H_2O_2. On the other hand, the amplitude of medium and slow afterhyperpolarisation (mAHP and sAHP), which plays important roles in controlling neuronal excitability and is mediated by small-conductance calcium-activated potassium (SK) channels, was significantly decreased by H_2O_2. When extrasynaptic $GABA_A$ receptors were completely blocked, these decreases of mAHP and sAHP persisted, and H_2O_2 increased excitability, suggesting that H_2O_2 per se might have the potential to increase neuronal excitability via decreased SK channel conductance. These findings indicate that activating extrasynaptic $GABA_A$ receptors or SK channels may attenuate acute neuronal damage caused by H_2O_2-induced hyperexcitability and therefore represent a novel therapeutic target for preventing and treating H_2O_2-induced motor neuron disorders.

Title: Temporal origin specifies an electrophysiological subpopulation of glutamatergic cells in the adulte dentate gyrus

Authors: *L. SAVE, A. BAUDE, R. COSSART;
INSERM U901, Marseille Cedex 09, France

Abstract: Temporal and spatial embryonic origin critically determines cortical neuron diversity. The Dentate Gyrus is the entry gate to the hippocampal trisynaptic circuit and comprises two subtypes of principal glutamatergic neurons, the granule cells and the semilunar granule cells. Although the latter represent a very small minority of neurons characterized by a stereotyped dendritic morphology, they have recently been identified as essential components of information processing through the Dentate Gyrus circuit. Since both early born GABAergic and glutamatergic neurons in CA3 were shown to develop into neurons supporting major network functions, we asked whether an early temporal origin could similarly specify semilunar cell fate. Here we show that semilunar granule cells, classified by their morphological features, are

generated and mature earlier than the general granule cell population. Besides morphology, adult semilunar cells display characteristic electrophysiological features contributing to a lower excitability. Such electrophysiological traits differ from most neurons but are shared with early born granule cells. Therefore an early birthdate specifies adult neuronal physiology whereas additional factors may combine to further produce morphological identity.

Title: Human cerebrospinal fluid promotes neuronal viability and activity of hippocampal neuronal circuits *In vitro*

Authors: *G. CULLEY[1], M. PEREZ-ALCAZAR[1], T. LYCKENVIK[1], K. MOBARREZ[1], A. BJÖREFELDT[1], P. WASLING[1], H. SETH[1], F. ASZTELY[1], A. HARRER[2], B. IGLSEDER[2], L. AIGNER[2], E. HANSE[1], S. ILLES[1];
[1]Univ. of Gothenburg, Goeteborg, Sweden; [2]Paracelsus Med. Univ., Salzburg, Austria

Abstract: ***Background***
For decades it has been hypothesized that molecules within the cerebrospinal fluid (CSF) diffuse into the brain parenchyma and influence the function of neurons. However, the functional

consequences of CSF on neuronal circuits are largely unexplored and unknown. A major reason for this is the absence of appropriate neuronal *in vitro* model systems, and it is uncertain if neurons cultured in pure CSF survive and preserve electrophysiological functionality *in vitro.*

Methods and Results

We present an approach to address how human CSF (hCSF) influences neuronal circuits *in vitro*. We validate our approach by comparing the morphology, viability, and electrophysiological function of single neurons and at the network level in rat organotypic slice and primary neurons cultivated either in hCSF or in defined standard culture media.

Summary

Our data indicate that hCSF represents a physiological environment for neurons *in vitro* and a superior culture condition compared to the defined standard media. Moreover, this experimental approach paves the way to monitor the functional consequences of CSF-derived molecules on neuronal circuits.

Title: Control of action potentials by Ca^{2+}-induced Ca^{2+} release

Authors: *T. IRIE[1,2], L. O. TRUSSELL[3];
[1]Oregon Hearing Res. Ctr., Oregon Hlth. Sci. Univ., Portland, OR; [2]Div. of Pharmacol., Natl. Inst. of Hlth. Sci., Tokyo, Japan; [3]Vollum Inst. & Oregon Hearing Res. Ctr., Oregon Hlth. Sci. Univ., Portland, OR

Abstract: Intracellular Ca^{2+} stores in the endoplasmic reticulum (ER) play crucial roles in electrical activity and signal transduction in muscle and neurons. In many cases, the release of ER Ca^{2+} is controlled by ryanodine receptors, which are opened by Ca^{2+} from the cytosolic side and contribute to amplification of Ca^{2+} signaling; this is known as Ca^{2+}-induced Ca^{2+} release, or CICR. In the central nervous system, CICR plays roles in synaptic plasticity and neuronal excitability. However, other physiological roles in the brain are poorly understood. The dorsal

cochlear nucleus of mammals integrates auditory and non-auditory information, and is thought to contribute to monaural sound localization. This region harbors glycinergic cartwheel interneurons, which have long been known to possess abundant subsurface ER cisterns in their cell bodies, and prominent Ca^{2+}-dependent signaling as well.
We investigated CICR-induced changes in cartwheel cell firing in current clamp, and associated outward currents in voltage clamp, using patch-clamp recordings from brainstem slice preparations of P18-26 mice. We also performed intracellular Ca^{2+} imaging by using two-photon microscopy.
Blockade of CICR by ryanodine dramatically changed the spontaneous spike output of cartwheel cells, transforming predominantly spontaneous regular firing into burst firing, and lengthening the duration of spontaneous burst firing. In voltage clamp recordings in the presence of synaptic blockers, 10 to 20 mV depolarizations from -70 mV holding potential led to appearance of spontaneous miniature outward currents (SMOCs), which were inhibited by iberiotoxin (a BK Ca^{2+}-activated K channel blocker), indicating the SMOCs are mediated by the activation of BK channels. The SMOCs were also inhibited by omega-agatoxin 4A (a P/Q-type Ca^{2+} channel blocker) or by ryanodine, indicating that SMOCs are mediated by CICR events triggered by Ca^{2+} influx through P/Q-type Ca^{2+} channels that leads to BK activation. In order to determine the sites of CICR in cartwheel cells, we monitored intracellular Ca^{2+} transients. Action potential-evoked Ca^{2+} transients in immediately under somatic membrane were attenuated by ryanodine, whereas the Ca^{2+} transients in the axon initial segment or in dendrites were not affected, indicating action potential-evoked CICR is present only in cell bodies.
We propose that action potentials rapidly trigger BK channel currents through CICR, and that this process tunes the size and duration of burst firing in cartwheel cells.

Title: Propofol-mediated spike firing suppression is more sensitive in pyramidal neurons than in fast-spiking interneurons in the rat insular cortex

Authors: K. KANEKO[1], Y. KOYANAGI[1], *K. YAMAMOTO[3], Y. OI[1], M. KOBAYASHI[2]; [1]Anesthesiol., [2]Nihon Univ. Sch. of Dent., Tokyo, Japan; [3]Dept. of Pharmacology, Nihon Univ. Sch. of Dent., Tokyo, Japan

Abstract: Propofol is a major intravenous anesthetic, which facilitates $GABA_A$ receptor-mediated inhibitory synaptic currents. Moreover, propofol modulates several ionic currents including I_h, K^+, and voltage-gated Na^+ currents. These propofol-induced modulation of ionic currents results in hyperpolarization of the resting membrane potential, decreasing the input resistance, and suppression of repetitive spike firing in pyramidal neurons in the cerebral cortex. However, it has been unknown whether these ionic currents are modulated by propofol in fast-spiking and non-fast-spiking GABAergic interneurons, which differentially express these ionic channels. The present study aimed to examine whether pyramidal and GABAergic neurons are differentially modulated by propofol in the rat insular cortex. We performed multiple whole-cell patch-clamp recording from pyramidal and GABAergic interneurons that were classified into fast-spiking (FS) GABAergic interneurons and non-FS GABAergic neurons by their spike firing properties. We found that 100 μM propofol commonly hyperpolarized the resting membrane potential and decreased the input resistance in pyramidal, FS, and non-FS neurons. Hyperplarization-induced sag, which was prominently observed in pyramidal neurons but not in the most FS and non-FS neurons, was diminished by propofol. In addition, propofol (100 μM) potently suppressed, in most cases eliminated, the repetitive spike firing in pyramidal, FS, and non-FS neurons. Therefore, quantitative analyses of propofol-induced firing modulation were performed at low concentration of propofol (30-50 μM). We found that 30-50 μM propofol decreased the neural firing of pyramidal neurons but had little effect on that of FS and non-FS neurons, suggesting that pyramidal neurons were most sensitive to propofol among cortical neurons.

Title: Dissecting the functional impact of sphingosine-1-phosphate signaling on pain modulation in the central amygdala

Authors: B. E. MORK[1], R. R. DONAHUE[3], B. K. TAYLOR[3], *P. L. SHEETS[4,2];

Abstract: Inflammation leads to the production of the bioactive lipid sphingosine-1-phosphate (S1P) which sensitizes peripheral nociceptors via activation of one of five G-protein coupled receptors (S1P receptors 1-5). Despite the expression of these receptors in the CNS, the contribution of S1P signaling to supraspinal circuits relevant in pain processing remains poorly understood. The amygdala is a temporal lobe structure essential to the affective component of pain and stress-induced analgesia. S1P stimulates G-protein activity in the amygdala yet the functional effects of S1P signaling on projectionally defined neurons in the amygdala is lacking. The central nucleus of the amygdala (CeA) is the major output pathway of the amygdala and contains a major subpopulation of GABAergic neurons that modulate pain-related behaviors. Using anatomical labeling techniques in the mouse, we identified CeA neurons that send projections to the periaqueductal gray (PAG), a midbrain structure essential to endogenous analgesia. In acute brain slices, the effects of S1P on the intrinsic properties of retrogradely-labeled CeA-PAG neurons were measured using whole-cell electrophysiology. Preliminary results suggest that exogenous S1P hyperpolarizes CeA-PAG neurons leading to a decreased firing frequency. Surprisingly, addition of S1P receptor 1 (S1PR1) agonist SEW2871 depolarized CeA-PAG neurons thereby increasing firing frequency. This suggests that the decrease in excitability caused by exogenous S1P may be mediated by a different S1P receptor. We are currently injecting S1PR agonists and antagonists within the CeA to test the hypothesis that S1P signaling modulates hyperalgesia in an inflammatory pain model. Ultimately, findings from this work may uncover therapeutic targets within intersecting pain and emotional-affective circuity that could lead to novel approaches exploiting S1P pathways for treating both chronic pain and anxiety disorders.

Title: Epileptic mice exhibit increased Kir6.2 in reactive astrocytes

Authors: *P. R. PATRYLO[1,2], A. A. SHARP[1,2], X. YAN[3], C. M. GRIFFITH[1];
[1]Dept of Physiol., [2]Anat., SIUC Sch. of Med., Carbondale, IL; [3]Dept of Anat. and Neurobio., Central South Univ. Xiangya Sch. of Med., Changsha, China

Abstract: Epilepsy is a devastating neurological condition characterized by recurrent spontaneous seizures. Approximately 30-40% of all epileptic cases are medically refractory to available therapeutics thus dictating the need to identify additional targets involved with epileptogenesis and ictogenesis. ATP sensitive potassium channels (K_{ATP}) may be such a target since 1) K_{ATP} channels contribute to the anti-convulsive effects of triamterene, the ketogenic diet and 2-deoxy-D-glucose (2-DG) and 2) defects in K_{ATP} channels (KCNJ11 mutations) underlie DEND syndrome which is characterized by developmental delay, epilepsy and neonatal diabetes. Subsequently, we hypothesized that alterations in K_{ATP} channels could occur in animal models of epilepsy, specifically the pilocarpine-mouse model of temporal lobe epilepsy. Adult male mice (C57Bl6/129; 2-4 months) were treated with methyl-scopolamine (1.2 mg/kg; IP) followed by either pilocarpine (295 mg/kg; IP) or vehicle and then behaviorally monitored to verify status epilepticus. Three to six months following the initial treatment, animals were behavioral monitored (8-10 hrs/week) to assess for spontaneous convulsive seizures. Mice were then sacrificed and their hippocampi were collected and fixed in 4% paraformaldehyde (epileptic pilocarpine-treated mice, n = 4; non-epileptic vehicle-treated controls, n = 4). Cresyl violet staining and immunohistochemistry (IHC) for BACE1 revealed that 100% of epileptic pilocarpine-treated mice, versus 0% of controls, exhibited extensive hippocampal cell loss and mossy fiber sprouting. To examine K_{ATP} channels, IHC for Kir6.2 (one of the pore-forming subunits of K_{ATP} channels) was performed. Saline treated controls exhibited Kir6.2 immunoreactivity (IR) in hippocampal pyramidal cells and dentate granule cells (primarily the cell body) which is similar to what has been previously reported (Zhou et al., 2002). Hippocampal interneurons were also Kir6.2-IR with very little astrocytic staining noted. Slices from epileptic pilocarpine treated mice exhibited a similar pattern of Kir6.2-IR in the remaining hippocampal neurons and strong Kir6.2-IR in the soma and primary processes of reactive astrocytes in both the grey and white matter. This aberrant increase of Kir6.2 in astrocytes was surprising since Kir6.2 has been suggested to be primarily neuronal. While the physiological consequences of this aberrant expression of Kir6.2 in astrocytes is unclear, it is interesting to note that modulation of K_{ATP} channels can affect astrocytic gap junctions which subsequently could affect hippocampal network activity.

Title: Blood brain barrier disruption: a potential mechanism for astrocyte dysfunction in epilepsy

Authors: *J. BONI, A. C. RANDOLPH, L. L. MCMAHON, M. L. OLSEN;
Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Kir4.1, a glial specific, inwardly rectifying potassium channel contributes significantly to astrocyte membrane properties and extracellular K+ homeostasis. Reduced protein expression and channel function is observed in nearly every CNS pathology and astrocyte specific rescue reduces neuronal hyperexcitability and dysfunction, leading to the notion that Kir4.1 may represent a novel therapeutic target. Recent work suggests Kir4.1 downregulation may be due, in part, to extravasation of serum components into the parenchyma upon blood-brain barrier (BBB) disruption. Using a pilocarpine model of status epilepticus and spontaneous recurrent seizures in adult male rats we observed a > 50% reduction in hippocampal Kir4.1 expression 24 hours post status epilepticus that was associated with hippocampal extravasation of Evans blue dye, used as an indicator of blood-brain barrier breakdown. Reduced Kir4.1 protein levels were maintained through the latent period, preceded the onset of spontaneous recurrent seizures and were maintained in epileptic animals. Treatment with Thiamet-G, a specific inhibitor of O-GlcNAcalyation (OGA) previously shown to be neuroprotective, one hour post status epilepticus rescued Kir4.1 levels to that of sham animals. Work underway is aimed at addressing 1) in the context of status epilepticus if BBB disruption is necessary for reduced Kir4.1 expression 2) if treatment with Thiamet-G rescue Kir4.1 protein levels at chronic time points after pilocarpine injection 3) if the rescue of Kir4.1 expression by Thiamet-G occurs by direct action on astrocytes or through attenuating BBB breakdown?

Title: Role of COX-2 mediated endocannabinoid degradation in postictal hypoxia

Authors: *R. COLANGELI[1], J. S. FARRELL[2], K. ADDO-OSAFO[2], M. N. HILL[2], G. C. TESKEY[2];
[1]Dept. Cell Biol. and Anat., [2]Univ. of Calgary, Calgary, AB, Canada

Abstract: The post-ictal period is often associated with acute neurological dysfunction, such as sensory, cognitive, and motor impairments. By using several models of seizures and epilepsy our laboratory has characterized the occurrence of a long-lasting period of hypoperfusion and severe hypoxia (pO_2 below 10 mmHg) which begins immediately after seizure cessation and lasts over an hour in the hippocampus. Furthermore, this local phenomenon is associated with acute postictal behavioural dysfunction that is related to the brain structure involved in the electrographic seizure. Postictal hypoperfusion/hypoxia is completely prevented by the pre-administration, but not post-administration, of Cyclooxygenase-2 (COX-2) inhibitors, which suggests a chief role of COX-2 activation during the electrographic seizure. COX-2 is an inducible enzyme which catalyses the conversion of arachidonic acid to the vasoactive prostaglandins (PG). However, selective inhibition of downstream PGE2 and thromboxane synthesis did not prevent postictal hypoxia. Like COX-2-dependent PG synthesis, the two main endogenous cannabinoids anandamide (AEA) and 2- arachidonoylglycerol (2-AG) are synthesised and released during sustained neuronal activity and increased intracellular Ca^{++} concentration. Seizures cause an intense pattern of neuronal activity, which potently co-activate both the COX-2 and endocannabinoid systems. AEA and 2-AG are primarily inactivated by fatty acid amide hydrolase (FAAH) and monoacylglycerol lipase (MAGL), respectively. Importantly, it has been demonstrated that COX-2 represents an alternative pathway for the breakdown of endocannabinoids and generation of long-lasting vasoactive metabolites. Based on this evidence we hypothesised that the COX-2-derived endocannabinoid metabolites, PG-glycerol esters (PG-G) for 2-AG and PG-ethanolamides (PG-EA or prostamides) for AEA, might be responsible for the long-lasting severe postictal hypoxia induced by electrographic seizures. We expect that administration of a FAAH inhibitor (URB597) or MAGL inhibitor (MJN 110) may worsen postictal hypoxia by increasing COX-2-dependent endocannabinoids degradation, whereas administration of substrate-selective COX-2 inhibitors, which inhibit endocannabinoid and not arachidonic acid breakdown, (LM4131 and (R)-flurbiprofen) may prevent hypoxia following seizures. These experiments contribute to our understanding of the mechanisms of postictal

hypoperfusion/hypoxia and provide further preclinical evidence for the development of new endocannabinoid-based pharmacological tools for the treatment of epilepsy.

Title: Status epilepticus triggers changes in microglia morphology that are associated with specific biochemical properties

Authors: S. K. WYATT, S. A. HERR, *A. L. BREWSTER;
Psychological Sci., Purdue Univ., West Lafayette, IN

Abstract: Long-lasting seizure activity (status epilepticus; SE) is often associated with hippocampal injury and the subsequent development of spontaneous seizures (epilepsy). One hallmark often associated with SE-induced hippocampal injury is activation and accumulation of microglial cells. Under pathological conditions (e.g. seizures) microglial cells develop an inflammatory phenotype that includes a change in morphology from highly ramified to hypertrophied and amoeboid, and the release of immunological messenger molecules such as cytokines. Recently, we reported SE-triggered changes in the morphology and accumulation of microglial cells in the hippocampus. These changes were evident between 1 to 14 days after SE, when microglia changed gradually from highly branched to amoeboid and accumulated in the CA1 hippocampal region. Interestingly, we found little correlation between accumulation of amoeboid microglia and the levels of multiple inflammatory cytokines using whole hippocampal homogenates. Thus, the objective of this study was to identify the cytokine profile expressed in the different morphological states of microglia after SE. SE was induced in rats using the chemoconvulsant pilocarpine and stopped after 1 hour with the anticonvulsant diazepam. Tissue was collected at 14-days after SE for immunohistochemistry. Antibodies against IBA1 or CD11b were used to identify microglia independently of their activation status. Microglial morphological properties were determined by using a 1-5 scale as follows: 1-ramified, 2-bushy/reactive, 3-hypertrophied, 4- amoeboid and 5-rod microglia. To understand the biochemical properties of these different morphologies of microglia, immunofluorescence was used with antibodies against inflammatory cytokines such as IL-1β, TNFα, IL-6, along with CD68 and MHCII. First, we found a significant increase in the total number of microglial cells in

the hippocampi of SE rats compared to the control group ($p<0.05$). Morphological analyses showed that in control hippocampi there was a higher number of ramified microglia compared to the other morphologies. In contrast, SE hippocampi displayed a significant increase in the numbers of amoeboid and rod-shaped microglia compared to the control ($p<0.05$) that correlated with a significant decline in ramified microglia. In addition, we found little to no cytokine expression in branched microglia and different cytokine profiles in hypertrophied, amoeboid, and rod-shaped microglia. These data suggest that SE triggers changes in microglia morphology as well as cytokine expression and that different microglia morphologies may have different functions.

Title: Cytokine-induced uncoupling of hippocampal astrocytes as a cause of human temporal lobe epilepsy

Authors: *P. BEDNER[1], T. DESHPANDE[1], J. MÜLLER[1], D. KHAN[1], M. SYLVESTER[2], V. GIESELMANN[2], P. DE GRAAN[3], C. STEINHÄUSER[1];

Abstract: Glial cells are now recognized as active communication partners in the CNS, and this new perspective has rekindled the question of their role in pathology. Recently, we have compared functional properties of astrocytes in hippocampal specimens from patients with mesial temporal lobe epilepsy (MTLE) with and without hippocampal sclerosis (MTLE-HS). The data showed that the sclerotic human hippocampus is completely devoid of *bona fide* astrocytes and gap junction coupling, whereas coupled astrocytes were abundantly present in non-sclerotic specimens. Employing a new mouse model of MTLE-HS, we could also show that astrocytic uncoupling and the consequential impairment of K^+ clearance temporally precede

neuronal death and the onset of spontaneous seizure activity (Bedner et al. 2015, Brain 138:1208-22). Here we report that similar uncoupling occurs in another seizure model, i.e. hyperthermia-induced febrile convulsions, providing strong evidence that this dysfunction represents a fundamental mechanism in epileptogenesis. Our current results suggest that the inhibition of astrocyte coupling during the early phase of epileptogenesis is not caused by reduced levels of gap junction proteins but by changes in the phosphorylation status of Cx43, as evidenced by Western blot and mass spectrometric analyses. Proinflammatory molecules appeared to mediate this posttranslational modification of Cx43, since astrocyte uncoupling was absent in toll-like receptor 4 knockout mice, could be induced by cytokines *in situ* and *in vivo,* and could be rescued by intraperitoneal injection of Xpro1595, a specific inhibitor of soluble TNFα, or of the antiepileptic drug levetiracetam. These data challenge the commonly accepted neurocentric view of epileptogenesis and demonstrate that astrocytes may be the prime cause of this condition.

Title: Prolonged seizures trigger activation of the classical complement pathway in the hippocampus

Authors: *N. D. SCHARTZ, A. L. BREWSTER;
Dept. of Psychological Sci., Purdue Univ., West Lafayette, IN

Abstract: Prolonged continuous seizure activity (status epilepticus; SE) can severely disrupt the hippocampal circuitry and promote the development of spontaneous recurrent seizures and cognitive deficits. Neuronal and dendritic losses along with remodeling of synaptic connectivity are pathological features often seen in hippocampal tissue resected from individuals with drug-resistant seizures and in experimental models of SE and epilepsy. However, the mechanisms underlying SE-induced remodeling of hippocampal synaptic circuitries are still elusive. Recent evidence points to the classical complement system as a candidate mechanism. The classical complement proteins C1q and C3b are associated with synaptic remodeling in the developing brain and have been shown to be altered in hippocampi from human and experimental epilepsy. Understanding the potential role that the classical complement pathway may play on the

dendritic and synaptic pathology associated with SE requires information on the extent to which C1q and C3b are altered and their distribution. Therefore, the objective of this study was to quantify SE-induced changes in the level and distribution of C1q and C3 proteins. SE was induced in with pilocarpine and stopped after 1 hour with diazepam. Hippocampi were collected at various time points after SE (3-, 14-, 21- and 35-days). Immunohistochemistry (IHC) and Western blots (WB) with antibodies against C1q and C3 along with densitometry analysis were used to identify and quantify subcellular and regional changes. IHC showed that C1q immunoreactivity was localized in the hippocampus of both control and SE rats. In control hippocampi, C1q signal was most evident within the stratum lacunosum moleculare while in SE hippocampi intense C1q signal was localized to the stratum radiatum. Densitometry analysis of immunoreactive signal showed a significant increase in the protein levels of C1q in the SE group compared to controls ($p<0.05$). C1q is the initiating protein of the classical pathway. Thus, an increase in C1q suggests increased activation after SE. WB showed a significant increase in the levels of C3 cleavage along with C3b fragments in the SE group compared to the control group ($p<0.05$). In order to act as an opsonin, C3 must be cleaved. This can occur downstream of C1q signaling. Therefore, an increase in C3 cleavage products further supports activation of at least the classical complement pathway after SE. Taken together these data suggest that SE triggers abnormal activation of the classical complement pathway in the hippocampus. Additional studies are underway to determine the role of this pathway in synaptic alterations associated with SE.

Title: Growth Associated Protein 43 (GAP-43) as a candidate biomarker of epileptogenesis

Authors: ***A. NEMES**[1], K. AYASOUFI[2], Z. YING[1], I. M. NAJM[1];
[1]Epilepsy Ctr., [2]Dept. of Immunol., Cleveland Clin., Cleveland, OH

Abstract: Epilepsy is a common, progressive neurological disorder affecting 1-2% of the population. Although various therapies are available, there is no known cure or biomarker of epilepsy. We have recently shown that growth associated protein 43 (GAP-43), a marker of axonal growth and synaptic plasticity, is highly and differentially expressed in tissue resected from patients with cortical dysplasia (CD), a malformation of cortical development associated with postnatal epileptogenesis. In the current study, we have found parallel results in a rat model

of CD following acute seizures. Baseline expression of GAP-43 was higher in CD rats as compared to controls. Acute seizures resulted in a significant and early increase of GAP-43 expression in both CD and control brains. However, GAP-43 expression continued to increase over time in CD, while returning to baseline in controls. Prolonged EEG monitoring revealed a progressive increase in the frequency of interictal epileptic spikes and the presence of spontaneous seizures in CD rats. Serum GAP-43 was significantly higher in CD rats with spontaneous seizures as compared to non-CD controls and non-epileptic CD rats. Double-labeling studies showed higher co-localization between GAP-43 positive axons and glutamatergic markers as compared to inhibitory markers, perhaps contributing to imbalanced neuronal networks leading to *in situ* small network hyperexcitation. Immuno-electron microscopic imaging supported this result with GAP-43 staining only found located at the growth cones of excitatory axons in a CD rat with spontaneous epilepsy. Finally, injection of a lentiviral vector containing siRNA against GAP-43 significantly decreased seizure duration and severity. Together, these results provide new insight into a potential candidate biomarker for CD and epileptogenesis; as well as a target for the treatment and prevention of progressive or intractable epilepsies.

Title: Histological pathophysiology in models of postmalarial epilepsy

Authors: ***P. SSENTONGO**[1], A. ROBUCCIO[1], F. BAHARI[1], D. G. SIMS[1], J. W. BACCON[2], A. F. READ[1], S. J. SCHIFF[1], B. J. GLUCKMAN[1];
[1]CENTER FOR NEURAL ENGINEERING, PENNSYLVANIA STATE UNIVERSITY, UNIVERSITY PARK, PA; [2]Dept. of medicine, PENNSYLVANIA STATE UNIVERSITY, Hershey, PA

Abstract: Cerebral malaria (CM) annually affects more than 3 million children typically under the age of 5. CM carries a high mortality rate even when treated. Epilepsy occurs in 10-16 % of children who survive CM. We have developed the first murine model of post-cerebral malaria epilepsy (PoME). We report here on histological analysis from the cohort of animals studied for

the development of epilepsy, and correlate the neuropathophysiology with electrographic semiology.
Cohorts of mice of 3 different strain Swiss Webster (SW), CBA, and C57BL/6 were inoculated with Plasmodium *berghei* ANKA (PbANKA) and Plasmodium *berghei* NK65 (PbNK65) infected erythrocytes. After developing severe CM, they were treated with Artesunate and cured of the infection. They were then implanted with electrodes and chronically monitored with video/EEG for development of seizures. Littermate controls were inoculated with uninfected erythrocytes and treated identically to infected animals. EEG was analyzed to identify seizures, which were then scored for electrographic origin and evolution.
Following chronic recording, their brains were fixed, sectioned and stained with GFAP and NeuN for astrocytes and neurons. Sections were analyzed using stereological technique to quantify hippocampal volume and region-specific cell densities. These quantities along with peak infectious phase Parasitemia were then correlated with animal specific seizure semiology. Infected animals showed a range of morphological changes that included significantly expanded ventricles, damaged cortices, and asymmetrically affected hippocampi.
There is an urgent need of effective adjunct therapy during and following CM to mitigate the effects of the insult and prevent chronic irreversible brain damage and associated deficits. This murine model of PoME will provide a useful platform to test mechanistic approaches for such interventions.

Title: Energy metabolism activity in slices of dorsal and ventral hippocampus.

Authors: *A. I. IVANOV, G. BRANCATI, C. RAWAS, C. BERNARD;
INS, UMR1106, Marseille Cedex 05, France

Abstract: Differences in anatomical connectivity, gene expression patterns, and neuronal excitability in the dorsal and ventral regions of the hippocampus are well characterized. These differences account for the regional particularity of the neuronal network activity but do not explain why the ventral hippocampus is more prone to seizure genesis than the dorsal hippocampus. Since the ventral hippocampal network is more excitable than the dorsal therefore,

it can be proposed that the ventral hippocampus requires more energy supply. However, the regional specificity of energy metabolism in the hippocampus is not known.
Using local field potential recodings coupled either with NAD(P)H/FAD^+ imaging or with glucose, oxygen, and lactate sensing, we investigated metabolic activity induced by neuronal network stimulation in ventral and dorsal hippocampal slices of adult control mice and mice with epilepsy (pilocarpine model).
In control animals, we found that neuronal network activity induced by Schaffer collateral electrical stimulation was accompanied by similar decreases in tissue oxygen in ventral and dorsal slices, indicating equal level of the oxidative metabolism in both hippocampal regions. However glucose consumption was 2-5 times higher in ventral slices than in dorsal, indicating a high level of non-oxidative glucose utilization. The analysis of the NAD(P)H/FAD^+ fluorescence transients induced by the same neuronal network stimulation protocol showed no regional difference in the oxidative metabolism but revealed higher intensity of the cytosolic glycolysis in ventral than dorsal slices. Thus, to meet its high-energy demand, the ventral hippocampus network takes advantage of paralleled use of both oxidative and non-oxidative glucose metabolism pathways whereas for the dorsal network the yield of oxidative metabolism is sufficient.
We applied the same experimental paradigm in the experimental model of epilepsy. We found that the pathology erased a regional difference in metabolic signals mainly via a dramatic decrease of non-oxidative metabolism activity in ventral slices. All together our results suggest that i) there is a regional difference in energy metabolism activity; ii) to meet the energy demand required to fuel higher excitability, the ventral network takes advantage from parallel use of non-oxidative and oxidative metabolic path-ways; iii) in experimental epilepsy, non-oxidative cytosolic glycolysis is highly reduced leading to energy deficit that may contribute to the seizure genesis and/or propagation.

Title: Alzheimer's related disease pathologies following nerve agent-induced seizures.

Authors: *D. L. SPRIGGS, J. L. WINKLER, C. E. KAROLENKO, K. M. BOWENS, J. W. SKOVIRA;
USAMRICD, Gunpowder, MD

Abstract: Recent epidemiological and animal studies have suggested a link between organophosphate (OP) exposure and dementia related diseases such as Alzheimer's disease. Typically affecting individuals 65 and older, Alzheimer's disease causes progressive neurodegeneration and is the sixth leading cause of death in the US. Alzheimer's related pathologies are characterized by deposits of the protein fragment beta-amyloid (Aβ plaques) and abnormal twisting of strands of the protein tau (neurofibrillary tangles). Substantial evidence supports that aggregated Aβ and neurofibrillary tangles are sources of neurodegeneration. In this study we evaluated the progression of Alzheimer's related pathologies in Sprague Dawley rats after the onset of seizures induced by the organophosphorus nerve agent soman. Rats were pretreated with HI-6 (125 mg/kg, ip) 30 min prior to receiving soman (180 ug/kg, sc). This dose of soman is known to reliably elicit seizures in 100% of exposed animals. Atropine methylnitrate (2.0 mg/kg, im) was administered 1 min after soman exposure to increase survival. Control animals were given an equivalent volume of saline in place of a soman injection. Animals were euthanized 8 weeks following soman exposure. Our data show that the hallmarks of Alzheimer's related pathologies, beta-amyloid plaques and neurofibrillary tangles, are present in the cortex and hippocampus 8 weeks following exposure to the nerve agent soman. The rapid onset of Alzheimer's related pathologies following soman exposure highlight the need to investigate treatments to mitigate the development of these pathologies. If left untreated, OP casualties could face lifelong consequences and potentially early death from the development of these pathologies.

Univ. Hosp. Erlangen, Erlangen, Germany

Abstract: Background: Neonatal seizure is a common pediatric emergency. During the acute seizure activity glutamate mediated excitotoxicity may contribute to aberrant apoptosis in the developing brain increasing the risk of survivors for developmental delay and later epilepsy. Since calcium-permeable α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors have important implication in disturbing glutamatergic transmission as well as early maturational glial and neuronal programs, we analyzed acute effects of pilocarpine-induced neonatal seizures on age- and region-specific cerebral expression of AMPA receptor subunits and AMPA receptor editing adenosine deaminases acting on RNA (ADAR).
Methods: Neonatal (P10) C57BL6/NCrl mice were injected intraperitoneally with methylscopolamine bromide (1 mg/kg, i.p.) and pilocarpine (400 mg/kg, i.p.). Seizures were terminated by diazepam (5 mg/kg, i.p.) 90 minutes after seizure onset. Thereafter, tissue preparation was performed after a regeneration period of 1 h, 24 h, and 72 h. Expression of AMPA subunits (GluR1, GluR2, GluR3, GluR4) and ADAR enzymes (ADAR1, ADAR2, ADAR3) was analyzed by real-time RT-PCR and immunohistochemistry. Induction of apoptosis-related gene expression (*bnip3*, *dusp1*, *ier3*) was monitored by real-time RT-PCR. Additionally, brain region specific apoptotic cell death was quantified by TUNEL and active caspase 3 staining.
Results: While absolute mRNA levels of AMPA receptor subunits GluR1, GluR2, GluR3, and GluR4 remained unaffected post pilocarpine-induced seizure activity, composition of the $GluR_{1/2/3/4}$ mRNA pool changed significantly within 1 h in pilocarpine-treated mice compared to controls. Thereby, the relative expression of GluR2 and GluR4 decreased significantly by 55% and 53%, respectively. While the mRNA level of regulatory ADAR3 remained stable over time, mRNA transcription of enzymatic active ADAR1 and ADAR2 enzymes was downregulated 24 h post pilocarpine treatment correlating with aberrant expression of BNIP3 and DUSP1 and increased TUNEL-positive cells in the subventricular zone.
Conclusions: Considering a crucial role of RNA-edited GluR2 for the permeability of AMPA receptors for calcium ions and subsequently calcium ions mediated neurotoxicity, aberrant expression of GluR2 as well as of the GluR2 pre-mRNA editing enzyme ADAR2 may explain enhanced and region specific activation of caspase 3 stimulated apoptosis. In conclusion, AMPA receptor antagonist may be a promising target to abolish excitotoxicity-induced neuronal loss in the developing brain.

Title: A novel inducible mouse model of Dravet syndrome

Authors: *M. SASNER[1], J. MORGAN[1], L. GOODWIN[1], K. CHENG[2], S. J. SUKOFF RIZZO[1], A. MINGORANCE[3];
[1]The Jackson Lab., Bar Harbor, ME; [2]Charles River Labs, Wilmington, MA; [3]Dravet Syndrome Fndn. Spain, Madrid, Spain

Abstract: Dravet syndrome (also called severe monoclinic epilepsy of infancy) is a rare, genetically determined disease with no effective therapies. Comorbidities include cognitive impairments, hyperactivity, attention deficits, delayed psychomotor development, sleep disorders, anxiety-like behaviors, impaired social interactions and premature death.
Existing Dravet mouse models are not ideal for therapy development projects for various reasons. Some have early onset lethality that prevents shipping and sharing of mice. Most are not widely available for drug testing efforts due to legal restrictions.
To address this need, we have developed a novel inducible model that is available for drug development projects with a no-cost license: B6(Cg)-*Scn1a*$^{tm1.1Dsf}$/J (#26133). Expression of the *Scn1a* gene is normal until exposed to *cre* activity, when the floxed wild-type exon 26 is deleted and an engineered exon 26 carrying the A1783V mutation (as found in human patients) is expressed. This means that un-induced mice are normal and healthy and can be easily distributed. As verified by sequencing of mRNA, mutant *Scn1a* expression can be induced in specific neuronal subsets by mating to the appropriate *cre*-expressing strain. The JAX mouse repository has wide variety of both broadly- and specifically-expressed *cre* lines. The engineered *Scn1a* allele is on a B6 genetic background. Initial experiments with mice generated using a ubiquitous *cre* on a C57BL/6J genetic background resulted in lethality at ~ 3 weeks of age consistent with reports from other Dravet mouse models. However, a significant percentage of mice generated using a ubiquitous *cre* on a 129S1 genetic background survive (preliminary results indicate that nutritional support promotes viability) and have potential to be used for evaluating novel therapies for Dravet syndrome.
We will present detailed characterization of both the seizure and comorbid neuropsychiatric phenotypes of this novel line. We expect that making this model and corresponding *cre*-expressing mice lines easily available will facilitate its use as a drug screening platform and the development of effective therapies for Dravet syndrome.

Title: Investigation of doublecortin, GABA and V-GLUT immunoreactivties in the hippocampus of genetic absance epileptic rats: an ultrastructural study

Authors: *O. T. CILINGIR KAYA[1], D. GURSOY[1], C. MOORE[3], C. K. MESHUL[4,3], F. ONAT[2], S. SIRVANCI[1];

Abstract: The subventricular zone of the lateral ventricles and the dentate gyrus (DG) of the hippocampus are two distinct areas of the brain in which neurogenesis occurs throughout the lifetime period. Recent studies report that there is a relation between neurological disorders and neurogenesis. It is generally accepted that imbalances between GABA-mediated inhibitory and glutamate-mediated excitatory neurotransmissions which induce spike and wave discharges play an important role in the pathogenesis of epilepsy. Genetic absence epilepsy rats from Strasbourg (GAERS), the animal model of absence epilepsy, is a strain in which hippocampal neurogenesis has not yet been investigated. Since the age of animals is one of the determinant features on neurogenesis, we used both 21-day- and 3-month-old rats from GAERS and Wistar control rats.
In the present study, we questioned whether newly born neural cells form synapses with GABAergic and glutamatergic structures and thus integrate into the local circuitry. For this purpose, brain tissues were obtained after intracardiac perfusion fixation and 300 μm-thick

coronal vibratome sections were collected. DG regions were dissected from the sections and processed for electron microscopic assessments. For immunocytochemical investigations, ultrathin sections were obtained by using an ultramicrotome and double-labeled either for doublecortin (DCX), as a marker of immature neurons, and GABA or DCX and vesicular glutamate transporter 1 (VGLUT-1) using postembedding immunogold method. Labeled sections were photographed on a transmission electron microscope. NIH Image Analysis (Image J) was used for the quantitative analysis. One-way anova and Tukey tests were used for the statistical analysis.
In all groups, DCX was seen co-localized with both GABA or VGLUT-1 in axon terminals, dendrites and somata. We observed that newly born DCX-positive neurons synapsed not only with GABAergic or glutamatergic profiles but also with DCX-positive cells. While DCX-positive profiles including GABA showed a tendency to increase in 21-day-old groups compared to 3-month-old groups; profiles double-labeled for DCX and VGLUT1 showed an increase in 3-month-old groups compared to 21-day-old groups. Besides, DCX labeling was significantly increased in profiles forming asymmetrical synapses compared to those forming symmetrical synapses.
In conclusion, our findings in the present study suggest that newly born DCX immunoreactive neurons synapse with GABAergic and glutamatergic neurons and thus contribute to the local hippocampal circuitry in absence epileptic immature and adult rats.

Title: Postictal respiratory dysfunction is the primary cause of Sudden Death in a Dravet mouse model

Authors: *E. BRAVO[1,2], Y. KIM[3], G. B. RICHERSON[4,2,5];
[2]Neurol., [3]Biomed. Engin., [4]Mol. Physiol. and Biophysics, [1]Univ. of Iowa, Iowa City, IA;
[5]VAMC, Iowa City, IA

Abstract: Sudden death is one of the most common causes of death in Dravet Syndrome (DS) patients with refractory epilepsy. The mechanism is still undefined. In a DS mouse model with an *Scn1a*$^{R1407X/+}$ mutation, death occurs after spontaneous or induced seizures. Experiments on DS mice have shown that postictal death after induced seizures is due to bradycardia and asystole [Kalume et al, 2013]. Postictal bradycardia and death can be prevented in DS mice with atropine, suggesting the mechanism involves excessive vagal tone. However, postictal breathing has not been measured during experiments in DS mice, so it is unknown if respiratory dysfunction contributes to postictal death. Here we studied mice with an *Scn1a*$^{R1407X/+}$ mutation to determine the role of respiratory dysfunction in postictal death after spontaneous and heat-induced seizures.Spontaneous and induced seizures were monitored in a mouse EMU while recording EEG, EMG, EKG, whole body plethysmography (breathing), body temperature, room temperature, and humidity. To induce seizures by hyperthermia, DS mice were exposed to a heat lamp to cause a continuous increase in body temperature to 43° C. To study death after spontaneous seizures, DS mice were continuously monitored in a mouse EMU for 24 hours per day until postictal sudden death spontaneously occurred. In a separate set of experiment mice was exposure to hypoxia in a plethysmography chamber changing gases from 21%O_2 to 100% N_2, while monitoring EKG and breathing.

When the last tonic spontaneous or induced seizures occurred, mice invariably had apnea followed by death. When terminal apnea occurred, EKG activity continued for 3-5 minutes with progressively worsening bradycardia followed by asystole. Death could be prevented after heat induced seizures by mechanical ventilation. Bradycardia and death could also be prevented with 1 mg/kg atropine, but at that dose seizures were not followed by apnea. Two days later, the same atropine dose did not prevent apnea, bradycardia or death. Atropine given at a dose of 0.03 mg/kg, which is sufficient to block peripheral muscarinic receptors, did not prevent apnea, bradycardia or death. Exposure of wild-type mice to anoxia led to progressive bradycardia that was not prevented by 1 mg/kg atropine.

We conclude that primary respiratory arrest can play an important role in death due to spontaneous and induced seizures in DS mice with a *Scn1a*$^{R1407X/+}$ mutation. Bradycardia and asystole were due to hypoxia resulting from the apnea, and not due to parasympathetic inhibition of the heart. These data may lead to an understanding of SUDEP mechanisms in DS patients, as well as shed light on possible therapeutic approaches to prevent SUDEP.

Title: West Syndrome-associated mutation GABRB3(N110D) produces spontaneous seizures and electroencephalogram abnormalities in mice.

Authors: *L. G. JACKSON[1], S. QU[2], V. JANVE[3], C. C. HERNANDEZ[2], R. L. MACDONALD[2];

Abstract: Epileptic encephalopathies are severe neurological disorders characterized by multiform and intractable seizures and cognitive and behavioral deficits. For example, West Syndrome patients have infantile spasms that generally begin in the first year and about one half of patients will have other seizure types including partial, myoclonic, tonic, and tonic-clonic seizures. EEGs have a hypsarrhythmia pattern. We have made a knock-in mouse model of a WS-associated mutation in the β3 subunit of the $GABA_A$ receptowr, *GABRB3(N110D)*. We have previously shown that *GABRB3(N110D)* produces abnormal GABA currents in HEK293T cells, however surface expression of mutant-containing receptors remains unchanged. This suggests that trafficking of mutant receptors is not impaired, but the receptors do not function properly. Animals expressing the mutation have spontaneous seizures, including tonic-clonic, myoclonic and tonic jerks, head and forelimb "jerks" followed by brief periods of immobility. Electroencephalographic recordings of *Gabrb3*$^{+/N110D}$ mice with video-synchronized EEGs for 24 hour periods has shown multiform changes. The characterization of this mouse model of an epileptic encephalopathy aims to uncover behavioral mechanisms underlying the disease in order to better identify alternative interventions for patients with WS.

Title: Mice harboring the Lennox-Gastaut syndrome associated GABRB3(D120N) mutation exhibit spontaneous seizures and electroencephalogram abnormalities.

Authors: *V. S. JANVE[1], S. QU[2], R. L. MACDONALD[2];
[1]The Grad. Program of Neurosci., [2]Neurol., Vanderbilt Univ., Nashville, TN

Abstract: The Lennox-Gastaut syndrome (LGS) is a rare but catastrophic childhood epilepsy with an early onset, multiple seizure types, a characteristic electroencephalogram (EEG) pattern, motor delays and neuropsychiatric disorders. Most patients have intractable seizures. The cause of LGS remains unknown for about a third of the patients, and currently there are no animal models to study the disease pathogenesis. We have generated a mouse harboring the LGS-associated *GABRB3(D120N)* mutation to address this need. Our *in vitro* studies demonstrated that the *GABRB3(D120N)* mutation markedly reduced GABA-evoked currents by reducing GABA potency but not the surface levels of $GABA_A$ receptors, altered single channel properties, and perturbed the GABA binding site (Janve et al. 2016). The mice with the *GABRB3(D120N)* mutation had multiple types of spontaneous seizures including typical absences, atypical absences (characteristic of LGS), head drops, Straub tail, and tonic seizures. Here we report the results from the synchronous electroencephalography (EEG)-electromyography (EMG)-video monitoring of freely moving mice (4-6 months old), carried out for ~24 hours. Our preliminary findings show that compared to C57Bl/6 control mice the mutant mice had significantly increased number of typical absence seizures (peak 4-6 Hz), and atypical absence seizures (peak 2-3 Hz) associated with behavioral arrest, especially during the light period (inactive time for mice). The typical and atypical absence seizures lasted for less than 10s and greater than 100s, respectively. Several head drop events were also accompanied during typical and atypical absence seizures. The mutant mice also had hundreds of rearing events during the dark period (active time for mice), along with repetitive movements in circles around the edge of the cage. These results indicate that the mice harboring the *GABRB3(D120N)* mutation could be a valuable model for studying LGS.

Title: GABRB3(D120N), a Lennox-Gastaut Syndrome-associated mutation, induces behavioral abnormalities in mice

Authors: *M. CATRON[1,2], S. QU[1], V. JANVE[1,2], C. C. HERNANDEZ[1], R. L. MACDONALD[3];
[2]Neurosci. Grad. Program, [3]Neurol., [1]Vanderbilt Univ., Nashville, TN

Abstract: Lennox-Gastaut Syndrome (LGS) is an epileptic encephalopathy, a severe form of epilepsy, which is often intractable and characterized by early childhood onset (age 1-8), an abnormal electroencephalogram (EEG), and a broad range of seizure types. Additionally, it is often accompanied by several comorbidities, including attention deficit hyperactive disorder, severe intellectual impairment, and other abnormal behaviors. A *de novo* mutation, *GABRB3*$^{+/D120N}$, was identified in a patient with LGS. The D120N mutation is in the β3 subunit of the γ-aminobutyric acid type-A receptor ($GABA_AR$), and is specifically located near the GABA binding pocket formed by this subunit. After initial *in vitro* evidence that D120N impairs $GABA_AR$ function, we generated a knock-in mouse containing the mutation. We hypothesized that this animal would not only have a similar seizure phenotype to the patient condition, but that the animal would have similar behavioral abnormalities as can be seen in both LGS patients and in the D120N patient specifically. The work presented here is a suite of behavioral tests aiming to compare the D120N mouse and human LGS. We have performed preliminary tests which have revealed abnormalities in anxiety, hyperactivity, and cognitive ability in the D120N mice. We hope that sufficient parallels may be drawn between the D120N mouse and LGS such that this animal might serve as a model for this disorder, allowing us to further investigate mechanisms underlying the disorder and potentially identify novel or modified treatment options for patients with LGS.

Title: Early life febrile seizures worsens epilepsy and behavioral phenotypes in adult GEFS+ mutants

Authors: *S. B. DUTTON[1,2], L. A. PAPALE[2], A. P. ESCAYG[2];
[1]Biology/ Neurosci. Program, Agnes Scott Col., Decatur, GA; [2]Emory Univ., Atlanta, GA

Abstract: Mutations in the voltage gated sodium channel (VGSC) gene *SCN1A*, which encodes the alpha subunit of the $Na_v1.1$ VGSC, are responsible for a number of epilepsy disorders including genetic epilepsy with febrile seizures plus (GEFS+) and Dravet Syndrome (DS). A common feature of patients with *SCN1A* mutations is the frequent occurrence of early-life febrile seizures (FSs). The presentation of FSs in this patient population is often more prolonged and severe than typically observed, raising the possibility that these early life events may influence epileptogenesis. To gain a better understanding of this relationship, we first investigated whether prolonged early-life FSs influence adult seizures phenotypes. To achieve this, we developed two paradigms; one modeling a single prolonged FS, and the other modeling repetitive FSs. Mice subjected to each were evaluated for seizure susceptibility and spontaneous seizure frequency at 2 - 7 months periods post FS induction. Of important clinical relevance, we found that early-life prolonged FSs reduces seizure thresholds and increases the frequency of spontaneous seizures during adulthood. In addition, the early-life FSs resulted in hyperactivity and impairments in social behavior and recognition memory during adulthood. Lastly, we determined the possible contribution of neuroinflammation to these behaviors by tracking expression of 84 genes 6-hrs after exposure to the early-life FSs paradigm. Findings from this study highlight the long-term negative impact of early-life FSs on disease outcomes in this patient population and the need for therapeutic interventions that could ameliorate disease progression.

Title: Cas9-targeted KCNQ5 KO creates a mouse model for late-onset epilepsy

Authors: *A. D. WEI[1], F. KALUME[1,2], A. M. BARD[1], N. SAHAI[1], P. WAKENIGHT[1], T. ZWINGMAN[1], W. DOBYNS[1,3], K. MILLEN[1,3], J.-M. RAMIREZ[1,2];

[1]Seattle Children's Res. Inst., Seattle, WA; [2]Dept. of Neurolog. Surgery, [3]Dept. of Pediatrics, Univ. of Washington, Seattle, WA

Abstract: The mammalian KCNQ (Kv7) gene family encodes voltage-gated K^+ channel subunits that assemble in homomeric and heteromeric combinations to conduct M-currents, in association with a family of single-transmembrane accessory subunits (KCNE1-5). Four of the 5 members of the KCNQ gene family are linked to human hereditary channelopathies affecting cardiac, brain and auditory function, with the conspicuous exception of KCNQ5. Amongst the KCNQ genes, KCNQ5 uniquely expresses in both CNS and muscles, including vascular smooth muscles. We now report a mouse model for late-onset epilepsy caused by Cas9-targeted knockout of KCNQ5. Cas9/sgRNA was constructed to target a PAM site in exon 5 which encodes the extracellular turret domain 5' of the P-selective filter. Hybrid Black Swiss-C57BL/6J ES cells were transfected, and one ES clone carrying two independent biallelic deletions was selected for blastocyst injections. These targeted deletions resulted in frameshift mutations truncating the predicted channel protein within the turret domain. Both deletions thus likely result in loss of function selective for KCNQ5 homomeric channels, in contrast to a previously created dominant-negative KCNQ5 mouse line (T. Jentsch Lab) which may also inactivate heteromeric channels, since heteromerization association domains encoded in the cytosolic C-terminal domain are absent in our lines. Founder mice were recovered and bred to create homozygous lines for each of the two KCNQ5 deletional KOs. Homozygous KCNQ5 KOs are viable, but exhibit reduced fecundity and overt behavioral seizures beginning at mature adult ages (>P150). Seizures were observed with mild stressors such as cage changing, and manifested as both tonic clonic convulsions and absence-type behavioral arrests. Extended video/cortical EEG recordings from mature KCNQ5 KO animals revealed abnormal baseline high frequency activity and numerous interictal spikes. Propensity for abnormal EEG activities was increased following acute sleep deprivation. KCNQ5 KO animals also exhibited thermal seizures when their body temperatures were elevated to 40^o, indicative of susceptibility to febrile seizures. In addition, younger adults (~P50) were hyperactive by open-field assays. Taken together, these observations suggest that KCNQ5 is a significant new mammalian susceptibility gene for epilepsy.

Abstract: Several mutations causally linked to epilepsy have been identified in genes coding for ion channels and/or involved in neuronal development and synaptic transmission. An array of mutations in the Syn genes in human has been associated with epilepsy and/or autism spectrum disorders, diseases that display a frequent comorbidity. Although a plethora of drugs for the treatment of epilepsy are available, the disease cannot be adequately controlled in a relevant percentage of patients. Here, we report that the eEF2K/eEF2 pathway is essential for regulating excitation/inhibition balance in hippocampal circuits. We found that loss of eEF2K increased GABAergic synaptic transmission while up-regulating a defined subset of synaptic proteins. Because pharmacological or genetic inhibition of eEF2K can revert susceptibility to seizure in the Synapsin I knockout mice, we suggest that eEF2K is a potential novel target for antiepileptic drugs.

Title: Neuropathology of Munc18-1 mutants underlying infantile epilepsies

Authors: ***N. G. L. GUIBERSON**[1], A. PINEDA[1], K. E. CARNAZZA[1], J. S. DITTMAN[2], J. BURRÉ[1];
[1]Brain and Mind Res. Inst., [2]Dept. of Biochem., Weill Cornell Med., New York, NY

Abstract: Munc18-1 controls neurotransmitter release by regulating the SNARE protein syntaxin-1. Mutations in Munc18-1 are associated with Ohtahara, West, and Dravet syndromes, three devastating infantile epileptic encephalopathies. However, the mechanistic relationship between Munc18-1 mutations and these diseases is unknown. We aim to determine how mutations in Munc18-1 cause neuronal dysfunction. We hypothesize that these disease-related mutations cause defects in its folding, stability and localization, which subsequently impair syntaxin-1 and synapse function. Stability and turnover of Munc18-1 mutants were analyzed in transfected N2a cells via cycloheximide chase experiments. Solubility profiling, limited proteolysis, and immunocytochemistry were used to assess aggregation of Munc18-1 mutants. Syntaxin-1 stability, turnover, aggregation, and subcellular localization were assessed by the same paradigms used for Munc18-1. We found that Munc18-1 mutants are unstable and are turned over faster than wild-type Munc18-1. Mutants also demonstrated aggregation and decreased solubility. The reduction in Munc18-1 levels triggered a corresponding decrease in syntaxin-1 levels and stability, suggesting a loss-of-function disease mechanism of both Munc18-1 and syntaxin-1. To analyze the effect of Munc18-1 mutants on synapse function *in vivo*, we generated transgenic *C. elegans* strains overexpressing wild-type unc18 or the G544D mutant on an unc18 null background, and quantified the ability of these overexpressions to rescue the unc18 null phenotype by locomotion, heat shock, and aldicarb assays. Wild-type unc18 but not the G544D mutant ameliorated the synaptic defects in unc18 null worms. GFP-tagged wild-type unc18 showed diffuse somatic and axonal distribution while the G544D mutant aggregated. Overall, this work provides insight into the basic pathobiology of mutant Munc18-1 by demonstrating its instability, tendency to aggregate and impaired interaction with syntaxin-1 *in vitro*, as well as its profound mislocalization and failure to rescue synaptic function *in vivo*.

Hotchkiss Brain Institute, Univ. of Calgary, Calgary, AB, Canada

Abstract: Chronic temporal lobe epilepsy (TLE) involves prominent and progressive sclerosis and atrophy of the mesial temporal lobe which is thought to contribute to epileptogenesis. Given that amyloid-β (Aβ) is synaptically released in an activity-dependent manner, we hypothesized that seizures promote the generation and accumulation of β-amyloid. These deposits of potentially toxic Aβ aggregates might establish foci of neurodegeneration in the temporal lobe, leading to sclerosis and degeneration in these key areas, and thus contributing to the pathogenesis of TLE. To enhance the deposition of Aβ released by excessive electrical activity, here we chose to study the effect of seizures in 5XFAD transgenic mice, which harbor transgenes for five human familial AD (presenilin and amyloid precursor protein) mutations. Mice were implanted with unilateral hippocampal electrodes and received no stimulation (sham group; n = 14) or 60Hz kindling stimulation to elicit 21 hippocampal seizures (seizure group; n = 14) between the ages of P30 and P60 prior to perfusion and tissue collection at P61. Because we previously found that hypoxia occurs after seizure induction, and that this effect is COX-2 dependent and can be prevented with acetaminophen, we also treated half of the mice in each group with acetaminophen to examine the role of concomitant hypoxia in Aβ deposition. Amyloid deposition was assessed microscopically using tissue sections stained with the fluorescent amyloid probe X-34. **Results**: Seizure duration and severity (Racine scale) did not differ between vehicle- and acetaminophen-treated mice. Sham (seizure-free) control mice showed no amyloid deposition in the hippocampi at P61. In contrast, mice subjected to unilateral stimulation exhibited marked bilateral amyloid deposition in both hippocampi, and novel object recognition testing revealed significant memory impairment in this group. Acetaminophen prevented hippocampal hypoxia and memory impairment, and partially reduced amyloid deposition, indicating a significant contribution of hypoxia to the seizure-induced hippocampal amyloidosis. **Conclusion**: Seizure-related electrical hyperactivity promotes significant hippocampal amyloid deposition in the 5XFAD transgenic mouse. While this strain was deliberately chosen to exaggerate plaque generation, reports of AD-like amyloid pathology in human TLE raise the possibility that chronic (possibly subclinical) seizure activity promotes potentially toxic amyloid deposition that contributes to the pathogenesis of TLE.

Title: mTOR-dependent changes in cellular morphology following GATOR complex subunit knockdown: novel insights into DEPDC5 and NPRL3 associated cortical malformation

Authors: *P. H. IFFLAND, M. BAYBIS, P. B. CRINO;
Lewis Katz Sch. of Med. Temple Univ., Philadelphia, PA

Abstract: Malformations of cortical development (MCD) are common causes of neurological deficits in children including seizures and intellectual disability. Recent studies have found loss-of-function mutations in genes encoding the DEPDC5 and NPRL3 subunits of the mTOR regulatory complex GATOR 1. These mutations have been linked to various MCD-subtypes associated with seizures. However, the cellular consequences of these mutations remain undefined. We hypothesize that knockdown (KD) of DEPDC5 or NPRL3 leads to enhanced cell size, altered cell polarity, and altered subcellular localization of mTOR.
Multiple cells lines, including HEK 293FT, N2A and mouse neural progenitor cells (mNPCs) were used to define the morphological consequences of shRNA KD of DEPDC5 or NPRL3 compared to control scramble shRNA construct. Cell size was assessed by FACS or direct measurement of the soma in digital images. Outgrowth of actin labeled filopodia in mNPCs was assessed in digital images. The mTOR dependency of DEPDC5 or NPRL3 KD was determined using rapamycin (50 nM, 48hrs) or a p70S6 kinase inhibitor (PF-4708671; 1nM, 48 hrs.). Functional localization of mTOR to the lysosomal membrane or cytoplasm following DEPDC5 or NPRL3 KD was determined by immunochemical staining and colocalization analysis examining the proximity of mTOR to the lysosomal surface (LAMP 2 staining) with or without rapamycin or PF-4708671 treatment.
HEK 293FT and N2A cells transfected with DEPDC5 or NPRL3 shRNA were larger than scramble control or wildtype cells based on FACS analysis (n= 100,000 cells per group). Direct measurements of mNPCs revealed a larger soma size in DEPDC5 or NPRL3 KD cells compared to scramble control (n= 50; $p < 0.05$). mNPCs transfected with DEPDC5 or NPRL3 shRNAs displayed an increased number of filopodia versus scramble control (n= 50 per group; $p < 0.05$). DEPDC5 or NPRL3 transfected cells treated with rapamycin or PF-4708671 were significantly smaller in size as measured by both FACS (N2A and HEK 293FT; n= 100,000) and direct measurement (mNPCs, n= 50). There was a higher degree of mTOR and lysosomal protein

colocalization in KD versus rapamycin treated cells following DEPDC5 or NPRL3 KD in mNPCs. As PF-4708671 acts downstream of mTORC1, no change was observed in colocalization in treated cells.
We demonstrate changes in cellular morphology in multiple cell lines after DEPDC5 or NPRL3 KD. These findings recapitulate what is observed in patients with DEPDC5 or NPRL3 mutations and a rat model of DEPDC5 knockout. Further, we have defined the mTOR–dependency of these morphological abnormalities, which may provide novel avenues for treatment of MCDs associated with GATOR complex subunits.

Title: Network dysfunction in Arx expanded mice; developing an insight into a pediatric epileptic network.

Authors: *F. SIDDIQI, A. MCCOY, L. OLEAR, D. JOSEPH, E. MARSH;
Dept. of Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: ARX is a transcription factor expressed throughout interneuron development. Mutations in ARX lead to a range of neurological disorders with epilepsy being common to all cases. Little is known about why children with ARX mutations have seizures and developmental delays. To address this question, we have utilized an Arx mutant mouse (Arx^{E}) that recapitulates some of the human phenotypes. We previously demonstrated aberrations within hippocampal interneurons and pyramidal cells as well as local CA1 network dysfunction. To further probe the network level dysfunction in Arx^{E} mice we recording neuronal activity using in-situ multi electrode array (MEA) and in vivo multi-unit recordings.
Post-natal day (P)30 to P52,Arx^{E} mice and age matched WT littermates, both on a Bl6 background were employed. For MEA recordings, 350 µm Hippocampal-entorhinal cortical slices were prepared using Leica Vibratome in aCSF with 192mM sucrose and then incubated at 37°C in a water bath for 45 min and then equilibrated to room temp for 1 hr in recording aCSF. The slices were then transferred to the MEA (Multi Channel Systems) recording system that spans the hippocampus. 15 min of baseline gap-free data was collected, followed by an IO

stimulus protocol and finally a repetitive stimulus protocol (2s, 60Hz train, 100μs pulse width with 10min intervals repeated 3x's). For in vivo recordings in house made 25um tetrode bundles were placed into CA1, CA3 regions in the hippocampus using a microdrive. Unit activity was recorded and analyzed using DataWave Software. Finally, immunohistochemistry was performed using NeuN and Delta FosB.
MEA recordings demonstrated increased unit firing and ictal discharges in Arx^{E} mice in the CA3 region compared to controls while CA1 is hypo-excitable, with reduced unit firing and fewer ictal discharges. Further analysis of I/O curves is pending. In vivo multi-unit recording was performed to determine if the changes in network level activity in the slice are present in vivo. Lastly, our histological studies demonstrate no changes in neuronal numbers in CA1 (NueN staining) with paradoxical hyperactivation of CA1 compared to CA3 as determined by an increase in Delta FosB activity.
First, we confirm our previous studies showing hypoexcitability in CA1 using a different approach to record network activity. The MEA results demonstrate local network dysfunction, which is also confirmed with delta FosB staining. The dynamic alterations in activity in CA3 and CA1 lead to the epileptic phenotype in these Arx^{E} mice. By highlighting regions of dysfunction in the ARX mice we can begin to consider targeted approaches to restoring normal function.

Title: A de novo mutation in KCNT2 (SLICK) gene produces a change of channel function and underlies an epileptic encephalopathy phenotype

Authors: *S. GURURAJ[1], E. PALMER[3], G. SHEEHAN[1], T. KANDULA[3], R. MACINTOSH[3], W. LO[4], G. ELAKIS[4], Y. ZHU[5], M. BUCKLEY[4], M. DINGER[6], M. COWLEY[6], R. SACHDEV[3], E. KIRK[3], T. ROSCIOLI[3], A. BYE[3], M. E. DUFFEY[1], A. BHATTACHARJEE[2]; [2]Pharmacol. and Toxicology, [1]Univ. at Buffalo - The State Univ. of New York, Buffalo, NY; [3]Sydney Children's Hosp., Sydney, Australia; [4]SEALS Pathology, Randwick, Australia; [5]Genet. of Learning Disability Service, Waratah, Australia; [6]Garvan Inst., Sydney, Australia

Abstract: There are two members of the sodium-activated potassium (K_{Na}) channel family- KCNT1 (SLACK) and KCNT2 (SLICK), which exhibit similarities in sequence and structure yet displaying distinct expression patterns, function and regulation throughout the central and peripheral nervous systems. Several mutations of the KCNT1 gene have been recently described as causal to epileptic disorders, almost universally associated with cognitive impairments. Predominantly, these variants have been shown to be gain-of-function mutations. We report the first identification of a KCNT2 channel variant associated with an epileptic encephalopathy phenotype. We have identified a *de novo* heterozygous missense mutation at Phe240Leu in the pore region of KCNT2 in a patient with severe epileptic encephalopathy. Electrophysiological studies were performed in recombinant mammalian cell systems and in *Xenopus Laevis* oocytes to characterize the phenotypic consequences of this mutation to understand its role in pathogenicity. First, the Phe240Leu mutation appears to behave as a gain-of-function mutation, wherein the Phe240Leu KCNT2 channels exhibit significantly higher currents compared to Wild Type (WT) KCNT2, in the case of both rat Kcnt2 channels recorded in CHO cells and human KCNT2 channels recorded in *Xenopus* oocytes. We demonstrate that the gain-of-function is in fact the result of constitutive activation of channels. Second and more significantly, the Phe240Leu mutation appears to produce a 'change-of-function' in the channel, in that mutant KCNT2 channels demonstrate a pronounced rightward shift in reversal potential (towards E_{Na}) as would be the case for non-selective cation channels. These indicate that the Phe240Leu mutation results in a sodium-permissive conductance compared to predominantly potassium-selective WT KCNT2 conductances. Examining surface expression of the channels in *Xenopus* oocytes using membrane biotinylation assays revealed that Phe240Leu KCNT2 channels are significantly lower at the membrane as compared to WT channels, suggesting that mutated channels may be subject to misfolding and are targeted for degradation or undergo reduced trafficking to the membrane. Taken together, our results identify a change-of-function Phe240Leu *KCNT2* mutation to be the first description of altered selectivity of KCNT2 channels, and indeed of K_{Na} channels. Of clinical importance, the above described findings are evidence to establish pathogenicity of the Phe240Leu Slick mutation in the reported epileptic encephalopathy patient.

Abstract: Mutations in *PRRT2* (proline-rich transmembrane protein 2) cause a wide spectrum of neurological diseases, ranging from paroxysmal dyskinesia to epilepsy and mental retardation. Previous *in vitro* studies suggested that PRRT2 interacts with SNAP25 (synaptosomal-associated protein, 25kD) and may be involved in neurotransmitter release at the synapses. However, it is still not fully understood how mutant PRRT2 causes pathological effects on the nervous system *in vivo*. Using synaptic membrane fractionation and immunostaining techniques, we first showed that Prrt2 was localized at the pre- and post-synaptic membranes with a close spatial association with SNAP25 in rat neurons. We then examined the subcellular localization of six truncating *PRRT2* mutations identified in our Taiwanese patients of paroxysmal kinesigenic dyskinesia (PKD) and found that these mutant proteins accumulated in the cytoplasm and thus failed to target to the cell membrane. We also found that the R308C missense mutant protein had significantly reduced expression regardless of its correct localization at the plasma membrane. These results suggested loss-of-function effects generated by these mutations. To test the pathological effects of PRRT2 loss-of-function *in vivo*, we used *in utero* electroporation of Prrt2 shRNA to knock down Prrt2 expression in the neocortex of mouse embryos. Surprisingly, Prrt2 knockdown in cortical neurons led to delayed neuronal migration, demonstrating a novel role of PRRT2 in embryonic neural development. We further utilized two-photon microscopy to investigate the effects of Prrt2 knockdown on synapses of GFP-labeled neurons *in vivo* and

found a marked decrease in the density of dendritic spines in the brain at adolescence. In conclusion, our study using advanced *in vivo* techniques uncovered a novel mechanism whereby PRRT2 loss-of-function caused by altered subcellular localization and/or decreased expression leads to abnormal neuronal migration and synaptic development. These defects in turn results in the severe neurological symptoms in *PRRT2*-related diseases.

Title: Age-dependent plasticity of cortical GABAergic innervation lessens seizure severity in Cacna1a conditional mutant mice

Authors: *X. JIANG;
neuroscience, CHU Res. Centre, Univ. of Montreal, Montreal, QC, Canada

Abstract: *CACNA1A* loss-of-function mutations result in cerebellar ataxia and epilepsy in humans. We previously showed that the pre-natal deletion of *Cacna1a* in the $Nkx2.1^{Cre}$; $Cacna1a^{c/c}$ mutant mice, causing the ablation of voltage-gated $Ca_V2.1$ Ca^{2+} channels in forebrain GABAergic interneurons (IN), results in synaptic impairment of parvalbumin (PV) fast-spiking basket cells and induces generalized epilepsy. As *CACNA1A* mutation-associated epilepsy improves with age in patients, we propose that specific compensatory mechanisms may occur that, in the face of cortical disinhibition, re-establish the inhibition/excitation balance with time. We generated conditional mutant mice carrying a post-natal deletion of *Cacna1a* in PV^+ neuronal populations (PV^{Cre};$Cacna1a^{c/c}$). PV^{Cre};$Cacna1a^{c/c}$ mutant mice develop cerebellar ataxia and a mild epileptic phenotype with spike-wave seizures after postnatal day 45 (P45). We show a comparable reduction of GABAergic perisomatic boutons on cortical PC and a similar impairment of synaptic release from PV-INs in paired-recordings in both pre-natal ($Nkx2.1^{Cre}$)

and post-natal (PV^{Cre}) mutants, suggesting that both mutant lines develop a significant impairment of perisomatic inhibition. However, surprisingly, $PV^{Cre};Cacna1a^{c/c}$ mutants displayed a two-fold increase in the frequency of miniature inhibitory synaptic currents (mIPSC) in cortical pyramidal cells (PC) at P60, whereas these events were unchanged in $Nkx2.1^{Cre};Cacna1a^{c/c}$ mutants at P20, suggesting that age-dependent compensatory plasticity changes in GABAergic circuits occur in the $PV^{Cre};Cacna1a^{c/c}$ mutant mice. In particular, we demonstrate a significant increase of functional dendrite-targeting GABAergic projections from somatostatin (SOM) INs in $PV^{Cre};Cacna1a^{c/c}$ mutants, using a combination of paired-recordings, immunostaining and two-photon imaging. Therefore, we propose that, in the face of altered PV-INs synaptic function, progressive reorganization of dendritic inhibition, including synaptic connectivity of SOM-INs, restricts cortical excitability and lessens seizure severity in $PV^{Cre};Cacna1a^{c/c}$ mutants. A similar phenomenon has recently been described in chronic post-status epilepticus epilepsy models suggesting that this is a common phenomenon in genetic and non-genetic forms of chronic epilepsy.

Abstract: Developmental delay and intellectual disabilities (DD/ID) include devastating phenotypes and comprise a large fraction of rare undiagnosed conditions in children.

Unfortunately, little is known about the cellular mechanisms that lead to disease, and as a consequence, therapeutic advancements have suffered. Previous studies have indicated a strong genetic component to these phenotypes, and successful identification of causal genetic variants through exome or whole genome sequencing sometimes leads to clinical diagnoses, revision of treatment strategies, community and support network building, and increased quality of life. However, sequencing-based diagnostic efforts typically solve only a subset of cases; while precise numbers vary according to ascertainment and study enrollment criteria, large fractions of children cannot be given a precise genetic diagnosis even after whole genome sequencing. In our own work as part of the Clinical Sequencing Exploratory Research consortium, we have found diagnostic genetic variants in ~27% of children with conditions refractory to standard diagnostic tests. Rigorous experimental evaluation of variants and genes implicated in DD/ID is needed to increase diagnostic rate, particularly for the subset of the undiagnosed cases where a potential genetic cause is identified but not confirmed, termed to be variants of uncertain significance (VUSs). VUSs typically arise as a result of a lack of information about the relevance (or lack thereof) of a given gene to disease, the impact (or lack thereof) of a given variant on gene function, or both. In our studies to date, ~15% of affected children harbor a VUS, and others harbor variants that may be of interest, but are non-returnable even as a VUS. We are developing a pipeline to assess the effect of VUSs and non-returnable variants in human neurons derived from neural precursor cells. We have tailored the design of this pipeline to detect changes in excitability, as ~50% of our patient population exhibits seizures. This pipeline will provide evidence for or against the association of these sequence variants on key molecular and cellular phenotypes including global gene expression, neuronal excitability, and synapse and/or ion channel composition profile. Thus, this pipeline will provide critical insights regarding the biological roles of genes and variants associated with DD/ID and, more broadly, will establish a framework for future mechanistic interrogation of genetic variation as it relates to other neurologic diseases.

Title: Tmem151b, a novel seizure susceptiblity gene encoding a putative ER protein

Authors: *W. N. FRANKEL[1], T. C. MCGARR[2], S. SUKOFF-RIZZO[2], R. M. BOUMIL[2], S. PETRI[1];
[1]Columbia Univ. Med. Ctr., New York, NY; [2]The Jackson Lab., Bar Harbor, ME

Abstract: A new mouse mutant - Nmf389 - was identified in the former Neuroscience Mutagenesis Facility (NMF) of The Jackson Laboratory. Homozygous adults have a significantly reduced electroconvulsive threshold, often bypassing the minimal generalized seizure endpoint to maximal tonic-clonic seizures at low stimulus settings. Heterozygotes have a modestly reduced electroconvulsive threshold, but are not especially susceptible to pentylenetetrazole- or kainate-induced tonic-clonic seizures, although some homozygotes have been observed to exhibit handling-associated tonic-clonic seizures later in life. The recessive electroconvulsive phenotype was mapped to Chr 17, and whole brain RNA sequencing was used to identify a single nucleotide mutation in the Tmem151b gene, encoding an anonymous, putative 2-transmembrane domain containing protein of unknown function. The Nmf389 mutation created a new splice acceptor site 42 nt in exon 3, used by all Tmem151b mRNA, corresponding to an in-frame deletion of 14 amino acids. Confirming candidacy, the Tmem151b knockout allele (from the NIH KOMP program) conferred a similarly low seizure threshold and did not complement the low seizure threshold of Nmf389. While further phenotypic assessment of knockout homozygotes identified no interictal EEG abnormalities or other overt phenotypes, comprehensive behavior profiling revealed homozygotes to be more hyperactive than wildtype littermates with a suggestion of anxiolytic-like behavior. Grossly the brain histology was normal, except for patchy H&E staining in the molecular areas of the hippocampus, between CA1 and dentate gyrus. Confocal imaging of Tmem151b homozygous, YFP-H transgenic mice revealed abnormal dendritic branching, currently under further examination. Although we were unsuccessful with commercial antisera, synthetic epitope-tagged wildtype or mutant Nmf389 cDNA showed localization to the endoplasmic reticulum when expressed heterologously in COS-7 cells. In summary, although the biological function of Tmem151b or role in neurological disease of the highly-conserved human orthologue (Chr 6p 21.1) is unknown, its significant loss of function effect on electroconvulsive threshold and other behaviors in mice suggests TMEM151B as a novel ER protein involved in brain development or function.

Title: Neuronal hyperexcitability and seizure-like motor pattern generation arising from the Shaker Wings-Down mutation in the *Drosophila* sodium channel gene paralytic

Authors: *A. IYENGAR[1], A. UEDA[1], J. KASUYA[1], S. GRATZ[2], K. O'CONNOR-GILES[2], T. KITAMOTO[1], C.-F. WU[1];
[1]Univ. of Iowa, Iowa City, IA; [2]Univ. of Wisconsin, Madison, WI

Abstract: Mutations in genes encoding voltage-gated sodium (Na_V), potassium (K_V), and calcium (Ca_V) channels are associated with a variety of heritable epilepsy syndromes. In this report, we present a novel hyperexcitable mutant, *Shaker-wings-down* (*Swd*) that displays severe ether-induced shaking and convulsions. We mapped *Swd,* to a single non-polar amino acid substitution in the D3-S4 voltage sensor of *paralytic,* the only gene encoding Nav channels in *Drosophila.* At the larval neuromuscular junction (NMJ), we found extreme excitability indicated by aberrant spontaneous firing in motor axons reminiscent of the K_V double mutant *eag Sh*, but normal synaptic transmission properties. Although spontaneous firing is abolished by TTX in both mutants, electrotonic stimulation of *eag Sh* nerve terminals results in large and sustained neurotransmitter release. In contrast, electrotonically evoked neurotransmitter release in *Swd* was similar to WT in terms of size and time course.
The observed neuronal hyperexcitability in *Swd* led to uncoordinated walking, abnormal motor program outputs, and aberrant spike discharges across the nervous system. Consistent with the observations at the larval NMJ, recordings of adult flight muscle revealed ectopic firing. This spontaneous activity consisted of rhythmic firing (8 Hz) punctuated by brief bursts exceeding 100 Hz. Interestingly, we observed a high degree of bilateral coordination between burst discharges, suggesting a central origin of these seizure-like events.
To demonstrate that the entire functional consequences, from neuronal hyperexcitabilty to seizure behavior, arose from a single amino acid substitution in the Na_V channel mutation, we adopted a CRISPR-based genome editing strategy. The characteristic behavioral and electrophysiological phenotypes of the *Swd* mutation is recapitulated by CRISPR genome editing of the same amino acid replacement. This rules out contributions from unknown genetic background effects and defines a neomorphic mutation of the *paralytic* Na_V channel gene that results in a unique hyperexcitability phenotype. Together, these findings represent a potentially

important mechanism within the Na_V channel that leads to specific neuronal hyperexcitability and neural circuit dysfunction as delineated by the *Swd* mutation.

Ctr. and David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract: Here, we define the microscopic features of Lafora Bodies (LfBs), emphasizing the histologic profile and the extra- and intraneuronal distribution of LBs. We provide strong evidence to support a putative tropism between Type I LfBs and blood vessels, which cross the vascular wall and become intraluminal particles, ready to be taken away by the blood flow. Moreover, the presence of vascular hyperplasia in several parts of the brain of the Lafora mice, especially in the ventral pons, suggests that hyperplasia is a response to the high metabolic activity. We also observed thickening and darkening of neurofilamentous elements of the cytoskeleton in the external ring of type II LfBs. This finding establishes a potential relation between type II LfBs and the neurocytoskeleton. Persistence of the circular pattern shown by the type II LfBs allows us to say that these intracytoplasmic inclusions are spherical. Detailed neuropile microscopic scrutiny in which type II LfBs are present lead us to discover a morphological sequence that suggests the transformation of some type I LfBs into type II LfBs.

This process involves a dynamic 3D mechanism that transforms an amorphic, uniformly stained inclusion into a delicate and organized intrasomatic type II LfB. The vascular hyperplasia could be related to an tropism. Finally, how and why do type I LfBs penetrate these vessels and what is their destination? Is this a natural way for getting rid of these inclusions? Is it possible to enhance this mechanism for the clinical improvement of Lafora Disease patients?

Title: Phenotypic and transcriptional differences resulting from two different non erythrocytic spectrin mutations

Authors: *P. R. LEE, JR[1], E. BOSLET[1], V. GARTNER[1], T. MARKELLO[1], A. THURM[2], M. MAEDA[2], G. GOLAS[1], C. TIFFT[1], W. GAHL[1];
[1]NHGRI/Undiagnosed Dis. Program, [2]NIH, Bethesda, MD

Abstract: Previous studies have linked Early Infantile Epileptic Encephalopathy type 5 (EIEE5) with *de novo* mutations in Spectrin Alpha Non-Erythrocytic 1 (SPTAN1). These earlier studies suggest that EIEE5 is a result of mutations that are dominant-negative in nature. The aim of our study was to understand the etiology of disease seen in two additional patients diagnosed via Whole Exome Analysis for *de novo* mutations in SPTAN1 who have severe neurological phenotypes but who do not have seizures. The first of these two cases is a 13-year-old Caucasian male who is heterozygous for a *de novo* nonsense mutation leading to a protein truncated in exon 21. He has global microcephaly, intellectual disability, autism spectrum disorder, and documented thyroid abnormalities, but he has never had an epileptic episode. The second case is a 10-year-old Caucasian male who is heterozygous for a *de novo* intronic missense mutation that results in a premature splice acceptor site and the insertion of five amino acids in the C-terminus of this protein. He has cerebellar and brain stem hypoplasia on MRI, hypothyroidism, intellectual disability, hypotonia, ataxia, autism spectrum disorder, and ADHD, but no epilepsy. The neuroanatomy of patient two is more similar to patients previously described in the literature except he does not have the hypomyelination seen in other patients. The second patient also has a more severe phenotype than the first patient described here, although less severe than those with

EIEE5. Multiplexing digital PCR assays were designed to detect both mutant and wild type alleles, specific for each patient at the site of their mutations. Assays were performed on fibroblast cDNA from cultured patient skin biopsy samples. Results of these assays indicate significant down regulation of wild type and mutant SPTAN1 allele expression in both patient cell lines, suggesting haploinsufficiency may be an alternative etiology, or an additional factor important for understanding disease caused by SPTAN1 mutations.

Title: Pathogenic aspects of SCN1A haploinsufficiency in human ipsc derived cortical neurons.

Authors: ***D. SIMKIN**[1,2], G. L. ROBERTSON[2], E. KISKINIS[2], A. L. GEORGE, Jr.[1];
[1]Pharmacology, Feinberg Sch. of Med., [2]Neurology, Feinberg Sch. of Med., Northwestern Univ., Chicago, IL

Abstract: More than 1100 different heterozygous epilepsy-associated *SCN1A* mutations have been identified, (Claes et al., 2009) with more than 70% occurring in children with Dravet syndrome (DS), a condition characterized by onset of seizures during the first year of life with an ensuing epileptic encephalopathy consisting of cognitive, behavioral and motor impairments, brain malformations as well as premature death (Scheffer et al., 2001, Dravet et al., 2011, Dravet and Oguni, 2013, Brunklaus and Zuberi, 2014). In Dravet syndrome, *SCN1A* loss-of-function is the established molecular mechanism. However, the specific mechanisms explaining how stable genetic mutations in human ion channels cause paroxysmal dysfunction and how the early age of seizure onset affects neurodevelopment remain to be determined. Recent advances in the generation of patient-specific human induced pluripotent stem cells (hiPSCs) have opened the door to elucidating human pathogenic mechanisms of genetic disorders such as the epileptic channelopathies. Hence, we aimed to establish a developmental timeline of pathogenicity associated with *SCN1A* epileptic channelopathies using hiPSC-derived neurons. We have assessed the functional electrophysiological phenotypes of excitatory glutamatergic neurons differentiated from stem cells (Zhang et al., 2013) with haploinsufficient *SCN1A* expression as compared to isogenic controls generated through CRISPR/Cas9 gene editing and healthy controls. We assessed the trajectory of neuronal differentiation and maturation, using current-

clamp electrophysiology and multi-electrode array technology (MEA; Axion Biosystems), at three time-points in differentiation/maturation. Our data suggest that passive properties such as RMP and input resistance mature over time in both DS and control neurons. However, in the first time point of differentiation there was a significant difference between DS and control neurons for both RMP and input resistance. Moreover, active excitability properties such as rheobase and fAHP were enhanced in the DS neurons. Patch-clamp results are consistent with MEA network activity studies showing enhanced excitability in DS neuronal cultures. These data suggest that a haploinsufficiency of *SCN1A* may have cell autonomous effects on the time course of cortical excitatory neuron development leading to enhanced excitability. These important findings help establish an alternative developmental approach to childhood epileptic channelopathies and propel further research into cell autonomous and non-autonomous effects of *SCN1A* haploinsufficiency.

Title: Electrophysiological characterization of two Nav1.2 mutations implicated in epilepsy

Authors: *E. MASON[1], R. PATEL[2], Y. XIAO[1], T. R. CUMMINS[1];
[1]Pharmacol. and Toxicology, [2]Stark Neurosciences Res. Inst., Indiana Univ., Indianapolis, IN

Abstract: Mutations in the genes encoding voltage-gated sodium (Nav) channels have been implicated in several types of epilepsy, including many mutations in the alpha subunit of Nav1.2, a sodium channel isoform found primarily in excitatory cortical neurons. These mutations are believed to cause seizures via inducing hyperexcitability and repetitive firing in these neurons. We characterized two such arginine-to-glutamine Nav1.2 mutations, R853Q and R1882Q, in HEK cells. These mutations affect different regions of the channel structure, so we hypothesized that they differentially alter channel function and kinetics. Voltage-clamp studies revealed loss of function resulting from the R853Q mutation as evidenced by lower current density, a faster rate

of inactivation, and a negative shift in the voltage dependence of inactivation compared to wild-type Nav1.2 channels. This channel mutation also enhanced gating pore currents. These currents, generated by ions entering the cell through a gap in the voltage-sensor rather than the central pore, provide a gain of function with this mutation. The R1882Q mutant channel exhibited only gain-of-function effects, including increased current density, enhanced persistent currents, a slower rate of inactivation, and a positive shift in the voltage dependence of inactivation compared to the wild-type Nav1.2. This mutation also increased the amplitude of resurgent currents induced by a Navβ4 peptide in the intracellular patching solution. These observations suggest that the R853Q and R1882Q mutant Nav1.2 channels contribute to the generation of epileptic seizures via different gain-of-function mechanisms, and that treatment of epileptic patients with these mutations may require different pharmacotherapeutic strategies specifically targeting the associated aberrant current activity.

Title: Dual and Opposing roles of microRNA-124 in epilepsy are mediated via inflammatory and NRSF mediated pathways

Authors: *G. P. BRENNAN[1], D. DEY[2], Y. CHEN[2], K. PATTERSON[2], H. ALICIA[2], C. DUBE[2], T. Z. BARAM[3];
[1]Physiol. and Med. Physics, Royal Col. of Surgeons Ireland, Dublin, Ireland; [3]Pediatrics, Anat. & Neurobio., [2]Univ. of California Irvine, Irvine, CA

Abstract: Insult-insult formation of epileptic networks involves multiple mechanisms. Intervention studies have identified both dysregulated inflammation and aberrant NRSF/REST activity as contributors to epileptogenesis. However, it remains unclear how epilepsy-provoking insults (e.g., prolonged seizures) induce both inflammation and NRSF and whether common mechanisms exist. Using a high throughput rat model of epileptogenesis we examined miR-124

as a candidate dual regulator of NRSF and inflammatory pathways. We induced status epilepticus (SE) using repeated low dose kainic acid which led to reduced miR-124 expression. ChIP analysis revealed that this repression of miR-124 was mediated by SIRT1-and, in turn, miR-124 repression-via C/EBPα upregulated NRSF. We then tested whether augmenting miR-124 after SE would abort epileptogenesis by preventing inflammation and NRSF upregulation. Epilepsy development was monitored using 24h video EEG for 2 months. SE-sustaining animals developed epilepsy, but supplementing miR-124 did not modify epileptogenesis. Examining this result further, we found that synthetic miR-124 not only effectively blocked NRSF upregulation and rescued NRSF target genes, but also augmented microglia activation and inflammatory cytokines. Thus, miR-124 attenuates epileptogenesis via NRSF while promoting epilepsy via inflammation.

Title: Effect of newly designed mTOR inhibitors on seizure threshold and target activation in normal versus epileptic mice

Authors: C. BRANDT[1], D. FABBRO[2], P. HILLMANN[2], K. ROEMERMANN[1], A. NOACK[1], *W. LOSCHER[3];
[1]Univ. of Vet. Med., Hannover, Germany; [2]PIQUR Therapeut. AG, Basel, Switzerland; [3]Univ. of Vet. Med. Hannover, Hannover, Germany

Abstract: Dysregulation of the mTOR (mammalian target of rapamycin) pathway occurs in different types of epilepsy, thus rendering mTOR an interesting target for antiepileptic and antiepileptogenic strategies. However, results about the potential benefit of rapamycin are controversial, which may be due to poor brain penetration and inhibition of only mTOR-complex 1 (mTORC1). Newer compounds with improved brain uptake were designed to inhibit both mTORC1 and mTORC2 (ATP-competitive mTOR inhibitors) or to additionally block phosphoinositide 3-kinase (PI3K), a regulator upstream of the mTOR complexes (dual PI3K/mTOR inhibitors).
The efficacy of rapamycin and the rapalog everolimus was compared to two new compounds (Cpd-A and Cpd-B). Cpd-A belongs to the group of ATP-competitive mTOR inhibitors while

Cpd-B is a dual PI3K/mTOR inhibitor. For evaluation of the anti-seizure effect of these drugs, the maximal electroshock seizure threshold test (MEST) was performed in nonepileptic and epileptic mice.
The following aims were pursued: (1) Determination of differences in the anti-seizure properties of the drugs; (2) evaluation of the impact of epilepsy on the outcome of drug treatment; (3) investigation of the activation of the mTOR pathway in epileptic vs nonepileptic epileptic mice; (4) comparison of the inhibitory potency of the test compounds on the mTOR pathway.
Female NMRI mice were subdivided into two groups. One group underwent pilocarpine induced status epilepticus in order to induce development of epilepsy and the other group served as nonepileptic control. Different drug dosages and pretreatment times for rapamycin, everolimus, Cpd-A, and Cpd-B were tested in the MEST test. For evaluating mTOR activation, the phosphorylated ribosomal protein S6 was quantified in the hippocampus using Western blot. Difference in mTOR activation was evaluated in nonepileptic versus epileptic mice. For comparison of drug effects on mTOR activation, phosphorylated S6 was analyzed in mice treated with the most efficacious anti-seizure protocol for each compound determined by MEST test.
S6 phosphorylation was increased in epileptic mice compared to naïve mice indicating an activated mTOR pathway. Unexpectedly we found that drug treatment was more efficient in normal compared to epileptic mice in the MEST test. Among all mTOR pathway inhibitors tested, the dual PI3K/mTOR inhibitor Cpd-B exhibited the most pronounced anti-seizure effect. In both normal and epileptic mice, the two new compounds exhibited the strongest inhibition on S6 phosphorylation. This could indicate an advantage in the treatment of epilepsy compared to rapamycin or rapalogs such as everolimus.

Title: The S940A residue of the potassium-chloride transporter type 2 (KCC2) regulates the onset of soman-induced seizures in mice

Authors: *L. M. MATSON[1], S. M. MILLER-SMITH[1], H. S. MCCARREN[1], D. H. MORROW[2], T. G. DEEB[2], S. J. MOSS[2], J. H. MCDONOUGH[1], C. D. SMITH[3];

[3]USARIEM, Natick, MA

Abstract: Exposure to nerve agents induces numerous symptoms, including benzodiazepine-resistant seizures within 40 minutes of seizure onset. One hypothesis to explain this resistance is that dysfunction of KCC2, a protein that permits GABA's inhibitory tone by maintaining the Cl- gradient, may decrease benzodiazepine efficacy following prolonged seizures. Seizures rapidly decrease KCC2 levels, which may increase intracellular Cl- concentrations and reduce GABA-mediated inhibition. KCC2 function is regulated by phosphorylation at key residues. Importantly, phosphorylation of S940 (pS940) increases KCC2 activity, whereas phosphorylation of T906 (pT906) decreases KCC2 activity. Recently, we showed that soman-induced convulsions are associated with time-dependent changes in KCC2 phosphorylation. In the hippocampus, soman-induced convulsions increased T906 levels at 15 and up to 60 minutes, but did not alter pS940 levels. In the cortex, soman-induced convulsions increased pT906 and pS940 at 15 minutes; however, concentrations of pS940 were equivalent to saline-exposed mice by 60 minutes. Based on these results, how pS940 is involved in soman-induced convulsions is unclear. In Experiment 1, seizure susceptibility in mice lacking the S940A residue (S940A mutant) was increased with shorter seizure latency compared to wild type (WT) controls. In Experiment 2, we determined the median effective dose (ED50) of diazepam for terminating soman-induced seizures in WT mice. Experiment 3 examined diazepam's ability to terminate seizures in S940A mutant and WT mice. Initial evidence suggests that seizure termination latency is higher in S940A mutant compared to WT mice, though additional subjects are required to determine if S940A regulates diazepam efficacy following soman-induced seizures. Our data suggest that KCC2 reactivation may provide a therapeutic strategy for terminating benzodiazepine-resistant seizures.

Title: Conditional upregulation of the KCC2 membrane transporter in a transgenic mouse and the effects on neuronal excitability *In vitro*

Authors: *C. S. GOULTON[1], K. WANG[1], A. KHOSHABA[1], M. WATANABE[2], J. NABEKURA[3], A. J. MOORHOUSE[1];
[1]Sch. of Med. Sci., UNSW Australia, Sydney, Australia; [2]Dept. of Neurophysiol., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [3]Div. of Homeostatic Develop., Natl. Inst. for Physiological Sci., Okazaki, Japan

Abstract: Normal brain function is critically dependent on maintaining a balance between excitation and inhibition. The K^+Cl^--cotransporter (KCC2) plays an important role in regulating intracellular Cl^- concentration and thereby in the efficacy of $GABA_A$-receptor mediated inhibition. This study characterizes a transgenic mouse in which forebrain-restricted expression of KCC2 in pyramidal neurons could be regulated by doxycycline in the diet. Withdrawal of doxycycline resulted in marked upregulation of KCC2, with the mRNA distribution confirmed using *in-situ* hybridization and the time course of protein upregulation measured using western immunoblotting. Upregulation of KCC2 expression was associated with enhanced KCC2 membrane transport function, as judged by an increase in NH_4^+- mediated fluorescence changes measured in hippocampal brain slices loaded with a pH sensitive fluorophore (AM-BCECF). To assess the functional consequences of increased KCC2 on neuronal excitability, field potentials were recorded from hippocampal CA1 in acute slices. There was no effect on the characteristics of orthodromically evoked responses, with similar input-output relationships and paired-pulse ratios being observed ($p>0.05$). There was also no difference in muscimol concentration-response curves, with a similar concentration for half maximal inhibition (IC50) observed in KCC2-upregulated mice (0.85 ± 1.1 μM vs. 1.34 ± 1.1 μM in controls; $p>0.05$). In contrast, KCC2-upregulation was found to reduce hyperexcitability in a range of *in vitro* seizure models when compared to controls. In the tetanus-induced afterdischarge model, the number of afterdischarges was significantly reduced (0.57 ± 0.5 vs. 11.6 ± 5; $p<0.01$). In the zero Mg^{2+} /high K^+ model, spontaneous discharges had a longer latency to onset (12.4 ± 2 vs. 5.7 ± 1 min; $p<0.01$) and were decreased in frequency (0.14 ± 0.03 vs. 0.39 ± 0.05 Hz; $p<0.01$). Our data indicate that this conditional transgenic mouse can be used to produce a rapid upregulation of functional KCC2 protein *in vivo*. While increasing KCC2 has little effect on basal synaptic

transmission, it reduces the susceptibility of neurons to becoming hyperexcitable. Increasing KCC2 may enable greater Cl^- homeostasis and maintain more efficacious GABAergic inhibition, hence providing a novel strategy to enhance neuronal inhibition. The use of this animal model should enable more specific investigations into the neuroprotective potential of targeting KCC2 for the treatment of conditions such as epilepsy.

Title: The effect of upregulated KCC2 expression on chemically induced seizures and diazepam therapy *In vivo*

Authors: *D. L. CHEUNG[1], C. S. GOULTON[1], M. WATANABE[2], J. NABEKURA[3], A. J. MOORHOUSE[1];
[1]Sch. of Med. Sci., UNSW Australia, Sydney, Australia; [2]Dept. of Neurophysiol., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan; [3]Div. of Homeostatic Develop., Natl. Inst. for Physiological Sci., Okazaki, Japan

Abstract: Chloride influx via $GABA_A$ receptor channels is the primary means of hyperpolarizing inhibitory neurotransmission in the brain. It is critically dependent on a low intracellular Cl^- concentration which is maintained by the Cl^- export activity of the K^+-Cl^- cotransporter (KCC2).
During a seizure event, the balance between excitatory and inhibitory activity is disrupted. Given its central role in Cl^- homeostasis we hypothesized that increased KCC2 activity would improve resistance to seizures by enhancing GABAergic inhibition. We tested this using two acute chemical seizure models, systemic pentylenetetrazol (PTZ) and systemic kainic acid (KA), in control and KCC2 upregulated mice. We used a tetracycline conditional expression mouse to over-express KCC2 following withdrawal of doxycycline from the diet. All experiments were approved by the UNSW Animal Care and Ethics Committee (ref. # 12/147B, 15/136A).
In the PTZ challenge, mice were pre-treated with either diazepam (0.6 mg/kg, IP) or vehicle 15 minutes prior a single PTZ injection (85 mg/kg, IP). Behavioural responses were videotaped and

the experiment terminated 30 minutes later or once mice developed maximal tonic-clonic seizures with hind-limb extension. Seizures were subsequently quantified by blinded scoring according to a modified Racine scale. There was no significant effect of KCC2 upregulation on either the latency or severity of seizures, in both the vehicle and diazepam pre-treated groups. In the KA challenge, mice underwent an escalating dose regime receiving two KA injections (5 mg/kg, IP) administered 1 hour apart. Behavioural seizures were terminated after the second hour by a single diazepam injection (5 mg/kg, IP). EEG, from surgically implanted cortical screw electrodes, was recorded throughout the entire procedure. Seizures were initially quantified by integrating the EEG power spectrum density plots for the two KA periods (45 mins each) and post-diazepam period (20 mins). Mice with KCC2 upregulated by withdrawal of doxycycline prior to electrode implantation still displayed clear KA-induced seizures, although the mean power was modestly decreased (49.22 ± 9.223, mean ± SEM, n=10) as compared to control transgenic mice (101.9 ± 39.31, n=10). The efficacy of diazepam in reducing EEG activity in the same cohorts was markedly increased in KCC2 upregulated mice (mean power of 56.78 ± 11.69, n=11), compared to controls (454.2 ± 131.7, n=9).
Our results suggest that increased KCC2 activity by itself has only a limited effect on seizure thresholds but may potentiate the ability of positive GABAergic modulators, such as diazepam, to ameliorate seizures.

Title: Bumetanide enhances the pharmacological effect of phenobarbital on electroencephalographic and behavioral parameters, in an animal model of temporal lobe epilepsy

Authors: *C. A. MANTELLERO[1], C. SALAZAR[2], M. BORQUEZ[2], J. AMARO[2], A. OCAMPO[2], M. INOSTROZA[3], J. VALDES[2], P. ROJAS[1];
[1]Biol., Univ. De Santiago De Chile, Santiago, Chile; [2]Biofísica y Fisiologia, Univ. de Chile, Santiago, Chile; [3]Inst. of medical psychology and behavioral neurobiology, Univ. of tubingen, Tubingen, Germany

Abstract: Temporal lobe epilepsy (TLE) is the most common type of refractory epilepsy to drug treatment. Within the structures involved in TLE, the most important pathophysiologically is the hippocampus, where sclerosis is associated with neuronal loss. This has been related to the cognitive impairment observed in patients. In epileptic conditions neurons have an increased excitability due in part to a reduced synaptic inhibition and a change in the effect of GABA from inhibitory to excitatory. This is due to a change in the direction of electrochemical gradient of Chloride, whose concentration is maintained by the interplay of co- transporters KCC2 and NKCC1. Several studies in experimental models of acute seizures have shown that NKCC1 is highly expressed and KCC2 is decreased, explaining the high intracellular chloride, like in early development. In a model of neonatal hypoxia-induced seizures, Bumetanide, a specific NKCC1 inhibitor, in combination with Phenobarbital shows a significant improvement in seizure control, more effectively than Phenobarbital alone. The aim of this work is to study in an animal model of TLE the refractoriness to a GABAA agonist Phenobarbital, and if in combination therapy with Bumetanide enhances its pharmacological effect decreasing the number of seizures, and a behavioral level reversing cognitive impairment. Male 7 weeks old Sprague Dawley rats were administrated with Pilocarpine to induce Status Epilepticus (SE), and after two weeks they have spontaneous seizures. Animals were administrated with Phenobarbital (N=3), Bumetanide (N=3), or Bumetanide with Phenobarbital (N=3) during two weeks, and electroencephalogram (EEG) recordings were performed before and after this treatment to quantify alterations in epileptiform activity. The results show that Phenobarbital in combination with bumetanide decreases the number of seizures. To determine the effect of these treatments on cognitive impairment, object recognition test were performed, to evaluate episodic memory. Open field was conducted to evaluate anxiety, and last, social interaction was studied to evaluated sign that suggesting depression. The results show that the combination therapy improves behavioral parameters. These findings support the idea that NKCC1 contributes to refractoriness to drug treatment and suggest that Bumetanide might be used as a supplemental therapy in TLE.

Title: Characterization of the relationship between diet mitochondrial function and oxidative stress in a fly model of epilepsy

Authors: *E. R. REYNOLDS, A. AUSTIN, K. DELLOVADE, S. NGANGA;
Program in Neurosci., Lafayette Col., Easton, PA

Abstract: *Drosophila* mutants known as "bang-sensitive" have been utilized as models for neurological conditions including epilepsy, sensorineural deafness, and age-dependent neurodegeneration. While the mechanisms producing these phenotypes are unique to each strain, some of the gene products suggest mitochondrial dysfunction and a reduced capacity to tolerate oxidative stress as a possible underlying cause. Diet is an important factor in determining energetics and oxidative stress levels. For example, a ketogenic diet has been shown to be an effective treatment for refractory epilepsy in humans, and antioxidant therapies have been explored in Parkinson's disease. We wanted to more clearly define the connection between diet, mitochondrial function, and reactive oxidative species in this fly model system. Bang-sensitive mutant strains were reared on a standard molasses, yeast and cornmeal (MYC), which is a low protein/high carbohydrate diet, or a protein-rich yeast sugar (1:1 YS) diet. The mutants display a lower percentage of seizures on the YS food, but also reduced viability, lifespan and fecundity. Seizure thresholds were also impacted by the YS diet. Several biochemical methods were utilized to define the effects of diet, including a cytochrome oxidase (CO) assay, a superoxide dismutase (SOD) assay and lipofuscin quantitation. Preliminary results indicate reduced CO activity in mutants as compared to wildtype, with increased CO levels in all flies raised on the YS food. Strain differences were also observed using the SOD assay, however the impact of diet was less clear. However, lipofuscin accumulation appeared to increase in flies raised on YS as compared to MYC. Alterations in mitochondrial function correlate with improvement in epilepsy phenotype, while changes in oxidative capacity may underlie changes in viability.

Title: Culture medium composition has limited influence on epileptogenesis in organotypic hippocampal cultures

Authors: *J. LIU[1], Y. SAPONJIAN[3,4], M. M. MAHONEY[2], K. J. STALEY[3,4], Y. BERDICHEVSKY[1,2];

Abstract: Organotypic hippocampal cultures are increasingly used as an in vitro model of post traumatic epilepsy. Chemically defined medium were developed to maintain organotypic cultures. However, it is based on the composition of blood plasma, not of cerebrospinal fluid (CSF). The opening of blood-brain barrier (BBB) due to brain insults may be one of the causes of epileptogenesis in vivo. It is possible that epileptogenesis in organotypic cultures is due to exposure of hippocampal neurons to components of blood serum in the culture medium that are present at different concentration or not present at all in normal CSF. Commercially available culture medium Neurobasal-A (usually supplemented with B27) contains electrolytes, glucose, amino acids and other components that are not present at same concentrations in CSF. We examined the influence of medium composition on epileptogenesis. Slices were maintained in culture media with various compositions. Epileptogenesis was evaluated by measurements of lactate and lactate dehydrogenase (LDH) levels (markers of ictal activity and cell death, respectively) in culture supernatant collected twice a week, immunohistochemistry and automated 3-D cell counts, and extracellular recordings from CA3 and CA1 regions. Changes to culture medium composition moderately reduced lactate and LDH levels as well as electrographic seizure. However, epileptogenesis could not be prevented by composition modification without decreasing the number of surviving neurons. We conclude that medium composition is unlikely to be the cause of epileptogenesis in organotypic hippocampal culture.

Title: Time-restricted feeding exerts anti-inflammatory and neuroprotective effects on acute seizure model.

Authors: *J. SANTILLAN-CIGALES, J. LANDGRAVE-GOMEZ, O. F. MERCADO-GOMEZ, R. GUEVARA-GUZMAN;
Physiol., Univ. Nacional Autónoma De México, Facultad, Ciudad De Mexico, Mexico

Abstract: Introduction: During the past decade, experimental research has demonstrated a prominent role of the pro-inflammatory molecules on epileptogenic and ictogenic processes. On the other hand, our research group recently demonstrated that time-restricted feeding (TRF) had an anticonvulsant effect, however, the precise mechanism by which this diet exerts its beneficial effects are still unknown. Objective: Our aim was to investigate whether TRF is able to exert its beneficial effect decreasing the expression of pro-inflammatory molecules and thus might have a neuroprotective role after seizure induction. Methodology: Briefly, TRF consisted in allowing rats to eat for two hours daily during their light phase for 20 days; conversely, control group was fed ad libitum (AL). After dietary schedule, status epilepticus (SE) was induced using a pre-treatment with a injection of lithium chloride (3 mEq/kg) followed by pilocarpine administration (60 mg/kg). Both protein and mRNA expression of pro-inflammatory molecules such as interleukin 1 beta (IL-β), tumor necrosis factor alpha (TNF-a) and interleukin 6 (IL-6) were measured in hippocampus from each group 24 h after SE. Additionally, coronal brain slices were processed with fluoro-Jade C to mark degenerate neurons. Results: Our preliminary data showed that the group that followed TRF before SE had a significant decrease in both of mRNA and protein expression of pro-inflammatory molecules (IL-β, TNF-a, IL-6), in comparison with AL group after seizure induction. Furthermore, the hippocampus from TRF group showed a significant decrease on reactive gliosis and less FluroJade-positive cells were observed after SE. Conclusion: Our data demonstrate that TRF may exert a neuroprotective effect by decreasing the mRNA and protein expression of pro-inflammatory molecules and reactive gliosis after seizure induction.

Title: Fluorobenzenamides as anticonvulsants

Authors: *S. E. MEZA TOLEDO, J. G. CERVANTES ESPINOZA, M. SUÁREZ QUEZADA, J. PERALTA CRUZ, G. CHAMORRO CEVALLOS;

Abstract: In an effort to discover novel anticonvulsants, we prepared and characterized several DL-fluorobenzenamides and studied their anticonvulsant activity against seizures induced by 4-aminopyridine, maximal electroshock and pentylenetetrazol in CD-1 mice. Compounds 2-hydroxy-2-(3'-trifluoromethylphenyl)butyramide (**1**), 2-hydroxy-2-(3',5'-bis(trifluoro methylphenyl) butyramide (**2**), 3-hydroxy-3-(3'-trifluoromethylphenyl) pentanamide (**3**) and 2-hydroxy-2-(3',5'-bis(trifluoromethylphenyl) pentanamide (**4**) were prepared using condensation reactions and characterized through infrared spectrophotometry and nuclear magnetic resonance spectroscopy. Each of the four compounds exhibited an anticonvulsant activity in mice greater than that of sodium valproate, a widely-used antiepileptic, against seizures induced by maximal electroshock, 4-aminopyridine or pentylenetetrazol. Compounds **1**, **2**, **3** and **4** were more potent than phenobarbital against seizures induced with 4-aminopyridine and equipotent with phenobarbital against seizures induced by maximal electroshock or pentylenetetrazol. In the rotarod ataxia test, compound **1** exhibited the lowest ataxicity of the four compounds. Incorporation of trifluoromethyl groups in the meta position of the phenyl ring in compounds **1** and **3** increased the duration of their anticonvulsant activity. This study shows that fluorobenzenamides represent a new class of anticonvulsant compounds worthy of further development for potential antiepileptic therapy.

Title: Phenytoin halts convulsions, but not electrographic seizure activity, in a rat model of status epilepticus, whereas both are eliminated by next generation neuroactive steroids

Authors: *G. M. BELFORT, A. ALTHAUS, R. S. HAMMOND, M. C. QUIRK, G. MARTINEZ BOTELLA, F. G. SALITURO, A. J. ROBICHAUD, J. J. DOHERTY;

Abstract: Established status epilepticus (SE) is a life threatening condition characterized by unremitting seizures that have failed to respond to first line therapy with benzodiazepines. We report pre-clinical results comparing the electrographic activity of a standard second line anti-epileptic drug with next generation neuroactive steroids and demonstrate the differentiation of these novel potential treatments for SE. Phenytoin is a commonly used second line antiepileptic drug that blocks voltage gated sodium channels. Here we investigated the effect of phenytoin in the rat lithium-pilocarpine model of SE with EEG recording. Phenytoin (5, 15 and 50 mg/kg, IV) administered within 2 minutes of SE onset failed to reduce aberrant EEG spike probability at all doses notwithstanding brain concentrations as high as 37±4.2 μg/g. Despite this lack of effect on EEG, dose dependent sedation and arrest of behavioral convulsions was observed. All animals that received 50 mg/kg exhibited a loss of righting reflex (LRR) up to 30 minutes after dosing and 3 of 4 animals exhibiting LRR for 4 hours. Lamotrigine (3, 10 and 30 mg/kg, IV), another antiepileptic drug that targets sodium channels, also failed to reduce spike probability at all doses when administered immediately after SE onset, despite brain concentrations as high as 26.5±0.6 μg/g. Unlike phenytoin, lamotrigine was not sedating. In contrast to phenytoin and lamotrigine, next generation neuroactive steroid anticonvulsants, reduced aberrant spike probability immediately after SE onset, and retained this activity even when administered up to 60 minutes later. Taken together, these data highlight the discrepancy between behavioral and electrographic measures of ongoing seizure activity and illustrate the potential value of EEG for uncovering ongoing SE in non-convulsive patients. Finally, the sustained activity of next generation neuroactive steroids after SE onset in the lithium-pilocarpine model supports assessing the activity of this class of compounds in humans with established SE.

Title: Naringenin ameliorates kainic acid-induced morphological alterations in the dentate gyrus in a mouse model of temporal lobe epilepsy

Authors: *J. PARK[1,2], H. JANG[1,2], K. JEONG[1,2], U. JUNG[4], S. KIM[1,2,3];

Abstract: Granule cell dispersion (GCD) in the dentate gyrus (DG) of the hippocampus is a morphological alteration characteristic of temporal lobe epilepsy. Recently, we reported that treatment with naringin, a flavonoid found in grapefruit and citrus fruits, reduced spontaneous recurrent seizures by inhibiting kainic acid (KA)-induced GCD and neuronal cell death in mouse hippocampus, suggesting that naringin might have beneficial effects of preventing epileptic events in the adult brain. However, it was still unclear whether the beneficial effects of naringin on the inhibition of GCD could be mediated by naringenin, a major metabolite of naringin, in the KA-treated hippocampus. To investigate this possibility, we evaluated whether intraperitoneal injections of naringenin could mimic naringin-induced effects against GCD formation following intrahippocampal KA injections in mouse brains. Our results showed that treatment with naringenin delayed the onset of KA-induced seizures and attenuated KA-induced GCD. Moreover, we found that its treatment inhibited the activation of mammalian target of rapamycin complex 1 (mTORC1) both in neurons and reactive astrocytes in DG of KA-treated hippocampus. These results suggest that naringenin may be an active metabolite of naringin, which has a capacity to control GCD formation, resulting in preventing the progression of epileptic insults in the hippocampus *in vivo*.

Title: Pharmaceutical effects of naringin in the kainic acid-treated animal model of epilepsy

Authors: *H. JANG[1,2], K. JEONG[1,2], M.-T. JEON[1,2], E. LEEM[1,2], U. JUNG[4], S. KIM[1,2,3]; [1]Sch. of Life Sci. & Biotech., [2]BK21 plus KNU Creative BioResearch Group, [3]Brain Sci. and Engin. Inst., Kyungpook Natl. Univ., Daegu, Korea, Republic of; [4]Dept. of Food Sci. and Nutr., Pukyong Natl. Univ., Busan, Korea, Republic of

Abstract: Kainic acid (KA) is well known as a chemical compound to study epileptic seizures and neuronal excitotoxicity, resulting in the death of hippocampal neurons by autophagic stress and microglia-derived neuroinflammation. In addition, epileptic seizures show the abnormal morphological characteristics such as granule cell dispersion (GCD) in the dentate gyrus (DG) of hippocampus, which may be involved in seizure susceptibility and spontaneous recurrent seizure again. Thus, these results suggest that the control of neurotoxic events such as neuroinflammation, excitotoxicity and GCD may be important strategies for inhibition of epileptic events. We recently reported that naringin, a major flavonoid found in grapefruit and citrus fruits, has neuroprotective activities such as anti-neuroinflammation and induction of neurotrophic factors against neurodegeneration in the animal model of Parkinson's disease, suggesting that naringin-induced effects may be useful to other brain diseases. To evaluate the beneficial effects of naringin against epileptic seizures, we have examined the effects of naringin

against KA-induced neurotoxic effects in the hippocampus of mouse brains. Our results showed that intraperitoneal injection of naringin could induce an increase in a threshold for KA-induced seizures, resulting in the delayed onset of seizures, and significantly ameliorated the KA-induced neurotoxicity through anti-autophagic stress and anti-neuroinflammation in the hippocampus compared with KA alone. Moreover, treatment with naringin attenuated the KA-induced mTORC1 activation, which caused GCD in the hippocampus. Therefore, these results suggest that naringin, which induces neuroprotective effects such as anti-autophagic stress, anti-neuroinflammation and anti-GCD, may be a beneficial natural compound against epileptic seizures.

FACES: Finding a Cure for Epilepsy and Seizures

Title: Regulation of excitatory/inhibitory coordination by LPI-GPR55 signaling: implications for seizure generation and management with cannabinoids

Authors: *E. C. ROSENBERG[1], M. BAZELOT[3], A. SALAH[1], B. WHALLEY[3], O. DEVINSKY[2], R. W. TSIEN[1];
[1]Neurosci. and Physiol., [2]Neurol., NYU Sch. of Med., New York, NY; [3]Pharmacol., Univ. of Reading, Reading, United Kingdom

Abstract: Cannabis has been used for centuries as an anti-epileptic therapeutic, and non-psychoactive components of cannabis have reduced seizure activity in both pre-clinical animal models and recent clinical trials (Devinsky et al. 2015). However, the exact mechanism of action of cannabinoids such as cannabidiol (CBD) remains unclear. In one leading hypothesis, CBD acts as a competitive antagonist at the G-protein coupled receptor, GPR55, inhibiting binding of a membrane phospholipid, lysophosphatidylinositol (LPI). CBD blocks LPI-mediated increases in presynaptic Ca^{2+} and consequential vesicular release, thus reducing excitability at excitatory axon terminals (Sylantyev et al. 2013). However, the function of LPI-GPR55 signaling at excitatory postsynaptic sites, inhibitory synapses, and in epilepsy, remains to be explored. Using a multidisciplinary approach, we found that LPI produces distinct pre- and postsynaptic effects at excitatory and inhibitory synapses. At 5-10 min post-application, LPI increased mEPSC frequency in CA1 hippocampus, consistent with previous reports. However, prominent GPR55 immunostaining in CA1 pyramidal neurons cell bodies was also observed, suggesting potential postsynaptic GPR55 expression. LPI elevated GluA1 AMPAR expression at 50-60 min post-application and increased Ser831 and Ser845 phosphorylation. Additionally, LPI reduced inhibitory postsynaptic strength with concomitant decreases in $GABA_AR$ γ_2 subunit expression and Ser327 phosphorylation. Taken together, these results suggest that LPI increases the excitatory/inhibitory ratio in hippocampal neuronal networks by a dual mechanism: enhancing excitatory transmission and attenuating inhibition. This predicts that CBD, by opposing LPI action at GPR55, may exert its beneficial anti-seizure effects at both excitatory and inhibitory synapses.
We further observe that LPI-mediated increases in mEPSC frequency are potentiated in hippocampal slices from animals rendered epileptic following lithium-pilocarpine induced epileptogenesis. Consistent with this finding, acute kainic-acid induced seizures elevated membrane-bound GPR55 expression. Collectively, these results predict a potential positive feedback loop in which seizures elevate GPR55 expression, augmenting the effect of LPI and its seizure-promoting effects on excitatory / inhibitory coordination. Thus, GPR55 represents a potential biomarker for susceptibility to prolonged seizures.

Title: Anticonvulsant effect of cannabinoid receptor agonists in a model of neonatal seizures

Authors: *M. HUIZENGA, E. WICKER, V. BECK, P. FORCELLI;
Georgetown Univ., Washington, DC

Abstract: Neonatal seizures and seizures of infancy represent a significant cause of morbidity. 30-40% of infants and children with seizures will fail to achieve seizure remission with current anti-epileptic drug (AED) treatment. Moreover, less than half of electrographic neonatal seizures are effectively controlled with the current first (phenobarbital) or second (phenytoin) line drug treatments. Identification of new therapies for neonatal/infantile epilepsy syndromes is thus of high priority.
Recent case reports have appeared suggesting that cannabis extracts, such as cannabidiol, may exert clinical anticonvulsant effects in young patients. While drugs targeting the cannabinoid system (e.g., CB1 receptor agonists) display anticonvulsant efficacy in adult animal models of seizures/epilepsy, they remain unexplored in neonatal models. However, the cannabinoid system emerges and is active early in development across species, supporting the investigation of targeting this system in neonates. Therefore, we examined the therapeutic potential of drugs targeting the cannabinoid system in a neonatal rodent model of seizures. Postnatal day (P) 10 or P20 male, Sprague-Dawley rat pups were challenged with the chemoconvulsant DMCM (300 ug/kg) 20 min after treatment with either: CB1/2 mixed agonist (WIN 55,212-2), CB1 agonist (ACEA) or antagonist (AM-251), CB2 agonist (HU-308) or antagonist (AM-630), FAAH inhibitor (URB597), and GPR55 agonist (O-1602). Only the mixed CB1/2 agonist and the CB1 agonist displayed anticonvulsant effects in this model. The severity of seizures was significantly decreased and the latency to behavioral seizure symptoms was increased. These effects were seen in P10 animals but not P20 animals. By contrast, both CB1 and CB2 antagonism increase seizure severity.
Together, these results indicate that in neonates, anticonvulsant action of the cannabinoid system is specific to CB1 receptor activation during a specific developmental window. These data provide justification for further examination of CB1 receptor agonists as novel antiepileptic drugs targeting epilepsy in infants and children.

Title: Effect of Krill Oil on seizures induced by pentylenetetrazole in adult rats with postnatal seizure induction

Authors: *F. V. VILLALPANDO VARGAS[1], A. M. LARA-VÁZQUEZ[1], L. MEDINA-CEJA[1], L. FLORES-MANCILLA[2];
[1]Biologia Celular y Mol., Univ. of Guadalajara, Guadalajara, Mexico; [2]Univ. Autonoma de Zacatecas, Zacatecas, Mexico

Abstract: Epilepsy is a disease characterized by an enduring predisposition to generate epileptic seizures and by the neurobiological, cognitive, psychological, and social consequences of this condition. It affects 50 million people all over the world. The Krill oil (KO) is an extract of the Antarctic crustacean, *Euphausia superba*, contains phospholipids and omega-3. However, the anticonvulsive effect of the KO has not been reported in literature before. Accordingly, we evaluated its effect on pentylenetetrazole (PTZ) model of generalized seizures, at behavioral level. Male Wistar rats with chronic intragastric administration of Palm oil (300 mg/kg, n=4), water (n=4) and KO (300 mg/kg, n=6), from birth to the end of the experiment, approximately 40-60 postnatal days (PD) and with febrile seizure induction at 4-5PD were used for control and experimental groups. After PTZ administration (90 mg/kg, i.p.) we evaluated the survival period, duration of seizures, loss of posture and convulsive behavior according to Pohl and Mares scale (1987): phase 0.5 sniffing, extensive washing, orientation; phase 1 isolated myoclonic jerk; phase 2 atypical (unilateral or incomplete) clonic seizure; phase 3 fully developed bilateral forelimb clonus; phase 3.5 forelimb clonus with a tonic component and twist of body; phase 4 refers to tonic-clonic seizure with suppressed tonic phase; only clonus of all limbs; phase 5 fully developed tonic-clonic seizure. The results showed a delay in the onset of phase 2 in animals treated with KO compared with palm oil group ($p<0.05$), also an increase in the survival time post-PTZ was observed in the KO group, however it was not statistically significant. In conclusion, the KO did not show anticonvulsant effect at behavioral level in animals with seizures induced by PTZ.

Title: Pregabalin intervention during development is antiepileptogenic in the transgenic epilepsy model of α2δ-1 overexpressing mice

Authors: *W. ZHANG, D. PRINCE;
Neurol. Dept., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: The alpha2delta-1 subunit (α2δ-1) of voltage-gated calcium channels is a receptor for astrocyte-secreted thrombospondins (TSPs) that promote developmental synaptogenesis. Overexpression of α2δ-1 alone in uninjured transgenic mice (α2δ-1 TG mice) results in increased excitatory connectivity and consequent epileptiform seizures. Gabapentinoids, including pregabalin (PGB), are anticonvulsant/antiallodynic drugs that interrupt TSP binding to α2δ-1 and have antiepileptogenic effects in models of cortical injury. However, little is known about the effects and the critical time window of PGB intervention in transgenic epilepsy models like α2δ-1TG mice. To address these questions, we compared the electrophysiological outcomes of PGB treatment administrated at different developmental times in α2δ-1TG mice. We initially treated TG mice with PGB (50 mg/kg ip daily) from P20 to P34 or from P14 to P28 and obtained whole cell recordings of miniature EPSCs (mEPSCs) in layer V pyramidal cells. There were no significant differences in amplitude or frequency of mEPSCs between treated TG mice and saline-treated controls, indicating that existing hyper-connected excitatory circuits were not affected. We obtained epidural EEGs, rather than *in vitro* mEPSC recordings, from a 3rd group of implanted mice treated with PGB from P7 to P28. EEG signals were filtered (1Hz high-pass; 15Hz low-pass) and a Fourier transform power analysis done. EEGs of both untreated and treated TG mice showed epileptiform discharges with peak frequency at 2-4 Hz, 4 and 5 days after the end of treatment. However, the amplitudes of absolute power at 2-4 Hz were decreased to 1/3-1/2 of controls in the PGB-treated group (0.0012-0.0013 vs 0.0006-0.0009 mV^2/Hz). These results suggest that PGB administration from P7 to P28 is effective in attenuating the epileptiform discharges in α2δ-1TG mice. Taken together, our preliminary data show that early PGB intervention can attenuate epileptogenic outcomes in α2δ-1 TG mice. Results raise the possibility of prevention of epileptogenesis in similar genetic models once receptors and appropriate agonists or antagonists are identified.

Abstract: Antiepileptic drug (AED) treatment failures may occur because there is insufficient drug in the brain or because of a lack of relevant therapeutic response. Until now there is no possibility to measure these factors. It has been recently shown that the combination of transcranial magnetic stimulation and electroencephalography (TMS-EEG) can measure the effects of central nervous system acting drugs in healthy volunteers. The EEG response evoked by TMS, named TMS-evoked EEG potentials (TEPs), comprises a series of positive and negative deflections which were specifically modulated by drugs with a well-known mode of action targeting the inhibitory neurotransmission. Hence, we hypothesised that TMS-EEG can depict fingerprints of two widely used AEDs, lamotrigine and levetiracetam, in healthy volunteers. Fifteen healthy subjects participated in a pseudo randomized, placebo-controlled, double-blind, crossover design, using a single oral dose of lamotrigine (300mg), a voltage-gated sodium channel blocker, and levetiracetam (3000mg), which blocks neurotransmitter release by binding to specific vesicles. TEPs were recorded before and 120 min after drug administration and the effects of the drugs on the potentials amplitudes were statistically evaluated. A non-parametric cluster-based permutation analysis of amplitudes at channel-level was run for placebo, lamotrigine and levetiracetam conditions. Both AEDs increased the amplitude of the negative potential at 45ms after stimulation (N45) and suppressed the positive peak at 180ms (P180), whereas placebo did not cause any significant modulations.We demonstrate for the first time AED-induced modulation of TMS-EEG measures. Despite the different mechanism of action that lamotrigine and levetiracetam exert at molecular level, both AEDs are impacting the TMS-EEG response in a similar way. These TMS-EEG fingerprints observed in controls are candidate predictive markers of treatment response in patients on monotherapy with lamotrigine and levetiracetam.

Title: Staged anticonvulsant screening for chronic epilepsy

Authors: *Y. SAPONJIAN[1,2], Y. BERDICHEVSKY[3], K.-I. PARK[4], B. ROACH[5], W. POULIOT[5], K. LU[6], W. SWIERCZ[1,2], E. DUDEK[5], K. STALEY[1,2];

Gangham Ctr., Seoul, Korea, Republic of; [5]Dept. of Neurosurg., Univ. of Utah Sch. of Med., Salt Lake City, UT; [6]Boston Univ. Sch. of Med., Boston, MA

Abstract: Significant limitations are associated with studying seizures induced by acute exposure to convulsants in otherwise normal *in vitro* and *in vivo* preparations, which current anticonvulsant screening programs are predominantly based on. One third of epileptic patients do not respond to the numerous anticonvulsants produced as a result of decades of drug screening and development efforts. The slicing preparation of organotypic hippocampal slice cultures parallels traumatic axonal shear injury and subsequently slices develop a dense recurrent synaptic connectivity that results in the development of spontaneous seizures after 1 week *in vitro*. We present a drug discovery program utilizing a tiered compound screening platform based on chronic epilepsy and spontaneous seizures, with compounds advancing from high-throughput *in vitro* models to low-throughput *in vivo* models. The initial stage utilizes the reproducible, accessible and accelerated course of epileptogenesis in the *in vitro* organotypic hippocampal slice culture model of severe post-traumatic epilepsy to conduct a blind screen of an array of compounds and conditions for anticonvulsant, antiepileptic and neuroprotective effects in chronic epilepsy. Lactate production and release of lactate dehydrogenase into spent culture media were used as biomarkers of seizure activity and cell death, respectively, to quantify epileptogenesis. Compounds exhibiting significant reducing effects were retested and subsequently advanced to a second stage comprised of wash-out screens to differentiate anticonvulsant from antiepileptogenic effects, as well as *in vitro* electrophysiological confirmation. The third stage was comprised of double-blind, crossover-controlled, *in vivo* continuous electrographic monitoring of spontaneous seizures in the kainate model of chronic epilepsy. We have screened 140 compounds (most at multiple concentrations) or combinations

of drugs, in over 400 separate drug-concentration experiments alongside control slices from the same animal. We have identified 79 toxic drug-concentrations and over 40 hits. Most current anticonvulsants had modest effects in the initial *in vitro* stage. The cyclooxygenase inhibitor celecoxib had no effect on chemically-induced acute epileptoform activity in normal brain tissue but exhibited robust anticonvulsant activity in all models of chronic epilepsy. This tiered program comprises a promising strategy for the rapid, staged investigation of drug efficacy in post-traumatic epileptogenesis with the ultimate goal of discovering and developing drugs that prevent or modify epileptogenesis and the progression of epilepsy.

Title: Ionic alterations during apoptosis in the developing hippocampus.

Authors: *T. BALENA, Y. SAPONJIAN, K. J. STALEY;
Massachusetts Gen. Hosp., Charlestown, MA

Abstract: New fluorophores and microscopy techniques have made possible more detailed explorations of the process of neuronal death. In the present study we evaluated the death of neurons in a chronically epileptic in vitro preparation in which multiphoton microscopy could be performed over a period of several days. Organotypic hippocampal slice cultures were made from wild-type C57BL/6J mice, and imaged with transgenic fluorophores as well as the Na^+ dye SBFI. Organotypic slice cultures were prepared on P6 and incubated *in vitro* until use, with SBFI added 24 hours prior to imaging. Two-photon imaging was used to excite SBFI at both Na^+-sensitive and -insensitive wavelengths, allowing for the ratiometric determination of the $[Na^+]_i$. Propidium iodide (PI), an indicator of cell death, was used as a costain in most experiments to exclude damaged neurons from the analysis. Immediately post-trauma, neurons had significantly higher $[Na^+]_i$ than has been reported in undamaged neurons. After a brief recovery period, $[Na^+]_i$ again rose to high levels and remained elevated for days. Elevated $[Na^+]_i$ followed decreased

synthesis of virus-induced fluorescent proteins such as TurboRFP, preceded morphological changes such as cell shrinkage and retraction of processes, and coincided with increases in membrane permeability (allowing for the passive influx of dyes and stains such as propidium iodide). The high $[Na^+]_i$ was mitigated by the activity of Na^+/K^+ ATPases, cation/Cl^- cotransporters, and Na^+/Ca^{2+} exchangers in order to support high rates of transmembrane Na^+ flux during epileptogenesis. Inhibition of COX-2 and the protein Bax significantly lowered $[Na^+]_i$, suggesting that an apoptotic pathway leading to the insertion of permeability pores in the cytoplasmic membrane may be responsible for the rise in $[Na^+]_i$ and related changes. Overall, a stereotypical sequence of events preceded neuronal death by at least several days, beginning with quenched emission of fluorescent proteins, dendritic retraction, elevation in $[Na^+]_i$, and terminal cell shrinkage. ATPase activity and secondary ion transport remained robust throughout this process. We are currently testing whether the mitigation of elevated $[Na^+]_i$ reflects a translationally useful neuroprotective effect or a specific effect on $[Na^+]_i$.

Title: Inhibition of O-GlcNAcase is anticonvulsive and alters hippocampal O-GlcNAcylation levels in the kainic acid model of temporal lobe epilepsy

Authors: *R. G. SANCHEZ, M. C. RICH, F. D. LUBIN;
Neurobio., Univ. Of Alabama At Birmingham, Birmingham, AL

Abstract: Abnormal brain glucose metabolism contributes to the progression of epilepsy disorders. Temporal Lobe Epilepsy (TLE) is a complex disorder that is associated with glucose hypometabolism. Metabolic *O*-linked N-acetylglucosamine (*O*-GlcNAc) signaling that is downstream of the hexosamine biosynthesis pathway (HBP), a metabolic target of glucose metabolism. In the roundworm *Caenorhabditis elegans*, the fruit fly *Drosophila melanogaster*, rodents and humans, the *O*-GlcNAc transferase (OGT) and *O*-GlcNase (OGA) add and remove

O-GlcNAc groups on proteins, respectively. To date, there is virtually nothing known regarding the role of protein *O*-GlcNAcylation in epilepsy. Here, we examined the contribution of *O*-GlcNAcylation to epileptogenesis using kainate-induced experimental TLE model. We found significant decreases in *O*-GlcNAc and OGT levels in the epileptic hippocampus that was more pronounced in hippocampal regions that may be responsible for a loss of cellular glucose homeostasis. Importantly, we observed similar decreases in *O*-GlcNAc and OGT levels in human epileptic hippocampal tissue compared to aged-matched controls (Average age: 39.6yrs). We found that both neurons and astrocytes express OGT and *O*-GlcNAc at baseline, and that *O*-GlcNAcylation levels in these cell-types are differentially regulated in response to potassium chloride or methionine sulfoximine, respectively. To test the contribution of *O*-GlcNAcylation in epilepsy, we treated epileptic animals with the OGA inhibitor Thiamet-G (TMG). We found that TMG treatment restored protein *O*-GlcNAcylation levels in the rat epileptic hippocampus, reduced epileptiform activity and frequency oscillations in our TLE rodent model. Collectively, these findings demonstrate the therapeutic potential of TMG, and a novel role for protein *O*-GlcNAcylation in TLE.

Title: Contrasting effects of perampanel and midazolam on EEG seizure measures in tetramethylenedisulfotetramine-induced status epilepticus

Authors: *D. ZOLKOWSKA[1], D. J. TANCREDI[2], L. OLSEN[1], P. J. LEIN[3], M. A. ROGAWSKI[1];
[1]Dept. of Neurol., Sch. of Med., [2]Dept. of Pediatrics and Ctr. for Healthcare Policy and Res., Univ. of California, Davis, Sacramento, CA; [3]Dept. of Mol. Biosciences, Sch. of Vet. Med., Univ. of California, Davis, Davis, CA

Abstract: Tetramethylenedisulfotetramine (TETS) is a highly lethal neurotoxic rodenticide that acts as a noncompetitive GABA-A receptor. Severe TETS intoxication in humans produces refractory convulsive status epilepticus (SE). We previously reported that perampanel enhances survival of mice in a TETS SE model. Here we assess the impact of perampanel on EEG

measures in the TETS SE model. For comparison, some animals were treated with midazolam, which also reduces mortality in the model. Mice implanted with EEG electrodes were pretreated with a single dose of riluzole (10 mg/kg, IP) and 10 min later received a lethal dose of TETS (0.2 mg/kg, IP). Riluzole does not inhibit TETS-induced SE but does protect against the lethal effects of TETS in mice. Perampanel (3 mg/kg, IP) and midazolam (1.8 mg/kg, IM) were administered 40 min after the first myoclonic twitch. Each 1 min epoch in the EEG recording during the 45 min period after treatment injection was scored for the presence of: isolated spikes/sharp waves (0.08-0.5 Hz), spikes/polyspikes/sharp waves clusters (0.5-2 Hz), and organized seizures. Rates are expressed as total number of rat-minutes with the observed behavior divided by total number of rat-minutes under observation and compared with Poisson regression models for longitudinal data. Perampanel decreased seizures (RR=0.27, 95% CI: 0.14, 0.55) and spike clusters (RR=0.66, 95% CI: 0.43, 1.01) but markedly increased isolated spikes (RR=1.77 95% CI: 1.34, 2.34). In contrast, midazolam did not significantly reduce the rate of seizures (RR=0.68, 95% CI: 0.37, 1.26) but did reduce isolated spikes (RR=0.29, 95% CI: 0.15, 0.55) and spike clusters (RR=0.51, 95% CI: 0.28, 0.94). Peramperal versus midazolam contrasts were statistically significant for organized seizures (RR=0.40, 95% CI: 0.17, 0.95) and for isolated spikes (RR=6.14, 95% CI: 3.30, 11.43) but not for spike clusters (RR=1.28, 95% CI: 0.66, 2.47). Our results demonstrate that perampanel is highly effective at reducing TETS-induced electrographic seizures but interictal-like activity increases. Midazolam, a benzodiazepine which is often used clinically in the treatment of status epilepticus, is less effective in reducing TETS-induced EEG seizures but effectively suppresses epileptiform activity. Our results indicate major difference between AMPA receptor blockade by perampanel and GABA-A receptor positive modulation by midazolam on the electrographic features of TETS-induced SE. The results suggest that perampanel is superior to midazolam in reducing spread of local activity to form organized seizures but discharges overall increase. The long term implications on outcome remain to be determined.

Title: Long-term effects of neonatal monosodium glutamate treatment over the expression level of NCX1-3 and their participation in electrographic seizure activity

Authors: *M. HERNANDEZ-OJEDA, M. E. UREÑA-GUERRERO, P. E. GUTIÉRREZ-BARAJAS, A. I. FERIA-VELASCO, C. BEAS-ZARATE;
Dept. de Biologia Celular y Mol., Univ. De Guadalajara-CUCBA, Guadalajara, Jalisco, Mexico

Abstract: A significant neuronal impairment could lead to epileptogenesis in which cellular and molecular modifications persist and bring sudden and recurrent epileptic seizures. Monosodium glutamate (MSG) applied as neonatal treatment produces excitotoxic neuronal damage with several short- and long-term modifications. Increments in the expression level of NCX3 were observed after that treatment as a short-term effect. NCX3 belongs to a genetic family known as SLC8A1-3 that encoding the proteins called NCX1-3. NCX transporters exchange $3Na^{+}$ and $1Ca^{2+}$, and are mainly implicated in Ca^{2+} homeostasis maintenance. Changes in NCXs expression observed after neuronal damage have been associated with epilepsy development. In this work, NCX1-3 expression level was estimated by western-blotting in the hippocampus and entorhinal cortex of adult (60 days) control and MSG-treated animals (4 mg /kg of body weight, subcutaneously applied at postnatal days 1,3,5 and 7). Significant increments in NCX1 and NCX3 were observed in both cerebral regions of MSG-treated animals with respect to controls without significant changes in NCX2. Then, NCX blocking effects were evaluated on electrographic seizures induced by intracerebroventricular administration of 4-aminopyridine (4AP, 3 nmol). KB-R7943 a benzyloxyphenyl derived, which is three fold more efficiently on NCX3 were used as NCX blocker. In control animals, KB-R7943 (62.5 pmol) administered simultaneously to 4AP increased the seizure electrographic activity observed in the hippocampus and entorhinal cortex with respect to convulsive drug administered alone. However, in MSG-treated animals, KB-R7943 delayed the bursts onset and reduced that activity. Results suggest that NXC blocking could control seizures observed after an excitotoxic neuronal damage.

Title: Optogenetic silencing attenuates the activity of acute focal 4-aminopyridine seizures in mouse neocortex

Authors: *M. ZHAO[1,2], E. R. BAIRD-DANIEL[1], R. ALLEVA[1], J.-Y. LIOU[3], H. MA[1,2], T. H. SCHWARTZ[1,2];
[1]Dept Neurolog Surg, [2]Brain and Mind Res. Inst., Weill Cornell Med. of Cornell Univ., New York, NY; [3]Columbia Univ., New York, NY

Abstract: Epilepsy is a neurological disorder that affects roughly 1% of the population worldwide. Although effective treatments with antiepileptic drugs are available, more than 20% of patients have seizures that are refractory to medical therapy and many patients experience adverse effects. Hence, there is a continued need for novel therapies for those patients. Recently, neuromodulations with the optogenetics toolbox have already been shown to be somewhat effective at treating seizures in animal models of epilepsy and may offer a new hope for these refractory patients. However, more studies showed that optogenetics in seizure control must be carefully considered to avoid its potential negative effects. Here, we combined local field potential recordings and optogenetics to test the function of optogenetic silencing in the acute epileptic model. We stereotaxically injected the eNpHR3.0 or Jaws AAV viral vector with CaMKII promoter into neocortex of adult mouse to inhibit cortical pyramidal neurons. Acute focal seizures were induced by 4-aminopyridine (4-AP, 15mM, 0.5 µl) injection. We utilized the local field potential (LFP) to identify ictal discharge and measure epileptic activity. Photostimulation was performed using a TTL-controlled LED light. Histological studies confirmed the expression of eNpHR3.0 or Jaws in excitatory glutamatergic neurons. The total of 101 seizures was recorded from 9 mice. Following 5-8 weeks of eNpHR3.0 and jaws injections, there was no difference in the duration of seizures between the control and the light stimulation. LFP power, however, decreased from 1895.1 ±238.1 mV^2 to 1317.8±107.3 mV^2 in eNpHR 3.0 group ($p<0.05$, n=4 mice, 50 seizures), and from 2148.3 ± 393.8 mV^2 to 1575.5±486.3 mV^2 in the Jaws group ($P<0.05$, n=5 mice, 51 seizures). Taken together, these results demonstrate that optogenetic silencing of principal network can reduce the seizure activity in neocortex. Furthermore, much work is still needed to improve the strategy of optogenetic therapies for epileptic disorders.

Title: Identification of novel HCN channel phosphosites in human and animal model epilepsy

Authors: F. A. CONCEPCION[1], A. L. KO[2], J. G. OJEMANN[2], *N. P. POOLOS[3];
[1]Neurol., [2]Neurosurg., [3]Univ. of Washington, Seattle, WA

Abstract: Alterations in hyperpolarization-activated, cyclic nucleotide-gated (HCN) channel expression and function have been reported following status epilepticus (SE) in the pilocarpine-induced epileptic rat model (Jung et al., 2010, 2011; Williams et al., 2015). We have shown in these epileptic rats that the altered HCN properties in hippocampal principal neurons (such as changes in surface expression and current (I_h) amplitude) are regulated by phosphorylation. However, the actual phosphorylation sites (phosphosites) on HCN channel proteins that are altered in epilepsy have not been identified. In our current study, our objective was to identify these phosphosites on HCN1 and HCN2 channels through tandem mass spectrometry (MS). We enriched for HCN1 by immunoprecipitating with a monoclonal α-HCN1 antibody in CA1 hippocampal homogenates from male P90-101 epileptic rats (5-6 weeks post SE, n = 7) and age-matched naïve controls (n = 8). Mass spectrometry analyses revealed 6 phosphorylation sites on HCN1 in both our experimental and control samples, located in the cytoplasmic side of the protein at both the N- and C-terminal regions. No statistically significant differences were observed in the frequency of phosphosite identification in epileptic versus naïve samples. For HCN2 channels, we observed 10 phosphorylation sites. Interestingly, we found a statistically significant reduction in phosphorylation at one phosphosite in the C-terminus in epileptic tissue. Finally, we analyzed HCN channel phosphorylation patterns in neocortical tissue from 6 human patients with refractory epilepsy undergoing resection of the epileptogenic zone. For HCN1 channels, we identified 5 phosphosites in human tissue: 3 which were homologous to rat phosphosites, one which was novel, and one with no corresponding homolog on the rat sequence. For HCN2 channels we found 9 human phosphosites, eight of which corresponded to rat homologs, and one which was novel.
In summary, we have identified novel phosphosites on both HCN1 and HCN2 channels, and provide the first evidence of differential phosphorylation of HCN2 channels in an animal model of epilepsy. Also, we show for the first time that phosphorylation of human neocortical HCN channels occurs at predominantly the same phosphosites as in rat hippocampal HCN channels.

Title: Increased brain expression of tau and hyperphosphorylated tau in human therapy-resistant epilepsy

Authors: *L. JACOBS, C. A. COTO, H. JUUL, M. A. DICHTER, F. E. JENSEN, D. M. TALOS;
Neurol., Univ. of Pennsylvania, Sch. of Med., Philadelphia, PA

Abstract: Temporal lobe epilepsy (TLE) is the most common type of partial epilepsy in adulthood and is often the most treatment resistant. In addition, in TLE patients, epilepsy duration and severity positively correlate to impaired cognition. Recent studies in rodent epilepsy models have demonstrated that tau, a microtubule associated protein, may play a key role in enhancing neuronal excitability, and in both human patients and fmouse models, tauopathies are associated with cognitive impairment. We thus hypothesized that in human TLE hippocampal and cortical tissue, both tau and phospho-tau are expressed at higher levels, as compared to controls and that this might be related to both the hyperexcitability and the cognitive impairment seen in these patients.
We evaluated tau and phospho-tau Ser202/Thr205 (At8) expression by Western blot and immunofluorescent double labeling of human hippocampal and cortical samples from subjects with confirmed therapy-resistant TLE who underwent resective epilepsy surgery (n=8, ages 20-56 years). These were compared to hippocampal and temporal lobe cortex samples from neuropathplogically normal autopsy cases (n=5, ages 20-58 years) as controls.
Western blot quantification demonstrated a significant increase of both total tau (700.2% of

control, p<0.0001) and phospho-tau (238.3% of control, p<0.1) in hippocampal tissue homogenates (n=6). Temporal neocortical samples (n=8) also showed increases in total tau (162.9% of control, p<0.1) and phospho-tau (404.7% of control, p<0.01) proteins. Immunohistochemical analysis revealed increased neuronal expression of tau and phospho-tau in both brain regions. The increased expression was also observed in reactive astrocytes and endothelial cells of microvessels.
Together these results indicate a significant tau pathology in human TLE that may contribute to epileptogenesis and possibly cognitive decline. Our data, corroborated with previous pre-clinical studies, further suggest that targeting tau signaling may represent a novel therapeutic strategy for management of refractory TLE and its cognitive consequences.

Abstract: Pharmacoresistant epilepsy is a chronic neurological condition in which a basal brain hyper excitability results in paroxysmal hyper synchronous neuronal discharges. Human temporal lobe epilepsy has been associated with dysfunction or loss of the potassium-chloride co-transporter KCC2 in a subset of pyramidal cells in the subiculum, a key structure generating epileptic activities. KCC2 regulates intra-neuronal chloride and extracellular potassium levels by extruding both ions. Absence of effective KCC2 may alter dynamics of chloride and potassium levels during repeated activation of GABAergic synapses due to interneuron activity. In turn such GABAergic stress may itself affect Cl- regulation. Such changes in ionic homeostasis may switch GABAergic signaling from inhibitory to excitatory in affected pyramidal cells and also increase neuronal excitability. Possibly they contribute to periodic bursting in pyramidal cells, an essential component in the onset of ictal epileptic events. We tested this hypothesis with a computational model of a subicular network with realistic connectivity. The pyramidal cell model explicitly incorporated the cotransporter KCC2 and its effects on the internal/external chloride and potassium levels Our network model suggested the loss of KCC2 in a critical number of pyramidal cells increased external potassium and intracellular chloride concentrations leading to seizure-like field potential oscillations. These oscillations included transient discharges leading to ictal-like field events with frequency spectra as in vitro. Restoration of KCC2 function suppressed seizure activity and thus may present a useful therapeutic option. These simulations therefore suggest that a reduced KCC2 cotransporter activity alone may underlie the generation of ictal discharges.

Title: Seizure prediction based on intracortical microelectrode-array LFPs in human focal epilepsy

Authors: *M. AGHAGOLZADEH[1,4], L. HOCHBERG[2,3,4,5], S. CASH[5], W. TRUCCOLO[1,4,2]; [1]Neurosci., [2]Inst. for Brain Sci., [3]Sch. of Engin., Brown Univ., Providence, RI; [4]Ctr. for Neurorestoration and Neurotechnology, U.S. Dept. of Veterans Affairs, Providence, RI; [5]Dept. of Neurol., Massachusetts Gen. Hosp. and Harvard Med. Sch., Boston, MA

Abstract: Novel therapeutic interventions for treating pharmacologically resistant focal epileptic seizures have led to the development of closed-loop systems for seizure control. In a closed-loop seizure control system, electrical stimulation is delivered to prevent seizure initiation or spread once a seizure is detected or predicted to occur imminently. Current systems for seizure prediction/detection have been limited to tracking scalp-based electroencephalogram (EEG) or intracranial EEG (iEEG) signals. Here, we examine seizure prediction based on local field potentials (LFPs) recorded via a 10×10 intracortical microelectrode array implanted in a 4×4 mm^2 neocortical patch in a patient with focal seizures. We formulated the seizure (ictal) prediction problem in terms of discriminating between a period immediately leading to a seizure (preictal) and the interictal neural activity preceding that. In this study, we defined *a priori* the preictal time period as the 5 minute period leading to the ictal onset. We trained convolutional neural networks (CNNs) followed by fully-connected multilayer perceptrons (MLPs) under cross-validation. Input features consisted of the spectral power of LFP channels within consecutive 1-second time windows (0.5-second overlap). We estimated the spectral power within 10 separate frequency bands, namely Δ (0-4 Hz), θ (4-8 Hz), α (8-12 Hz), β_1 (12-18 Hz), β_2 (18-25 Hz), γ_1 (25-50 Hz), γ_2 (50-80 Hz), high frequency oscillations (80-150 Hz), multiunit activity MUA_1 (150-300 Hz), and MUA_2 (300-500 Hz). The dataset included 5 seizures. Seizures were separated by at least 68 minutes. A postictal period of 20 minutes after seizure termination was removed from both the training and testing datasets. The total interictal data spanned 8.12 hours and a leave-one-seizure-out cross-validation approach was used. We show that periods of preictal activity can be successfully discriminated from periods of interictal activity several (2 - 18) minutes prior to seizure onset (80% detection; no false positives). A preictal classification (i.e. seizure prediction) made before the defined preictal period was considered correct if it extended continuously until the seizure onset time. Our preliminary results show that intracortical LFPs may be a promising neural signal for seizure prediction in human focal epilepsy.

Title: A modular platform for closed-loop, low-latency intracranial stimulation in people with neurological disorders

Authors: *A. A. SARMA[1,2,4], B. CROCKER[5], S. S. CASH[6,7,5], W. TRUCCOLO[3,2,4]; [1]Sch. of Engin., [2]Inst. for Brain Sci., [3]Neurosci., Brown Univ., Providence, RI; [4]Ctr. for Neurorestoration and Neurotechnology, Providence VA Med. Abstract: Closed-loop electrical stimulation of the brain can be used to investigate, probe, and potentially treat a range of neurological disorders. The effects of ongoing neural state and dynamics on stimulation response have broad implications for the development of closed-loop neuromodulation approaches. We describe the development of a low-latency platform for pre-clinical, closed-loop neuromodulation studies with human participants. The system can detect neural events in real-time applications on up to 256 electrodes, with a brain-to-stimulation loop latency of 5ms. We illustrate the uses of the platform in exploratory stimulation sessions with individuals with epilepsy undergoing neuromonitoring prior to resective surgery. In these sessions, we tracked interictal epileptiform discharges, estimated as downward crossings of a dynamically computed RMS threshold on the local field potential, to trigger intracranial electrical stimulation. Our preliminary results suggest the relevance of ongoing neural state, at fine timescales, to the stimulation response.

Title: Non-invasive low frequency sensory stimulation suppresses seizures in two rodent models of epilepsy

Authors: *N. H. COUTURIER, L. GONZALEZ-REYES, C.-C. CHIANG, D. M. DURAND; Biomed. Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: Rationale: Low Frequency Electrical Stimulation (LFES) has proven to be effective as an alternative treatment for refractory epilepsy. However, LFES requires brain surgery and deep implantation of electrodes in the brain. We investigated whether a non-invasive implementation of this method using low frequency sensory stimulation (LFSS) could provide an effective alternative to surgical resection or electrical stimulation for temporal lobe epilepsy. Methods: The kainic acid animal model of Mesial Temporal Lobe Epilepsy (MTLE) was implemented in order to assess the effect of Low Frequency Audio-Visual stimulation on the frequency and duration of seizures. Stimulation was presented in the form of 1-Hz flashing light and clicking sound. EEG recordings were obtained a week prior to stimulation and compared against EEG recordings during stimulation. Furthermore, evoked potentials were recorded during audio stimulation, visual stimulation, and paired audio-visual stimulation to compare amplitude and latency of each over a 2 hour recording period. Results: A 55% $p<0.001$ (from a baseline of 21.14 ± 1.08 seizures/day to 5.47 ± 0.79 (N=8)) reduction in daily seizures was observed in the kainic acid model. The duration of seizures was also significantly reduced 63% $p=0.0002$. In comparing the evoked potentials from each of the stimulation paradigms all methods demonstrated sustained amplitude and latency over the course of the 2 hour stimulation session. The evoked potential from audio stimulation had an average amplitude of $100\ \mu V \pm 4.58$ and an average latency of $41.1\ ms \pm 0.4$. The paired audio-visual stimulation had an amplitude $142\ \mu V \pm 4.82$ and a latency of $40.3\ ms \pm 0.4$. The visual stimulation had an amplitude of $139\ \mu V \pm 4.11$ and a latency of $60\ ms \pm 1.1$. Conclusion: Significant reduction of seizure frequency/duration indicates that 1-Hz sensory stimulation can decrease excitability and frequency of seizures in the hippocampus. Moreover, the lack of habituation to the stimulation suggests that low frequency sensory stimulation can be effective over long periods of time. Keywords: epilepsy, low frequency stimulation, sensory stimulation, non-invasive treatment. Support: This study was supported by the NIH through grant 2R01NS060757-05A1

Title: Temporal Lobe Epilepsy & treatments with antiepileptic drugs modify the expression of the Transcription Factor REST/NRSF in patients

Authors: *V. NAVARRETE, SR[1], S. OROZCO-SUAREZ[2], I. A. FERIA-ROMERO[2], M. A. ALONSO-VANEGAS[3], L. ROCHA[4];

Politécnico Nacional (CINVESTAV), Mexico City, Mexico

Abstract: REST (RE1-Silencer Transcription Factor), also known as NRSF (Neuron Restrictive Silencer Factor), acts at chromatin level as a neural transcriptional repressor of genes. Several studies have shown that after induction of seizures in animal models there is an overexpression of REST/NRSF. At present it is unknown if the expression of REST/NRSF is modified in brain tissue of patients with pharmacoresistant epilepsy. The aim of this study was to determine the expression of the gene coding for REST/NRSF Transcription Factor in hippocampus of patients with pharmacoresistant Mesial Temporal Lobe Epilepsy (MTLE), and investigate if clinical variables, like age, gender, treatments, etc., are associated with the results obtained. mRNA was extracted from hippocampal tissue of patients with intractable MTLE (n=28). The extracted mRNA was re-purified by magnetic bead affinity to ensure integrity and cDNA was synthesized. The levels of expression of the gene encoding REST/NRSF, were evaluated using hippocampal tissue from autopsy as controls (n=7) by real-time PCR. Finally we evaluated the correlation with clinical variables. The results show that gene expression of REST/NRSF in hippocampus of patients with MTLE increases 141.63% compared to autopsy tissue ($p<0.05$). No differences in the expression of REST/NRSF was observed in patients treated with valproic acid (VPA) alone or in combination with other antiepileptic drugs (AEDs) compared to tissue autopsy, whereas in those treated with other AEDs is overexpressed 46.53% ($p<0.05$). In addition, in tissue from

autopsies, there is a negative correlation with age ($r=-0.809$, $p<0.05$), the older a lower expression of REST/NRSF. We conclude that in patients with TLE, the gene encoding REST/NRSF is overexpressed, regardless of the clinical variables, but treatment with VPA prevents this overexpression. In neurologically healthy subjects, the expression of REST/NRSF decreases with aging.

Title: Characterization of mesial temporal lobe epilepsy network

Authors: *S. KARUNAKARAN[1], G. P. KALAMANGALAM[2], B. AAZHANG[4], N. TANDON[3];
[2]Neurol., [3]Neurosurg., [1]Univ. of Texas Hlth. Sci. Ctr., Houston, TX; [4]Electrical and Computer Engin., Rice Univ., Houston, TX

Abstract: Rationale: The pathological substrate in mesial temporal lobe epilepsy (MTLE) extends beyond the hippocampus to a network of cortical and subcortical structures. Identification of patient-specific epileptogenic networks is essential for modulating these networks to decrease seizure probability and characterize commonly involved structures in a cohort of MTLE patients. Multiple non-invasive methods including fMRI, scalp EEG, PET have been used to characterize epileptogenic networks. These methods do not have consistent activation or precise localization of interictal spikes and ictal onsets and effectively lack the spatio-temporal resolution to characterize epileptogenic networks. An optimal method for delineating these networks would be to use intracranial recordings in the inter-ictal state. As opposed to seizures, that are less frequent, inter-ictal spikes are numerous and occur over multiple components of the MTLE network, allowing us to estimate the flow of information between different brain regions.
Methods: Intracranial recordings of 1 hour duration with frequent inter-ictal discharges were selected from pre-surgical intracranial recordings of 10 medically refractory epilepsy patients. Conditional probability and latency of propagation of inter-ictal spikes were computed using

pairwise estimates of activity in all channels. These were then used to generate a graph theoretical model between all nodes (channels). A logistic regression model was then used to predict surgically resected channels using directed node degree, number of spikes in each channel and their interaction as predictors. The best predictor from the regression was normalized, thresholded and combined across patients to visualize a grouped MTLE network.
Results: Directed node degree was the best predictor to classify the resected epileptogenic zone, determined by conventional clinical methods based on ictal onsets. The grouped network map in these MTLE patients revealed strong connections between hippocampus, amygdala and regions in frontal lobe, limbic system and temporal lobes.
Conclusions: When compared to imprecise non-invasive techniques and interventional, time-consuming stimulation methods, our method utilizes the routinely collected inter-ictal data to generate a map of the MTLE network. These maps may allow us to i) identify targets of a broader network for neuromodulation ii) identify patients with deviations from the "typical" epilepsy network who may not benefit from a resective procedure targeting medial structures iii) compare inter-ictal maps with a similar network obtained during seizure onset.

Title: Increased damage to autonomic brain regions in patients with left temporal lobe seizure onset

Authors: *R. K. HARPER[1], J. A. OGREN[2], K. W. CHOW[3], R. KUMAR[4], D. S. ELIASHIV[5], J. M. STERN[5], S. D. LHATOO[6], R. M. HARPER[2];

Abstract: Introduction: Sudden Unexpected Death in Epilepsy (SUDEP), accounts for up to 17% of deaths in individuals with epilepsy, and more than half of deaths in patients with intractable epilepsy. The mechanisms underlying SUDEP remain unclear, but likely involve

cardiac and/or respiratory dysfunction, which are partially mediated by temporal lobe structures. We used MRI-based analyses to determine if patients with left temporal lobe epilepsy (LTLE) exhibit more injury to autonomic-regulatory areas than healthy subjects or patients with other forms of epilepsy.
Methods: Subjects were 10 patients with LTLE(mean age ± SD: 51 ± 16.6 yrs; 6 female) and 10 age/gender-matched healthy controls (49 ± 10.4 yrs; 6 female). Additionally, we examined 11 patients with complex motor seizures (40 ± 14.1 yrs; 8 female) relative to 11 age/gender-matched healthy controls (40 ± 14.8 yrs; 8 female). Subjects were derived from Case Western Reserve University and the University of California at Los Angeles as part of the Center for SUDEP Research. High-resolution T1-weighted images, collected with a 3.0 Tesla MRI scanner, were subjected to entropy-based analysis to detect tissue homogeneity and randomness, with higher values corresponding to greater randomness, and thus, long-term injury. Images were bias-corrected, entropy maps calculated, normalized to a common space, smoothed, and compared between patients and controls using ANCOVA (covariates age, gender; SPM12, uncorrected threshold $p<0.005$). **Results**: LTLE patients exhibited significantly ($P<0.005$) higher levels of tissue entropy over controls throughout the brain in temporal lobe structures and in autonomic-regulatory brain regions, including the insular cortex, hypothalamus, basal forebrain, dorsal and midline thalamus, cingulate cortex, brainstem, and cerebellum (particularly deep autonomic cerebellar nuclei). LTLE patients exhibited clear bilateral hippocampal injury, despite the left hemispheric onset. Only minimal tissue homogeneity differences appeared in patients with complex motor seizures. Patients with complex motor seizures did not exhibit consistent, major long-term injury throughout the brain, likely a consequence of diverse focal origin. Damage was principally confined to small areas of white matter, thalamus, and occipital and cerebellar cortex.
Conclusion: LTLE patients exhibited damage in regions associated with areas of seizure onset. The marked tissue homogeneity differences in autonomic brain regions of LTLE subjects did not appear in all types of epilepsy, and may contribute to elevated SUDEP risk.

Title: A sparse autoregressive model as feature extraction for seizure prediction in temporal lobe epilepsy

Authors: ***P.-N. YU**, C. N. HECK, C. Y. LIU, D. SONG, T. W. BERGER;
USC, Los Angeles, CA

Abstract: Seizure prediction offers patients with epilepsy a better quality of life by allowing them to remove themselves from a dangerous situation. In addition, seizure prediction opens up the possibility to stop the ictal event. Autoregressive (AR) model has been used to extract the features of the interictal state and the preictal state of EEG data. After the extracted features are recognized by a classifier, the classifier can predict a seizure is coming if the following EEG data is recognized as the preictal state. However, determining which EEG channels to train the classifier is a judicious and subjective issue.
This study proposes using sparse logistic regression as the classifier to statistically determine which EEG channels and AR coefficients to be used in seizure prediction. EEG data with 97 channels were processed through the autoregressive model with order of 6 combined with the standard deviation of the residuals, thus ending up with 679 features. Approximately 100 out of the 679 features were statistically chosen by the sparse logistic regression. The 10 cross-validation results show that the overall prediction error from the in-sample data is around 15%. In this study, autoregressive model with order of 6 are currently used. In the future, we will optimize the order of autoregressive model and hopefully decrease the prediction error.

Abstract: Various interictal electrophysiologic biomarkers now exist as consistent indicators of epileptic brain regions such as High Frequency Oscillations HFOs and Interictal Epileptiform Discharges (IEDs). Phase-amplitude coupling (PAC) to date has not been heavily investigated as an interictal biomarker of seizure onset zone (SOZ). In a series of patients with drug-resistant epilepsy undergoing evaluation for surgery with intracranial EEG monitoring the effect of behavioral state (wake/sleep) and brain region (epileptic/non-epileptic) on PAC was investigated. The gold standard SOZ channels were determined by clinical review and behavioral state determined using simultaneous scalp EEG recordings. We show that spontaneous PAC occurs during interictal time far removed from seizures, and is markedly increased during IEDs. Furthermore, both the variance and the absolute value of PAC within a patient can be used to localize SOZ. The particular sleep state of the patient also appears to correlate with periods of significant changes in both PAC values and within channel PAC variance. Receiver-Operator Curves were used to evaluate the efficacy of localization relative to gold standard and the range of Area-Under-the-Curve (AUC) in this series was 0.52 - 0.90. The spectral characteristics of these PAC were also evaluated and while there was no significant difference seen between low-gamma (30-55Hz), high-gamma (65-100 Hz), or epsilon-gamma (100-150Hz) frequency for amplitude ranges, there was in the alpha and beta frequency for phase ranges. Increases in PAC highly correlate with IEDs. However, after removing the segments containing IEDs localization was still possible. These findings reveal that PAC is increased in epileptic brain, and in many cases can be used as an additional interictal biomarker of SOZ, giving complementary information to currently utilized electrophysiologic measures.

Title: Quantification of seizurogenic activity with multiwell microelectrode array technology for proconvulsant risk assessment and disease-in-a-dish epilepsy models

Authors: ***D. C. MILLARD**, H. B. HAYES, A. M. NICOLINI, C. A. ARROWOOD, J. D. ROSS;
Axion Biosystems, Atlanta, GA

Abstract: The lack of advancement in anti-epileptic drugs (AEDs) over the last 30 years, along with the continued need for improved proconvulsant screening in drug safety, motivates the need for new assays of seizurogenic neural activity. Previous work has established an in vitro approach for detecting and quantifying seizurogenic activity using multiwell microelectrode array (MEA) technology, providing a predictive and high-throughput avenue for the evaluation of the efficacy of AEDs and the proconvulsant risk of other drug candidates. Here, we present an updated assay of seizurogenic activity using the Axion BioSystems Maestro multi-well MEA system. We used previously published metrics for the detection of burst spiking events and the quantification of synchronization across a neural population, in spontaneous and evoked conditions. In addition, optogenetic approaches were used to systematically vary the network activity states. Data are included from rat cryopreserved cortical neurons evaluated with 16 compounds, including AEDs (i.e. Carbamazepine, Phenytoin, Tiagabine), reference compounds with known proconvulsant risk (i.e. 4-Aminopyradine, Strychnine, Pentylenetetrazole, Picrotoxin), and negative control compounds. Our results support the combined use of evoked and spontaneous neural activity, collected using multi-well MEA technology, for the high throughput evaluation of complex neuronal networks in vitro to inform the development of AEDs, while also quantifying the proconvulsant risk of candidate pharmaceuticals in a pre-clinical setting.

[4]Neurol., Univ. Col. London, London, United Kingdom; [5]Neurol., Case Western Reserve Univ., Cleveland, OH

Abstract: Rationale: Patients with epilepsy are at risk for Sudden Unexpected Death in Epilepsy (SUDEP); those who exhibit generalized tonic-clonic seizures (GTCs) are at even greater risk. Of recorded SUDEP deaths, a substantial proportion occurred nocturnally after a GTC. Using MRI-based entropy procedures, we assessed tissue texture, indicative of brain changes, in GTC patients relative to healthy controls to evaluate ongoing detrimental processes which may contribute to autonomic or breathing dysfunctions underlying SUDEP. **Methods:** As part of the Center for SUDEP Research, high resolution T1-weighted images were collected with a 3.0-Tesla MRI scanner from 53 patients with GTCs and 53 age- and gender-matched healthy controls at Case Western Reserve University, University College, London, and the University of California at Los Angeles. Images were bias-corrected, entropy maps calculated, normalized to a common space, smoothed, and compared between GTC patients and controls using ANCOVA (covariates age, gender; SPM12, family-wise error correction for multiple comparison, $p<0.01$). **Results:** Decreased entropy values, likely reflecting neuronal swelling, appeared in primary cortical motor/sensory areas, as well as key autonomic sites. The ventromedial prefrontal cortex, hippocampus and surrounding temporal cortex, and the insula also showed lower entropy values. In addition, decreased entropy appeared in the basal ganglia, anterior-medial cerebellum (including the deep autonomic nuclei), and external surfaces of the pons, with the more caudal medulla prominently affected. The anterior and posterior thalamus and midbrain also showed decreases. Only a few isolated regions showed increased entropy. **Conclusions:** Decreased entropy (increased tissue homogeneity, potentially resulting from inflammation or another cause of neuronal swelling) appears in major autonomic regulatory areas (ventromedial prefrontal cortex, insula, hippocampus, dorsal and ventral medulla, deep autonomic cerebellar nuclei) and multiple motor regulatory areas (sensory and motor cortex, basal ganglia, cerebellum), suggesting that GTC seizures have the potential to initiate injury both to autonomic regulatory and motor control sites. Since seizures in GTC patients arise from widespread brain areas, these analyses are unlikely to uncover areas of long-term injury that are consistent across patients, particularly as some have only infrequent GTCs. Future analyses, grouping patients by GTC severity or frequency, may reveal processes contributing to increased entropy, such as which appears in temporal lobe epilepsy.

Title: A personalized, molecular diagnosis of Lafora epilepsy patient mutations

Authors: *M. S. GENTRY;
Biochem., Univ. of Kentucky, Lexington, KY

Abstract: Of all the severe and intractable epilepsies, Lafora disease (LD) is among the most severe, and is inevitably fatal. Mutations in two genes have been identified that cause LD, *EPM2A* (laforin) and *EPM2B* (malin). *Identification of the genetic basis for LD has opened up a new era in our understanding of the cause of LD, leading to rapid progress in the field.* Mutations in either of these genes cause glycogen to transform into malformed (starch-like), aggregated inclusions called Lafora bodies. These inclusions overtake the cytoplasm of dendrites, and drive the progressive refractory seizure disorder.

The human *EPM2A* gene encodes the phosphatase laforin and recessive mutations in *EPM2A* result in Lafora disease (LD). We previously defined that the physiological function of laforin is to dephosphorylate glycogen. In the absence of laforin activity, glycogen transforms into hyper-phosphorylated, water-insoluble, starch-like inclusions that drive neuronal apoptosis, neurodegeneration, and eventual death of LD patients. LD patient missense mutations are dispersed throughout laforin, bringing to question the structural mechanism(s) of disease.

We recently determined the crystal structure of human laforin at 2.4 Å bound to oligosaccharides with a phospho-glucan product at the active site. The structure reveals an integrated tertiary structure of the carbohydrate binding module and dual specificity phosphatase domains as well as an antiparallel dimer mediated by the phosphatase domain that results in a tetramodular architecture, positioning the two active sites ~31 Å from each other. We utilized the crystal structure and three solution-based, biophysical techniques along with biochemical analyses of LD patient mutations and structured guided mutations to probe this unique tertiary and quaternary structure. We define a cooperative mechanism of action for laforin as well as establish the effect of LD disease mutations, thereby providing atomic level insights that connect basic glycogen metabolism to human neurodegenerative disease.

Cumulatively, this work allows us to provide a patient specific, molecular diagnosis of each LD laforin mutation. This personalized, molecular diagnosis will prove invaluable as our groups and others move towards a LD therapeutic and/or cure.

Title: Genetic and pharmacological treatment of hypomyelination in the zebrafish model for psychomotor retardation

Authors: *L. APPELBAUM, D. ZADA, A. TOVIN;
The Fac. of Life Sci. and The Multidisciplinary Brain Res. Ctr., Bar Ilan Univ., Ramat Gan, Israel

Abstract: Hypomyelination is a key symptom of the psychomotor retardation Allan-Herndon-Dudley syndrome (AHDS), which is associated with mutations in the thyroid hormone transporter *mct8*. AHDS is characterized by severe intellectual deficiency, neuromuscular impairment, and hypothyroidism in the brain. In order to study the neurological mechanism and find potential treatments, we developed an *mct8* mutant zebrafish (*mct8*-/-) as a model for AHDS. The transparent zebrafish is a vertebrate with simple yet conserved brain structure and function, and is amenable for live imaging of single cells and molecules. The *mct8*-/- larvae showed neurological phenotypes including pronounced hypomyelination. We found that the expression of genetic markers for oligodendrocyte progenitor cells increased while the expression of markers for mature oligodendrocytes decreased in *mct8*-/- larvae and adults. Two-photon live imaging showed that the number of oligodendrocytes in the brain and the spinal cord is reduced in *mbp:EGFP*/*mct8*-/- larvae and juveniles. Pharmacological treatment with thyroid hormone analogs and other myelin promoting compounds partially recovered myelination in *mct8*-/- larvae. Intriguingly, treatment with the thyroid hormone T3 did not affect myelination in relatively late developmental stages, after the maturation of the blood-brain barrier (BBB), suggesting that T3 can not cross the BBB in the absence of the MCT8 transporter. Thus, we transiently expressed a MCT8-tagRFP fusion protein in the vascular system. This relatively low

mosaic expression of MCT8-tagRFP specifically in endothelial cells of the vascular system completely recovered the number of oligodendrocytes in *mct8*-/- larvae. These results suggest that TH analogs and BBB-targeted gene-therapy can enhance myelination in AHDS and possibly in other thyroid-dependent brain disorders.

Title: Nanoparticle therapies for the treatment of X-linked adrenoleukodystrophy

Authors: ***C. L. NEMETH**[1], B. R. TURK[1], O. GOK[2], S. P. KAMBHAMPATI[2], J. S. MARX[1], B. E. THEISEN[1], R. R. RAMIREDDY[2], F. ZHANG[2], M. V. JOHNSTON[1], R. M. KANNAN[2], S. KANNAN[3], A. FATEMI[1];
[1]Dept of Neurol., Kennedy Krieger Inst., Baltimore, MD; [2]Ctr. for Nanomedicine, [3]Anesthesiol. and Critical Care Med., Johns Hopkins Univ., Baltimore, MD

Abstract: X-linked adrenoleukodystrophy (X-ALD) is a devastating, rapidly progressing, demyelinating condition affecting boys with an incidence of about 1:17,000. Symptoms of X-ALD first appear between the ages of 4 and 10 years of age and is almost always fatal within 2-3 years. Hallmark pathophysiology includes accumulation of very long chain fatty acids (VLCFA), increased oxidative stress, and progressive axonopathy. Although a monogenic disease, arising from defects in the peroxisomal membrane transporter protein, ABCD1, it exhibits little to no genotype-phenotype correlation and this phenotypic variability complicates prognosis and treatment. Hematopoietic cell transplant during early-stage disease progression has shown some success, however adjuvant treatments are necessary and otherwise promising pharmacotherapies demand chronic treatments at dangerous doses. Recent advancements in dendrimer nanoparticle therapeutics provide platforms in which dendrimer-drug conjugates enable targeted and intracellular slow release of drugs requiring fewer treatments at lower drug concentrations. Previous work has shown the use of dendrimer-drug conjugates to be a non-toxic and effective mechanism of drug delivery. Moreover, we have demonstrated uptake of dendrimer-drug conjugates by affected cell types in both *in vivo* and *in vitro* models of X-ALD, and the adult slowly progressing form adrenomyeloneuropathy (AMN). Dendrimer conjugates have been

detected within spinal cord neurons of the ABCD1 knockout mouse as well as within patient-derived primary macrophages and fibroblasts. Furthermore, use of the anti-inflammatory/anti-oxidant N-acetyl-L-cysteine (NAC)-dendrimer conjugate (D-NAC) has resulted in reduced levels of inflammation within X-ALD patient macrophages as compared to drug treatment alone. Together, these models recapitulate the hallmark pathophysiology of ALD-related diseases and these findings demonstrate reductions in disease burden following nanoparticle treatment. Nanotherapeutic treatment strategies offer a novel method to effectively and selectively target affected cells and may provide new therapeutic opportunities for complex diseases such as X-ALD.

Title: Activation of oligodendroglial PGC-1a by physical exercise accelerates remyelination

Authors: *S. K. JENSEN, N. J. MICHAELS, M. B. KEOUGH, J. N. HAHN, V. YONG; Univ. of Calgary, Calgary, AB, Canada

Abstract: Treatment modalities that promote the functional regeneration of myelin, termed remyelination, remain in their infancy despite considerable investigation. In multiple sclerosis, physical exercise and participation in activities of daily living are associated with reduced disability with little mechanistic rationale. Considering environment-derived stimuli and activity are known to stimulate myelination in the healthy central nervous system, we investigated the capability of physical exercise to promote remyelination during pathology. We show that immediate therapeutic access to a running wheel enhances oligodendrocyte generation following a lysolecithin-induced demyelinating insult. We observe a 39% and 30% increase in oligodendrocytes at 7 and 14 days post lesion (dpl), respectively. At 7 dpl, 50% of all oligodendrocytes are PDGFRα^+ progenitors and label for the proliferation marker Ki67. At 14

dpl, these newly formed progenitors functionally differentiate into $CC1^+$ mature oligodendrocytes, with progenitors making up <20% of all oligodendrocytes. Moreover, exercise increases the capacity for individual oligodendrocytes to form myelin segements resulting in a 2.7 fold increase in the number of myelinated axons at 14 dpl and accelerates the thickening of myelin. We identify PGC-1α as an exercise-induced factor in oligodendrocyte progenitors, mature oligodendrocytes, and select astrocytes. Further, RNA sequencing of micro-dissected lesions reveals increases in key metabolic genes as a result of exercise. We suggest this is a PGC-1α-driven effect, as it is known to coordinate the transcription of metabolic genes in other contexts, and that this increased metabolic capacity in oligodendrocytes enhances remyelination. We are currently investigating this link further. Overall, this study demonstrates that physical exercise is an efficacious means to enhance remyelination and describes a novel PGC-1α-dependant mechanism through which oligodendrocytes respond to physical activity and myelination is coupled to metabolism.

Title: Neuregulin-1 promotes oligodendrocytes replacement and fosters a pro-regenerative inflammatory response in focal demyelinating lesions of the spinal cord

Authors: *H. KATARIA, A. ALIZADEH, G. M. SHAHRIARY, K. T. SANTHOSH, S. KARIMI-ABDOLREZAEE;
Dept. of Physiol. & Pathophysiology, Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Oligodendroglial cell death and demyelination are hallmarks of CNS injuries and multiple sclerosis resulting in axonal damage and functional impairments. Restoration of myelin sheath (remyelination) remains a major obstacle as the ability of endogenous neural precursor cells (NPCs) for oligodendrocyte replacement is hindered in the unfavorable milieu of

demyelinating conditions. Our recent evidence in spinal cord injury indicates that drastic downregulation of Neuregulin-1 (Nrg-1), a critical growth factor for development and function of oligodendrocytes, may challenge the endogenous replacement of oligodendrocytes following injury. Here, in a rat model of lysolecithin (LPC)-induced demyelination, we demonstrate that Nrg-1 is also dysregulated in focal demyelinating lesions. We delivered recombinant human Nrg-1β1 (rhNrg-1β1) intraspinally at the time of LPC injections using poly lactic-co-glycolic acid (PLGA) nanocarriers. Spinal cord tissues were analyzed with ELISA, Western blotting and immunohistology at different time-points after LPC injections. Our findings show that rhNrg-1β1 treatment enhances oligodendrocyte and axonal preservation and promotes oligodendrocyte generation and myelin basic protein expression. Interestingly, Nrg-1 also fosters a neuroprotective and pro-regenerative inflammatory response characterized by induced interleukin-10 (IL-10) and arginase-1 (Arg1) expression in LPC-demyelinating lesion. Our complementary *in vitro* studies using brain derived primary rat adult NPCs and adult rat dorsal root ganglion neurons (DRGs) also provided direct evidence that availability of Nrg-1 significantly increases the number of myelin basic protein expressing cells in DRG-NPC co-cultures cells. Mechanistically, our co-immunoprecipitation studies for ErbB receptors in NPCs revealed that Nrg-1 specifically mediates it effects through ErbB4 receptor activation. In conclusion, our work provides new evidence suggesting an impact for Nrg-1 in promoting oligodendrocyte replacement and axonal remyelination in demyelinating lesions of the CNS that is in part attributed to the anti-inflammatory effects of Nrg-1. *Supported by the CIHR, Research Manitoba and Rick Hansen Institute.*

Title: Antisense oligonucleotides (ASOs) targeting mouse GFAP reverse pathology in a model of Alexander disease

Authors: *B. POWERS[1], T. HAGEMANN[2], S. WHEELER[2], C. MAZUR[1], E. SWAYZE[1], A. MESSING[2];
[1]Neurosci. Drug Discovery, Ionis Pharmaceuticals, Carlsbad, CA; [2]Waisman Ctr. and Dept. of Comparative Biosci., Univ. of Wisconsin-Madison, Madison, WI

Abstract: Alexander disease (AxD) is a rare, generally fatal leukodystrophy caused by autosomal dominant missense mutations in the gene for glial fibrillary acidic protein (GFAP). Considerable evidence supports the hypothesis that these mutations act in gain-of-function fashion, with accumulation of GFAP above a toxic threshold causing a cascade of effects both within astrocytes and on other cells of the CNS. GFAP and other proteins accumulate into Rosenthal fibers, the aggregates within cell bodies and processes of astrocytes that are the pathological hallmark of the disease. Seizures, megalocephaly and developmental delay are common symptoms, although many late-onset patients exhibit bulbar signs and motor disturbances instead. AxD has been modeled in mice by engineering point mutations in the endogenous mouse gene (*Gfap*) orthologous to those found in patients. *Gfap*$^{+/R236H}$ mice spontaneously increase GFAP mRNA and protein, exhibit the pathognomonic Rosenthal fibers, and an increased sensitivity to kainate-induced seizures. There are currently no treatments for AxD, but one possible therapeutic route is to reduce GFAP gene expression. To investigate the potential of ASOs to reduce mouse GFAP expression and disease pathology in AxD models, we screened for ASOs that efficiently targeted mouse GFAP. We chose ASOs that most potently reduced GFAP mRNA in mouse primary cortical cultures and injected them via single intracerebroventricular (ICV) bolus in wild-type mice. Four ASOs significantly reduced GFAP mRNA and protein in brain and spinal cord up to 8 weeks after a single bolus injection. Next, lead ASOs were injected via ICV bolus in *Gfap*$^{+/R236H}$ mice. We found marked suppression (up to 99%) of GFAP mRNA as well as protein in soluble, insoluble, and Rosenthal fiber enriched brain lysate fractions. Strikingly, GFAP ASOs also reversed Rosenthal fiber pathology in mutant mouse brains, and markedly reduced microglial activation/recruitment as indicated by Iba1 staining. Last, ASOs also significantly reduced Nqo1 mRNA in *Gfap*$^{+/R236H}$ mice, indicating a reversal of activation of the Nrf2/ARE antioxidant stress pathway found in this model. In conclusion, we have developed several ASOs targeting mouse GFAP that show great promise in preclinical studies as an approach for treating AxD.

Title: FTY720 restores brain-derived neurotrophic factor expression in a multiple system atrophy model

Authors: I. SEGURA-ULATE, B. YANG, J. VARGAS-MEDRANO, *R. G. PEREZ; Biomed. Sci., Texas Tech. Univ. Hlth. Sci. Ctr. - El Paso Campus, El Paso, TX

Abstract: Multiple system atrophy (MSA) is a rare and rapidly progressing demyelinating neurodegenerative disorder with no effective treatments. Most MSA patients progress from diagnosis to death in 10 years. MSA pathology is characterized by accumulation of the protein α-synuclein (aSyn) in oligodendroglia cells (OLGs), the myelinating cells of the brain. Importantly, aSyn is not normally expressed in mature OLGs but rather taken up from extracellular aSyn secreted by neurons. aSyn accumulation has deleterious effects in OLGs; including decreased expression of the potent protective molecule, brain derived neurotrophic factor (BDNF). Additionally, increasing BDNF in an MSA mouse model or supplementing an MSA OLG cell model with BDNF reduces their respective MSA dysfunction. Therefore, increasing OLG BDNF may be beneficial for MSA. We first modeled the effects of aSyn neuron-to-OLG transfer on BDNF expression in OLGs, using an *in vitro* aSyn uptake model using the OLG cell line, OLN-93. We incubated cells with recombinant human aSyn for 12 hr and confirmed aSyn uptake by immunoblot and immunocytochemistry. aSyn uptake decreased BDNF expression in OLN-93 cells as determined by qPCR. In an attempt to reverse the BDNF downregulation in response to aSyn, we also evaluated FTY720 (fingolimod, Gilenya), an FDA-approved drug for multiple sclerosis that is known to stimulate BDNF expression in many neural cells. Treatment with FTY720 alone significantly increased BDNF expression in OLN-93 cells, and the loss of BDNF in response to aSyn could be reversed by co-treating with FTY720 + aSyn. As FTY720 has also been shown to inhibit histone deacetylases (HDAC); we evaluated OLN-93 cells for FTY720 effects on histone acetylation, both globally and at BDNF promoters. Immunoblots confirmed

increased histone 3 acetylation (AcH3) levels in response to FTY720. Furthermore, chromatin immunoprecipitation assays showed that AcH3 levels were specifically increased at BDNF promoter 1 in OLN-93 cells treated with FTY720. Here, we report that BDNF expression in OLGs was downregulated by aSyn uptake and that this effect was reversed by FTY720. Furthermore, we found that HDAC inhibition is a potential mechanism by which FTY720 upregulated BDNF in OLN-93 cells. Similar studies with our novel FTY720 analogues, FTY720-Mitoxy and FTY720-C2, also increased neurotrophic factor expression in OLN-93 cells. Thus, FTY720s may be beneficial for MSA, as we are now pre-clinically exploring in an MSA mouse model.

Title: Mir-146a promotes oligodendrogenesis in the demyelinating central nervous system

Authors: *J. ZHANG[1], Z. ZHANG[1], M. LU[2], S. ELIAS[3], M. CHOPP[1,4];
[1]Neurol. Res., [2]Biostatistics and Res. Epidemiology, [3]Neurol., Henry Ford Hlth. Syst., Detroit, MI; [4]Dept. of Physics, Oakland Univ., Rochester, MI

Abstract: Multiple sclerosis (MS) is a demyelinating autoimmune disease in the central nervous system (CNS) characterized by failure of remyelination. Inefficiency of oligodendrocyte progenitor cell (OPC) differentiation into myelinating oligodendrocytes is a key factor leading to failure of remyelination. MicroRNAs (miRNAs) are mediators of post-transcriptional control of gene expression. We hypothesized that miR-146a, by promoting differentiation of OPCs, will enhance remyelination. Two models of demyelination were employed: 1) experimental autoimmune encephalomyelitis (EAE), an animal model of MS. EAE mice were intravenously injected with miR-146a mimics or controls labeled with fluorescent CY3 once a week for six weeks, starting at day 14 post immunizations (p.i.); and 2) cuprizone (CPZ) diet model, a non-

inflammatory demyelination model. After fed CPZ diet for 5 weeks, mice were continuously infused miR-146a mimics or controls into the corpus callosum for 7 days using an mini osmotic pump. Immunofluorescent staining, ELISA, RT-PCR and Western blot were used to measure the profile of differentiation of OPCs, remyelination and T cell responses, and to investigate the possible underlying mechanisms of miR-146a action. Data revealed that in the EAE model, miR-146a mimics 1) significantly improved neurological outcome from day 27p.i. up to day 90p.i; 2) targeted OPCs in the lesion areas; and 3) significantly increased the number of BrdU+/APC+ cells (newly generated oligodendrocytes), APC+ mature oligodendrocytes and myelin basic protein (MBP) level in the spinal cord; 4) increased Th2 and Treg cells, and decreased Th1 and Th17 cells, as well as their related cytokines, compared with the controls ($p<0.05$), respectively. Furthermore, we confirmed that miR-146a mimics targeted OPCs and promoted OPC differentiation into myelinating oligodendrocytes in the CPZ demyelinating model. Elevation of miR-146a level inhibited the toll-like receptor 2 (TLR2) and interleukin-1 receptor-associated kinase 1 (IRAK1) pathways in the both demyelinating models. Collectively, miR-146a promotes remyelination by indirectly acting on CD4+ T cells, and directly acting on OPCs to enhance functional recovery. This study provides the cellular and molecular basis for the therapeutic effects of miR-146a on remyelination with great potential for treatment of demyelinating disorders.

Title: MAPC® provides benefit in multiple models of multiple sclerosis and promotes differentiation oligodendrocyte *In vitro*

Authors: *S. A. BUSCH[1], R. CUTRONE[1], B. T. LANG[1], J. A. HAMILTON[1], R. H. MILLER[2], R. W. MAYS[1];
[1]Regenerative Med., Athersys, Inc., Cleveland, OH; [2]George Washington Univ., Washington, DC

Abstract: Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease of the central nervous system. Considerable research has targeted the immune system as a mediator of disease progression. Infiltration by a heterogeneous population of immune cells including T cells, B cells

and macrophages, along with increased levels of pro inflammatory cytokines contribute to disease. While current standard of care is effective in preventing progression, comprehensive treatment will include both a reduction in the inflammatory response as well as promotion of remyelination. Multipotent adult progenitor cells (MAPC®) are a well characterized population of bone marrow-derived cells that exhibit immunomodulatory effects in central nervous system injury models such traumatic brain injury, stroke, and spinal cord injury. Here we show that MAPC cell therapy reduces deficits in a mouse model of myelin oligodendrocyte glycoprotein (MOG)-induced experimental allergic encephalomyelitis (EAE). MAPC administered at the time of symptom onset, or two weeks following symptom onset, resulted in statistically significant behavioral improvement compared to vehicle treatment. Luxol fast blue staining demonstrated decreased lesion burden within the spinal cord, and a shift from complete to partial lesions, in MAPC-treated animals compared to controls and electron microscopic analysis provided evidence of remyelination. Additionally, direct injection of MAPC cells into lysolecithin-induced spinal cord lesions resulted in an increased white matter density, suggesting a reduction in demyelination and/or promotion of remyelination. As the immunomodulatory capacity of MAPC therapy is well characterized, we next investigated the ability of MAPC cells and MAPC cell-secreted factors to promote the differentiation of mouse oligodendrocytes. In vitro, we observed a significant increase in the number of myelin basic protein (MBP) and O1 positive oligodendrocytes in the presence of MAPC cells or MAPC cell-conditioned media when compared to control. Depletion of extracellular vesicles from MAPC cell-conditioned media diminished the increase of MBP and O1 positive cells. Our results suggest that MAPC cell-secreted soluble factor(s) and/or extracellular vesicles are capable of driving oligodendrocyte differentiation. We are currently investigating the role of MAPC cell therapy in the regulation of human oligodendrocyte maturation.

Title: Remyelinating human oligodendrocyte progenitors for regenerative treatment of demyelinating diseases and spinal cord injury

Authors: *M. P. HEFFERAN[1], K. SCHWARTZ[3], T. HAZEL[2], K. JOHE[2], M. LEVY[3]; [1]Neuralstem Inc., San Diego, CA; [2]Neuralstem Inc., Germantown, MD; [3]Johns Hopkins Univ., Baltimore, MD

Abstract: Demyelinating diseases of the central nervous system, including Multiple Sclerosis, Optic Neuritis, and Transverse Myelitis, affect over 400,000 individuals in the United States alone. In addition, progressive demyelination is a pathological component of spinal cord injury, which affects over 200,000 additional individuals. A promising strategy for restoring neurologic function in such populations involves transplantation of expanded precursor cell populations with the capability to remyelinate host axons. However, this approach requires that grafted cells survive in a hostile environment, migrate throughout areas of injury or damage, and produce structurally organized myelin sheath. Here we report results obtained using a clinical grade human neural precursor cell line, NSI-777, that can be expanded extensively ($>10^9$-fold) under chemically defined conditions and can myelinate host axons after demyelination induced by diverse mechanisms including autoimmune processes, chemical injury, or contusion. We tested the ability of NSI-777 to integrate and generate myelin after grafting. NSI-777 injected into corpus callosum and striatum of nude rats survived for at least 6 months and migrated extensively from the graft site, as demonstrated by HuNu staining. Similarly, upon grafting into brains of myelin-deficient *shiverer* pups NSI-777 showed myelination of axon tracts throughout the brain, including corpus callosum, fimbria, and cerebellum, indicated by expression of Olig2 and myelin basic protein (MBP) in HuNu-positive cells. We also evaluated the ability of NSI-777 to engraft in rodent models of demyelination. We first assessed the survival and differentiation of cells in models of focal chemical demyelination and spinal cord contusion. In both cases cells migrated widely from the site of grafting and differentiated into oligodendrocytes in high proportions, reflected by expression of Olig2 and MBP in HuNu-positive cells. We then evaluated the ability of NSI-777 to survive and integrate in an inflammatory environment using a mouse model of multiple sclerosis, experimental autoimmune encephalomyelitis (EAE). A large portion of grafted cells were found within EAE lesions. The cells were Olig2/MBP immunopositive and had fibrous processes with MBP ring-like terminal structures, likely examples of putative myelination by NSI-777. We conclude that NSI-777, a clinical grade line of human neural precursors that can be extensively expanded, can survive, migrate, and differentiate into functional oligodendrocytes in unmyelinated and demyelinated rodent models.

Title: Therapeutic effect of sephin1 on the mouse model of multiple sclerosis, experimental autoimmune encephalomyelitis

Authors: *Y. CHEN, B. POPKO;
Univ. of Chicago, Chicago, IL

Abstract: Multiple sclerosis (MS) is a chronic autoimmune neurological disease most often initiating in young adults. Clinical manifestations are diverse and often disabling, and current immunomodulatory therapies have limited benefit. Immune-mediated oligodendrocyte apoptosis along with subsequent demyelination and axonal degeneration are key attributes of MS progression. Here we explored the therapeutic potential of the integrated stress response (ISR) in providing increased protection to oligodendrocytes and myelin from inflammatory insults. The ISR is a cytoprotective response that is activated by a variety of cytotoxic insults, including inflammation. The ISR is initiated by phosphorylation of eukaryotic translation initiation factor 2 alpha (P-eIF2α) to diminish global protein translation and selectively allow for the synthesis of protective proteins. P-eIF2α is dephosphorylated to terminate the ISR, ensuring the re-initiation of translation . Sephin1 is a recently-identified ISR modifier that inhibits eIF2α dephosphorylation, thereby prolonging the ISR protective response. We demonstrated that sephin1 significantly delayed the onset of clinical symptoms in a mouse model of MS, experimental autoimmune encephalomyelitis. Importantly, we found that the protection provided by sephin1 correlates with reduced oligodendrocytes loss and demyelination in the lumber spinal cord. Moreover, sephin1 suppressed the inflammatory infiltration into the central nervous system. Our results suggest that an oligodendrocyte-protective treatment based on the enhancement of the ISR would likely have significant therapeutic value for MS patients.

Title: Thromboxane A_2 levels are increased in the cerebrospinal fluid of active multiple sclerosis patients.

Authors: *F. MIR, D. BLEMUR, S. A. SADIQ;
Tisch MS Res. Ctr. of NY, New York, NY

Abstract: The prostanoid thromboxane A_2 is an arachidonic acid metabolite generated by the activation of phospholipase A_2 from the cell membrane phospholipid pool. Thromboxane A_2 binding to its receptor (TPR) has been documented to have varied effects in cell types and regulates hemostasis, immune function and inflammation among others. TPR signaling has been shown to function in multiple cell types in the brain. In the current study we investigate its involvement in multiple sclerosis and its animal model experimental autoimmune encephalomyelitis (EAE). Thromboxane A_2 I levels in the cerebrospinal fluid (CSF) were determined by measuring its downstream metabolite thromboxane B_2 using an ELISA from Cayman chemicals, USA. CSF was obtained from controls and MS patients with informed consent under an IRB-approved protocol. We found that thromboxane A_2 levels were significantly increased in the CSF of multiple sclerosis patients (222.6±45.1 pg/ml; n = 75) as compared to controls (108.2 ± 14.3 pg/ml; n = 25). This increase was more pronounced in the CSF of active MS patients. In a parallel EAE study, the expression levels of the thromboxane A_2 receptor (TPR) in the brain and spinal cord were found to be upregulated in the wild-type mice and this increase in TPR levels correlated with the disease course. Furthermore, using an inducible oligodendrocyte specific TPR knockout mouse model, we found that TPR deficiency in oligodendrocytes exacerbates EAE scores in these mice as compared to wild type controls. The upregulation of thromboxane A_2 signaling during active MS and EAE indicates its potential involvement in the pathophysiology and warrants further investigation.

Title: Cerebrospinal fluid biomarkers of disease phenotype and activity in multiple sclerosis.

Authors: J. TUDDENHAM, *V. K. HARRIS, S. A. SADIQ;
Tisch MS Res. Ctr. of New York, New York, NY

Abstract: Multiple sclerosis (MS) is an inflammatory demyelinating disease, which is associated with progressive disability, cerebellar dysfunction, and cognitive impairment. There is an unmet need for accurate and predictable biomarkers that reflect ongoing disease activity and allow for optimized therapeutic management. In recent years, a number of candidate cerebrospinal fluid (CSF) biomarkers have been discovered through unbiased proteomic approaches. Angiotensinogen has been implicated in regulating the permeability of the blood-brain barrier, and lowered CSF levels of its metabolite, Angiotensin II, have been correlated with MS. Contactin-1 has been identified at reduced levels in the CSF of MS patients. Kallikrein-6 is elevated in the CSF of secondary progressive MS patients. Heightened expression of Superoxide Dismutase (SOD) 1 and 2 has been found in MS gray matter. Increased levels of CSF Osteopontin have been correlated with disease severity and relapse rate. Significant elevation of CSF Fetuin-A has been correlated with active disease. Finally, decreased CSF levels of ITM2B (Bri2) have been associated with cerebellar and cognition impairment. Our objective was to correlate CSF biomarkers with MS subtype, levels of disability, disease activity, clinical phenotype, and treatment. CSF was collected from consenting patients seen at the International Multiple Sclerosis Management Practice, along with demographic and clinical information including MS subtype, treatment, and EDSS. Cerebellar function was assessed by FS2 scale. CSF was immediately centrifuged, and cells were counted using hemacytometer. CSF supernatant was stored at -80°C until use. Angiotensinogen, soluble SOD1, soluble SOD2, Fetuin-A, Osteopontin, Kallikrein-6, Contactin-1, and ITM2B were measured in CSF by Luminex Assay or ELISA. We found a very strong relationship between CSF levels of SOD1, SOD2, Kallikrein-6 and Contactin-1, whereas neither Angiotensinogen nor ITM2B showed a significant correlation with any other biomarker. Moreover, there was a significant correlation between Angiotensinogen and CSF cell count, supporting its involvement in blood brain barrier permeability. A number of biomarkers were found to be significantly reduced in CSF from patients with cerebellar dysfunction, including ITM2B, SOD1, SOD2, Contactin-1 and Kallikrein-6. In addition, ITM2B levels were significantly reduced in the overall pool of patients on disease-modifying treatment compared to untreated patients. Our results identify a panel of CSF biomarkers that reflect neuroinflammation and cerebellar dysfunction associated with MS.

Title: Alterations of tryptophan metabolites in patients with multiple sclerosis

Authors: ***B. KEPPLINGER**[1], B. SEDLNITZKY-SEMLER[2], J. REUSS[3], H. BARAN[2]; [1]Karl Landsteiner Res. Institute, Mauer, Mauer-Amstetten, Austria; [2]Karl Landsteiner Res. Institute, Mauer, Mauer-Amstetten, Austria; [3]Neurol., Gen. Hosp., Amstetten, Austria

Abstract: **Background:** Aim of the present study was to investigate changes of tryptophan metabolites along the kynurenine pathway in the cerebrospinal fluid (CSF) and serum of patients with multiple sclerosis (MS).
Patients and Methods: Patients were recruited from the Neurological Department of the General Hospital Amstetten and Neuropsychiatric Hospital Mauer, Austria. Two groups were formed: clinically probable MS (n=63) and clinically definite MS (n=44) according to diagnostic criteria for MS. The amount of L-tryptophan, L-kynurenine, kynurenic acid and anthranilic acid in CSF and serum of patients (n=107) and corresponding control subjects (CO; n=26) were analysed by HPLC method. Correlations of changes were evaluated. Student's t-Test and one-way-ANOVA were applied. The study was performed according to the ethical regulations of the government of Lower Austria.
Results: Kynurenic acid levels were increased significantly in the serum of definite and probable MS (143% and 170% of CO, $p<0.01$) and in the CSF of definite MS (352% of CO; $p<0.01$) but not in CSF of probable MS patients. Anthranilic acid was increased significantly in serum of definite and probable MS (284 % and 291% of CO, $p<0.01$). Ratio: anthranilic acid to L-kynurenine was increased significantly in the serum of probable MS (246% of CO) but not in the CSF; ratio anthranilic acid to kynurenic acid was increased significantly in the serum of probable and of definite MS (212% and 241% of CO, $p<0.05$), but not in the CSF.
Conclusion: Tryptophan metabolism along kynurenine pathway is activated differently in the periphery and in the CNS of definite and probable MS patients. Significant augmentation of kynurenic acid levels was observed in the CSF of definite MS patients, but not of probable MS

patients, suggesting activation of cells, respectively of cell compartments, synthesizing kynurenic acid and specific for MS development. Lowering of glia depressing factor, which we have proposed previously, might be involved in the overactivation of cells respectively, activation of tryptophan metabolism along the kynurenine pathway in MS patients. Title: Cellular and molecular mechanisms of spine loss in an animal model of cortical multiple sclerosis

Authors: *A. SCHUMACHER[1,2], M. JAFARI[1,2], T. NEZIRAJ[1,2], S. SCHMIDT[1,2], T. JÜRGENS[3], M. KREUTZFELD[3], D. MERKLER[3,4], M. KERSCHENSTEINER[1,2,5]; [1]Inst. of Clin. Pathology, Geneva Univ. Hosp., Geneva, Switzerland; [5]Munich Cluster of Systems Neurol. (SyNergy), Munich, Germany

Abstract: In Multiple Sclerosis (MS), the inflammatory, demyelinating lesions in the white matter have traditionally been attributed to be the main cause of neurological disability. However, over the recent years it has become increasingly clear that the degree of neurological disability shows only limited correlation to the observed numbers and extent of lesions in the white matter. In addition, most MS patients develop also complex and most disabling neuropsychological impairments, such as fatigue, cognitive decline and depression. Indeed refined histopathological and MRI techniques have revealed that MS lesions also appear in the gray matter of MS patients. In previous work, our group was able to show a primary reduction of spine density that occurred both in demyelinated lesions and even in normal-appearing areas of MS cortex. We could now reproduce the widespread spine loss seen in the MS tissue in an animal model of cortical MS pathology. Using transgenic reporter mouse lines, we then

characterized the distribution and contribution of infiltrating mononuclear phagocytes and activated resident microglia. In vivo 2-Photon imaging of neurons, which we virally labeled with the genetically-encoded calcium indicator protein Twitch-2B, further allows us to monitor neuronal calcium levels in relation to spine and dendrite pathology. By studying the interactions between mononuclear phagocytes and neurons and the resulting changes of intracellular calcium levels over time, we aim to resolve the mechanisms underlying inflammatory spine loss and thereby establish the basis for the development of new treatment strategies that counteract cortical MS symptoms.

Hosp., Geneva, Switzerland; [5]Munich Cluster of Systems Neurol. (SyNergy), Munich, Germany

Abstract: Multiple Sclerosis (MS) is an inflammatory disease of the CNS and one of the major causes of neurological disability. Damage to cortical grey matter is reported from early stages of the disease increase with disease duration and are associated with physical disability and cognitive impairment. To better understand how grey matter pathology is initiated we recently reconstructed cortical projection neurons in autopsy tissue from multiple sclerosis patients. Our analysis revealed a widespread and pronounced loss of dendritic spines that was present both in demyelinated and normal-appearing areas of the MS cortex. To further investigate the mechanisms involved in the elimination of dendritic spines, we have now established a mouse model of cortical MS pathology that is induced by the stereotactic cortical injection of pro-

inflammatory cytokines in mice immunized with the myelin oligodendrocyte glycoprotein. In this model cortical demyelination was primarily detected in subpial areas reminiscent of the cortical lesion type III pathology observed in human MS samples. Using high resolution confocal imaging, we studied the apical dendrites of transgenically labelled cortical layer 5 pyramidal neurons and detected a widespread loss of spines both ipsi- and contralateral to the injection site in all cortical layers mimicking the pathology we previously reported in human tissue and supporting an inflammatory pathogenesis of the synaptic pathology.

Title: Tracking axonal conduction changes in multiple sensory modalities in a mouse model of oligodendrocyte loss.

Authors: ***B. J. FARLEY**, E. MOROZOVA, J. AMACKER, B. WANG, B. D. HARVEY, D. GIANNI, B. T. WIPKE, M. HAJOS;
Biogen, Cambridge, MA

Abstract: In multiple sclerosis patients, sensory evoked potentials can serve as a biomarker of functional neurotransmission in central nervous system pathways. However, since changes in myelination, inflammation, and axonal degeneration can occur together in the disease, it is challenging to know how any one process contributes to evoked potential changes. In the Rosa26-DTA; PLP-Cre ("DTA") mouse model of induced oligodendrocyte ablation, demyelination and subsequent remyelination have been reported without extensive axonal degeneration or inflammation (Traka et al., *Brain*, 2010). We monitored visual, auditory, and somatosensory evoked potentials (VEP, AEP, and SSEP) longitudinally in DTA mice with electrodes chronically implanted over the respective sensory cortical areas. Beginning 4 weeks after model induction (by tamoxifen administration), we observed an increase in AEP latency ($p<0.0001$, 2-way ANOVA) and SSEP latency ($p<0.001$, 2-way ANOVA) in tamoxifen-injected mice relative to vehicle-injected (control) mice. VEP latencies, in contrast, were unaffected at the tamoxifen dose employed. Continued monitoring of AEPs revealed that the latency increase was maximal 8 weeks after model induction, when the peak latency was 35% longer in tamoxifen-treated compared to control mice (23.7 +/- 0.4 vs. 17.6 +/- 0.2 ms). Thereafter, AEP latencies

gradually recovered, being only 11% longer in tamoxifen-induced mice by week 12 (19.9 +/- 0.3 vs. 18.0 +/- 0.3 ms). The timecourse of the AEP latency increase and its subsequent recovery suggests that it may reflect changes in CNS myelination (demyelination followed by remyelination) previously reported in this model. To assess peripheral neurotransmission, we also measured the compound muscle action potential (CMAP) in the mice. Pronounced changes in CMAP latency ($p<0.0001$, 2-way ANOVA) as well as amplitude ($p<0.0001$, 2-way ANOVA) were observed in tamoxifen-induced mice. However, these changes began and recovered with an accelerated timecourse relative to the AEP and SSEP changes, suggesting that the mechanisms driving peripheral changes are distinct from those driving the AEP and SSEP changes. To further test the hypothesis that AEP and SSEP latency changes reflect CNS demyelination and remyelination, and support their use as a translational biomarker of these processes, histological examination of relevant neural pathways are being performed.

Title: Human macrophages in Adrenoleukodystrophy show phenotypic specific cytokine and glutamate response to very long chain fatty acid stimulation

Authors: ***B. R. TURK**[1], C. TIFFANY[3], B. E. THEISEN[1], M. ROSEN[2], C. NEMETH[3], J. MARX[3], R. O. JONES[3], P. WATKINS[2], A. B. MOSER[3], S. KANNAN[4], A. FATEMI[3]; [1]Neuroscience, Kennedy Krieger Inst., [2]Johns Hopkins Univ., Baltimore, MD; [3]Kennedy Krieger Inst., Baltimore, MD; [4]Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Adrenoleukodystrophy is an X-linked peroxisomal disorder due to ABCD1 mutation and very long chain fatty acid (VLCFA) accumulation. Metabolic and oxidative stress are proposed central effectors of general ALD cell pathology, while microglia activation in brain has been indicated as a mediator of deadly cerebral disease. We attempted to create indiviual macrophage models from each ALD patient and phenotype in order to determine reaction to stimulation with VLCFAs C24:0 and C26:0.Peripheral Blood Mononuclear Cell (PBMC) culture was derived froml consented ALD patients (n=21) and healthy controls (n=5) at Kennedy Krieger Institute, then differentiated into M1 polarised macrophages over 7 days. Monocyte and macrophage cultures were stimulated with VLCFA and lipopolysaccharide (LPS) at multiple timepoints and doses.Monocytes and Macrophages showed dose dependant response to LPS stimulation in secretion of pro-inflammatory cytokines IL-6 and TNFalpha. VLCFA stimulation showed high fold over base increase in cerebral ALD phenotype, but not heterozygote female carrier (Het) or adrenomyeloneuropathy (AMN) of TNF alpha and Glutamate.
A phenotypic specific PBMC in-vitro cytokine response may indicate either a cytokine profile shift after cerebral disease onset, or discernible prognistic parameter before cerebral onset. Additionally, this novel in-vitro model may serve in testing pharmacological agents in reducing pro-inflammatory cytokine production or other oxidative stress parameters in ALD.

Title: Enlarged perivascular spaces are not associated with disease worsening in patients with relapsing-remitting multiple sclerosis

Authors: *M. CAVALLARI[1], S. EGOROVA[2], B. C. HEALY[2], M. PALOTAI[1], J. PRIETO[1], M. POLGAR-TURCSANYI[2], M. ANDERSON[2], B. GLANZ[2], T. CHITNIS[2], C. R. G. GUTTMANN[1];
[1]Radiology - Ctr. for Neurolog. Imaging, [2]Brigham and Women's Hosp., boston, MA

Abstract: Enlarged perivascular spaces (EPVS) have been recently proposed as a means to investigate abnormalities of the brain glymphatic system, which is considered to have a role in the clearance of neurotoxic metabolites. Multiple Sclerosis (MS) patients showed higher EPVS count and volume compared to healthy individuals in a few recent case-control MRI studies. EPVS have also been associated with relapses and brain atrophy in MS patients, thus supporting the role of impaired glymphatic clearance of neurotoxic metabolites in neuroinflammatory and neurodegenerative features of the disease.
In this study we investigated the relevance of EPVS to clinical disease worsening in MS. We retrospectively selected from the CLIMB (Comprehensive Longitudinal Investigation of Multiple Sclerosis at Brigham and Women's Hospital) study cohort relapsing-remitting MS patients (RRMS) who converted to confirmed (≥2 years) Expanded Disability Status Scale (EDSS) score ≥3 within a follow-up period ≥3 years. We contrasted the baseline EPVS score of 30 converters, obtained from 1.5T dual-echo proton density/T2-weighted MRI images before conversion to EDSS ≥3, with that of 30 non-converter RRMS patients matched for baseline characteristics (age, sex, disease duration). We also investigated the predictive role of EPVS towards magnetic resonance imaging (MRI) measures of accrual of brain atrophy and T2 lesion volume (T2LV) after the EPVS assessment (median MRI follow-up: 2 years, range: 0-11 years). Baseline EPVS scores were not significantly different between converters and non-converters to EDSS ≥3, and were not significantly associated with accrual of brain atrophy or T2LV.
In this pilot study of a well characterized cohort of MS patients followed longitudinally for up to 11 years we did not find significant associations between EPVS and clinical or radiological indicators of disease worsening. Since the small sample size, as well as the suboptimal MRI data characteristics for visualization of EPVS might have limited our ability to detect a significant effect, future studies are warranted to investigate the potential clinical relevance of EPVS in MS.

Title: Pathogenesis of experimental autoimmune encephalomyelitis is modulated by glutamatergic signaling and inflammatory cytokines in the hippocampus and prefrontal cortex

Authors: R. ROTOLO[1], J. DEMURO[2], G. DRUMMOND[1], J. WOOD[3], C. LITTLE[3], L. TELISKA[3], T. STRANGE[3], J. VIDAL[3], L. FRUEHAUF[3], A. BARBER[3], A. WOLF[3], J. BLAKE[3], L. JOHNS[1], *A. J. BETZ[3];
[1]Hlth. Sci., [2]Mol. and Cell. Biol., [3]Psychology, Quinnipiac Univ., Hamden, CT

Abstract: There is a great demand for therapeutic advancements with respect to autoimmune disorders such as Multiple Sclerosis (MS). Experimental Autoimmune Encephalomyelitis (EAE) is an inflammatory disease of the central nervous system with neurological and pathological similarities to MS. In this study, EAE-exposed C57BL/6 mice were used to characterize the cognitive and physical impairments and to establish the molecular markers associated with EAE pathogenesis. A group of mice was pre-trained on behavioral tasks (BEH) while being calorie restricted (CR) prior to myelin oligodendrocyte glycoprotein (MOG) exposure, inducing EAE. A combination of CR and BEH resulted in a delay of symptom onset and reduced clinical severity, as indicated by the daily progression of ascending tail paralysis. In addition, nociceptive sensitivity was preserved in mice exposed to EAE + CR and CR + BEH, similar to controls, whereas EAE-exposed mice demonstrated a greater latency to perceive a painful stimulus at the peak of disease severity. These results suggest that CR and BEH may play a modulatory role in the development of EAE. In a second experiment, mice were treated with riluzole, a glutamate release inhibitor, to assess EAE pathology. Since glutamate excitotoxicity has been found in MS lesions, we proposed that clinical severity would be regulated by glutamate availability in the

central nervous system. The histopathological similarities of EAE and MS reveal the presence of inflammation and immunological mechanisms complementary to disease initiation and progression. The presence of glutamate, infiltrating immune cells, and immune-regulatory cytokines, can influence the pathology of EAE by providing insight as to which cytokines are expressed at heightened disease states. Taken together, these data reveal distinct molecular markers that are associated with ameliorated symptoms. More specifically, alterations in prefrontal cortex (PFC) cytokine expression of GM-CSF, IL-1α, MIG, RANTES, and TNFα, and hippocampal expression of GFAP, TRAF3, Foxp3, and NF-κB, may provide insight as to the molecular mechanisms responsible for hallmark EAE pathogenesis and possible therapeutic remedies.

Abstract: One of the major challenges in multiple sclerosis (MS) is to comprehend disease severity progression. The recently demonstrated correlation between disease severity and remyelination emphasizes the importance of identifying factors leading to a favorable outcome. Why remyelination fails or succeeds in MS patients remains largely unknown, mainly because remyelination has never been addressed within a humanized pathological context. Therefore, we developed a new paradigm mimicking MS lesion by grafting human lymphocytes (LT) in the demyelinated lesion of Nude mice spinal cord. We show that LT play a major role in remyelination whose efficacy is significantly decreased in mice grafted with MS LT compared to those grafted with healthy donor LT. Mechanistically, we demonstrated *in vitro* that LT-derived mediators influenced oligodendrocyte precursor cells (OPC) differentiation through a crosstalk with microglial cells. Among mice grafted with LT from different patient, we observed diverse remyelination patterns reproducing for the first time the heterogeneity observed in MS patients. Comparing LT secretory profile from patients exhibiting high and low remyelination ability, we identified novel molecules involved in OPC differentiation and validated one as a target to improve remyelination. In summary, MS LT do exhibit intrinsic capacities to coordinate myelin repair, an effect implying that remyelination heterogeneity arises in part from patients specific LT activation profile. Furthermore, our data strongly suggest that studying MS patients who display high remyelination capacities might provide new pro-regenerative strategies.

Title: The effects of ambient temperatures and exercise modality on corticospinal excitability of the soleus in persons with multiple sclerosis

Authors: *G. GROVER[1], D. T. G. PHILPOTT[1], E. M. WALLACK[2], L. P. KELLY[2], A. J. DEVASAHAYAM[2], M. C. KIRKALND[2], A. R. CHAVES[2], M. PLOUGHMAN[1,2], K. E.

POWER[1,2], D. C. BUTTON[1,2];
[1]Sch. of Human Kinetics and Recreation, [2]Fac. of Med., Mem. Univ. of Newfoundland, St. John's, NL, Canada

Abstract: Corticospinal excitability (CSE) in persons with multiple sclerosis (PwMS) is reduced, likely contributing to fatigue and limiting one's ability to engage in physical activity. Given that fatigue is task- and temperature-dependent, the purpose of the study was to determine how a combination of temperature (cool vs. room) and exercise (treadmill vs. recumbent NuStep) affects CSE in PwMS. We hypothesized that CSE, irrespective of exercise modality, would be higher following exercise in the cool environment than in a room temperature due to lower levels of fatigue. Fourteen heat sensitive MS patients (10 Females), 49.28 ± 13.56 years of age with relapsing remitting MS and baseline expanded disability status scores ranging from 3.4 ± 2.37 participated in the study. Transcranial magnetic stimulation (TMS) elicited motor evoked potentials (MEPs) and were assessed prior to and following aerobic exercise interventions at 65% of VO_{2max}. Tibial nerve stimulation elicited maximal muscle compound action potential (M_{max}). Measurements were taken from the soleus muscle of the weakest limb both at rest and during a torque equivalent to 10% of maximal voluntary contraction (MVC). Participants attended four randomized experimental sessions including temperature ((Cool (16°C) and Room (21°C)) and exercise modality ((Treadmill (T) and NuStep (N)). Therefore, the experimental sessions were T in cool (TC), T in room (TR), N in cool (NC) and N in room (NR). MEP amplitudes were made relative to M_{max} amplitudes for analysis. MVC torque of the plantar flexors did not differ pre- and post-condition (TC, p = .09; TR, p = .11; NC, p = .125; NR, p = .327). MEPs recorded from the soleus during rest were elicited in 5/14 and 6/14 patients, pre- and post-exercise, respectively. MEPs recorded at 10% of MVC occurred in 6/14 and 7/14 patients, pre- and post-exercise respectively. CSE was increased in room temperature conditions post-exercise (MEP amplitudes as a percentage of M_{max} in C, 4.78 ± 0.9%; R, 23.19 ± 3.15%; p = .026) and increased following exercise using the NuStep (MEP amplitudes as a percentage of M_{max} in N, 21.84 ± 3.93; T, 6.12 ± 1.21%; p = .029). The lack of decrease in MVC suggests that the exercise interventions employed in this study did not induce fatigue of the plantar flexors. Temperature and the exercise modality influence CSE such that exercising in cool temperature and exercising on a NuStep enhance post-exercise CSE in PwMS.

Title: Astrocytic activity modulated by S1P signaling in experimental autoimmune encephalomyelitis (EAE) revealed in a c-Fos reporter mouse

Authors: *D. JONNALAGADDA[1], A. GROVES[2], Y. KIHARA[3], J. CHUN[3];
[1]Mol. and Cell. Neurosci., The Scripps Res. Institute, La Jolla, CA, La Jolla, CA; [2]Sch. of Med., UCSD, La Jolla, CA; [3]Dept. of Mol. and Cell. Neurosci., The Scripps Res. Inst., La Jolla, CA

Abstract: Background. FTY720 (fingolimod, Gilenya) is an FDA-approved, highly effective oral drug for treating MS, showing efficacy in both EAE (a mouse model of human MS) and MS. FTY720 crosses the blood brain barrier and becomes phosphorylated to produce FTY720-P that is a chemical analog of sphingosine 1-phosphate (S1P). S1P signaling is altered in MS patients. FTY720-P binds to S1P receptors ($S1P_{1,3-5}$) expressed on various cell types. FTY720's efficacy in EAE is largely dependent on specific binding of FTY720-P to $S1P_1$ expressed on astrocytes, which is required for drug efficacy in EAE. It remains unknown how this astrocyte mechanism of action produces efficacies, which we examine here. **Methods and Results:** A transgenic mouse line with a tetracycline-suppressible *cis* element (tTA) and a c-Fos driven nuclear GFP-histone fusion protein was crossed with an astrocyte specific, conditional $S1P_1$-null mouse line. Monophasic EAE was induced, then tTA activated upon onset of EAE signs, allowing c-Fos activated cells to express a semi-permanent GFP signal. Astrocytes are the predominantly activated cell-type. The extent of activation correlated with disease severity as demonstrated by flow cytometry. Peripheral activation of astrocytes was visualized in the intact lower spinal cord using tissue clearance techniques. GFP-positive EAE-activated astrocytes were isolated by FACS and processed for RNAseq to identify transcriptional changes that revealed clear differences among the untreated, FTY720 treated, and astrocyte specific $S1P_1$ null astrocytes. These differences are being further interrogated. **Conclusions:** The c-Fos reporter mouse identifies a sub-set of astrocyte population that gets activated upon EAE sign onset. The extent of activation correlates with clinical severity. FTY720 administration and astrocyte-targeted $S1P_1$ removal reduces the number of activated astrocytes, indicating role of $S1P_1$ signaling in ameliorating clinical score. Three-dimensional examination of the lower spinal cord during the course of EAE development shows an increase in activated astrocytes in lesions, as well as along the periphery of the spinal cord. Distinct transcriptional changes during EAE were identified.

Title: Cuprizone model - correlation between fine motor performance and white matter changes

Authors: K. LEHTIMÄKI, *S. KIM, A.-M. ZAINANA, A. NURMI;
Charles River Discovery, Kuopio, Finland

Abstract: The cuprizone exposure has been used to model a wide range of pathological and behavioral deficits endpoints that recapitulate demyelinating diseases and multiple sclerosis (MS). We and others have described the behavioral, pathological and immunological phenotype of mouse cuprizone model at different stages during and after cuprizone challenge. Besides traditional behavioral tools, we have applied kinematic analysis to understand more in detail affected motor behavior due relatively mild phenotype during and after cuprizone exposure. In addition, we have also evaluated the extent of the demyelination, both with classical histological/immunohistochemical tools, but also by applying non-invasive imaging. DTI-MRI revealed progressive demyelination in the major white matter structures during cuprizone exposure. Given that many of the behavioral end-points demonstrate recovery following discontinuation of cuprizone treatment, we wanted in the present study evaluate correlation between white matter changes and fine motor behavior more in detail, during and after cuprizone challenge. C57Bl/6 female mice were subjected to oral cuprizone exposure or vehicle for 6 weeks, followed by 3 weeks of recovery without cuprizone. Diffusion tensor magnetic resonance imaging (DTI-MRI) was performed at 3 and 6 weeks while on cuprizone, and on 7, 8 and 9 weeks after removal of cuprizone challenge. Kinematic gait analysis of the cuprizone and vehicle treated mice were performed on weeks 3, 6 and 9 during the study to correlate white matter changes with fine motor gait changes. We found that there are significant correlations between gait parameter changes and white matter changes. Strongest correlations between gait parameters and white matter changes were seen in subregions of corpus callosum (genu, body and splenium) and external capsule, whereas other white matter rich regions did not show either robust demyelination nor did show strong correlation between gait parameters and the structure analyzed. Taken together, data presented in this presentation provide further insight to cuprizone model demyelination, but also to kinetics of remyelination in the model after elimination of the

cuprizone challenge. We also present how different phases demyelination and remyelination are correlated with fine motor performance.

Title: Multiple measures of corticospinal excitability account for clinical disability in transverse myelitis

Authors: *N. F. WYMBS[1,3], M. LEVY[2], K. SCHWARTZ[2], G. CANTARERO[1,4], M. A. MEALY[2], D. BECKER[2], C. A. PARDO[2], P. A. CELNIK[1], K. M. ZACKOWSKI[1,3]; [1]Physical Med. and Rehabil., [2]Neurol., Johns Hopkins Univ., Baltimore, MD; [3]Kennedy Krieger Inst., Baltimore, MD; [4]Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Transverse myelitis (TM) is a neurological disorder caused by inflammation of both sides of at least one segment of the spinal cord. Damage often leads to persistent disability of upper and lower limbs, which can result in the substantial impairment of activities in daily life. Little is known regarding the underlying motor neurophysiology and its relationship to clinical disability. Here, we used transcranial magnetic stimulation (TMS) to study corticospinal excitability in participants with TM with the goal of utilizing physiological evidence as a biomarker for disability. Corticospinal excitability of first dorsal interosseous (FDI) and tibialis anterior (TA) muscles, localized to the subject-identified less-impaired side of the body, were assessed using motor evoked potential (MEP) following single-pulse stimulation in 19 individuals with TM and 10 aged-matched healthy controls. Corticospinal excitability was assessed in both relaxed and active muscle states, with stimulation intensity set to generate MEP amplitude of 1 mV (S1mV). In addition, input-output curves (IO-curve) of resting FDI were collected. Relative to controls, we found that TM participants had increased MEP onset latency for both resting FDI (n_{TM} = 19) and TA (n_{TM} = 12). This effect of increased MEP latency was observed for multiple measures (S1mv and IO-curve samples) for TM participants. Further, resting MEP latency (S1mV) was correlated with disability (EDSS) for both FDI (R^2 = 0.27, p = 0.02; Rho = 0.54, p = 0.02) and TA (R^2 = 0.30, p = 0.06; Rho = 0.72, p = 0.008). Using stepwise regression with frontward selection of inputs, TM disability was supported by a 2-variable model

($R^2 = 0.77$, $p < 0.0005$) first by selection of resting FDI latency (S1mV) and second, by lesion location (upper segment as cervical or thoracic). All additional model variables, including active S1mV for FDI and TM, as well as demographic factors, did not reach selection criteria significance ($p < 0.05$). Because we did not observe differences in MEP amplitude for any measure between control and TM groups, our results suggest similar activation of corticospinal populations. Together, these results suggest that demyelination of the spinal cord is central to TM disability. Moreover, these findings indicate that corticospinal physiology may aid in the clinical evaluation and rehabilitation of people with TM.

Title: Effects of electromagnetic waves emitted by cell phones on rat optic and trigeminal nerve

Authors: *O. E. TOK[1], D. AKAKIN[2], N. DAGBASI[2], D. ANIL[2], A. AKAKIN[3], S. SIRVANCI[2], F. ERCAN[2];
[1]Bezmialem Vakif Univ., Istanbul, Turkey; [2]Histology and Embryology, Marmara Univ., Istanbul, Turkey; [3]Neurosurg., Bahcesehir Univ., ISTANBUL, Turkey

Abstract: Being increasingly used the cell phones have payed attention for their potential effects on living cells. Thermal and electromagnetic wave (EMW) effects of cell phones have been reported on the cranial nerves beside many other different organs. However, their effects on the

optic and trigeminal nerves have not been reported. In addition, because the thickness of the skull is very thin, rate of absorption of EMW in children are higher than adults. Therefore, we aimed to study the effects of EMW emitted from cell phones on the optic and trigeminal nerves beginning from the fetal period.
Male Wistar-albino rats (5 groups; 6 animals in each group) were used in this study. Cell phone was either on call to another cell phone of similar SAR (specific absorption rate) value or on stand-by mode (2 hours/day). Rats in Stand-by/EMD group were exposed to EMW of cell phones starting from intrauterine 14^{th} day to postnatal 60^{th} day. Rats in Stand-by fetal/EMD fetal group were exposed to EMW of cell phones starting from intrauterine 14^{th} day to birth. Rats in the control group were not exposed to cell phone. At the end of the second month, optic and trigeminal nerve samples obtained from rats perfused with 4% paraformaldehyde were processed for electron microscopic evaluation. Semi-thin sections were stained by Toluidine blue and photographed by light microscopy. Optic and trigeminal nerve areas were measured and the myelinated axons were counted in four photographs (100x magnification) from each animal using Image J Programme. Thin sections were evaluated and photographed by transmission electron microscopy.
The optic and trigeminal nerve areas showed no significant difference between experimental groups. The number of myelinated axons were observed significantly decreased in the Stand-by and EMW groups in optic nerve and the EMW group in trigeminal nerve compared to control group. Electron microscopic examination showed normal axon morphology in control groups of optic and trigeminal nerve. For optic nerves, myelin sheath disturbance and degenerated neurofilaments in axoplasma were found in EMW group. In addition, thickened myelin sheath was evident in EMW fetal group. Myelin sheath disturbance in stand-by, EMW fetal and EMW groups and vacuole formation in axoplasma in EMD group were seen in trigeminal nerves.
The findings of this study shows that the EMW emitted by cell phones may have effect on optic and trigeminal nerve from fetal period until adulthood and may create potentially serious consequences in the long-term use. Our study is important to show the effects of the EMWs associated with the exposure cell phones on the cranial nerves at intrauterine life, childhood and adolescence.

Title: Plexin-A4 regulates secretion and expression of tau in Alzheimer's disease mouse model

Authors: *J. YANG[1], W. LEE[1], A. KIM[1], J.-C. PARK[1], H. CHOI[1], H. CHOI[1], E. HWANG[2], I. MOOK-JUNG[1];
[1]Seoul Natl. Univ. Col. of Med., Seoul, Korea, Republic of; [2]Ctr. for Functional Connectomics, Korea Inst. of Sci. and Technol. (KIST), Seoul, Korea, Republic of

Abstract: Recent genome-wide association studies identified several single nucleotide polymorphisms in *PLXNA4* of late-onset Alzheimer's disease (AD). It was reported that *PLXNA4* transcript 1 (TS1) mRNA was increased in late AD and was involved in hyperphosphorylation of tau stimulated by SEMA3A. Plexins are receptors or coreptors of SEMA family and have been well known for their functions in neurodevelopment such as axon guidance, lamination of the hippocampus, cytoskeletal regulation of growth cones and recruitment of receptor subunits along the axon. However, it is unknown that how Plexin-A4 can lead to pathophysiology of tau in AD. Here I show whether Plexin-A4 regulates secretion and expression of tau in an isoform dependent manner. In addition, when Plexin-A4 was knock-downed in mouse neurons, pTau was decreased. Finally, AAV-Plexin-A4 shRNA-GFP was used to reveal the role of Plexin-A4 *in vivo*.

Title: Characterization of pathological Tau species from mouse Tauopathy models and AD brain

Authors: *A. MARREIRO[1,2], K. VAN KOLEN[1], W. BRUINZEEL[1], D. VAN DAM[3], P. P. DE DEYN[3], L. TEMMERMAN[2], G. DEPUYDT[2], L. SCHOOFS[2], M. H. MERCKEN[1];
[1]Janssen Pharmaceutica, Beerse, Belgium; [2]Div. of Animal Physiol. and Neurobio., Katholieke Univ. Leuven, Leuven, Belgium; [3]Dept. of Biomed. Sci. Inst. Born-Bunge, Univ. of Antwerp, Antwerp, Belgium

Abstract: Objectives: Although several studies demonstrate that Tau filaments have seeding potential on both cellular and *in vivo* models, the information on the size of these aggregates has

been ambiguous [1,2]. The aim of this study is to characterize Tau species by their molecular weight and other molecular properties, such as phosphorylation status.
Methods: Aggregates were isolated from *post mortem* AD and transgenic mice (P301S) brain tissue using different extraction procedures. Biochemical characterization was done by Western blotting (reducing and non-reducing), sucrose gradient, size exclusion chromatography and aggregate specific immuno-assays. Structural differences between Tau seeds were analyzed by immuno-EM. Seeding efficiency was then assessed by a FRET cellular model [3].
Results: It has been shown that spinal cord and brainstem total extracts from P301S mice trigger Tau aggregation in HEK293 cells expressing K18 FRET sensors [3]. First, it is investigated which subfraction of such total extracts is the most potent for seeding in this cellular model. By differential centrifugation and detergent treatment, different fractions from aging mice and AD *post mortem* brain tissue are used for aggregation induction and biochemical analysis. In the P301S mouse brain extracts we observed an age-dependent correlation between Tau aggregate load and seeding efficiency. We also observed that both total extract and insoluble fraction from *post mortem* AD brain tissue can induce aggregation in this cellular model. Molecular weight separation both by sucrose gradient and SEC is performed to identify which species show seeding efficiency.
Conclusions: This study further elucidates the molecular properties, regarding molecular weight, phosphorylation status and seeding efficiency of high molecular weight Tau species. This information is essential to understand which forms of Tau should be targeted in a Tau-based therapeutic approach.

Title: Tau association with protein tyrosine phosphatase SHP2: mechanism and cellular location

Authors: Y. KIM[1], M. B. FRANCIS[1], C. J. LEUGERS[1], *G. LEE[2];
[1]Univ. of Iowa, Iowa City, IA; [2]Intrnl. Med., Univ. Iowa, Iowa City, IA

Abstract: The microtubule-associated protein tau is involved in regulating microtubule assembly and function in neurons. Tau function is regulated by phosphorylation and we have previously shown that tau is tyrosine phosphorylated. Here we report that tau co-immunoprecipitated with protein tyrosine phosphatase SHP2 in PC12-derived cell lines as well as in COS7 cells expressing tau by transfection. To investigate the role of phosphorylation in the tau-SHP2 association, we performed *in vitro* binding assays where *E.Coli* synthesized tau was added to SHP2 immunoprecipitated from COS7 cells. The assays confirmed the association, suggesting that phosphorylation of tau was not required for the SHP2 association. However, we also found that phosphomimetic tau (T231D) bound to SHP2 approximately twelve-fold higher than wild type tau, suggesting that phospho-T231 promoted SHP2 association. Using several tau deletion fragments, we found that tau residues 256-282, which contain the microtubule binding repeat 1 of tau, were essential for the tau association with SHP2, suggesting that phosphorylation of tau at Thr231 increased the accessibility of tau residues 256-282 for SHP2 binding. To visualize the spatial localization of the tau-SHP2 complexes in cells, *in situ* proximity ligation assays (PLAs) were conducted using non-neuronal (COS7) or neuronal (PC6-3) cells where tau was expressed by transfection. Tau-SHP2 complexes appeared as a punctate pattern, with 3D reconstruction of the confocal images suggesting that the tau-SHP2 complexes were localized on the plasma membrane. In PC6-3 cells, complexes of endogenous tau and SHP2 were also found on the plasma membrane. When cells were stimulated with EGF (COS7) or NGF (PC6-3), activated SHP2 increased dramatically and complexes of tau and activated SHP2 were detected. Relative to non-stimulated PC6-3 cells, NGF-stimulated cells also exhibited an increase in the number of complexes between tau and total SHP2. The increase in tau-SHP2 complexes was probably, in part, due to the increase in the levels of phospho-Thr231-tau following NGF stimulation, which we had found using both immunoprecipitation and flow cytometry. Lastly, *in vitro* phosphatase assays, performed on tyrosine phosphorylated full-length tau or on tau peptide, showed that SHP2 dephosphorylated phospho-Tyr18- tau, indicating that phospho-Tyr18-tau is a substrate for SHP2. Given the regulation of phospho-Tyr18-tau we have previously reported for Alzheimer's disease brain, SHP2 might be active during neurodegeneration.

Title: Characterizing the depolarization-dependent synaptic release of tau

Authors: *E. E. MIYOSHI, T. BILOUSOVA, K. H. GYLYS;
UCLA, Los Angeles, CA

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by two main neuropathological hallmarks—amyloid beta plaques and neurofibrillary tangles. Neurofibrillary tangles are formed from hyperphosphorylated tau filaments. Tau is a microtubule-associated protein, and its sequestration leads to the disruption of microtubule stability and the formation of highly toxic intermediate tau oligomers, resulting in massive neuronal loss and dementia. It has been proposed recently that tau pathology can synaptically propagate through the brain in an activity-dependent manner. We have used human brain-derived synaptosomes (resealed presynaptic terminals) from AD and control subjects to assess synaptic tau release *in situ*. Our data shows that depolarization of AD synaptosomes using a high-potassium solution induced discharge of a mixture of tau oligomers and monomers. Depolarization of the synaptosomes was confirmed by the anionic fluorescent dye $DiBAC_4(3)$. Western blot analysis using tau proteoform-specific antibodies revealed that the majority of released tau is C-terminally truncated and also part of it is present as SDS stable oligomers. Uptake of the released tau oligomers may induce tau oligomerization in recipient cells, accelerating the propagation of the pathology. Synaptosomes from cryopreserved human brain autopsy samples represent a unique system for investigation of synaptically released tau proteoforms.

Title: Identification of tau internal segment for efficient internalization

Authors: *K. CHO, Y. JANG, D. KIM, S. YOON;
Asan Med. Ctr., Seoul, Korea, Republic of

Abstract: Propagation of tau aggregates is critical for tauopathy in Alzheimer's disease. In many progressive neurodegenerative disease, various protein aggregates such as tau, amyloid-β, huntingtin and α-synuclein shows prion-like spreading and infectivity. Recent studies suggest that cellular uptake of Tau is mediated by macropinocytosis. However, internal domain involved in tau internalization is unknown. Here we identified tau domain involved in efficient internalization through in silico prediction of cell permeable peptide site in Tau sequence. Recombinant GFP-tau which has been deleted this segment showed slower cellular uptake than GFP-Tau control. This segment deleted GFP-tau was resistant to treatment of sodium cholate, inhibitor for HSPG critical for tau macropinocytosis, suggesting that identified tau segment is important for tau internalization. Our study demonstrated more precise mechanism for tau internalization and provided novel target for development of anti-tauopathy.

Title: Depletion of laforin portends "molecular crowding" in Alzheimer's disease: Implications for protein aggregation and the role of glycemic derangement in neurodegeneration

Authors: K. WOLFE[1], S. Y. AGHDAM[2], S. Z. IMAM[3,2], *S. W. BARGER[2,4];
[1]Col. of Med., [2]Dept Geriatrics, Univ. of Arkansas for Med. Sci., Little Rock, AR; [3]Div. of Neurotoxicology, Natl. Ctr. for Toxicological Res., Jefferson, AR; [4]Geriatric Research, Educ. and Clin. Ctr., Central Arkansas Veterans Healthcare Syst., Little Rock, AR

Abstract: Protein aggregation is a common element of all neurodegenerative diseases, suggesting a particular vulnerability of neurons to this phenomenon. One potential explanation is the unique electrostatic status conferred by the high concentration of RNA in neuronal cytosol, which can be more three orders of magnitude that of other cell types. This elevates the potential for "molecular crowding," a phenomenon by which proteins lose solubility due to neighboring hygroscopic macromolecules that compete for their interactions with polar water molecules. Glycogen is an ideal mediator of molecular crowding, and the high neuronal concentration of RNA—itself a highly charged, hygroscopic molecule—may explain why glycogen levels are typically kept very low in neurons. Neurons constitutively express glycogen synthase, but it is degraded by a ubiquitin-proteasome system requiring an adapter known as laforin. The protein derives its name from Lafora's disease, some cases of which arise from loss-of-function mutations of the laforin gene (*EPM2A*); the resulting neuronal accumulation of glycogen synthase and its product results in seizures and dementia. We have documented a 50% reduction of laforin expression in Alzheimer's disease temporal-lobe cortex. We also find that primary cultured neurons, unlike most cells, reduce their expression of laforin under low-glucose conditions. This may occur as a consequence of decreased levels of the transcription factor hypoxia-inducible factor 1α (HIF1α), which has four potential binding sites in the *EPM2A* promoter and is likewise depleted in Alzheimer's brain. These events may explain the age-related accumulation of polyglucosan aggregates known as corpora amylacea, which have been connected to axonal transport disruptions in Alzheimer's disease. They may also contribute to the documented aggregation of tau in laforin-knockout mice. Implications for hypotheses about the role of peripheral glucose tolerance and insulin dysregulation in Alzheimer's disease will be discussed.

Title: Tools development for studying a new N-terminally truncated Tau species and its relevance to Alzheimer disease

Authors: C. LEGHAY[1], M. DERISBOURG[1], D. DEMEYER[1], S. EDDARKAOUI[1], R. CAILLIEREZ[1], V. BUÉE-SCHERRER[1], D. BLUM[1], V. DERAMECOURT[2], L. BUÉE[1], *M. HAMDANE[1];
[1]Alzheimer & Tauopathies, UMR 1172 Inserm, Univ. De Lille, CHU Lille, Lille Cedex, France; [2]CMRR, Hôpital Salengro, Univ. Lille, Lille, France

Abstract: Tau protein plays an important role in Alzheimer's Disease (AD) where it is found aggregated and abnormally modified in degenerating neurons. Truncation is among post-translational modifications of Tau and its role in AD pathological process is far from being elucidated. By using a dedicated proteomics approach (liquid chromatography coupled to tandem mass spectrometry), we have identified new N-terminally truncated Tau species (Trunc-Tau) from human brain. Our interesting findings provided us the basis for the development of appropriate immunological tools with which to monitor these new species and to establish their role in AD physiopathological process. We have focused our work on an N-terminally Trunc-Tau species starting at the middle of Tau exon 1 sequence to develop a specific monoclonal antibody. This antibody is a mandatory tool: 1) to uncover the consequences of this N-terminal truncation on Tau function and properties; 2) to establish whether there is an association between this new Trunc-Tau species and AD. We have succeeded in development of an antibody that specifically labels the Trunc-Tau species without any cross reactivity with full-length Tau. We performed immunohistochemistry (IHC) using brains from well characterized AD patients and control subjects (Lille Neurobank). Our preliminary data identified the new Trunc-Tau species in AD neurofibrillary tangles while no immunoreactivity was observed in control brains. We are currently performing IHC using a large number of brain samples to establish whether the new Trunc-Tau species is a signature of AD and other Tauopathies. Besides, we have established inducible stable cell lines expressing the full-length Tau protein and the Trunc-Tau species in order to analyze functional and biochemical properties of the new Trunc-Tau, compared to its related full-length Tau. This work will provide new knowledge on Tau biology and the physiopathological process of AD.

Title: Toxic synergy between amyloid aggregates in disease and their role in tau oligomeric strain formation

Authors: *R. KAYED, J. E. GERSON, D. L. CASTILLO-CARRANZA, U. SENGUPTA, M. J. GUERRERO-MUNOZ;
Neurol., Univ. of Texas Med. Br. Dept. of Neurol., Galveston, TX

Abstract: Recent studies suggest that the toxicity of tau in disease may rely on its prion-like characteristics, including the ability to seed the aggregation of natively unfolded protein and the transport of aggregates from one cell to another. A growing body of research shows that the most toxic and efficient seeds in disease are tau oligomers, rather than insoluble, fibrillar aggregates. Furthermore, evidence suggests that tau aggregates may exhibit conformational diversity important for their toxicity, as seen in prion disorders. However, the relevance of other aggregant proteins to the formation of tau strains has not been well-established though the most prevalent neurodegenerative disorders—Alzheimer's (AD) and Parkinson's disease (PD)—are mixed protein pathology diseases. We have shown that amyloid-â (Aâ) and á-synuclein oligomers colocalize with oligomeric tau in AD, PD and Lewy body dementia brain tissue. Moreover, oligomeric Aâ and á-synuclein can cross-seed the aggregation of tau. Studies show that much of the toxicity of the two proteins is dependent on the presence of tau, highlighting the toxic synergy between tau and other amyloid proteins. Furthermore, we find that targeting oligomeric tau in mouse models over-expressing mutated amyloid precursor protein and á-synuclein protects against behavioral deficits and pathology associated with disease-like phenotypes. Thus, we evaluated tau oligomeric strains derived from mixed pathology diseases and pure tauopathies and found that oligomers could be differentiated based on stability as well as recognition with tau oligomer-specific monoclonal antibody (TOMA) clones. In order to directly investigate secondary amyloidosis and tau oligomeric strain formation and the effect on toxicity, tau was cross-seeded with Aâ and á-synuclein oligomers to form distinct tau oligomeric strains with differing levels of toxicity when applied to neuroblastoma cells in culture. These results highlight the importance of studying the diverse oligomeric structures of complex mixed pathology disorders and suggest that these diseases will likely best be targeted using personalized, combination therapy approaches that target the most toxic strains.

Title: Identifying novel interactions of the Hsp90 kinase co-chaperone Cdc37 *In vivo* and *In vitro*

Authors: ***M. NARAYAN**[1,2], U. K. JINWAL[2];
[1]Pharmaceut. Sci., Univ. of South Florida, Tampa, FL; [2]Pharmaceut. Sci., Byrd Alzheimer's Institute-University of South Florida, Tampa, FL

Abstract: The co-chaperone Cdc37 specifically recruits kinases to the Hsp90 complex for stabilization and folding. The Hsp90-Cdc37 complex is known to regulate kinases involved in the phosphorylation of tau, a microtubule associated protein. Tau hyperphosphorylation and formation of neurofibrillary tangles is a major pathological hallmark of Alzheimer's disease (AD). Our group has previously shown that Cdc37 plays a role in preserving hyperphosphorylated tau. However, the mechanism of how this occurs is poorly understood. While Cdc37 has been shown to interact with numerous kinases, we hypothesized that identification of the components of the Cdc37 interactome in AD brain tissue would lead a better understanding of Cdc37 function in tau biology. For *in vivo* identification of novel Cdc37-binding proteins, five AD patient and five age-matched control brain tissue samples were screened for phosphorylated tau levels by Western blotting. Three samples from each group were chosen based on robust phosphorylated tau levels for immunoprecipitation (IP) using a Cdc37 antibody. IP samples were processed and analyzed by mass spectrometry (MS). Briefly, samples were digested to produce tryptic peptides and desalted peptides were injected into the spectrometer. Data from MS analysis were matched subsequently against a human peptide database. A total of 110 proteins were identified, and upon further data analysis we found 39 novel proteins that were found to interact with Cdc37 in AD cases and 7 proteins that were found only in controls. Several of these proteins are implicated in signaling via the PI3K / Akt, NF-B, JNK and TGFβ pathways. Novel interactors of Cdc37 included Shroom3, β-catenin and annexin A2. To validate these interactions we used an *in vitro* cell culture model and found that Cdc37 does interact with these proteins. Overall, data from these *in vivo* and *in vitro* studies not only

help in better understanding of the functional role of Cdc37, but also reveal novel Cdc37-interacting proteins and pathways in AD that might lead to the identification of new AD drug targets.

Title: Sod2 rescues p301l tau-transfected primary neurons

Authors: ***K. A. BASKERVILLE**, N. M. CHIKWEM, N. WEIGEL;
Biol., Lincoln Univ., Lincoln University, PA

Abstract: Alzheimer’s disease is characterized by two hallmark pathologies – neurofibrillary tangles and beta amyloid plaques. Oxidative stress plays an apparent role in the pathogenesis of Alzheimer’s disease. Neurofibrillary tangles result from the filamentous aggregation of hyperphosphorylated tau, leading to neurodegeneration. After the hyperphosphorylation of tau, we suspect that antioxidant systems within neurons become progressively dysfunctional and, thus, are unable to scavenge reactive oxygen species effectively. The purpose of this study was to investigate whether mitochondrial superoxide dismutase (SOD2), an antioxidant, can rescue hyperphosphorylated tau-transfected neurons (cortical and hippocampal) in primary cell culture from neurodegeneration and oxidative damage. Primary cortical and hippocampal neurons were co-transfected with a common form of hyperphosphorylated tau, P301L, construct and a SOD2 construct; GFP DNA constructs and vector constructs served as controls. P301L-transfection alone induced degeneration and oxidative stress in primary cultured neurons but were rescued by SOD2. “Sick,” i.e. degenerated, neurons displayed morphological changes in their neurites and cell bodies. Oxidative damage (lipid peroxidation and nucleic acid damage) was observed in the P301L-transfected neurons. The number of healthy, intact neurons increased after mutant tau and SOD2 co-transfection; 70% of neurons co-transfected with P301L and SOD2 compared to 45% healthy with P301L tau transfection alone. We suspect that SOD2 protects the P301L tau-transfected neurons from oxidative stress, thereby reducing degeneration.

Title: Disassembly of the MID1-PP2A complex causes dephosphorylation of Tau

Authors: *F. MATTHES[1], S. SCHWEIGER[3], M. M. HETTICH[2], D. EHNINGER[2], S. KRAUSS[1];
[1]AG Krauss, [2]AG Ehninger, DZNE, Bonn, Germany; [3]Inst. for Human Genet., Univ. of Mainz, Mainz, Germany

Abstract: Alzheimer's disease (AD) is the most common form of dementia and the most prominent neurodegenerative disorder associated with aging. One of the pathological hallmarks observed in AD patients' brains is the development of paired helical filaments (PHFs), which are composed of hyperphosphorylated Tau protein dissociating from microtubules. The most important phosphatase that is capable of dephosphorylating Tau at AD-specific phosphorylation sites is protein phosphatase 2A (PP2A).
We show that disassembly of the MID1-PP2A complex by a natural polyphenol induces PP2A activity and significantly reduces Tau phosphorylation at PP2A-dependent epitopes in cultured primary neurons. The MID1 protein is a ubiquitin ligase that mediates ubiquitin-specific modification and degradation of the catalytic subunit of PP2A, specifically at the microtubules. Western blot and quantitative real-time PCR analyses indicate that disassembly of the MID1-PP2A complex leads to reduced MID1 mRNA and protein levels, suggesting a self-regulating effect of MID1 on its own mRNA. In line with our observations *in vitro*, treatment of mice with a MID1-PP2A destabilizing compound resulted in dephosphorylation of Tau *in vivo*.
Our data suggest a promising role for drugs interfering with the MID1-PP2A complex as a novel approach for reducing Tau phosphorylation in the prophylaxis and therapy of AD and other tauopathies.

Title: Charge interplay in tau fibrillization: a mechanistic insight

Authors: *G. VISWANATHAN[1], S. GUPTA[2];
[1]Biol. Engin., Indian Inst. of Technol. Gandhinagar, Gandhinagar, India; [2]Biol. Engin., Indian Inst. of Technology, Gandhinagar, Gandhinagar, India

Abstract: Tau is an intrinsically disordered protein responsible for maintaining the stability of axonal microtubules in neurons. In AD, abnormal Post Translational Modifications (PTMs) may cause detachment of Tau which undergoes complex aggregation pathways to form Neurofibrillary Tangles (NFTs). Traditionally, heparin induced tau aggregation referred as pseudophosphorylation is used as a model to understand the aggregation mechanism. Since heparin is a polyanion, it attracts unmodified positively charged tau and promotes aggregation in a shorter time frame. But *in vivo*, tau undergoes several PTMs at the same temporal scale which may be charge driven (e.g. phosphorylation) or uncharged (e.g. glycation). We asked whether these modified tau species aggregates in the same manner *in-vitro*? Using Thioflavin T fluorescence based aggregation assay we mapped heparin induced unmodified tau aggregation in real-time but when we used chemically phosphorylated tau, the trajectories diverged indicating a change in pathway as well. Addition of negative charge on tau tends to repel heparin causing aggregation to be much slower. We verified this hypothesis by using different ratios of modified to unmodified tau. On the other hand, these modified tau species have a unique tendency to aggregate independently without any aggregation inducer. Atomic Force Microscopy (AFM) images of self-aggregating chemically modified tau resemble that of PHFs found in human brain. This charge interplay between phosphorylated tau and heparin can be very crucial in understanding the intricate pathways of tau aggregation. We observed that heparin based *in-vitro* tau aggregation models are not sufficiently reliable for high throughput screening of small molecule and peptide based inhibitors. Moreover, to mimic tau fibrillization, we require ~1mg of tau protein per well as tau aggregates at higher concentration *in-vitro*. To increase the availability of tau, we have further developed a strategy of co-transformation where we supply deficient tRNAs to *E. coli* which codes for rare amino acids to increases the rate of translation. We have also developed a heat based quick and clean tau extraction method which can provide assay-ready tau from cell pellet in less than an hour.

Title: Tau oligomers and the dysregulated proteasome in Alzheimer's disease

Authors: ***A. N. NILSON**, J. DEGER, J. GERSON, R. KAYED;
Mitchell Ctr. for Neurodegenerative diseases, Neuroscience, Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: Tau is a microtubule-associated protein that pathologically aggregates into inclusions and neurofibrillary tangles in Alzheimer's disease (AD) and other neurodegenerative diseases. However, there is evidence that synapse loss and cell death occur prior to, or independently of, the formation of neurofibrillary tangles. Smaller, soluble aggregates of tau, known as oligomers, appear early in disease and have been shown to be the primary toxic entity in disease. In addition, it is known that tau oligomers can be modified by both mono- and poly-ubiquitination, which may play a role in the dysregulation of the ubiquitin-proteasome system in neurodegeneration. Poly-ubiquitination typically targets a protein for degradation. The role of small ubiquitin-like modifiers (SUMO) on tau oligomer formation, stability, and toxicity is less understood. Thus, we investigated the role of ubiquitination versus sumoylation of tau oligomers in vitro and in post-mortem brain samples, as well as how proteasome inhibition influences tau oligomer toxicity. Using immunofluorescence and biochemical analyses with tau oligomer-specific antibodies, we systematically dissected the relationship between tau oligomers, ubiquitin, and SUMO. We found that tau oligomers were preferentially ubiquitinated in AD while they were sumoylated in controls. Moreover, inhibition of the proteasome increases the presence of hyperphosphorylated tau as well as other aggregation prone proteins. These results suggest that the pattern of post-translational modification in conjunction with the proteasome is altered in AD, exacerbating the toxicity of tau oligomers and leading to their accumulation and the buildup of other aggregation prone proteins. This may lead to a cycle in which tau oligomers

inhibit the proteasome, increasing the abundance of oligomeric tau, thereby maintaining proteasome inhibition, all of which increases tau toxicity. Thus, increasing proteasome activity or preventing the interaction of tau oligomers with the proteasome may slow the progression of AD.

Title: Liquid-liquid phase separation of human tau protein

Authors: ***S. WEGMANN**[1], B. EFTEKHARZADEH[1], A. M. PALUD[2], J. P. TAYLOR[2,3], B. T. HYMAN[1];
[1]Neurol., Mass Gen. Hosp. / Harvard Med. Sch., Charlestown, MA; [2]Dept. of Cell and Mol. Biol., St. Jude Children's Res. Hosp., Memphis, TN; [3]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: Liquid-Liquid Phase Separation (LLPS) is a major principle underlying cellular organization. Because LLPS is present even in prokaryotes, this organizational strategy likely evolutionarily preceded the elaboration of intracellular membrane-derived organelles; it is for example used to locally increase the concentration of certain proteins and RNA molecules, independently of cellular organelles. The formation of liquid droplets in the cell is facilitated by intrinsically unstructured multivalency domains with low folding propensity (low-complexity domains) in the contributing proteins and drives, for example, the spatially asymmetry of P-bodies in germ cells, the rapid and reversible assembly of RNP granules, but also the assembly of microtubules during spindle formation, membrane receptor clustering, orchestration of DNA repair, the assembly of transcription factories, and control of permeability through the nuclear pore. Tau, alike other microtubule binding proteins, contains a long unstructured N-terminus, which projects into the cytoplasm when bound to microtubules (projection domain) and has biochemical properties similar to low complexity domains reported in LLPS performing proteins. Here we tested if the intrinsically unfolded protein tau - or its fragments - can form liquid

droplets in a cellular environment. We used microscopy and different biophysical techniques to examine LLPS characteristics of recombinant human tau and its different fragments (wild-type, mutant P301L, full-length (tau441), repeat domain, N-terminus (tau256)). We then tested the cellular function of tau256 LLPS in cells and primary neurons. The N-terminal half of human tau (tau256) undergoes LLPS when exposed to a molecular crowded environment. At physiological concentrations of tau (5-10 uM), tau256 forms viscous droplets in a ion strength dependent manner; this phase transition appears independent of temperature, and tau constructs comprising the repeat domain (microtubule binding domain) cannot undergo LLPS. Accordingly, expression of GFP-tau256 but not GFP-tau441 leads to intracellular droplets in cells and in neurons. The unstructured N-terminus of tau has biophysical properties enabling LLPS in a cellular environment. Intracellular droplets of tau256 might occur after cleavage of tau by proteases such as calpain or thrombin, which releases the N-terminus of tau into the cytosol. The biological function of tau droplet formation is unknown, but by analogy to other systems could represent a combined phase separation with RNPs such as hnRNPA1, TDP-43 and FUS, or a microtubule-associated function of the N-terminal projection domain.

Title: Transient cerebral ischemia promoters brain mitochondrial dysfunction and exacerbates cognitive impairments in young 5xFAD mice

Authors: ***J. TIAN**[1], L. LU[2], E. GAUBA[3], L. GUO[3], H. DU[3];
[1]Mol. and Cell biology Dept., The Univ. of Texas At Dallas, Richardson, TX; [2]Dept. of Neurology, Shandong Provincial Hosp. Affiliated to Shandong Univ., Ji Nan, China; [3]The Univ. of Texas at Dallas, Richardson, TX

Abstract: Alzheimer's disease (AD) is heterogeneous and multifactorial neurological disorder; and the risk factors of AD still remain elusive. Recent studies have highlighted the role of vascular factors in promoting the progression of AD and have suggested that ischemic events increase the incidence of AD. However, the detailed mechanisms linking ischemic insult to the

progression of AD is still largely undetermined. In this study, we have established a transient cerebral ischemia model on young 5xFAD mice and their non-transgenic (nonTg) littermates by the transient occlusion of bilateral common carotid arteries. We have found that transient cerebral ischemia significantly exacerbates brain mitochondrial dysfunction including mitochondrial respiration deficits, oxidative stress as well as suppressed levels of mitochondrial fusion proteins including optic atrophy 1 (OPA1) and mitofusin 2 (MFN2) in young 5xFAD mice resulting in aggravated spatial learning and memory. Intriguingly, transient cerebral ischemia did not induce elevation in the levels of cortical or mitochondrial Amyloid beta (Aβ)1-40 or 1–42 levels in 5xFAD mice. Therefore, the simplest interpretation of our results is that young 5xFAD mice with pre-existing AD-like mitochondrial dysfunction are more susceptible to the effects of transient cerebral ischemia; and ischemic events may exacerbate dementia and worsen the outcome of AD patients by exacerbating mitochondrial dysfunction.

Abstract: Pathological deposition of amyloid-beta (A-beta) is one of the major hallmarks of Alzheimer’s dementia (AD). The incidence of AD and other neurodegenerative diseases is rising with age, and thus often contributing to common comorbidity state of mixed dementia. Microglia are the primary immune effector cells of the brain. In resting state their highly motile processes continually survey the brain parenchyma and transiently contact synaptic elements (Tremblay et al., 2010). In neuropathological conditions microglia cells rapidly become activated, thicken and retract their processes, migrate to the site of inflammation, and proliferate. In addition, they also contribute to the presentation of antigens, phagocytosis of cellular debris, and secretion of proteases that promote cell motility, myelin and extracellular matrix degradation (Avignone et

al., 2015). However, little is known about the role of extracellular matrix (ECM) molecules in the regulation of microglia function. Thus, we aimed to study the effects of ECM removal by chondroitinase ABC (ChABC) on microglia response to a minor brain lesion (laser ablation of a single cell) in the 5xFAD mouse model of AD. *In vivo* multiphoton laser microscopy imaging was used to study microglial behavior in the retrosplenial cortex (RSC) of 3-4 months old CX3CR-1-eGFP mice cross-bred with 5xFAD mice. Microglial morphology and dynamics were studied before and after single microglia cell laser ablation (SMCLA) upon injection of ChABC or vehicle for 24, 48 and 72h. A-beta plaques were traced by intravenous injection of the *in vivo* marker Methoxy-XO4. Microglia cells displayed activated phenotype in RSC of 5xFAD/CX3CR-1-eGFP mice, but not in WT/CX3CR-1-eGFP mice. Interestingly, at the age studied, amyloid plaques were not yet visible after injection of Methoxy-X04. Measurement of basal process-motility revealed a significant impairment in single microglia cell of 5xFADxCX3CR-1-eGFP mice when compared to controls. Moreover, kinetic deficits of total processes spreading were observed in 5xFAD-xCX3CR-1-eGFP microglia at the population level in response to SMCLA. Intracerebral injection of ChABC improved microglia dynamics comparable to WT controls in 5xFADxCX3CR-1-eGFP mice. Furthermore, we detected significantly reduced recruitment of microglial cells to the site of damage in 5xFADxCX3CR-1-eGFP mice 24h after laser ablation compared to the CX3CR-1-eGFP group. ChABC ameliorated these defects 48h upon application. Our findings suggest that microglia may lose adequate response to inflammatory stimulus at early stages of AD, but this response could be restored after administration of ChABC.

Title: Raising *In vivo* microdialysis to the next level: Evaluation of long-term extracellular amyloid-β and tau in mouse models of Alzheimer’s disease

Authors: *M. MEINHARDT, M. KATSUR, G. PLOTZKY, E. CHATZIKONSTANTINOU, S. BENOE, I. MAIRHOFER, J. HOPPE, S. TALMON, K. BUCK;
Neurosci. Res., Abbvie Deutschland Gmbh & Co. KG, Ludwigshafen, Germany

Abstract: Amyloid-β and tau are key players in Alzheimer's disease (AD), both of which have been found as pathological species in the extracellular space, suggesting a significant role of amyloid-β and tau in this compartment during AD progression. The only possible approach to monitor these proteins in the extracellular space *in vivo* is cerebral microdialysis. This technique is classically used to measure small molecules but with several modifications also allows protein sampling. These adaptations add another level of complexity to an already sophisticated technique. Therefore, particular attention should be paid to various experimental factors to achieve high quality results and enhance our understanding of the role of extracellular amyloid-β and tau in AD. We here tackled these challenges by setting up a push/pull microdialysis technique, equipped with a 1MDa molecular weight cut-off membrane. Due to the fact that molecular dynamics of proteins require long-term monitoring, we optimized the set-up allowing continuous sampling for up to 72h. Experimental parameters such as the flow rate (0.6 vs. 1µL/min), the type/material of the membrane, additives to the perfusion media (Dextran vs. 0.2/4% BSA) as well as the impact of coating procedures for the system turned out to be very critical in achieving long-term stability. Moreover, we used miniaturized microdialysis probes allowing to place multiple probes in mice as well as an optimized analytical readout enabling simultaneous quantification of amyloid-β and tau within the same sample of wild-type and transgenic mice. Finally, we set the focus on investigating the disruption of the blood-brain-barrier, which inevitably occurs with probe insertion, and is particularly important for PK/PD studies. In conclusion, this in-depth characterization of an amyloid-β and tau microdialysis method increases experimental possibilities and will further enhance our understanding of these proteins in the extracellular compartment. Therefore, this set-up provides a powerful tool for uncovering their role in the disease progression and facilitates experiments investigating the efficacy of treatments and the search for new biomarkers.

Title: *In situ* harvest of neural stem cells from subventricular zone and cell replacement in live rat brains

Authors: *Z. S. QING[1], L. KAI LI[2], L. N. P.[2], Y. K. L.[1];
[2]Biol., [1]Hong Kong Baptist Univ., Hong Kong, Hong Kong

Abstract: We have invented a novel method in harvesting neural stem cells (NSCs) from the subventricular zone of rats (Lui et al., *Angew Chemie Int Ed* 52: 12298-12302, 2013). Neural stem cells were harvested from the subventricular zone using *in situ* harvesting procedures. Then use the antibodies to conjugate with the magnetic NPs to enhance the specificity for the stem cell extraction. The antibody-conjugated magnetic nanoparticles (Ab-MNPs) can target and attach to NSCs. The NSCs pellet can be harvest by syringe and then culture in the neuro base medium. The Ab-MNPs shows a low cytotoxicity and will sooner be metabolized during the cell differentiation process. Using this method, neural stem cell can be harvested from live subjects and can be further differentiated into neuronal phenotypes for cell replacement in the brain. Neural stem cells were harvested from the subventricular zone using *in situ* harvesting procedures. Neural stem cells were cultured *in vitro* for 2-3 weeks using a novel nanomatrix. Cell samples were lysed and were assayed for expression of nestin, Tuj-1 and MAP-2 throughout the period. After confirmation of stable expression of Tuj-1 and MAP-2 proteins, living cells were transplanted into the cerebral cortex of the same rat subject for assessment of cell survival. Neuronal cells were found to surviving in the cortex of the animals. Neurites were found to extend from the transplanted neuronal cells and were found to be in close apposition to native neurons. There was no sign of neurological deficits in the animals. In some animals, the neural stem cells were found to be regenerated after 3-4 months after the harvesting procedures. The present results indicate that our method can harvest neural stem cells from live animal subjects. Neural stem cells harvested can be differentiated into neuronal phenotypes and can be used as cell replacement therapy for neurological diseases in the same animal subjects. These results have a strong implication in development into personalized neuronal cell replacement therapy for patients with neurodegeneration.

Title: Proteasomal Inhibition restores long term potentiation in hippocampal CA1 pyramidal neurons of APP/PS1 mice

Authors: *K. MUTHUKUMARAPPAN, S. SAJIKUMAR;
Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Synthesis of new plasticity proteins and degradation of worn out proteins are required for the maintenance of long term potentiation (LTP), the cellular correlate of memory. The ubiquitin proteasome system (UPS) is the critical protein quality control system regulating this equilibrium during LTP. Blockade of the UPS has been shown to accumulate new plasticity proteins involved in the early induction phase of late LTP. In Alzheimers disease (AD), the induction phase of late LTP is particularly impaired. In this study we have shown that LTP impairment can be restored in APP/PS1 mice by inhibiting the UPS by proteasome inhibitors such as Lactacystin and MG 132.

Title: Role of transient receptor potential ankyrin 1 channels in Alzheimer's disease

Authors: *H.-T. LEE;
No 155, Section 2, Li-Nong Street, Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Transient receptor potential ankyrin 1 (TRPA1) channel plays an important role in pain and inflammation. However, little is known about the significance of the TRPA1 channel in the pathophysiology of Alzheimer's disease (AD). Wild-type (WT), TRPA1$^{-/-}$, amyloid precursor protein (APP)/presenilin 1 (PS1) transgenic (APP/PS1 Tg) mice,the mouse model of AD, and APP/PS1 Tg/TRPA1$^{-/-}$ mice were used to examine the role of TRPA1 in pathogenesis of AD. Western blot was used for protein expression; immunohistochemistry was used for histological examination. The mouse behaviors were evaluated by locomotion, nesting building, Y-maze and Morris water maze tests; levels of interleukin (IL)-1β, IL-4, IL-6 and IL-10 and the activities of protein phosphatase 2B (PP2B), NF-κB and nuclear factor of activated T cells (NFAT) were measured by conventional assay kits; Fluo-8 NW calcium (Ca^{2+}) assay kit was used for the measurement of intracellular Ca^{2+} level in primary astrocytes and HEK293 cells. The protein expression of TRPA1 channels was higher in brains, mainly astrocytes of the hippocampus, from APP/PS1 Tg mice than WT mice. ablation of TRPA1-channel function in APP/PS1 Tg mice alleviated behavioral dysfunction, Aβ plaque deposition and pro-inflammatory cytokine production but increased astrogliosis in brain lesions. TRPA1 channels were activated and Ca2+ influx was elicited in both astrocytes and TRPA1-transfected HEK293 cells treated with fibrilized $Aβ_{1-42}$; these were abrogated by pharmacological inhibition of TRPA1 channel activity, disruption of TRPA1 channel function or removal of extracellular Ca2+. Inhibition of TRPA1 channel activity exacerbated $Aβ_{1-42}$-induced astrogliosis but inhibited $Aβ_{1-42}$-increased PP2B activation, the production of pro-inflammatory cytokines and activities of transcriptional factors NF-κB and NFAT in astrocytes and in APP/PS1 Tg mice. Pharmacological inhibition of PP2B activity diminished the fibrilized $Aβ_{1-42}$-induced production of pro-inflammatory cytokines, activation of NF-κB and NFAT and astrogliosis in astrocytes. TRPA1− Ca^{2+} − PP2B signaling may play a crucial role in regulating astrocyte-derived inflammation and pathogenesis of AD.

Abstract: Neurodegenerative diseases, such as Alzheimer's (AD) and Parkinson's disease (PD), are of growing importance in the aging population necessitating biomarkers for early diagnosis and treatment response. Due to its close contact to the brain, cerebrospinal fluid (CSF) is a promising source for the discovery of such markers reflecting protein alterations within the central nervous system. Previous work has shown that amyloid precursor protein (APP) transgenic mice mimic alterations of amyloid-β (Aβ) and tau levels in CSF observed in patients with sporadic and familial forms of AD making them a valuable model for translational biomarker research. In the present study we analyzed CSF-proteome changes in two well-established transgenic mouse models for β-amyloidosis and synucleinopathy, the pathological hallmark lesions of AD and PD, respectively. Therefore, we used mice either overexpressing mutant human Presenilin-1 and amyloid precursor protein (APPPS1), or mutated human α-Synuclein (A30P-aSyn) for CSF collection. We applied mass spectrometry-based label-free quantification to assess the CSF proteome in young vs. aged mice of both lines compared to age-matched non-transgenic controls. 1039 and 1269 CSF proteins could be quantified in the APPPS1 and in A30P-aSyn cohorts, respectively. Interestingly, this unbiased shotgun approach did not only reveal age- and transgene-related changes in analytes that have already been associated to AD or PD, like soluble APP, soluble TREM2, ApoE or NfL, but also yielded novel proteins that might be interesting candidates for further evaluation and validation. This dataset provides new insights into CSF protein alterations in models of β-amyloidosis and synucleinopathies and may contribute guidance for the identification of novel biomarkers for human disease.

Title: The p3-Alcβ peptide shows an effect to protect neurons from Aβ toxicity.

Authors: *A. UCHIYAMA, A. KIMURA, C. OMORI, S. HATA, T. SUZUKI;
Hokkaido Univ., Sapporo-Shi, Japan

Abstract: Alcadeins (Alcs; Alcα , Alcβ, and Alcγ) are evolutionarily conserved type I transmembrane proteins that undergo the proteolytic cleavages as does amyloid β-protein precursor (APP) (1, 2). Alcs are primarily cleaved by APP α-secretase (ADAM10/17) to produce the N-terminal extracellular ectodomain (sAlc) and the membrane-associated C-terminal fragment (Alc CTF). The Alc CTF is subsequently cleaved by γ-secretase to generate the N-terminal p3-Alc peptide and the C-terminal intracellular cytoplasmic domain (Alc ICD) fragment. Thus, Alcβ secrets major molecular species p3-Alcβ37 into CSF (3), and we found that the level of p3-Alcβ37 significantly decreased in Alzheimer's disease patients. Further study indicates that p3-Alcβ37 suppresses neuronal impairment induced by Aβ42 oligomer in vitro, and we identified the core amino acid sequence composed of 11 amino acids within p3-Alcβ37. Our results suggest that this small peptide composed of 11 amino acids (p3-Alcβ-11) might be a seed or a lead to develop a novel therapeutic agent to Alzheimer's disease. To understand the molecular function of p3-Alcβ to neurons, we explored the target molecule of p3-Alcβ37 and p3-Alcβ-11 peptide. Using the biotinylated p3-Alcβ-11 peptide probe, we isolated candidate neuronal proteins, and the proteins were analyzed with LC-MS. Identification of target protein(s) of p3-Alcβ37 will also contribute for understanding of the physiological function of this endogenously generated peptide.

Abstract: Alzheimer disease (AD) is characterized by the accumulation of misfolded beta-amyloid (AB) and tau proteins. Acceleration of AD-related protein aggregation following human AD brain homogenates inoculation has been demonstrated in transgenic rodents. Studies in primates are however not as conclusive. This study's goal was to determine the impacts of experimental transmission on both brain function and integrity in mouse lemur primates. Twelve adult mouse lemurs, (3 to 4 yrs.) were bilaterally inoculated in the hippocampus and subjacent cortex with human brain homogenates from AD patients or control (CTRL) age-matched subjects. Longitudinal tests of cognition, EEG and morphology (via MRI) were done up to 18 months post-inoculation followed by of brain tissue immunohistopathology. AD-inoculated animals progressively developed cognitive impairments affecting first long-term memory and later learning abilities. EEG profiles of AD-inoculated lemurs shifted progressively towards fast frequencies compared to CTRL-inoculated lemurs. Compared to the CTRL-inoculated group, AD animals displayed an atrophy of the retrosplenial and posterior cingulate cortices as well as adjacent regions of the limbic connectome Immunohistochemistry revealed few cortical amyloid plaques and sparse cortical amyloid angiopathy in some AD-inoculated animals. We demonstrate for the first time that inoculation with AD brain homogenates induces functional and morphological alterations in primates without induction of immunohistopathological-detectable forms of AB or tau proteins.

Title: Novel Osmotin inhibits SREBP2 via AdipoR1/AMPK/SIRT1 pathway to improve Alzheimer's disease Neuropathological Deficits

Authors: ***M.-O. KIM**[1], S. ALI SHAH[2], G. YOON[2], M. KIM[2], M. JO[2], M. CHO[2];
[1]Col. of Nature Sci., Dept. of Biol., Gyeongsang Natl. Univ., Gajwa 900, Jinju, Korea, Republic of; [2]Dept. of Biology, Gyeongsang Natl. Univ., Jinju, Korea, Republic of

Abstract: Extensive evidence has indicated that a high rate of cholesterol biogenesis and abnormal neuronal energy metabolism play key roles in Alzheimer's disease (AD) pathogenesis. Here we used osmotin for the first time, a plant protein homolog of mammalian adiponectin, to know its therapeutic efficacy in different AD models. Our results reveal that osmotin treatment modulated adiponectin receptor 1 (AdipoR1) and significantly induced AMPK/SIRT1 activation, reduced SREBP2 expression both *in vitro* and *in vivo* AD models and in Adipo$^{-/-}$ mice. Osmotin via AdipoR1/AMPK/SIRT1/SREBP2 signaling pathway significantly diminished the amyloidogenic Aβ production, abundance and aggregation accompanied by improved pre-and post-synaptic dysfunction, cognitive impairment, memory deficits and most importantly reversed the suppressed LTP in AD mice. Interestingly, AdipoR1, AMPK and SIRT1 silencing not only abolished osmotin capability but also further enhanced AD pathology by increasing SREBP2, APP, β-secratase (BACE1) expressions and the levels of toxic Aβ production, while the opposite is true for SREBP2 when silenced with its siRNA in APPswe/ind-transfected SH-SY5Y cells. Similarly, osmotin treatment also enhanced the non-amyloidogenic pathway by activating α-secratase gene i.e. ADAM10 in AMPK/SIRT1 dependent manner. These results suggest that osmotin or osmotin-based therapeutic agents might be potential candidates for AD treatment.

Title: Calmodulin-like skin protein prevents spatial learning impairment of Alzheimer's disease model mice

Authors: *S. KUSAKARI[1], M. NAWA[1], K. SUDO[2], M. MATSUOKA[1,3];
[1]Dept. of pharmacology, [2]Animal Reserch Ctr., [3]Dept. of Dermatological Neurosci., Tokyo Med. Univ., Shinjuku-ku, Tokyo, Japan

Abstract: Alzheimer's disease (AD) is the most prevalent dementia-causative neurodegenerative disorder. AD is pathologically characterized by neuronal loss, senile plaque, and neurofibrillary tangle. Three familial AD-causative genes, APP, PSEN1 and PSEN2, are identified by genetic analysis.
We previously found that a secreted neuroprotective peptide, humanin, inhibits neuronal cell death, caused by the AD-linked genes via the heterotrimeric Humanin receptor. Level of humanin in the central nervous system may be insufficient to exert a protective effect. Recently, we found that calmodulin-like skin protein (CLSP) is another physiological agonist of the Humanin receptor with an anti-cell death activity 100000-fold more potent than Humanin. CLSP is secreted from skin and related epithelial tissues, circulates in the bloodstream, and is transported to the central nervous system through the blood-brain barrier.
To investigate the effect of CLSP against the AD pathology and AD-related dementia, we generated mouse CLSP-1 transgenic mice and crossed them with the APPswe/PSEN1dE9 mice, AD model mice with the Swedish mutant gene of amyloid beta precursor protein (APP) and the presenilin-1 (PSEN1) gene lacking exon 9. It has previously established that senile plaques are deposited in hippocampus and cerebellum cortex of the aged APPswe/PSEN1dE9 mice and spatial learning was impaired in these mice. Performing the Morris water maze, we found in the current study that the constitutive co-expression of the mCLSP-1 gene prevented the impairment of spatial learning in APPswe/PSEN1dE9/CLSP-1 mice at the age of 13 months. This result suggests that CLSP behaves as a neuroprotective factor against AD in vivo.

Title: DA-9803 prevents deposition of amyloid plaques and maintains calcium homeostasis in Tg2576 mice

Authors: *G. PAGNIER[1], K. KASTANENKA[1], M. SOHN[2], S. CHOI[2], H. GO[2], B. BACSKAI[1];
[1]Massachusetts Gen. Hosp., Charlestown, MA; [2]Dong-A ST, Yongin, Korea, Republic of

Abstract: Alzheimer's Disease (AD) is a neurodegenerative disorder characterized by deposition of amyloid plaques and formation of intracellular neurofibrillary tangles, resulting in a progressive memory loss and cognitive decline. The molecular mechanisms driving these pathologies are potential targets for the treatment of AD. We studied the effects of DA-9803, a multimodal botanical cocktail in a transgenic mouse model of AD. Using multiphoton microscopy, longitudinal imaging of the senile plaques was performed and intracellular calcium was monitored. Cytosolic calcium is an indirect marker of neuronal activity and is normally tightly regulated. Our past research has shown that resting calcium is elevated in a fraction of neurites in APP transgenic mice. Thus, an effective AD treatment would restore calcium to control levels. 100 mg/kg DA-9803 was administered daily to 5 month-old Tg2576 mice via a gavage treatment for 2 months. Longitudinal imaging was performed before and during the treatment. Plaques were labeled with methoxy-XO4 while intraneuronal calcium levels were measured with the genetically encoded calcium sensor YC3.6. Chronic administration of DA-9803 prevented amyloid plaque deposition over the 2 months treatment period in these mice. Elevated calcium was detected in a subset of neurons before treatment. DA-9803 decreased the elevated neurite calcium levels to control levels over this time course. Treatment with a vehicle cocktail failed to decrease the rate of plaque deposition or restore intracellular calcium. In summary, these results demonstrate that treatment of young Tg2576 mice with 100 mg/kg DA-9803 prevents deposition of amyloid plaques and maintains calcium homeostasis in Tg2576 mice. Thus, DA-9803 treatment could have a protective effect on neuronal function and delay the progression of AD.

Title: DeltaFosB gene targets in an Alzheimer's disease mouse model: implications for hippocampal neuronal function

Authors: *G. S. STEPHENS[1], J. C. YOU[2], C.-H. FU[1], X. ZHANG[1], J. CHIN[1]; [1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Neurosci., Thomas Jefferson Univ., Philadelphia, PA

Abstract: Increasing evidence suggests that seizures contribute to cognitive decline in Alzheimer's disease (AD). Therefore, understanding the mechanisms by which they do so may enable the discovery of novel therapeutic targets. Our studies of seizure-related changes in the hippocampus of human amyloid precursor protein (hAPP) transgenic mice, a mouse model of AD, have revealed that expression of the transcription factor ΔFosB is markedly increased by seizures. ΔFosB has an unusually long half-life (~8 days) and interacts with various histone modification enzymes to regulate multiple neuronal functions. Identifying targets of ΔFosB in hAPP mice may therefore provide insight into the mechanisms by which even infrequent seizures can lead to long-lasting impairments in memory. Our unbiased ChIP- and RNA-sequencing analyses have identified many putative ΔFosB gene targets in wild-type and hAPP mice. Gene clustering analyses of these targets demonstrate the potential involvement of ΔFosB in regulating pathways critical to neuronal function, including glutamatergic synapse maintenance, cytoskeletal organization, and dendritic development. Further benchtop confirmation of several notable ΔFosB targets in the hippocampus of hAPP mice reveals altered expression. Overall, our data suggest that seizure-induced ΔFosB in the hippocampus of hAPP mice critically coordinates several programs of gene expression to regulate neuronal function. Abstract: Epidemiological and clinical studies show that beta amyloid aggregation at any stage is insufficient to develop a sporadic Alzheimer's Disease (AD) which accounts for more than 85% of both sporadic and familial AD. Moreover, recent studies show that sporadic AD arises from dysregulation of brain glucose metabolism which the amyloid hypothesis does not explain. Also it is known to occur before beta amyloid plaques accumulates in the brain. In this study, we investigated the correlation between dysregulation in brain glucose metabolism and early-time pathophysiology in AD using high fat diet (HFD)-fed mouse. The mouse, to detect alteration of glucose metabolism in the AD-like mouse brain, was subjected to dynamic nuclear polarization-enhanced hyperpolarized **^{13}C-** magnetic resonance spectroscopic imaging (DNP-MRSI), following HFD for 6 months. Specifically, metabolic amounts and its speed of hyperpolarized **^{13}C**-labeled pyruvate were 1) temporally analyzed with dynamic MRS and 2) spatially analyzed with chemical shift imaging (CSI) methodology. Abnormal lactate conversion, which is similar to the Warburg Effect, from hyperpolarized 13C pyruvate was observed in the hippocampal region of HFD-fed mice. Memory function loss was confirmed with Morris Water Maze (MWM) and aggregation of beta amyloid 1-42 was found in CA1 and DG. Together, our results demonstrate that the abnormal accumulation of beta amyloid and of lactate residues through Warburg effect in the brain could play a role in the neuropathology of AD.

Title: Tau-mediated circadian rhythm disruption and cognitive dysfunction in Alzheimer's disease mouse model

Authors: *A. KIM[1], H. SONG[2], I. MOOK-JUNG*[2];
[1]Col. of Medicine, Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Two pathological characteristics of Alzheimer's Disease (AD), the most common type of dementia, are Aβ senile plaques and Neurofibrillary tangles (NFTs), composed of hyperphosphorylated tau aggregation. Circadian rhythm disruption is commonly reported by patients with AD and Mild cognitive impairment (MCI). Clock genes, such as PER2, BMAL1, and CLOCK, show oscillating expression patterns in Suprachiasmatic Nucleus (SCN), the master pacemaker generating circadian rhythm. This rhythmic expression influences several physiological function including metabolism and memory formation. Moreover, some of hippocampal gene expressions are also modulated by circadian rhythm generated by SCN and show similar oscillation pattern. Thus, disruption in circadian rhythm can attributes to cognitive dysfunction in AD patients. Here, we showed that the oscillating patterns of clock genes are altered in SCN and hippocampus of AD mouse model with human tau P301L mutation. Moreover, NIH-3T3 cell lines transfected with human tau P301L mutation showed different clock genes promotor activity oscillations. Therefore, the mechanism of tau-mediated circadian dysfunction will provide a probable solution for AD patients to treat their difficulties caused by circadian rhythm disruption.

Title: Mechanisms of redox perturbation in the 2nd generation App knock-in mouse model of Alzheimer's disease

Authors: *S. HASHIMOTO, T. SAITO, T. C. SAIDO;
RIKEN BRAIN SCIENCE INSTITUTE, Wako-City, Saitama, Japan

Abstract: Objectives: Perturbed balance between oxidant and antioxidant species, such as glutathione, in brain may contribute to etiology of Alzheimer's disease (AD). A number of studies have revealed decreased levels of glutathione in the blood and CSF from AD patients. In this study we investigated the mechanisms that alter glutathione homeostasis in AD using APP knock-in (KI) mouse model (*App*$^{NLGF/NLGF}$-KI). **Methods and Results:** 12 month-old *App*$^{NLGF/NLGF}$-KI mice, carrying saturated Aβ pathology, exhibited lower glutathione levels in both blood and cortex than age matched controls. We then determined the levels of glutamate cysteine ligase catalytic subunit (GCLC), a rate-limiting enzyme in glutathione biosynthesis. Western blot and RT-PCR analyses showed a significant decrease of GCLC protein and mRNA levels in the cortex of *App*$^{NLGF/NLGF}$ mice. We next examined Nrf2 levels because Nrf2 regulates the expression of antioxidant genes and facilitates GCLC expression. Despite our hypothetical presumption, the protein levels of Nrf2 remained unchanged in *App*$^{NLGF/NLGF}$ mice. Intriguingly, *App*$^{NLGF/NLGF}$ mice exhibited higher levels of matured cortical TGF β1, which negatively regulates Nrf2-mediated GCLC expression. **Conclusions:** TGFβ1 may contribute to the decrease of glutathione and, consequently, increase oxidative stress in *App*$^{NLGF/NLGF}$ mice: TGFβ1 thus may become a target for prevention and treatment of AD.

Title: Alzheimers related gene expression and neurosteroid production in the brains of hypogonadal kisspeptin receptor knockout mice

Authors: M. GOSS, A. R. HARVEY, *J. T. SMITH;
The Univ. of Western Australia, Perth, Australia

Abstract: Gonadal sex steroids have been implicated in the processing of β-amyloid precursor protein which generates β-amyloid (Aβ), a primary driving factor for Alzheimer's disease (AD). Neurosteroidogensis has also been evidenced in localized regions of the brain associated with AD, and has been suggested as a potential compensatory neuroprotective mechanism in response to Aβ pathology and loss of circulating sex steroids. Kisspeptin signalling controls the hypothalamic-pituitary-gonadal axis responsible for regulation of circulating sex steroid levels, however kisspeptin is also neuroprotective against Aβ toxicity, independant of its receptor, through direct binding to the Aβ peptide. We used a hypogonadal kisspeptin receptor (Kiss1r) knockout (KO) mouse model to investigate the relationship between kisspeptin signalling /sex steroid deficiency and AD-like neuropathological characteristics. Brain regions were dissected and analysed for gene expression of AD- and neurosteroidogenic-associated markers. Behavioural testing was also performed in the male cohort. Hippocampal-associated behavioural deficiencies in 6 month Kiss1r KO males were linked to increased expression of the Aβ-associated gene presenilin 1 (PSEN) within the hippocampus. Gene expression analysis of brain regions in male and female mice showed variably increasing expression of Aβ-associated genes β-amyloid cleaving enzyme (BACE), presenilin 1 (PSEN), and apolipoprotein E with age in males. Females tended to exhibit higher levels of expression of these markers than males. The neurosteroidogenic markers, steroidogenic acute regulatory protein, 3β-hydroxysteroid dehydrogenase, and cytochrome P450scc (CYP), were also generally elevated in females and increased in males with aging. Within the hypothalamus a significant ($p<0.05$) correlation between BACE and PSEN expression was found, and between BACE and CYP. The results of this experiment suggest that neurosteroid production may be acting as a compensatory neuroprotective mechanism in Kiss1r KO mice and potentially implicates kisspeptin as a significant regulator of Aβ and AD-like behaviours.

Abstract: Compelling evidence indicates that Type 2 Diabetes Mellitus (T2DM) and Alzheimer's Disease (AD) may possibly share a common pathological origin, but the underlying mechanism(s) remains poorly understood. While insulin in the brain act as neurotrophic factor, T2DM is a known risk factor for AD and Insulin Resistance (IR - a hallmark signature of T2DM) has been extensively documented in the Central Nervous System (CNS) of AD patients. Notably, insulin plays a key-role in learning and memory, suggesting that reduced insulin signaling in the AD brain may contribute to impaired cognitive function. We developed a mouse model of T2DM that overexpresses ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1), a membrane glycoprotein that acts as an inhibitor of insulin receptor, in adipose tissue (At-ENPP1-Tg mouse) offering a unique chance to explore novel mechanistic pathways involved in IR, metabolic syndrome diabetes complications, including AD. Our initial studies showed that At-ENPP1-Tg mice display altered lipid composition of hippocampal synaptosomes, suppressed basal synaptic transmission and reduced insulin receptors. Furthermore, synapses from brain slices of At-ENPP1-Tg demonstrate increased vulnerability to Aβ oligomers, an event known to play a key role in the onset and progression of cognitive decline in AD. Adiponectin, reduced in At IR, reduces the binding of Aβ oligomers to synaptosomes of At-ENPP1-Tg mice. This initial evidence suggests the attractive possibility that targeting adipose tissue IR could be a potentially effective therapeutic strategy for AD. With this goal in mind, in the present work, we investigated the putative protective role of Wharton's Jelly-derived Mesenchymal Stem Cells (WJ-MSCs) after their transplantation in the subcutaneous adipose tissue of At-ENPP1-Tg mice. Our results show that these cells may be able to rescue the diseased At tissue and ameliorating its dysfunctional CNS impact. We are further measuring glucose and insulin level in the blood after intraperitoneal injection of glucose or insulin 12 weeks following WJ-MSCs transplantation into the At, along with tissue protein and RNA expression levels. Collectively, these studies indicate that WJ-MSCs may be used as novel therapeutic strategy to correct At IR, thus reducing associated CNS deficits.

Title: Experimental neprilysin activation strategy for prevention of AD

Authors: *N. KAKIYA, T. SAITO, P. NILSSON, T. C. SAIDO;
RIKEN Brain Sci. Inst., Wako-Shi / Saitama, Japan

Abstract: Neprilysin is one of major amyloid-β peptide (Aβ) degrading enzymes, the expression of which decreases in the brain with aging, resulting in a metabolic imbalance of Aβ quantity. This imbalance is likely to contribute to the amyloidosis underlying sporadic Alzheimer's disease (AD). Pharmacological activation of neprilysin during aging therefore represents a potential strategy to decrease the amyloidosis and attenuate the pathological progression of AD. We have previously reported that the neuropeptide somatostatin (SST) enhances neprilysin activity. However, it still remains to be shown whether SST receptor(s) are feasible targets. To identify alternative druggable target, we first carried out an in vitro screening using mouse cortical/basal ganglia-derived neuronal co-culture system. This led to a finding of a novel promising candidate, which reduced Aβ level in the conditioned medium. Of particular importance, this candidate compound can cross the blood-brain barrier and reach the brain parenchyma after intraperitoneal injection. Thus, we investigated its in vivo effects on the neprilysin and Aβ levels in brain. We observed a significant reduction of the Aβ levels in association with an increased neprilysin expression after drug administration. We confirmed that this does not happen in neprilysin knock-out mice, indicating that neprilysin mediated the effect. We then evaluated the long-term effects, by continuously implanting pellets containing the drug under the skin of aged AD model mice (single App knock-in mice) for 90 days. We then measured cognition of the mice 2 weeks after drug administration was ceased. The drug treatment attenuated cognitive impairment observed in the AD model mice. These observations indicated that this drug-induced neprilysin activation may be applied for prevention of AD.

Title: Insulin dysregulation leads to hippocampal neprilysin downregulation

Authors: *J. MORALES-CORRALIZA[1], H. WONG[2], M. J. MAZZELLA[2], S. CHE[1], S. LEE[1], E. PETKOVA[1], J. D. WAGNER[3], S. E. HEMBY[4], S. D. GINSBERG[1], P. M. MATHEWS[1]; [1]Nathan Kline Institute-New York Univ., Orangeburg, NY; [2]Nathan Kline Inst., Orangeburg, NY; [3]Wake Forest Sch. of Med., Winston-Salem, NC; [4]High Point Univ., High Point, NC

Abstract: Objectives: To understand the mechanisms of increased Alzheimer's disease (AD) risk caused by diabetes and altered brain insulin signaling. **Methods**: Tissue from multiple brain regions of a vervet monkey model of streptozotocin-induced type 1 diabetes supported with daily insulin treatment were examined for biochemical changes in brain insulin signaling, tau protein, amyloid precursor protein (APP) and Aβ peptide, as well as changes in key enzymes that contribute to tau and APP posttranslational processing. Using primary neuronal cultures, we modeled chronic insulin dysregulation by means of prolonged insulin treatment to determine whether altered insulin signaling may directly drive AD risk in diabetics. Additionally, we manipulated insulin signaling in the brain in mice using shRNA constructs to knockdown hippocampal expression of insulin receptor substrate 1 (IRS1), a key molecule in the insulin-signaling cascade. **Results**: Regional brain analyses showed a brain-wide inhibition of IRS1, while changes in ERK1/2 phosphorylation argue for activation of this kinase, in diabetic compared to control monkeys. Increased tau phosphorylation was also seen throughout the brain in the diabetic monkeys. However, a diabetes-induced increase in Aβ levels was specific to temporal brain structures, with the greatest increase observed in the hippocampus. A

hippocampal specific decrease in the Aβ-degrading enzyme neprilysin (NEP) appears to be an important contributor to this regional Aβ increase in the diabetic monkeys. In primary hippocampal neurons, we found that prolonged insulin treatment leads to an increase in an inhibitory phosphorylation of IRS1 and, similar to the diabetic hippocampus, a reduction in NEP protein and RNA levels. Hippocampal injection of an IRS1-shRNA adeno-associated virus in wild-type mice reduced IRS1 protein levels in 3 weeks. NEP protein levels were also found to be reduced in the ipsilateral compared to contralateral hippocampus after IRS1 knockdown. **Conclusions**: In a non-human primate model of type 1 diabetes treated with exogenous insulin, reduced NEP expression in the hippocampus correlates with biochemical alterations in the insulin-signaling pathway that has been described as "brain insulin resistance". Direct manipulation of insulin levels and the key insulin-signaling mediator IRS1 supports the conclusion that disruption of insulin signaling leads to the reduced NEP expression seen in the diabetic hippocampus. Our findings are consistent with the idea that brain insulin resistance increases the risk for AD both by increasing brain Aβ levels and by altering tau phosphorylation.

Title: Near infrared light reduces amyloid beta oligomer-driven synaptic dysfunction.

Authors: *M. M. COMEROTA[1], G. TAGLIALATELA[2];
[2]Mitchell Ctr. for Neurodegenerative Diseases, Dept. of Neurol., [1]Univ. of Texas Med. Br., Galveston, TX

Abstract: Alzheimer's disease (AD), the most common age related neurodegenerative dementia, is characterized by deposits of aggregated amyloid beta (Aβ) plaques and neurofibrillary tangles comprised mainly of hyper-phosphorylated tau protein. However, it is believed that the association of small toxic Aβ oligomers with synapses contributes to the cognitive decline that is associated with AD. This association results in dysfunctional synaptic morphological and physiological changes including retraction of synaptic spines and reduced long term potentiation

(LTP). Because current pharmaceutical therapeutic options have limited efficacy and the prevalence of AD is rising, the development of alternative treatments are imperative. Near infrared (NIR) light treatment (600-1000 nm) is a novel noninvasive therapeutic strategy that has been suggested as an effective option for the treatment of AD. Notably, it has been reported that NIR light treatment on APP/PS-1 transgenic mice induced a reduction of Aβ plaque load and improved memory function. However, the effect of NIR light on the most toxic form of Aβ, oligomers, and their impact on synapses remained undescribed. In the present study, we investigated the presence of Aβ oligomers at synapses and the susceptibility of synapses to Aβ binding (an important event linked to Aβ-driven synaptic disruption and memory deficits) after a NIR light treatment at 670 nm (90 sec a day for 4 weeks). We further examined the changes in the synaptic morphological and physiological properties after such NIR light treatment. We found that after NIR light treatment, the amount of $A\beta_{1-42}$ was significantly reduced at synapses of 6 month old APP transgenic mice (Tg2576) that was paralleled by an increased retention of long term potentiation induction. We further found that the synapses of wild type mice treated with NIR light showed a reduction in *ex vivo* Aβ oligomer binding. Collectively these results indicates that NIR light, in addition to reducing levels of Aβ oligomers, further promotes synaptic resistance to Aβ oligomer binding thus alleviating the ensuing synaptic impairments. This study thus provides evidence that NIR can effectively reduce Aβ driven synaptic dysfunction, thus furthering light therapy as a viable treatment for AD.

Col. of Med., Philadelphia, PA

Abstract: Cholesterol metabolism may play a role in modulating Alzheimer's disease (AD) risk and pathogenesis. Recent studies suggest that apoE receptors and very low density lipoprotein (VLDL) receptors may be implicated in memory and neurodegenerative disorders like AD. VLDL receptor-deficient mice have a moderate deficit in long term potentiation (LTP). Liver X receptors (LXRβ and LXRα) are nuclear oxysterol receptors and metabolic sensors initially found to regulate cholesterol metabolism and lipid biosynthesis. The synthetic LXR agonist T0901317 inhibits APP processing and lowers Aβ in the brains of APP transgenic mice possibly via ABCA1 (ATP-binding cassette transporter A1) dependent mechanism, and activation of LXR/ABCA1 pathway in the brain can positively affect Aβ metabolism. Thus, LXR agonists may provide a potential pharmacological strategy for AD treatment. However, LXR agonists target both LXRβ and LXRα to elevate hepatic and serum trigylceride levels. Therefore we tested the efficacy of subtype-specific LXR agonists. We synthesized 41 compounds of flavonoids using the typical flavone and chalcone skeletons as the templates for structure-diversity expanding, 37 compounds of them are new compounds. We confirmed that some compounds, particularly compound 19, activate LXRβ rather than LXRα, and upregulate the expression of ABCA1 and/or apoE. Further, these compounds facilitate intracellular Aβ clearance. The 7 month-old APP/PS1 transgenic mice were injected with compound 19 (10 mg/kg, IP, once every other day for 3 months), with positive control mice being given T0901317 (25 mg/kg, by gavage daily). We found that compound 19 significantly reduced Aβ and senile plaques in the brain, and more importantly it had no effect in serum or hepatic triglyceride levels compared with those given T0901317. Moreover, we provided the first evidence that compound 19 significantly enhanced LTP in CA1 (169.2±7.1% in control AD mice vs. 212.8±8.3% in AD mice with compound 19). Our findings suggest that compound 19 or its analogues may serve as new selective LXR modulators for treatment of Alzheimer's disease.

Title: Scanning ultrasound as a treatment tool of proteinopathies including Alzheimer disease

Authors: *J. GOETZ, G. LEINENGA, R. NISBET, A. VAN DER JEUGD, R. HATCH; Queensland Brain Inst., The Univ. of Queensland, Brisbane (St Lucia Campus), Australia

Abstract: Background: Treatment strategies for diseases are hampered by the fact that the blood-brain barrier (BBB) establishes an efficient barrier for therapeutic agents. We have recently shown that scanning ultrasound (SUS) allows microglial-mediated clearance of amyloid-beta in APP mutant APP23 mice and restores memory functions to wild-type levels (Leinenga and Götz, Science Transl Med 2015; Leinenga et al., Nat Rev Neurol 2016). While no damage was detected by histology, the effect of SUS on neuronal firing or complex neuronal morphology was not studied. We also determined whether SUS treatment is safe long-term and whether it reduces the intracellular tau pathology that characterizes Alzheimer's disease, in addition to amyloid deposition. **Methods:** For the safety study, we treated C57BL/6 wild-type mice both acutely and chronically with either one or several weekly SUS treatments. Upon sacrifice, the electrophysiological properties and morphology of hippocampal neurons of treated mice were analysed. To assess the efficacy and drug-delivering ability of SUS in tau models, we established four groups, using a novel anti-tau antibody which was injected weekly over four weeks, either on its own, or together with SUS. A third group used SUS only, and a fourth was the anaesthesia control group. As an experimental model, P301L tau transgenic pR5 mice were used. **Results:** Whole-cell patch-clamp electrophysiology revealed that SUS does not have any harmful effects on neuronal firing, as treatment (even three months after six weekly treatments) did not alter action potential firing. Further SUS treatment prevented age-related loss of synaptic spines. A histological and biochemical analysis of the pR5 tau transgenic mice revealed that SUS as well as the employed antibody ameliorate the tau pathology that characterizes the pR5 mice, and that there are synergistic effects, presenting opportunities to use SUS for drug delivery. **Conclusions:** Our study demonstrates that long-term treatment of mice with ultrasound is safe using electrophysiology and maintains synaptic structure. The study further suggests that SUS is a method that benefits diseases with protein aggregates more generally, whether they are intra- or extracellular.

Title: Neurochemical changes in the anemic neonatal mouse hippocampus and prefrontal cortex following erythropoietin therapy

Authors: *D. WALLIN, I. TKAC, M. K. GEORGIEFF;
Univ. of Minnesota, Minneapolis, MN

Abstract: Background: Alterations to brain energy and phospholipid metabolism have been shown in the hippocampus of a neonatal mouse model of phlebotomy-induced anemia (PIA). Other brain regions such as the prefrontal cortex that are developing during this time period are also at risk for metabolic abnormalities. These changes may be due to hypoxia, iron deficiency (ID), or both. Erythropoietin is commonly used in the neonatal intensive care unit (NICU) and could alleviate the hypoxic effects of PIA on the brain without the risk of a red blood cell transfusion. However, erythropoietin could also exacerbate brain ID by prioritizing the neonate's limited iron reserves to the growing red blood cell mass. Objective: Our objective was to use a mouse model of PIA that is both physiologically and developmentally relevant to study the effect of erythropoietin treatment in the hippocampus and prefrontal cortex of anemic neonatal mice. Methods: Neonatal mice were bled starting at postnatal day (P)3 to a hematocrit of less than 25% and then treated with recombinant human erythropoietin (RhEpo) to achieve a hematocrit above this threshold. Metabolic profiles of PIA, PIA and RhEpo treated, and nonbled controls were obtained through in vivo ^{1}H NMR spectroscopy at 9.4T in the hippocampus and prefrontal cortex. Results: Lactate was significantly increased in the PIA mouse hippocampus as compared to nonbled control. An increase was also found in the prefrontal cortex. Lactate concentrations in both structures were not different between PIA mice and PIA mice given RhEpo treatment. Glutamate is increased in both structures in the PIA mice (trending in prefrontal cortex), and RhEpo treatment begins to normalize these concentrations. A similar trending effect is found for GPC+PCho in both structures and for GSH within the prefrontal cortex. Conclusions: RhEpo

treatment did not alleviate the bioenergetics alterations due to PIA, indicating that these alterations may primarily be due to brain ID and not anemia. Concentrations that were altered with anemia and normalized with RhEpo treatment such as glutamate appear to be due to anemia, rather than brain ID. Better understanding of the underlying neurochemical alterations during anemia and the long-term risks posed will lead to more informed decisions regarding phlebotomy (number of blood draws), RBC transfusions and the use of RhEpo by clinicians caring for preterm infants in the NICU.

Title: Identification of selective sigma 1R ligand EPGN644 for evaluation in Alzheimer's disease

Authors: ***S. RAVULA**[1], F. C. TUCCI[1], G. BEATON[1], C. BORSAN[1], R. DAGAR[1], S. KIM[2], D. DALWADIDI[2], J. A. SCHETZ[2];

Abstract: Alzheimer's Disease (AD) is a significant public health problem yet available treatments offer limited benefit and none are truly disease-modifying. Cognitive decline is slower in AD patients with higher levels of brain BDNF, while interference with BDNF trafficking and secretion is associated with an increased risk of AD. Lead discovery identified several novel small molecules that facilitate BDNF secretion via their high affinity and selective interactions with the Sigma-1 (S1R) suggesting that they would be beneficial in AD by making neurons more resilient to inflammatory stress and promoting neurogenesis. EPGN644 is one of these compounds and it has pharmacokinetic properties suitable for conducting further studies in rodent models.

Title: Chronic administration of imidazoline ligands improves memory deficits and reduces neuroinflammation in a mouse model of Alzheimer's disease

Authors: *N. MIRZAEI, A. BIRCH, L. KATSOURI, D. NUTT, M. SASTRE;
Imperial Col. London, London, United Kingdom

Abstract: An accumulating body of evidence supports the use of imidazoline type-2 (I2) receptor ligands as a potential avenue for therapeutic intervention in Alzheimer’s disease (AD). These ligands seem to be neuroprotective by reducing cell death, neuroinflammation and the release of neurotoxic substances such as glutamate.
To investigate this further, 6 month old female 5XFAD mice and wild-type controls (n=8 per group) were treated with 5 $mg.kg^{-1}$ BU224 twice a day for a period of 10 days. At this age, 5XFAD mice show severe memory impairment, amyloid deposition and neuronal loss. BU224-treated 5XFAD mice showed a significant increase in exploring the displaced object on testing day, compared to both training day and vehicle-treated controls. Fear conditioning testing also revealed that both hippocampal-dependent and -independent memory functions in the BU224-treated 5XFAD mice were also improved following learning by association. Subsequently, mouse brains were perfused and used for immunohistochemical assessment and protein quantification. GFAP staining was performed and showed that BU224 treatment increases the levels of GFAP expression, as has been published before for other imidazoline ligands (Olmos et al., 1994; Alemany et al., 1995). In hippocampal and cortical homogenates, BU224 induced a decrease in the levels of certain cytokines such as IL-1β and TNF-α measured by ELISA, suggesting an anti-inflammatory effect.
In conclusion, our preliminary data indicate that chronic treatment with BU224 improves

memory and cognitive performance and reduces inflammation, at a severe stage of AD pathology. Therefore, I2-imidazoline drugs could have potential benefits for AD patients.

Title: Gastrointestinal dysbiosis in the development of alzheimer disease

Authors: ***T. HARACH**[1], N. MARUNGRUANG[2], F. FÅK[2], N. DUTILLEUL[1], V. CHEATHAM[1], K. MCCOY[3], J. NEHER[4], M. JUCKER[4], T. LASSER[1], T. BOLMONT[1]; [1]EPFL STI IMT LOB, EPFL, Lausanne, Switzerland; [2]Food for Hlth. Sci. Centre, Lund Univ., Lund, Sweden; [3]Mucosal Immunol. Lab. Dept. of Clin. Res., Univ. of Bern, Bern, Switzerland; [4]German Ctr. for Neurodegenerative Dis. (DZNE), Tübingen, Germany

Abstract: Alzheimer disease is the leading cause of dementia in western societies featuring huge societal and personal cost and burden. To date, there is no early diagnosis or cure for this devastating neurodegenerative disorder. Gastrointestinal microbiota is key player to many physiological processes including nutrition, inflammation, vitamins synthesis, drug processing, but also defense against pathogens. A growing body of evidence suggests that gastro-intestinal microbiota impacts on brain disorders such as autism and Parkinson’s disease. However, the role of the intestinal microbiota in AD has never been investigated. Herein, we showed that sequencing bacterial 16S rDNA extracted from fecal samples of transgenic CONVAPPPS1 and wild type mice revealed major shifts in the gut microbiota composition at both phylum and genus level. Furthermore the absence of intestinal microbiota in the germ free GFAPPPS1 transgenic mice was sufficient to significantly decrease cerebral Abeta amyloid pathology. Not only the biochemical levels of Aβ but also the extent of congophilic Aβ plaques was consistently decreased in the brains of APPPS1 transgenic mice without gut microbiota. In contrast, whereas colonization of GFAPPPS1 mice with microbiota from transgenic CONVAPPPS1 mice increases

AD pathology, colonization of GFAPPPS1 mice with Altered Schaedler Flora did not increase amyloidosis in GFAPPPS1 mice. Altogether, our results indicate that gastro-intestinal dysbiosis is involved in the development of AD and supports the view that neurodegenerative disorders may be tackled by gastro-intestinal modulation.

Title: Astrocyte volume regulation during the progression of Alzheimer's disease

Authors: D. KOLENICOVA[1,2], P. HONSA[1], J. KRISKA[1], D. KIRDAJOVA[1], L. VALIHRACH[3], M. KUBISTA[3], *M. ANDEROVA[1,4];

Abstract: Astrocytes are deeply involved in the maintenance of extracellular brain homeostasis and failure of their homeostatic functions may contribute to the progression and outcome of neuropathological processes, including Alzheimer’s disease (AD). Recent evidence suggests that early stages of AD are accompanied by astrocytic atrophy and by a dis-balance in neurotransmitter homeostasis, which results in neuronal death, and also in an increased uptake of osmotically active substances, predominantly provided by astrocytes, which leads to marked volume changes in these cells. Here, we aimed to elucidate to what extent the progression of AD affects astrocyte volume changes and their regulatory volume mechanisms in response to various pathological stimuli, such as hypoosmotic stress or increased extracellular K^+ concentration (50 mM) in the mouse hippocampus using three-dimensional confocal morphometry *in situ*. We quantified the changes in total cell volume as well as the contribution of two compartments, i.e.,

cell processes and the cell soma in the hippocampal astrocytes from 3 months- (3M), 9 months- (9M) and 12 months old mice. In order to visualize individual astrocytes we used EGFP/GFAP mice (controls), in which astrocytes are fluorescently labeled and enerated new transgenic mice by crossbreeding GFAP/EGFP mice, with triple transgenic mice, in which amyloid precursor protein, presenilin and tau are mutated (3xTgAD mice). In addition, a single cell RT-qPCR profiling was carried out to reveal possible differences in the expression profiles of astrocytic ion channels/transporters that participate in maintaining ionic/neurotransmitter homeostasis. Three-dimensional confocal morphometry revealed comparable swelling of hippocampal astrocytes from 3M old controls and aged-matched GFAP/EGFP/3xTgAD mice in response to hypo-osmotic stress, however in astrocytes of 9M- and 12M old GFAP/EGFP/3xTgAD mice a slower/smaller swelling was observed when compared to that of controls. After astrocyte exposure to elevated K^+ we detected similar slower/smaller astrocytic swelling already at 3M old GFAP/EGFP/3xTgAD mice. A marked difference in ability of astrocytes to regulate their volume was detected between 12M old GFAP/EGFP/3xTgAD mice and aged matched controls. Interestingly, there were no differences in astrocyte volume regulation during physiological aging.

Title: Hippocampal gene expression patterns in a mouse model of Down syndrome (Ts65Dn) following maternal choline supplementation (MCS)

Authors: *M. J. ALLDRED[1,4], H. M. CHAO[1,4], S. LEE[2], J. BEILIN[1], E. PETKOVA[3,5], S. D. GINSBERG[1,4,6];

Abstract: Down syndrome (DS) is the most frequent genetic cause of intellectual disability (ID) with an increasing prevalence in the USA, with current estimates of 1 in 691 live births. Individuals with DS have system-wide impairments, notably in the central nervous system, with ID and decreased cognitive function seen by impairments in hippocampal learning and memory, degeneration of basal forebrain cholinergic neurons (BFCNs), and language and communication skills. Individuals with DS also develop the pathological hallmarks of Alzheimer's disease (AD) early in mid-life, including senile plaques, neurofibrillary tangles, and early endosomal abnormalities. DS mouse models, including the Ts65Dn mouse, are trisomic for a segment of mouse chromosome 16 (MMU16) orthologous to human chromosome 21 (HSA21), and exhibit ~55% gene conservation of protein-encoding genes between MMU16 and HSA21. This model recapitulates several critical components of DS/AD, including cognitive dysfunction and BFCN degeneration, providing a platform for mechanistic assessments for translation to humans. We used the Ts65Dn mouse model to determine gene expression changes associated with DS/AD and test maternal choline supplementation (MCS) as a treatment modality. We examined gene expression changes in CA1 pyramidal neurons at two distinct timepoints, at 4-6 months (pre-BFCN degeneration) and 10-12 months (post-BFCN degeneration), postulating that MCS will improve cognition and could delay the septohippocampal degeneration seen in Ts65Dn offspring. Microarray results on a custom-designed platform indicate that MCS produces significant gene expression level changes compared to age-matched unsupplemented maternal choline (UMC) offspring in CA1 pyramidal neurons both independent and dependent of genotype, which is confirmed by Nanostring nCounter and/or qPCR analysis. Specifically, alterations at both timepoints indicate that MCS has long-term positive effects on gene regulation in Ts65Dn mice. Several classes of transcripts showed significant alterations due to MCS treatment including neurotrophin receptors, AD-related genes, synaptic-related markers, and cell death genes in both genotypes examined, presumably showing benefits of this early intervention. We hypothesize that long-term effects of MCS treatment in both Ts65Dn and normal disomic (2N) littermates will highlight pathways and mechanisms that may be sites of intervention for cognitive decline and neurodegeneration. Moreover, these may help elucidate the link between choline requirements throughout neurodevelopment and cognitive maturation.

Abstract: Current estimates suggest autism spectrum disorder (ASD) effects as many as 1 in 68 children. ASD is a developmental neurological disorder characterized by abnormal cognition, inhibition of social behaviors and onset of focused or isolated behaviors. Although the underlying causes are not clearly known, recent large-scale genomic studies have identified candidate genes involved in synaptic transmission and brain development that are highly associated with ASD patients. Mutations found in the candidate genes were de novo and were not a result of inherited mutations. Among the risk genes identified, ANK2 is repeatedly found in large-scale exome sequencing studies. Loss of function missense mutations identified at specific amino acid residues were shown to be highly associated with autistic patients. Ankyrin-2 is a membrane associated scaffolding protein that plays an integral role in protein localization and axon guidance and growth. Thus, any disruption to ankyrin function may have critical consequences for synaptic function and neurotransmission. Neuroanatomical studies in living patients and postmortem tissue have revealed that autistic patients have abnormal connectivity within their brain and altered development of key brain structures involved in executive function. Therefore, it is important to identify and dissect the mechanisms underlying these impairments. To address this, genome editing techniques were used to evaluate how mutations in ANK2 affect development of cultured neurons and ultimately how these mutations influence brain development and the onset of ASD-like behaviors in mice. Clustered regularly interspaced short palindromic repeat (CRISPR) guide RNA were designed to target ANK2 in cultured human neural progenitor cells. Cas9 nickase and guide RNA were cloned into lentiviral vectors to facilitate delivery into cultured cells and introduce the point mutations in the ANK2 gene. After verification of the mutation, the positive cells were used to evaluate the effects on neuronal

growth, differentiation and architecture of the cytoskeleton. Taken together, this information will advance our understanding of the molecular, cellular and neural network impairments underlying ASD.

Abstract: Genome-wide association studies (GWAS) have identified many genetic variants associated with risk for schizophrenia. Here we investigate the genomic region flanking rs10791097, the 16th ranked SNP in the latest Psychiatric Genomics Consortium (PGC) GWAS for schizophrenia, a risk variant which appears to be unique to the disorder. We performed RNA sequencing (RNAseq) using 495 dorsolateral prefrontal cortex (DLPFC) samples from the Lieber Institute collection of postmortem human brains, and tested for association between the genotypes at schizophrenia risk variants and expression, to detect “expression quantitative trait loci” (eQTLs). Genotype at rs10791098 (an LD proxy for rs10791097, r-squared=1) was associated with the expression of the entire SNX19 gene (p=0.0014), as assayed by RNAseq of the DLPFC from 188 adult Caucasians. We then analyzed the two more transcript-specific features of expression - exons and the splice junctions between them, and found that the rs10791098 GWAS risk allele (A) was strongly positively associated with expression of the junction between exons 8 and 10 (n=108; Junc8.10 p=3.40e-9) whereas it is not associated with expression of the junction between exons 8 and 9 (n=108; Junc8.9 p=0.538). Expanding the sample to include African American cases and controls and Caucasian cases yielded much stronger results (n=372; Junc8.10 p=1.55e-29, Junc8.9 p=0.0415). Interestingly, only 46% of the 495 postmortem DLPFC samples had Junc8.10 read counts > 0. RNAseq results were confirmed

by qPCR in DLPFC (n=79; Junc8.10 p=2.23e-7, Junc8.9 p=0.240) and in hippocampus (n=44; Junc8.10 p=8.96e-8, Junc8.9 p=0.710). Junc8.10 read counts measure primarily the predicted transcript XM_005271546, which we validated by end-to-end PCR followed by sequencing of clones. Junc8.9 read counts measure primarily the “full length” SNX19 transcript NM_014758. GTEx RNAseq data from cortex showed a similar pattern of association - strong with Junc8.10 (n=95; Junc8.10 p=2.05e-8) and weak or absent with full length transcript (p=0.0419), which was also evident in hippocampus (n=85; Junc8.10 p=3.74e-4, Junc8.9 p=0.756), and other brain regions. Finally, we found additional variants (rs34529622 and rs3831404) nearby that are in only partial linkage disequilibrium with rs10791098 but are also strongly associated with both schizophrenia and specific expression of Junc8.10 in postmortem brain. We characterized a truncated transcript of SNX19, and postulate that a critical element of the molecular mechanism of schizophrenia risk from this GWAS locus is initiated by its increased expression.

Title: Association between amyloid-beta precursor protein (APP) genetic variant and cognitive abilities

Authors: O. NIKOLAIENKO[1], C. MYRUM[1], *C. R. BRAMHAM[2], J. HAAVIK[1], T. ZAYATS[1];
[1]Univ. of Bergen Dept. of Biomedicine, Haukeland Univ. Hospital, and K.G. Jebsen Ctr. for research on Neuropsychiatric Disorders, Bergen, Norway; [2]Univ. of Bergen, N-5009 Bergen, Norway

Abstract: Individual differences in general cognitive ability are key aspects of important life outcomes including health, longevity, education, and occupation. Cognitive function is substantially heritable and thought to have a polygenic nature. Here we focused on a set of genes functionally linked to the Arc/Arg3.1 gene (ARC complex), a key regulator of long-term synaptic plasticity, learning, and memory formation. We tested for an enrichment of association

signals with intelligence, as measured with the Weschler Intelligence Scale for Children (WISC-III) in a sample of 8.5-year-old children from the Avon Longitudinal Study of Parents and Children (ALSPAC). Permutation-based family-wise correction was applied to account for multiple testing. As Alzheimer's disease (AD) shares genetic etiology with cognitive functioning, signals surviving the correction for multiple testing were further assessed in a large case-control sample of AD (17,008 cases and 37,154 controls). Tentative association was observed between the functional gene set of ARC complex and verbal as well as total IQ measures (p = 0.027 and 0.041, respectively) in ALSPAC, with the strongest association observed for rs2830077 located within APP gene (empirical p = 0.018). This association was confirmed in the AD sample (p = 2.76E-03). Potential functional significance of this SNP was examined in silico in RegulomeDB, and further assessed using electrophoretic mobility shift assay and luciferase assays. eQTL analyses of rs2830077 showed significant alteration of APP expression (p = 2.19E-09 in the whole blood tissue).

Abstract: MicroRNAs (miRNAs) are small noncoding RNAs that are primarily involved in the posttranscriptional control of gene expression. Recently, their critical role in neurodevelopment and aging has gained momentum, associating them with neuropsychiatric disorders. Common genetic variants as well as single nucleotide polymorphisms (SNPs) in miR-137 have been associated with severe cognitive impairments in schizophrenia. Moreover, in the mature brain, miR-137 has a functional role in presynaptic vehicle release as well as synaptic strength within the hippocampal area. As such, we hypothesized that dysregulation in miR-137 expression is associated with Alzheimer's Disease (AD). Further, based on the well-documented role of DNA methylation in AD, we investigated whether differential miR-137 expression is regulated by this epigenetic modification. We thus examined the expression and methylation patters of miR-137 in middle temporal gyrus (MTG) tissue of AD patients and non-demented controls, by means of PCR and the Illumina Infinium 450K Beadarray, respectively. Our novel findings show significantly decreased miR-137 expression in the MTG of AD patients in comparison to controls. Additionally, we detected a reduction in the methylation levels of the same samples, showing a small, but significant correlation with expression levels. This study investigated the effect of dysregulated expression and methylation of miR-137 in AD and is the first one attempting to show that expression changes of this miRNA are epigenetically regulated. Our perspective objective is to investigate differential expression and methylation patterns of miR-137 in brain structures associated with the symptomatology of the most incipient stages of AD, namely brainstem nuclei. Further, we aim to elucidate whether a 15bp variable number tandem repeat (VNTR) that regulates miR-137 expression is associated with unique methylation patterns and whether its length can predict cognitive decline in a longitudinal cohort of individuals suffering from mild cognitive impairment (MCI).

Title: Neuron-specific methylome analysis reveals epigenetic regulation of BRCA1 against Aβ-induced DNA damage in Alzheimer's disease brain

Authors: *T. MANO[1], K. NAGATA[2], S. MURAYAMA[3], S. C. TAKAOMI[2], S. TSUJI[1], A. IWATA[1];
[1]Grad. Sch. of Medicine, The Univ. of Tokyo, Tokyo, Japan; [2]Lab. for Proteolytic Neuroscience, RIKEN BSI, Wako, Japan; [3]Dept. of Neuropathology, Tokyo Metropolitan Geriatric Hosp., Tokyo, Japan

Abstract: [Background] We performed neuron-specific methylome analysis of AD brains and found profound hypomethylation in *BRCA1* promoter region. BRCA1 is known to play an important role in DNA repair and its mutation is risk factor of hereditary breast cancer, while it has been seldom studied in neuroscience. We analyzed *in vitro* and i*n vivo* models of AD
[Objective] Tto elucidatexamine the role of BRCA1 in Alzheimer's disease pathomechanism, we analyzed cellular and mice models..
[Methods] We first analyzed the effect of Aβ on BRCA1 expression and DNA damage in N2a swe.10 cells harboring mutant APP transgene with Swedish mutation. We further analyzed tested BRCA1 expression pattern, and solubility of BRCA1, and, the balance between DNA damage and repairfragmentation level of BRCA1 in post-mortem AD, 3× ×Tg-AD and APP/PS1 mice brains . We also analyzed the effect of Aβ on BRCA1 expression in APP swe. 10 cells.
[Results] N2a swe.10 cells showed increased soluble BRCA1 expression which was attenuated at the presence of γ-secretase inhibitor. They were positive for DNA double strand break (DSB) marker γ-H2ax but showed no detectable DNA fragmentation. BRCA1 was mislocalized at the cytoplasm in neuronal cells of AD and 3× ×Tg-AD brains and was found mostly at detergent insoluble fractions. However, in APP/PS1 mice it was only found at soluble fraction and cytoplasmic BRCA1 was not observed was not mislocalized. In Braak stage 3 AD brains, cytoplasmic staining of BRCA1 was limited to found only at the hippocampal CA1 region, while at Braak stage 5, they were positive beyond entorhinal through neocortex. APP swe.10 cells was positive for DNA double strand break (DSB) marker γH2ax but shoed no detectable DNA fragmentation. They showed increased BRCA1 expression which was attenuated at the presence of γ-secretase inhibitor. Compared Comparing between 3× ×Tg-AD and APP/PS1 mice, positive DNA fragmentation was only observed in 3× ×Tg-AD brains. Promoter region of *Brca1* in 3× ×Tg-AD mice was hypomethylated compared to the wild type mice.
[Conclusions] Aβ induces DNA DSB and the cell copes with the damage by up-regulating BRCA1 through epigenetic mechanism. However, in the presence of aggregated aggregated tau, BRCA1 can no longer function properly and DSB is accelerated in AD brains.

Title: Correlation network analysis of frontal cortex gene expression changes during the progression of Alzheimer's disease

Authors: *S. E. COUNTS[1,2], E. MCKAY[1], Z. MADAJ[3], J. S. BECK[1], M. WINN[3]; [1]Transl Sci. and Mol Med, Family Med., Michigan State Univ., Grand Rapids, MI; [2]Hauenstein Neurosci. Ctr., St. Mary's Hosp., Grand Rapids, MI; [3]Bioinformatics and Biostatistics Core, Van Andel Inst., Grand Rapids, MI

Abstract: Alzheimer’s disease (AD) is characterized by the progressive dysregulation of multiple gene families in forebrain projection systems regulating cognitive function. However, the spatiotemporal overlap of these gene expression changes presents a challenge for pinpointing causal vs. epiphenomenal events. In this regard, gene expression profiling in frontal cortex during AD progression is an attractive option given the relatively delayed involvement of this region in AD pathogenesis and its ability to respond to the onset of mild cognitive impairment (MCI) by neuronal reorganization. To address these possibilities, we performed microarray analysis using frozen frontal cortex (BA10) samples from Rush Religious Orders Study subjects who died with a clinical diagnosis of no cognitive impairment (NCI), MCI, or AD (n = 12/diagnostic group). Total RNA was analyzed using NimbleGen 12 x 135K arrays and probe intensity levels were quantified with RMA preprocessing (NimbleScan v2.5). A systems-based Weighted Gene Co-expression Network Analysis (WGCNA) was then performed to identify modules of co-expressed genes that correlated with disease progression based on clinical or neuropathological diagnostic criteria. For example, a network module annotated by clinical diagnosis was enriched for insulin signaling (FDR p = 0.016) and included hub genes associated with cell cycle control, including p16INK4, and p14ARF. By contrast, a network module annotated by Braak and CERAD diagnosis was enriched for hypoxia signaling (FDR p = 0.04) and included hub genes associated with cell surface adhesion, including the integrin ITGA6 and

the α-secretase ADAM10. Intriguingly, Braak stage variability among the cases was most strongly associated with peroxisomal alkylglycerone phosphate synthase (AGPS) expression (FDR p = 0.007). Additionally, second order linear modeling was performed to identify eigengene networks correlated with differential expression in the MCI diagnostic group. Notably, annotation by clinical diagnosis identified the hub gene FOXP2, a transcription factor prominently involved in language development, whereas annotation by CERAD score variability was associated with the natural killer cells KLRC2 (FDR p = 0.002) and KLRC3 (FDR p = 0.0007). These gene networks may represent underlying plasticity responses in frontal cortex associated with the onset of dementia. Taken together, these data suggest that multiple gene co-expression network alterations in frontal cortex may provide new clues to the biological systems underlying the onset and progression of AD.

Title: Gene expression profiling of cathepsin D immunopositive pyramidal neurons within the precuneus in mild cognitive impairment and Alzheimer’s disease

Authors: *B. HE[1], S. E. PEREZ[1], S. LEE[2], E. PETRKOVA[3], S. D. GINSBERG[2], E. J. MUFSON[1];
[1]Neurobio., Barrow Neurolog. Inst., Phoenix, AZ; [2]Dept. of Psychiatry, Nathan Kline Inst., Orangeburg, NY; [3]Child and Adolescent Psychiatry, New York Univ. Langone Med. Ctr., New York, NY

Abstract: The precuneus is a component of the default memory network (DMN). Antemortem amyloid imaging studies using Pittsburgh compound B (PiB) revealed that this cortical region is particularly vulnerable to amyloid-beta (Aβ) deposition in the earliest, pre-clinical stages of Alzheimer’s disease (AD), suggesting that Aβ deposition plays a role in the neuronal dysfunction

of this component of the DMN in AD. However, there is virtually no information on the effect that amyloid deposition has upon gene expression of presumed vulnerable neurons in the precuneus. Numerous studies indicate the endosomal-lysosomal (E-L) pathway plays a key role in amyloid-beta precursor protein (APP) processing and Aβ generation. Although E-L activation occurs prior to the appearance of Aβ pathology, the effect of amyloid pathology upon gene expression in precuneus neurons displaying lysosomal network activation remains to be determined. Cathepsin D (Cat D), the main acid hydrolase in human lysosomes, is over-expressed early in vulnerable cortical neurons and is implicated in the pathogenesis of AD. Here, we employed Cat D immunohistochemistry to identify layer III pyramidal neurons from the precuneus and interrogated them via laser capture microdissection coupled with custom-designed microarray analysis to determine their genetic signature from cases that came to autopsy with a preclinical diagnosis of no cognitive impairment (NCI), mild cognitive impairment (MCI) and AD from the Rush Religious Orders Study. Preliminary results indicate approximately 15% of the transcripts on the array platform were differentially regulated between AD and NCI, 8% between MCI and NCI, and 17% between AD and MCI, indicating both early and late gene expression level changes during the progression of dementia. Classes of transcripts that displayed significant levels of alterations included cytoskeletal elements, cholinergic and monoaminergic neurotransmission markers, and cell death genes. Individual genes with notable expression differences include significant upregulation of the cholinergic synthesis regulatory elements choline acetyltransferase (ChAT), acetylcholinesterase (AChE), and butyrylcholinesterase (BChE) in AD compared to NCI and MCI. These findings suggest compensatory upregulation of the cholinergic system as part of a presumed neuroplasticity response, consistent with alterations observed in the frontal cortex and hippocampus at the early stages of AD pathology. Furthermore, the profiling of precuneus neurons did not reveal alterations in Aβ transcripts suggesting a disconnection between elevated Aβ binding and the upregulation of genes within this DMN region.

Abstract: High-throughput functional genomics enables gene transcripts and noncoding RNAs (ncRNAs) to be assessed quantitatively, which is relevant towards understanding the molecular pathogenesis of Alzheimer's disease (AD). RNA sequencing (RNA-seq) is at the center of this paradigm shift. To date, the majority of RNA-seq studies in AD and AD models are at the regional level. However, performing RNA-seq using RNA extracted from homogeneous populations of cells is possible. This approach avoids contamination from relatively spared neuronal and non-neuronal cells. To test the feasibility of single population RNA-seq, CA1 pyramidal neurons and layer II/III cortical pyramidal neurons were microaspirated from 20 μm thick frozen tissue sections mounted onto PEN membrane slides (Leica) obtained from C57Bl/6 mice and nondemented human brains by laser capture microdissection (LCM; Leica). Tissue sections were rapidly stained with Nissl and ~500 cells were acquired per reaction, per cell type. CA1 pyramidal neurons and neocortical pyramidal neurons were isolated and RNA was extracted. Preliminary data using LCM-captured cortical pyramidal neurons from wild-type mice and postmortem nondemented human brain indicate that 500 neurons were sufficient to generate robust cDNA libraries for RNA-seq. High quality RNA was demonstrated with clear 18S and 28S peaks by bioanalysis and RIN values of 4-6 after LCM. cDNAs from murine and human cortical pyramidal neurons were of high concentration and fragmented to sizes between 300-500 basepairs per the RNA-seq protocol. RNA sequencing libraries were generated in conjunction with the HiSeq 2500 platform (Illumina). Sequencing results were de-multiplexed and converted to FASTQ format using Bcl2FastQ software (Illumina). Paired-end reads were aligned to the mouse and human genomes (build mm10/ GRCm38 and hg19/GRCh37, respectively) using the splice-aware STAR aligner. HTSeq was employed to generate counts for each gene based on how many aligned reads overlap exon sequences. Counts were normalized and used to test for differential expression using negative binomial generalized linear models implemented by the DESeq2 R. By employing RNA-seq, we will be able to examine changes seen in the entire transcriptome of select vulnerable neuronal populations, which will be invaluable for determining mechanisms underlying neurodegenerative disorders without contamination of admixed cell types.

Title: Sex differences in the molecular pathology of the 5XFAD mouse model of Alzheimer's disease

Authors: *J. L. BUNDY[1], C. VIED[2], C.-D. BADGER[1], R. S. NOWAKOWSKI[1];
[1]Biomed. Sci., [2]Translational Sci. Lab., Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: Alzheimer's Disease (AD), a progressive neurodegenerative disorder, is the most common form of dementia, affecting approximately 48 million people worldwide. AD has been shown to have a sex-biased epidemiological profile, affecting twice as many women as men. In an effort to elucidate molecular mechanisms that provide a basis for this difference, we conducted a molecular investigation of both females and males using the 5XFAD mouse model of AD. This investigation focused on early stages of disease development (1, 2, and 4 months of age) using RNA-sequencing of the hippocampus of heterozygous 5XFAD males and females. At one month of age, only the transgene is differentially expressed. At 2 months of age, some molecular pathological changes could be detected with 39 transcripts identifiable as differentially expressed between transgenic animals and wild-type littermates. By 4 months of age, disease-associated transcriptomic changes are wide-spread, with over 1300 differentially expressed transcripts identified. Pairwise comparisons between 4 month old transgenic females and males indicate that disease-associated genes are more highly-expressed in female 5XFAD mice than their male counterparts. Furthermore, comparisons of female transgenic vs female wild-type animals yield more differentially expressed genes than the comparison between transgenic and wild-type males, reinforcing the finding that disease-associated molecular changes are more wide-spread in female animals. Overall, these data indicate that female 5XFAD mice exhibit more profound AD-like molecular pathology than their male counterparts. The sex-biased genes identified in this investigation are possible contributors to the observed sex-bias in AD in humans, and also provide potential candidate targets for pharmacologic intervention for disease amelioration or prevention.

Title: Apoeε4 status impacts exercise-induced serum bdnf levels in elderly african americans with mci.

Authors: *J. S. ALLARD[1,2,3], O. NTEKIM[2], S. P. JOHNSON[3], J. S. NGWA[4], R. F. GILLUM[5], T. V. FUNGWE[2], T. O. OBISESAN[3];

Abstract: Possession of the Apolipoprotein E (ApoE) gene ε4 polymorphism is the most prevalent genetic risk factor for Alzheimer's disease (AD), and is also associated with other neurodegenerative conditions. Evidence indicates that ApoE plays important roles in critical brain functions including response to brain injury, cerebrovascular function and synaptic plasticity. Recent evidence has also suggested that ApoE genotype differentially affects expression of brain-derived neurotrophic factor (BDNF). Notably, aerobic exercise-induced upregulation of BDNF is well documented; and exercise has been shown to improve cognitive function, in many disease states, in both young and elderly populations. Thus, BDNF upregulation is a highly proposed mechanism for the cognitive-enhancement effects of physical exercise. In this study we examined the effects of ApoEε4 carrier status on exercise-induced changes in BDNF expression. Elderly African Americans diagnosed with mild cognitive impairment participated in a six-month, supervised program of either stretch or aerobic exercise. Participants engaged in 40 minutes of supervised exercise training 3 times per week. Aerobic exercise consisted of treadmill walking or jogging at an initial intensity that correlated with 50% VO_2Max and gradually increased to 70% VO_2Max. Stretch exercise consisted of a variety of dynamic stretch positions that were held for 15-30 second intervals. BDNF levels in serum were measured using ELISA. Age, BMI, MMSE scores, VO_2Max and baseline BDNF did not differ between ApoEε4 carriers and non-ε4 carriers. There was a statistically significant interaction between ApoEε4 status and 6-month serum BDNF levels ($p=0.010$). Non-ε4 carriers showed a significant increase in BDNF levels at the 6 month exercise time point, while ε4 carriers showed no significant effect of the exercise intervention. We have identified an important relationship

between the ApoEε4 genetic polymorphism and BDNF response to physical activity which likely impacts the extent of neuroprotective benefit gained from engagement in physical exercise.

Abstract: Over last few years, ample evidence has been generated pointing towards an epigenetic dysregulation in Alzheimer's disease (AD). Our understanding of the full scope of the epigenetic apparatus is still rapidly evolving, with techniques to investigate the mechanisms involved barely keeping up. DNA methylation is one of the most studied epigenetic mechanisms, and many of the methods used depend on bisulfite (BS) conversion of the DNA to distinguish methylated from non-methylated cytosines. The inability of these methods to distinguish DNA methylation from DNA hydroxymethylation, another, functionally different epigenetic modification, has been somewhat neglected due to methylated cytosines generally being much more abundant. This limitation, however, may be especially problematic in brain tissue, which is enriched in hydroxymethylated cytosines. As some of the major findings in relation to methylomic alterations in relation to AD have been made using Illumina's Infinium HumanMethylation450 BeadChip (450k) array, we used a recently established technique using both BS converted and oxidative bisulfite (oxBS) converted DNA, to investigate the methylome and hydroxymethylome in the middle temporal gyrus of 47 AD patients and 36 controls.

Differentially (hydroxy)methylated positions (D(h)MPs) and regions (DMRs) related to AD were determined and compared with those resulting from the combined methylation and hydroxymethylation signal. Previously reported genes with altered DNA methylation in AD, *ANK1* and *RHBDF2*, were in our top 100 for the combined signal and the methylation signal only, indicating these genes are only affected by alterations in DNA methylation in AD. Interestingly, we identify a DMP and DMR, and a DhMP in the *OXT* gene, suggesting this gene is regulated through both methylation and hydroxymethylation. Genes associated with our top DMPs, include *SYNJ2*, *PRKCSH* and *EFNA3*, and genes associated with our top DhMPs, include *GNB3*, *PDE4D* and *PRKCSH*. We also investigated the relation between DNA (hydroxyl)methylation and mRNA expression. In conclusion, as there are currently no arrays available for the genome-wide investigation of DNA hydroxymethylation, we used an approach based on the 450k array, combining BS and oxBS treated DNA, and identified genes with altered methylation or hydroxymethylation in AD.

Title: Genetic determinants of clinical progression in Alzheimer's disease: a pilot study

Authors: *B. A. KENT, L. TOOMAN, I. GUELLA, D. EVANS, E. DWOSH, D. SADOVNICK, G.-Y. HSIUNG, M. J. FARRER, H. B. NYGAARD;
Djavad Mowafaghian Ctr. for Brain Hlth., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Recent Genome-wide Association Studies (GWAS) and the wider availability of High Throughput Sequencing (HTS) continue to refine our understanding of the genetic basis for Alzheimer’s disease. To date, more than 22 genes that increase the risk of AD have been identified, providing targets for potential therapeutic intervention. However, the genetic basis for clinical progression in AD is not well understood. To identify deterministic genetic factors for disease progression in AD, we collected 100 multi-incident families. All patients were followed in the UBC Hospital Clinic for Alzheimer disease and Related Disorders, with deep, longitudinal cognitive assessments. Rate of cognitive decline up to 10 years from symptom onset was

recorded by measuring standardized scores on the Montreal Cognitive Assessment Scale (MoCA), Mini-Mental State Examination (MMSE), and the Modified Mini Mental (3MS) exams. Whole exome analysis was performed on 100 affected probands using 57Mb Ampliseq™ library preparation with an Ion Proton system. Results were complemented by Illumina MEGA-Ex genotyping (1.8M single nucleotide polymorphisms (SNPs)) and subsequent copy number analyses. All known and novel variants in genes linked/associated with dementia syndromes were documented; when required pathogenicity was confirmed by Sanger sequencing or Taqman probes, and segregation analyses within families. Association between SNPs and long-term clinical disease progression was assessed using logistic regression models. A genetic panel to predict clinical progression would be a valuable tool in the overall assessment of patients with AD.

Title: Down Syndrome and Alzheimer's Disease brains contain neurons with increased genomic mosaicism

Authors: ***G. E. KAESER**, B. SIDDOWAY, M.-H. LEE, S. ROHRBACK, C. SAUVEY, J. CHUN;
The Scripps Res. Inst., La Jolla, CA

Abstract: Traditional understanding of the genome is that every cell in the human body contains a constant and identical genomic sequence. However, a growing body of evidence has shown that neurons in the brain are an exception to this dogma. Neurons within a single brain display genomic mosaicism, the phenomenon that is produced by neurons having distinct genomes, like individual tiles in a mosaic. Genomic mosaicism encompasses aneuploidy, copy number

variation, line-1 elements, and single nucleotide variants. We first identified brain aneuploidies in neural progenitors and functionally integrated neurons; and documented region-specific changes in total DNA content in human neurons by DNA flow cytometry. Recently, we identified an ~8% increase in total DNA content in sporadic Alzheimer's disease (SAD) prefrontal cortical neurons compared to controls, that was accompanied by mosaic *APP* copy number amplifications, and independent of trisomy 21 [Bushman et al., *eLife* 2015]. This work demonstrated the first functional significance for mosaic DNA changes in neurons. We assessed the possibility that genomic mosaicism may also function in other neurodegenerative diseases, including genetic forms of AD via the well-documented AD association with Down Syndrome (DS). Remarkably, DS cortices, from age 0-60 years, displayed a highly significant linear increase in total DNA content that was not observed in non-diseased brains. The greatest increases were observed in brains displaying AD pathology, and increases were equivalent to those observed in SAD brains. These data implicate genomic mosaicism and DNA content increases as common events in both SAD and genetic AD. Importantly, the linearity of increasing DNA implicates post-mitotic neuronal DNA synthesis accumulating with age. Targeted genomic analyses of cell populations and single cells are under investigation and preliminary data have revealed mosaic copy number events and unique structural alterations.

Title: Role of Unc5c, Alzheimer's risk gene in late-onset Alzheimer's disease

Authors: *D. KARUNAKARAN[1], J. ATWAL[2], R. VASSAR[1];
[1]Northwestern Univ., Chicago, IL; [2]Genentech, South San Francisco, CA

Abstract: Alzheimer's disease (AD) is characterized by amyloid plaques, neurofibrillary tangles, and synaptic and neuronal loss. Recently, a rare autosomal dominant coding mutation, T835M, was discovered in the Un-coordinated 5c (Unc5c) netrin receptor gene that segregated with late-onset AD (LOAD). T835M alters a conserved amino acid in the hinge region of the Unc5c death domain, suggesting the mutation may increase apoptosis. Indeed, in primary hippocampal neurons, overexpression of Unc5c T835M increased cell death in response to neurotoxic stimuli including beta-amyloid (Aβ). These results suggest a mechanism by which Unc5c T835M may

confer increased risk of LOAD, however the effects of this mutation in an AD animal model have not yet been explored. Toward this end, we have obtained a mouse knock in (KI) model of Unc5c T85M that we will cross with the 5XFAD mouse model of amyloid pathology and neuron loss. We hypothesize that the Unc5c T835M mutation will exacerbate neuronal death in the 5XFAD brain via increased sensitivity to Aβ-induced neurotoxicity and Unc5c death domain activation. We will investigate mechanisms of cell death in 5XFAD; Unc5c T835M KI mice by behavioral, biochemical, and cellular approaches, and unbiased RNA deep sequencing (RNAseq). Although neuron loss is a hallmark of AD, the exact molecular mechanism of cell death in AD is unclear. We expect our results to provide valuable insight into AD-associated cell death and how Unc5c is involved in AD pathogenesis, and thereby identify novel therapeutic targets for preventing neuron loss in AD.

Title: FYN expression is associated with regulatory region genetic variation in Alzheimer's disease

Authors: *J. A. ZAHRATKA[1], Y. SHAO[1], M. SHAW[1], K. TODD[1], M. KHRESTIAN[1], T. MONTINE[2], J. B. LEVERENZ[3], L. M. BEKRIS[1];
[1]Genomic Med. Inst., Cleveland Clin. Lerner Res. Inst., Cleveland, OH; [2]Pathology, Stanford Univ., Stanford, CA; [3]Lou Ruvo Ctr. for Brain Hlth., Cleveland Clin., Cleveland, OH

Abstract: Alzheimer’s disease is characterized by neuritic plaques, consisting primarily of amyloid-beta (Aβ) aggregates, and neurofibrillary tangles (NFTs), assemblies of hyperphosphorylated forms of the protein tau. Tau phosphorylation is under the control of multiple kinases and phosphatases, including GSK3β, Fyn, and PP2A. Previously, our group correlated a regulatory region single nucleotide polymorphism (SNP), rs7768046, in the *FYN* gene as associated with increased cerebrospinal fluid total tau levels. In this study, we

hypothesized that *FYN* expression in the brain is directly influenced by AD status and genetic content. Our results suggest that *FYN* mRNA levels stay constant but protein levels are increased in AD patients, which are further altered by regulatory SNPs in each *FYN* isoform promoter as well as the shared 3' untranslated region (3' UTR). Additionally, expression of the *FYN* 3' UTR can differentially inhibit *FYN* isoform promoter activity in multiple human cell lines, suggesting regulatory region variation can play an important role in *FYN* modulation and isoform expression. Further study supports a potential role for microRNAs (miRNAs) participating in regulatory roles of *FYN* expression. Several miRNA are predicted to target the *FYN* 3'UTR. Of these predicted miRNA a few are differentially expressed in AD compared to control post-mortem hippocampus. Our preliminary data suggest two of these differentially expressed miRNAs, hsa-miR-200c-3p and hsa-miR-15a-5p, do not significantly affect *FYN* expression in CHP-212 or SH-SY5Y cells. Taken together, these data suggest that *FYN* expression is regulated according to AD status and promoter haplotype, and such genetic variants may be instrumental in the development of NFTs in AD and other tauopathies.

Title: Mosaic genomic variation in the sporadic Alzheimer's disease brain

Authors: ***C. SAUVEY**[1], M.-H. LEE[2], G. KAESER[2], B. SIDDOWAY[2], J. CHUN[2];
[1]The Scripps Res. Inst., LA Jolla, CA; [2]The Scripps Res. Inst., La Jolla, CA

Abstract: Alzheimer's Disease (AD) is a common, devastating, progressive neurodegenerative disease that results in dementia and eventually patient death. While a wide variety of theories exist regarding AD's underlying pathological mechanism, the consensus agrees on the involvement of the proteins amyloid β (Aβ) and Tau, encoded by the APP and MAPT genes respectively. Aβ is a major component of the amyloid plaques, and Tau forms the neurofibrillary tangles, which are both suspected of playing a causative role in the development or pathogenesis

of AD. While modern biology holds that nearly all healthy cells in a given organism are genomically identical, several reports published within the past decade have begun to call this assumption into question. These reports found that in both developing and mature mammalian brains many different types of large-scale genomic alterations such as aneuploidy and copy number variations (CNVs) occur in a mosaic fashion. This phenomenon is referred to as genomic mosaicism. We recently reported neuronal genomic mosaicism in the form of increased DNA content variation (DCV) associated with sporadic AD. (Bushman et al., *eLife* 2015). Based upon these findings, we have pursued further characterization of DNA content changes using flow cytometry and fluorescence activated cell sorting (FACS) analyses of isolated NeuN+ nuclei. Analyses have focused on variations associated with 1) SAD and other neurodegenerative disorders, 2) brain regions, and 3) neuronal subtypes. Preliminary data indicate that non-random alterations to DCV are occurring regionally and in neuronal subtypes, and current efforts are identifying changes in putative genes associated with DCV. These findings have implications for our understanding of both origins and roles for genomic mosaicism in SAD.

Abstract: Alzheimer's disease (AD) is an age-related neurodegenerative disease accounting for 60-70% of dementia cases. Large-scale genetic studies have aimed to elucidate potential risk genes. Among the approximately 300 genes studied in different AD cohorts to date, APOE has emerged as the most consistent marker associated with late-onset AD, the most common form of AD. Although the allele frequency of APOE is moderately lower in the Chinese population than Caucasian populations, few genetic studies of the Chinese AD population have been conducted. Here, we analyzed the APOE locus using our in-house low-pass whole-genome sequencing data from a Chinese AD cohort. We not only confirmed the existence of a long-range haplotype in the 40-kb region around APOE, which is strongly associated with AD, but also identified other novel variants linked to AD in this region. These results suggest a multigenic effect contributing to the late-onset AD pathogenesis in chromosome 19q13.32 involving PVRL2, TOMM40, APOE, and APOC1. Our findings will facilitate the determination of potential biomarkers for the diagnosis of AD in the Chinese population.

Title: New elements of genomic mosaicism in sporadic Alzheimer's disease

Authors: *M.-H. LEE, G. E. KAESER, R. R. RIVERA, B. SIDDOWAY, C. R. SAUVEY, S. E. ROHRBACK, W. S. MCDONALD, Y. WEI, J. CHUN;

Abstract: Alzheimer’s disease (AD) is a devastating neurodegenerative disease and clinically characterized by cognitive function decline, short-term memory loss, language disturbance, and executive function impairment. A relatively new feature of the normal brain is genomic mosaicism, that consists of aneuploidy, LINE elements, copy number variations, and single nucleotide variations. Recently, genomic mosaicism was identified in sporadic AD (SAD) brains and was associated with increased DNA content and APP copy number increases, supporting the operation of genomic mosaicism mechanisms in SAD (Bushman *et al*. eLIFE, 2015). To further explore genomic mosaicism in SAD, small populations of neuronal nuclei were stained by propidium iodide and NeuN, and isolated by fluorescence-activated cell sorting (FACS). Genomic DNA was extracted and being assessed by a range of PCR strategies including multiplex methodologies, using collections of primers designed against a range of AD-related genes - both coding and non-coding regions - including those identified from genome-wide association studies (GWAS). Preliminary results have identified regionally distinct signals that are consistent with genomic mosaicism, and further validation is ongoing, results of which will be presented.

Title: Interaction of NMDA-receptor antagonist medication use and ADORA2A genotype on hippocampal volume in patients with Mild Cognitive Impairment and Alzheimer's Disease

Authors: *E. HORGUSLUOGLU-MOLOCH[1,2], K. NHO[3,4], S. L. RISACHER[3,2], A. J. SAYKIN[3,2];
[1]Med. and Mol. Genet., [2]Indiana Alzheimer Dis. Ctr., [3]Radiology and Imaging Sci., [4]Computat. Biol. and Bioinformatics, Indiana University, Sch. of Med., Indianapolis, IN

Abstract: Alzheimer's disease (AD), the most common form of dementia, includes the features of decline in memory impairment and other cognitive domains as well as prominent hippocampal atrophy. Although there is no disease modifying medication for AD yet, cholinesterase inhibitors and an NMDA (N-methyl-D-aspartate) receptor antagonist (memantine HCL) are often used clinically. Previously, we performed a gene-based association analysis of neurogenesis pathway-related candidate genes in participants from the Alzheimer's Disease Neuroimaging Initiative (ADNI) cohort and identified *ADORA2A* and a SNP (rs9608282-T) upstream of *ADORA2A* to be significantly associated with larger hippocampal volume and better memory scores. Based on previous studies suggesting that *ADORA2A* plays an important role controlling NMDA-dependent synaptic toxicity and memory impairment (Tebano, Martire et al. 2005, Yee, Singer et al. 2007, Sarantis, Tsiamaki et al. 2015), we examined the interaction of memantine use and rs9608282 (*ADORA2A*) on hippocampal volume and memory performance. **Methods:** Non-Hispanic Caucasian participants (N=1,102) from ADNI with structural magnetic resonance imaging (MRI) scans were included. We evaluated the effect of rs9608282 on hippocampal volume and composite memory score in ADNI participants diagnosed with MCI (mild cognitive impairment) or AD. Participants were further classified as a memantine user (NMDA (+)) or a memantine non-user (NMDA (-)). Two-way analysis of covariance (ANCOVA) for continuous variables and chi-square for categorical variables were performed in SPSS 23.0. **Results:** NMDA (-) participants carrying at least one copy of the minor allele (T) of *ADORA2A* rs9608282 had a larger mean hippocampal volume ($p<0.001$). There was also a significant interaction of NMDA-receptor antagonist use and *ADORA2A* rs9608282 on memory performance ($p = 0.009$). NMDA (+) participants carrying at least one copy of the minor allele (T) of the *ADORA2A* rs9608282 had poorer memory performance. **Conclusion:** The synaptic localization of A2a receptors (ADORA2A) plays a key role controlling NMDA-dependent synaptic transmission in the hippocampus (Rebola, Sachidhanandam et al. 2007). Individuals with genetic variation in *ADORA2A* gene associated with glutamate signaling pathway may show differential responsiveness to NMDA-receptor targeted treatment.

Title: Cholinergic surveillance over hippocampal RNA metabolism and Alzheimer's-like pathology

Authors: *M. A. PRADO[1], B. KOLISNYK[2], M. AL-ONAIZI1[2], L. SOREQ[3], J. ULE[3], H. SOREQ[4], V. PRADO[2];

Abstract: The relationship between long-term cholinergic dysfunction and risk of developing dementia is poorly understood. Here we used mice with deletion of the vesicular acetylcholine transporter (VAChT) in the forebrain to model cholinergic abnormalities observed in dementia. Whole genome RNA-sequencing of hippocampal samples revealed that cholinergic failure causes changes in RNA metabolism. Remarkably, key transcripts related to Alzheimer's disease are affected. *BACE1* for instance, shows abnormal splicing caused by decreased expression of the splicing regulator hnRNPA2/B1. Resulting BACE1 overexpression leads to increased APP processing and accumulation of soluble $A\beta_{1\text{-}42}$. This is accompanied by age-related increases in GSK3 activation, tau hyper-phosphorylation, caspase-3 activation, decreased synaptic markers, increased neuronal death and deteriorating cognition. Pharmacological inhibition of GSK3 hyperactivation reversed deficits in synaptic markers and tau hyperphosphorylation induced by cholinergic dysfunction, indicating a key role for GSK3 in some of these pathological changes.

These results suggest that changes in RNA processing caused by cholinergic loss can facilitate Alzheimer's-like pathology in mice, providing a mechanism by which decreased cholinergic tone may increase risk of dementia.

Title: Rpph1 regulates Cdc42 by competing endogenous miR-330-5p and modulates dendritic spine formation in hippocampal pyramidal neurons

Authors: ***Y. CAI**[1,2], Z. SUN[2], H. LUO[2], Q. WU[2], J. WAN[2,3];
[1]SZ-PKU-HKUST Med. Ctr., Peking Univ., Beijing, China; [2]Shenzhen PKU-HKUST Med. Ctr., Shenzhen, China; [3]Hong Kong Univ. of Sci. and Technol., Hong Kong, China

Abstract: Background: Alzheimer's disease (AD) is a heterogeneous neurodegenerative disease, which accompanies with impaired synapses and memory loss. Compensations were reported in AD brains by enlarging the remaining synapses connections or by paraterminal sprouting of dendritic spines. However, the underlying mechanism is not yet understood. Recent studies showed that non-coding RNAs can crosstalk through microRNA response elements (MRE) and manipulate biological processes, but few was studied in AD. Working on the hypothesis that non-coding RNAs can mutually interact in a competing endogenous RNAs (ceRNA) manner and contribute to the AD processes, we attempted to identify the functional ceRNAs in AD and the biological processes that they involved.
Materials and methods: CeRNA network was constructed based on a whole transcriptome

sequencing and a previous studied microRNA-seq of APP/PS1 transgenic mice. CeRNA mechanism was testified by dual luciferase reporter assay. Overexpression and RNA interference assay was detected by quantitative RT-PCR and western blot in Neuro-2a cell line. Dendritic spine study was performed in primary cultured hippocampal neurons by calcium transfection. **Results:** A lncRNA-microRNA-mRNA network based on APP/PS1 mouse model was firstly demonstrated. Four seed lncRNAs and five hub miRNAs were mainly enriched in nine pathways and an AD related gene pool. Ribonuclease P RNA component H1 (Rpph1) is up-regulated APP/PS1 mice cortex compared to those of wild type and competes to bind miR-330-5p, subsequently increasing Cdc42 mRNA and protein level, moreover, overexpression of Rpph1 increased dendritic spine density in primary cultured hippocampal pyramidal neurons. Visa versa, knockdown of Rpph1 decreased Cdc42 expression level and dendritic spine density. **Conclusion:** These results indicate that Rpph1 post-transcriptionally regulates Cdc42 dynamics in a ceRNA manner, which can modulate dendritic spine formation in hippocampal neurons. Furthermore, these could be one of the molecular mechanisms underlying the compensations of AD process.

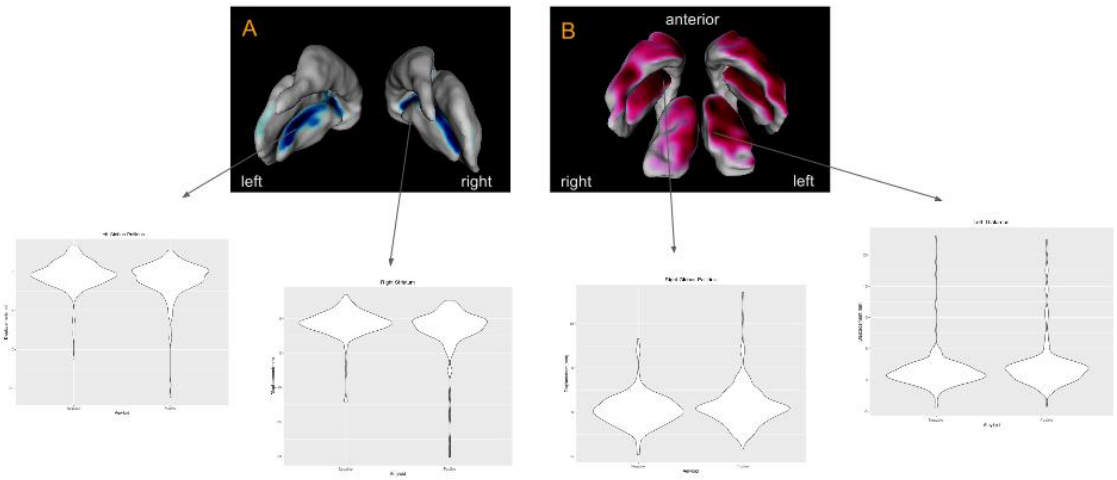
Title: Influence of amyloid burden on subcortical volume and morphometry

Authors: *G. AYRANCI[1], R. PATEL[2], G. DEVENYI[1], V. KONG[3], M. CHAKRAVARTY[1,2,4], A. ALZHEIMER'S DISEASE NEUROIMAGING INITIATIVE[5];
[1]Cerebral Imaging Ctr. - Douglas Mental Hlth. Un, Verdun, QC, Canada; [2]Dept. of Biomed. Engin., McGill Univ., Montreal, QC, Canada; [3]McGill Univ., Integrated Program in Neuroscience, QC, Canada; [4]Dept. of Psychiatry, McGill Univ., Montreal, QC, Canada; [5]USC, Los Angeles, CA

Abstract: An essential hallmark of Alzheimer's Disease (AD) is β-amyloid plaque formation. However, a strong association between β-amyloid deposition and structural atrophy has been lacking. Thus, we sought to investigate the influence of amyloid burden on subcortical structures. Data obtained from Alzheimer's Disease Neuroimaging Initiative consisted of baseline 3T T1-weighted MR images and respective [18F]-florbetapir (FBP) PET analyses. Subjects were classified into amyloid positive or negative, using average FBP standardized uptake rate with cerebellum as a reference region, and AD patients excluded due to low power. MR images were pre-processed with minc-bpipe-library, and then processed with MAGeT brain for outputs of volume, vertex displacement and surface area. Influence of amyloid burden on subcortical volumes and morphometry were analyzed via multiple linear regression; accounting for diagnosis, age, sex, APOE ε4, and total brain volume. Analyses of vertex displacement and surface area were corrected for multiple comparisons with FDR.Our analyses did not show an effect of amyloid burden on the volume of either subcortical structure. Inward and outward pointing displacements in the amyloid positive individuals were observed in all structures analyzed in the absence of volume changes and survive correction for multiple comparisons at 1% false discovery rate and are highlighted in Fig 1. Our results point to a strong heterogeneity of amyloid burden, and suggest an overall effect on subcortical morphometry with no influence on subcortical volume, and provide further insight into the complex interplay between β-amyloid deposition and structural features in AD.



Linear modelling of amyloid burden on subcortical volume and morphometry: analyses did not show an effect of amyloid burden on the volume of either striatum (p = 0.88, left; p = 0.95, right hemispheres) or thalamus (p = 0.39, left; p = 0.81, right hemispheres), with a marginal decrease on the volume of right (p = 0.055) but not left (p = 0.13) globus pallidum (not shown). T-statistics mapped onto subcortical regions (corrected to 1%FDR) showed amyloid positive subjects had increased inward displacement in the external surface (A), counterbalanced with increased outward displacement (B) in the internal surface of globus pallidus. Same subjects also showed increased inward displacement in the precommissural caudate (A) with an outward displacement in the ventral posterior thalamus (B). Further exploration of peak vertices revealed strong heterogeneity of amyloid burden across individuals.

Abstract: Alzheimer's disease (AD) is a gradual neurodegenerative disease that results in memory loss and can be accompanied by dementia and even death. Although AD is the 6th leading cause of death in the US, there remain few methods to detect its early onset. Currently, there is no gadolinium-based contrast agent available for conventional magnetic resonance imaging (MRI) detection of amyloidal beta (Aβ) plaques in Alzheimer's disease. Its timely finding would be vital for patient survival and quality of life. Curcumin (CUR), a common Indian spice, effectively binds to Aβ plaques, which is a hallmark of AD. To address this binding, we have designed a novel nanoimaging agent (NIA) based on nature-derived poly(β-L-malic acid) (PMLA) containing covalently attached gadolinium–DOTA(Gd–DOTA) and nature-derived CUR. The all-in-one agent recognizes and selectively binds to Aβ plaques and is detected by MRI. It efficiently detected Aβ plaques in human and mouse samples by an ex vivo staining. The method can be useful in clinic for safe and noninvasive diagnosis of AD.

Title: Relationship between ^{18}F-Flutemetamol uptake and RBANS performance in non-demented community-dwelling older adults

Authors: *T. ATKINSON[1], D. B. HAMMERS[1], B. C. ALLRED DALLEY[1], K. R. SUHRIE[1], B. BEARDMORE[2], L. BURRELL[2], K. RASMUSSEN[2], K. DUFF[1], J. M. HOFFMAN[2]; [1]Neurol., [2]Huntsman Cancer Inst., Univ. of Utah, Salt Lake City, UT

Abstract: The Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) has been used extensively clinically and for research on Mild Cognitive Impairment and Alzheimer's disease (AD), however relatively few studies have evaluated the relationship between RBANS performance and AD imaging biomarkers. The purpose of the current study was to evaluate the association between a relatively new amyloid imaging biomarker, ^{18}F-Flutemetamol, and performance on the RBANS and select behavioral measures in 27 non-demented, community-dwelling older adults. Amyloid deposition and RBANS Indexes of

Immediate Memory, Language, Attention, Delayed Memory, and Total Scale score were significantly correlated (p's < .05, d's = 0.91-2.16), with greater amyloid burden being associated with lower RBANS scores. The Delayed Memory Index was particularly highly associated with ^{18}F-Flutemetamol binding (r^2 = .53). Neither ^{18}F-Flutemetamol binding nor RBANS performance was significantly correlated with levels of depression or subjective report of cognitive difficulties. Because of the limited usage of amyloid-PET imaging in clinical settings due to high cost, these findings suggest that in particular RBANS Delayed Memory Index may be a cost-efficient tool to identify early signs of AD pathology, and its use may enlighten clinical decision making regarding potential progression to dementia due to AD.

Title: Using ultra-short echo time (UTE) MRI to visualize Alzheimer's and cerebrovascular disease pathophysiology

Authors: *J. J. WISCO[1,4], A. NAZARAN[2], D. JEFFS[2], B. HELDT[1], J. KUDLACEK[1], H. W. LAMBERT[5], D. A. MORTON[4], R. K. WATT[3], H. V. VINTERS[6], N. K. BANGERTER[2]; [1]Physiol. and Developmental Biol., [2]Dept. of Electrical and Computer Engineering, Neurosci.

Ctr., [3]Chem. and Biochem., Brigham Young Univ., Provo, UT; [4]Neurobio. and Anat., Univ. of Utah Sch. of Med., Salt Lake City, UT; [5]Neurobio. and Anat., West Virginia Univ. Sch. of Med., Morgantown, WV; [6]Pathology and Lab. Med., David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract: INTRODUCTION: The severity of pathological protein deposition, and concomitant iron presence distinguishes neurological disorders. Tissues with high amounts of protein or iron deposits have a characteristically rapid T2* MRI signal decay. Therefore, these tissue components do not appear on traditional MRI, as the NMR signal has already gone through multiple time constants of decay before any signal can be acquired. Ultra-short Echo Time (UTE) imaging, however, significantly reduces the time between the appearance of an NMR signal and its sampling. The advantage of this rapid signal acquisition is that we can measure the characteristics of the components in the tissues correlated with iron and proteins. In this work, we explored the use of a custom 3D UTE technique to measure very short T2* values within the tissue in ex vivo human brain samples, each with known Braak VI taopathy or with cerebrovascular disease (CVD). We quantified the MR signal from tissues with T2* values of less than 1ms. METHODS: We implemented a 3D UTE MRI sequence with a 3D cones k-space trajectory using a 3T Siemens scanner on a formalin fixed, 20 mm thick, coronal human brain slab from a subject with known Braak VI taopathy, and from a subject with known cerebrovascular disease (CVD). Both slabs included the amygdala and head of the hippocampus, regions with expected deposits of beta amyloid plaques, tau tangles, associated non-heme iron, and possible inflammation. UTE images were acquired at TEs of 0.25, 0.5, 0.8, 1.0, 2.0, 3.0, and 5.0ms and TR of 12.1ms. Resolution was 1 mm isotropic, flip angle was 15 deg, and the FOV was 15 cm in all directions. Difference images were then formed by subtracting the TE=5ms images from the images acquired at the other TEs, effectively suppressing longer T2* tissues. Then, T2* maps of the brains constructed and two ROIs from the same location in hippocampus with short T2* values for both the brains were used for doing histology. RESULTS: We measured T2* values in the amygdala and hippocampus for the ROIs having 63 pixels. T2* values in the ROI of AD brain was 4.8+/-1.9ms (mean+/-SD), and T2* values in the ROI of CVD brain 2.2+/-1.1ms. We analyzed tissue sections for the presence Abeta-42, tau, and CD-68 immunohistochemical reactivity, and enhanced Perl's staining. We noted that the T2* signal decreased with the additive presence of amyloid plaques, tau tangles, non-heme iron, and activated microglia. CONCLUSION: A novel 3D UTE MRI sequence with a 3D cones k-space trajectory was used to image short T2* tissues in the amygdala and hippocampus. Future work will further examine the individual contributions of pathological proteins, non-heme iron, and inflammation to the T2* decay.

Title: Structural changes to the nucleus basalis of meynert and its projections in the cingulum in mild cognitive impairment

Authors: H. RISKIN-JONES, D. SULTZER, T. NARVAEZ, J. VELIZ, *R. MELROSE;
VA Greater Los Angeles Healthcare Syst., Los Angeles, CA

Abstract: Purpose: The Nucleus Basalis of Meynert (NBM) and its projections in the cingulum are among the first affected structures in Alzheimer's disease (AD). We evaluated the integrity and cognitive correlates of these structures in Mild Cognitive Impairment (MCI), a group at risk for AD. Method: We obtained high-resolution whole-brain T1-weighted images and 64-direction diffusion images from 22 participants with MCI (age: 75.86(8.74), MMSE: 27.23(1.85), 1 female) and 15 elderly controls (EC; age: 74.67 (7.62), MMSE: 29.07 (0.80), 1 female) on a Siemens 3T Skyra. Participants completed a thorough neuropsychological battery. NBM volume was calculated using a previously validated template of basal forebrain subfields. Maps of the cingulum bundle (a major tract in the medial pathway projecting from the NBM) were created on an individual basis using probabilistic tractography in FSL. Average diffusivity measures, including fractional anisotropy (FA), mean diffusivity (MD), and radial diffusivity (RD), were calculated for each subject's cingulum bundles. Results: NBM volume was lower in MCI than EC ($t(35.34)=2.31$, $p<0.05$). Across the entire group, NBM atrophy correlated with poorer verbal memory performance (e.g. logical memory II: $r= 0.41$, $p= 0.01$) and visual memory performance (e.g. BVMT: $r=0.43$, $p < 0.01$), but not hippocampal volume. The diffusivity measures in the cingulum bundle did not differ between groups but were associated with performance on verbal memory tests (e.g. logical memory II with left RD ($r=-0.48$, $p < 0.01$), left MD ($r=-0.33$, $p=0.051$), and left FA ($r=0.46$, $p < 0.01$)), visual memory performance (e.g. BVMT total with left RD ($r= -0.49$, $p < 0.01$), left MD ($r=-0.38$, $p<0.05$) and left FA ($r=0.48$, $p<0.01$)), and hippocampal volume (RD: $r= 0.40$, $p < 0.05$, MD: $r=-0.422$, $p=<0.05$, FA: n.s.). Conclusion: This study used state of the art imaging methods to evaluate the structural integrity of multiple components comprising the cholinergic system: the cell bodies of the NBM, the axons in the cingulum, and targets for cholinergic modulation like the hippocampus. These findings support the cholinergic hypothesis in AD by showing, in vivo, that each component is involved early in the disease process.

Title: Executive attention and white matter changes in mild cognitive impairment

Authors: ***A. M. JIMENEZ**, H. RISKIN-JONES, T. NARVAEZ, J. VELIZ, D. L. SULTZER, R. J. MELROSE;
VA Greater Los Angeles Healthcare Syst., Los Angeles, CA

Abstract: Mild cognitive impairment (MCI) is associated with deficits of memory and is generally considered a prodromal stage of Alzheimer's disease (AD). Deficits of attentional control and executive functioning have also been implicated in MCI, and may represent a risk factor for progression to AD. We examined the association between white matter integrity and performance on the color-word Stroop task in 22 patients with MCI (21M, 1F) and 15 elderly controls (14M, 1F). Diagnosis was made by clinician consensus after review of neuropsychological test battery. Each participant completed high resolution MPRAGE and diffusion tensor imaging (DTI, b=1000s/mm2, 64 directions, 2x2x2) scans on a Siemens 3T Skyra. Performance on the Stroop task (Golden version, 45 seconds per condition) was obtained as part of comprehensive neuropsychological testing. Participants with MCI demonstrated intact performance on the Color and Word task conditions, but were impaired relative to controls on the Color-Word condition ($t(35)=2.63$, $p = .01$), and the Color-Word Interference effect ($t(35)=2.59$, $p = .01$). Voxel-wise Tract-Based Spatial Statistics (TBSS) were correlated with the color-word interference effect of the Stroop using Randomise (TFCE applied, uncorrected $p < .02$). We found associations between Stroop performance and white matter integrity (fractional anisotropy; FA) in white matter tracts underlying right dorsolateral prefrontal cortex and superior parietal lobule, as well as right orbito-frontal cortex and insula. These regions correspond to two neural networks associated with the executive control of attention: a dorsal network comprising aspects of lateral frontal and parietal lobes, and a ventral network comprising medial frontal/cingulate regions and anterior insula. These findings suggest difficulties in MCI with both top-down and bottom-up attentional processing, impacting task-switching and conflict-monitoring abilities. They also join a growing body of work showing that AD-associated

pathology is not limited to the cortex, but includes alterations to white matter. Results point to potential mechanism for pathophysiology of early cognitive deficits leading to AD, and a potential imaging biomarker of early AD-related brain changes.

Title: Permeability in healthy people

Authors: B. PASCUAL[1], E. ROCKERS[1], S. BAJAJ[1], M. YU[1], C. KARMONIK[1], Z. XUE[1], *J. C. MASDEU[2,1];
[1]Houston Methodist Res. Institute, Weill Cornell Med. Col., Houston, TX; [2]Section on Integrative Neuroimaging, NIH, Washington, DC

Abstract: Vascular Permeability in Substantia Nigra, Globus Pallidus, Putamen and Thalamus is Higher in Older as Compared to Younger Subjects
Background: In older healthy subjects, [^{18}F]AV-1451, a PET tau tracer that is supposed to bind to hyperphosphorylated tau, seems to bind to regions (putamen and other nuclei) known not to have abnormal tau deposition on neuropathology. Our aim was to determine whether apparently increased specific [^{18}F]AV-1451 binding in areas unlikely to harbor hyperphosphorylated tau, such as the substantia nigra, thalamus, globus pallidus and putamen, of older subjects could be related to greater vascular permeability of these regions in older subjects as compared to younger ones.
Methods. In six younger (23±2.1 years of age, three women) and six older (68.8±7.6 years, three women) healthy subjects we measured dynamic [^{18}F]AV-1451 uptake over a three-hour period. In the same subjects we obtained dynamic gadolinium concentrations before and after a bolus injection of gadolinium, a large molecule commonly used to assess the permeability of the blood-brain barrier, by performing a pre-contrast 3D T1 map (five flip angle acquisitions) followed by a dynamic contrast enhanced MRI (DCE-MRI). During and after infusion, we acquired 180 consecutive T1-weighted volumes (3.4 sec per volume) over 10 minutes. SUVr of [^{18}F]AV-1451 and permeability parameters (K*trans*) of gadolinium were analyzed by volume-of-interest methods.
Results. There was greater SUVR of [^{18}F]AV-1451 in the thalamus, globus pallidus and

putamen (but not in cerebellum or cerebral cortex) of older as compared to younger subjects. Gadolinium K*trans* was similar in the cerebellum, temporal cortex, and choroid plexus of younger and older subjects, but there was higher permeability in the substantia nigra, thalamus, globus pallidus, and putamen (all $p<0.05$) of older as compared to younger subjects.
Conclusion. Increased capillary permeability in substantia nigra, pallidum and putamen of healthy older subjects could underlie some of the regional differences in [^{18}F]AV-1451 uptake observed in older as compared to younger healthy subjects.

Topic: C.02. Alzheimer's Disease and Other Dementias

Title: Leading-edge indicators of network disease spread in frontotemporal dementia.

Authors: *J. BROWN, J. DENG, M. GORNO-TEMPINI, H. J. ROSEN, W. W. SEELEY; Univ. of California San Francisco, San Francisco, CA

Abstract: In frontotemporal dementia syndromes including behavioral variant frontotemporal dementia (bvFTD) and semantic variant primary progressive aphasia (svPPA), neurodegeneration appears to originate in a selectively vulnerable epicenter region and spread outward via network connections. This model has been tested in cross sectional data but has not been validated with longitudinal data. In this study we developed a new unified model for predicting both cumulative regional atrophy and regional atrophy rate of change as a function of path length from the epicenter and disease stage.
We modeled cumulative gray matter atrophy over time in each region as its own sigmoidal function, where the sigmoid onset time is determined by network path length from the epicenter. If cumulative atrophy increases sigmoidally, the rate of change will follow the sigmoidal derivative curve. The main prediction of this model is that regional longitudinal atrophy rate will peak before cumulative atrophy plateaus, and thus rate of change will reveal the “leading edge” of disease spread earlier than cumulative atrophy.
We tested this model in patients with bvFTD (n=17), svPPA (n=22), and age-matched controls (n=26) T1 MRI scanned twice 12 months apart. A whole brain parcellation of 482 regions was

used to extract svPPA/bvFTD regional cumulative atrophy scores and longitudinal atrophy scores. We identified the syndrome epicenters in the anterior temporal lobe/frontoinsula from our previous study. Next, a healthy functional 482x482 connectome was used to determine each region's shortest path length from the epicenter. We built a model with sigmoid/derivative curves for each region based on path length, and then predicted the cumulative/longitudinal atrophy for each region by sampling each region's sigmoid/derivative curves at a fixed timepoint. We then tested the accuracy of this model against our observed data.
The combined model of spread in bvFTD from the epicenter in the right frontoinsula was significant for both cumulative atrophy ($r = 0.42$, $p < 0.0001$) and longitudinal rate of atrophy ($r = 0.30$, $p < 0.0001$). In svPPA, the model of spread from the left temporal pole was significant for cumulative atrophy ($r = 0.70$, $p < 0.0001$) and longitudinal rate of atrophy ($r = 0.38$, $p < 0.0001$). Thus, a network-based model making joint predictions about cumulative atrophy and rate of change can unify observations from baseline and longitudinal structural MRI studies, while providing a more accurate prognosis about downstream regions at greatest risk during disease progression.

Abstract: The assessment of resting-state functional connectivity (FC) has become an important tool in studying brain disorders. Here we define functional connectivity as correlations of brain activity between two or more anatomically distinct brain regions with data obtained from resting-state functional magnetic resonance imaging (rsfMRI). These brain regions can be classified as components of well-established resting state networks (RSNs). Recent evidence from rsfMRI studies have shown that brain network connectivity is altered in patients with neurodegenerative disorders. However, few studies have examined the complete connectivity patterns of these well-reported RSNs using a whole brain approach and how they compare between dementias. Here, we used advanced connectomic approaches to examine the connectivity of RSNs in Alzheimer's disease (AD), Frontotemporal dementia (FTD), and age-matched control participants.22 participants (10 controls [63.4±7.8 years], 8 AD [72.63±13.9 years], 4 FTD [62.75±8.1 years]) from an ongoing study at Indiana University School of Medicine underwent a ten minute rsfMRI session (eyes closed) on a Siemens MRI ^{3}T Prisma Scanner. Data was processed using an in-house pipeline modeled after Power et. al., 2014. Images were parcellated into 278 regions of interest (ROI) based on Shen et. al., 2013. Connectivity between each ROI pair was described by Pearson's correlation coefficient. Brain regions were grouped into seven canonical RSNs as described by Yeo et al. (2015). Pearson correlation values were then averaged across pairs of ROIs in each network and averaged across individuals in each group. These values were used to determine relative expression of FC in each RSN (intra-network) and create RSN profiles for each group. AD and FTD exhibited a similar profile of RSNs, showing higher FC within somatomotor, ventral attention, limbic, frontoparietal, and DMN networks compared to controls. However, intra-network FC in AD was lower for all networks compared to FTD. While previous studies noted changes in network patterns in specific neurodegenerative states, few have examined the relative expression of FC in each RSN using a whole brain connectivity approach. Therefore, our approach allows us to create profiles that could help compare intra-network FC in different neurodegenerative diseases. Future work with expanded samples will help us to draw more substantial conclusions regarding differences, if any, in the connectivity patterns between RSNs in various neurodegenerative diseases.

Abstract: Early morphological alterations of subcellular organelles from the endo-lysosomal pathway in Alzheimer's disease (AD) and Down Syndrome (DS) were widely observed by immunocytochemistry and confocal microscopy, notably an increase in size of early endosomes (EE). Neurons bearing enlarged EE have been described before amyloid pathology and clinical symptoms (Cataldo et al., 2000). Endosomal enlargement was also detected in primary fibroblasts of individuals with DS (Jiang et al., 2010, Cataldo et al., 2008), peripheral blood mononuclear cells from individuals with DS and AD patients (Cossec et al., 2012; Corlier et al., 2015), in the brain of mouse models of familial AD with mutations in the gene encoding APP (Choi et al., 2013) and in the brain of Ts65Dn mice modeling DS (Cataldo et al., 2003).
EE diameter ranges from 100 to 250 nanometers, making their observation hampered by the diffraction-limited resolution of conventional light microscopy which is the only technique used so far to investigate EE morphological alterations. In the present work we used super-resolution microscopy and ultrastructural imaging to further characterize the endosomal compartment in cellular and mouse models of DS.
We immunostained EE using an anti-EEA1 antibody (C45B10, Cell Signaling) in cells from individuals with DS (lymphoblastoid cell lines and fibroblasts) and in basal forebrain cholinergic neurons (BFCNs) from Ts65Dn brains. Electron microscopy revealed clusters of normal-sized EE in lymphoblastoid cell lines (EE mean area: control = 0.0538μm^2 vs. DS = 0.0473μm^2, t-test p-value = 0.52), in fibroblasts and in BFCNs from Ts65Dn (1.98-fold increase of endosomal clusters as compared to control mice), suggesting that previously described enlarged EE are rather aggregated EE. We next analyzed EE in neurons derived from induced pluripotent stem cell clones of an individual with a mosaic trisomy 21 (T21). We observed enlarged EE by widefield microscopy in neurons with T21 as compared to euploid neurons (mean volume: 0.017μm^3 vs. 0.021μm^3 respectively, t-test p-value = 0.01). Super-resolution structured illumination microscopy observations revealed that these apparently enlarged EE corresponded to clusters of normal-sized EE (mean volume: control = 0.00801μm^3 vs. DS = 0.0079μm^3, t-test p-value = 0.84).
Our work confirms the significance of EE dysfunction in DS as previously demonstrated in numerous studies. Furthermore, using high resolution microscopies we unveil the presence of aggregates of normal-sized EE rather than enlarged EE. This new result implies to redirect the effort made on the understanding of EE abnormalities and their implication in DS and AD pathogenesis.

Title: Live cell visualization of G2 phase transition in neurons driven by amyloid-β using a fluorescent ubiquitination-based cell cycle indicator (Fucci) system

Authors: *S. IPPATI;
UNSW, Unsw Sydney, Australia

Abstract: Cell cycle proteins are reported to be expressed in neurons in Alzheimer's disease (AD) (Yang et al., 2003). Despite supporting evidence that amyloid-β (Aβ) and tau-mediated toxicity is accompanied by neuron progression in the G_1, S or G_2 phase of the cell cycle, ectopic mitosis events have yet to be shown (Copani et al., 1999; Giovanni et al., 1999). Therefore, cell cycle re-entry events are hypothesized to contribute to neurodegeneration in mature neurons and the failure to complete the cell cycle results in neuronal cell death (Raina et al., 2001). The potential role of cell cycle proteins in neurodegenerative diseases associated with neuronal loss is still mechanistically unknown. Likewise, the temporal role of (Aβ) in inducing aberrant cell cycle reentry is also unknown. Here, we used a method designed to track cell-cycle progression described from Sakaue- Sawano and colleagues (2008). This fluorescent ubiquitination-based cell cycle indicator (Fucci) system allows the tracking of the G_1-G_2/S phase transition in living cells by exploiting the cell-cycle dependent proteolysis of the ubiquitination oscillators Cdt1 and Geminin. The fusion of the red- and green-emitting fluorescent proteins mKO2 and Azami Green (mAG) to portions of Cdt1 and Geminin respectively in the nuclei of cells causes cells in G_1 to emit red fluorescence and those in S/G_2/M phase to emit green fluorescence. We optimized this method in primary neurons to allow simultaneous tracking of the progression of live cells in the G_2 phase and the occurrence of cell death after the administration of different preparations of Aβ. It was shown that primary hippocampal neurons transduced via lentivirus with both the mKO2 and mAG fucci constructs re-enter the cell cycle in response to Aβ peptides administration. We also show that the number of neurons entering the G_2 phase of the cell cycle increases with longer incubation times and higher concentrations of Aβ. We did not observe any neurons in the G_2 phase in the untreated controls, suggesting that the G_1 to G_2 transition is an Aβ

dependent event. There were also no changes in the cell morphology or rate of cell death in response to Aβ treatment. We have used this system to dynamically study the neuronal cell behavior and to quantify the numbers of neurons that re-enter the cell cycle in response to oligomeric, fibrillary and monomeric forms of β-amyloid peptides. The physiological relevance of this *in vitro* cell based model is underscored by this data accurately reflecting those previously observed *in vivo* where we observed that Aβ expression in mice is associated with the expression of several cell cycle proteins in the brains of APP transgenic mice.

Title: Acceleration of synuclein pathology induced by seeding with recombinant preformed α-synuclein fibrils

Authors: *D. L. CZILLI, L. LI, M. HAYASHI, Y. TIAN;
Lilly Res. Labs, Eli Lilly and Co., Indianapolis, IN

Abstract: Parkinson's disease (PD) is pathologically characterized by a progressive loss of dopamine neurons in the substantia nigra, and aggregation of the α-synuclein (α-Syn) protein into Lewy bodies (LB). A53T (B6;C3-Tg(Prnp-SNCA*A53T)83Vle/J) is a transgenic animal model that expresses human A53T variant alpha-synuclein (full-length, 140 amino acid isoform) under the direction of the mouse prion protein promoter. Our experience with this model has shown that it can take 8 to 10 months for a subset of homozygous mice to develop the severe motor phenotype and concomitantly robust pathology primarily centered in the brainstem and spinal cord. Once pathology arises, those animals become moribund and die within a matter of days. To establish a more consistent symptomatic model, we performed intracerebral inoculation of pathological α-synuclein using recombinant preformed α-synuclein fibril seeds (sonicated PFFs) in 3 and 7 month old male Tg A53T mice. This inoculation initiated a rapid progression and spreading of α-synucleinopathy as described by Luk et al., 2012. At 90 days post infusion (dpi), we saw widespread LB-like α-synuclein pathology not only limited to the injection site, but also abundant on the contralateral side and other interconnected regions of brain stem, cortex and spinal cord in both 3 and 7 month old mice. The age of mice at the time of inoculation did not make a significant difference in pathology development. In addition, we developed biochemical methods to quantitatively examine the a-synuclein propagation. Phosphorylated and

mis-folded α-synuclein in spinal cord lysates were measured by ELISA and western blot and we showed a significant increase of both phosphorylated and mis-folded α-synuclein in the PFF-injected spinal cord lysates compared to a-synuclein monomer injected controls. Using this model, we were able to demonstrate that inoculation with synthetic α-Syn preformed fibrils (PFFs) can accelerate the formation and propagation of pathological inclusions throughout the mouse CNS. In addition, the inclusions formed appear consistent with those seen in PD-like α-Syn pathology.

Title: Chronic gut inflammation hastens the onset of motor dysfunction and pathology in alpha-synuclein mutant transgenic mice.

Authors: *Y. KISHIMOTO[1,2], W. ZHU[3], J. M. SEN[3], M. P. MATTSON[2];
[2]Lab. of Neurosciences, Natl. Inst. on Aging Intramural Res. Program, [3]Immune Cells and Inflammation Section, Lab. of Immunology, Natl. Inst. on Aging,, [1]NIH, Baltimore, MD

Abstract: Emerging evidence from studies of human subjects and animal models suggest that Parkinson's disease (PD) pathology (alpha-syunclein accumulation) and neuronal dysfunction may occur first in peripheral neurons of the autonomic nervous system including the enteric branches of the vagus nerve (for review see Del Tredici and Braak; *Neuropathol Appl Neurobiol.* 2016; 42:33-50). The risk of PD increases greatly in people over the age of 65, a period of life in which chronic inflammation is common in many organ systems including the gut. We previously reported that a pro-inflammatory diet (high fat, glucose and fructose) exacerbated autonomic (vagal parasympathetic) dysfunction, whereas an anti-inflammatory diet (alternate day fasting) ameliorated vagal dysfunction in transgenic mice overexpressing mutant human alpha-synuclein (A53T PD mice) (Griffioen et al., *Neurobiol Aging*. 2013; 34:928-935). In the present study we are testing the hypothesis that chronic low-level intestinal inflammation can accelerate the age of

disease onset, and worsen alpha-synuclein pathology and systemic and CNS inflammation in A53T alpha-synuclein mutant transgenic mice. Wild type (WT) and A53T PD mice were treated with or without 0.5% (w/v) dextran sodium sulphate (DSS) in their drinking water for 12 weeks beginning at 3 months of age. During the first 2 weeks of DSS treatment both WT and A53T PD modest weight loss and intermittent diarrhea which subsequently subsided. At 12 weeks of treatment the WT/DSS and A53T PD/DSS groups exhibited colon shortening and spleen enlargement compared with control mice that did not receive DSS. The age of onset of motor dysfunction, evaluated using a rotarod test, gait analysis and grip strength measurements, was significantly earlier in DSS-treated A53T PD mice compared to control A53T PD mice. Markers of systemic inflammation were also increased in DSS-treated A53T PD compared to A53T PD mice in the control group. We are currently evaluating alpha-synuclein pathology in the gut, vagus nerve and brain. These findings from a mouse model suggest the possibility that chronic gut inflammation can promote pathogenic processes in PD, and are consistent with the notion that the disease can be initiated in peripheral autonomic neurons and then progress into the brain a retrograde manner. Supported by the Intramural Research Program of the National Institute on Aging.

Sch. of Med., Tokyo, Japan

Abstract: Parkinson's disease (PD) is a neurodegenerative disease characterized by loss of dopaminergic neurons in the substantia nigra that causes tremor, akinesia and muscle rigidity. A pathological hallmark of PD brain is the appearance of Lewy bodies, which is comprised of more than 70 molecules. Among them, α-Synuclein is regarded as a major component of the Lewy body and one cause of the PD. In fact, mutations in SNCA gene encoding α-Synuclein cause familial PD. Nevertheless, the precise function of the α-Synuclein in PD onset is unclear. Although transgenic mouse models of PD carrying mutated α-Synuclein have been established so far, these models could not reproduce proper PD pathology because of differences in brain structure and function. This has been one of the major limitations for PD research. Hence, MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine)-induced PD models in non-human primates, which show phenotypes similar to progressive stage PD patient, have been widely used. However, it is still difficult to investigate phenotypes before onset or at early stages using this drug-induced non-human primate model. From this point of view, transgenic models of non-human primate are desired. In this presentation, we report establishment and analysis of transgenic common marmosets, a small non-human primate, harboring mutated α-Synuclein.

Title: A novel transgenic mouse model to investigate Parkinson's disease-like alpha-synuclein pathology in noradrenergic neurons

Authors: *L. M. BUTKOVICH, M. C. HOUSER, K. KHOSRAVIAN, T. CHALERMPALANUPAP, J. CHANG, D. WEINSHENKER, M. G. TANSEY;
Emory Univ., Atlanta, GA

Abstract: While cell loss and α-synuclein (αsyn) aggregates in the substantia nigra pars compacta (SNpc) are a major hallmark of Parkinson's disease PD, pathology in the locus coeruleus (LC) is commonly more severe, and may even precede that found in the SNpc and contribute to nigrostriatal loss. While most PD research has focused on the SNpc, we have lacked suitable models to understand how αsyn pathology specifically affects noradrenergic neurons in PD, and whether noradrenergic neurons are vulnerable to αsyn pathology. Increased expression of αsyn is a factor in its aggregation, as heritable triplication mutations in the *SNCA* gene are associated with early-onset PD. Transgenic models of αsyn overexpression have previously been unable to selectively target LC neurons, limiting our understanding of how αsyn pathology affects noradrenergic neurons. To examine this question, we have developed a BAC-transgenic mouse model overexpressing wild-type human αsyn under the control of the noradrenergic-specific dopamine β-hydroxylase promoter. These animals overexpress human αsyn in LC neurons, and enteric neurons derived from the neural crest. Preliminary analysis revealed human αsyn immunoreactivity and mRNA expression in noradrenergic neurons of the LC in transgenic mice, but not non-transgenic littermates. We are currently evaluating age-dependent LC neuron loss and fiber degeneration in these mice. In the transgenic gastrointestinal system there is a significant increase in αsyn expression in enteric neurons at 14 months, raising the possibility that the model may also prove useful for examining peripheral pathologies commonly seen in PD in the gastrointestinal tract related to αsyn accumulation. Combined, our preliminary findings indicate that this novel transgenic mouse model overexpresses human αsyn in noradrenergic neurons, and that it could provide insight into the mechanisms underlying PD-like αsyn aggregation and spread, as well as a platform to test future therapeutic strategies to target αsyn pathology in regions other than the SNpc.

Abstract: Manganese (Mn) is an essential metal that is found in all tissues, it has an important function in different metabolism processes and serves as a cofactor for many enzymes. It is known that Mn is essential for development and brain function; however, at high concentrations this metal is neurotoxic and concentrates mainly in the Basal Ganglia (BG), where developed a neurological disorder similar to Parkinson Disease (PD), referred to as Manganism. The clinical symptoms of Mn neurotoxicity include: psychiatric disorders, parkinsonism and dystonia, if the exposure continues and the disease progresses, the patients develop hypokinesia, rigidity and muscle tremor. In our laboratory was characterized a PD model through the inhalation of Mn^{+2} and Mn^{+3} that produces ultrastuctural changes, dopaminergic neurons degeneration in the Substancia Nigra pars compacta, (SNc) and motor impairments, the alterations are progressive and bilateral, which makes it advantageous to other models, so this study examines the motor and cytological changes in male mice while inhaled the Mn mixture (manganese chloride ($MnCl_2$) and Mn acetate ($Mn(OAc)_3$) for 7 months and compare with mice which inhaled for 5 months and were left 2 more months to determinate if the motor impairments improve after Mn inhalation has concluded. The experiments were carried out in CD1 male mice, divided into 3 groups: 10 mice (control) were exposed to deionized water, 10 mice were exposed to the Mn mixture for 7 months (continue inhalation) and 10 mice were exposed to Mn for 5 months and were left without inhalation for two months (post inhalation). The inhalation was performed in an acrylic box 1 hour 2 times per week. Every week, the motor performance was evaluated, in the walking beam and in the reaching task tests. After 7 months, the animals were sacrificed, perfused and the brains were extracted, we performed immunohistochemistry for tyrosine hydroxylase (TH), to count SNc TH-immunoreactive neurons. According to our results the exposition to the Mn mixture induced motor alterations, in both, Reaching Task and beam walking test, in addition to the loss of dopaminergic neurons of approximately 67 % in exposed animals. There were no recovery in the exposed groups for 5 months, in comparison to the continued exposition group (7 months) so we considerer that the inhalation of Mn compounds is a reliable model that simulates some behavioral and morphological disturbances as reported in PD since it is bilateral, progressive, non invasive, and the animals did not recover after the inhalation has been terminated and is easily reproduced.

Abstract: To investigate the molecular mechanism of dopaminergic (DA) neuron death related to α-synuclein pathology and to establish Parkinson's disease mice model, we aimed to establish mice, in which α-synuclein is overexpressed in DA neurons in a temporarily restrictive manner using Tet-off system. We used TetO-α-SynA53TTg/+ mice and DAT-tTA Tg/+ mice. TetO-α-SynA53TTg/+ mice express mutant A53T human α-synuclein (α-SynA53T) regulated by a tetracycline operator. DAT-tTA Tg/+ mice express a tetracycline-controlled transactivator protein (tTA) driven by the mouse dopamine transporter (DAT) promoter. We mated TetO-α-SynA53TTg/+ mice with DAT-tTA Tg/+ mice and analyzed their offspring including TetO-α-SynA53TTg/+;DAT-tTA Tg/+, TetO-α-SynA53TTg/+;DAT-tTA +/+, TetO-α-SynA53T+/+;DAT-tTA Tg/+, and TetO-α-SynA53T +/+;DAT-tTA +/+ mice. Immunohistochemical analysis showed that TetO-α-SynA53T Tg/+;DAT-tTA Tg/+mice successfully expressed α-SynA53T in DA neurons in the SN in the absence of doxycycline (Tet-off). These mice exhibited DA neurons loss in the SN in adulthood. TetO-α-SynA53T Tg/+;DAT-tTA Tg/+ mice are useful for the investigation of the molecular mechanism of DA neurons death in Parkinson's disease.

Title: AAV-mediated expression of alpha-synuclein in oligodendrocytes recapitulates key features of multiple system atrophy

Authors: F. BASSIL[1], P. A. GUERIN[1], N. DUTHEIL[1], S. DOVERO[1], W. G. MEISSNER[1,2,3], E. BEZARD[1], *P.-O. FERNAGUT[1];

Abstract: Multiple system atrophy (MSA) is a fatal neurodegenerative disorder characterized by a combination of autonomic dysfunction, cerebellar ataxia and l-dopa unresponsive parkinsonism. The hallmark of MSA is the accumulation of α-synuclein (α-syn) aggregates in oligodendrocytes forming glial cytoplasmic inclusions. Currently available models of MSA are transgenic mice with constitutive expression of α-syn in oligodendrocytes. These models replicate several features of MSA but do not display progressive and robust neurodegeneration in brain regions severely affected in MSA such as the striatum and substantia nigra. Adeno-associated viruses (AAV) allow targeting the expression of disease-associated genes in selected cellular ensembles and have proven useful to improve the modelling of Parkinson's disease by targeting the neuronal overexpression of α-syn in the substantia nigra of rodents and non-human primates. Here, we developed chimeric AAV1/2 vectors expressing either human wild-type α-syn or the green fluorescent protein (GFP) under the control of the mouse myelin basic protein (MBP) promoter. MBP-driven expression of GFP resulted in >80% oligodendroglial selectivity in rats and mice. Bilateral injection of AAV expressing α-syn in the striatum of rats resulted in progressive bilateral stepping deficits that were not improved by l-dopa when assessed 6 months after AAV-injection. Histopathological analysis revealed a significant loss of dopaminergic neurons at 3 months, further progressing at 6 months, together with a reduction of striatal medium spiny neurons. Prominent α-syn accumulation, including pS129 and proteinase-K resistant α-syn was detected in the striatum and substantia nigra. Histopathological assessment of AAV-injected monkeys is currently underway. AAV-mediated oligodendroglial expression of α-syn in rats allows inducing progressive and l-dopa unresponsive sensorimotor impairments associated with progressive nigral and striatal neurodegeneration, and accumulation of pathologically relevant forms of α-syn, thereby replicating some of the key features of MSA. This flexible strategy can be used to investigate, in several species, how α-syn accumulation in selected oligodendroglial populations contributes to the pathophysiology of MSA. This AAV-

mediated modelling of MSA expands the currently limited range of α-syn-based models and offers a new framework for the pre-clinical validation of therapeutic strategies.

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder characterized by motor symptoms such as resting tremor, bradykinesia, rigidity and muscle weakness. These changes result from the loss of dopaminergic neurons of the substantia nigra compacta (SNc). It is known that chronic exposure to high levels of manganese (Mn) tends to accumulate in the brain, especially in the basal ganglia, mainly in dopamine (DA) rich regions, altering the integrity of dopaminergic neurons and DA neurochemistry, resulting in a neurological syndrome resembling PD. The present study was designed to determine neuronal death laterality and progression of SNc dopaminergic neurons in mice exposed to inhaled divalent and trivalent manganese (Mn2+/Mn3+) mixture at different times. CD-1 male mice inhaled a mixture of 0.04 M manganese chloride (MnCl2) and 0.02 M manganese acetate (Mn(OAc)3), 1 h twice a week for 15 days, a month and also for two, three, four and five months. By the end of Mn exposure period, animals were killed. The mesencephalon was processed for tyrosine hydroxylase (TH) immunocytochemistry. After two months of Mn mixture inhalation the number of TH-immunopositive neurons in SNc decreased 25% and 42%, 51% and 61% at three, four and five months, respectively. We also note that the number of dopaminergic neurons was greater on the left side. This difference was significant only at two and three months after starting the inhalation

showing a loss of 16% and 14% for three months. These data provide evidence that Mn mixture inhalation produces alterations similar to those seen in PD since the death of dopaminergic neurons is bilateral, lateralized, gradual and progressive.

Title: Discovery of nigral dopaminergic neurogenesis in adult mice

Authors: *B. MORRISON, A. RAHMAN, J. ALBRIGHT, I. STOJKOVSKA, C. BROWN; Dept. of Biol. Sci., Boise State Univ., Boise, ID

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disease. PD is characterized by motor control deficits that arise from a loss of dopaminergic (DA) neurons in the substantia nigra (SN). However, the fundamental cause of DA neuron loss is unknown. Deficiencies in the process of adult neurogenesis have been strongly associated with Alzheimer's disease, a pathophysiologically related disorder. Conversely, investigations of neurogenesis in relation to PD have reported conflicting findings and the notion of adult neurogenesis for DA neurons remains controversial. The inability to reproduce previous studies favoring adult DA neurogenesis may result from technical limitations. To overcome these limitations, we created a mouse model to permanently label DA neuron precursors permitting mapping of their fate in adult animals. Using this model, we have discovered compelling evidence for adult DA neurogenesis. Surprisingly, we found that precursor cells responsible for mature DA neuron replacement express Nestin but not Sox2. This is the first report of a Nestin-positive/Sox2-negative neuronal progenitor pool perhaps indicating an atypical origin for these cells. Interestingly, it was also found that the rate of DA neuron regeneration mirrors that of DA neuron loss in an enhanced inflammatory response model of PD. This observation suggests that

progressive loss of DA neurons in PD might result from suppression of DA neurogenesis in adults by inflammatory response. These findings represent a substantial leap in current knowledge of adult DA neurogenesis *in vivo*, will enable improved modeling *in vitro*, and facilitate the harnessing of this process for therapeutic interventions for PD.

Title: Analysis of the extracellular matrix in a mouse model of Lewy-body induced neurodegeneration

Authors: *F. N. SORIA[1,2], B. DEHAY[1,2], E. BEZARD[1,2];
[1]Inst. Des Maladies Neurodégénératives, Bordeaux Cedex, France; [2]Univ. de Bordeaux, CNRS UMR 5293, Bordeaux, France

Abstract: The extracellular matrix (ECM) is an intricately arranged molecular framework comprised of secreted proteins and complex sugars that support cell function and survival. Changes in the highly-hygroscopic hyaluronan (HA) network, the structural scaffold of the ECM in the brain, can dramatically modify the extracellular space (ECS) volume. Parkinson´s Disease (PD) is characterized by severe neuronal loss leading to motor impairment. The neuropathological hallmark in PD is the presence of Lewy Bodies (LBs), intraneuronal proteinaceous cytoplasmic inclusions constituted, among other components, by alpha-synuclein. Abnormal alpha-synuclein species are transmitted between anatomically connected regions by a mechanism that remains unknown and the ECS appears to play a key role in the transmission of proteopathic seeds from cell to cell. Here we sought to explore the HA network in the ventral midbrain of mice injected with Lewy-body fractions derived from PD patients, an established model of alpha-synuclein-induced neurodegeneration. Since HA can be visualized with fluorescent probes, we analyzed its structure by confocal microscopy and developed a method to model and quantify the complexity of the HA network in vast regions of the brain. We provide

here a detailed description of the ECM scaffold and its spatial relationship with dopaminergic neurons, glial cells and alpha-synuclein in the substantia nigra of Lewy-body injected mice, where a substantial alteration of the ECM was observed. Our results provide insight on a crucial and underexplored component of the brain in a context of neurodegeneration and adds to our understanding of the pathophysiology of neurodegenerative disorders.

Title: Effects of photobiomodulation by Near Infra-Red light in a mouse genetic model of Parkinson's disease

Authors: ***J. MOLET**[1], K. ARVANITAKIS[2], F. REINHART[1], C. CHABROL[1], J. LE BER[1], G. BARBOUX[1], C. PERRIN[1], M. DORCHYMONT[1], D. AGAY[1], A. BENABID[1], J. MITROFANIS[2], C. MORO[1];
[1]CLINATEC, CEA MINATEC CAMPUS, Grenoble, France; [2]Univ. of Sydney, Sydney, Australia

Abstract: Rationale: Parkinson's disease (PD) is a degenerative disorder that affects movement, due to the progressive death of dopaminergic cells in the midbrain substantia nigra pars compacta (SNc) of the basal ganglia. Unfortunately, the progression of this cell death has proven to be difficult to slow and impossible to reverse. The "gold standard" treatments for most patients with PD (dopamine replacement drug therapy with or without surgery) are effective at attenuating the motor signs, at least initially, but they do not reliably slow the progression of the disease. Thus, there is a large need for new therapeutic strategies for treatment, particularly those that offer neuroprotection against PD insult. Several studies have highlighted neuroprotective properties of photobiomodulation by near infra-red (NIR) light (low intensity light therapy) in animal models of PD induced by a neurotoxin. However, these animal models of PD, based on the acute use of neurotoxin, are not fully representative of progressive stages of the disease. Here we assessed the effect of NIR illumination in a mouse genetic model exhibiting progressive

dopaminergic cell degeneration and motor deficits, the key features of the slow progressive human PD disease.
Methods: At 6 weeks half of the Engrailed 1 heterozygous ($En1^{+/-}$) and the Wild-Type (WT) mice were treated with a twice daily NIR illumination during 90 seconds for five days per week until one year old. All mice were tested for motor activity in both open-field and running wheel tests. Dopaminergic cell degeneration was examined using tyrosine hydroxylase (TH) immunohistochemistry.
Results: With the use of our behavioural tests, we found that motor activity was not improved greatly by NIR treatment in the $En1^{+/-}$ aged mice. However, we found that NIR treatment protected many SNc dopaminergic cells from degeneration. The number of TH-immunoreactive cells was higher in $En1^{+/-}$ mice exposed to NIR light (average = ~12650 cells) compared to $En1^{+/-}$ mice not subjected to NIR treatment (average = ~10100 cells) in the SNc.
Conclusions: Although the behavioural tests and time scale we used did not reveal large improvements in motor activity, our immunohistochemical findings revealed clear evidence for neuroprotection. These data indicate that NIR can reliably slow the progression of the neurodegeneration in PD; behavioural improvements may become more obvious at later time periods or with other tests.

Title: Assessment of neurodegeneration and spreading of alpha-synuclein pathology induced by distinct alpha-synuclein assemblies in mice

Authors: *B. DEHAY[1], M. BOURDENX[1], L. ARCURI[1], L. BOUSSET[2], R. MELKI[2], E. BEZARD[1];
[1]Inst. of Neurodegenerative Dis., Bordeaux, France; [2]Ctr. Natl. de la Recherche Scientifique, Univ. Paris-Saclay, Paris-Saclay Inst. of Neurosci., Gif-sur-Yvette, France

Abstract: Aggregation of alpha-synuclein is implicated in several neurodegenerative diseases. Emerging evidence have strongly implicated cell-to-cell transmission of misfolded alpha-synuclein as a pathogenetic mechanism in synucleinopathies. Several experimental paradigms have been used to study alpha-synuclein propagation in animals, in particular injections of exogenous *in vitro*-generated preformed alpha-synuclein assemblies (Bousset et al., 2013) or alpha-synuclein containing Lewy Bodies (LB) extracts from *postmortem* PD patient brain tissue (Recasens et al., 2014). The aim of this study was to investigate the pathophysiological similarities and differences associated with distinct alpha-synuclein assemblies regarding toxicity and spreading in wild-type animals. We tested alpha-synuclein-containing LB extracts and two types of highly purified and structurally characterized α-syn strains denoted “fibrils” and “ribbons”, at different concentrations. Wild-type mice received a stereotactic injection in the substantia nigra of either synthetic alpha-synuclein strains or LB extracts. Four months after injection, extensive analysis was performed to assess qualitatively, quantitatively and spatially in the whole brain the extent and pattern of lesion as well as the occurrence of synucleinopathy using both biochemical and histochemical procedures. This study allows establishing whether distinct alpha-synuclein assemblies follow different propagation pathways and exhibit specific tropism for cells or circuits. The underlying idea was to address key questions common to synucleinopathies, and develop a reliable model for testing neuroprotective therapies.

Title: The mechanism of rotenone induces alpha-synuclein phosphorylation by reducing PP2A activity

Authors: *H. YANG[1,2];
[1]Neurobio., Parkinson's Dis. Center, Capital Med. Univer, Beijing City, China; [2]Beijing Inst. for Brain Disorders, Beijing, China

Abstract: Rotenone has been shown to induce many parkinsonian features and has been widely used in chemical models of Parkinson's disease (PD). Its use is closely associated with α-synuclein (α-syn) phosphorylation both *in vivo* and *in vitro*. However, the mechanisms whereby rotenone regulates α-syn phosphorylation remain unknown. Protein phosphatase 2A (PP2A) has been shown to play an important role in α-syn dephosphorylation. We therefore investigated if rotenone caused α-syn phosphorylation by down-regulation of PP2A activity in mice. Rotenone increased the phosphorylation of α-syn at Ser129, consistent with the inhibition of PP2A activity by increased phosphorylation of tyrosine 307 of PP2A catalytic (pTyr307 PP2Ac). We further explored the interactions among rotenone, PP2A, and α-syn in SK-N-SH cells and primary rat cortical neurons. Rotenone inhibited PP2A activity via phosphorylation of PP2Ac at Tyr307. The reduction in PP2A activity and rotenone cytotoxicity were reversed by treatment with the PP2A agonist, C2-ceramide, and the SRC kinase inhibitor, SKI606. Immunoprecipitation experiments showed that rotenone induced an increase in calmodulin-SRC complex in SK-N-SH cells, thus activating SRC kinases, which in turn phosphorylated PP2A at Tyr307 and inhibited its activity. C2-ceramide and SKI606 significantly reversed the rotenone-induced phosphorylation and aggregation of α-syn by increasing PP2A activity. These results demonstrate that rotenone-reduced PP2A activity via SRC kinases is involved in the phosphorylation of α-syn. These findings clarify the novel mechanisms whereby rotenone can induce PD.

Abstract: Mutations of the leucine rich repeat kinase (LRRK2) are the most common genetic risk factor for Parkinson's disease (PD). Although the pathogenic mechanisms by which LRRK2 mutations facilitate the development of PD remain largely unknown, LRRK2 has been implicated in neuroinflammation. We investigated if LRRK2 mutations exacerbate neuroinflammation in response to an inflammatory trigger using lipopolysaccharide (LPS) and, consequently may lead to selective degeneration of dopaminergic neurons.
Rats carrying the G2019S LRRK2 mutation and wild type (WT) litter mates were subjected to an acute inflammatory insult using a 3 mg/kg LPS dose injected intraperitoneally (i.p.) at 4 months of age. A longitudinal PET study using ^{11}C-PBR28, a marker of microglia activation, ^{11}C-DTBZ, a VMAT2 marker of dopaminergic integrity and ^{18}F-DOPA, a marker of dopamine synthesis and turnover, was performed at baseline and 1 week to 10 months post-LPS. Behavioral tests were performed 6-10 months after treatment. Postmortem immunohistochemistry (IHC) for dopaminergic (tyrosine hydroxylase, TH) and inflammatory (CD68) markers is being performed. No difference in any of the PET markers was observed at baseline. The longitudinal ^{11}C-PBR, corrected for ageing, showed significant time effects between baseline and 10 months ($p = 0.035$). Additionally, a highly significant difference between the saline and LRRK2-LPS group was observed at 10 months post-LPS ($p =< 0.001$). No selective degeneration of dopaminergic

terminals or in dopamine synthesis and turnover was observed in TG or WT rats with ^{11}C-DTBZ and ^{18}F-DOPA. No treatment genotype interactions were observed with behavioural tests. TG animals showed a deficit in the rotarod performance independent of treatment. LPS treated animals showed decreased number of sniffs in olfactory test ($p = 0.04$ (TG), $p = 0.002$ (WT)). Preliminary analysis of the postmortem TH stain revealed no changes in density of dopaminergic neurons matching our ^{11}C-DTBZ PET results.
This longitudinal in vivo study supports the hypothesis that G2019S LRRK2 mutations increase neuroinflammation following an acute inflammatory insult. However, our PET and preliminary IHC results do not show selective degeneration of the dopaminergic system by a single acute exposure to an inflammatory trigger as shown in other models of PD. Currently, we are completing the postmortem analysis by IHC to validate our PET results.
The effect of repeated rather than single insults should be explored in further studies as well as the effect of inflammatory triggers on other systems than the dopaminergic system.

Title: Lymphocytes contribute to motor deficits in the AAV1/2 A53T alpha-synuclein mouse model of Parkinson’s disease

Authors: ***A. A. KARIKARI**[1], M. GEHMEYR[1], E. RIBECHINI[2], V. MALTESE[1], S. KNORR[1], J. VOLKMANN[1], J. M. BROTCHIE[3], J. B. KOPRICH[3], M. B. LUTZ[2], C. W. IP[1]; [1]Dept. of Neurology, Universitätsklinikum Würzburg, Wuerzburg, Germany; [2]Inst. für Virologie und Immunbiologie, Univ. Würzburg, Würzburg, Germany; [3]Toronto Western Res. Inst., Toronto, ON, Canada

Abstract: Background: The role of the adaptive immune system in the progression of Parkinson’s disease is still elusive. While changes have been described in immune response during PD, it is not evident if these alterations are pathogenically relevant. Results from animal models of PD have been controversial with reports of detrimental effect of T-cells in the MPTP

mouse model and a protective role in the 6-OHDA model. In this study, we characterized the impact of the adaptive immune system in a novel, non-toxic PD model. The model of AAV1/2 mediated overexpression of human A53T α-synuclein (aSyn) was chosen because it better reflects the clinical and paraclinical aspects of the human disease than the mentioned toxin models.
Objective: To ascertain the contribution of the adaptive immune system in the pathogenesis of the AAV1/2 driven expression of human A53T aSyn model of PD.
Methods: AAV1/2 A53T aSyn or AAV1/2 empty vector (EV) at a concentration of 5.1 x 10exp12 gp/ml were unilaterally injected into the right substantia nigra (SN) of male adult C57BL/6 or RAG-1-/- mice lacking mature T-and B-lymphocytes. Additionally, another group of RAG-1-/- mice that received wildtype bone marrow (RAG-1-/- wt BM AAV1/2 A53T aSyn), was included into the study. Clinical examination was performed by rotarod analysis and cylinder test examining paw use asymmetry. Immunohistochemistry was used to determine lymphocyte infiltration in the SN. FACS analysis was implemented to investigate brain infiltrates of immune cells.
Results: Significant impairment of rotarod performance and paw use asymmetry in the cylinder test with preference for the right front paw was observed in the wt A53T aSyn injected group compared to the wt EV group at 8 weeks post injection (rotarod $p<0.05$; cylinder test $p<0.01$). Immune deficient RAG-1-/- A53T aSyn injected mice improved significantly in their motor assessments compared to immune competent wt A53T aSyn mice (rotarod $p<0.05$; cylinder test $p<0.001$). RAG-1-/- wt BM A53T aSyn mice however demonstrated a significant deterioration in motor behavior compared to immune deficient RAG-1-/- A53T aSyn mice (rotarod and cylinder test $p<0.05$). Immunohistochemical staining revealed an increase of CD8>CD4 T-cell numbers in wt A53T aSyn SN. FACS analysis using CD69 as activation marker showed a high activation and infiltration of CD8+ and CD4+ T-cells in the brain after A53T aSyn injection.
Conclusions: The presence of lymphocytes worsens clinical symptoms in this AAV1/2 A53T aSyn mouse model of PD.

Abstract: Aim: In this study, our goal is to induce cognitive and motor dysfunction in an animal model aimed to recapitulate the late stages of Parkinson's disease (PD) dementia by adeno-associated viral vector (AAV)-mediated alpha-synuclein (a-syn) overexpression bilaterally in dentate gyrus (DG) together with substantia nigra (SN). Methods: Female Sprague-Dawley rats (200-250g) were used for streotactic injections. AAV-carrying either a-syn (n=11) or green fluorescent protein (GFP; n=11) gene, or as a sham control just saline (n=8) injected bilaterally both into DG and SN. Further seven animals used as naïve control. All animals were tested for memory, spatial learning, anxiety, hedony, motor coordination and locomotion by novel object recognition (NOR), Morris water maze (MWM), elevated plus maze (EPM), sucrose preference, rotarod tests and basal and apomorphine induced locomotor activity test respectivelty, between 16-18 weeks following injection. Brain samples were analyzed by western blotting for semi-quantitative a-syn and GFP expression. The study was approved by Hacettepe University Animal Experimentations Local Ethics Board (2014/51-08). Results: A-syn and GFP expression was shown both in DG and SN by western blotting. A-syn group spent shorter time with the novel object in NOR test, spent longer time to find the platform in MWM and spent longer time on open arm in EPM compared to controls ($p<0,05$). Also a-syn group consumed less sucrose compared to controls ($p<0,05$). In rotarod test; a-syn group displayed worse motor performance on the rod compared to controls ($p<0,05$). In locomotor activity test; all the groups showed increase in horizontal activity after apomorphine injection compare to basal activity however, only a-syn group showed a marked increase compare to controls ($p<0,05$). Conclusion: A-syn overexpression in SN and DG together led to memory impairment, spatial learning deficits and anhedonia besides motor dysfunction and apomorphine sensitivity. Neuronal loss as well as preceeding synaptic dysfunction in hippocampus together with SN might be responsible for the cognitive and motor impairments. The underlying mechanisms of these changes will be examined with further histopathological analysis.

Abstract: PD is a progressive movement disorder of the nervous system, which is characterized by motor-symptoms like tremor, rigidity and bradykinesia. Synapse degeneration of neurons in PD-relevant brain regions is typical for PD patients that develop dementia and was recently shown to be related to synaptic alpha-synuclein accumulation and aggregation. Alpha-synuclein is a presynaptic neuronal protein and is linked to the pathogenesis of PD. Only little is known about synapse loss and spine densities in PD mouse models that should mimic the human disease. To elucidate the quantitative distribution of synapses and spine density in the hippocampus of Line 61, D-Line and A53T transgenic mice, synaptophysin and spinophilin levels were analyzed over age. Synaptophysin is a vesicle protein and is presynaptically expressed while spinophilin is a postsynaptic marker highly enriched in dendritic spines. Our results show that in Line 61 transgenic mice both markers are highly increased at 6 months but not in other age groups. In D-Line mice, both markers are significantly decreased in all age groups while in A53T transgenic mice none of the markers is altered. Our results show different effects of alpha-synuclein expression on synaptic density and dendritic spines in the hippocampus of three different transgenic mouse models.

Abstract: Heterozygous mutations in the gene encoding the lysosomal hydrolase beta-glucocerebrosidase (GBA1) are an important risk factor for Parkinson's disease (PD). *In vitro*, altered GBA activity promotes alpha-synuclein accumulation and elevated levels of alpha-synuclein compromise GBA enzymatic function, thus supporting a pathogenic mechanism in PD. However, the mechanism by which GBA deficiency is linked to increased risk of PD *in vivo* remains unknown. Since knocking-out GBA in the entire central nervous system (CNS) in mouse induces massive neurodegeneration associated with early death, we sought to generate a mouse model of dopaminergic GBA deficiency to investigate the long-term consequences of compromised GBA function. We bred DAT-Cre with GBA-floxed mice to obtain selective homozygous disruption of glucocerebrosidase in midbrain dopamine neurons (DAT-GBA-KO), and analysed motor function, neuronal survival, alpha-synuclein phosphorylation and glial activation, in aged animals as well as in mice overexpressing the mutant (A53T) form of adenoviral-delivered human alpha-synuclein. Our results show that although DAT-GBA-KO mice display increased microglial activation in the substantia nigra, there is no neurodegeneration and alpha-synuclein pathology with respect to wild-type mice. This raises the question whether neuronal GBA deficiency is important for PD pathogenesis and suggests the involvement of GBA deficiency in other cell types as a potential mechanism.

Title: Aberrant adenosine A_{2A} receptor signaling contributes to neurodegeneration and cognitive impairments in a mouse model of synucleinopathy

Authors: *R. XIANGPENG[1], H. QIDI[1], L. YA[1], C. JIANG-FAN[1,2];

Abstract: Synucleinopathy is characterized by abnormal accumulation of misfolded α-synuclein (α-Syn)-positive cytoplasmic inclusions and by neurodegeneration and cognitive impairments, but the pathogenesis mechanism of synucleinopathy remains to be defined. Using a transmission model of synucleinopathy by intracerebral injection of preformed A53T α-Syn fibrils, we investigated whether aberrant adenosine A_{2A} receptor ($A_{2A}R$) signaling contributed to pathogenesis of synucleinopathy. We demonstrated that intra-hippocampal injection of preformed mutant α-Syn fibrils triggered a striking and selective induction of $A_{2A}R$ expression which was closely co-localized with pSer129 α-Syn-rich inclusions in neurons and glial cells of hippocampus. Importantly, by abolishing aberrant $A_{2A}R$ signaling triggered by mutant α-Syn, genetic deletion of $A_{2A}Rs$ blunted a cascade of pathological events leading to synucleinopathy, including pSer129 α-Syn-rich and p62-positive aggregates, NF-κB activation and astrogliosis, apoptotic neuronal cell death and working memory deficits without affecting motor activity. These findings define α-Syn-triggered aberrant $A_{2A}R$ signaling as a critical pathogenesis mechanism of synucleinopathy with dual controls of cognition and neurodegeneration by modulating α-Syn aggregates. Thus, aberrant $A_{2A}R$ signaling represents a useful biomarker as well as a therapeutic target of synucleinopathy.

Title: Viral vector mediated- human alpha-synuclein overexpression induces early axonopathy in the mouse nigro-striatal dopaminergic system.

Authors: *A. P. TAGLIAFERRO, T. KAREVA, N. KHOLODILOV, R. BURKE;
Columbia Univ., New York, NY

Abstract: Alpha-synuclein (α-syn) is the major component of Lewy bodies, histopathological hallmark of Parkinson's disease (PD), and it is implicated in both sporadic and familial cases. Point mutations (A30P, E46K, A53T) as well as whole locus multiplications in the α-syn gene cause autosomal dominant PD (Hardy et al., 2006). In this study we investigated the effects of human wild type α-syn overexpression in the mouse nigrostriatal dopaminergic system using an adeno-associated viral vector (AAV) construct which uses the neuron-specific synapsin-1 promoter. Adult mice (2 months old) received unilateral intranigral injection of either AAV2/7-α-syn or AAV2/7-tomato (used as a control protein) and they were sacrificed 4 and 8 weeks after injection. Tyrosine hydroxylase (TH) immunostaining was used to investigate the number of TH-positive neurons in the substantia nigra (SN), level of TH expression in the striatum and the number of dopaminergic axons in the medial forebrain bundle (MFB). In addition, TH-positive axons in the MFB were examined for signs of axonopathy, Including spheroids and fragmentation. At 4 weeks, experimental animals showed the presence of TH-positive axonal spheroids in the MFB while there was no decrease in the number of TH-positive neurons in the SN or TH-positive axons in the MFB. However, the level of TH expression in the dorso-lateral striatum was decreased. At 8 weeks α-syn overexpression induced a decrease in the number TH-positive neurons in the posterior region of the SN, the levels of TH expression in the dorso-lateral striatum and the number of TH-positive axons in the MFB. Axonal spheroids continued to be present in the MFB. The time course of changes observed in this mouse model of viral vector mediated human α-syn overexpression shows that an axonopathy is the first sign of pathology of the nigro-striatal dopaminergic system. This model will provide an opportunity to investigate the mechanisms involved in early axonal degeneration as well as new therapeutic approaches aimed to restore dopaminergic innervation.

Title: Novel mouse model for the initiation and propagation of alpha-synuclein oligomerization in Parkinson's disease

Authors: K. MARTIN[1], B. VON EINEM[1], V. GROZDANOV[1], C. BLIEDERHAEUSER[1], D. MARKX[2], J. WEISHAUPT[1], K. DANZER[1];
[1]Experimentelle Neurologie, Universitätsklinikum Ulm, Ulm, Germany; [2]Inst. für Proteinbiochemie, Univ. Ulm, Ulm, Germany

Abstract: Emerging evidence suggests that in contrast to Lewy bodies, alpha-synuclein (α-syn) oligomers are the principle toxic species in Parkinson's disease (PD). The concept of α-syn oligomers being transmitted from cell-to-cell in a prion-like manner is a subject of current debate and suitable *in vivo* models testing this hypothesis are largely missing. We have therefore generated two novel neuronal human α-syn overexpression mouse models in a tet-off-system inducible manner, based upon a reporter protein-fragment complementation assay. In our mouse lines, α-syn is fused to the N-terminal half of either human Gaussia Luciferase (S1) or venusYFP (V1S) and α-syn is fused to C-terminal half of human Gaussia luciferase (S2) or venusYFP (SV2). When α-syn starts to oligomerize, the reporter fragments will be in close proximity, complementing to an active enzyme or fluorescent protein.
Our results indicate a successful α-syn oligomer formation *in vivo* and that a variety of different α-syn oligomer species are present in different mouse brain areas as demonstrated by western blot analysis, immunofluorescent staining, size-exclusion chromatography and subsequent luciferase measurements.
Employing an inducible transgenic α-syn oligomer CaMKIIα mouse model allows spatial expression of α-syn oligomers restricted to specific brain regions. Thus spreading of viral particles in viral vector-mediated α-syn overexpression models or transmission of recombinant proteins due to blood stream transport in models of intracerebral inoculation of recombinant oligomers can be avoided. Neurons overexpressing the α-syn transgene under control of the CaMKIIα promoter transport α-syn to the pre-synaptic compartment. In contrast, neurons without CaMKIIα promoter activity lack pre-synaptic human α-syn oligomers but reveal only cytoplasmic aggregates of α-syn oligomers, indicating a neuron-to-neuron transmission of oligomers. Most importantly, spreading of α-syn-oligomers from neurons to other cell types in the brain like microglia or oligodendrocytes was also observed, possibly concomitant with secondary deleterious effects.
The formation of α-syn oligomers in our mouse models is accompanied by changes in animal

behavior in aged mice over 12 months of age. Significant motor deficits emerged as the major phenotype, regarding bradykinesia, fine motor coordination, balance and grip strength, analyzed by Pole-test, beam walking and accelerating RotaRod.
In summary, our new inducible transgenic α-syn oligomer mouse model provides a suitable tool for studying α-syn oligomerization, spreading and toxicity *in vivo*.

Title: Analysis of alpha-synuclein pathology in PINK1 knockout rats.

Authors: *R. B. CREED, M. S. GOLDBERG;
Ctr. for Neurodegeneration and Exptl. Therapeutics, Dept. of Neurol, Univ. of Alabama At Birmingham, Birmingham, AL

Abstract: Mutations in the PTEN induced kinase 1 (PINK1) gene cause autosomal recessive Parkinson’s disease (PD). The main pathological hallmarks of PD are loss dopamine neurons in the substantia nigra pars compacta, which are required for normal movement, and the formation of alpha-synuclein rich aggregates termed Lewy body inclusions. Previous studies of PINK1 knockout (KO) rats have reported mitochondrial dysfunction, behavioral deficits, loss of neurons in the substantia nigra and locus coeruleus, and alpha-synuclein aggregates in various brain regions. We sought to characterize PINK1 KO rats specifically with respect to alpha-synuclein pathology because spontaneous formation of alpha-synuclein aggregates (without alpha-synuclein overexpression or injection) is a rare and important feature of PD animal models and because abnormal alpha-synuclein has been implicated both genetically and neuropathologically as a key mechanism of PD pathogenesis. Given PINK1’s proposed function in mitochondrial autophagy, we also investigated the abundance of key mitochondrial proteins in the brains of PINK1 KO rats. We observed alpha-synuclein-immunoreactive aggregates in various brain regions of PINK1 KO rats including cortex, thalamus, striatum and ventral midbrain, but nowhere in wild-type (WT) rats. Proteinase K treatment revealed protease-resistant alpha-synuclein in the brains of PINK1 KO rats, however, the inclusions themselves were not

proteinase K resistant. Co-imunofluorescence showed that the alpha-synuclein-immunoreactive aggregates are both ubiquitin immunoreactive and thioflavin S positive. We did not find any tau-immunoreactive pathology or any differences between WT and KO rats in markers of neuroinflammation, such as GFAP and Iba1. Western analysis showed similar levels of key mitochondrial proteins in the brains of WT and PINK1 KO rats. Together, this data indicates that PINK1 deficiency can directly lead to abnormal alpha-synuclein aggregation in vivo. This suggests that alpha-synuclein aggregation may be directly involved in PD-related neurodegeneration caused by PINK1 mutations.

Title: Dopamine neuron specific translational profiling in a transgenic mouse model of PD

Authors: *K. WAGNER[1,2], S. JANEZIC[1], F. WESSELY[1], J. MONZON SANDOVAL[1,2], C. WEBBER[1,2], R. WADE-MARTINS[1,2];
[1]Dept. of Physiology, Anat. and Genet. (DPAG), Univ. of Oxford, Oxford, United Kingdom; [2]Oxford Parkinson's Dis. Ctr. (OPDC), Oxford, United Kingdom

Abstract: Aims:
To characterise and investigate targeted cell-type specific gene expression in a *TH-bacTRAP* transgenic mouse model.
Methods:
Early translational changes are examined specifically in dopaminergic neurons during Parkinson's disease (PD) *in vivo* by translating ribosome affinity purification (TRAP) in BAC-transgenic mice. These mice express an eGFP-tagged ribosomal protein (eGFP-L10a) under the control of the cell-type specific promoter of tyrosine hydroxylase (TH) specifically in dopaminergic neurons.
Transgene expression was characterized by native eGFP fluorescence and double immunohistochemistry for TH/GFP. Translated mRNAs have been immunoprecipitated from midbrains of homozygous *TH-bacTRAP* transgenic mice and littermate controls. The isolated mRNA has been analysed by qRT-PCR before performing gene expression profiling by

RNAseq.
Results:
The molecular characterisation of *TH-bacTRAP* mice reveals expression of eGFP in TH+ dopaminergic neurons. Pilot affinity-purifications of eGFP-tagged ribosomes and bound mRNAs from this defined cell population has been performed. The analysis of immunoprecipitated mRNA vs. total RNA via qRT-PCR and RNA-Seq demonstrate the specific enrichment of dopaminergic markers in *TH-bacTRAP* mice after TRAP.
Conclusion:
We could show that high-quality RNA can be isolated specifically from dopaminergic neurons. Next, we will combine TRAP methodology with our mouse model of PD that overexpresses alpha-synuclein from the complete human *SNCA* locus. Comparing our PD model with healthy controls will allow us to investigate perturbations in the expression of translated genes early during disease progression.

Abstract: The ability to knock out a desired gene in a specific cell type enables direct probing of gene function. The newest class of nucleases, CRISPR (clustered regularly interspaced short palindromic repeats)/Cas9 system, can be used to introduce frame-shifting mutations to knock

out a desired gene with high precision. It has been widely used in a variety of cells and microorganisms, but its application in mature neuronal tissue has been limited. We sought to investigate whether we could achieve efficient CRISPR/Cas9-mediated gene inactivation *in vivo*, specifically in dopaminergic neurons of the substantia nigra, the cells affected in Parkinson's disease (PD). As a proof of concept, we selected to target tyrosine hydroxylase (TH), the rate limiting enzyme in the production of the neurotransmitter dopamine. We also targeted alpha-synuclein (α-syn), vesicular transport protein 35 (VPS35) and EIF4G1, all of which are linked to familial forms of PD. We designed guide RNAs (gRNAs) against exon 1 and exon 2 of the TH gene and confirmed genomic DNA cleavage efficiency and reduction in protein levels *in vitro* in PC12 cells. We delivered the protein Cas9, together with the gRNAs as well as GFP as a transduction marker into the substantia nigra of 2 month old Sprague-Dawley rats using recombinant adeno-associated viral vectors (rAAVs). Immunostaining of brain sections revealed a robust decrease of TH protein expression in CRISPR/gRNA(TH) treated brains as compared to "unguided" control injected rats six weeks after surgery . Stereological quantification of TH immunoreactive neurons revealed a 48% reduction of TH expressing nigral neurons in the treated animals. These results validate the use of CRISPR technology *in vivo* in the nigrostriatal dopaminergic system in mature brains. Current experiments are focused to target the aforementioned PD-related genes: α-syn, VPS35 and EIF4G1 using a similar strategy. Upon project completion we will have a useful tool-box to interrogate gene function in nigral dopamine neurons *in vivo* while still in their native context

Abstract: The pathological hallmarks of Parkinson's disease (PD) are Lewy bodies and neurodegeneration of dopamine (DA) neurons of the substantia nigra pars compacta (SNc). The protein alpha-synuclein (α-syn) is the primary component of Lewy bodies and mutations in the α-syn gene result in familial forms of PD. Moreover, overexpression of α-syn results in aggregation and neurodegeneration. Consequently, the predominant hypothesis in PD posits that α-syn aggregates, or the process of aggregation, is a directly toxic event in PD pathology. The positive association between α-syn aggregation and PD progression has made α-syn a prevalent target for therapeutic strategies aimed at decreasing α-syn from affected neurons. However, work from our lab and others has demonstrated that removal of α-syn in mature DA neurons of mice, rats, and non-human primates result in dose-dependent and progressive neurodegeneration. Furthermore, this cell loss can be rescued by supplementation of α-syn. These results demonstrate that α-syn is essential for the survival of mature DA neurons. This is in stark contrast to the germline α-syn knockout, which does not show any overt neurodegeneration. To better study the consequences following α-syn removal in mature neurons *in vivo* we generated a conditional knockout mouse. Mice were engineered to have Exons 1-2 of the α-syn gene flanked by loxP sites. Successful insertion of LoxP sites was confirmed via genomic analysis and sequencing. Importantly, the inclusion of a LoxP site in the 5'UTR of the SNCA gene did not influence α-syn expression as confirmed via Western blot. Finally, we confirmed that expression of CRE recombinase (iCRE) excises the floxed genomic region, eliminating α-syn protein expression. To provide spatio-temporal control of α-syn removal, we utilized recombinant adeno-associated virus (rAAV) to deliver iCRE to the SNc. The integrity of the nigrostriatal system will be assessed at 1, 2, 4 and 6 months post-surgery via behavioral analysis. SNc neuron loss will be quantified using stereological cell counting of tyrosine hydroxylase and NeuN positive cells, and levels of striatal DA will be quantified using HPLC. We predict that a complete loss of α-syn (homozygous floxed) will result in more severe neurodegeneration and motor phenotype than partial loss of α-syn (heterozygous floxed). Once validated, this new model will provide a foundation for investigations into the physiological function of α-syn without the potential confounds that may occur due to genetic compensations following α-syn removal during development. Importantly, this model will also be valuable when investigating the role of α-syn in PD etiology.

Abstract: Understanding early, and therefore often subtle, disease processes in Parkinson's disease (PD) is essential for the development of disease modifying cures. But in patients, and in many PD animal models, measurable neurological symptoms typically occur at disease stages in which neuronal injury and loss has already progressed beyond repair. To investigate if measures of metabolite changes can help detect early disease processes, and thus open the way to biomarker and/or target identification, we investigated metabolic profiles in the brain of various genetic and induced PD models. Different aspects and disease stages of PD can be modeled in rodents by genetic (transgenic, knock-in or -out) of PD-associated genes, or by inducing spreading of misfolded alpha-synuclein (aSyn) through administration of an aSyn seeding source. We analyzed genetic models (LRRK1 knockin, SNCA transgenic, DJ-1 knockout, and crosses thereof) and induced models (spreading of aSyn induced by intrastriatal injection of recombinant aSyn fibrils in mice, or by intravagal injection of a construct expressing human aSyn in rats). We investigated metabolic profiles in brain extracts of these models using a Gas-Chromatography/Mass-Spectrometry platform, and compared them with behavioral and neuropathological measures. We analyzed changes in individual metabolites, as well as, using Principal Component Analysis or supervised machine learning, shifts in metabolite populations and the known cellular pathways they are associated with. By analyzing the brains of these models at different ages or disease stages, we drew out metabolic shifts that coincided with subtle, early motor disturbances (genetic models), and were, for the most part, independent of neuropathological changes such as the presence of aSyn aggregates, and overt neurodegeneration (induced models). Some metabolites, many them still unknown, correlated with motor performance in genetic models. Thus, by applying metabolic profiling in PD rodent models, we identified novel disease stage-related changes in metabolites, and these observations could pave the way for a better understanding of early PD disease processes.

Abstract: Animal models of Parkinson's disease (PD) are critical to the development of novel therapeutics. While there are a wide variety of existing mouse models of PD, none are ideal for therapy development projects, many are not available for for-profit use, and there has been no rigorous comparison of their molecular and phenotypic characteristics. The overall goals of this effort are to develop, characterize, and make available animal models of PD for both basic research and therapy development. The existing repository collection includes transgenic models over-expressing human *SNCA* with the E46K, A53T, or A30P patient mutations as well as a *GBA k*nock-in D409V allele. By combining a transgenic model over-expressing wild-type human *SNCA* with the *GBA* mutant, we expect to exacerbate *SNCA*-driven pathology and related phenotypes; characterization of aged cohorts is in process. *LRRK2* knock-in models express the T1348N, D1994A, or A2016T mutations. Transgenic models over-express human *LRRK2* with the R1441G, R1441C, G2019S, Y1699C mutations. The repository also makes available mouse strains useful for research such as those expressing GFP, Cre, tTA and optogenetic proteins. Here, we specifically focus on the comparison of transgenic *SNCA* and *LRRK2* models in order to better inform the community as to which models are more appropriate for a specific purpose. Transgenic *SNCA* message and protein levels in striatum and cortex are being assayed in cohorts at 4, 8 and 12 months of age, and *LRRK2* levels are being assayed at a single age. All information will be made freely available via publication and the web. We continue to seek novel models of PD. For further information see https://www.jax.org/parkinsons.

Title: *In vivo* structural abnormalities and decreased free water in mice showing increased Aβ42 accumulation

Authors: *L. M. COLON-PEREZ, K. TORROELLA, E. OFORI, Y. LEVITES, P. CHAKRABARTY, D. VAILLANCOURT, T. GOLDE, M. FEBO;
Univ. of Florida, Gainesville, FL

Abstract: Abnormal β-amyloid (Aβ) accumulation is implicated in Alzheimer's disease (AD) pathogenesis and may partly underlie structural and diffusion abnormalities detected using MRI. However, a direct relationship between Aβ accumulation, particularly the toxic Aβ42 fragment, and imaging-based pathologies remains difficult to establish. Imaging mutant mouse strains bred to selectively overproduce toxic Aβ (Bri2- Aβ42 mouse) could offer important insight in this regard. In the present study, we assessed multiple structural features of Bri2- Aβ42 mice and age and sex matched wildtype (wt) controls. In order to assess *in vivo* interactions between Aβ42 overproduction and neuroinflammation, diffusion images were processed for free water (FW) signal. Diffusion images, fluid attenuation inversion recovery (FLAIR) and T2 weighted images were collected at 11.1 Tesla. The following scan parameters were used: (1) FLAIR image resolution: 0.10 x 0.10 x 0.75 mm^3, TR/TI/TE = 5000/1500/12 ms, (2) T2-weighted image resolution: 0.10 x 0.10 x 0.75 mm^3, TR/TE = 2000/32.5 ms, and (3) diffusion weighted images image resolution: 0.15 x 0.15 x 0.75 mm^3, TR/TE = 3000/25.9 ms, 30 directions with b = 1000 s/mm^2, and one b = 0. In our preliminary analyses, images were co-registered using FMRIB software library's linear registration tool (*flirt*). T2 images were used to estimate ventricular volumes, FLAIR scans were used to assess tissue hyperintensities, and diffusion scans were processed for FW, fractional anisotropy (FA) and mean diffusivity (MD). T2 scans showed a much larger ventricular size in Bri2-Aβ42 mice compared to wt. FLAIR images revealed hyperintensities surrounding and inside ventricles in Bri2-Aβ42 mice. Diffusion MRI showed a decrease in FW index in Bri2-Aβ42 (0.26 ± 0.04) compared to wt mice, as well as a larger FA values in Bri42-Aβ42. No differences were observed in MD. The reported effects were observed in whole brain aged (>14 month old) mice and at the moment we are carrying out atlas based ROI analysis and analyzing effects of age (<8 month) and sex. Our present preliminary results provide evidence that Aβ42 production results in structural abnormalities such as enlarged

ventricles with surrounding hyperintensities. In addition, a potential link to neuroinflammation is supported by greater FW in Bri2-Aβ42 than in wt mice. In addition to translating results in animal models of toxic Aβ42 to understand mechanisms underlying MRI findings in AD subjects, these biomarkers are expected to offer a powerful approach for determine *in vivo* therapeutic efficacy.

Abstract: Clinical diagnosis of Parkinson's disease (PD) correlates to the topographic extent and severity of the Lewy pathology. Lewy pathology first appears in the peripheral nervous system (PNS) and the lower regions of the central nervous system (CNS), long before the typical motor symptoms of PD are evident. We previously reported that alpha synuclein (a-syn) and its aggregated forms, the key protein component in the Lewy pathology, could rapidly be transported from the intestine to the dorsal motor nucleus of the vagus of the medulla oblongata in rats. However, it is not clear whether the propagated a-syn can induce a-syn aggregation of the recipient neurons via a seeding effect after long distance transport from the peripheral tissues. Here, we report the propagation and seeding effects of exogenous a-syn species over a long time period *in vivo* in a-syn-overexpression or normal conditions. We injected recombinant human a-syn fibrils or brain lysates of a PD patient into the small intestinal wall of 2 months old C57/Bl6 mice or Bacterial Artificial Chromosome (BAC) transgenic PD mouse model overexpressing human a-syn fused to green fluorescent protein (GFP) under control of the mouse a-syn promoter.
Our preliminary data indicate that different a-syn species injected into the intestinal wall were transported over a long distance up to the brain. We observed elevated level of a-syn

accumulation at different levels of the brain in the a-syn injected BAC-a-syn-GFP animals (16 weeks after injection). Very interestingly, open field behavioral tests reveal a significant reduction in spontaneous locomotor activity after amphetamine administration in 10 months old C57/Bl6 as well as BAC-a-Syn-GFP mice (28 weeks after the injection) compared to the mice that received PBS injection. More detailed analyses on the changes in morphology, protein chemistry and behaviors are ongoing.

Title: Behavioral deficits in mice overexpressing human wild-type alpha synuclein: Exacerbation by elevated biogenic aldehydes

Authors: ***P. A. MARTINEZ**[1,3], V. E. MARTINEZ[1], E. FERNANDEZ[2,4], R. STRONG[2,4]; [1]Pharmacol., [2]Pharmacol. & Barshop Inst. for Longevity and Aging Studies, Univ. of Texas Hlth. Sci. Care Syst., San Antonio, TX

Abstract: Parkinson's disease (PD) is a chronic and progressive neurodegenerative disease affecting ~1% of people over the age of 65 years. A hallmark feature of PD is the presence of Lewy bodies (LBs) in surviving nigrostriatal dopamine neurons that are primarily composed of the presynaptic protein, alpha-synuclein (αSyn). While the exact cause of PD is unclear, studies indicate that a combination of genetic and environmental factors contribute to the neuropathology of PD. αSyn which is recognized as having a main role in neurotransmitter release, was first implicated in PD when point mutations and multiplication of the αSyn (SNCA) gene were linked to familial PD. Despite these findings, 90% of PD cases are idiopathic which have led to investigations of human wildtype αSyn transgenic mouse models of PD. Similar to mutant αSyn, wildtype αSyn localizes in the LB perimeter. The overexpression of αSyn leads to neurotoxicity in several cell lines and motor deficits resembling a parkinsonian phenotype that are responsive to L-dopa treatment in animals. The neurotoxicity of αSyn is believed to arise

through the formation of toxic oligomers. Under conditions of oxidative stress, natively folded αSyn can be driven to oligomer formation in the presence of toxic aldehydes. The dopamine metabolite, 3,4-dihydroxyphenylacetaldehyde, and the lipid peroxidation end product, 4-hydroxynonenal, are elevated in the PD brain and reported to promote aSyn oligomerization. In addition, reduced expression or polymorphisms in genes coding for the two enzymes primarily responsible for the detoxification of aldehydes in dopamine neurons, aldehyde dehydrogenase (ALDH)1a1 and ALDH2, are also implicated in PD. We previously reported that Aldh1a1$^{-/-}$x Aldh2$^{-/-}$ knockout mice exhibit neuropathological manifestations of PD, including elevated biogenic aldehydes, motor deficits that are ameliorated by L-dopa, and the loss of TH-immunoreactive neurons. The current study tests the hypothesis that αSyn is mechanistically related to the manifestations of PD that result from elevated biogenic aldehydes. To test this hypothesis, we generated mice that are null for both Aldh1a1 and Aldh2 and that overexpress human wildtype αSyn. Motor function was measured by examining performance on the accelerated rotarod and by gait analysis, and measures of grip strength. The results show that mice with elevated biogenic aldehydes, in the presence of overexpressed human wild-type aSyn, have more severe motor deficits as compared to mice that only overexpress aSyn. These data are consistent with the idea that elevated biogenic aldehydes impair motor function through mechanisms involving aSyn.

Title: Arginase overexpression thwarts synuclein pathology in animal models of lewy body dementia

Authors: J. HUNT[1], L. SANDUSKY[1], W. FRASER[1], M.-L. SELENICA[1], J. BAKER[2], C. DICKEY[2], K. NASH[3], *D. C. LEE[1];
[1]Col. of Pharm. & Pharmaceut. Sci., [2]Col. of Med. Mol. Med., [3]Col. of Med. Mol. Pharmacol. & Physiol., USF Byrd Alzheimer's Inst., Tampa, FL

Abstract: Synucleinopathies comprises of neurodegenerative disease the harbor alpha synuclein pathology and associated with Parkinson's disease, Lewy body dementia, and multiple system atrophy. Pathways the govern inflammation and the by products generated play a pivotal role in disease outcomes. We find that arginase 1 overexpression using adeno associated virus (AAV9) in models of tauopathies reduce many aspects of the tau phenotype. Herein, we overexpressed arginase 1 (Arg1) via AAV9 in the CNS of alpha synuclein (α-syn) transgenic mice harboring the human α-syn A53T mutant (tetO-SNCAA53T**)** under the control of a tetracycline (tet) responsive element and driven by Camk2a. Mice express α-syn in the forebrain and hippocampus mimicking a lewy body dementia model. At 4 months α-syn mice and non-transgenic littermates received an injection of AAV9-Arg1 or AAV9-GFP in the hippocampus and anterior cortex. Mice were allowed to survive for duration of 8 months and received battery of cognitive test and affective processing test. We found significant behavioral deficits in α-syn mice compared to non-transgenic littermates consisting of spatial working memory, fear associated memory, affective processing, anxiety measures, and compulsion. Arg1 expression reversed some but not all the behavioral deficits in α-syn mice compared to GFP controls. Additionally, Arg1 significantly reduced inflammation and several forms of α-syn including total α-syn and phospho S129, and Tyr136. Several synaptic markers increased in α-syn mice treated with Arg1 compared to AAV9-GFP. Arg1 reduced total arginine content while increasing orthinine in Arg1 treated mice in both genotypes. All together, these data reveal a potential therapeutic pathway associated with arginine metabolism and synucleinopathies. Additionally, arginine metabolism may serve as a novel target to treat a wide array of neurodegenerative disorders.

Title: Cognitive Impairment in Glucocerebrosidase (GBA) deficient mouse models

Authors: *A. HAM;
Dept. of Neurol., Columbia Univ., New York, NY

Abstract: Glucocerebrosidase (GBA) is a lysosome hydrolase encoded by *GBA1* gene, a newly identified susceptibility gene associated with Parkinson's disease (PD) and Lewy body

disease(LBD), with GBA protein identified as one important component of Lewy bodies. Homozygous mutations in *GBA1*cause Gaucher disease, the most prevalent lysosome storage disease, and heterozygous mutations in GBA1 constitute the most frequent risk factors for PD. Emerging evidence has linked GBA mutations to cognitive dysfunction in PD, but the precise mechanisms whereby GBA mutations mediate cognitive dysfunction remain unclear. This study is designed to explore the role of GBA1 gene mutations in hippocampal associated learning and memory using GBA1 L444P heterozygous mutant mice as well as CamKCre mediated neuronal specific GBA1 conditional knockout mouse model. We have found that both GBA1 mutant and GBA1 conditional KO mice show significant deficits in working memory in a Morris Water Maze test and in feared conditions. Our study indicates that GBA1 gene deficiency may contribute to cognitive impairment in PD patients.

Title: A novel, progressive, endogenous synucleinopathy model of Parkinson disease in rats

Authors: *A. D. VAN LAAR[1,2], K. R. WEBB[3], E. A. BURTON[2,1], J. T. GREENAMYRE[2,1]; [1]Neurol., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA; [2]Pittsburgh Inst. for Neurodegenerative Dis., [3]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: One of the greatest obstacles in developing effective neuroprotective therapeutics for Parkinson disease (PD) is lack of a predictive preclinical research model that replicates the human disease with fidelity. We now report a new rat model in which brief pesticide exposure causes progressive accumulation and aggregation of endogenous α-synuclein, culminating in a delayed and progressive behavioral and pathological parkinsonian phenotype over a period of months. Lewis rats (6-9 months old) received baseline behavioral testing and then were treated

with rotenone (i.p.) once daily for 5 days only. During treatment, rats became mildly parkinsonian, but there was no morbidity or mortality. All rats recovered to their behavioral baseline over the succeeding week. They remained behaviorally normal until about 3 months, at which point all rats began to show mild progressive parkinsonian symptoms, including postural instability and bradykinesia. From onset, symptoms progressed over 3-4 months and stabilized thereafter. Pathological studies indicate that during the quiescent latent period before symptom onset, nigrostriatal neurons accumulate α-synuclein, which becomes progressively consolidated into inclusions by 3 months. The accumulation of α-synuclein is accompanied by progressive microglial activation - and many microglia also contain intracellular α-synuclein, apparently derived from nigral neurons. By the time of symptom onset, there is loss of nigrostriatal dopamine neurons, which continues to progress over a period of months. By 9 months, there is α-synuclein accumulation in other brain regions, including in the cortex, and there are legitimate Lewy bodies in some remaining nigral neurons. These results indicate that a remote environmental exposure has the potential to set in motion a pathological cascade that results, after a long latent period in parkinsonism. The model has many advantages over conventional models, including the fact that (i) it is a spontaneously progressive endogenous synucleinopathy, and (ii) potential disease-modifying treatments can be started at symptom onset, which is analogous to current clinical practice.

Title: Modulation of central immune responses in aged LRRK2 G2019S overexpressing mice following sub-chronic administration of paraquat

Authors: *Z. DWYER, C. RUDYK, S. HAYLEY;
Neurosci., Carleton Univ., Ottawa, ON, Canada

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disease of which the primary risk factor is age, wherein the majority of clinical diagnoses occur between the ages of 55 and 65. Recent research has focused on the role of microglia in the generation and propagation of pro-inflammatory responses which are believed to be an important factor in PD related dopaminergic cell death. The prevailing hypothesis postulates that cumulative insults to the brain and immune system over many years on a background of genetic susceptibility results in dopaminergic degeneration. One such genetic vulnerability is the Leucine Rich Repeat Kinase (LRRK2) G2019S mutation. LRRK2 is the most commonly mutated PD related gene and is implicated in nearly 10% of familial and 1% of sporadic PD cases and recent evidence strongly suggests that LRRK2 is highly expressed in microglia. While several genetic and environmental insults have been tested in conjunction with LRRK2 relatively little *in vivo* work has been done. One previously untested environmental factor thought to contribute to the development of PD is paraquat, a herbicide which when metabolized produces intracellular oxidative stress, thereby contributing to the chronic neuroinflammation found in PD patients. In this current study we sought to determine whether the LRRK2 G2019S mutation interacted with age or a sub-chronic paraquat injection regime to produce Parkinsonian symptoms and neuropathology. Aged animals demonstrated a variable reaction to the paraquat including significant motor and weight decreases, however, the G2019S mutation did not appear to produce or enhance any behavioral deficits. Analyzing neuropathological hallmarks of PD we found that paraquat induced age-related alterations in inflammatory states but that the G2019S mutation did not interact with these findings. Overall while age and paraquat seem to induce neuroinflammatory reactions and dopaminergic cell loss, LRRK2 G2019S overexpression does not appear to modulate these effects.

Title: Propagation and aggregation of alpha synuclein in murine models

Authors: K. R. WALKER, W. ARIAS, J. BERGER, N. CHIRICHELLA, B. S. NUNEZ, R. SPRINGER, K. CIRILLO, J. SANCHEZ-PADILA, G. TOMBAUGH, A. GHAVAMI, *S. RAMBOZ;
Psychogenics Inc., Tarrytown, NY

Abstract: Aggregation of mis-folded proteins is a feature common to many neurodegenerative diseases. Parkinson's disease is a progressive movement disorder which is characterized neuropathologically by the presence of intraneuronal Lewy bodies and Lewy neurites. Alpha synuclein is a highly soluble pre-synaptic protein that is implicated in vesicular trafficking. Mis-folded and aggregated α synuclein (fibrillar α synuclein) is a major component of both Lewy bodies and Lewy neurites. Experimental studies have demonstrated that cerebral injection of brain lysates from α synuclein aggegrate bearing transgenic mice into pre-symptomatic young transgenic mice accelerates formation of α synuclein pathology (Luk, K.C. et al., 2012). A growing body of evidence has emerged demonstrating that synthetic α synuclein fibrils (both human and murine) are capable of 'seeding' and propagating α synuclein pathology not only in α synuclein transgenic mouse models but importantly in non-transgenic (WT) neuronal cultures and mice (Luk, K.C. et al., 2012a ; Luk, K.C. et al., 2012b; Volpicelli-Daley, L.A. et al., 2014). PsychoGenics has extensive experience working with both human and murine synthetic alpha synuclein fibrils in a variety of murine neurodegenerative disease models. Stereotaxic administration of 5μg of murine pre-formed fibrils (Proteos Inc.) is sufficient to induce a progressive α synuclein pathology, reduced dopamine levels and motor deficits in murine models (Martinez, T. et al., SFN 2014). As a continuation of our previous study sponsored by the Michael J Fox Foundation, PsychoGenics has expanded the study in WT mice as well as other murine models to assess the behavioral and pathological consequences of α synuclein propagation and aggregation.

Title: N acylphosphatydilethanolamines (napes): early players in parkinson's disease

Authors: *F. PALESE[1], S. PONTIS[1], A. BASIT[1], N. REALINI[1], A. ARMIROTTI[1], D. PIOMELLI[1,2];
[1]D3, Fondazione Inst. Italiano Di Tecnologia, Genova, Italy; [2]Departments of Anat. and Neurobio., Univ. of California Irvine, Irvine, CA

Abstract: N-acyl-phosphatidylethanolamines (NAPEs) are membrane phospholipids present in the brain and other tissues. They are cleaved by a selective phospholipase D (NAPE-PLD) to form bioactive fatty acyl ethanolamides (FAEs) such as the endocannabinoid anandamide (Ueda, 2010). NAPEs have been primarily studied for their role as FAE precursors, but their multiple effects are suggestive of independent signaling functions. For example, NAPEs organize amphitropic cell division proteins at specific sites on the membrane surface, and help terminate inflammation by reducing phagocytosis (Coulon, 2011). It is known that NAPE levels increase following brain injury (Moesgaard, 2000).
Parkinson's Disease (PD) is a chronic neurodegenerative disorder characterized by emotional, cognitive and motor symptoms. Its primary neural substrate is the progressive loss of dopaminergic neurons in the substantia nigra pars compacta, accompanied by intraneuronal inclusions termed Lewy bodies. The etiology of PD is unclear. Nevertheless, there is evidence that chronic neuroinflammation plays a central role.
To investigate the possible contribution of NAPEs to PD we injected the neurotoxin 6-OHDA (6-hydroxy-dopamine) in the caudate putamen of C57BL6/J mice. Control animals were given only vehicle (ascorbic acid-saline). 48 h after 6-OHDA injection the mice were killed and brain tissue was processed for lipid analysis. A significant upregulation of NAPEs was observed in the striatum of 6-OHDA mice, compared to controls.
We also examined the effects of 6-OHDA on NAPE production in the human neuroblastoma SH-SY5Y cell line. Cells were treated with 6-OHDA (100 μM) and harvested at different time points after treatment. NAPE levels were increased 6h after treatment. Consistent with this effect, qPCR and protein analyses revealed a reduction in NAPE-PLD mRNA and protein starting from 2h and 4h after treatment, respectively.
The results suggest that NAPE accumulation may be increased during the early stages of PD. Further studies are needed to fully test this hypothesis and determine the function of endogenously produced NAPEs in the pathogenesis of PD and other forms of neuroinflammation.

Title: Stronger cortical spindles and less power variability in hippocampal ripples in a LRRK2 mouse model of Parkinson's disease

Authors: *J.-P. WIEGAND[1,2], K. GIES[3], M. BARTLETT[4,5], T. FALK[4,5], S. COWEN[1,3];
[1]Evelyn F. McKnight Brain Inst., [2]Dept. of Neurosci., [3]Dept. of Psychology, [4]Dept. of Neurol., [5]Dept. of Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: The LRRK2 mutation is the most common genetic cause of Parkinson's disease (PD). Despite this, no study to date has investigated its impact on network-level neural activity. Recent data from Beccano-Kelly et al. (2014) suggest that LRRK2 knock-in mice exhibit an increase in glutamatergic release in cortical neurons. Such changes could significantly alter cortico-thalamic networks and enhance oscillatory activity produced by cortico-thalamic interactions.
Objective: We hypothesized that sleep-spindle oscillations are enhanced in LRRK2 knock-in mice. To investigate this question, we compared ripple and spindle activity recorded from LRRK2 knock-in and wild-type mice. **Methods:** 5 LRRK2 G2019S and 9 WT C57bl/6 male mice (The Jackson Laboratory) were implanted with depth electrodes and surface EEG electrodes. Depth electrodes were implanted into the motor cortex (M1), anterior cingulate cortex (ACC), hippocampus and striatum. Surface electrodes were implanted above somatosensory (S1) and visual cortex (V1). We recorded neural activity during sleep periods preceding and following an open-field foraging task and novel object exposure. Activity was recorded at 20kHz and down-sampled to 2kHz. We filtered for spindle activity (9-16Hz) that exceeded 2.5 std above the mean power and ripple activity (80-180Hz) that exceeded 5.5 std above the mean power.
Results: LRRK2 mice expressed a significant increase in the power of both early and late peak spindle frequency (dB/Hz) relative to controls ($p < 0.05$, Student's t-test) in all cortical regions (M1, ACC, S1, and V1). In contrast, no difference in the distributions of peak spindle frequencies and durations was observed between LRRK2 and wild-type mice. Moreover, preliminary results from our analysis indicate that ripple-to-ripple variance in the power of each ripple event is reduced in LRRK2 relative to WT mice ($p < 0.05$, Student's t-test). **Conclusions:** Our results support the conclusion that the LRRK2 G2019S mutation results in lasting alterations in two sleep-associated patterns of neural activity that are linked to memory consolidation. Because cortical sleep spindles and ripple oscillations are highly preserved across species, these alterations could serve as a diagnostic biomarker for LRRK2 PD.

Title: Micronized palmitoylethanolammide: a new pharmacological strategy to prevent neurodegenerative diseases associated to the old age

Authors: ***R. CRUPI**[1], M. CAMPOLO[2], R. SIRACUSA[3], D. IMPELLIZZERI[3], M. CORDARO[3], G. CASILI[3], E. ESPOSITO[4], S. CUZZOCREA[4];
[1]Biol. and Envrn. Sci., [2]Univ. of Messina, Messina, Italy; [3]Uniersity of Messina, Messina, Italy; [4]Unirersity of Messina, Messina, Italy

Abstract: Parkinson's disease (PD) is a disorder resulted by degeneration of dopaminergic neurons. The common symptoms of the disease are: resting tremor, rigidity, and hypokinesia, with onset asymmetrical. At the moment there is no cure. Ageing remains the biggest risk factor for developing idiopathic PD. Recent studies have already demonstrated the neuroprotective effects of Palmitoylethanolamide (PEA), alone or in combination with antioxidants, in an experimental model of PD after 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induction.
The aim of the present study was to evaluate the pretreatment effect of micronized PEA formulation (PEA-m), on the neuroinflammation process and on the neuronal death on *in vivo* model of PD on aged mice. The old animals were pretreated for 60 days with PEA-m at dose of 10mg/kg. After pretreatment, they received four injections of the dopaminergic neurotoxin MPTP and were sacrificed 7 days after induction. On the 8th days, brains were processed for histological and immunohistochemical analysis. Pretreatment with PEA-m significantly ameliorated behavioral deficits, reduced the expression of specific markers of PD such as tyrosine hydroxylase (TH), dopamine transporter (DAT), as well as decreased the upregulation of α -synuclein and β-tubulin in the substantia nigra after MPTP induction. In addition, the strong increase in neuroinflammation, detected by GFAP, Iba-1, TNF-α, IL-1β expression and the neurotrophic factors levels such as BDNF and NGF were evaluated.
In conclusion, we demonstrated that the pretreatment with PEA-m in aged mice was able to ameliorate the development of PD disease. Thus, this strategy could prevent neurodegenerative diseases associated to the old age.

Title: Induction of alpha-synuclein pathology by neonatal delivery of adeno-associated virus.

Authors: ***M. DELENCLOS**[1], A. KURTI[1], M. YUE[1], J. D. FRYER[1,2], P. J. MCLEAN[1,2]; [1]Mayo Clin., Jacksonville, FL; [2]Mayo Grad. School, Mayo Col. of Med., Jacksonville, FL

Abstract: Abnormal accumulation of alpha synuclein (α-syn) is a pathological hallmark of Lewy body related disorders such as Parkinson's disease (PD) and Dementia with Lewy body disease (DLB). Over the years myriad of animal models have been developed to mimic pathological features of synucleinopathies by over-expressing human α-syn under a variety of promoters. Although different strategies have been used, most models have little or no reliable and predictive phenotype. Novel animal models are a valuable tool for understanding neuronal pathology and to facilitate development of new therapeutics for these diseases. Here, we report the development and characterization of a novel model in which mice express wild-type α-syn via somatic brain transgenesis mediated by adeno-associated virus (AAV). After 1, 3, and 6 months of age following intracerebroventricular (ICV) injection, mice were subjected to a battery of behavioral tests followed by pathological analyses of the brains. Remarkably, significant levels of αsyn expression are detected throughout the brain as early as 1 month old including olfactory bulb, hippocampus, striatum, and cerebellum. Immunostaining with a phospho-αsyn (p-αsyn) specific antibody reveals abundant p-αsyn expression and pathologic α-syn is detected using the disease specific antibody 5G4. However, no abnormal behavior or motor dysfunction could be observed in the 3 months of age group when performing rotarod, beam walk and pole test. Longer cohorts and behavioral tests for motor performance and memory tasks are still ongoing. We predict that whole brain transduction of neonatal mouse will recapitulate pathological, neurochemical, and behavioral features of Lewy body disorders by 6 months.

Title: Progressive loss of dopamine function in a primate model of Parkinson disease

Authors: *J. S. PERLMUTTER[1], L. TIAN[2], S. K. LOFTIN[2], H. P. FLORES[2], S. A. NORRIS[2]; [1]Washington Univ. Sch. Med., Saint Louis, MO; [2]Washington Univ. Sch. of Med., St. Louis, MO

Abstract: Objective: Parkinson disease (PD) is a progressive neurological disease involving loss of nigrostriatal neurons in the substantia nigra (SN). Unilateral internal carotid delivery of a single dose of MPTP produces nigrostriatal damage but the time-course of this injury remains to be determined. This study was designed to measure the time-dependent change in the nigrostriatal dopamine system in this primate model of PD. **Methods:** Fifteen macaques had baseline MRI and PET to assess presynaptic dopaminergic nigrostriatal neurons: 6-[^{18}F]fluorodopa (FD; primarily reflects decarboxylase activity), [^{11}C]dihydrotetrabenazine (DTBZ; reflects vesicular monoamine transporter type 2 [VMAT2]), and 2beta-[^{11}C]carbomethoxy-3beta-(4-fluorophenyl)tropane (CFT; reflects membranous dopamine transporter [DAT]), then received a single dose of unilateral intracarotid 0.25mg/kg of MPTP. PETs were repeated after 10, 21, 30, 60 days. Animals were trained to perform several behavioral tasks to assess motor abilities, and ratings were done before and after MPTP. The animals were euthanized at different time points for measurements of striatal AADC enzymatic activities, striatal dopamine concentration and unbiased stereological counts of tyrosine hydroxylase (TH)-immunoreactive (ir) neurons in SN. The influx constant (K_{occ}) for FD and non-

displaceable binding potentials (BP_{ND}) for CFT and DTBZ were calculated for the caudate and putamen using an occipital reference region. **Results:** Motor parkinsonism increased at 10 days and reached maximum at 21 days then remained stable until euthanasia (Skillings-Mack test: p = 0.02, n = 18). The striatal PET measures decreased over time (Skillings-Mack test: p = 0.02, n = 16; p = 0.007, n = 16; p = 0.03, n = 16; for FD *K*occ , CFT BP_{ND} and DTBZ BP_{ND}, respectively). **Conclusions:** Taken together these results demonstrate a time-dependent change *in vivo* measures of striatal dopaminergic function from a single dose of MPTP. These results indicate the importance of considering these time-dependent changes in studies of biomarkers reflecting nigrostriatal function or interventions to alter nigrostriatal injury.

Title: N-acylethanolamine acid amidase (NAAA) inhibitors are protective in a model of Parkinson's disease.

Authors: *N. REALINI[1], S. PONTIS[1], F. PALESE[1], M. MIGLIORE[1], A. ARMIROTTI[1], E. ROMEO[1], M. SUMMA[1], R. SCARPELLI[1], D. PIOMELLI[2,1];
[1]Italian Inst. of Technol., Genova, Italy; [2]Departments of Anat. and Neurobiology, Pharmacol. and Biol. Chem., Univ. of California, Irvine, CA

Abstract: NAAA is lysosomal cysteine hydrolase that catalyses the biodegradation of palmitoylethanolamide (PEA) and oleoylethanolamide (OEA) (Tsuboi et al., 2005; Ueda et al., 2010), two endogenous lipid amides that suppress inflammation by activating the ligand-operated transcription factor, peroxisome proliferator-activated receptor-α (PPAR-α) (Pontis et al., 2016). Resident macrophages and other host-defense cells constitutively generate PEA and OEA in amounts that are sufficient to fully engage PPAR-α (Piomelli and Sasso, 2014). This process is halted during inflammation, however, leading to a decrease in PPAR-α-mediated signaling and an acceleration of the inflammatory response (Bandiera et al., 2014). Accordingly, small-molecule NAAA inhibitors restore normal PEA and OEA levels in inflamed tissues and exert profound anti-inflammatory effects in animal models, pointing to NAAA as a potential target for therapy (Bandiera et al., 2014). Even though NAAA may offer a new target for anti-inflammatory therapy, the lipid-like structures and reactive warheads of current NAAA inhibitors

limit the use of these agents as oral drugs. Here, we describe a series of novel benzothiazole-piperazine derivatives that inhibit NAAA in a potent and selective manner via a non-covalent mechanism. In vitro and in vivo experiments indicate that a representative member of this class, ARN19702, is potent, selective for NAAA, and orally available. ARN19702 crosses the blood-brain barrier and elevates PEA and OEA levels in the CNS. Based on the promising in vivo profile of this compound, we tested the effect of ARN19702 treatment in the 6OHDA mouse model of Parkinson's disease (PD): a 21-day treatment with ARN19702 (30 mg-kg-1, twice daily, i.p.) elicited a a marked protective effects, preventing the behavioral and neurodegenerative effects of 6-OHDA injections. In conclusion, the compound ARN19702 exemplifies a second generation of non-covalent NAAA inhibitors that may be useful in the treatment of PD and other chronic CNS disorders.

Title: Manipulating mitochondrial decay and regeneration in a *Drosophila* model of neurodegeneration

Authors: ***D. YOON**[1], A. N. SPIERER[2], D. M. RAND[2];
[1]Dept. of Neurosci., [2]Dept. of Ecology and Evolutionary Biol., Brown Univ., Providence, RI

Abstract: Nearly one in six individuals will develop a neurodegenerative disorder in their lifetime, according to the WHO. Olfactory dysfunction may serve as an early indicator of neural decline and progression in several disorders, including Alzheimer's and Parkinson's disease. Additionally, there is evidence that mitochondrial dysfunction plays a role in the progression of such neurological disorders. We aimed to model neurodegeneration in *Drosophila* using the Gal4-UAS system to express a mitochondrially-targeted restriction enzyme to cleave mtDNA in olfactory receptor neurons. To confirm the efficacy of this model we first expressed the mitochondrially-targeted restriction enzyme in the progenitor germline cells, alone, and in combination with *Spargel,* a gene that upregulates mitochondrial biogenesis. Flies overexpressing the restriction enzyme against mtDNA in their germlines had extremely low fertility compared to those of the various control crosses. Flies expressing both the mitochondrial restriction enzyme and *Spargel* constructs showed intermediate levels of fertility relative to the controls. This suggests that increased mitochondria biogenesis can rescue the cellular and tissue defects associated with linearized mtDNA. We sought to apply this system in an olfactory paradigm by screening for differences in chemotactic response to apple cider vinegar and ethanol. Using four olfactory Gal4 drivers, we identified a target Gal4 line for which expression of the mtDNA restriction enzyme significantly altered the preference of flies for ethanol, in both males and females, when compared to a expression of a GFP control. These findings serve as the foundation for future work dissecting the role of mitochondria in neurological health and decline via manipulation of mitochondrial turnover dynamics that may enhance existing neurodegenerative treatments.

Abstract: Multiple system atrophy (MSA) is a synucleinopathy in which alpha synuclein preferentially aggregates in oligodendroglia. To date, only murine models of MSA exist for the study of this disease. Towards this end, we sought to develop novel rat and nonhuman primate models of MSA by overexpressing alpha synuclein in oligodendroglia cells using a novel oligotrophic adeno-associated virus (AAV). vector where expression was driven by a CBA promoter. Initially, rats received unilateral injections of this novel AAV–CBA-GFP vector (AAV-Oligo-GFP) stereotaxically in the striatum. After 3-months, rodents were sacrificed and histological methods were used to assess the specificity of the viral vector. Our data shows 30,000-35,000 GFP-positive cells in the striatum, with 94-97% of the GFP-positive cells co-localizing with oligodendroglial marker Olig2. There was little or no co-expression in NeuN (2.9-4.7%) or GFAP (0.18-0.49%)-positive cells. We next sought to test the efficacy of this vector in nonhuman primates. Three rhesus macaques received intrastriatal injections of AAV-Oligo-GFP (1x10^13 vg/mL) unilaterally (3 in the putamen and 2 injections in the caudate nucleus). The animals were sacrificed after 1 month and analyzed using histological and stereological methods. As in the rodents, stereological estimates of transfected profiles revealed a large number of striatal cells expressing GFP (monkey 1: 639,877; monkey 2: 630,520; monkey 3: 161,948) in the striatum. Additionally, 90-94% of the GFP expressing cells co-localized with Olig2, with sparse co-localization with either NeuN (0.23-1.42%) or GFAP (0.09-0.12%). Finally, we recently injected three monkeys into the striatum as before, with the vector expressing the alpha synuclein transgene (AAV-Oligo-α-syn). Histological analyses in all monkeys 3 months after injection demonstrated wide spread monomeric and aggregated alpha synuclein expression as determined by LB509 and serine 129 alpha synuclein immunoreactivity. This expression was preferentially seen in oligodendroglia. Quantitative analyses of the staining pattern in these monkeys is currently underway. These data support the establishment of a viral over expression model of MSA.

Abstract: Parkinson's Disease (PD) is the second most-prevalent neurodegenerative disease, affecting more than 4 million individuals worldwide. Presently, there are no disease-modifying therapies available. The National Institute of Neurological Disorders and Stroke (NINDS) Parkinson's Disease Biomarkers Program (PDBP) is a consortium of scientists and movement disorder clinicians established to support biomarker discovery and advance biomarker utility in Phase II clinical trials for PD and related disorders. The PDBP collects standardized longitudinal clinical data as well as biospecimens from PD and Parkinsonism cases, and healthy controls. Currently, there are twelve hypothesis-driven projects supported within the PDBP, of which nine are clinical. As of April 2016, there are more than 1400 enrolled participants. Clinical sites follow standardized protocols for subject visits and biospecimen collection. The PDBP data management resource (DMR) catalogs data electronically, while allowing users to query for expansive clinical and biospecimen data. Moreover, through the DMR users can request biospecimens from the NINDS Repository at no cost, following review by the PD Biospecimen Resource Acquisition Committee (BRAC). Presently, there are more than 1300 DNA and 3500 longitudinal RNA samples available. Most of the DNA has been genotyped using the NeuroX chip and this data is available in the DMR. Furthermore, there are more than 2700 samples each of serum, plasma, and whole blood, as well as over 700 CSF samples collected over time which are available for analysis. Overall, the PDBP cohort serves as a well-standardized cohort of clinical information regarding how to request access to the DMR, query for data and samples, and order biospecimens can be found on the PDBP website (https://pdbp.ninds.nih.gov).

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disorder, diagnosed only at an advanced disease stage, by a series of motor deficits that manifest over years or decades. Aberrant epigenetic modifications, including hypomethylation of α-synuclein in PD, exist across a range of diseases, from cancer to schizophrenia, and are non-invasively detectable in many body fluids and blood tissue as markers of disease. We aimed to characterize DNA methylation and gene expression patterns in blood from PD patients and matched healthy controls to identify disease-specific biomarkers that may be used to aid earlier, more accurate disease diagnosis and tracking of disease progression.
Two whole-blood samples were collected from PD patients and healthy controls, one for DNA methylation detection and one for RNA sequencing. DNA methylation sites were probed with the Illumina Infinium HumanMethylation450 BeadChips and analyzed for differential methylation. We used the Illumina HiSeq2000 platform for RNA sequencing and performed differential expression analysis. Intersection analysis of DNA methylation and RNA-seq was done with Bedtools.
PD methylation profiles are readily distinguishable from healthy controls, even in whole blood DNA samples. Differential expression analyses of RNA-seq data identified global changes in gene regulation, including overall gene expression levels and expression levels of specific transcript splice variants. Combined methylation quantitative trait loci analyses (meQTL) identified cis-acting meQTLs associated with differential expression of proximal loci. Establishing clear patterns of altered disease-specific DNA methylation, RNA expression and processing, and meQTL analyses from whole blood, a non-invasive tissue collection option, provides increased promise for the development of a molecular biomarker for PD with sufficient sensitivity and specificity to aid in the diagnosis and tracking of this disorder.

Abstract: The availability of uniformly collected biospecimens from extensively phenotyped subjects is essential for the identification of high quality biomarkers which can advance the development of therapeutic interventions for Parkinson disease (PD). The Michael J. Fox Foundation (MJFF) and the National Institutes of Neurological Diseases and Stroke (NINDS) are committed to obtain and distribute a range of biospecimens and associated clinical data collected under standard operating procedures from research subjects in the following groups: (1) PD patients at various stages of disease: early, moderate (mod), advanced (adv); (2) healthy controls (HC); and (3) other subgroups. These samples are banked within a single umbrella biorepository located at Indiana University. The biorepository at Indiana University houses biospecimens from multiple ongoing and closed studies. Some of the studies collect longitudinal (long) samples. The table below summarizes the studies and types of biospecimens banked at Indiana University. More information for particular studies can be obtained at www.michaeljfox.org/dataspecimens and https://pdbp.ninds.nih.gov/. Biospecimens collected under these protocols are now available and are being used in ongoing research studies. Researchers request biospecimens through an application process (https://pdbp.ninds.nih.gov/biospecimens) or http://www.ppmi-info.org/access-data-specimens/request-specimens/.

Title: Using eye movements to identify early biomarkers of disease progression in Parkinson’s patients with and without LRRK2 gene mutations

Authors: *J. MORRIS[1], J. HUANG[1], D. BRIEN[1], B. COE[1], J. HUANG[2], N. VISANJI[2], T. GHATE[2], A. E. LANG[2], C. MARRAS[2], D. P. MUNOZ[1];

Abstract: In some patients with Parkinson’s disease (PD), variations of the Leucine-rich repeat kinase 2 (LRRK2) gene have been associated with the development of the disease. There is evidence suggesting the importance of identifying deficits in executive functioning in patients with PD, as it may lead to earlier diagnosis. One promising approach is to use eye tracking. Patients with PD exhibit specific deficits in voluntary saccade control, specifically the anti-saccade task, where participants must look in the opposite direction of a peripheral visual stimulus. This task assesses the ability to inhibit of the automatic response and requires a generation of a voluntary command to look in the opposite direction. Commonly interleaved with the anti-saccade task, the pro-saccade task assesses the basic sensory-motor processing of eye

movements via automatic tendencies to look at the peripheral visual stimuli. PD patients exhibit deficits include increased saccadic reaction times (SRTs) and direction errors during the anti-saccade task. There are also significant alterations of pupil responses during voluntary movement preparation in patients with PD. It is unclear whether LRRK2 mutation carriers before they manifest PD symptoms (LRRK2 carriers) exhibit the same behavioural and pupillary discrepancies as patients with PD. By exploiting these known behavioural variations, saccade tasks may be used as a diagnostic tool to help differentiate between the healthy population and pre-PD patients. We conducted interleaved pro- and anti-saccade trials with age-matched controls, patients with idiopathic PD, and LRRK2 carriers. Preliminary analysis showed no significant differences between the LRRK2 group and controls in SRTs and direction errors, although there were significant pupillary differences between the two groups. LRRK2 carriers had on average smaller baseline pupil size when starting the either saccadic task than healthy age-matched controls. The pupils of LRRK2 carriers also did not constrict as much as controls during both the pro- and anti-saccade task. This may be an indication that pupillary abnormalities may be a prodromal symptom of PD. Further analysis is essential to identify pre-symptomatic behavioural biomarkers of PD that accurately predict disease and thus lead to earlier PD detection.

Title: NLRP3 expression in distressed neurons and a NLRP3 polymorphism associated with decreased risk of Parkinson's disease

Authors: *K. VON HERRMANN[1], L. A. SALAS[1], E. M. MARTINEZ[1], W. W. FENG[1], W. F. HICKEY[2], B. C. CHRISTENSEN[1], S. L. LEE[1,2], M. S. FELDMAN[1,2], M. C. HAVRDA[1]; [1]Geisel Sch. of Med. At Dartmouth, Lebanon, NH; [2]Dartmouth-Hitchcock Med. Ctr., Lebanon, NH

Abstract: Neuroinflammation is a pathophysiology associated with Parkinson's disease (PD). Characterizing the cellular and molecular basis of neuroinflammation is critical to understanding the progression of PD. The NLRP3 inflammasome is a cell-intrinsic pro-inflammatory mediator capable of initiating inflammation. NLRP3, a key component of the multi-protein NLRP3 inflammasome complex, is a NOD-like receptor (NLR) containing a highly conserved NACHT domain along with an n-terminal pyrin domain and a c-terminal leucine rich repeat domain. NLRP3 activity has been associated with the progression of Alzheimer's disease, however the role of NLRP3 in PD is not known. Recent evidence that misfolded synuclein can activate NLRP3 *in vitro* suggests that the NLRP3 inflammasome might play an important role in the development and progression of PD. NLRP3 expression was examined in post-mortem CNS tissues from PD patients (n=17) and control subjects of similar age (n=11). Our histologic and biochemical findings indicate elevated NLRP3 expression in mesencephalic tissues from Parkinson's patients as compared with controls. NLRP3 immunoreactivity was readily detectable in pigmented neurons and Lewy neurites in PD patients indicating that degenerating neurons are a cell-of-origin for inflammasome activity in PD. We independently confirmed neuronal NLRP3 expression in distressed neurons proximal to areas of cerebral infarction and in differentiated SH-SY5Y cells treated with neurotoxins. Although PD most often occurs sporadically, increasing evidence points to underlying genetic predispositions that can alter the incidence and progression of PD. Having identified elevated levels of NLRP3 in DA neurons in the degenerating mesencephalon of PD patients, we undertook an evaluation of NLRP3 in the germline of PD patients and control individuals. In analyzing newly available exome sequencing data obtained from the Parkinson's Progression Markers Initiative (PPMI) database, we found multiple SNPs clustered in the NLRP3 NACHT domain with an individual SNP associated with a reduced risk of developing PD. We were able to use these data to differentiate Parkinson's patients from a population of SWEDD (scans without evidence of dopaminergic deficit) individuals. Our studies identify the NLRP3 inflammasome as a polymorphic neuron-intrinsic inflammatory mediator in Parkinson's and suggest that understanding NLRP3 polymorphisms may help distinguish PD from early stage disease or non-classical parkinsonism. In addition, these findings may provide the basis for novel therapeutic approaches aimed at modulating NLRP3 activity in neuroinflammatory disorders.

Title: H-ferritin in serum and cerebrospinal fluid in Parkinson's disease

Authors: *A. M. SNYDER[1], J. R. CONNOR[1], G. DU[2], C. STETTER[3], M. M. LEWIS[2], X. HUANG[2];

Abstract: It is well established that the substantia nigra (SN) is an area of iron enrichment in the brain, with levels increasing with advancing age. In Parkinson's disease (PD), iron levels are further enhanced, yet the role that iron plays in disease progression remains enigmatic. Ferritin is a key iron sequestration protein and is comprised of H- and L- subunits. The ferroxidase activity of H-ferritin makes this protein of particular interest in PD because it may limit iron toxicity in a condition demonstrated to have iron overload. Data from autopsy tissue suggest that H-ferritin levels are decreased in PD, but H-ferritin levels in the central nervous system, as reflected by cerebrospinal fluid (CSF), or in the periphery are unknown in living PD patients. The overall goal of our work is to establish a biomarker profile to better understand the role of iron in PD pathophysiology. We hypothesize that the correlation between serum and CSF H-ferritin levels will be useful in understanding disease progression. We measured H-ferritin levels in serum and CSF from 109 control, 183 PD, and 12 PDism cases; the latter group includes multiple system atrophy and progressive supranucelar palsy. There was no relationship between serum and CSF H-ferritin levels in controls but PD subjects displayed a significant positive correlation. Sub-division of PD cases into disease duration categories of less than one year, one to five years, five to ten years, and over ten years, revealed that there was a significant positive correlation between serum and CSF in PD cases with disease duration of one to five years and greater than ten years, suggesting this correlation is dynamic rather than stable during disease progression. We also assessed H-ferritin immunostaining in the SN in autopsy sections from control, PD, and PDism cases. H-ferritin protein was found to strongly stain in glia in disease conditions but not in controls. These data suggest that iron management is not causative of PD pathology but does signify a shift in iron homeostasis two to five years after PD diagnosis and also in later stages of the disease. Investigation is ongoing to determine if H-ferritin levels have prognostic value for determining rate and severity of disease progression or if it is informative in PDism cases.

Title: Cerebrospinal fluid as a source of alpha-synuclein related biomarkers for detection of early stage Parkinson's disease

Authors: *W. P. PASLAWSKI, X. ZHANG, P. SVENNINGSSON;
Dept. of Clin. Neurosci., Karolinska Institutet, Stockholm, Sweden

Abstract: Parkinson's disease (PD) is affecting up to 10 million people worldwide and even though 200 years passed from the time when James Parkinson published "*An Essay on the Shaking Palsy"* we are still unable to cure the disease or detect it in the early stages. PD is characterized by progressive loss of dopaminergic neurons and presence of abnormal inclusion called Lewy bodies (LBs) in surviving neurons. Although several medication strategies exist against PD, they are aimed to slow down disorder progression or relieve the symptoms and none of them is able to stop or reverse the damage caused by the disease. More importantly, only few indirect methods are currently available to detect PD in its early stage when no visible symptoms are yet observed and no irreversible brain damage occurred. We are also facing a problem of many possible culprits of the disease, among which alpha-synuclein (αSN) is a leading target for medical intervention.
αSN is a natively unfolded presynaptic protein with unknown function in the cell. It can aggregate into stable oligomeric forms and amyloids, which are a main component of LBs found in the postmortem brain tissue of PD patients. Most importantly, it is known that abnormalities in αSN handling are present in PD patients' brains long before neuronal cell loss, what makes it even more interesting target for further research.
CSF is in direct contact with the extracellular space of the brain and it is commonly believed that what is happening in the brain is reflected in the CSF. Subsequently, it is extensively investigated in PD to search for possible biomarkers of early disorder. It has been previously shown that αSN can be found in CSF samples obtained from PD patients. However, the findings are not conclusive and contrary results are presented by different laboratories. Moreover, they are mostly based on total αSN molecules count and therefore do not consider changes in different aggregated species present in CSF.
In our laboratory we have established a new method for detection of αSN aggregates in CSF. Our preliminary data suggest presence of a high molecular weight species, which we are now investigating. We are also testing if with our method we can distinguish control, healthy subjects

from PD cases and if the levels of αSN aggregate changes with severity of disease. Finally, we are also looking for potential αSN interactions in CSF.
We believe that our findings will greatly complement currently available methods for αSN detection and might in the future be useful as a clinical method for assessing PD risk or even confirm occurrence of early stage of this disorder.

Abstract: Parkinson's disease (PD) is the second common neurodegenerative disease. It is crucial to identify reliable and robust biomarkers for early diagnosis and prediction of disease progression. In order to investigate the alterations of serum protein levels in PD patients, two-dimensional fluorescence differential gel electrophoresis was used to identify differentially expressed serum proteins that might serve as potential biomarkers for PD. The comparative proteomic study of serum samples followed by ELISA confirmation identified that protein expression of Rab35 was upregulated in PD patients (n=213) compared with matched control subjects (n=177) and other parkinsonian disorders, progressive supranuclear palsy (PSP, n=46) and multiple system atrophy (MSA, n=80). The serum level of Rab35 was negatively correlated with the age at onset of PD. There was a significantly correlation between the expression of Rab35 and disease duration of PD. Importantly, PD patients with a high serum level of Rab35 showed shorter overall survival compared to patients with a low expression of Rab35. Moreover, an increased expression of Rab35 protein was observed in the substantia nigra of MPTP-treated mice, rotenone-treated mice, (R1441C) LRRK2 or (G2019S) LRRK2 PD transgenic mice. Furthermore, overexpression of Rab35 significantly increased the aggregation and secretion of A53T α-synuclein in dopaminergic SH-SY5Y cells. Co-expression of Rab35 with wild-type or A53T α-synuclein in SH-SY5Y cells deteriorated cell death. Our results suggest that Rab35 is potentially useful in the differential diagnosis of parkinsonian disorders and is implicated in the pathogenesis of PD.

Title: Frontal dysfunction of Parkinson's disease

Authors: *M. KANAI;
NHO Takasaki Gen. Med. Ctr., Takasaki-City, Gunma, Japan

Abstract: [OBJECTIVE] As a non-motor symptom of Parkinson's disease (PD), cognitive decline and executive dysfunction are pointed out. In comparison with a decrease of memory function, I experience the case that a frontal lobe dysfunction is seen in early. As PD symptoms, I pay my attention to a frontal lobe sign and examine it. [METHOD] I intended for 30 PD patients (a man, a woman each 15) who were under the medical treatment in my hospital. After

having obtained its consent from a patient for the case not to be seen of the memory disorder, I inspected the neuropsychiatric test by clinical psychologists. The inspection battery went mini-mental state examination (MMSE), frontal assessment battery (FAB), trail making test (TMT) and the tower of Hanoi task (TOH). About MMSE and FAB, I added evaluation about the lower item. TMT performed part A and B and evaluated the time required. TOH performed by for each three times with three disks and four disks, and examined it in the shortest achievement time. I set 24 points in a cut-off level about having failure of memory or not in MMSE. [RESULT] 30 all cases were more than 24 points in MMSE. After examining it in a lower item, a drop was seen by attention in MMSE. The conflicting instructions and the prehension behavior were kept in FAB, but a mistake was outstanding in the other subtests. Extension of the time was seen in TMT in complicated part B in comparison with part A. The tendency that time extended to with aging at three disks was seen in TOH, and the case that could not be accomplished with four disks to reflect an executive dysfunction more was seen. FAB score was significant correlation with TMT part B and TOH, but it had no correlation with MMSE score. [CONCLUSION] In the case not to be seen of the cognitive impairment in PD, the deterioration of an attention disorder and the executive dysfunction is accepted. I think that there is the need to diagnose the disorder that is not caught early in MMSE. I provide treatment not only for the motor symptom of PD but also for the frontal lobe dysfunction, under the medical treatment. I think TOH to be effective tools to find out the condition of early stage in the executive dysfunction of PD.

Title: Exercise targeting cognitive impairment in Parkinson's disease

Authors: *L. HAWTHORNE[1], M. E. GOMEZ[1], V. FILOTEO[4], A. PETKUS[2], B. JARRAHI[5], I. KUO[3], E. SY[1], S. MCEWEN[5], B. FISHER[3], G. M. PETZINGER[1];

Abstract: Mild cognitive impairment, particularly of the executive function (EF) subtype, is common in Parkinson's Disease (PD), frequently transitions to dementia, and there are no effective interventions to alleviate or slow these cognitive declines. EF processes are needed to learn and optimize performance of complex cognitive and motor skills. Our studies in PD demonstrate that exercise facilitates neuroplasticity of the basal ganglia, supporting the hypothesis that exercise will reverse EF deficits in PD. In addition, our translational animal studies and recent studies in aging and exercise have suggested that skill-based exercise may facilitate cognitive circuitry to a greater extent than aerobic exercise. The aim of this study is to compare and elucidate the effects of skill-based exercise versus aerobic exercise versus control on mild cognitive impairment in Parkinson's disease. Patients will be randomized to 1 of 3 groups (N=20/group) to participate in a community-based neuro-physical therapy guided intervention that will involve either:(i) skill-based exercise; (ii) aerobic exercise or (iii) social-engagement (control) for 36 hours across 12 weeks. Patients assigned to either exercise group will complete 3 one-hour, individual sessions per week in a neurologic physical therapy practice. Blinded evaluators will conduct all assessments at pre-intervention, post-intervention and 3-month follow up visits. Patients will be examined for changes in neurocognitive measures and changes in the connectivity and function of the brain circuits sub-serving executive function seen during an fMRI scan. These outcomes will be compared to changes in measures of cardiovascular and motor/skill-related fitness and body mass index (BMI). Findings from this clinical study could help elucidate the type (skilled vs. aerobic) of exercise that may be most beneficial for improving cognitive function in PD-MCI and the role of exercise in facilitating neuroplasticity (brain connectivity) and repair.

Title: Measuring alpha synuclein protein turnover kinetics in cerebrospinal fluid via immunoprecipitation tandem mass spectrometry

Authors: *K. L. PAUMIER, J. G. BOLLINGER, R. MILLER, J. JOCKEL-BALSAROTTI, B. W. PATTERSON, T. M. MILLER, R. J. MILLER, P. T. KOTZBAUER;
Dept. of Neurol., Washington Univ., Saint Louis, MO

Abstract: Parkinson's Disease (**PD**) is defined by the accumulation of alpha-synuclein (**aSyn**) fibrils in neuronal cytoplasmic and neuritic inclusions known as Lewy bodies and Lewy neurites (Forno, 1996). Multiple therapeutic approaches targeting aSyn accumulation are being pursued for the treatment of PD including: 1) inhibition of aSyn protein synthesis, 2) prevention or reversal of aSyn aggregation, and 3) enhancement of aSyn clearance. Hindering the overall development of these therapeutic interventions is the lack of robust methodologies that assess aSyn target engagement and pharmacodynamics. To address this need, we developed an immunoprecipitation tandem mass spectrometry (**IP-LC/MS**) method based on the Stable Isotope Labeling Kinetics (**SILK**) technique to quantitate aSyn and measure its turnover kinetics in human cerebrospinal fluid (**CSF**). SILK has already been successfully applied to measure the turnover of other disease-related proteins in the central nervous system (**CNS**), including amyloid-beta (Bateman et al., 2006, Potter et al., 2013), soluble Amyloid Precursor Protein (Cook et al., 2010, Basak et al., 2012), Apolipoprotein E (Basak et al., 2012, Wildsmith et al., 2012), and superoxide dismutase 1 (Crisp et al., 2015). These studies provide valuable insight into CNS disease mechanisms (Mawuenyega et al., 2010, Potter et al., 2013) as well as in measuring the pharmacodynamic action of proposed disease-modifying drugs (Dobrowolska et al., 2014). Leveraging our previous experience with the development of SILK protocols and monoclonal antibodies, we first developed an IP protocol by screening a panel of both in-house and commercial antibodies under a set of commonly applied IP conditions. We then optimized a LC/MS method based on bottom-up proteomics capable of characterizing the aSyn proteoforms present in human CSF. Using a set of 15-Nitrogen uniformly labeled proteins in addition to a set of peptides with differentially labeled individual amino acids, we designed our quantitative assay around five key proteolytic peptides containing either a Leucine residue (for SILK turnover analysis) or sites of documented post-translational modifications. With optimized assay parameters in hand, we will define a suitable labeling strategy for SILK analysis to determine the production and clearance rates of aSyn in CSF from a set of control human participants and corresponding PD patients. We hypothesize that measurement of aSyn production and clearance rates by SILK will define altered aSyn metabolism related to PD. Further, this technique will provide a valuable measure of target engagement and pharmacodynamics for future clinical studies targeting aSyn.

[1]Physiol., [2]Emory Univ., Atlanta, GA; [3]Univ. of Florida, Gainesville, FL; [4]Parkinson's Ctr., Boca Raton, FL; [5]Univ. of Miami, Miami, FL; [6]Univ. of South Florida, Tampa, FL

Abstract: The identification of the leucine-rich repeat kinase 2 (LRRK2) mutation as causative in dominantly inherited form of Parkinson’s disease, led to a new target for investigation in PD. Both idiopathic PD and LRRK2-associated PD have similar clinical presentation and the study of LRRK2 function could shed light onto disease mechanisms and progression which could result in improved therapeutics. LRRK2 mutations are associated with roughly 1-2% of total PD cases and an incidence of 40% in the Ashkenazi Jewish PD population. LRRK2 is abundantly expressed in cells of the immune system, including CD4+ and CD8+ T cells, CD14+ monocytes, and CD19+ B cells; yet its function in the immune system and the relationship of LRRK2 function in immune cells to PD pathogenesis is largely unknown. In this study, we use flow cytometry to characterize immune cell populations in blood of PD patients with and without the LRRK2 mutation as well as healthy controls with and without the mutation. Flow cytometry used with a cocktail of antibodies enables us to identify monocytes, B cells, and T-cells including central and effector memory populations as well as Th_1, Th_2, Th_{17}, and T_{reg} populations. These studies are expected to show alterations in activation responses in immune

cell populations as a result of a pathogenic LRRK2 mutation. This study can provide the first evidence of immune effector cell differences between pathogenic LRRK2 mutations and controls.

Title: ^{123}I-Ioflupane SPECT predicts the efficacy of selegiline monotherapy for motor symptoms in drug-naïve Parkinson's disease

Authors: *H. MURAKAMI[1], S. ISHIGAKI[2], H. KATOH[3], K. ONO[1];
[1]Dept. of Neurol., Sch. of Medicine, Showa Univ., Shinagawa-ku Tokyo, Japan; [2]Dept. of Neurol., Showa University, Northern Yokohama Hosp., Yokohama, Japan; [3]Dept. of Neurol., Showa Univ. Fujigaoka Hosp., Yokohama, Japan

Abstract: (Background) Selegiline, a monoamine oxidase inhibitor, enhances the patient's own endogenous dopamine in their brain by inhibiting the metabolism of dopamine. Dopamine improves Parkinsonian symptoms. Thus, efficacy of selegiline monotherapy for de novo Parkinson's Disease (PD) patients is speculated to depend on residual nigrostriatal dopaminergic neurons. ^{123}I-Ioflupane single photon emission computed tomography (SPECT) is a method to assess striatal degeneration. (Aim) We examined the utility of ^{123}I-Ioflupane SPECT to predict the efficacy of selegiline monotherapy for motor symptoms in drug-naïve PD patients. (Methods) Nineteen drug-naïve, de novo PD patients (6 males, 13 females) began taking selegiline monotherapy, and the dose was increased until improved
motor function without side effects (maximum 10 mg per day) was obtained. Motor function at baseline and after the medication had reached the stable dose was assessed using the Unified Parkinson's Rating Scale (UPDRS). ^{123}I-Ioflupane SPECT was performed before the start of the medication, and the Specific Binding Ratio (SBR) in the striatum was calculated for each participant. The SBR and improvement in motor assessment score were compared using Spearman's correlation coefficient. (Results) The UPDRS part III (motor score) at baseline did not correlate with the SBR in the stratum ($p=0.19$). Improvement from baseline in the UPDRS part III showed a significant negative correlation with the SBR in the striatum ($p<0.01$). In other words, patients with a low SBR had grater improvement with the selegiline monotherapy than

those patients with a higher SBR. Multiple regression analysis taking into account the age of the patient and the selegiline dose showed that improvement in the UPDRS part III significantly correlated with the SBR ($p<0.05$), but it did not correlate with the age of the patient ($p=0.45$) and the drug dose ($p=0.28$). (Conclusion) ^{123}I-Ioflupane SPECT can predict the efficacy of selegiline monotherapy when used as an initial treatment for drug-naïve PD patients.

Title: Microscopic, biochemical, and immunohistochemical characterization of peripheral nerve tissue used in brain autografts for the treatment of Parkinson's disease

Authors: *A. S. WELLEFORD[1,2], C. G. VAN HORNE[1,2], J. E. QUINTERO[1,2], Y. AI[1], G. A. GERHARDT[1,2];
[1]Univ. of Kentucky, Lexington, KY; [2]Brain Restoration Ctr., Lexington, KY

Abstract: Currently two clinical trials (NCT01833364 and NCT02369003) are underway which feature the implantation of a peripheral nerve autograft to the brain (targeted either to the Substantia Nigra or the Nucleus Basalis of Meynert) in combination with Deep Brain Stimulation (DBS) for the treatment of patients with Parkinson’s disease. This nerve tissue is harvested from the sural nerve, a cutaneous sensory nerve located in the lateral ankle, of patients undergoing DBS surgery. Two tissue samples per patient are collected for study (one during the Stage I surgery, another during the Stage II surgery 5-7 days later) in addition to the tissue used for the graft. As of 5/1/16, 28 patients have received a graft.
The character of the peripheral nerve tissue used in these clinical trials has yet to be described. This study examines several aspects of the peripheral nerve tissue; including microscopic appearance, levels of neurotrophic factors, morphology of Schwann Cells, and presence of

macrophages. These results are supplemented by immunohistochemical analysis of the brain of non-human primates that have undergone an analogous procedure. The results of this model show growth of tyrosine hydroxylase-containing nerve fibers, which are a marker of dopamine-producing neurons, into the area of the peripheral nerve graft. In addition, results in this model show the presence of S100beta-containing cells as well as GFAP-containing cells within and surrounding the graft.

Title: Optimized programming algorithm for cylindrical and directionally segmented deep brain stimulation electrodes

Authors: ***D. N. ANDERSON**, B. OSTING, A. DORVAL, C. R. BUTSON;
Univ. of Utah, Salt Lake City, UT

Abstract: **Introduction:** Deep brain stimulation (DBS) programming is a complex process likely to become more complex with the introduction of leads with larger numbers of contacts. We developed an automated programming algorithm to optimize DBS parameter selection for targeted neural activation in a patient-specific manner. The purpose of this study is to assess algorithm performance by applying it to conventional and directional electrode geometries. **Methods:** We used finite element models to solve the bioelectric field problem for a conventional 4-contact DBS lead (Medtronic 3387) and three directional leads: the directSTNactute (Pollo et al., 2014), the segmented lead (Bulmann et al., 2011), and the Sapiens electrode (Decré et al., 2013). As shown in Figure 1A, a 3D rendering of the stimulation target area and fiber tractography were generated from patient MRI and diffusion tensor imaging (DTI). We used values derived from the Hessian matrix of voltage second derivatives as an estimate of neural activation to maximize stimulation in the STN and limit activation of axon

fibers in the internal capsule. **Results:** We have demonstrated an ability to program the electrode to stimulate a target area while avoiding neural tracts that may be responsible for side effects. We tested that the algorithm settings were robust by adjusting the magnitude of optimized electrode settings as shown in Figure 1B. Optimal parameter settings from the algorithm show STN activation while limiting stimulation outside the target area and the internal capsule. **Conclusion:** We have developed a method of optimization that can be applied to the clinical electrode and additional complex DBS lead designs. Deviation away from the optimized parameters showed more stimulation outside the target area or activation of neighboring fiber tracts. A real-time, patient-specific, automated programming algorithm may increase efficiency and positive outcomes of clinical DBS programming, as well as enable the use of more complex lead designs, which are likely to be too complex for manual programming.

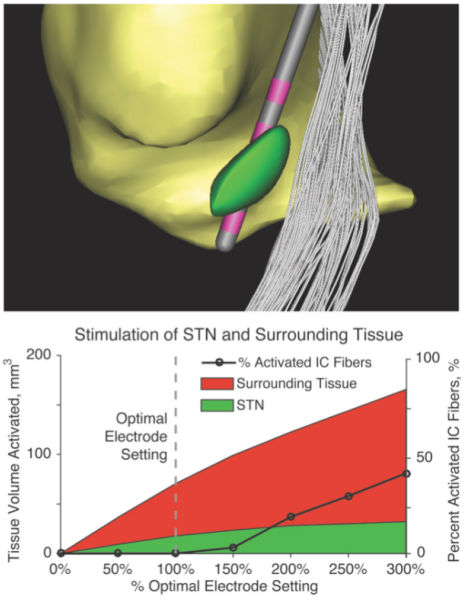

Figure 1. **A.** The neural target for our study is the subthalamic nucleus (STN), in green, a common surgical target for DBS for Parkinson's disease. Stimulation of the internal capsule (IC), a white matter tract adjacent to the STN, is associated with unwanted sensorimotor side effects, and will be used as an area of avoidance in our algorithm (Xu et al., 2011). **B.** We compare activated volume of the STN, surrounding tissue, and percent activation of internal capsule tracts to verify optimized settings for the conventional electrode. Optimal settings using a neural activation threshold of 8 mV were calculated to be 0.3 V and 0.8 V for contacts 0 and 1, respectively. As applied voltage increased, more surrounding tissue and IC fibers were activated, while lower settings did not activate as much of the STN volume.

Title: Spatial and geometric performance of particle swarm optimization (PSO) for programming deep brain stimulation arrays

Authors: ***E. PEÑA**[1], S. ZHANG[2], Y. XIAO[2], M. JOHNSON[2];
[1]Biomed. Engin., Univ. of Minnesota Twin Cities, Saint Paul, MN; [2]Univ. of Minnesota, Twin Cities, Minneapolis, MN

Abstract: Deep brain stimulation (DBS) therapy relies on both precise neurosurgical targeting and systematic optimization of stimulation settings to achieve beneficial clinical outcomes. One recent advance to improve targeting is the development of DBS arrays (DBSAs) with electrodes segmented both along and around the DBS lead. However, increasing the number of independent electrodes creates the logistical challenge of optimizing stimulation parameters efficiently. We developed a robust and efficient particle swarm optimization (PSO) approach to solve this complex multi-objective programming problem through a swarm of individual particles representing a range of electrode configurations and stimulation amplitudes. The approach was evaluated across several axonal fiber orientations relative to the DBSA lead (0°, 30°, 60°, 90°, 120°, and 150°). The fiber tracts consisted of a region of interest (ROI) and a region of avoidance (ROA). Accuracy of PSO activation predictions was assessed using biophysical NEURON models. To investigate the specificity of PSO, we generated complex, angled fiber tracts with an

ROI and ROA. The lead was then shifted relative to the fiber tracts. For all fiber tracts, finite element models were used to determine the nodal voltages for each electrode configuration. The PSO algorithm solved the multi-objective ROI-ROA problem by producing consistent Pareto fronts. The angle of fibers was found to influence the activation threshold needed for the PSO output to match the biophysical model predictions. The specificity of the PSO algorithm was maintained across DBSA lead shifts, such that activation in the ROI was always 25 to 100 times higher than in the ROA. These results suggest that if one accounts for the axonal orientations around a DBS lead, the PSO algorithm can provide a computationally efficient way to program DBS systems especially those with higher electrode counts.

Title: Deep brain stimulation Activa SC neurostimulator battery longevity; initial clinical data

Authors: *R. P. PATEL[1], R. J. DIPAOLA[2], S. F. DANISH[1], S. WONG[2], E. L. HARGREAVES[1];
[1]Div. of Neurosurg., [2]Dept. of Neurol., Rutgers Robert Wood Johnson Med. Sch., New Brunswick, NJ

Abstract: Deep Brain Stimulation (DBS) is an adjunct neurosurgical treatment for Movement Disorders. At the core of the DBS system is the neuromodulation device. Medtronic's most recent Activa (SC) neuromodulation device became available 3/15/2011, and purports to have a 2-5 year battery life. We reviewed the charts of 27 individuals implanted with 50 Activa SCs between 3/15/2011 and 9/24/2013. Twenty of the individuals were diagnosed with Parkinson's Disease, 18 Subthalimic Nucleus, 2 Globus Pallidus interna (GPi), two were diagnosed with Dystonia, 2 GPi, 4 with Essential Tremor, 4 Ventral Intermediate nucleus of the thalamus (VIM), and one individual with Multiple Sclerosis tremor 1 VIM. Of the implanted Activa SCs, 23/50 have been exchanged, while 16/50 continue to function, while the final 11/50 have been lost to follow up. The mean start value of the 50 devices was 3.11V, with a range of 3.04V-3.17V. The mean end value of the 23/50 exchanged devices were split into those that passed below the Elective Replacement Indicator (ERI) threshold (n=16, mean 2.50V, sem .03; range 2.22V-2.60V) and those that were tied to a below threshold device and exchanged at the same time (n=7, mean 2.80V, sem .02; range 2.71V-2.86V). The 16/23 exchanged devices from 15

individuals had a mean duration 2.87 years ranging from 1.75 years to 3.98 years, while the ongoing 16/50 devices from 9 individuals currently have a mean duration of 3.3 years ranging from 2.61 years to 4.18 years. Both these values may underestimate the eventual longevity as the devices have only been available for 5.20 years. Of the 16 Activa SCs exchanged at or below the ERI 2.60V threshold, full battery tracking data were available for 10 of the devices. Examination of the plotted battery charge decay curves suggests a cubic spline best fit with an initial concave up followed by a concave down, and a central plateau in between. The first upward concavity is characterized by a rapid decline from the respective start values to a leveling off value ranging from 2.95V to 2.98V occurring by the end of the initial six months. The central plateau occurs between the battery charge values of 2.95V to 2.88V, lasting from 6 months to 3 years dependent upon programmed neuromodulation parameters. The second downward concavity declines more rapidly as the battery runs down with durations of approximately 6 months. The initial upward concavity was fairly homogenous across curves, while the downward concavity was fairly heterogeneous, fanning out to cross the 2.60V ERI threshold at different durations. We believe that the battery duration will continue to grow as the window from the initial implant expands to encompass 5 years from our last implant inclusion.

Title: DBS Plus: combining deep brain stimulation and autologous peripheral nerve grafts as an approach to treat motor and cognitive symptoms of Parkinson's disease

Authors: *C. G. VAN HORNE, G. QUINTERO, J. GURWELL, A. ANDERSON, A. WELLEFORD, J. R. LAMM, J. SLEVIN, G. GERHARDT, G. GERHARDT;
Dept Neurosurg, Univ. of Kentucky, Lexington, KY

Abstract: Introduction: We are investigating a strategy that couples a biological therapy with DBS surgery in an attempt to restore areas of the brain affected in PD. We grafted autologous Schwann cells from the sural nerve, known to release a host of growth factors including GDNF, NGF, BDNF, and NT-3. We describe our ongoing clinical trials examining the safety and

feasibility of implanting autologous peripheral nerve grafts in PD in patients undergoing DBS surgery.
Methods: DBS surgery targeting the subthalamic nucleus or internal globus pallidus was performed using standard procedures. A 5mm section of sural nerve was excised, stripped of the epineurium, cut into 1mm pieces, and unilaterally delivered into the area of the substantia nigra (SN) or nucleus basalis of Meynert (NBM). Adverse events were continuously monitored. Assessments included neurocognitive performance, quality of life, gait, (123I-ioflupane) SPECT imaging, and MR imaging at baseline and at the end of the study, 24 months after the implant surgery. Subjects undergo a Unified Parkinson's Disease Rating Scale (UPDRS) evaluation before surgery and at 6, 12, 18 and 24 months after surgery.
Results: We recently completed a 1-year Phase I study (NCT01833364) of 8 participants and found an adverse event profile comparable to standard DBS surgery. In addition, 6 of 8 participants showed a lower UPDRS III motor score than at baseline (25.5 ± 16.8 at 12 months vs. 32.5 ± 9.8 at baseline; Mean ± SD, N=8) considered a moderate clinically important difference (Shulman et al. 2010). This compares to 12 PD patients with bilateral DBS alone at 12 months showing a 5 point increase (60.7 ± 14.1 at 12 months vs. 55.7 ± 17.4). A follow-up, open-label, two-year study of safety and feasibility (NCT02369003) has been initiated that allows DBS of the GPi. Mean age for participants was 66.6 ± 6.9, Hoehn & Yahr score: 3.2 ± 0.5, UPDRSIII OFF medication: 37.7 ± 9.5, and UPDRSIII ON medication: 18.3 ± 10.5. One year data for this group will be presented. Participants showed a decrease in striatal 123I-ioflupane binding with SPECT imaging. Overall, we have successfully completed peripheral nerve graft delivery to the SN in 14 participants, and to the NBM in 6 participants in this study. Immediate post-operative MRIs did not indicate evidence of abnormal tissue disruption. There have been no serious adverse events related to graft placement.
Conclusions: Initial results from two clinical trials indicate a potentially safe and feasible means of delivering biological therapy with DBS surgery. With respect to motor symptoms, participants with grafts have reduced UPDRS III scores compared to baseline and to controls, who showed and increase in their score.

Title: Dopaminergic medication and subthalamic deep brain stimulation do not improve inter-limb coupling in Parkinson's disease

Authors: *J.-F. DANEAULT[1,2], B. CARIGNAN[3], A. SADIKOT[2], C. DUVAL[3];
[1]Physical Med. and Rehabil., Harvard Med. Sch., Charlestown, MA; [2]McGill Univ., Montreal, QC, Canada; [3]Univ. du Québec à Montréal, Montréal, QC, Canada

Abstract: INTRODUCTION: Parkinson's disease (PD) is a progressive neurodegenerative disorder that leads to severe motor and non-motor impairments. The motor impairments are believed to be caused by aberrant neuroplastic changes in the basal ganglia as well as primary and accessory motor networks. We have previously demonstrated that inter-limb coupling is altered in patients with PD. Inter-limb coupling is a specific feature of bimanual tasks characterized by the harmonization of movement parameters between limbs. OBJECTIVES: The goal of the current study was to identify the impact of subthalamic deep brain stimulation (DBS) and dopaminergic medication on inter-limb coupling. METHODS: Twenty patients with PD were first tested approximately one week before subthalamic DBS surgery. After surgery, when their motor state was deemed stable by their treating physician, patients were again assessed. Pre- and post-surgery assessments were performed on and off medication. Post-surgery assessments were also performed on and off DBS. Patients were asked to perform rapid repetitive pronation-supination movements unimanually and bimanually. The difference in mean amplitude and mean duration of cycles between hands was computed in order to assess spatial and temporal inter-limb coupling, respectively. Structural coupling between hands during the bimanual task was also computed. RESULTS: Pre-surgery off medication data replicated our previous data showing that PD patients exhibit temporal inter-limb coupling but not spatial inter-limb coupling. Results of the current study demonstrate that the temporal inter-limb coupling exhibited by patients with PD is not altered by either dopaminergic medication or subthalamic DBS. This indicates that temporal inter-limb coupling is likely mediated by structures not affected by PD and that lie outside the networks whose activity is altered through dopaminergic medication or subthalamic DBS. The lack of spatial inter-limb coupling was not corrected by either dopaminergic medication or subthalamic DBS. This indicates that spatial inter-limb coupling is likely mediated by structures that are affected by PD but that lie outside the networks whose activity is altered through dopaminergic medication or subthalamic DBS. CONCLUSION: The current study provides preliminary insight into the possible neural mechanisms mediating inter-limb coupling. This may lead to a better understanding of bimanual coordination as well as the development of novel interventions to improve the performance of bimanual tasks in patients with PD.

Title: A low-cost, intraoperative movement quantification system for DBS surgery and neurophysiology

Authors: *E. SCHAEFFER[1], D. LIU[1], M. AHN[1,2], J. A. GUERIN[1,2], S. LEE[1,2], W. F. ASAAD[1,2,3,4,5];
[1]Neurosci., Brown Univ., Providence, RI; [2]Brown Inst. for Brain Sci., Providence, RI; [3]Neurosurg., Brown Univ. Alpert Med. Sch., Providence, RI; [4]Neurosurg., Rhode Island Hosp., Providence, RI; [5]Rhode Island Hosp. Norman Prince Neurosciences Inst., Providence, RI

Abstract: Parkinson's Disease (PD) and Essential Tremor (ET) are the two most common movement disorders. In severe, medication-refractory cases, Deep Brain Stimulation (DBS) is often performed as an awake neurosurgical procedure to help alleviate these motor symptoms. During the surgical implantation of DBS electrodes, microelectrode recordings are employed to identify the position of the electrodes as they are advanced toward the predetermined therapeutic target area of the brain. For PD, this target is often the subthalamic nucleus (STN) or the globus pallidus internus (GPi), and for ET the target is the ventral intermediate nucleus of the thalamus (VIM). The somatotopic organization of these target structures is utilized to guide the final placement of DBS electrodes by assessing changes in neural activity in response to passive or active movements of the patients' extremities. Typically, however, the audible detection of such modulations of neural activity is reliant upon the perception of trained observers, which can be a biased assessment. Background noise from both neural and non-neural sources contribute to the inherently qualitative nature of this assessment. Thus, in the intraoperative setting, there is a need for online quantification of synchronized neural activity and movement data to increase the sensitivity and specificity of localizing the final stimulation target. To perform a principled assessment with high temporal precision of neural changes due to movement, we developed a low-cost, Arduino-based Inertial Measurement Unit (IMU) with generalized analog outputs to enable synchronization with our neural data acquisition hardware. We discuss how our system

may help to improve understanding of the relationship between somatotopy and therapeutic benefit, ultimately leading to improved care for PD and ET patients.

Title: Impact of dbs-stn on speech for people with parkinson disease impact of dbs-stn on speech for people with parkinson disease impact of dbs-stn on speech for people with parkinson disease

Authors: *L. A. MAHLER[1], D. RYDER[2];
[1]Interdisciplinary Neuroscience/Communicative Disorders, [2]Interdisciplinary Neurosci. Program, Univ. of Rhode Island, Kingston, RI

Abstract: *Objective:* The purpose of this study was to describe speech characteristics of two adults with idiopathic Parkinson disease before and after receiving deep brain stimulation of the subthalamic nucleus (DBS). *Methods:* A single-subject A-B-A-A research design was used to detect the impact of DBS on characteristics of speech and voice. Evaluations were obtained at three time points; pre-surgery, post-surgery, and follow-up. DBS01 was a 53-year-old male two years post diagnosis. His speech characteristics were consistent with hypokinetic dysarthria including reduced speech intensity, mildly imprecise articulation, and monotone pitch. He received bilateral electrode placements in the subthalamic nucleus. DBS02 was a 58-year-old male five years post-diagnosis. He had hypokinetic dysarthria characterized by reduced speech intensity, breathy voice, monotone pitch, and mildly imprecise articulation. He received unilateral electrode placement in the left subthalamic nucleus. The dependent variables included: intelligibility for words and sentences, speech intensity (dB SPL), and vowel space area. *Results:* There was a statistically significant decrease ($p=0.01$) in single word intelligibility for DBS01 from 86.8% (11.2) pre-surgery to 70.4% (4.6) at follow-up. Sentence intelligibility remained unchanged. There was a statistically significant increase ($p=0.02$) in single word intelligibility for DBS02 from 79.6 (6.2) to 90.4 (3.8) post-surgery that returned to baseline at follow-up. Sentence intelligibility remained unchanged. Both participants read words and sentences at reduced intensity and this did not change following surgery. Average loudness for DBS01 during

word reading was 58.9 (1.9) pre-surgery and 58.1 (2.9) post-surgery and for DBS02 was 59.8 (3.2) pre-surgery and 59.2 (3.0) post-surgery compared with average normal loudness for a male of 72.0 dB SPL measured at 40 cm. Vowel space area decreased for DBS01 from 199,000 Hz^2 pre-surgery to 175,000 Hz^2 at follow-up and increased for DBS02 from 170.000 Hz^2 pre-surgery to 218,000 Hz^2 at follow-up. *Conclusions:* DBS01 received bilateral DBS and his results showed a decline in single word intelligibility following surgery and a compression of vowel space area associated with less precise articulation. DBS02 received unilateral DBS and his results showed an increase in single word intelligibility and an expansion of vowel space area associated with greater precision of articulation. The variability of responses in these two participants indicates that further research is necessary to understand the impact of DBS on speech, which can affect quality of life for people with PD.

Title: Modeling speech disorders in parkinson’s disease using parsimonious factors

Authors: *I. EL MOUDDEN[1], M. OUZIR[2], B. BENYACOUB[1], S. ELBERNOUSSI[1]; [1]Fac. of Sci. Mohammed V Univ. In Rabat, Rabat, Morocco; [2]Dept. of Biol., Lab. of biochemistry and Immunology, Fac. of Sciences, Mohammed V Univ. in Rabat, Rabat, Morocco

Abstract: Speech disorders represent an early and common manifestation of Parkinson’s disease. The speech impairment relevant to Parkinson’s disease is described as dysphonia (inability to produce normal vocal sounds) and dysarthria (difficulty in pronouncing words). Class prediction is an essential task in automatic speech treatment. Many classification experiments have been performed which focuses on the automatic detection of Parkinson’s disease patients from healthy speakers, but results are still not optimistic. High dimensionality of data is a major problem usually seen in accomplishing this task. A proposed framework to solve this problem is to employ dimension reduction statistical techniques. In this work, the potential of Common factor analysis (CFA), Principal Component Analysis (PCA) based modeling in dimensionality reduction is taken into consideration as the data smoothening tool with multiclass target expression data. After, on the basis of suggested CFA and PCA-based modeling, the power class prediction of logistic regression (LR) and decision tree (DT) in numeric data to develop an advanced classification model is investigated. This framework is applied to a publicly

available Parkinson's disease dataset Silverman voice treatment (LSVT). The main advantage of those approaches is that the number of factor can be effectively reduced from p=309 to k=32 for LSVT Voice Rehabilitation dataset, with a fine classification accuracy of 100% and 99,92% for CFA-LR and PCA-LR respectively. In addition, using only 9 dysphonia features, classification accuracy was (99.20%) and (99.11%) for CFA-DT and PCA-DT respectively. In sum, our combined dimension reduction and data smoothening approaches have significant potential to minimize the number of features and increase the classification accuracy and then automatically classify subjects in Parkinson's disease patients from healthy speakers.

Title: Stimulation of the subthalamic nucleus exacerbates dysarthria in a rat model of Parkinsonism

Authors: *A. D. DORVAL[1], N. O. KING[3], C. J. ANDERSON[2];
[1]Dept. of Bioengineering, [2]Dept. of Neurol., Univ. of Utah, Salt Lake City, UT; [3]Dept. of Biomed. Engin., Washington Univ., St. Louis, MO

Abstract: Deep brain stimulation (DBS) of the subthalamic nucleus typically alleviates most of the primary motor symptoms of parkinson disease (PD) - resting tremor, bradykinesia, and rigidity - but its effect on more centralized symptoms (e.g., postural instability) is less universally therapeutic. Recent work suggests that DBS may worsen medial, secondary motor symptoms including parkinsonian dysarthria, an umbrella term that describes vocal articulation problems resulting in soft, slurred speech, and presumably related to an underlying hypokinesia. Because the mechanisms of DBS-exacerbated dysarthria are poorly understood and difficult to study in patients with PD, we developed a rodent model of DBS-exacerbated dysarthria. We used a standard rat model of DBS-alleviated PD: 6-hydroxydopamine was injected to the medial

forebrain bundle of adult male rats, lesioning dopaminergic neurons in substantia nigra pars compacta; and therapeutic high frequency stimulation was delivered to the subthalamic nucleus. Ultrasonic (20-100 kHz) mating calls were recorded from sexually -experienced and -frustrated males as they were exposed to, but restrained from, female rats in estrus. Vocalization statistics were calculated from mating calls collected under naïve, PD, and DBS-alleviated conditions. Compared to naïve, rats in the PD condition made fewer calls of shorter duration and less complex structure. To the extent that these changes represent aspects of hypokinetic dysarthria, each aspect was exacerbated by putatively therapeutic DBS. Interestingly, individual utterances spanned a wider frequency range in the PD condition compared to naïve, and this effect was also exaggerated by DBS. We propose that together, the changes in vocalization statistics — call recurrence, duration, complexity, and frequency range — constitute a rodent model of parkinsonian dysarthria. Our presentation will include a detailed procedure for vocalization filtering and statistic calculation, as well as analyses of these vocalization statistics in both the low (20-40 kHz) and high (40-100 kHz) frequency call ranges. In future work, this rodent model will enable explorations of the mechanisms of DBS-exacerbated parkinsonian dysarthria, and potentially help modify DBS therapy to alleviate dysarthria and improve other medial symptoms.

Title: Cellular pathomechanisms of Hereditary Sensory Neuropathy type 1 (HSN1) in mammalian motor neurons

Authors: ***E. WILSON**[1,2], B. KALMAR[1], M. KUGATHASAN[1,2], A. ABRAMOV[3], M. M. REILLY[2], L. GREENSMITH[1,2];

[1]Sobell Dept. of Motor Neurosci. and Movement Disorders, [2]MRC Ctr. for Neuromuscular Dis., [3]Dept. of Mol. Neurosci., UCL Inst. of Neurol., London, United Kingdom

Abstract: HSN1 is a peripheral neuropathy most frequently caused by missense mutations in the *SPTLC1* or *SPTLC2* genes, which code for two subunits of the enzyme serine palmitoyltransferase (SPT). SPT catalyzes the first and rate limiting step of *de novo* sphingolipid synthesis. It has been shown that mutations in SPT causes a change in enzyme substrate specificity which results in the production of two atypical sphinganines, deoxysphinganine (DSp) and deoxymethylsphinganine (DMSp), rather than the normal enzyme product, sphinganine (Sp). Levels of DSp and DMSp are elevated in the blood of HSN1 patients and this is thought to cause the peripheral nerve damage characteristic of the disease, which affects both sensory as well as motor axons. However, the underlying pathomechanism of how DSp and DMSp damage neurons remains elusive. In this study DSp and DMSp mediated neurotoxicity was examined in primary mammalian motor neurons by assessing cell survival and neurite outgrowth. These abnormal enzyme products were found to have a rapid, dose dependent, neurotoxic effect in motor neurons. We also explored the potential mechanisms that may underlie DSp and DMSp neurotoxicity and found that mitochondrial dysfunction and calcium handling deficits may be key mediators of abnormal sphingolipid neurotoxicity.

Title: Temporal course and relationship to nerve injury severity of the glucose hypermetabolism in denervated skeletal muscle

Authors: *S. LEE[1], H. SEO[2], B.-M. OH[2], H. CHOI[3], G. CHEON[3,4], S.-U. LEE[5], K. KIM[2]; [1]Dept. of Rehabil. Med., Seoul Natl. Univ. Hosp., Seoul-City, Korea, Republic of; [2]Dept. of Rehabil. Medicine, Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of; [3]Dept. of Nuclear Medicine, Seoul Natl. Univ. Ctr., Seoul, Korea, Republic of

Abstract: Glucose hypermetabolism in denervated skeletal muscle is a peculiar phenomenon which has been shown by our previous animal study. The purpose of this study is to investigate the relationship between the severity of nerve injury and the signal intensity of l8F-FDG uptake and the temporal course of glucose hypermetabolism in denervated muscles. One week after partial ligation of left peroneal nerve, 18F-FDG PET scans were done and mean lesion-to-normal counts ratios (LNR_{mean}) were calculated for anterolateral compartment regions of interests (ROIs). To examine the temporal course, serial 18F-FDG PET scans and electromyography (EMG) were done in complete sciatic transection with contralateral sham-operation. In the partial peroneal injury model, there was strong positive correlation between electrophysiologically calculated nerve injury severity and LNR_{mean} (Pearson correlation coefficient 0.63, $p<0.03$). Seiral 18F-FDG PET scans in complete injury model showed significantly increased l8F-FDG uptake began at 2 days (LNR_{mean}, left, 3.15 ± 0.82; right, 1.33 ± 0.21, $n = 5$, $P < 0.05$) after denervation and continued to 12 weeks. Fibrillation potentials and positive sharp waves in EMG were abruptly appeared in 3 days and disappeared in 12 weeks after the surgery. Our study demonstrated that the amount of glucose hyperrmetabolism in denervated skeletal muscle is related to nerve injury severity and it has temporal characteristics after nerve injury.

Title: Target expression of human heat shock protein 27 transgene in neurons promotes synapse reinnervations & functional recovery after prolonged muscle denervation

Authors: *P. ASTHANA[1], G. KUMAR[1], C. H. E. MA[1,2];
[1]Dept. of Biomed. Sci., City University of Hong Kong, Kowloon, Hong Kong; [2]Ctr. for Biosystems, Neuroscience, and Nanotechnology, City University of Hong Kong, Kowloon, Hong Kong

Abstract: Peripheral nerves are fragile and susceptible to physical trauma such as car accidents, traction injury, compression and lacerations. The slow growth rate of peripheral axons limits functional recovery in patients, which involve long-distance axonal regeneration. Delay in target muscle reinnervation makes the distal milieu non-permissive for the regenerating axons and the denervated muscle undergoes atrophy. Previous studies showed that these regenerating axons must arrive at the target muscle within a "critical period" of about 35 days in mice after multiple sciatic nerve crush (to delay muscle reinnervations), in order to restore motor function recovery. Our previous studies showed that forced expression of human Hsp27 (hHsp27) in neurons accelerated axonal regeneration and functional recovery in transgenic (Tg) mice after peripheral nerve injuries. In the present studies, sensory and motor functional recovery was significantly improved in hHsp27 Tg mice compared with the littermate (LM) controls. The number of axons in Tg and LM mice was comparable, however; higher number of fully innervated neuromuscular junction (NMJ) was observed in hHsp27 Tg mice than in the LM controls. Electrophysiological studies showed that muscle electrical activity increased considerably in hHsp27 Tg mice, which in line with the NMJ data. In addition, Plantar muscle mass was significantly higher in hHsp27 Tg mice than the LM controls, which showed reduction of muscle atrophy in Tg mice.

Title: Sensory neuron fate is developmentally perturbed by Gars mutations in peripheral neuropathy

Authors: *J. N. SLEIGH[1], J. M. DAWES[2], S. J. WEST[2], E. L. SPAULDING[3], A. GÓMEZ-MARTÍN[1], R. W. BURGESS[3], M. Z. CADER[2], K. TALBOT[2], D. L. BENNETT[2], G. SCHIAVO[1];

Abstract: Charcot-Marie-Tooth disease type 2D (CMT2D) is a peripheral nerve disorder caused by dominant, toxic, gain-of-function mutations in the widely expressed housekeeping gene, *GARS*. *GARS* encodes glycyl-tRNA synthetase (GlyRS), which serves to link glycine to its cognate transfer RNA, thereby ensuring the fidelity of the genetic code. The mechanisms underlying selective nerve pathology in CMT remain unresolved, as does the cause of the mild-to-moderate sensory involvement that distinguishes CMT2D from the allelic disorder distal spinal muscular atrophy type V. To elucidate the origin of afferent nerve pathology, we examined the sensory nervous system in CMT2D mice. We show that the equilibrium between functional subtypes of sensory neurons in dorsal root ganglia is distorted by *Gars* mutations, leading to sensory defects in peripheral tissues and correlating with overall disease severity. CMT2D mice display sensory behaviour deficits concordant with the afferent imbalance, which is present at birth and non-progressive. These data indicate that sensory neuron identity is prenatally perturbed in *Gars* mice, suggesting that both neurodevelopmental and neurodegenerative mechanisms contribute to CMT2D pathogenesis.

Abstract: Introduction: Inherited peripheral neuropathies are an important health concern for which there is currently no disease-modifying therapy. Dogs are affected by a variety of peripheral neuropathies that are breed-specific, indicating a strong genetic component. The use of in-bred populations, such as pure-bred dogs, is advantageous for genetic dissection of disease. Acquired peripheral neuropathy (APN) is an inherited late-onset generalized polyneuropathy with high prevalence in Labrador Retrievers. The most prominent features of APN, laryngeal paralysis and pelvic limb weakness, are associated with the longest peripheral motor nerves in the dog. The pathologic features of APN are similar to human peripheral neuropathy. The genetic basis of APN has not been determined.
Objective/Hypothesis: Our objective was to undertake a discovery genome-wide association study (GWAS) of APN in Labrador Retriever. APN is most likely a monogenic trait although more than one causal variant may explain a common phenotype.
Methods: We conducted a GWAS using 91 pure-bred Labrador Retrievers (n=65 cases, n=26 controls) using linear mixed model analysis with GEMMA. Direct siblings were excluded.
Case criteria: Dogs either received airway surgery for APN or had clinical signs of inspiratory noise and pelvic limb deficits indicating polyneuropathy. Dogs were excluded if evaluation suggested APN was not idiopathic.
Control criteria. Dogs usually exhibit signs by 11 years of age. Control dogs were ≥11.5 years of age with no clinical signs of respiratory obstruction and no evidence of polyneuropathy on neurologic examination. Dogs are continually monitored to confirm phenotype-negative status.

We used 118,952 SNP markers for analysis. Genome-wide significance was $P<2.7E-6$, based on Bonferroni correction of $P<0.05$ for 18,481 haplotype blocks using PLINK.
Results: This GWAS yielded a significant SNP association with the APN trait at $P=6.74E-7$. Genotypes-phenotype association analysis suggest that APN is an autosomal dominant Mendelian trait.
Discussion: We have identified a candidate locus in the dog genome that associates with a naturally occurring degenerative peripheral neuropathy with high prevalence in the most common dog breed in the USA. Our results suggest that APN is an autosomal dominant Mendelian trait in the Labrador Retriever. The work presented here is expected to enable discovery of the APN causal genetic variant. This work is a critical step towards development of a naturally occurring animal model for human peripheral neuropathy.

Title: Regulation of human peripheral myelin protein 22 by miR-29a

Authors: *L. NOTTERPEK[1], J. SERFECZ[2], A. FAN[2], S. LEE[2], R. RENNE[2];
[1]Neurosci., McKnight Brain Inst, Univ. Florida, Gainesville, FL; [2]Univ. of Florida, Gainesville, FL

Abstract: Peripheral myelin protein 22 (PMP22) is a dosage sensitive, disease-associated protein primarily expressed in myelinating Schwann cells. The restricted expression of the PMP22 protein in comparison to its ubiquitously detected mRNA supports a role for post-transcriptional regulation. MicroRNAs (miRNA) are small regulatory molecules that function at a post-transcriptional level by targeting predominantly 3'UTRs of mRNAs. Previously we demonstrated that in rat and mouse Schwann cells PMP22 is post-transcriptionally regulated by miRNAs, as over-expression of miR-29a reduces steady-state PMP22 levels, while inhibition of endogenous miR-29a relieves the miRNA-mediated repression of the gene (Verrier et al., 2009).

In the current study we asked if the human PMP22 transcript could be similarly inhibited by miR-29a in samples from Charcot-Marie-Tooth 1A (CMT1A) patients and in a rodent model of the disease. By bioinformatics we determined that the human PMP22, including the duplicated gene in CMT1A patients, indeed contains the full-length 3'UTR, and the conserved seed sequence of the miR-29a binding site. Next, using a Luciferase reporter assay in HEK293 cells we demonstrated that transfection with a miR-29a mimic, but not with a negative mimic control, is associated with an approximately 20% reduction in PMP22-like reporter activity. In dermal fibroblasts from CMT1A patients, we detected an elevated expression of PMP22 mRNA, which was effectively repressed by approximately 28-50% after transfection with a miR-29a mimic. As a control of specificity, a scrambled mimic did not lead to a reduction in PMP22 message levels. To further validate this approach, we cultured Schwann cells from the CMT1A mouse model named C22, which express approximately 8-10 fold elevated levels of the human PMP22 mRNA, as compared to the endogenous mouse mRNA. In agreement with data from the experiments in human fibroblasts, transfection with a miR29a mimic, but not with control scrambled miR, led to a reduction in the human PMP22 mRNA in cultured Schwann cells from the C22 mouse. Significantly, the human miR-29a mimic did not affect the expression of the mouse transcript, which indicates specificity of this approach. Together these results support further studies with miR29a as a potential therapeutic strategy to modulate increased expression of PMP22 in Schwann cells from CMT1A patients.

Title: Blockade of adenosine A_{2A} receptors protects against corticosterone effects in hippocampal neuronal cell line

Authors: *M. P. KASTER[1], N. PLATT[2], A. B. H. HRYB[2], F. N. KAUFMANN[2], M. P. CUNHA[2], A. COSTA[2], A. S. RODRIGUES[2];
[2]Dept. of Biochem., [1]Univ. Federal De Santa Catarina, Florianópolis, Brazil

Abstract: Stressful events may elicit different levels of arousal responses across individuals, leading to a continuum range of adaptive to extreme and maladaptive responses that are ultimately involved in disease manifestation. Indeed, hyperactivation of the hypothalamic-pituitary-adrenal (HPA) axis is a common finding in major depression, leading to increased levels of glucocorticoids, which are known to cause oxidative stress imbalance and cellular death, particularly in the hippocampus, a key region implicated in mood regulation. We recently demonstrated that blockade of adenosine A_{2A} receptors (A2AR) is capable to prevent behavioral and synaptic dysfunction in animal models of depression (Kaster et al., PNAS, 2015; Machado et al., Molecular Neurobiology, 2016). Thus, A2AR manipulation emerges as and attractive neuroprotective strategy to counteract stress effects in brain circuits. The main goal of this study was to investigate the effect of A2AR blockade in a model of stress induced by corticosterone in HT-22 hippocampal cell line. Western blot analysis demonstrated that HT-22 cells express glucocorticoid receptors (GR) and A2AR. Treatment with corticosterone significantly reduced the cellular viability evaluated by MTT reduction (24h, 50-1000 μM, $p<0.05$) and LDH release (24h, 500-1000uM, $p< 0.05$). Corticosterone (50 uM for 24h) also increased cell death assessed by propidium iodide ($p< 0.05$). The immunocontent of the pro-apoptotic protein Bax was increased after 24h incubation with corticosterone 50 uM, with no changes in Bcl-2 levels. Also, incubation of HT-22 cells with DCFDA demonstrated increased production of reactive oxygen and nitrogen species in the first 60 min of exposition. The results were compared using one-way ANOVA followed by Duncan *post-hoc* test).Pre-incubation (24h before) and co-incubation of ZM-241385 (a A2AR antagonist, 0.5 uM) and corticosterone (50 uM, 24h) was capable to prevent the effects of corticosterone on cell viability. These results were also obtained with the GR antagonist RU486 (2.5 e 5 μM) and with the selective serotonin reuptake inhibitor fluoxetine (10 uM). The results suggest that blockade of A2AR was capable to prevent the reduction in cell viability induced by corticosterone in HT-22 cells, suggesting that A2AR might represent an important strategy to counteract the effects of stress.

Title: Characterization of M2 pathway following steroid exposure in neonatal microglia

Authors: *I. LONDONO[1], W. C. PIERRE[2], S. CHEMTOB[3], G. A. LODYGENSKY[3]; [1]Ste-Justine Hosp. Res. Ctr., Montreal, QC, Canada; [2]Pediatrics, [3]Pediatrics and Pharmacol., CHU Sainte Justine, Univ. de Montréal, Montreal, QC, Canada

Abstract: Introduction: Microglia activation is the primary hallmark of white-matter injury in preterm. Microglia phenotype in vivo and in vitro, following stimulation, has been described as pro-inflammatory (M1) and anti-inflammatory (M2). Corticosteroids such as dexamethasone (Dex) and hydrocortisone (HC) are well known anti-inflammatory agents extensively used to treat or prevent chronic bronchopulmonary dysplasia in preterm. Dex was mainly associated with impaired neurodevelopmental outcome. Objective: Compare the effect of hydrocortisone and dexamethasone on pro-inflammatory (M1) and anti-inflammatory (M2) pathways in activated neonatal microglia. Methods: Primary mixed glial cell cultures were prepared from whole brain of P1 Sprague-Dawley rats. Primary microglia culture were isolated from mixed glial cell cultures after 14 days in vitro and plated in 6-well plates at a density of $5x10^5$ cells/ml in DMEM supplemented with 10% FBS. Forty-eight hours later, microglia were treated with DMEM, LPS (1µg/ml) ± Dex (0.5µg/ml) or HC (13.33µg/ml) (n=3 for each condition). After 24h, cells were harvested and RNA was collected to evaluate the expression of M1 (iNOS and Il-1β) and M2 (Il-10 and arginase 1) related genes. Statistical comparisons between groups were done using Kruskal-Wallis tests. Results are presented as fold change to DMEM-treated microglia ±SEM. Results: LPS caused an activation of primary microglial cell toward an M1 phenotype as seen with the increased expression of iNOS and IL-1β. Co-incubation of Dex with LPS prevented the induction of M1 genes and induced significant but small increase in IL-10 expression. HC prevented the LPS-induced M1 phenotype in microglia without any effect on M2. Conclusion: Corticosteroids inhibited LPS-induced M1 activation phenotype in microglia. Dex induced a slight increase in the expression of IL-10, a known anti-inflammatory cytokine. An extensive study with more animals is underway evaluating a wide array of markers in each pathway. It appears that steroids don't have a large impact on neonatal M2 pathway.

Title: Components of an Hsp70 disaggregation/refolding machine co-localize at nuclear speckles following thermal stress in differentiated human neuronal cells

Authors: ***C. A. DEANE**, I. R. BROWN;
Ctr. for the Neurobio. of Stress, Dept. of Biol. Sci., Univ. of Toronto Scarborough, Toronto, ON, Canada

Abstract: Heat shock proteins (Hsps) are a set of highly conserved proteins involved in cellular repair and protective mechanisms. They counter protein misfolding and aggregation that are characteristic features of neurodegenerative diseases. Hsps act co-operatively in disaggregation/refolding machines that assemble at intracellular sites of protein misfolding and aggregation. Members of the Hsp40 family act as 'holdases' to detect and bind misfolded proteins, which are then transferred to members of the Hsp70 family that act as 'foldases' to refold proteins to biologically active states. Hsp105α is an important additional member of the mammalian disaggregation/refolding machine that acts as a 'disaggregase' to promote the dissociation of aggregated proteins. Components of a disaggregation/refolding machine co-localized at nuclear speckles following thermal stress in differentiated human SH-SY5Y neuronal cells, namely: Hsp70-1 (HSPA1A), Hsp40-1 (DNAJB1), Hsp40-4 (DNAJA1) and Hsp105α (HSPH1). Nuclear speckles are rich in mRNA splicing factors, and heat shock is known to disrupt mRNA splicing which must recover following stressful stimuli. Interestingly, constitutively expressed Hsc70 (HSPA8) also co-localized at nuclear speckles with elements of a disaggregation/refolding machine following heat shock. Hence, neurons have the potential to rapidly assemble a disaggregation/refolding machine after cellular stress using constitutively expressed Hsc70 without the time lag needed for synthesis of stress-inducible Hsp70. Constitutive Hsc70 is abundant in particular classes of neurons in the mammalian brain and has been proposed to play a role in pre-protecting neurons from cellular stress.

Title: Hipoglucemia coma induces overexpression of endoplasmic reticulum stress markers and caspase activation in parietal cortex and hippocampus: B-hydroxybutyrate as an alternative energy source

Authors: *M. FLORES, T. MONTIEL, C. TORRES-ESQUIVEL, L. MASSIEU;
Inst. de Fisiología Celular, Univ. Nacional Autónoma de México, Mexico, Mexico

Abstract: The brain consumes 20% of the total body energy and therefore it requires a continuous supply of glucose. Glucose is the main energy source in the brain and when blood levels drop below 54 mg/dl, some symptoms arise such as irritability, dizziness, blurred vision, confusion and tachycardia. If this condition is not corrected and blood glucose decays to less than 20 mg/dl, the hypoglycemic coma (isoelectricity) might occur leading to neuronal death. It has been observed that under conditions of prolonged fasting, other energy substrates, such as the ketone body, D-B-hydroxybutyrate (BHB) can be used as energy source, as it is converted to acetyl coenzyme A (acetyl-CoA). In previous studies we have observed that rats subjected to severe hypoglycemia and treated with D-BHB, show decreased cell death in the cerebral cortex. Similarly, cortical cultures exposed to glucose deprivation in the presence of D-BHB, preserve ATP levels and show increased survival, suggesting that D-BHB can be used as an alternative energy source in these conditions (Julio-Amilpas et al. 2015. J.Cereb. Blood Flow Metab 35:851-60). One of the most energy demanding cellular processes is protein synthesis and disruption of the endoplasmic reticulum (ER) homeostasis during energy failure, can block protein synthesis through the unfolded protein response (UPR). The UPR is triggered through the activation of three sensors able of detect the accumulation of misfolded proteins. One of them is the PERK pathway; under ER stress, GRP78 dissociates from PERK and triggers its dimerization and activation. PERK phosphorylates eIF2a, which inhibits global protein synthesis, alleviating ER stress. However, if ER stress persists, eIF2a promotes the translation of the mRNA of the transcription factor ATF4, which up-regulates chop gene expression. CHOP protein promotes the mitochondrial apoptosis pathway by the down regulation of Bcl-2. We have observed that rats subjected to the hypoglycemic coma, show an increase in the protein content of GRP78, ATF4 and CHOP, as well as an increase in eIF2a phosphorylation in the parietal cortex and the hippocampus. We also observed the proteolytic activation of caspase-7 and caspase-12. These

effects are attenuated when rats are treated with BHB. Results suggest that the hypoglycemic coma induces ER stress, which is possibly involved in apoptotic neuronal death and that attenuation of ER stress by D-BHB treatment might contribute to its protective action against neuronal death.

Title: Histone deacetylase inhibitor MS-275 protects Neuro2a cells from endoplasmic reticulum stress via mitochondrial enhancement

Authors: ***K. NAGAI**, H. SHIRAZAWA;
Dept. of Nutr., Koshien Univ., Takarazuka-Shi, Japan

Abstract: Histone deacetylase (Hdac) inhibitors are focused on the preventing function against neurodegenerative diseases. However, the specificity of Hdac inhibition and the detailed mechanisms on neuroprotection are remained unsolved. We previously observed that Hdac inhibition protected Neuro2a cells from endoplasmic reticulum induced cell death which is known to causes some neurodegenerative diseases, and increased intracellular mitochondria in Neuro2a cells. Thus, we hypothesized that Hdac inhibition protected the neuronal cells via mitochondrial enhancement. In this study, we analyzed effects of subtype specific Hdac inhibitors on the mitochondrial activity and protective functions against endoplasmic reticulum stress inducers, tunicamycin, thapsigargin, or amyloid β 1-40 in Neuro2a cells. Mitochondrial activities were analyzed by image-based cytometry analysis of the cells stained with mitochondrial membrane potential dependent fluorescent dye JC-1. Broad Hdac inhibitor sodium butyrate increased the number of the cells with high amount of mitochondria. Regarding subtype specific Hdac inhibitors, Hdac1 and 3 specific inhibitor MS-275 increased the number of the cells with high amount of mitochondria, but Hdac2 specific inhibitor apicidin and class IIA Hdac inhibitor MC1568 did not. The mitochondria increasing effect of MS-275 was inhibited by bromodomain inhibitor JQ1. It suggests that the effect is Hdac associated transcription was

involved in the mitochondrial enhancement. Regarding cell protective effect, MS-275 attenuated tunicamycin, thapsigargin, and amyloid β 1-40 toxicity. And these protective effects were reduced in the presence of JQ1. It suggests that inhibition of Hdac 1 and/or 3 protects Neuro2a cells from endoplasmic reticulum stress induced toxicity. Our data suggest that inhibition of Hdac 1 and/or 3 protects neuronal cells from endoplasmic reticulum stress via mitochondrial enhancement, and the mitochondrial effect might contribute neurodegeneration preventing effects of Hdac inhibitors.

Title: Inhibition of autophagy by activation of M_3 muscarinic acetylcholine receptors in human SH-SY5Y neuroblastoma cells.

Authors: *P. ONALI, S. DEDONI, M. C. OLIANAS;
Univ. of Cagliari, Dept.Biomedical Sci., Monserrato, Italy

Abstract: Muscarinic acetylcholine receptors (mAChRs) have been shown to regulate neuronal cell proliferation and differentiation and to protect neuronal cells from apoptosis induced by a variety of insults. However, relatively little is known on the ability of mAChRs to regulate autophagy, an evolutionary conserved cellular response to different physio-pathological conditions. In the present study, we investigated the effect of mAChR stimulation on autophagy induced in human SH-SY5Y neuroblastoma cells by removal of serum and L-glutamine from the growth medium. Autophagy was monitored by measuring the levels of the autophagosome marker LC3-II and the autophagy substrate p62. We found that cell exposure to the cholinergic agonist carbachol (CCh) (30 μM) inhibited LC3-II accumulation and enhanced the levels of p62. The effects of CCh were mimicked by the mAChR agonist oxotremorine-M (100 μM) and blocked by atropine or the M_3 mAChR-preferring antagonist darifenacin, but not MT7, a selective M_1 mAChR blocker. CCh inhibition of autophagy was counteracted by blockade of $G_{q/11}$ with YM254890 and protein kinase C (PKC) with Go6983, bisindolylmaleimide and chronic treatmen with phorbol 12-myristate 13-acetate. Cell treatment with the mammalian target of rapamycin complex 1 (mTORC1) antagonist rapamycin completely suppressed CCh-induced

phosphorylation of S6 ribosomal protein, a mTORC1 target, and prevented the inhibitory effect of CCh on autophagy. These data indicate that in SH-SY5Y cells activation of $G_{q/11}$-coupled M_3 mAChRs inhibits starvation-induced autophagy by activating the PKC-mTORC1 signaling pathway.

Title: Ceftriaxone attenuates chronic mild stress induced spatial learning and memory deficits. Correlation with hippocampal NeuN and c-Fos expression.

Authors: ***J. A. SCHROEDER**[1], L. PEREZ[1], L. MININBERG[1], S. PIERCE[1], E. L. GOMYAW[1], S. F. KORNACKI[1], G. UMAN[1], R. CAREDENAS[1], A. F. WARREN[1], S. M. RAWLS[2];
[1]Dept Psychol, Connecticut Coll, New London, CT; [2]Pharmacol., Temple Univ. Sch. of Med., Philadelphia, PA

Abstract: Prolonged exposure to stress can result in a depressive state that is associated with hippocampal damage and learning and memory deficits that may be related to increased brain glutamate levels. The beta-lactam antibiotic ceftriaxone reduces extracellular glutamate by activating the glutamate transporter and enhancing synaptic glutamate clearance. The present study examined the effects of ceftriaxone on chronic mid stress (CMS)-induced depressive-like behavior and spatial learning and memory performance in rats. Twenty-five day CMS did not result in depressive-like behavior measured by sucrose preference and open field tests. However CMS resulted in acquisition and expression learning and memory deficits in Morris Water Maze performance. These deficits were attenuated by administration of ceftriaxone during stress exposure. Ongoing immunohistochemical studies will attempt to correlate hippocampal expression of c-Fos and NeuN with behavioral measures. These results suggest that stress-induced deficits in learning and memory are associated with increased brain glutamate levels and that these deficits can be prevented by enhancement of synaptic glutamate clearance.

Title: Control of neuronal inositol 1,4,5-trisphosphate receptor mediated calcium signaling by steroid hormone receptors

Authors: *P. KOULEN, A. A. LOPEZ, J. C. MEANS;
Basic Med. Sci. & Ophthalmology, Univ. of MO - Kansas City, Kansas City, MO

Abstract: Controlling the cytoplasmic concentration of free calcium ions (Ca^{2+}) is essential for the physiological activity of neurons and for neuronal survival under disease conditions. At the same time, the steroid hormones progesterone and the estrogen 17β-estradiol have been identified as neuroprotective and critical for proper neuronal viability. The present study determined novel mechanisms of action how signaling mediated by the interaction of inositol 1,4,5-trisphosphate receptors with steroid hormone receptors controls the intracellular Ca^{2+} concentration in neurons. Specifically, it was identified how direct binding of cytoplasmic estrogen receptors to inositol 1,4,5-trisphosphate receptors affects the activity of this major type of ligand-gated intracellular Ca^{2+} release channels in neurons. Using immunochemistry, optical imaging and electrophysiology, as well as immunochemical assays for determining protein-protein binding, changes in the activity of inositol 1,4,5-trisphosphate receptors after binding of steroid hormone receptors were determined. Binding of steroid hormone receptors to the intracellular Ca^{2+} release channel resulted in distinct changes in both channel open frequency as well as the number of channel openings at the single channel level and preservation of key biophysical parameters of the channels such as single channel conductance. These molecular changes in channel open probability were mirrored at the cellular level by altered release of Ca^{2+} from intracellular stores and altered susceptibility of neurons to disease stimuli. The work indicates that neuronal Ca^{2+} signaling mediated by inositol 1,4,5-trisphosphate receptors as Ca^{2+} dependent intracellular Ca^{2+} release channels is critically modulated by steroid hormone receptor binding. Such signaling controlled by protein-protein interactions in the central nervous system potentially provides a novel mechanism for drug development in the area of neurodegeneration.

Abstract: Because different neurodegenerative diseases share common pathological elements including neuroinflammation, calcium dyshomeostasis, excitotoxicity, blocked autophagy and cytoskeletal disruption it seems plausible that common junction points in cellular pathophysiology might be found such that one could treat a broad spectrum of neurodegenerative disorders with the same therapeutic agent. We have accumulated a body of data that bioavailable derivatives of the natural brain sulfur amino acid metabolite, lanthionine ketimine (LK) have potent neuroprotective and neurotrophic properties and treat preclinical models of diverse neurodegenerative conditions by a novel mechanism. In particular LK-ethyl ester (XN001) slows disease or reduces histopathological correlates of injury in mouse models of amyotrophic lateral sclerosis (ALS); Alzheimer's disease; Batten disease (BD); glioma; multiple sclerosis; stroke and traumatic brain injury. XN001 acts in a novel fashion to bind the microtubule-associated protein CRMP2 (collapsin response mediator protein-2) to influence its conformation and sensitivity to phosphorylation. In stem cell derived neurons XN001 inhibits CRMP2 phosphorylation and promotes complex association of CRMP2 with Vps34 autophagy complex including AMBRA1 and beclin-1 and induces autophagy flux. In iPSC-derived neurons from Batten disease patients bearing a common 1kb deletion in *Cln3* (Battenin), CRMP2 phosphorylation is increased and autophagy flux is decreased which underlies CLN3-linked BD pathology. XN001 overcomes these impairments and normalizes CRMP2 phosphorylation as well as autophagy progression. In the $Cln3^{\Delta ex7/8}$ mouse model of BD, we show that in aging $Cln3^{\Delta ex7/8}$ mouse brain CRMP2

becomes hyperphosphorylated. Of practical importance to BD, XN001 significantly reduces autofluorescent ceroid in the cerebellum of these mice. These findings are discussed with reference to possible clinical utility of XN001 to treat a broad spectrum of neurodegenerative diseases involving pathological hyperactivation of CRMP2. KH is inventor of LKE; KH, LBW, and IN have financial interests in XoNovo.

Title: Phosphonate analogues of lanthionine ketimine as stimulators of cellular autophagy: development of small molecule treatments for neurological disorders

Authors: ***T. T. DENTON**[1], D. SHEN[2], A. HRISTOV[3], K. VENKOVA-HRISTOVA[3], K. HENSLEY[3];
[1]Washington State Univ. Col. of Pharm., Spokane, WA; [2]Pharmaceut. Sci., Washington State Univ. Col. of Pharm., Spoknae, WA; [3]Pathology, Univ. of Toledo, Toledo, OH

Abstract: Lanthionine ketimine (LK) is a natural amino acid metabolite found at low concentrations in mammalian brain tissue. LK and its synthetic ester derivative, LKE (XN-001) have potent neuroprotective, neurotrophic and anti-neuroinflammatory properties and increase autophagy in neurons and glia. In published and ongoing studies, LKE shows benefit in diverse preclinical models of Alzheimer's disease; amyotrophic lateral sclerosis; Batten disease; glioma; multiple sclerosis; traumatic brain injury and stroke. Using LK and LKE as lead compounds, we

have recently developed novel chemical approaches that allow access to new regions of structure-activity space around the LK core structure by replacing the carboxyl group on position 3 of LK with a phosphonate group (LK-P) either with retention or removal of the carboxylate group on position 5. We are assessing bioavailability and activity in an RG2 glioma cell based autophagy assay, employing quantitative western blot densitometry, wherein the new compounds were shown to increase autophagic flux evidenced by the compounds' ability to increase phosphatidylethanolamine conjugation to microtubule associated protein 1 light chain 3 (LC3-I ➔LC3-II conversion) in the presence of bafilomycin-A1. These results suggest that phosphonate analogues of LK retain cell penetrating ability and bioactivity with respect to autophagy stimulation in glial cell culture.

Title: Acute and chronic tissue effects of focused ultrasound neuromodulation assessed at the cellular and bulk tissue scale

Authors: *I. GUMENCHUK, J. A. N. FISHER;
Physiol., New York Med. Col., Valhalla, NY

Abstract: The use of transcranial low intensity focused ultrasound (FUS) is an emerging neuromodulation technique that shows promise for both therapeutic and research applications. In humans, for example, FUS can modulate EEG (Legon et al., *Nat. Neurosci.* 2014) and has been shown to affect mood (Hameroff et al., *Brain Stim.* 2013), suggesting general utility in treating psychiatric conditions for which the neural basis is not well understood. Compared with other noninvasive neuromodulation techniques such as transcranial magnetic stimulation (TMS), key technical advantages include high lateral resolution of stimulation (millimeter scale) at deep penetration depths (~10 cm) as well as increased MRI compatibility. With an eye toward eventual clinical implementation of the technology, a central criterion of regulatory agencies is that radiation emitting devices do not cause tissue modification. We explored potential biomarkers for adverse tissue effects by using real-time optical imaging as well as histological analysis following exposure to FUS with parameters previously utilized in the literature. Using a custom ultrasonic transducer apparatus that permits simultaneous optical imaging at the focus, we observed in brain slices, above ultrasound intensities sufficient to evoke motor responses but well below the regime of high-intensity focused ultrasound (HIFU), the emergence of focal lesions with increasing durations of exposure to pulsed ultrasound. The mechanical effect varied depending on the targeted brain region and stimulation parameters, and differed as well between the mouse and rat. At longer FUS exposures, we observed in survival experiments elevated levels of glial fibrillary acidic protein (GFAP) expression as well as evidence of neurodegeneration (via Fluoro Jade staining) as early as 24 hours post FUS and persisting at least 72 hours. At shorter US exposures, we observed less intense, diffuse patterns of expression and neurodegeneration that were nonetheless confined to the hemisphere of sonication. Consistent with the measured axial intensity profile at the acoustic focus, altered GFAP and Fluoro Jade labeling was observed at regions well below the cortex, most notably in the hippocampus and corpus callosum. Our results suggest that rather than a specific damage threshold, there appears to be a gradation of chronic tissue effects that result from exposure to the upper range of previously employed FUS neuromodulation parameters.

Title: The treatment of chronic craniofacial pain with novel gene therapy approaches.

Authors: *O. P. KEIFER, JR[1], J. MADER[2], N. M. BOULIS[2];
[2]Dept. of Neurosurg., [1]Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Chronic craniofacial pain is a devastating condition that significantly disables those who suffer from it. Despite being a well-known disease entity, little is understood about the pathophysiology. Further, there are few treatment options that provide any consistent or long-term solutions to the chronic pain (treatments may include pharmacological approaches or surgical approaches). Thus, the treatment of patients with chronic craniofacial pain presents a challenge to clinicians and researchers. In a readdress, we are presenting novel application of gene-based neuromodulation for the control of craniofacial pain, using established rodent models of Temporomandibular joint disorder (TMJD) and Trigeminal Inflammatory Compression (TIC) to assess efficacy. The TMJD model is a model for chronic nociceptive pain (pain caused by stimulation of pain receptors), while the TIC model is a model for neuropathic pain (pain caused by injury to the nerve). We show proof-of-concept results for the delivery of transgenes that are designed to affect the process of neural transmission and were delivered to the trigeminal pain pathway (i.e. pathways such as the Trigeminal Ganglion and Spinal Nucleus of V). The utility of different viral vector-based delivery systems and routes is also discussed for the two rodent models and compared. As a translational laboratory, our ultimate intention is to develop a gene-based neuromodulatory therapy that can be validated through human clinical trials.

Title: Biochanin A protects against stroke by induction of glutamate oxaloacetate transaminase

Authors: *S. KHANNA, R. STEWART, S. GNYAWALI, S. ROY, C. K. SEN, C. L. RINK; Surgery, Ohio State Univ., Columbus, OH

Abstract: Glutamate serves multi-faceted (patho)physiological functions in the central nervous system as the most abundant excitatory neurotransmitter and under pathological conditions of ischemic stroke as a potent neurotoxin. Glutamate oxaloacetate transaminase (GOT) has emerged as a new therapeutic target against ischemic stroke by metabolizing neurotoxic glutamate. In search of a small molecule inducer of GOT, we identified Biochanin A (BCA) as the most potent phytoestrogen isoflavone that increases GOT expression in neuronal cells. Here we hypothesize that BCA induces GOT expression by an estrogen related receptor alpha (ERRα) dependent mechanism. To test this hypothesis, neuronal cells in culture were treated with BCA. BCA treated cells showed significant increase in ERRα mRNA at 6h and GOT mRNA and protein expression at 24h. Cells treated with BCA were significantly protected against glutamate toxicity. Notably, this protection was lost in BCA treated cells when GOT was knocked down. To validate these findings in vivo, C57Bl/6 mice were intraperitoneally injected with either vehicle control (75% DMSO in water) or BCA (5 or 10 mg/kg body weight) daily for 4 weeks. Following delivery, mice were subjected to ischemic stroke using the intraluminal thread method of middle cerebral artery occlusion (MCAO). BCA levels were significantly increased in blood and brain of IP-injected mice as measured by HPLC. Immunohistochemical analysis confirmed increased expression of GOT in brain. BCA treatment significantly improved post-stroke sensorimotor function and attenuated stroke-induced lesion volume as measured by MRI. In this work we have identified BCA as a natural small molecule inducer of GOT. BCA is a safe, naturally occurring phytoestrogen isoflavone that represents a therapeutic target that lends itself to be translated to clinical study.

Title: CD163 has distinct temporal influences on intracerebral hemorrhage outcomes

Authors: *J. L. LECLERC, A. LAMPERT, C. LOYOLA AMADOR, B. SCHLACKMAN, S. DORE;
Anesthesiol., Univ. of Florida, Gainesville, FL

Abstract: Hemoglobin (Hb)/heme-induced toxicity following intracerebral hemorrhage (ICH) is a precipitating factor for neuroinflammation and secondary brain injury, which results in irreversible brain damage and enduring neurological deficits. The haptoglobin (Hp)-CD163 scavenging system is the primary defense mechanism in the body against the deleterious effects of extracorpuscular Hb/heme. Hp immediately and irreversibly binds any free Hb, and the complex is endocytosed by cells of the monocyte lineage via the CD163 receptor. When Hp levels are depleted, CD163 has been reported to directly decrease the toxic effects of Hb through direct binding. CD163 also has potent anti-inflammatory properties participating in the downregulation of inflammatory responses. This study is the first to investigate the role of CD163 after ICH. ICH was induced in wildtype and CD163-/- mice and various anatomical and functional outcomes were temporally assessed by histology and neurobehavioral testing. At 72h, CD163-/- mice have 33.2±4.5% and 43.4±5.0% smaller lesion and hematoma volumes, respectively, which are associated with 34.8±3.4% less perihematomal tissue injury (n=19-20/group, $p<0.0001$). These anatomical improvements were accompanied by significantly less neurological deficits, as identified by neurological deficit scoring and rotarod performance. At 10d, CD163-/- mice have 49.2±15.0% larger lesion volumes and worse neurological deficits, as identified by neurological deficit scoring and open field ambulatory ability (n=11-12/group, $p<0.05$). Mortality analyses and regressions of the neurobehavioral results identified the inflection point at 4d post-ICH. Mortality on or before day 4 (total deaths, n=13) and after day 4 (total deaths, n=9) significantly differed between the groups ($p = 0.0390$). WT mice accounted for the majority of deaths on or before day 4 compared to CD163 mice (76.9% vs. 23.1%). Immunohistochemical staining for heme oxygenase 1, iron, GFAP, IgG, Hb, VEGF, and PECAM-1 also revealed distinct temporal-dependent mechanistic changes. These novel findings reveal that CD163 has distinct temporal influences on ICH outcomes, with early beneficial effects but delayed injurious properties, signifying a discrete therapeutic window.

Abstract: Male neonate brains are more susceptible to the effects of hypoxia-ischemia (HI) related brain injury. Sex differences in expression and actions of neurotrophins may account for sexually differentiated consequences of HI. Our recent findings reveal that tyrosine kinase B receptor (TrkB) agonist, 7,8-dihydroxyflavone (7,8-DHF), exerts a profound neuroprotective effect in the hippocampi of female but not male neonate mice through phosphorylation of the TrkB post-HI *(in-vivo)*. Differential hippocampal TrkB phosphorylation is associated with increased hippocampal ERα expression in $ER\alpha^{+/+}$ female mice and gets ablated in $ER\alpha^{-/-}$ female mice. These results suggest a role of ERα in conferring responsivess to TrkB phosphorylation in female mice only. We hypothesized that differential ERα expression followed by TrkB phosphorylation and neuroprotection takes place in hippocampal neurons after in-vitro ischemia. Sexed hippocampal primary neuronal cultures were prepared from P1 C57BL/6J $ER\alpha^{+/+}$ and $ER\alpha^{-/-}$ mice in estrogen free medium and exposed to either normoxia or OGD for 4 h at DIV 7 followed by VC or 7,8-DHF treatment. After 24 h REOX, cells were stained for cell survival and p-TrkB. Expressions of ERα and aromatase were performed 3 and 24 of REOX using qPCR. For multiple comparisons ANOVA was used. 7,8-DHF enhanced TrkB phosphorylation in a dose responsive manner and promoted cell survival only in $ER\alpha^{+/+}$ female hippocampal neurons following OGD-REOX ($p < 0.05$). HI and 7,8-DHF mediated increases in TrkB phosphorylation

was ablated in ERα$^{-/-}$ male and female hippocampal neurons. Four h of OGD and 3 h of REOX induced higher ERα mRNA expression only in ERα$^{+/+}$ female hippocampal neurons. No differences were detected in aromatase mRNA expressions. Sexually differentiated TrkB phosphorylation in response to *in-vitro* ischemia enhanced with TrkB agonist therapy in the female hippocampal neurons is dependent on ERα and can be ligand independent. Future research will attempt to identify the mechanisms in which TrkB and ERα are related following *in-vitro* ischemia in hippocampal neurons. By understanding the sexually differential role of ERα-TrkB interaction in neuronal survival, we hope to provide novel insights into the etiology and targeted therapies post- HI.

Title: *In vitro* inhibition of tissue plasminogen activator induced neutrophil degranulation is time dependent following acute brain injury

Authors: *I. IWUCHUKWU[1], D. NGUYEN[2], N. MAHALE[2], L. ALLULLI[2], O. SULAIMAN[3];
[1]NEUROLOGY, Ochsner Hlth. Syst., New Orleans, LA; [2]Inst. of Translational Med., [3]Neurosurg., Ochsner Med. Ctr., New Orleans, LA

Abstract: Background Neutrophils are rapidly mobilized following acute brain injury and associated with MMP-9 release due to degranulation. Elevated MMP-9 levels are associated with blood brain barrier damage, cerebral edema, hemorrhagic transformation and expansion. TPA induces neutrophil degranulation. In this study, we compared the inhibition of TPA-induced neutrophil degranulation and MMP-9 release ex vivo, in neutrophils isolated from healthy individuals and patients with intracerebral hemorrhage (ICH). Methods Neutrophils were isolated from blood samples obtained from patients with ICH (within 24 hrs of symptom onset and daily; admission days 1-4) and healthy controls (N=4). Isolated neutrophils were plated on a 24-well poly-L-lysine coated tissue dish. This was followed by preincubation with sulfasalazine or pentoxyfylline for 30mins followed by addition of TPA (3mg/ml) and then incubated for 20, 30, 40 and 60mins. Cell media was removed and analyzed for proMMP-9 activity by gelatin gel

zymography. Band intensity corresponding to pro-MMP9 and active MMP-9 were quantified using ChemiDoc MP Imager. Results In both healthy controls and ICH patients, degranulation and release of proMMP-9 was observed in neutrophils incubated with TPA at all time points. In healthy controls, preincubation with sulfasalazine (10uM, 20uM, 50uM and 100uM) or pentoxyfyline (1nM) for 30mins followed by addition of TPA achieved 50% reduction in release of proMMP9 at all time points. However, in neutrophils obtained from ICH patients, 50% reduction in proMMP-9 was only observed in neutrophils obtained within 24 hrs of symptom onset (admission day 1 of ICH). Sulfasalazine and pentoxyfyline had no effect in blocking TPA induced degranulation of neutrophils obtained greater than 24 hrs of symptom onset (admission day 2-4 of ICH). Conclusion Sulfasalazine and pentoxyfyline ex-vivo inhibition of TPA induced neutrophil degranulation is more effective in the early phase of acute brain injury (within 24 hrs of symptom onset) but not in later isolations likely as a result of neutrophil priming and activation.

Title: TNFα alters occludin and cerebral endothelial permeability: role of p38MAPK

Authors: *G. Y. SUN[1], Y. NI[1], T. TENG[2], J. LEE[2];
[1]Univ. Missouri, Columbia, MO; [2]Univ. of Illinois at Chicago, Chicago, IL

Abstract: Occludin is one of the key tight junction (TJ) proteins in endothelial cells and it plays an important role in modulating blood brain barrier (BBB) function. This protein (65kDa) has been shown to engage in many signaling pathways and subjected to phosphorylation by a number of protein kinases. Activation of endothelial cells by pro-inflammatory cytokines and endotoxin (lipopolysaccharides, LPS) may alter TJ proteins and BBB functions. Here we describe the responses of occludin in immortalized human cerebral endothelial cells (hCMEC/D3 cells) stimulated by TNFα, IL-1β and LPS. Exposing cells to TNFα resulted in a rapid and transient band shift of occludin suggesting an increase in phosphorylation whereas IL-1β and LPS produced significantly less effects on the band shift. TNFα also caused transient stimulation

of p38MAPK and ERK1/2 in hCMEC/D3 cells, and TNFα-induced occludin phosphorylation was suppressed by SB202190, inhibitor for p38MAPK. Cells treated with TNFα for 24h resulted in cell morphology changes, a decrease in the expression of occludin, and enhanced endothelial permeability, as determined by the FITC-dextran assay and TEER measurement with cells grown in transwell inserts. In addition, TNFα-induced reduction of occludin was abrogated by SB202190. Collectively, these data demonstrate effects of TNFα on occludin and cerebral endothelial cell function through the activation of p38MAPK pathway.

Title: The mammalian specific protein ARMCX1 promotes mitochondrial transport, neuronal survival and axonal regeneration

Authors: *R. CARTONI[1], M. W. NORSWORTHY[1], F. BEI[1], C. WANG[1], S. LI[1], C. V. GABEL[2], T. L. SCHWARZ[1], Z. HE[1];
[1]Neurol., Boston Children's Hospital/Harvard Med. Sch., Boston, MA; [2]Physiol. and biophysics, Photonic Ctr., Boston Univ., Boston, MA

Abstract: Whether and how mitochondrial dynamics impact neuronal injury responses, such as neuronal survival and axon regeneration, remain unknown and untested. Here we find that ARMCX1, a mammalian-specific gene that encodes a mitochondrial localized protein, was significantly up regulated in injured mouse retinal ganglion cells (RGCs) with co-deletion of PTEN and SOCS3 (dKO), an established model of robust axon regeneration. ARMCX1 over-

expression enhances mitochondrial transport in both adult RGCs and embryonic mouse cortical neurons. ARMCX1 is necessary for dKO RGCs axonal regeneration and neuronal survival as ARMCX1 knockdown drastically impaired axonal re-growth and neuroprotection after optic nerve crush in adult mice. ARMCX1, but not an ARMCX1 mutant that does not localize to mitochondria, promotes both neuronal survival and axonal regeneration. Moreover, ARCMX1 can induce axon regenerations from RGC subtypes that are refractory to PTEN-deletion manipulation alone. Thus ARMCX1 represents a potential new target for designing neural protective and repair strategies after injury.

Title: Distinct signaling pathways underlie neurophysiological effects of toll-like receptor 4 signaling in the normal and injured brain

Authors: *A. A. KORGAONKAR[1], J. GUEVARRA[1], K. C. H. PANG[1,2], V. SANTHAKUMAR[1];
[1]Dept. of Pharmacology, Physiol. and Neurosciences, Rutgers New Jersey Med. Sch., Newark, NJ; [2]Neurobehavioral Res. Lab., Veteran Affairs Med. Center–New Jersey Hlth. Care Syst., East Orange, NJ

Abstract: Concussive brain injury results in neuronal degeneration, reactive astrocytosis and enhanced excitability in the hippocampal dentate gyrus, increasing the risk for epilepsy and memory dysfunction. Endogenous molecules released during injury can activate innate immune responses including toll-like receptor 4 (TLR4). Enhanced neuronal TLR4 signaling contributes to an increase in dentate excitability after TBI. In contrast, TLR4 agonists reduced excitability in

uninjured rats suggesting that TLR4 signaling engages distinct molecular effectors in the control and injured brain. Here, we examine potential mechanisms and consequences of suppressing TLR4 signaling. Wistar rats (25-27 days old) were subject to sham- or moderate fluid percussion injury (FPI). The effects of specific antagonists on perforant path-evoked dentate population responses were analyzed in hippocampal slices obtained one week after injury. Neurophysiological outcomes were examined in rats treated with focal (LPS-RS-U) or systemic (CLI-095) TLR4 antagonist or vehicle. Similar to acute incubation, CLI-095 (i.p) decreased afferent-evoked dentate population spike amplitude 1 week after FPI yet enhanced dentate excitability in shams. Pre-incubation of hippocampal slices in glial metabolic inhibitors blocked TLR4 ligand modulation of dentate excitability in shams but not after FPI. TNFα inhibitor eliminated TLR4 agonist modulation of excitability in slices from both sham and FPI suggesting a novel neuronal TLR4-TNFα signaling after brain injury. Working memory function on a delayed match to sample Morris Water Maze task was impaired for one month after FPI and 62% of FPI rats developed of spontaneous seizures. Both focal and systemic TLR4 antagonist administration 24 hrs after FPI improved working memory function at 1 week and 1 month post-FPI. The treatments also prolonged the latency to kainic acid induced seizures and reduced seizure severity (by Racine scale) after injury. The same treatments impaired working memory function and enhanced seizure severity in shams. Delayed TLR4 antagonism one month after injury failed to limit seizure susceptibility. These data demonstrate differential involvement of glia and identify a potential role of neuronal TNFα in TLR4 signaling in the normal and injured dentate gyrus. The results show that early post-injury TLR4 antagonism alleviates long-term behavioral deficits and reveals adverse treatment outcomes in controls. Thus, selectively targeting the processes underlying pathological TLR4 signaling may be efficacious in reducing epilepsy and memory impairments after brain injury.

Title: High sodium diet increases Th17 differentiation and promotes neurovascular and cognitive dysfunction through IL-17 and Rho kinase-dependent eNOS inhibitory phosphorylation

Authors: *G. FARACO, D. BREA, G. WANG, G. RACCHUMI, H. CHANG, L. GARCIA-BONILLA, I. BUENDIA, K. KOIZUMI, J. ANRATHER, C. IADECOLA;
Brain and Mind Res. Inst., Weill Med. Col. of Cornell Univ., New York, NY

Abstract: High sodium diet (HSD) is thought to be a risk factor for stroke and dementia, independent of its effect on blood pressure (BP), but the mechanisms remain unclear. Therefore, we sought to investigate the cerebrovascular and cognitive impact of HSD. To this end, we fed HSD (4-8% NaCl) to C57BL/6 mice for 12 weeks and assessed cerebral blood flow (CBF) in the somatosensory cortex by laser-Doppler flowmetry. HSD did not increase BP (Control: 76.9±3.0mmHg; HSD: 76.3±1.6mmHg), but attenuated the CBF increase induced by neocortical application of acetylcholine (ACh) (-30.6±0.5%; $p<0.05$; n=8), a response mediated by endothelial nitric oxide synthase (eNOS), without affecting the response to the smooth muscle relaxant adenosine ($p>0.05$). These vascular changes were associated with a deficit in novel object exploration (Novel Object Exploration Time: ND 71±1.5%; HSD 54±1.8%; $p<0.05$; n=20), suggesting cognitive impairment. The impairment of the ACh response induced by HSD was associated with an increase in inhibitory eNOS phosphorylation (≈1.6 fold increase vs ND; $p<0.05$; n=7) in pial microvessels. Since HSD may lead to the expansion of intestinal helper T cells producing the vasotoxic cytokine IL17 (Th17 cell) (Nature, 496:518-22, 2013), we investigated whether IL-17 contributes to the effects of HSD. HSD increased the number of intestinal Th17 cells, assessed by flow cytometry (ND 211±45/cm; HSD 691±114/cm; $p<0.05$; n=8), as well as IL-17 plasma levels (ND 0.9±0.2pg/ml; HSD 6.5±1.4pg/ml; $p<0.05$; n=5). Consistent with a role of lymphocytes, the HSD-induced attenuation of the ACh CBF response was not observed in $Rag1^{-/-}$ mice, which lack both T and B lymphocytes. Furthermore, deletion of IL-17 or systemic administration of an IL-17 blocking antibody reduced plasma IL17, prevented inhibitory eNOS phosphorylation, and rescued the vascular and cognitive effects of HSD, whereas chronic injection of IL-17 reproduced fully the neurovascular effects of HSD. In brain endothelial cell cultures, IL-17 suppressed endothelial NO production in vitro, an effect associated with Rho-kinase-dependent increases in inhibitory eNOS phosphorylation. We conclude that HSD induces profound alterations in neurovascular regulation and cognitive function. The effect is mediated by expansion of intestinal Th17 cells, resulting in increases in circulating IL-17, which, in turn, lead to Rho kinase-induced inhibitory eNOS phosphorylation and reduced NO production. The data suggest a mechanism for the increased risk of stroke and dementia with HSD, and a putative therapeutic target for the deleterious effects of high salt on the brain.

Title: Vibrotactile stimulation discrimination in the upper extremity of healthy humans

Authors: *V. SHAH[1], D. PETERS[1], M. GAGAS[1], A. KRUEGER[1,2], R. IANDOLO[3,2], M. CASADIO[2,3], R. A. SCHEIDT[1,4,5,6];

Engin., Marquette Univ., Milwaukee, WI; [2]Dept. of Informatics, Bioengineering, Robotics and Systems Engin., Univ. of Genova, Genova, Italy; [3]Dept. of Robotics, Brain and Cognitive Sci., Italian Inst. of Technol., Genova, Italy; [4]Dept. of Physical Med. and Rehabil., Northwestern Univ. Feinberg Sch. of Med., Evanston, IL; [5]Sensory Motor Performance Program, Rehabil. Inst. of Chicago, Chicago, IL; [6]Dept. of Neurol., Med. Col. of Wisconsin, Wauwatosa, WI

Abstract: Proprioception is critical for effective planning and real-time control of movement. Unfortunately, proprioception can be impaired after stroke. Our long-term goal is to develop technologies that provide supplemental sensory feedback, via vibrotactile stimulation, to restore closed-loop control of the arm in stroke survivors who lack proprioceptive integrity. As a first step, we test the null hypothesis that vibrotactile stimulation of the different dermatomes within the arm give rise to similar perceptions (e.g., vibrotactile discrimination thresholds). The results of this study will allow us to determine whether some dermatomes are better suited than others as stimulation sites for providing supplemental kinesthetic feedback.
Eight neurologically intact subjects (age: 22 to 29 years) consented to participate in a two-alternative forced choice experiment. 10mm coin-motor “tactors” (Precision Microdrives, Ltd.) delivered vibratory stimuli at 5 different locations on the arm and hand (dermatomes C5, C7, C8, T1 and on the Ulnar Head, UH). Presentation of stimulus pairs conformed to the method of constant stimuli, wherein the standard vibratory stimulus was always presented at a frequency of 122 Hz. The probe stimulus could take on one of 10 different intensity values, spanning the range from 60 Hz to 172 Hz. 550 stimulus discrimination trials were presented in a single experimental session. Psychometric function estimation found the discrimination thresholds for the five locations to be: C5 = 22.7 Hz ± 11.7 (mean ± SEM), C7 = 16.3 Hz ± 11.8, C8 = 24.1 Hz ± 11.4, T1 = 27.7 Hz ± 11.0, and UH =19.4 Hz ± 10.9. Mixed model ANOVA found a significant difference in perception of vibrotactile stimuli across dermatomes. Post-hoc t-test found the discrimination threshold at C7 was significantly less than at T1 ($p=0.004$). Mean

discrimination thresholds at C5, C8, and UH did not differ from those at C7 or T1 ($p>0.05$ all cases).
As dermatome C7 had a significantly lower threshold than dermatome T1, we rejected the null hypothesis. Pacinian Corpuscles (PCs) which sense vibration on the skin, are sensitive to vibrations within the 50-350 Hz range (~300 Hz bandwidth). Thus, dermatome C7 can detect differences in stimulation frequency as small as ~5% of the PC full dynamic range. By contrast, C8 and T1 exhibited discrimination thresholds ~9% of the PC range. Thus, sensory augmentation and/or substitution via vibrotactile stimulation may exhibit constraints imposed by limited acuity of vibrotactile sensation. Future work should explore ways to enhance vibrotactile acuity in frequency discrimination and closed-loop control. Supported by NIH R01HD053727.

Title: Resting state EEG power predicts peripheral neuromodulatory outcomes

Authors: N. NATRAJ, A. TSU, *K. GANGULY;
UCSF, San Francisco, CA

Abstract: Somatosensory peripheral nerve stimulation (PNS) is a promising method to promote motor recovery after stroke or brain injury. While past studies have indicated that there are significant effects of PNS on motor function, the underlying neural substrates are unclear. To this end, we conducted a pilot study to determine the neural correlates (via EEG) of PNS treatment on improvements in affected finger fractionation ability. Eight participants with a 6-month or greater history of acquired brain injury and distal upper limb motor impairment received a single two-hour session of submotor/suprasensory threshold stimulation using a transcutaneous electrical nerve stimulation (TENS) unit applied to the affected hand. Resting state EEG data over bilateral sensorimotor electrodes and finger fractionation ability were collected both pre and post PNS. PNS resulted in a significant drop in resting state low frequency power over

ipsilesional cortex at the group level, especially over ipsilesional motor cortex. Furthermore, the loss of ipsilesional motor cortex power was a significant predictor of individual fractionation improvements due to PNS in a ridge regression model. Results in this study warrant further investigations to optimize PNS for promoting hand dexterity recovery after acquired brain injury specifically targeting the aforementioned biomarker.

Title: Morphology of neurons in penumbra area of ischemic insult after lentiviral delivery of neurotrophins to the rat brain cortex.

Authors: *G. SMIRNOVA[1], M. SVINOV[2];
[1]Cell. Neurobio. of Learning Lab., [2]Functional Neurocytology Lab., Inst. of Higher Nervous Activity and Neurophys, Moskva, Russian Federation

Abstract: Therapeutic approaches in ischemic insult treatment include wide range technologies. One of these technologies is lentiviral delivery of neurotrophins. The popular sites of delivery are brain ventricles. And the main measure of such treatment effectiveness is volume of infarct size In the present study, we examined the influence of neurotrophins on the morphology of neurons and astrocytes in ischemic penumbra. We injected lentiviral suspension in cerebral cortex 2 weeks before photothrombotic insult in rats. On the second day after insult rats were sacrificed, parallel brain slices were stained by Toluidine Blue or by antibodies to GFP, GFAP, and DAPI. The area of parenchymal delivery of neurotrothins was overlapped with the area of ischemic penumbra. In this overlapping area we analyzed morphology of neurons. The neurotrothins injection leads to decrease of dark pyramidal neurons in V layer of cerebral cortex.

Title: Extracellular matrix structures and modulators in the rat somatosensory cortex: molecular substrates for experience-dependent plasticity during stroke recovery

Authors: *M. QUATTROMANI[1], M. PRUVOST[2], C. GUERREIRO[1], F. BACKLUND[1], K. RUSCHER[1], D. VIVIEN[2], T. WIELOCH[1];
[1]Lund Univ., Lund, Sweden; [2]GIP Cyceron / Univ. of Caen, Caen, France

Abstract: Stroke can be conceived as a site of complete cellular death surrounded by tissue that undergoes reorganization. Experience-dependent plasticity exerted through an enriched environment (EE) promotes neuronal remodeling and neuroplasticity after central nervous system injury (i.e. stroke). After stroke, a number of growth-inhibitory molecules are differentially expressed within the ischemic hemisphere, leading to inhibition of neuronal plasticity. Particular interest has been focused on the inhibitory role of chondroitin sulfate proteoglycans (CSPGs) and their formation into dense lattice-like structures, termed perineuronal nets (PNNs). PNNs enwrap sub-populations of neurons, such as parvalbumin-containing GABAergic (PV/GABA) positive cells, important in sensori-information processing. Our recent study (Madinier and Quattromani et al., 2014) demonstrates that during stroke recovery, EE induces a reduction in the number of PNNs in peri-infarct and regions remote from the infarct. The objective of this study was to investigate if extracellular matrix (ECM) modulators such as metalloproteinases (MMPs), especially MMP-2 and MMP-9, tissue plasminogen activator (tPA) and type 4 disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS-4) may participate in the degradation of PNNs that we observe after stroke and EE conditions. Male

Sprague Dawley rats were subjected to photothrombotic stroke (PT) in the motor cortex and functional deficits assessed at 2 and 7 days of recovery. Shams and stroked rats were housed in either standard (STD) or EE conditions for 5 days and infarct volumes calculated. Aggrecan-containing PNNs were visualized by immunohistochemistry (Cat-315$^+$ neurons) and immunofluorescence (Cat-315/PV$^+$ neurons) and counted in bright-field and confocal microscopy in the somatosensory cortex of both hemispheres. PNN protease mRNA levels were assessed by qRT-PCR and their activity analyzed by real-time-FITC-gel zymography and casein-plasminogen zymography. EE starting 2 days after PT and continuing for 5 days did not influence the size of the infarct, but induced a remarkable difference in behavioral recovery between the housing groups. A reduction in the number of Cat-315$^+$ and Cat-315/PV$^+$ neurons was observed in the somatosensory cortex of the ipsilateral hemisphere after PT and EE and was accompanied by modulation in the expression and activity of ECM proteases. Elucidating the mechanisms and pharmacology of CSPGs and ECM turnover after experimental stroke may then provide new therapies supporting rehabilitation.

Title: The effects of an augmentative and alternative communication intervention on functional communication and neural activity patterns in individuals with aphasia

Authors: *S. ROSENBERG, M. LAM, J. DIVINE, H. MILLAN, N. FULLMER;
Res. Inst., Casa Colina Hosp. and Centers for Healthcare, Claremont, CA

Abstract: Aphasia is a communication disorder caused by neurological damage, which can impair one's ability to understand and use both written and spoken language. Annually, 80,000 individuals in the United States will acquire aphasia as a result of a stroke. The purpose of this pilot study was to evaluate the effect of an augmentative and alternative communication (AAC) program on the functional communication abilities and neural activity patterns of individuals

with aphasia. Individuals (n = 20) enrolled in the study were between the ages of 18 to 90 and were at least 3 months post-onset of aphasia. Participants attended six one-hour therapy sessions with a certified speech and language pathologist to work on their communication abilities using the AAC program. Participants completed pre-evaluations prior to the intervention sessions and post-evaluations approximately one week after completion of the intervention. Evaluations included the Western Aphasia Battery (WAB), which measures expressive and receptive communication capabilities. Results from the study indicate improvements on the WAB following completion of the AAC intervention. Participants also completed a prompt and response task in which prompts involved verbal commands to arrange provided items in a specific manner. Verbal commands were provided alone or were accompanied with static or dynamic visual cues. Preliminary data from the prompt and response evaluation show a statistically significant difference between the ability to respond correctly to verbal only prompts as compared to verbal prompts with visually augmentative cues. Pre/post intervention evaluations also included electroencephalogram (EEG) recordings to assess the potential for use of wireless EEG recordings during clinical outcome measures. A 24-channel wireless EEG system was used to record neural activity patterns during both the prompt/response task and during an eyes open/eyes closed paradigm. Preliminary analysis of the resting state EEG recordings indicates the presence of relative power spectral density patterns similar to those of previous studies conducted with individuals with aphasia. Furthermore, these pilot recordings support the feasibility of conducting EEG recordings during clinical outcome measurements. The results of this pilot study suggest the potential for assessing correlations between neural activity patterns and functional communication abilities and provide support for the idea that supplementing verbal commands with visual aids and utilizing AAC interventions with visual cues may help enhance the communication abilities and daily lives of individuals with aphasia.

Title: Human cerebral endothelial cell transplantation in a rat model of cerebral ischemia for neuroprotection

Authors: S. YU[1], H.-W. RYU[1,3], J.-T. PARK[2], *H. KIM[2,3];
[1]Forensic Med., [2]Chonnam Natl. Univ. Med. Sch., Gwangju, Korea, Republic of; [3]Ctr. for Creative Biomed. Scientists at Chonnam Natl. Univ. Med. Sch., Gwangju, Korea, Republic of

Abstract: Human cerebral microvascular endothelial cell line (hCMEC)/D3 cells, which are from a stable clonal cell line of human immortalized cerebral endothelial cells, were intra-arterially transplanted through the common carotid artery in a rat model of photochemical-induced cerebral ischemia. Their therapeutic effects on infarct size, blood-brain barrier (BBB) breakdown, and outcome were examined. The hCMEC/D3 cells were genetically modified with the firefly luciferase gene for in vivo imaging post-transplantation. Transplanted hCMEC/D3 cells were identified in the infarcted brain by bioluminescence imaging at 1 day after transplantation. Compared with the control group, the hCMEC/D3-transplanted group showed reduced infarct size on day 3, reduced Evans blue dye leakage on day 1 indicating decreased BBB breakdown, and early recovery from Rotarod test neurological deficits. The hCMEC/D3-transplanted group also showed decreased levels of matrix metalloproteinase (MMP)-9, which were inversely correlated with TIMP-1 levels on post-transplantation days 1 and 3. The expression of tumor necrosis factor-α and interleukin-1β were markedly diminished in the hCMEC/D3-transplanted group compared with controls. The systemically transplanted cells selectively migrated and integrated into the ischemically lesioned area, which accelerated neurological recovery. This new cerebral endothelial cell-based therapy may hold promise for clinical trials in patients with ischemic stroke. ** This work was equally distributed. Title: Altered autophagy activity after ischemic stroke in GPR37 knockout mice

Authors: *M. R. MCCRARY[1], M. Q. JIANG[2], J. Y. ZHANG[2], X. GU[2], M. GIDDENS[2], R. HALL[3], S. P. YU[4], L. WEI[4];

Abstract: Stroke is a debilitating brain injury leading to mortality and neurological disability. GPR37 is a G protein-coupled receptor that has been found to exert neuroprotective and glioprotective effects in vitro, but the relationship between GPR37 and mechanisms of cell survival or death remain unclear. Autophagy plays a dual role in promoting cell survival via digestion and recycling of cellular components, and also contributes to cell death by lysosomal processes of self-induced intracellular degradation. Autophagic cell death has been implicated in secondary damage after ischemic stroke. In the present investigation, we tested a possible role of GPR37 signaling in regulating autophagy in the ischemic brain using wild type (WT) and GPR37 knockout (GPR37 KO) mice. Adult mice were subjected to focal cerebral ischemia targeting the sensorimotor cortex. Infarct volume was measured using 2,3,5-triphenyltetrazolium chloride (TTC) staining 3 days after stroke. Images of stained slides were analyzed using ImageJ under double-blind conditions. Stroke animals were sacrificed at 6, 12, 24, and 48 hours after stroke for Western blot analyses. Tissue was isolated from the infarct core, the peri-infarct regions, and the contralateral cortex. TTC measurement revealed that GPR37 KO mice experience significantly enlarged infarct volumes compared to WT stroke controls ($p=0.0424$). To evaluate autophagy activity, we measured the expression of Beclin-1, a primary component of the pre-autophagosomal structure, and microtubule-associated protein 1 light chain 3 (LC3), an effector of autophagy. Compared to WT controls, Beclin-1 levels in GPR37 KOs were increased in the peri-infarct area at 6 and 12 hours post-stroke. LC3 levels were also increased in the GPR37 KOs at 12 hours after stroke. The anti-apoptotic gene Bcl-2 was differently regulated. Taken together, these data suggest that autophagy is upregulated in the peri-infarct region of GPR37 KO mice, raising the possibility that GPR37 plays a role in regulating apoptosis and/or autophagy. Future studies will elucidate the complex interactions between autophagy, programmed cell death, and GPR37 signaling in ischemic stroke.

Title: Adult deletion of PTEN in cortical motoneurons leads to robust cell body enlargement that is maintained as the steady-state cell size

Authors: *E. A. GUTILLA, O. STEWARD;
UC Irvine, Irvine, CA

Abstract: Adult neurons often undergo atrophy following axonal injury, in neurodegenerative diseases and with aging; such atrophy is thought to reflect decreased vitality. Neurons in which *PTEN* has been deleted are enlarged one year post-deletion, but it is not known if there is a transient growth response after *PTEN* deletion that results in a larger steady-state cell size, whether growth continues progressively as long as *PTEN* is absent, or whether deletion of *PTEN* prevents age-related neuronal atrophy. To address this question, we assessed changes in neuron size with time following deletion of *PTEN* in the sensorimotor cortex of adult (8 week old) mice. To positively identify neurons in which *PTEN* was deleted, we used double transgenic mice with a lox-P flanked exon 5 of the *PTEN* gene and lox-P flanked STOP cassette that regulates expression of tdTomato. Cre-mediated recombination leads to deletion of *PTEN* and expression of tdTomato in the same neurons. Mice received unilateral intracortical injections of AAV-Cre, and were allowed to survive for 3, 4, 5, 6, 9, or 12 months before being given bilateral injections of fluorogold at cervical level 5 of the spinal cord to retrogradely label the cortical motoneurons (CMNs) that give rise to the corticospinal tract. Retrogradely-labeled CMNs expressing tdTomato (also *PTEN*-negative) were compared with retrogradely-labeled CMNs in the contralateral cortex. Quantitative assessments revealed that cell bodies of CMNs lacking *PTEN* are 1.3 times the size of control CMNs by 4 months after the deletion. CMNs lacking *PTEN* remained significantly enlarged at all time points beyond 4 months but the magnitude of the differences between CMNs lacking *PTEN* and contralateral controls did not increase further after 4 months. Immunostaining for the phosphorylated form of ribosomal protein S6 (a biomarker for activation of the mammalian target of rapamycin, or mTOR, pathway) revealed continued activation at all time points after *PTEN* deletion up to 12 months. These results indicate that deleting *PTEN* in adult neurons triggers robust neuronal growth in which neurons enlarge to a

new steady-state size that is maintained throughout life. These findings suggest novel strategies to prevent neuronal atrophy due to aging, traumatic injury, or neurodegenerative disease.

Title: Development of gene therapy for Niemann-Pick Type C disease

Authors: *M. HUGHES[1], D. SMITH[2], L. MORRIS[2], J. TORDO[3], N. PALOMAR-MARTIN[3], E. HENCKAERTS[3], S. WADDINGTON[4], F. PLATT[2], A. RAHIM[1];

Abstract: Niemann-Pick type C is a lysosomal storage disorder with neurological and visceral pathology, for which there is currently no major disease modifying treatment. Loss of NPC1 function, a late endosomal transmembrane protein, leads to systemic intracellular lipid accumulation. However, premature death is associated with neurological manifestations, such as severe neurodegeneration and neuroinflammation. Advances in viral vector technology and recent successful clinical trials display the potential beneficial use of gene therapy for these types of monogenic disorders.
This project focuses on the development of an adeno-associated viral (AAV) vector capable of delivering and expressing human *NPC1* in the mouse brain, via perinatal intracranial or intravenous injection, with the ultimate aim of ameliorating brain and visceral pathology in the *Npc1*$^{-/-}$ mouse model. AAV vectors exhibit efficient and widespread gene delivery throughout the brain, however their limited packaging capacity of 4.7kb can be a constraint for larger genes. Extensive construct modifications were made to incorporate the relatively large 3.8kb *NPC1*

gene into a functional AAV serotype 9 vector. *NPC1* expression is controlled by the constitutively active neuronal promoter human *synapsin I*, which in combination with an AAV9 vector produces impressive levels of gene delivery and neuronal specificity, following administration to the CNS.
Initial *in vivo* tests demonstrated successful NPC1 over-expression in administered mouse brains, compared to endogenous Npc1 levels in un-administered controls. No indications of toxicity or neuroinflammation were observed as a result of NPC1 over-expression *in vivo*. A preliminary very low dose study was carried out on the *Npc1*$^{-/-}$ model, where newborn *Npc1*$^{-/-}$ mice were administered with $4.6x10^9$ vector genomes of AAV9.SYN1.NPC1 via intracranial injections. Treated *Npc1*$^{-/-}$ mice exhibited an increased lifespan (n=8; median survival of 116.5 days; $P<0.0001$) compared to untreated Npc1-/- mice (n=6; median survival of 75.5 days). Combined with significant behavioural improvements these results demonstrate the potential beneficial use of gene therapy for Niemann-Pick type C and support the continuation of this approach with higher dose studies.

Abstract: Gaucher Disease is caused by mutations in the *GBA* gene encoding the lysosomal enzyme glucocerebrosidase (GCase). Deficiency of GCase causes the accumulation of

glucosylceramide in enlarged “Gaucher cells” within visceral organs and brain. Recombinant human enzyme is commercially available and is successfully used to treat the visceral pathology in non-neuronopathic Gaucher Disease patients. Acute neuronopathic Gaucher Disease (nGD) is characterised by neuronal loss, astrocytosis and microglial proliferation. nGD is untreatable since enzyme replacement therapy cannot cross the blood-brain barrier.
In this study, I tested the hypothesis that neonatal intravenous injection of adeno-associated viral vector serotype 9 (AAV9), carrying functional *GBA* gene, would improve lifespan, behavior, brain and visceral pathology in a mouse model of nGD.
AAV9 has been demonstrated to be able to efficiently transduce the Central Nervous System and visceral organs following intravenous administration to mice and non-human primates.
Untreated knock-out mice die 12-14 days after birth. Treated mice showed a >10-fold increase in their lifespan. Neuropathological markers such as microglia-mediated inflammation, astrogliosis and lysosomal accumulation were ameliorated and some of the most affected areas of the brain, like thalamus, brain stem and cerebellum were partially rescued. Histologic analysis, enzymatic assay and blood test revealed improvement in the visceral pathology. In the lung, spleen and liver the presence of Gaucher cells is significantly reduced and tissue architecture is preserved.

Title: Stroke affects intestinal immune cell trafficking to the CNS

Authors: *D. BREA[1], C. BENAKIS[2], M. MURPHY[2], C. IADECOLA[2], J. ANRATHER[2];
[1]Weill Cornell Med. Col., Joan and Sanford I Weill Med. Col. of Cornell Univ., New York, NY;
[2]Weill Cornell Med., New York, NY

Abstract: Stroke is an acute neurological disease with a strong inflammatory component that can be regulated at the intestinal level by mediation of intestinal microbiota and intestinal immune cells (Nature Medicine 22, p. 516, 2016). Although stroke has been shown to alter immune cell populations in the gut (Neuroimmunomodulation 16, p. 213, 2009), the dynamics of cell trafficking have not been elucidated. To study the trafficking of gut-derived immune cells, we used mice expressing the photoconvertible protein Kikume Green-Red. Mice underwent laparotomy and the small intestine (6 cm) was exposed to violet light (405 nm) using a laser

source. Immune cells were isolated from the small intestine immediately, 2, 7 and 14 days after photoconversion. Percentage of immune cells ($CD45^{hi}/KikR^{+}$) that expressed the red variant of the protein (KikR) was higher at days 0 (37.76±1.11%) and 2 (35.03±1.15%) than at days 7 (11.60±1.77%) and 14 (4.87±0.37%) in the intestinal segment exposed to violet light. Extrapolating these results to the total intestinal immune cell population, we calculated that 5.9±0.8% of gut immune cells were expressing KikR at day 2 after photoconversion. To investigate whether intestinal immune cells traffic to the periphery after stroke, we analyzed KikR+ immune cells (2 days after photoconversion) in mesenteric and cervical lymph nodes, spleen, bone marrow, meninges and brain, 3 and 14 days after tMCAo. Gut-derived KikR+ immune cells were found in all analyzed organs at 3 and 14 days after stroke or sham surgery. KikR+ cell numbers and frequencies were similar in peripheral organs both at 3 and 14 days after stroke. The number of KikR+ immune cells was higher in brains 3 and 14 days after stroke when compared to sham animals (3 days: 187 ± 133 vs. 5 ± 3 cells/hemisphere, n=5-7, $p<0.01$; 14 days: 155 ± 102 vs. 3 ± 1 cells/hemisphere, n=5-6, $p < 0.01$). Numbers of meningeal KikR+ immune cells in sham animals were higher than in the brain indicating the presence of gut-derived immune cells under homeostatic conditions. Meningeal KikR+ immune cells were not significantly altered 3 or 14 days after stroke. KikR+ immune cells were found in all lymphoid organs analyzed but were not affected by stroke. We conclude that intestinal immune cells traffic to peripheral lymphoid organs and meninges under homeostatic conditions and this behavior is not affected 3 and 14 days after tMCAo, while gut-derived immune cells are increased in the brain at 3 and 14 days after stroke. Our data suggest stochastic intestinal immune cell trafficking under homeostatic conditions and a directed recruitment to sites of sterile inflammation such as ischemic brain injury.

Title: Systemic immune responses and neutrophil activation in the propagation of neuroinflammation after cerebral ischemia-reperfusion

Authors: *N. MAI, L. PRIFTI, M. W. HALTERMAN;
Univ. of Rochester, Rochester, NY

Abstract: Post-ischemic neuroinflammation remains an elusive therapeutic target for patients suffering from global cerebral ischemia following cardiac arrest. While heightened inflammatory responses portend poor neurologic recovery, the lack of pre-clinical models that faithfully reproduce features of post-cardiac arrest syndrome (PCAS) remains a barrier to developing effective neuroprotective therapies. Here we demonstrate that serologically undetectable endotoxemia causes acute, peripheral neutrophil activation and enhanced CNS inflammation when combined with global cerebral ischemia.
Transient global ischemia was induced in 5-8 week-old C57/B6 mice using the 3-vessel occlusion (3VO) model, which involves basilar artery cauterization followed by 15-minute occlusion of the common carotid arteries. During reperfusion, mice were given saline or 50 μg/kg lipopolysaccharide (LPS) intraperitoneally to mimic enteric endotoxin leak and systemic inflammatory responses observed during PCAS. Animals receiving saline or LPS served as sham controls.
While 50 μg/kg LPS yielded undetectable endotoxin levels in serum 6 hours after injury, upregulation of the neutrophil activation marker CD11b was observed in sham-treated animals, with greater activation in those also undergoing 3VO. Three days after ischemia-reperfusion, animals with concomitant systemic inflammation experienced the greatest blood-brain barrier permeability, as evidenced by upregulation of vascular platelet endothelial cell adhesion molecule-1, enhanced perivascular IgG deposition, and neutrophil migration into the brain parenchyma. Animals receiving 3VO and LPS exhibited pronounced microglial activation characterized by Iba1 upregulation and amoeboid morphology. These phenotypic changes were specific to areas of dense neutrophil infiltration, suggesting that the effects were likely cell-mediated and not a consequence of passive endotoxin transfer across the blood-brain barrier. While the role of neutrophils in cerebral ischemia reperfusion injury remains controversial, our data indicate that neutrophil activation and migration remain particularly relevant targets for mitigating neuroinflammation in the setting of cardiac arrest.

Title: Anti-inflammatory role of g-protein coupled receptor 30 (gpr30) in the brain following global cerebral ischemia

Authors: *R. WANG, D. BRANN;
Dept. of Neurosci. and Regenerative Med., Augusta Univ., Augusta, GA

Abstract: The NLRP3 inflammasome is now recognized to have an important role in neuroinflammation and delayed neuronal death following ischemic injury to the brain. G-Protein Coupled Receptor 30 **(**GPR30) is a seven trans-membrane protein and is purported to function as an estrogen receptor to help mediate estrogen signaling and actions in the body. In the current study, we examined whether GPR30 may exert an anti-inflammatory regulatory effect to inhibit NLRP3 inflammasome activation and signaling following global cerebral ischemia (GCI). A GPR30 agonist (G1) or antagonist (G36) were administrated to ovariectomized female rats by minipump beginning at 1d after ischemic reperfusion and continued until 7d or 14d of reperfusion. The following endpoints were examined: 1) cell type localization of GPR30 in the hippocampal CA1 region, 2) protein levels of NLRP3, ASC, TXNIP, and caspase 1, which are essential components of the NLRP3 inflammasome pathway, 3) expression of IL1RA, an antagonist of the Interleukin 1 receptor (IL-1R). The results showed that GPR30 was expressed in neuron in the sham (non-ischemic) group, however at 7d and 14d reperfusion, GPR30 was mainly expressed in reactive astrocytes, with some expression also noted in microglia. Immunofluorescence staining of NLRP3, ASC, TXNIP, Caspase 1 showed that protein levels of the inflammasome components significantly increased at reperfusion 7d and 14d. Simultaneously, the levels of cleaved IL1β were markedly enhanced in ischemia groups, compared to the sham control. Furthermore, there was a concomitant decrease of IL1RA protein levels following GCI. Importantly, post-ischemic administration of the GPR30 agonist, G1, enhanced GPR30 protein levels in hippocampal neurons and was neuroprotective against GCI. G1 treatment also attenuated the GCI-induced elevation of inflammasome components and cleaved IL1β, and reversed the GCI-induced decrease of IL1RA. Finally, continuous administration of G36, a GPR30 specific antagonist, prevented the G1 anti-inflammatory effects at 7d and 14d after GCI. Taken together, the current results suggest that GPR30 signaling can inhibit NLRP3 inflammasome activation after GCI, and exerts potent anti-inflammatory and neuroprotective effects in the hippocampus.

Title: Immunization with Cop-1 induces changes in gene expression at the choroid plexus of rats subjected to focal cerebral ischemia reperfusion.

Authors: *Y. CRUZ[1,2], E. GARCÍA[1], T. RODRÍGUEZ[1], E. STA.MARÍA[1], H. BONILLA[2], J. ROJAS[3], V. GÁLVEZ[1], K. CANTÚ[1], G. OJEDA[1], A. IBARRA[1];
[1]Univ. Anáhuac, México, Mexico; [2]Univ. Autónoma Metropolitana Unidad Iztapalapa, Ciudad de México, Mexico; [3]Inst. Nacional de Pediatría, Ciudad de México, Mexico

Abstract: Cerebrovascular diseases are pathologies caused by alterations in blood flow. Cerebral ischemia results in events such as excitotoxicity, necrosis, apoptosis and inflammation, leading to neuronal death. Immunization with neural-derived peptides such as Copolymer-1 (Cop-1) has demonstrated to provide neuroprotective and neurogenic effects in a cerebral ischemia model, thus preserving tissue, and promoting better motor recovery and neurogenesis.
Cop-1 modulates the immune response through the induction of lymphocyte differentiation towards a Th-2 phenotype during the event; these Th-2 lymphocytes modulate the production of anti-inflammatory cytokines and trophic factors that promote neural tissue restoration.
Recent studies have shown that physiological communication between the immune and nervous system takes place in the choroid plexus (CP) through cytokines and neurotrophic factors. This microenvironment determines processes such as neurogenesis and brain plasticity; for this reason, it was analyzed whether Cop-1 immunization can modify gene expression of cytokines and neurotrophic factors at the CP and if this change correlates with neurogenesis after ischemia.
Cytokine (IFNγ, TNFα, IL-1β, IL-17, IL-4) and neurotrophic factor (IGF-1 and neurotrophin 3 (NT-3)) gene expression was evaluated in rats subjected to cerebral ischemia and immunized with: Cop-1+complete Freund's adyuvant (CFA), Cop-1 + Saline and CFA+ Saline; non-immunized rats were used as controls. Neurogenesis was evaluated at the subventricular zone, hippocampal dentate gyrus, and cerebral cortex by immunofluorescence using the following markers: BrdU (bromodeoxyuridine) and DCX (doublecortin).
Seven days after ischemia, immunization with Cop-1+ CFA induced a reduction in the expression of IFNγ, TNFα, IL-1β, IL-4, IGF-1 and NT-3 genes. Fourteen days later, the expression of these genes increased; however, the gene encoding for IL-4 remained reduced. Neurogenesis was significantly increased at 7 and 14 days in the group treated with Cop-1 + CFA.
These results demonstrate that Cop-1 has the ability of modulating the production of cytokines

and neurotrophic factors at the CP. These changes could be involved in the process of neurogenesis.

Title: Amelioration of cerebral ischemic stroke by induction of Nrf2/HO-1 pathway

Authors: ***P.-C. KUO**[1], B. A. SCOFIELD[1], D. A. BROWN[2], J.-H. YEN[1];
[1]Dept. of Microbiology and Immunol., Indiana Univ. Sch. of Med., Fort Wayne, IN; [2]Dept. of Pharmaceut. Sci., Manchester Univ. Col. of Pharm., Fort Wayne, IN

Abstract: Cerebral ischemic stroke is involved in over 80% of all stroke cases. During cerebral ischemia, reactive oxygen species (ROS) is produced in brain tissue, which can then initiate numerous signaling pathways and cause oxidative stress and inflammatory response. Studies suggest that both oxidative stress and inflammatory damage are essential pathological mechanisms in cerebral ischemia. To date, recombinant tissue plasminogen activator (tPA) is the only available therapy for the treatment of ischemic stroke; however, the treatment does not prevent ischemia-induced oxidative stress and reperfusion-mediated inflammation in ischemic brains. Therefore, the development of new anti-oxidant and anti-inflammatory therapies for the treatment of ischemic stroke is necessary and urgent. Nuclear factor erythroid 2-related factor 2 (Nrf2), a major regulator of oxidative responses, is a key transcription factor which induces a wide set of anti-oxidant enzymes and phase II detoxification enzymes, including heme oxygenase 1 (HO-1) and NAD(P)H dehydrogenase, quinone 1 (NQO1). In addition, Nrf2 exerts an anti-inflammatory effect through HO-1/NF-κB pathway. Our lab has identified a small molecule (BY-23) with a property of inducing Nrf2 activation, and we evaluated its therapeutic potential for the treatment of ischemic stroke in the animal model of transient middle cerebral artery occlusion/reperfusion (tMCAO/R). Our results show BY-23 treatment not only ameliorated neurological deficits in ischemic stroke mice but dramatically reduced infract size in ischemic brains. We also observed significant reduction of CNS infiltrating cells including

neutrophils and monocytes in the ischemic brain of BY-23-treated when compared to those of vehicle-treated tMCAO/R mice. At the molecular level, BY-23 treatment enhanced the expression of anti-oxidant enzymes HO-1 and NQO1 in the ischemic brains of tMCAO/R mice. In the presence of BY-23, the expression of Nrf2, HO-1, NQO1, and glutamate-cysteine ligase, catalytic subunit (GCLC) was significantly upregulated in LPS-activated microglia (MG). Importantly, BY-23 suppressed MG activation in the ischemic brain of tMCAO/R mice, and the protective effect of BY-23 on attenuating brain infarct in ischemic stroke was abolished in the presence of HO-1 inhibitor. Altogether, our results suggest that BY-23-activated Nrf2/HO-1 pathway confers a protective effect against ischemic stroke.

Abstract: Zinc administration might be used as a prophylactic agent in cerebrovascular disease in the CNS, because acute and subacute administration of zinc is known to exert neuroprotection in hypoxia-ischemia animal models. However, chronic administration of zinc is cytotoxic. The effect of prophylactic chronic administration of zinc on neuroinflammation is still unknown. To clarify this issue, we administered the zinc at tolerable doses,0.5 mg/kg $ZnCl_2$ every 24 h for 14 days, to rats before a common carotid artery occlusion, CCAO. After CCAO, the level of zinc was measured by atomic absorption spectrophotometry, nitrites were determined by Griess method, lipoperoxidation by Gerard-Monnier assay, mRNA expression of 84 genes coding for cytokines, chemokines and their receptors by qRT-PCR (Qiagen, Inc), whereas nitrotyrosine,

chemokines and their receptors were assessed by ELISA and histopathological changes in the temporoparietal cortex-hippocampus at different time points (0 h, 8 h and 7 days). We found that only zinc administration in control rats increases inflammatory chemokines/receptors such as CXCL12, CXCL5 CCL4 and the growth factors FGF2 and VEGF that would be associated with a preconditioning process. In addition, zinc administration in rats with CCAO also increased CCL20, CXCL5, CCR2, CCR4, CCR6, CCR8 and CXCR2 levels at 8 h and 168 h post-reperfusion, and FGF2 and VEGF at 168 h following CCAO. This data show that the prophylactic chronic administration of zinc at tolerable doses aggravates CCAO-induced neuroinflammation and suggest a preconditioning effect in treated control rats, such effect was unable to prevent the cerebral damage after CCAO.

Title: Calcium release-activated calcium (CRAC) channel inhibition protects against experimental brain injury by inhibiting microglial activation

Authors: *R. KACIMI[1,2], J. KIM[1,2], K. STAUDERMAN[3], M. DUNN[3], S. HEBBAR[3], M. YENARI[1,2];
[1]VA Med. Center, Neurol. Dept. (N127), Univ. of California San Francisco, San Francisco, CA; [2]San Francisco VA Med. Ctr., San Francisco, CA; [3]CalciMedica Inc, La Jolla, CA

Abstract: Inflammatory responses following brain injury are known to worsen neurological outcome, and represent a potential target for therapeutic intervention. Store-operated Ca2+ entry mediated by Ca2+ release-activated Ca2+ (CRAC) channels, contributes to calcium signaling in immune cells. CRAC channels consist of endoplasmic reticulum resident Ca2+-binding/sensing protein stromal interaction molecule 1 (STIM1) and the calcium channel protein ORAI1 located in the plasma membrane. Prolonged Ca2+ entry through CRAC channels activates, via

calcineurin, nuclear factor of activated T cells (NFAT), involved in T cell proliferation and cytokine expression. Microglia mediate inflammation in the injured brain, but little is known whether CRAC channels are involved. We studied novel CRAC channel inhibitors to explore their therapeutic potential in models of microglia-mediated neuronal injury. Neuro-2A cells were cultured alone or with microglial BV2 cells, then exposed to 2h oxygen glucose deprivation (OGD). Some cultures were treated with a novel CRAC channel inhibitor, after which cell viability was determined. Toll-like receptor (TLR) -3 , -4 agonists or IFNγ were used to induce inflammatory responses in microglia. Western blots revealed the presence of the canonical CRAC channel proteins STIM1 and ORAI1 in BV2 cells. CRAC channel inhibition decreased NO release and inflammatory proteins iNOS and COX-2 expression in activated microglia. Basal cytoplasmic calcium levels in microglia were elevated by a TLR-4 agonist, and were reduced by CRAC channel inhibition. Similarly, a TLR-4 agonist activated JNK1/2 kinase, NFAT, NF-κB, CREB & STAT1, but only JNK1/2 kinase & NFAT were attenuated by the inhibitor. OGD decreased N2A neuronal cell viability, further exacerbated by BV2 cells, but cells were protected by the CRAC channel inhibitor (n=3-5, *$p<0.05$). We then treated C57/BL6 mice exposed to experimental brain trauma (TBI) and found that treatment led to decreased lesion size, brain hemorrhage and improved neurological deficits (n=6-7/grp, *$p<0.05$). CRAC channel inhibition led to neuroprotection, mediated at least in part through JNK and transcription factor NFAT signaling pathways. We suggest a novel anti-inflammatory approach for treating acute brain injury. Our observations also shed light on new calcium signaling pathways, not previously described in brain injury models.

Title: Impaired microglial responses to cerebral microbleeds in hyperglycemic mice can be prevented with insulin therapy.

Authors: *S. L. TAYLOR[1], E. R. WHITE[2], C. E. BROWN[2];
[1]Div. of Med. Sci., [2]Univ. of Victoria, Victoria, BC, Canada

Abstract: Approximately 7-9% of the population is living with some form of diabetes. When poorly controlled (which is often the case), this disease is associated with cerebrovascular pathology such as microbleeds and impairments in cognitive function. The presence and burden of microbleeds in the brain has been strongly linked with reduced cognitive function and increased risk of dementia. Microglia are the resident immune cells of the central nervous system, that dynamically respond to vascular insults by extending their processes to the site of injury. The rapid actions of microglia are thought to play a beneficial role in vascular repair since inhibiting these responses can exacerbate injury. Here, we hypothesized that diabetes, especially if not well controlled with insulin, will disrupt microglia based repair of damaged microvessels in the brain. Using 2-photon in vivo imaging, we show that chronic hyperglycemia in the streptozotocin model of type 1 diabetes leads to decreased microglial process accumulation around the site of microvascular injury. Importantly, this impaired microglial response could be prevented with tight control of blood glucose levels with insulin. These results indicate that chronic hyperglycemia disrupts microglial based repair of damaged microvessels, which may help explain why poorly controlled diabetes is associated with greater risk of cerebrovascular dysfunction and cognitive decline.

Title: Characterization of inflammation in acute and non-acute ischemic infarcts in human and mouse brain tissue

Authors: *T.-V. V. NGUYEN[1], J. B. FRYE[2], J. C. ZBESKO[2], A. URZUA[2], K. STEPANOVIC[2], M. HAYES[2], K. P. DOYLE[3];

Abstract: Approximately 30% of stroke survivors develop dementia following a stroke. We hypothesize that one of the mechanisms that contributes to this delayed cognitive decline is a chronic inflammatory response that persists at the site of the stroke lesion and causes bystander damage to surrounding tissue. To address this hypothesis, we present a comprehensive

characterization of the cytokine and chemokine response to stroke in the human brain at different stages of wound healing. Our data indicate that inflammation following stroke may not be as efficiently self-limiting as it is in other tissues. In addition, due to most basic and preclinical research being conducted in rodent models of stroke, we also present a comparison of the cytokine and chemokine response to stroke in human and mouse brains at two different stages of wound healing, using C57BL/6 and BALB/c mice to control for strain related differences in the immune response. Our data indicate that the acute inflammatory response to stroke is largely conserved in mice as well as in humans. In each mouse strain and in humans, there is a significant increase in levels of GM-CSF, IL-6, IL-12 (p70), IP-10, KC/IL-8, MCP-1, MIP-1α, MIP-1β, RANTES, and TNFα in the infarct core during the acute time period. However, in the weeks after stroke, during the stage of liquefactive necrosis, the chronic inflammatory response to stroke diverges in both mouse strains and humans; only the sustained elevation of IL-6 and MCP-1 is conserved in mice and humans, with each strain of mouse and each species displaying a unique profile of chronically elevated pro-inflammatory cytokines in the area of infarction. Furthermore, because nearly 75% of all strokes occur in patients over the age of 65, and approximately 25% of strokes are recurrent strokes, we also present findings that reveal how the inflammatory response to stroke is impacted by age and multiple strokes in mice. Our data indicate that the chronic inflammatory response to stroke is not exacerbated by age in 18-month old mice compared to 3-month old mice but is significantly exacerbated by a recurrent stroke.

Title: Development of a novel anti-inflammatory and anti-osteoclastic peptide based on RANKL for treatment of ischemic stroke

Authors: ***H. KURINAMI**[1], M. SHIMAMURA[2], H. NAKAGAMI[3], H. MOCHIZUKI[2], R. MORISHITA[4];

[1]Osaka Univ., Suita/Osaka, Japan; [2]Dept. of Neurol., [3]Dept. of Hlth. Develop. and Med., [4]Osaka Univ. Grad. Sch. of Med., Suita, Japan

Abstract: Background & Purpose: We previously showed that stimulation of RANKL (receptor activator of nuclear factor-B ligand)/ RANK (receptor for RANKL) signal with recombinant RANKL worked as protective in ischemic brain through inhibiting TLR signaling pathways. However, augmentation of RANK signaling is also causative for increasing osteoclast differentiation and osteoporosis, which is one of risk factors in poor prognosis in ischemic stroke. To overcome the problem, we developed a novel RANKL-based peptide, which is anti-inflammatory and anti-osteoclastic.
Methods: We made three peptides: MHP1 and 2 with DE loop and EF loop; MHP3 including complete CD loop and DE loop. The action of the peptides was evaluated in MG6 cells (microglia), RAW 264.7 cells (macrophage), primary osteoclast precursor cells, and primary mixed neuron-glia cultures. The effects of the peptide were also checked in 40 min-transient cerebral artery occlusion (tMCAo) model in C57BL6/J mice.
Results: In LPS-stimulated MG6 and/or RAW 264.7 cells, MHP1 and MHP2 inhibited expression of IL-6 and TNFα, whereas MHP3 showed no effects. This anti-inflammatory effects of MHP1 was dependent on RANK signals because knockdown of RANK showed lack of action. The effects of anti-inflammation of MHP1 were also shown in LPS-stimulated primary mixed neuron-glia cultures. In primary osteoclast precursor cells, MHP1 did not stimulate osteoclast differentiation, which is quite different from recombinant RANKL. Interestingly, MHP1 also inhibited RANKL-induced osteoclast differentiation. The expression of IL-6 and TNFα was prevented in the stimulation of FSL-1 (a ligand for TLR2/6) but not S100β (a ligand for RAGE), indicating that the action of MHP1 might be specific in TLRs signaling. Finally, we injected MHP1 intracerebroventricularly at 4 hrs after the ischemia and evaluated the effects. MHP1-treated mice showed less infarct volume and activated microglia/macrophages in ischemic brain at 72 hrs after ischemia.
Conclusions: Thus, MHP1 is a partial agonist of RANKL, which could inhibit TLR-related inflammations without activation of osteoclasts. MHP1 could be a novel agent for preventing inflammation and osteoporosis in ischemic stroke.

Title: Estrogen regulation of inflammasome activation and microglial phenotype in the hippocampus after global cerebral ischemia

Authors: *R. D. THAKKAR[1], R. WANG[1], Q. ZHANG[1], R. VADLAMUDI[2], D. BRANN[1]; [1]Dept. of Neurosci. and Regenerative Med., Med. Col. of Georgia, Augusta Univ., Augusta, GA; [2]Dept. of Obstetrics and Gynecology, Univ. of Texas Hlth. Sci. Ctr., San Antonio, TX

Abstract: 17β-estradiol (E2) is a well-known neuroprotective factor in the CNS. Recently, our lab showed that the estrogen receptor (ER) co-regulator protein, Proline-, glutamic acid-, and leucine-rich protein 1 (PELP1) is critical for its neuroprotective and cognitive effects. In the current study, we examined whether E2, acting via PELP1, can exert anti-inflammatory effects in the ovariectomized rat and mouse hippocampus to regulate NLRP3 inflammasome activation, cytokine production and microglial M1/M2 phenotype after global cerebral ischemia (GCI). The results showed that activation of the NLRP3 inflammasome pathway and expression of its downstream products, cleaved caspase-1, and IL1β, are temporally increased in the hippocampus after GCI, with peak levels observed at 6-7 days. E2 robustly inhibited NLRP3 inflammasome pathway activation, caspase-1 and pro-inflammatory cytokine production, as well as gliosis after GCI at gene as well as protein levels. Moreover, E2 also profoundly suppressed the pro-inflammatory M1 microglial phenotype, while increasing the anti-inflammatory M2 microglial phenotype early after GCI. Intriguingly, the ability of E2 to exert all of these anti-inflammatory effects was lost in PELP1 forebrain-specific knockout mice. Collectively, our study demonstrates that E2 signaling via the ER co-regulator, PELP1 exerts robust anti-inflammatory effects in the hippocampus after GCI to regulate inflammasome activation, cytokine production and microglia phenotype. Thus, in addition to its neuroprotective actions, E2 can also exert robust anti-inflammatory effects following ischemic injury to the brain.

Title: Oosteopontin attenuates secondary neurodegeneration in the thalamus after experimental stroke

Authors: *M. SCHROETER[1], A. LADWIG[1], J. HUCKLENBROICH[2], A. WILLUWEIT[3], M. SCHOENECK[3], K.-J. LANGEN[3], G. R. FINK[1,4], M. RUEGER[1];

Abstract: Background: Cortical cerebral ischemia elicits a neuroinflammatory reaction not only at the site of the infarction, but also in remote areas. Typically, neurodegeneration affects reciprocally connected thalamic nuclei. Thalamic injury contributes to persisting clinical disability, pain syndromes, and neuropsychiatric problems after stroke. Osteopontin (OPN) is a cytokine-like glycoprotein that is excreted in high amounts after cerebral ischemia and which exerts various immunomodulatory functions. In this study we examined its protective effects on thalamic neurons.
Methods: Male wistar rats were subjected to photothrombosis and subsequently injected intracerebroventricularily with 500µg OPN or vehicle. Immunohistochemical and fluorescence staining were used to detect inflammation (Iba1, Ox42, ED1), neurodegeneration (NeuN), regenerative processes (NG2), cell proliferation (BrdU), microglia M1 (iNOS) and M2 polarisation (CD206, Arg1, and Ym1). Autoradiography scans were used to visualize degeneration (D-Prolin) and proliferation (thymidine).
Results: Extensive secondary neurodegeneration with microglial activation and neurodegeneration in the thalamus was found in all animals with cortical ischemia. Microglial infiltration co-distributed with neurodegeneration. Treatment with osteopontin significantly decreased neurodegeneration, inflammation, and microglial proliferation and improved regenerative processes. Although microglia was classified as activated by morphological criteria, microglia did not express markers of M1 or M2 polarisation. D-Prolin uptake mirrored degeneration. Within the infarct tissue it was not significantly changed, whereas it visualized attenuated thalamic degeneration in OPN treated animals.
Conclusion: Thalamic secondary neurodegeneration can be ameliorated by pharmacological treatment with OPN. Whether this also improves clinical outcome warrants further investigation.

Title: Post-ischemic whole body vibration reduces inflammation in the brain of middle-aged female rats

Authors: *M. SCHATZ[1,4], N. D'ADESKY[4], P. BHATTACHARYA[4], A. P. RAVAL[4], D. W. DIETRICH[2], H. M. BRAMLETT[3,5];
[1]Neurol., Univ. of Miami, Weston, FL; [2]Neurolog. Surgery, [3]Neurol., Univ. of Miami, Miami, FL; [4]Neurol., Cerebral Vascular Dis. Res. Labs., Miami, FL; [5]VA, Bruce W. Carter, Miami, FL

Abstract: A woman's risk of stroke increases exponentially after menopause, and even a mild ischemic episode can result in increased frailty. Studies performed in laboratory animals and humans support that whole body vibration (WBV) reduces or reverses pathological remodeling of bone and lessens frailty-related physiological deterioration. Using a rodent model of stroke, we have examined whether WBV reduces inflammation and post-ischemic damage and improves motor function in middle-aged female rats. Middle-aged Sprague–Dawley female (9–11 months) rats were exposed to transient middle cerebral artery occlusion (tMCAo; 60 min) and randomly assigned to either WBV or control groups. Animals placed in the WBV (40 Hz) group underwent 30 days of WBV treatment performed twice daily for 15 min each session for 5 days each week. During the treatment period, we tested motor function using a rotarod test at the 7th, 15th and 30th day after tMCAo. Animals were sacrificed on 30th day of WBV treatment and brain tissue was harvested for histopathological and inflammasome protein analysis performed by western blotting. Western blot results demonstrated a two-fold decrease in the inflammasome proteins caspase-1, caspase recruitment domain (ASC), and interleukin-1β. The rotarod test scores from the WBV treatment group were significantly higher than the control group on day 30 ($p < 0.05$) at 10, 30 and 40 RPM speeds, suggesting a significant improvement in functional activity of the WBV group. Overall, WBV has shown promising results in decreasing inflammation and increasing functional activity after stroke in middle-aged female rats.

Title: The therapeutic effects of pomalidomide to attenuate inflammation <and> mitochondrial dysfunction of cerebral ischemia

Authors: *Y.-R. TSAI[1,2], C.-F. CHANG[3], J.-H. LAI[1,2], K.-Y. CHEN[1,2], J.-C. WU[3], Y.-H. CHIANG[3,1,2];
[1]The Ph.D. Program for Neural Regenerative Med., [2]Ctr. for Neurotrauma and Neuroregeneration, Taipei Med. Univ., Taipei, Taiwan; [3]Dept. of Neurosurg., Taipei Med. Univ. Hosp., Taipei, Taiwan

Abstract: Stroke is one of the top major leading causes of death and severe disability in the world. After cerebral ischemia, inflammation plays a key role in the development of permanent neurological damage. Evidences indicated that reactive oxygen species (ROS) was involved in the mechanism of post-ischemic inflammation. ROS is produced by activation of several inflammatory enzymes and then suppresses the activity of mitochondria causing further tissue damage. In this study, we investigated pomalidomide, an immunomodulatory drug, in in primary neuronal culture of H2O2-induced injury model and in middle cerebral artery occlusion (MCAO) rodent model of ischemic stroke. The effects of pomalidomide were consistent for in vitro and in vivo models. In vitro results, we found that use of low dose pomalidomide in H2O2-insulted neuronal culture significantly decreased the level of LDH release and MTT assay was provided results consistent with LDH assay. In addition, the protein level of complex III expression in low dose of pomalidomide with H2O2-insulted group was superior to H2O2-insulted group in primary neuronal culture. Also, the Apoptosis-inducing factor (AIF) expression, low dose of pomalidomide with H2O2-insulted group was distinctly lower than H2O2-insulted group. Similarly, for in vivo results, triphenyltetrazolium chloride (TTC) stain brain showing a markedly decreased infarct volume in pomalidomide group compared with the control group in MCAO model. In conclusion, our in vitro and in vivo results showed that pomalidomide exhibits neuroprotective effects and reduces cerebral ischemia/reperfusion injury. And these results suggest that pomalidomide may preserve mitochondiral function by reducing mitochondrial ROS production and also decrease apoptosis after ischemic brain damage.

Title: Changes of forebrain activity after partial infraorbital nerve ligation: a manganese-enhanced magnetic resonance imaging <MEMRI > study

Authors: *W.-T. ZHAO[1,2], R.-F. CHEN[1,3], J.-H. CHEN[1,2,4,5], C.-T. YEN[1,3];
[2]Grad. Inst. of Biomed. Electronics and Bioinformatics, [3]Life Sci., [4]Electrical Engin., [5]Mol. Imaging Ctr., [1]Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Peripheral neuropathy often leads to spontaneous pain, allodynia and hyperalgesia. However, the neuroplastic changes in the brain relate to the progression of neuropathic symptoms remain unclear. In this study, we used partial ligation of infraorbital nerve (pIONx) rat model to longitudinally follow behavioral and functional brain changes associated with the development of hypersensitivity. Female Sprague-Dawley rats were first trained to endure 26g of von frey filament stimulation in the whisker pad. Thereafter, each rat was scanned 3 times of whole brain MEMRI. The First time is baseline, the second time is on the same day after pIONx, and the third time is 15-d after pIONx. For MEMRI, $MnCl_2$ solution (20 mg/Kg) was given intraperitoneally and the rat was returned to home cage for 24 hours of Mn^{2+} accumulation. All MEMRI scans were acquired under isoflurane anesthesia. For pIONx, the rat was anesthetized with sodium pentobarbital (65 mg/ Kg, i.p.), and 1/3 to 1/2 of the left ION was isolated and ligated. The rat had 24hr free access to ibuprofen in the drinking water to reduce the surgical pain. Our within-animal results showed (1) elevated trigeminal ganglion and cortical activities 24 hours after pIONx. (2) Widespread cortical activity increases 15 days after surgery. Additionally, we compared group MEMRI according to behavioral response of the rat (i.e. pain group vs non-pain group) on day 15 after pIONx. Rats with neuropathic pain showed enhanced activity in bilateral cingulated cortex, nucleus accumbens, and caudate putamen; ipsilateral sensorimotor cortex, orbitofrontal cortex, and insular cortex. These observations suggest that partial ligation of infraorbital nerve increases limited cortical regions in 24 hours and neuropathic pain symptoms were associated with increased limbic and sensorimotor activity.

Title: Neural correlates of trigeminal pain

Authors: *Q. ZHAO[1], C. SPECTOR[2], J. NEUBERT[2], M. DING[1];
[1]J. Crayton Pruitt Family Dept. of Biomed. Engin., [2]Dept. of Community Dent. & Behavioral Sci., Univ. of Florida, Gainesville, FL

Abstract: Trigeminal Neuralgia (TN) is a debilitating chronic facial pain disorder. It is generally believed that focal demyelination due to vascular compression of the trigeminal nerve is the cause of the condition. However, unpredictable responses to surgical treatment, and variability in long-term clinical outcomes suggest that TN may involve both peripheral and central mechanisms. The goal of this study was to investigate the neural correlates of trigeminal pain. Eight patients (6 females) clinically diagnosed with TN enrolled and underwent MRI scanning. The scanning session had two periods: (1) pain rating period and (2) visuomotor tracking period, each lasting 10 minutes. During the pain rating period, subjects rated the moment-to-moment intensity fluctuations of their facial pain using a trackball on a visually displayed 0-100 scale. During the visuomotor tracking period, subjects were provided with the pain intensity fluctuations recorded from the pain rating period and instructed to track the cursor movement with the trackball. During analysis the visuomotor tracking period was subtracted from the pain rating period to remove motor-related activations. Simultaneous EEG-fMRI was recorded from the patients during the experiment. One subject did not complete the scan and was excluded. Analysis of the remaining 7 subjects revealed the following results. First, correlating the pain intensity fluctuation with blood-oxygen-level-dependent (BOLD) activity, we found that BOLD in insula and anterior cingulate cortex (ACC) was positively correlate with pain intensity, whereas BOLD in thalamus and postcentral gyrus was negatively correlated with pain intensity. Second, extracting the power of theta-band (4 to 8 Hz) EEG oscillations from frontal channels and the power of alpha-band (8 to 12 Hz) EEG oscillations from occipital channels using a moving window, we found evidence that theta and alpha power was correlated with the pain intensity fluctuation in some patients. Third, correlating theta power with BOLD, we found positive BOLD-theta correlation in insula, and negative BOLD-theta correlation in thalamus and ACC. Fourth, correlating alpha power with BOLD, we found positive BOLD-alpha correlation in insula, ACC and fusiform face area, and negative BOLD-alpha correlation in thalamus, putamen and caudate. These results demonstrate that TN was associated with the activation and deactivation of a complex brain network. Rhythmic brain oscillations might provide an index of the level of pain intensity.

Title: Behavioral and local field potential changes in the thalamus and anterior cingulate cortex of behaving rats experiencing post herpetic neuralgia

Authors: *J. N. STRAND[1], M. RAO[2], Y. PENG[1], L. BELLINGER[2], P. KRAMER[2];
[1]Univ. of Texas At Arlington, Arlington, TX; [2]Dept. of Biomed. Sci., Baylor Col. of Dentistry, Texas A&M Univ., Dallas, TX

Abstract: Post herpetic neuralgia (PHN) is experienced as burning pain in the facial region, caused by nerve damage from the herpes zoster virus. The pain often becomes chronic and debilitating. Investigations into the pain pathway become vital. Pain itself is multidimensional, consisting of both the sensory and affective experiences. One of the primary brain substrates for transmitting sensory signals in the facial muscles is through ventral posterior medial thalamus (VPM). Anterior cingulate cortex (ACC) has been shown to be vital in the affective experience of pain, so investigating both of these areas in freely behaving animals can provide important information. Local field potential (LFP) recordings measure changes to the summation of subthreshold neuronal activity. A new investigational method of using a designer receptor activated by a designer drug (DREADD) (Armbruster et al, 2007) has been shown by our lab to inhibit both neuronal activity in the VPM and spontaneous pain behavior in a formalin pain model in rats. By application of DREADD, the LFPs of both VPM and ACC were recorded simultaneously to see how the inhibition of neuronal activity in the VPM affects neuronal activity in the ACC in freely behaving rats in a more clinically relevant pain model, PHN. Additionally, a place escape-avoidance paradigm was used to measure affective experience of pain (Fuchs et al, 2014). Methods: DREADD was infused into the VPM of Sprague-Dawley rats and LFP recording electrodes were implanted into the VPM and ACC. A week later, the whisker pads were injected with either varicella zoster virus (VZV) infected cells or MeWo (control) uninfected cells. Within 7-14 days, the LFP for both VPM and ACC were recorded, DREADD was activated via IP injection (or saline for control) of clozapine-N-oxide. A new baseline was recorded and the animals were tested using a preferred escape-avoidance paradigm. We found that, similar to the spontaneous pain behavior, escape-avoidance behavior is significantly

reduced in the drug group compared to the no drug group in PHN. Changes in LFP activity of theta, alpha, beta, and gamma wavelengths were noted in both the ACC and VPM with increased activity observed in PHN rats compared control and also between the drug and no drug group in PHN. Understanding how manipulation of thalamic activity can affect changes in both neuronal activity and pain behavior can bring us closer to identifying novel ways to relieve post herpetic neuralgia in humans.

Title: Blockade of central of angiogenesis promotes antinociceptive effects in rats with trigeminal neuropathic pain

Authors: *D. K. AHN[1], J. SON[1], M. KIM[1], H. KIM[1], J. JU[1], K. YANG[1], M. PARK[2], M. LEE[3], H. KIM[1];

Abstract: Angiogenesis factors, Hypoxia-inducible factor 1 alpha (HIF-1α) and vascular endothelial growth factor (VEGF), stimulate the vascular function through modulation of endothelial cell functions and vascular permeability. The present study investigated a role of HIF-1α and VEGF in the development of trigeminal neuropathic pain. Sprague-Dawley male rats were anesthetized with ketamine (40 mg/kg) and xylazine (4 mg/kg). Under anesthesia, the left lower second molar was extracted, followed by the placement of a mini-dental implant to intentionally injure the inferior alveolar nerve. The blood-brain-barrier (BBB) permeability was assessed by detecting the concentrations of sodium fluorescein (NaF) in the medullary dorsal horn. Inferior alveolar nerve injury by mal-positioned dental implant produced prolonged mechanical allodynia compare to the sham group. Intracisternal infusion of VEGF antibody (250, 500 ng/ 24 hr/ 7 days) significantly attenuated mechanical allodynia produced by mal-positioned

dental implants. Intracisternal injection of ZM 306416 (100 μg), a VEGF receptor 1 inhibitor, or Vandetanib (20 μg), a VEGF receptor 2 inhibitor, produced inhibition of mechanical allodynia. Western blotting analysis reveals that inferior alveolar nerve injury produced up-regulation of both HIF-1α and VEGF expression in the medullary dorsal horn. Double immnuoflurosence data showed that VEGF receptor 2 co-localized with astrocyte cells but VEGF receptor 1 found in vessels stained positive with the BBB in the medullary dorsal horn. Intracisternal injection of PX-12 (50 μg), a HIF-1α inhibitor, produced inhibition of mechanical allodynia. In addition, inferior alveolar nerve injury increased extravasated NaF level which was blocked by intracisternal infusion of VEGF antibody. These results suggest that central HIF-1α and VEGF pathway play a critical role in the development of trigeminal neuropathic pain and blocking of HIF-1α or VEGF pathway is a new potential therapeutic target for neuropathic pain control including the orofacial area.

Title: Toll like receptor 4 signaling contributes to compound 4880 evoked light aversion in a murine migraine model

Authors: *R. RAMACHANDRAN[1], C. SAVEEDRA[1], Z. WANG[2], N. MASCARENHAS[2], A. DINARDO[2], M. CORR[3], T. L. YAKSH[1];
[1]Dept of Anesthesiol., [2]Dept. of Medicine, Div. of Dermatol., [3]Dept. of Medicine, Div. of Rheumatology, Allergy and Immunol., UCSD, San Diego, CA

Abstract: Background: Neurogenic inflammation is considered to be a major component of migraine and the role of toll-like receptor 4 has been implicated in chronic inflammatory pain states. Compound 48/80 induced mast cell degranulation activates migraine pain pathway and we assessed the development of light aversive behavior, as a surrogate of photophobia following compound 48/80 in both male and female mice. We also determined the role of toll-like receptor

4 in mast cell degranulation induced migraine -like behavior and neuronal activation. **Methods:** Mice (male and female, C57Bl6), WT and TLR4 KO's were acclimatized for 15 min a day before the actual testing day in a test system composed of two equally sized chambers (light and dark) where animals could move freely through a small portal. On the day of testing baseline behavior was determined for 15 min prior to the injection with saline or the drug i.p. Following saline/compound 48/80 administration, animals were tested for 15 mins at different time points (15 min, 1 hr, 2 hrs and 4 hrs). Time spent in the light and dark box was assessed by the obscuration by the animal of red light LEDs. Effect of pre-treatment with sumatriptan (45 min) and TLR4 antagonist TAK-242 (3 hrs) were also analyzed in this model. Another group of WT and KO mice were sacrificed at 10 min following compound 48/80 for analyzing p-ERK activation in nucleus caudalis. **Results:** Compound 48/80 induced i) light aversive behavior that lasted for 2 hrs with a complete reversal to the 40/60 ratio by 4 hrs ii) neuronal activation (measured by p-ERK) in nucleus caudalis in males and females and pre-treatment with sumatriptan reversed these effects. Genetic knockouts and pharmacological intervention of TLR4 reversed the effects of compound 48/80 in males, but not in females. **Significance:** We demonstrate that i) compound 48/80 induced mass cell degranulation elicits light aversive behavior in mice ii) Reduction in light aversion was observed when pre-treated with specific anti-migraine drug sumatriptan iii) Importantly, the present study provides the first evidence for the involvement of TLR4's in initiating and maintaining migraine-like behaviour and neuronal activation in a murine migraine model.

Title: ASIC3 inhibitor APETx2 elicits a differential effect on neuropeptide expression in trigeminal afferent neurons after masseter muscle repetitive acid exposure

Authors: *J. MORRIS-WIMAN[1], C. G. WIDMER[2];
[1]Biomed. Sci., West Virginia Sch. of Osteo. Med., Lewisburg, WV; [2]Orthodontics, Univ. of Florida, Gainesville, FL

Abstract: Persistent orofacial pain conditions such as temporomandibular disorders involve pain in the temporomandibular joint and masticatory muscles with a predominance of pain in the jaw closing muscles such as the masseter. The biological basis for this persistent pain is still unclear and models that may mimic some portion of the pathophysiology of the muscle pain are lacking. Earlier we reported on a model for orofacial pain in which repetitive unilateral injections of acidic saline (pH 4) into masseter muscle elicited persistent bilateral pain that was associated with changes in chewing behavior and with significant increases in the expression of neuropeptides (substance P and CGRP), BDNF and ASIC3. The objective of this study was to determine if increases in expression of SP and CGRP could be prevented by an inhibitor (APETx2) specific to ASIC3. Methods: Female CD-1 mice were repetitively injected with either neutral saline (pH 7, n=5), or acidic saline (pH 4, n=5) into the right masseter separated by five days. Five mice were injected with 10µl of APETx2 in PBS (3µM) into the right masseter just prior to the second acidic saline injection; five mice were used as unmanipulated controls. Seven days after the second injection the mice were sacrificed, ganglia harvested, snap-frozen, and stored at -80° until cryosectioned. 12µm cryosections of right ganglia were immunostained for either SP or CGRP (Peninsula Labs) and images acquired using a Zeiss MRm digital camera and Axiovision software. Images were histogram-matched and thresholded to produce binary images to eliminate bias. The total number of ganglion cells and the number immunolabeled for CGRP or SP were counted for three sections, 150 µm apart, for each animal. Results: No significant differences were observed between controls or neutral saline-injected in the percentage of ganglion cells expressing either CGRP (25% controls; 29% neutral) or SP (25% controls; 30% neutral). A significant increase was detected between acidic saline-injected and all other groups in the percentage of ganglion cells immunolabeled for CGRP (71% acid) and SP (75% acid). Whereas no significant difference was detected between ganglia from APETx2-injected and controls or neutral saline-injected in the percentage of cells immunolabeled with CGRP (31% APETx2), a significantly increased number of ganglion cells expressing SP was detected in APETx2- injected (50%). Conclusions: The results of the study support a role for ASIC3 in the initiation and maintenance of persistent pain in our repetitive acidic saline injection model for orofacial pain.

Title: Fusobacterium nucleatum enhances oral cancer-induced activation of primary afferent neurons innervating the tongue

Authors: *N. SCHEFF, R. VEERAMACHANENI, J. MACRAE, W. M. KWON, D. G. ALBERTSON, B. L. SCHMIDT;
New York Univ., New York, NY

Abstract: Oral cancer patients report severe function-related pain, induced by mediators from the cancer. We recently reported that bacterial communities associated with a patient's oral cancer differ from that of the patient's clinically normal anatomically matched contralateral site. Analysis of the cancer associated and normal microbiomes of 46 patients who had completed the University of California San Francisco Oral Cancer Pain Questionnaire revealed significant differences in abundance of bacterial taxa correlated with the patients' responses regarding function related pain. The cancers displayed reduced abundance of *Streptococcus* and increased abundance of *Fusobacterium*. We hypothesize that *Streptococcus mitis (S. mitis)* protects the oral microenvironment from carcinogenesis and cancer-associated pain, while *Fusobacterium nucleatum (F. nucleatum)*, implicated in colon carcinogenesis, promotes oral cancer and pain. To test this hypothesis, we co-cultured a human oral cancer cell line, HSC-3, with *F. nucleatum* or *S. mitis*, applied the culture supernatants to retrogradely-labeled primary afferent neurons innervating the tongue and imaged Ca^{2+} influx. Supernatant from HSC-3 cells with *F. nucleatum* or *F. nucleatum* alone evoked a significantly greater Ca^{2+} response in trigeminal neurons compared to HSC-3 supernatant alone, HSC3 + *S. mitis* or *S. mitis* alone. These observations suggest that *F. nucleatum* enhances neuronal activation by oral cancer and potentially worsens cancer pain. *In vivo* experiments are on-going using the 4-NQO (4-nitroquinoline 1-oxide) murine model of oral carcinogenesis. Male and female C57Bl/6 mice are treated with 100 µg/ml 4NQO in the drinking water for 16 weeks *ad libitum* and monitored for an additional 8 weeks. Pain is measured using an operant gnawing assay throughout treatment. The model recapitulates human sex differences, as female mice with tongue cancers or severely dysplastic lesions showed significantly greater pain compared to males. To determine whether *F. nucleatum* or *S. mitis* promotes or protects from oral cancer development and pain in this model, pain is being measured in an additional group of female mice, inoculated with $1x10^{10}$ of either bacteria. From our *in vitro* experiments, we expect that mice inoculated with *F. nucleatum* will show accelerated

cancer development and increased pain. This work was kindly supported by the IASP John J Bonica 2014 award.

Title: Sequential changes in rat cortical excitation during orthodontic treatment.

Authors: E. HORINUKI[1,2], *S. N. FUJITA[2,3], N. SHIMIZU[1,2], M. KOBAYASHI[2,3]; [1]Orthodontics, [3]Pharmacol., [2]Nihon Univ. Sch. of Dent., Tokyo, Japan

Abstract: Somatosensory information derived from the periodontal ligaments (PDL) plays a critical role in identifying the strength and direction of occlusal force. The orthodontic force often causes uncomfortable sensations including nociception around the tooth, and disturbs somatosensory information processing. However, it has remained unknown whether orthodontic treatment modulates higher brain functions, especially cerebrocortical activity. To address this issue, we first elucidated the cortical regions involved in sensory processing from the PDL. In vivo optical imaging was performed to identify the cortical responses evoked by electrical stimulation of the maxillary and mandibular incisor and the first molar PDL in the rat. In naive rats, electrical stimulation of the mandibular PDL initially evoked neural excitation in the rostroventral part of the primary somatosensory cortex (S1), the ventrocaudal part of the secondary somatosensory cortex (S2), and the insular oral region (IOR), whereas maxillary PDL stimulation elicited excitation only in S2/IOR rostrodorsally adjacent to the mandibular PDL-responding region. In contrast, maximum responses to mandibular and maxillary PDL stimulation were observed in S1 and S2/IOR, and these responses almost overlapped. Next, we examined the sequential changes in the cortical excitation induced by stimulation of the maxillary 1st molar PDL during experimental tooth movement (ETM). Optical imaging was performed 1, 3, and 7 days after ETM. To apply orthodontic force in the ETM models, the

maxillary incisors and the right first molar were bound with a closed coil spring. The ETM models showed facilitated cortical excitatory propagation in comparison with controls one day after ETM, however, the facilitation gradually recovered to the control level 3-7 days after ETM. These findings suggest that orthodontic force does not induce a long-lasting neuroplastic change in the somatosensory and insular cortices. The temporal profile of the facilitated cortical responses is comparable to that of pain and discomfort induced by clinical orthodontic treatments. Finally, immunohistochemical experiment was performed to examine the relationship between cortical responses and expression of inflammatory cytokines in PDL of the maxillary 1st molar. The peak amplitude of optical signals responding to PDL stimulation tended to be increased in parallel to the number of IL-1β and TNF-α immunopositive cells, suggesting that at least in part, the enhancement of cortical responses are induced by PDL inflammation.

Title: The role of serotonin in peripheral trigeminal nociception

Authors: *C. GUERRERO-TORO[1,2], E. KILINC[2], A. ZAKHAROV[2,3], C. VITALE[1,2], M. GUBERT-OLIVE[1,2], R. GINIATULLIN[1,2];

Abstract: Despite the generally accepted view that serotonin plays a key role in migraine pathology, the precise contribution of serotonin to this disorder remains largely unknown.To approach this issue, we studied, in rats, the action of serotonin (5-hydroxy-tryptamine, 5-HT) and its analogues on meningeal afferents, trigeminal neurons and satellite glial cells (SGC) using patch-clamp recordings and calcium imaging in primary cultures of trigeminal ganglia. In the whole mount meningeal preparation with preserved trigeminal innervation, we found that serotonin evoked a robust and long-lasting nociceptive firing (71% were either transient or persistent) in the peripheral terminals of meningeal afferents. Similar effect was induced by the specific 5-HT3 agonist m-chlorophenylbiguanide (m-CPBG). Thus, 5-HT has a pro-nociceptive peripheral effect mainly via the ligand gated 5-HT3 receptors. We have shown that intracellular calcium was elevated in 21% of the primary cultured neurons after the administration of 20 uM serotonin. Interestingly, the majority of these neurons also responded to capsaicin suggesting a

co-expression of TRPV1 and serotonin receptors. In the same manner, 21% of SGCs responded to serotonin. The specific 5-HT3 agonist m-CPBG increased intracellular calcium response in 26% of trigeminal neurons suggesting expression of 5-HT3 receptor type in neurons. In contrast, m-CPBG was not effective in SGC suggesting expression of metabotropic receptors in these glial cells. Our data suggest that serotonin acting via 5-HT3 receptor in the trigeminal nociceptive network provides an excitatory nociceptive drive. Serotonin also activate glial cells potentially contributing to chronization of migraine pain.

Title: The effect of anandamide on the expression of CaMKIIα and TRPV1 in an animal model of migraine

Authors: *C. F. LABORC[1], G. NAGY-GRÓCZ[1,2], Z. BOHÁR[3], A. FEJES-SZABÓ[1], L. VÉCSEI[1,3], Á. PÁRDUTZ[1];
[1]Dept. of Neurol., [2]Fac. of Hlth. Sci. and Social Studies, [3]MTA-SZTE, Neurosci. Res. Group, Univ. of Szeged, Szeged, Hungary

Abstract: Migraine is one of the most prevalent primary headache disorders. The underlying mechanisms are still unclear, however the activation and sensitization of the trigeminal system is essential in the pathogenesis. A well-known human and animal model of migraine headache is the systemic administration of nitroglycerin (NTG), a nitric-oxide donor. It can induce an immediate headache in healthy subjects, and a migraine-like attack in migraineurs after several hours. NTG is able to activate and sensitize the trigeminovascular system in animal experiments. Calcium/calmodulin-dependent protein kinase II α (CaMKIIα) is present in the dorsal horn of the spinal cord. The peripheral inflammation induced central sensitization depends on the levels of CamKIIα, thus CamKIIα is pivotal in this mechanism. Transient receptor potential cation channel, subfamily V member 1 (TRPV1) is a non-selective cation channel which occurs in the

trigeminal nerve system. In chronic pain the expression of TRPV1 is increased, it might be involved in the sensitization process. The endocannabinoid anandamide (AEA) is the endogenous agonist of the TRPV1 and the cannabinoid receptors. Beside its antinociceptive effect it is able to reduce allodynia and hyperalgesia in animal models of neuropathic pain. Therefore the aims of our study were to investigate that if AEA and/or NTG are capable of changing the CaMKIIα, TRPV1 expression levels after systemic NTG treatment in the dorsal horn of the cervical 1-cervical 2 (C_1-C_2) segments of the spinal cord, where the secondary trigeminal neurons are located. To achieve this, we used adult, male SPRD rats (n=20). In the first group we administered physiological saline intraperitoneally (i.p.), the second group received i.p. NTG. 30 minutes prior to the NTG/saline injection and 1 hour after, we gave i.p. AEA to the animals in the third and fourth group. Four hours after the saline/NTG treatment the rats were perfused and the C_1-C_2 spinal cord was removed. CaMKIIα, TRPV1 expression levels were detected with Western-blot analysis. Our results showed that both NTG and AEA alone was able to increase CamKIIα expression in the C_1-C_2 segments. NTG and AEA together had an opposite effect on this marker, possibly via negative feedback. In the case of TRPV1, NTG increased the expression, while this response was not observed with pretreatment with AEA. Consequently AEA can prevent the NTG induced sensitization in the secondary trigeminal sensory neurons.

Title: Heterogeneous expression of purinergic receptor subtypes in rat odontoblasts

Authors: *G. CHUNG[1], B.-M. LEE[1], Y. KIM[1], C.-K. PARK[2], S. JUNG[3], S. OH[1]; [1]Oral Physiol. & Neurobio., Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Gachon Univ., Incheon, Korea, Republic of; [3]Hanyang Univ., Seoul, Korea, Republic of

Abstract: Odontoblasts form dentin at the outermost surface of tooth pulp. Increasing number of evidences in recent years along with the locational advantage support the secondary role of odontoblasts as sensory or immune cells. Extracellular ATP is well characterized signaling molecule in both neuronal and immune systems, and its potential involvement in inter-odontoblast communications was demonstrated recently. In an effort to elaborate the purinergic signaling mechanism in odontoblasts, current study investigated expression of calcium-signaling ATP receptors in odontoblasts isolated from incisal teeth of 8-10 week old rats through single cell RT-PCR, and their response to ATP application in vitro by calcium imaging expreriment. While RT-PCR analysis of tooth pulp detected all seven $P2X_1$- $P2X_7$ subtypes, single cell RT-PCR analysis of acutely isolated rat odontoblasts revealed $P2X_2$, $P2X_4$, $P2X_6$, $P2X_7$, $P2Y_2$ and $P2Y_4$ expression in 23-47% of cells tested, with no evidence for $P2X_1$, $P2X_3$ and $P2X_5$ expression. Increase of intracellular Ca^{2+} concentration in response to 100μM ATP, which was repeated after pretreatment of thapsigargin or under 0 Ca^{2+} condition, suggested function of both ionotropic and metabotropic ATP receptors in odontoblasts. Positive calcium response to 2',3'-O-(benzoyl-4-benzoyl)-ATP (BzATP) and negative response to α,β-methylene ATP confirmed $P2X_2$, $P2X_4$ and $P2X_7$ as functional subunits in rat odontoblasts. The enhancement of ATP-induced calcium response by ivermectin and inhibition by 5-(3-Bromophenyl)-1,3-dihydro-2H-benzofuro[3,2-e]-1,4-diazepin-2-one (5-BDBD) further confirmed functional P2X4 subtype in odontoblasts. The functional expression of $P2X_4$ and $P2X_7$ was corroborated with scRT-PCR analysis of the cells harvested after positive response from the calcium imaging experiment. Overall, this study demonstrates heterogeneous expression of calcium-related purinergic receptor subtypes in subsets of individual odontoblasts, suggesting extracellular ATP as potential signal mediators for odontoblastic functions.

Title: Nociceptive inputs to trigeminal nucleus caudalis neurons - implications for migraine

Authors: *B. PRADIER[1], D.-S. KIM[2], D. LIPSCOMBE[3], J. A. KAUER[1];
[1]Dept. of Mol. Pharmacology, Physiol. and Biotech., Brown Univ., Providence, RI; [2]Dept. of Anat., SoonChunHyang Univ., Asan, Korea, Democratic People's Republic of; [3]Dept. of Neurosci., Providence, RI

Abstract: Migraine is a disabling and episodic brain disorder with high prevalence and complex pathophysiology. Animal models suggest that sensitization of the trigeminal pathway plays a major role in the pathology of migraine, yet little is known about long-term changes in trigeminal afferents or their synapses in the brainstem trigeminal nucleus *pars caudalis* (TNC). We used mice expressing channelrhodopsin-YFP in TRPV1 lineage neurons (generated from TRPV1-Cre (B6.129-Trpv1tm1(cre)Bbm/J)) to investigate different forms of synaptic plasticity at nociceptive primary afferents projecting onto second order relay neurons within the TNC. We found with immuno-labeling that these afferents mostly colocalize with CGRP-containing C- and Aδ-fibers, thereby indicating that light stimulation would only activate a specific subset of primary afferents predominantly designated to the transmission of nociception. Light stimulation at the slice edge (473 nm, 0.4 - 1 msec) evoked excitatory postsynaptic currents (EPSCs) and often polysynaptic activity in neurons in laminae I-II in acutely prepared transverse TNC slices. Using low-frequency stimulation with light (LFS, 1 Hz) we robustly induced long-term depression of light-evoked EPSCs ($n = 6$, $58\% \pm 13\%$, $p < 0.05$). Similar effects were observed on light-evoked EPSCs by bath applying PACAP, a neuropeptide that induces migraine in humans and sensitizes the trigeminal pathway in mice ($n = 5$, $66\% \pm 8\%$ at 10 - 20 min after washout, $p < 0.05$). We hypothesize that reduced excitatory input onto inhibitory neurons could disinhibit projecting neurons, thereby yielding an increased net output to connected brain regions. In contrast to LFS using light, after application of electric high-frequency stimulation (HFS) EPSCs either potentiated ($n = 5$ out of 14, $\Delta > 20\%$ 20 min post stimulation) or depressed ($n = 7$ out of 14, $\Delta < 20\%$ 20 min post stimulation), while the overall average remained unaffected ($101\% \pm 14\%$). The variability in these responses may reflect the heterogeneity of the neuronal population and might differ in GABAergic vs glutamatergic postsynaptic cells. Our data demonstrate various forms of persistent synaptic plasticity, which might be relevant to migraine that depend on the type and frequency of stimulation.

Title: Involvement of GABAergic transmission in the sensory processing in the agranular insular cortex.

Authors: *K. ADACHI[1], M. KOBAYASHI[2], H. SAKAGAMI[1];
[1]Meikai Univ. Sch. of Dent., Sakado-Shi, Japan; [2]Pharmacol., Nihon Univ. Schoo of Dent., Tokyo, Japan

Abstract: The insular cortex (IC) has morphologically and functionally unique features compared with other sensory areas including somatosensory and visual cortices. Cytoarchitectural difference based on the pattern of granular cell layer (layer IV) divides IC into three subregions: granular (GI), dysgranular (DI) and agranular IC (AI). These subregions are connected each other, and also reciprocally connected between limbic system and thalamus. These morphological features are thought to be important for process of multimodal sensory information including gustation, olfaction, visceral and thermal sensation, and nociception in IC. Recently the voltage-sensitive dye imaging revealed that the peripheral (e.g., tongue) stimulation induced region specific excitatory responses in the middle region (approximately 1 mm rostral from middle cerebral artery) of AI. And the involvement of layers II/III pyramidal neurons in the middle region of AI with these responses was confirmed by *in vivo* whole-cell patch clamp recording. The amplitude of tongue stimuli-induuced evoked excitatory postsynaptic potentials (eEPSPs) was dependent on both the stimulation intensity and the membrane potential oscillation of AI pyramidal neurons. In this study, we investigated the effects of GABA application on the alteration of membrane potential oscillation in AI II/III pyramidal neurons. We performed *in vivo* whole-cell patch clamp recording from middle region of AI. To reconstruct morphological feature of recorded cells, only one
AI neuron was recorded in each animal. AI pyramidal neurons exhibited spontaneous membrane oscillation similar with pyramidal neurons in GI and DI (Adachi et al., 2013). Electrical stimulations (7 V) of caudal IC (around middle cerebral artery) elicited eEPSPs (11.5 ± 2.9 mV, n = 8). Repetitive electrical stimulation with 5 pulses at 50 Hz induced summation of eEPSP. Topical application of pentobarbital (2.2 nM in ACSF) reduced the incidence of up state (93.9 %) and spontaneous action potentials (42.3 %). These findings suggest that GABAergic transmission in the middle AI may be involved in sensory processes from tongue.

Title: Ultrastructural analysis of the synaptic connectivity of transient receptor potential ankyrin 1 (TRPA 1)-expressing primary afferent terminals in the rat trigeminal sensory nuclei

Authors: ***Y. BAE**[1], Y. CHO[1], H. HAN[1], Y. KIM[1], J. BAE[1], K. NOGUCHI[2], W. MAH[1]; [1]Sch. of Dentistry, Kyungpook Natl. Univ., Daegu, Korea, Republic of; [2]Dept. Anat. and Neurosci., Hyogo Col. of Med., Hyogo, Japan

Abstract: Transient receptor potential ankyrin 1 (TRPA 1), responding to noxious cold (<17 ℃) and pungent compounds, is implicated in the mediation of nociception, but, little is known about the processing of TRPA1-mediated craniofacial nociceptive information at the 1st relay nucleus of the CNS. To address this issue, we investigated synaptic connectivity of TRPA1-positive (+) axon terminals in the rat trigeminal sensory nuclei (TSN) by using electron microscopic immunohistochemistry and analysis of serial sections. Most TRPA1+ terminals made synaptic contact with small and medium caliber dendrites or spines. A few of them received axoaxonic synapse with pleomorphic vesicles containing endings (p-ending), which were immunolabeled for glutamic acid decarboxylase, the synthetizing enzyme for the inhibitory neurotransmitter γ-aminobutyric acid (GABA). TRPA1+ terminals showed distinct synaptic connectivities among each subnuclei of the TSN. i.e., trigeminal principal (Vp), oral (Vo) and caudal (Vc) nucleus. Number of postsynaptic dendrites per TRPA1+ terminal was significantly higher in the Vp and Vc than in Vo. But, frequency of axoaxonic synapse per TRPA1+ terminal was significantly higher in the Vp than Vo and Vc. TRPA1+ terminals showing synaptic contact with soma or primary dendrites were frequently observed in the Vo but were rare in the Vp and Vc. These findings suggest that TRPA1-mediated nociception is processed in a distinct manner among each subnuclei of the TSN which is associated with distinguished neural circuits.

Title: Cortical spreading depression evokes mechanical sensitization of meningeal nociceptors mediated by astrocyte signaling.

Authors: *J. ZHAO, D. LEVY;
Beth Israel Deaconess Med. Ctr., Boston, MA

Abstract: We have shown previously that cortical spreading depression (CSD), the underlying cause of the migraine aura, promotes persistent activation of trigeminal meningeal nociceptors - a likely source of the migrainous intracranial headache. Here we report that in rats, CSD also leads to increased mechanical responsiveness of meningeal nociceptors, a mechanism suggested to mediate the headache exacerbation during activities that involve increased intracranial pressure and brain motion. In-vivo extracellular recording of the afferents' responses to threshold and suprathreshold mechanical stimulation of the meninges revealed increased mechanosensitivity in about 50% of the units tested. Sensitization was detected in most cases at 15 min following the CSD and was maintained for at least 30 min. Local treatment with the astrocyte toxins L-α-Aminoadipic acid or sodium fluoroacetate blocked CSD-evoked sensitization of meningeal nociceptors. Local administration of carbenoxolone, which blocks connexin and pannexin gap junctions that are involved in astrocyte signaling also inhibited the CSD-evoked mechanosensitization. Local treatment with probenecid, which only inhibits pannexins, did not block the CSD-evoked sensitization. ATP, which is released during CSD potentially through connexin hemi-channels, could mediate the sensitization. Local treatment with PPADS, a broad-spectrum antagonist of the P2X ATP receptor family inhibited CSD induced sensitization. However, treatment with TNP-ATP, a more selective inhibitor of $P2X_3$ and $P2X_{2/3}$ ATP receptors, which are expressed by nociceptors, was ineffective. None of the inhibitors tested had an effect on the CSD-evoked persistent activation of meningeal nociceptors. Our data suggest that CSD-evoked meningeal nociceptor sensitization is mediated by cortical astrocytes and involves connexin and ATP signaling. Activation of nociceptive $P2X_3$ and $P2X_{2/3}$ receptors is unlikely to mediate the sensitization. However, upstream ATP signaling, potentially mediated through astrocytic P2X7 receptors, could play a role. CSD induced sensitization and activation of meningeal nociceptors likely involve different signaling pathways.

Title: Chronic back pain patients learn to control spinal nociception under feedback about their nociceptive withdrawal reflex (RIII reflex).

Authors: *S. KRAFFT[1,2], H.-D. GÖHMANN[3], J. SOMMER[4], A. STRAUBE[1], R. RUSCHEWEYH[1];
[1]Dept. of Neurol., [2]Grad. Sch. of Systemic Neurosciences, Ludwig-Maximilians-University Munich, Munich, Germany; [3]Dept. of Anesthesia, Intensive Care and Pain Therapy, Hosp. of Traunstein, Traunstein, Germany; [4]Dept. of Psychiatry and Psychotherapy, Philipps-University Marburg, Marburg, Germany

Abstract: Question: The descending pain inhibition is a powerful endogenous pain control system, originating in the brainstem, inhibiting nociceptive transmission in the spinal dorsal horn, and therefore reducing nociceptive input to the brain. The descending inhibition is susceptible to cognitive-emotional modulation. The nociceptive withdrawal (RIII) reflex is a measure of spinal nociception. Young healthy subjects can learn to use cognitive-emotional strategies to suppress their spinal nociception when receiving feedback about their RIII reflex, likely by learning to deliberately activate their descending pain inhibition. Here, we investigated if RIII feedback training also improves descending pain inhibition in chronic pain patients and may help to reduce clinical pain.
Methods: The RIII reflex was evoked every 8-12 s by electrical stimulation of the sural nerve and recorded from the biceps femoris muscle for 8 min. During min 4 to 6, subjects used self-selected cognitive-emotional strategies to reduce the RIII reflex, while receiving immediate feedback about their RIII reflex size. Subjects were: Chronic back pain patients receiving 1) true (n = 18) or 2) sham RIII-feedback (FB, n = 15), and 3) healthy controls receiving true RIII-feedback (n = 15). Before and after the three training sessions, we assessed descending pain inhibition using the Conditioned Pain Modulation (CPM) paradigm and clinical back pain intensity on the numerical rating scale [0-10].
Results: All three groups achieved a significant RIII-suppression, to 82 ± 13% (true-FB patients), 89 ± 14% (sham-FB patients) and 76 ± 26% (true-FB controls, all groups $p \leq 0.05$) of baseline, with simultaneous electrical pain reduction (all groups $p < 0.001$). RIII-suppression was significantly smaller in sham-FB patients than in true-FB controls ($p < 0.05$). After training, only true-FB patients had significantly improved their CPM effect (by 18 ± 23%, after vs. before

training: $p < 0.01$) and showed a significant reduction of average (-0.8 ± 1.5 [0-10]; $p < 0.05$) and maximum (-1.4 ± 1.8; $p < 0.01$) back pain. Sham-FB patients neither showed a significant improvement of CPM (by 6 ± 28%, $p = 0.4$) nor a reduction of back pain (-0.3 ± 1.1, $p > 0.2$). Discussion: Results suggest that chronic pain patients are able to learn control over their spinal nociception under feedback of the RIII reflex, to a somewhat lesser extent than healthy subjects. Furthermore, RIII feedback training improved the descending pain inhibition (CPM) and chronic back pain in chronic pain patients. Consequently, RIII feedback training might be a useful method to enhance endogenous pain inhibition in chronic pain patients.

Title: Availability of cerebral μ-opioid and type-2 dopamine receptors predicts haemodynamic responses to vicarious pain: A combined fMRI and PET study

Authors: T. KARJALAINEN[1,2], J. LAHNAKOSKI[1], E. GLEREAN[1], H. KARLSSON[2], P. NUUTILA[2], I. P. JÄÄSKELÄINEN[1], M. SAMS[1], R. HARI[1], *L. NUMMENMAA[1];
[1]Aalto Univ., Espoo, Finland; [2]Turku PET Ctr., Turku, Finland

Abstract: Background Functional neuroimaging experiments suggest that seeing others in pain activates a part of the brain circuitry involved in first-hand experience of pain. Accordingly, it has been proposed that observers automatically mimic the affective state of the individual they see suffering from pain, which possibly promotes prosociality and helping behaviour. It has been speculated that endogenous mu-opioid (MOR) and dopamine D_2 receptor (D2R) systems, the primary neurotransmitter systems modulating physical pain, would also underlie vicarious pain. Here we search for the first direct *in vivo* evidence for this proposal.
Methods We studied 34 healthy subjects with positron emission tomography (PET) to quantify MOR and D2R availabilities, and, subsequently, with functional magnetic resonance imaging (fMRI) to unravel haemodynamic brain activity elicited by movie clips (total duration 20 min)

containing painful and painless scenes. We then explored whether regional MOR (anterior cingulate cortex, thalamus, insula) and D2R availabilities (striatum) would explain individual differences in haemodynamic responses to vicarious pain.

Results Seeing others in pain increased fMRI signals in cortical and subcortical areas known to be involved in perception of physical pain, including anterior insular cortex, thalamus and secondary somatosensory cortex. MOR availability in the regions specified above correlated *negatively* with haemodynamic responses in various parts of the pain matrix, including anterior insula, anterior cingulate cortex (ACC), thalamus, and the primary and secondary somatosensory cortices. On the contrary, striatal D2R availability correlated *positively* with haemodynamic activity in multiple brain regions, including ACC, cerebellum and primary somatosensory cortex.

Conclusions Because both opioid and dopamine systems mediated haemodynamic activity to vicarious pain, our results are in line with the idea that partially shared neurochemical pathways support first-hand physical and vicarious pain.

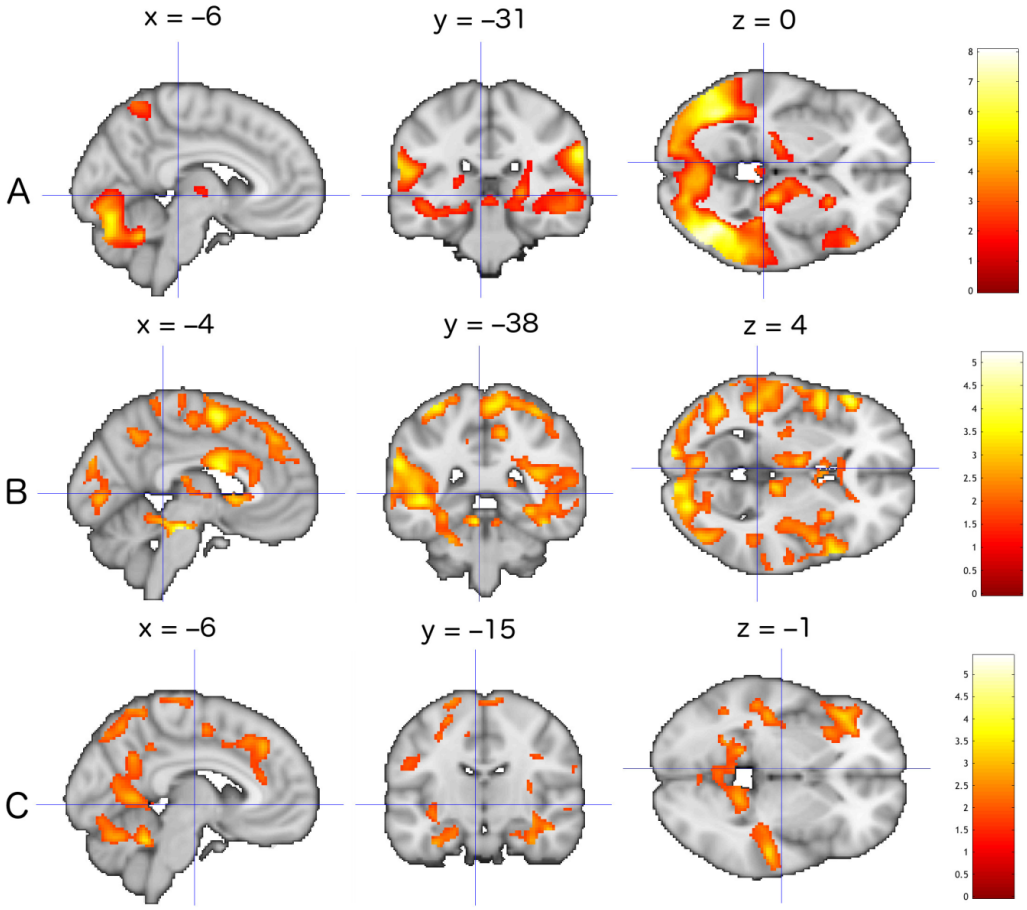

Figure 1. (A) Brain regions responding to vicarious pain during BOLD-fMRI. (B) Brain regions whose BOLD responses to vicarious pain depended negatively on MOR availability in the insula. (C) Brain regions whose BOLD responses to vicarious pain depended positively on D2R availability in the putamen. All data are thresholded at $p < 0.05$, FDR corrected at the cluster level.

Title: Integrity of endogenous pain inhibition mechanisms in patients with chronic non-specific low back pain

Authors: ***A. LADOUCEUR**[1], J.-D. DUBOIS[2], N. RUSTAMOV[3], A. LEHMANN[4], M. DESCARREAUX[5], P. RAINVILLE[6], M. PICHÉ[3];

Abstract: Chronic non-specific low back pain (LBP) affects a large proportion of the population and its pathophysiology remains undefined. As for other chronic pain conditions, one of the mechanisms potentially contributing to chronic non-specific LBP is the alteration of pain inhibition processes, including conditioned pain modulation (CPM) and pain inhibition by selective attention. Thus, the aim of this study was to determine whether CPM and pain inhibition by selective attention are altered in patients with chronic non-specific LBP. Seventeen participants with chronic non-specific LBP and age/sex matched controls were recruited. CPM and pain inhibition by selective attention were assessed while controlling for non-specific temporal effects. The experimental design comprised 3 sessions including 4 blocks: 1) painful test stimulus (baseline) 2) painful test stimulus with heterotopic innocuous cold (innocuous conditioning) 3) painful test stimulus with heterotopic noxious cold (noxious conditioning) 4) painful test stimulus (recovery). Selective attention was manipulated across two of these sessions

by instructing participants to focus their attention on either the test or the conditioning stimulus. In the third session (control), the same test stimulus was delivered in 4 blocks without any conditioning or attention intervention. The painful test stimulus consisted in transcutaneous electrical stimulation of the sural nerve while innocuous and noxious cold stimuli (conditioning) consisted in contact cold and a frozen ice pack applied on the left upper limb, respectively. Pain inhibition was not significantly different between groups across sessions and blocks ($p = 0.99$). However, it was different between sessions across blocks when combining all participants from both groups ($p < 0.001$). Indeed, pain inhibition was significantly greater when attention was focussed on the innocuous conditioning stimulus in comparison to when attention was focussed on the test stimulus ($p = 0.008$). This indicates pain inhibition by selective attention. For CPM assessed with attention focussed on the test stimulus, noxious conditioning produced greater pain inhibition compared with innocuous conditioning and this effect was greater compared with the corresponding contrast (block 3 vs 2) in the control session ($p = 0.049$). This shows significant CPM. Altogether, these results suggest that patients with chronic non-specific LBP have similar CPM and pain inhibition by selective attention compared with age/sex matched controls. Therefore, chronic non-specific LBP seems to rely on mechanisms other than altered pain inhibition processes assessed in this study.

Title: Testing assumptions in human pain models: Psychophysical differences between first and second pain.

Authors: ***N. R. ECKERT**, C. J. VIERCK, C. B. SIMON, Y. CRUZ-ALMEDIA, R. FILLINGIM, J. L. RILEY, III;
Univ. of Florida, Gainesville, FL

Abstract: Acute pain arises from activation of myelinated (A delta) and unmyelinated (C) nociceptive afferents, leading to 1st (A-fiber) or 2nd(C-fiber) pain sensations. The current study sought to investigate first and second pain within glabrous and hairy skin sites in human upper limbs.Fifty healthy adults (25 males/25 females, 18-30 yrs: mean = 20.5+- 1.4) participated in a psychophysical study investigating electronically rated, thermal first and second pain sensations within the glabrous skin at the palm and hairy skin of the forearm. Repeated measures ANOVA indicated that the threshold for first pain was lower(more sensitive) than for second pain ($p = .004$), and thresholds at glabrous skin were higher than for hairy skin ($p = .001$). Hairy skin presented a steeper slope for testing, whereas there were no differences in slope between first and second pain. The study findings support assumptions associated with mechanistic differences between first and second pain sensations, while offering a novel method for producing first and second pain with the same thermal stimulus. Efforts to understand abnormalities among people with clinical pain and development of new therapeutic agents will benefit from specific psychophysical methods.

Title: Females in physical pain trust more on others for self-interest

Authors: *C. WANG, J. GAO, X. DONG;
East China Normal Univ., Shanghai City, China

Abstract: Pain modulates cognition and brain activities in humans. Research found that pain enhances interoception sense and self-focus; meanwhile, individuals in pain are motivated to reconcile the painful feeling by pursuing potential reward (Navratilova & Porreca, 2014). As a consequence, social interactions might be modulated among painful individuals. However, it's not clear about the mechanisms of how pain influences social cognition and behaviors. To address the issue, 112 healthy university students were recruited. They were treated with either Capzasin cream (pain group) or hand cream (control group) and manipulated with intergroup relationship. Subsequently, participants completed the trust game, the dictator game and the

investment game (Cameron et al., 2013), by which levels of trust, altruism and risk taking were measured. Results showed that female subjects in acute pain (compared with control condition) sent more money transfers (12.5 vs. 9.7, p = 0.024) to intergroup members (Fig. a), which indicated that physical pain increased trust. In contrast, female participants showed no difference on altruism and risk-taking behaviors (Fig. b). In addition, the trust level was positively correlated with individual's expectation of money profit (Fig. c). Furthermore, mediation analysis revealed that the effect of pain on trust was mediated by expectation of money profit, which was confirmed by bootstrap analysis (Effect Size = 1.98, CI = [0.019 3.00], Fig. d). We further tested the pain effects on male sample and the whole sample. Unlike females, the trusting behavior along with altruism and risk-taking behaviors of males were not affected by acute pain (Fig. e). Our findings demonstrated an effect of physical pain on trust in females, and uncovered the underlying mechanisms that increased trust by pain may not be driven by altruistic motivation, but possibly by expectation of self-interest. The study extends the biopsychosocial model of pain (Gatchel et al., 2007) and may provide rationale for improving social interactions for pain patients.

Title: Body ownership, illusory limb movement and pain perception: a virtual reality study

Authors: *M. MARTINI, B. CAOLA, A. G. LEADBETTER;
Univ. of East London, London, United Kingdom

Abstract: Recent studies have shown a crucial relationship between the motor system and pain management. For instance, transcranial direct current stimulation (tDCS) and transcranial magnetic stimulation (TMS) of the primary motor cortex, brought about a successful pain modulation in different neuropathic syndromes. Recently it has been shown that even the observation of hand movements led to an increased pressure pain threshold specific for the limb involved in the movement (left/right), as well as to a decrease in intracortical inhibition in healthy subjects. Noteworthily, the vision of the own body part in pain has been shown to be analgesic, and such effect holds true even during the vision of an avatar's body that is felt as own body. However, it is still unknown whether the vision of the movement of an embodied avatar's arm may add up to the beneficial effects of seeing limb movements. Therefore, in this study twenty-one healthy right-handed subjects were exposed to four virtual reality (VR) observational conditions, while receiving increasing ramps of heat stimulation on their right arm. After each observational conditions participants were asked to answer questions about ownership, illusory movement, attention and illusory ownership of multiple limbs, via a likert scale (1 to 7). For the VR exposure two factors were taken into account: the vision of the right avatar's arm VS a non corporeal object, both seen from a first person perspective (factor "Body"), and the movement VS stillness of the virtual arm/tube ("Movement"). Preliminary results on pain threshold show only a trend to significance of the main factor "Movement" and the interaction "Movement*Body". As expected, the conditions were a movement was involved were generally more distracting, and the conditions were the avatar's arm were shown were those were a higher significant level of body ownership was reported. The illusion of having more than one right arm was stronger in the conditions were the avatar's arm was shown. A compelling significant negative correlation has been found between the illusion of having more than one arm and the pain threshold. These preliminary results show that seeing limb movements in a body ownership set-up do not lead to a higher heat pain threshold. Moreover, as suggested in the literature, our data show that a distortion in the representation of one's own body could contribute to hyperalgesic processes to kick in.

Title: The placebo analgesic effect in healthy individuals and patients: a meta-analysis

Authors: *J. T. FORSBERG[1], M. MARTINUSSEN[2], M. FLATEN[3];
[1]The Arctic Univ. of Norway, Uit, 9037, Norway; [2]The Arctic Univ. of Norway, Uit, Tromso, Norway; [3]Norwegian Univ. of Sci. and Technol., Trondheim, Norway

Abstract: Objectives: The present meta-analysis investigates whether the magnitude of placebo analgesia is different in patients compared to healthy individuals, and whether placebo analgesia is different in experimentally induced pain compared to clinical pain in patients. **Methods:** A literature search in Web of Science (ISI) on the term "placebo analgesia" was conducted. The search resulted in 68 studies, including 3924 participants. Fifty-two studies included healthy individuals and 16 studies included patients. Of the 16 studies with patients, five studies investigated clinical pain and 11 studies investigated experimentally induced pain. **Results:** The average effect size was g = 1.25 for healthy individuals and g = 1.51 for patients (n.s.). In the studies with patients, the average effect sizes of placebo treatment was g = 1.73 for experimentally induced pain and g = 1.05 for clinical pain (n.s.). However, a chi-square test revealed that there were relatively more studies in which there was a clinically significant reduction in pain with patients compared to healthy volunteers (p =.04). **Conclusions:** The findings suggest that studies on healthy individuals may underestimate the magnitude of the placebo analgesic effect in patients, and that clinical pain respond to placebo to the same degree as experimentally induced pain.

Title: Minimal neuropathy with intraperitoneal nab-paclitaxel in patients with advanced malignancies

Authors: ***N. PRAKASH**[1], C. MIHAELA[2], P. FRANKEL[2], H. OPENSHAW[1], R. MORGAN[2]; [1]Neurol., [2]City of Hope, Duarte, CA

Abstract: Purpose: Previous clinical trials have demonstrated an advantage to IP chemotherapy. However neurotoxicity in the form of painful sensory neuropathy is a common treatment-limiting toxicity. A phase I study was undertaken to evaluate the safety, tolerability, and pharmacokinetics of IP *nab*-paclitaxel.
Methods: Eligible patients received IP *nab*-paclitaxel on days 1, 8, 15 of a 28-day cycle with a 3+3 dose-escalation design. Plasma and peritoneal pharmacokinetic samples were drawn prior to dose, immediately upon completion of infusion, 1, 2, 4, 6, 8, 12, 24 and 48 hours post-dose on C1D1 and C1D15. Patients also underwent voluntary neurological exam, nerve conduction studies, and quantitative sensory nerve testing at baseline and at pre-cycle three.
Results: The trial completed with 27 patients with peritoneal carcinomatosis secondary to gynecological malignancies (n=14), gastrointestinal malignancies (n=12), and peritoneal mesothelioma (n=1). The starting dose level was 35mg/m2 and escalated to 170mg/m2. The maximum tolerated dose (MTD) of IP nab-paclitaxel was established at 140 mg/m2, while to the MTD of weekly IV nab-paclitaxel was established at 100 mg/m2 in heavily pretreated patients and 150 mg/m2 for the lightly pretreated group. Drug limiting toxicities included grade 3 neutropenia resulting in treatment delay >15 days, grade 3 abdominal pain and grade 4 neutropenia > 7 days. Fourteen patients underwent voluntary neurological exam, nerve conduction studies, and quantitative sensory nerve testing at baseline and at pre-cycle three. Although there was a slight trend towards worsening neuropathy, no significant differences were found for any of the measured parameters.
Discussion: IP *nab*-paclitaxel achieved therapeutic levels in the peritoneum and systemically, without causing significant objective or subjective neuropathy. This is in contrast to other forms of taxane-based chemotherapies and IV *nab*-paclitaxel, for which neuropathy is a common treatment-limiting toxicity**.**
Conclusion: IP *nab*-paclitaxel has a favorable neuro-toxicity profile and can be safely administered in patients with prior exposure to paclitaxel.

Title: Adaptive neurotechnologies for improved management of chronic pain

Authors: *S. N. JOSHI[1], A. DE PESTERS[1,2], P. BRUNNER[1,3], J. P. CLEARY[4], J. FUDIN[4,5,6], G. SCHALK[1,2,3];
[1]Natl. Ctr. For Adaptive Neurotechnologies, Albany, NY; [2]State Univ. of New York at Albany, Albany, NY; [3]Dept. of Neurol., Albany Med. Col., Albany, NY; [4]Stratton VA Med. Ctr., Albany, NY; [5]Remitigate, LLC, Delmar, NY; [6]Western New Eng. Univ. Col. of Pharm., Springfield, MA

Abstract: Chronic pain costs billions of US dollars yearly. Pharmacologic treatment options are expensive and have treatment barriers that include neurotoxicity, gastrointestinal bleed, kidney dysfunction, cardio-pulmonary toxicities, opioid addiction sequalae, and opioid related concerns that include tolerance, dependence, respiratory depression and various public health detriments. Recent recognition of the remarkable plasticity of the nervous system opens up the exciting possibility to develop systems that establish real-time adaptive interactions with the nervous system to improve functions impaired by injury or disease. In the context of chronic pain, these systems, called adaptive neurotechnologies, could induce beneficial neuroplasticity that reduces pain perception and thus creates an entirely new, non-pharmaceutical, approach to management of chronic pain.
The possibility for this approach to pain modulation is further supported by the growing recognition that pain may not be proportional to peripheral nociceptive input alone. Indeed, it is now well known that nociceptive input is modulated at multiple levels in the brain, including subcortical and cortical areas, and nociception may neither be sufficient nor necessary for the experience of chronic pain (Moseley, 2003, Jensen et al., 2008). Different functional imaging techniques provide a window into these modulatory brain processes. For example, in subjects

experiencing acute pain, specific frequencies in electroencephalographic (EEG) signals are related to the magnitude of the experience of pain. Specifically, many studies have shown that reduced power in the alpha (8-12 Hz) band is associated with increased experience of acute pain (Jensen et al. 2008) that may be due to increased transfer of nociceptive information through thalamo-cortical and cortico-cortical channels (Jacobs et al. 2015).
Our overall goal is to develop, implement and validate a novel adaptive neurotechnology to improve the management of chronic pain. In the present pilot study, we hypothesize that, for patients with chronic pain in their extremities, the power of sensorimotor alpha is negatively related to pain perception, that patients can learn to associate pain perception with an increase in alpha power, and that this change in brain function reduces perception of chronic pain in the extremities.
To date, we have studied 3 patients who underwent non-invasive monitoring of scalp EEG. Initial results show that alpha power is reduced on the hemisphere contralateral to the painful extremity, and that contralateral alpha power is decreased further during attention to or stimulation of the painful hand.

Title: Topical Lidoderm® (lidocaine 5% patch) alters the density of sodium channel subunits in epidermal keratinocytes among patients with diabetic neuropathy

Authors: *P. J. ALBRECHT[1], C. E. ARGOFF[2], J. P. WYMER[3], F. L. RICE[1];
[1]Integrated Tissue Dynamics, LLC, Rensselaer, NY; [2]Dept. of Neurol., Albany Med. Ctr., Albany, NY; [3]Dept. of Neurol., Univ. of Florida Col. of Med., Gainsville, FL

Abstract: According to the NIH, in 2012 there were close to 30 million people in the United States with diabetes, effecting men and women equally, and estimates of up to 1 in 5 of those patients (roughly 6 million individuals) experience painful diabetic neuropathy (PDN). The purpose of this research study was to document the extent of topical lidocaine, administered via Lidoderm®, to provide therapeutic benefit to patients suffering with PDN, and to determine if epidermal keratinocyte expression of voltage-gated sodium channel subunits was altered in patients compared with controls, and to document if the expression was changed following patch treatment. The final cohort of study contained 21 painful diabetic neuropathy patients, 12 non-painful diabetic neuropathy patients, and 11 healthy control subjects. Each of the subjects underwent a detailed quantitative sensory testing (QST) battery, followed by a 3mm cutaneous punch biopsy, application of the Lidoderm® 5% patch for 4-weeks, followed by a subsequent QST and punch biopsy. Clinical reporting measures were maintained to determine responders from non-responders, and immunochemical evaluations were performed on the pretreatment and post-treatment biopsies to determine innervation and voltage-gated sodium channel expression changes. Lidoderm® provided substantial analgesic relief to painful diabetic patients. Evaluations of the cutaneous innervation revealed that no changes among the epidermal, subepidermal, or upper dermal compartments were detected that corresponded with the response to, or effectiveness of, the treatment. In contrast, a significant decrease in keratinocyte expression of Nav1.6 correlated with reduced painfulness after treatment, whereas keratinocyte Nav1.7 expression remained generally unaltered. The results indicate that the use of Lidoderm® to treat painful peripheral neuropathy may involve mechanisms associated with keratinocyte expression of sodium channel subunits, and that epidermal keratinocyte expression of specific Nav subunits may serve as a predictor of patch treatment efficacy.

Title: Selective stimulation of silent, mechano - insensitive C nociceptive fiber in humans?

Authors: *M. I. NEMENOV[1,2], M. KLUKINOV[2], D. C. YEOMANS[2], M. SCHMELZ[3], M. BACKONJA[4];
[1]Lasmed LLC, Mountain View, CA; [2]Anesthesia, Stanford Univ., Stanford, CA; [3]Anesthesiol., Heidelberg Univ., Mannheim, Germany; [4]Neurol., Univ. of Wisconsin, Madison, WI

Abstract: Mechanisms of painful peripheral neuropathies (PPN) are still unclear and biomarkers are not available. Abnormal spontaneous activity of C-mechano-insensitive silent fibers (CMi) is a likely source of the pain in animals and humans with PPN. Activation of CMi fibers produces axon-reflex related flare (1). However, CMi activation thresholds are substantially higher compared to C-polymodal CMH fibers which makes these fiber inaccessible for any behavioral, psychometric (QST) or cortical evoked potential tests. These high thresholds are likely due to the deeper location of CMi fibers compared to CMH fibers. Thus, assessment of CMi fibers is impossible for clinic practice, clinical research or preclinical analgesic development. We developed a diode laser C-fiber type selective stimulation (C-DLss) technique that may selectively test CMi fibers (2). DLss radiation penetrates deep into the skin, homogeneously heating superficial and subepidermal skin layers, thereby allowing access to deeply located C fibers. A decreased density of intraepidermal fibers and 50% lower density of CMH vs. CMi fibers (3) as well as sensitization to heat of CMi fibers allows for their selective activation in PPN patients (4). Here we present a modified method that may provide selective activation of CMi vs. CMH fibers in healthy subjects. We hypothesized that controlled cooling of skin surface allows to temporarily decrease response from epidermal C fibers mimicking functional denervation, though deeper located dermal CMi fibers would be spared from cooling allowing for study by DLss. Thus, selective stimulation of CMi nociceptors could be possible. The activation of CMi fibers was confirmed by generation of axon-reflex flare. The C-DLss stimuli with duration 1 s were applied to cooled (22 C°+/-1 C°) and non-cooled (32 C° +/-1 C°) inner forearm skin of healthy subjects. Sub- and supra pain threshold intensities did not produce warm or hot sensations in cooled skin, but only a single modality step function of pain perception. We conclude that DLss stimulation combined with superficial skin cooling provides specific noxious heat stimulation of deeper skin layers that activates CMi nociceptors.

Title: Oxidant-mediated release of high mobility group box 1 (HMGB1) and inflammatory cytokines in synovial fibroblasts through TLR-4 activation: Effect on cell death.

Authors: *A. A. ALSOUSI, O. J. IGWE;
Pharmacol. and Toxicology Div., Univ. of Missouri -KC, Kansas City, MO

Abstract: BACKGROUND: As a chronic autoimmune systemic disease, rheumatoid arthritis (RA) is a leading cause of disability that affects about 1% of the worldwide population, especially women. RA is characterized by synovial inflammation that lead to tissue and bone destruction. The factors that initiate, propagate and maintain RA are not clear. Reactive oxygen species (ROS) can interact with and modify cellular macromolecules, which results in structural and/or functional changes in gene and protein expressions. ROS are recognized as an important initiating factor in many diseases. Trace metals as pro-oxidants are sources of reactive species that can cause cellular oxidative stress. High mobility group box 1 (HMGB1) is a nuclear protein that is released by damaged or stressed cells. HMGB1, involved in both acute and chronic inflammatory process, is a representative damage-activated molecular pattern (DAMP) molecule that can activate TLR-4. A pathophysiological aspect of RA is an increase in the number of resident synovial cells and the resistance of fibroblasts to receptor induced apoptosis. Molecular changes in synovial fibroblasts that are induced by the exogenous pro-oxidants point to profound oxidative adaptations, which suggest their involvement in RA pathogenesis.
METHODS: We used three trace metal agents as exogenous sources of pro-oxidants. These include potassium peroxychromate (PPC) (Cr^{+5}), cuprous chloride (Cu^{+}), and ferrous chloride (Fe^{2+}), which we used to examine the biochemical interactions of pro-oxidants in HIG-82 synovial fibroblasts. HMGB1 release was measured by immunofluorescence (IF), ELISA and flow cytometry (FC). Cell death was measured by FC and WB, whereas inflammatory cytokines were quantified by ELISA.
RESULTS: The pro-oxidants increased HMGB1 release from the nucleus to the cytoplasm and upregulated its protein expression. Pro-oxidants increased release of both pro-inflammatory cytokines TNF-α, IL-1β and the anti-inflammatory cytokine IL-10. Furthermore, pro-oxidants increased proliferation of synoviocytes and appear to protect cells against apoptosis through activation of autophagy pathway.

CONCLUSIONS: Oxidant-induced TLR-4 activation caused release of HMGB1 as a pro-inflammatory response and other inflammatory cytokines such as TNF-α, which mediates pro-inflammatory actions and contribute to the pathogenesis of RA. The trace metals as pro-oxidants may protect against apoptosis by inducing autophagy while increasing synovial fibroblasts proliferation, which is in agreement with the pathophysiological changes that occur in active RA.

Title: VAMPs involved in voltage-gated cation channel trafficking in DRG neurons

Authors: ***M. ALVES SIMOES**, B. DAVLETOV, M. NASSAR, E. P. SEWARD;
Univ. of Sheffield, Sheffield, United Kingdom

Abstract: Dorsal root ganglion (DRG) neurons perceive and discriminate diverse types of sensations. Nociceptors are a subgroup of DRG neurons specialized in translating noxious pain stimuli to the spinal cord and higher brain centers. Following a noxious insult nociceptors are known to have enhanced excitability and peptide secretion (England et al., 1994; Garry and Hargreaves, 1992) both of which, are likely to be a consequence of increased membrane trafficking and vesicle fusion with the plasma membrane.
Vesicle associated membrane proteins (VAMPs) are vesicular SNARE proteins (v-SNAREs) which complex together with cognate target SNARE proteins (t-SNAREs) found on 'acceptor' compartments to regulate membrane trafficking and vesicle fusion; while much is known about the v- and t-SNAREs involved in the fusion of neurotransmitter and neuropeptide containing vesicles with the plasma membrane, to date the identity of SNAREs involved in trafficking ion channels to the plasma membrane of nociceptors is unknown.
Microarray data indicates all 7 isoforms of vamp mRNA are expressed in primary cultures of DRG neurons. Using subtype selective antibodies, we have confirmed DRG neurons express the 7 isoforms at the protein level, although our immunocytochemistry data analysis suggests differences in expression levels of specific isoforms across somata sizes.
Preliminary studies using novel engineered clostridium neurotoxins (Bitox A and Tetbot A) (Ferrari et al., 2013; Mangione et al., 2016) targeting the neuronal t-SNARE SNAP-25 suggest

that inflammation induced trafficking of voltage-gated cation channels to the plasma membrane does not use the same SNARE machinery as is required for neurotransmitter release.

Title: Temporal contribution of the CCL2/CCR2 chemokine axis to chronic inflammatory pain elucidated by dicer substrate small interfering RNA

Authors: ***M.-A. DANSEREAU**[1], A. M. JACOBI[2], S. S. ROSE[2], M. A. BEHLKE[2], J.-M. LONGPRE[1], P. SARRET[1];
[1]Univ. De Sherbrooke, Sherbrooke, QC, Canada; [2]Integrated DNA Technologies, Coralville, IA

Abstract: There is now compelling evidence suggesting that chemokines, and especially CCL2 and its cognate receptor CCR2, contribute to the development and maintenance of chronic pain. However, due to the chemokine redundancy and lack of selective antagonists, classical pharmacological approaches did not provide specific insights into the regulation of chemokines in different chronic pain paradigms. In this study, we thus investigated the temporal contribution of the CCL2/CCR2 axis to mechanical hypersensitivity in a chronic inflammatory pain model by using specific 27-mer double-stranded dicer substrate small interfering RNA (DsiRNA). DsiRNA were encapsulated into lipid nanoparticles (LNPs) with the NanoAssemblr™ system from Precision NanoSystems Inc. LNPs containing DsiRNA targeting either CCL2 or CCR2 were intrathecally (i.t.) administered to Sprague Dawley rats at different time points before or after intraplantar administration of complete Freund's adjuvant (CFA). CFA-induced mechanical hypersensitivity was measured using von Frey hairs. Firstly, LNPs containing the Dil fluorescent dye intrathecally injected between L5 and L6 vertebrae were shown to be up-taken by L4-L6 dorsal root ganglia (DRG). However, no fluorescence staining was detected in the corresponding L4-L6 spinal cord segment. Accordingly, western blot analysis demonstrated that knockdown of the target protein by LNPs containing DsiRNA only occurred in DRG tissue. Secondly, repeated i.t. injections of 5 µg of DsiRNA against CCL2 or CCR2 48 h and 24 h before CFA administration completely prevented CFA-induced mechanical hypersensitivity up to day 5 post-

CFA. Finally, when injected 24 h and 48 h after CFA, DsiRNA against CCR2 also reverted the mechanical hypersensitivity up to day 5 post-CFA, while DsiRNA against CCL2 only exerted a significant anti-allodynic action up to day 3. Interestingly, while the mechanical hypersensitivity was present on days 7-10 post-CFA, animals treated on days 1 and 2 post-CFA with DsiRNA against either CCR2 or CCL2 exhibited a significantly higher mechanical threshold on day 14 post-CFA than rats treated with non-targeting control DsiRNA. These experiments thus reveal, through the development of nanoparticle-encapsulated DsiRNA, that the CCR2/CCL2 axis expressed at the DRG level contribute in a time-dependent manner to the generation of chronic inflammation-induced pain. These results further support the use of RNAi-based gene therapy as a highly specific alternative to classical pharmacological approaches to treat central pathologies such as chronic pain.

Title: Effects of the cytokine Interferon-gamma in combination with other cytokines on slowly or fast conducting nerve fibers in rat *In vivo*

Authors: *F. RICHTER, S. WANDT, F. SLOWIK, H.-G. SCHAIBLE;
Univ. Hosp. Jena, Jena, Germany

Abstract: Interferon-γ (IFN-γ) in slowly conducting nerve fibers both in normal and in inflamed knee joints acts as an antinociceptive cytokine, whereas its effect on fast conducting fibers depends on the situation in the knee joint (inflamed or non-inflamed). In this study we investigated whether the antinociceptive effect of IFN-γ is still maintained in normal knee joints when it is applied simultaneously with or consecutively after sensitization by a pronociceptive cytokine (IL-17A or TNFα). Healthy adult WISTAR rats were anesthetized with sodium thiopentone (100 mg/kg, i.p.). The knee joint was mechanically stimulated by innocuous (20 mNm) or noxious (40 mNm) rotations of the lower leg against the fastened femoral bone for 15 sec each. Action potentials were recorded from nerve fibers that were classified as C- or as Aδ-fibers by their conduction velocity (<1.4 m/s or <10 m/s, respectively). Compounds were injected into the joint cleft at a volume of 0.1 ml each. In normal knee joints a single intraarticular injection of 10 ng of IFN-γ together with 100 ng of IL-17A decreased significantly

the net response rate of C-fibers to noxious stimulation within three hours (IFN-γ alone by 171±56, IFN-γ+IL-17A by 335±66 APs/15s, mean±SEM, respectively). The combination of IFN-γ+IL-17A decreased to a minor degree the response rates in Aδ-fibers (no change after IFN-γ alone, IFN-γ+IL-17A decrease by 76±40 APs/15s). When slowly conducting C-fibers were first sensitized by an injection of 50 ng of IL-17A (increase in net response rate to noxious stimulation within 2 hours by 42±15 APs/15s), a subsequent injection of 10 ng of IFN-γ decreased the net response rate within 1 hour by 64±26 APs/15s below control values. The utilization of the same protocol to fast conducting Aδ-fibers did not induce any changes in the response rate to either innocuous or noxious stimuli. Simultaneous application of 10 ng of IFN-γ together with 5 ng of TNFα completely prevented the sensitizing effect of TNFα in slowly and in fast conducting nerve fibers throughout the 3 hours observation period (C-fibers control 169±13, after 3 hours 179±18 APs/15s, Aδ-fibers control 379±28, after 3 hours 407±18 APs/15s, respectively). The antinociceptive effect of IFN-γ in slowly conducting nerve fibers is still maintained, when it is applied together with pronociceptive cytokines. IFN-γ is also able to desensitize these nerve fibers after previous sensitization with a pronociceptive cytokine. Therefore, IFN-γ is an important player in the precise adjustment of the different cytokines released in the joint cleft.

Title: Rac 1 dependent structural plasticity of the anterior cingulate cortex regulates the emotional aspect of chronic pain

Authors: ***S. PEZET**, M. THIBAUT, M. PALUD, Z. LENKEI;
Lab. of Brain Plasticity, Paris, France

Abstract: Painful experiences are multi-layered, composed of sensory, affective, cognitive and behavioural facets. While it is well accepted that the development of chronic pain is due to

maladaptive neuronal changes, the underlying molecular mechanisms and their relationship to the different pain modalities is still not well understood. We have previously shown that a BDNF (Brain-Derived Neurotrophic Factor) - dependent plasticity takes place in the anterior cingulate cortex in a inflammatory model of chronic pain induced by intraplantar injection of Complete Freund ‘s Adjuvant (CFA). In this brain area, BDNF is a key mechanism in the development and maintenance of the affective-emotional aspect of chronic pain, while it does not modify the sensory discrimivative aspect (Thibault et al., 2014). In the current study we explore i) the presence of structural plasticity in the ACC in this animal model and ii) the putative role of the Rac-1 signaling pathway. Using Golgi- and immune-staining for several pre- or post-synaptic components, as well as behavioural tests that explore specifically the sensory discriminative (Von Frey hairs, cold plate) or the emotional aspect of pain (passive avoidance tests to either mechanical or cold stimuli), we show that the anterior cingulate cortex is indeed the site of structural plasticity, through a Rac-1 dependent mechanism and that pharmacological blockade of Rac-1 specifically prevents the development of the emotional aspect of chronic pain.

Title: Cystatin c attenuates cathepsin s-evoked and par2-mediated pain and inflammation

Authors: *T. LIEU, P. ZHAO, N. BUNNETT;
Monash Inst. of Pharmaceut. Sci., Parkville, Australia

Abstract: Introduction. Extracellular proteolytic activity depends on the balance of zymogen activation, protease secretion, and the availability of endogenous inhibitors. During inflammatory and neuropathic pain, lysosomal cathepsin S is released from peripheral macrophages and spinal microglial cells, and peripheral cathepsin S can cause pain *via* biased agonism of protease-activated receptor-2 (PAR_2). Endogenous cysteine protease inhibitor cystatin C is present in extracellular fluid, but its role in regulating pain is unknown. We evaluated contributions of PAR_2 and cystatin C to cathepsin S-evoked pain.
Methods. We administered cathepsin S by intraplantar or intrathecal routes, or made intraplantar injections of macrophage activator zymosan to mice. We measured paw thickness to assess

inflammatory edema and withdrawal from von Frey filaments to assess mechanical allodynia. To determine mechanisms of cathepsin S-evoked inflammation and pain, we studied PAR_2 and cystatin C knockout (KO) mice, or treated wild-type (WT) mice with cathepsin S inhibitor Z-FL-COCHO, or substance P (SP) neurokinin 1 receptor (NK_1R) antagonist SR140,333. We used activity-based probes to assess cathepsin S activity in tissue.
Results. In WT mice, intraplantar cathepsin S induced edema and mechanical allodynia of the paw, and intrathecal cathepsin S also caused allodynia. Proinflammatory and algesic actions of peripherally and centrally-mediated cathepsin S were diminished in PAR_2-KO mice. Intrathecal SR140,333 also blunted algesic effects of intrathecal cathepsin S, consistent with a neurogenic mechanism involving PAR_2-dependent release of SP from central projections of nociceptive neurons and activation of NK_1R on spinal neurons. Doses of cathepsin S that was too low to induce inflammation and allodynia in WT mice, caused a slowly developing but marked inflammation and allodynia in cystatin C KO mice. After administration of cathepsin S, enzymatic activity in tissues, determined using an activity based-probe, was markedly higher in cystatin C KO that WT mice, consistent with the exacerbated inflammation and pain in cystatin C KO mice. Cathepsin S inhibitor attenuated inflammatory and hyperalgesic actions of zymosan, implicating a key role for endogenous cathepsin S.
Conclusions. Our results show that PAR_2 mediates proinflammatory and algesic actions of cathepsin S both in the periphery and in the spinal cord, and implicate SP and NK_1R in central mechanisms of cathepsin S-evoked and PAR_2-mediated algesia. Cystatin C attenuates proinflammatory and algesic actions of cathepsin S by suppressing cathepsin S activity in extracellular fluid and limiting activation of PAR_2.

Title: Antibiotic-mediated changes in formalin-induced pain responses differ between genders in DID model

Authors: H. BLANTON[1], C. BEZBORUAH[1], D. CURTIS[1], J. MARTINEZ[1], S. BERGESON[1], *J. GUINDON[2];
[2]Dept. of Pharmacol. and Neurosci., [1]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX

Abstract: Inflammatory pain is a condition in which tissue becomes over sensitized and produces an exaggerated pain response to both painful stimuli, and in the case of allodynia, otherwise innoculous stimuli. Inflammatory pain can be induced through a variety of mechanisms and treatment can be difficult due to the complex signaling mechanisms that mediate the state, examples of which include prostaglandins, growth factors, and inflammatory cytokines. Inflammatory cytokines, such as TNF-alpha, are often released in response to chronic alcohol consumption, a common cause of inflammatory pain. Anti-inflammatory agents such as NSAIDs are among the most common treatments for inflammatory pain, but present problems such as liver toxicity when co-administered in the presence of chronic alcohol consumption. Novel approaches for treating inflammatory pain are now being investigated through the repurposing of readily available medications such as antidepressants, anxiolytics, and as is the case in this study, antibiotics. Aside from their main application as antibiotics, the tetracycline class of compounds has demonstrated anti-inflammatory properties. The goal of this study was to evaluate the efficacy of a synthetic tetracycline derivative as an anti-nociceptive agent in the formalin model (10ul at 2.5 % i.pl.) of pain using male and female mice in both chronic-drinking and non-drinking conditions. The results demonstrate a polarizing effect on pain perception between male and female mice across all experimental conditions. Females demonstrated the lowest pain threshold when exposed to the combined treatment of tetracycline and alcohol while males demonstrated the opposite effect. Males in the combined treatment were the least sensitive to pain of any condition. These results raise questions as to whether gender differences influence the efficacy of tetracyclines as treatments for pain and if so, what the mechanism behind these differences may be.

Title: Analgesic effects of sialidase in inflammatory pain: the role of gangliosides in nociceptive signaling.

Authors: *S. WATANABE, K. TAKANO, M. SAGAWA, T. IWAI, Y. IKEDA-MATSUO, Y. NAITO, M. TANABE;
Dept. of Pharmacol. Sch. of Pharm., Kitasato Univ., Tokyo, Japan

Abstract: Gangliosides play essential roles in nervous system functions through regulating membrane organization. Gangliosides are sialic acid containing glycosphingolipids synthesized from ceramide and divided into four groups (asialo-, a-, b-, and c-series gangliosides) based on their biosynthetic pathway. Handa et al. revealed that *St8sia1* knockout mice, which lack b- and c-series gangliosides but not asialo- and a-series gangliosides, show altered nociceptive behavior (1). However, the molecular mechanism underlying pain defects remains unknown. To address this issue, we first examined whether gangliosides in skin tissues are involved in nociception. Intraplantar injection of b-series ganglioside GT1b, but not a-series ganglioside GM1, produced nociceptive behavior and enhanced 0.05% formalin-induced nociception (GT1b-induced hyperalgesia) in ICR mice. GT1b-induced hyperalgesia was blocked by glutamate receptor antagonists and elimination of glutamate in subcutaneous tissues using glutamate degradation enzymes. Furthermore, subcutaneous microdialysis analysis revealed that intraplantar GT1b injection increased glutamate concentration. These findings suggested that GT1b increased extracellular glutamate concentration in subcutaneous tissues, thereafter activating peripheral glutamate receptors, which in turn resulted in nociceptive behavior and hyperalgesia (2).
When compared with a-series gangliosides, b-series gangliosides have two sialyl residues linked to the galactose in the second position from ceramide. Therefore, sialyl residue seems to be important in nociceptive behavior after intraplantar injection of gangliosides. We examined the effects of sialidase, which degrades sialyl conjugates including gangliosides, in nociceptive behavior. One day after intraplantar injection of complete Freund's adjuvant, sialidase from *Arthrobacter Ureafaciens* was injected into the same plantar area. Indeed, sialidase treatment reduced mechanical allodynia caused by complete Freund's adjuvant induced inflammation. Consistent with analgesic effects of sialidase, intraplantar injection of GT1b into naïve mice induced mechanical allodynia. Furthermore, lipid extracts from inflammatory skin tissues but not naïve skin included complex gangliosides. These results suggested that inflammation leads to increased complex gangliosides in skin tissues, which is involved in inflammatory pain.

Title: The effects of hypoglutamatergic tone on physiological nociception and inflammatory pain:evaluation of glutaminase type 1 mutant Sprague-Dawley rats

Authors: *Z. ZHANG, S. DAS, M. B. ANDERSON, K. E. MILLER;
Anat. & Cell Biol., Oklahoma State Univ-CHS, Tulsa, OK

Abstract: Increased glutamatergic tone contributes to peripheral sensitization during tissue inflammation. Glutaminase type 1 (GLS1) is the synthetic enzyme that converts glutamine to glutamate in the nervous system. Several pharmacological studies have demonstrated the significant role of GLS1 in maintaining high glutamate level during acute and chronic inflammatory pain. In the current study, GLS1 heterozygous knockout ($GLS1^{+/-}$) rats were custom made out from outbred Sprague-Dawley rats, generating a rat model with hypoglutamatergic tone. Inflammatory pain was measured during an adjuvant-induced arthritis (AIA) model. A 2 × 2 design was made with genotype (WT vs $GLS1^{+/-}$) and inflammation (naïve vs AIA) as the two variables. Four experimental groups were generated (WT-naïve, WT-AIA, $GLS1^{+/-}$-naïve and $GLS1^{+/-}$-AIA). Behavioral, histopathological and molecular analyses were performed. $GLS1^{+/-}$ rats have no detectable alterations in anatomical or histological structures compared to the WT littermates. Under physiological conditions, $GLS1^{+/-}$ rats have decreased GLS1 expression in the dorsal root ganglion (DRG) neurons and peripheral tissues, but normal nociception compared to the WT littermates. When evaluating the inflammatory pain, $GLS1^{+/-}$-AIA rats developed less sensitization compared to WT-AIA rats. Both WT and GLS mutants had increased GLS1 in the associated lumbar DRG after AIA. However, the magnitude of elevation between $GLS1^{+/-}$-naïve and $GLS1^{+/-}$-AIA rats was smaller than those of WT littermates. The characterizations of $GLS1^{+/-}$ rats help us understand the role of GLS1 in maintaining glutamatergic tone. These results support that glutamatergic signaling has various contributions in physiological nociception and inflammatory pain.

Title: Expression of anoctamin-1 and bestrophin-1 in inflammatory and neuropathic pain models in rats

Authors: *I. VELAZQUEZ LAGUNAS, J. B. PINEDA-FARIAS, V. GRANADOS-SOTO; Farmacobiología, Cinvestav, Sede Sur, Ciudad de Mexico, Mexico

Abstract: Intracellular chloride (Cl^-) concentration could increase in primary sensory neurons when exposed to inflammatory mediators or after nerve injury. Such increase modifies the Cl^- electrochemical potential and turns it more positive. In this way, calcium-activated chloride channels (CaCCs) activation produces a Cl^- efflux that under these particular conditions might facilitate the nociceptive terminals depolarization contributing to the generation of action potentials. Previous studies have suggested the participation of bestrophin-1 and anoctamin-1, members of the CaCCs, in inflammatory and neuropathic pain, but their regulation during these states are unclear. The aim of this investigation was to study the expression of anoctamin-1 and bestrophin-1 in inflammatory and neuropathic pain models. Experiments were carried out in adult female Wistar rats (body weight 140-220 g). Rats received an intraplantar injection of vehicle (saline or 10% ethanol, 10% Tween 20, and 80% saline), formalin (1%), bradykinin (10 nM), serotonin (0.1%) or capsaicin (0.1%) in to the right hind paw or spinal nerve ligation. Bestrophin-1 and anoctamin-1 mRNA and protein expression were determined in the lumbar spinal cord and dorsal root ganglia (DRG) in *naïve*, injected (1 h, 1, 3 and 6 days) and neuropathic rats (1, 7, 14 days) by PCR, Western blot and Immunofluorescence, respectively. Bestrophin-1 and anoctamin-1 mRNA and protein were expressed in the lumbar spinal cord (SC) and DRG of all groups. Intraplantar inject of formalin, bradykinin, serotonin and capsaicin increased mRNA and protein expression of bestrophin-1 and anoctamin-1 compared to the *naïve* group in the SC and DRG from 1^{st} to 6^{th} day after injection. Nerve ligation increased mRNA and protein expression of anoctamin-1, but not bestrophin-1, at the SC and DRG. Immunofluorescence showed that bestrophin-1 is expressed in non-peptidergic fibers and microglia at outer laminas of the dorsal horn SC. Moreover, the expression of bestrophin-1 and anoctamin-1 was observed in small to medium sized peptidergic and non-peptidergic DRG neurons. Results suggest that bestrophin-1 and anoctamin-1 are present in sites involved in the transmission of nociception and their expression is being modulated under inflammatory and

neuropathic pain conditions. Likewise, the data suggest that the CaCCs may represent a possible therapeutic target to develop analgesic drugs.

Title: Increase of t-type ca^{2+} current underlies protease-activated receptor 2-dependent sensitization of rat isolectin-b4 positive nociceptor

Authors: *S. CHUNG[1,2], Y.-H. KIM[3], J.-H. JOENG[3];
[1]Dept. of Physiology, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [2]Brain Korea 21 Project for Med. Science, Yonsei Univ. Col. of Med., SEoul, Korea, Republic of; [3]Dept. of Physiology, Yonsei Univ. Col. of medicine, Seoul, Korea, Republic of

Abstract: The protease-activated receptor (PAR)2 family, a group of G-protein coupled receptors, is expressed on peripheral sensory neurons. Its activation evokes mechanical hyperalgesia; however, its cellular mechanism is still unknown. Recently, it has been reported that T-type Ca^{2+} channels contribute to nociception, and augmentation of the T-type calcium current (I_{Ca-T}) may evoke hyperalgesia by sensitizing peripheral nociceptors. Therefore, we hypothesized that PAR2-induced pain may be due to sensitization of primary sensory DRG neurons evoked by augmentation of I_{Ca-T}. Trypsin (30 nM) and PAR2-activating peptide H-Ser-Leu-Ile-Gly-Arg-Leu-NH_2 (SL-NH_2) (100 μM) augmented I_{Ca-T}. In current-clamp experiments, PAR2 agonists increased excitability by increasing after-depolarizing potentials (ADP)s, lowering the threshold for action potential (AP) firing. These effects were completely reversed to the control levels by application of mibefradil, (1 μM), a potent T-type channel blocker. In addition, intraplantar (i.pl.) injection of PAR2 agonists induced a prolonged mechanical hyperalgesia and elevated spinal c-Fos protein expression. These effects were prevented by co-treatment with mibefradil (5 μg/paw). These observations suggest that PAR2 activation readily augments I_{Ca-T} in peripheral nociceptive neurons, and this augmentation of I_{Ca-T} may be involved, at least in part, in PAR2-evoked mechanical hyperalgesia.

Title: The role of mir23b and let-7a in glutamatergic myenteric innervation in trinitro-benzene-sulphonic acid-induced colitis in rats.

Authors: S. DAS[1], Z. ZHANG[1], M. B. ANDERSON[1], B. GREENWOO-VAN MEERVELD[2], *K. E. MILLER[1];

Abstract: Chronic inflammatory bowel disease such as colitis is characterized by abdominal pain and pharmacological therapies are very limited. At the same time, the excessive and exacerbated immune response within the gastrointestinal tract makes the underlying mechanisms of colitis more complex to understand. Our previous finding showed elevated levels of glutaminase (GLS) in dorsal root ganglion (DRG) neurons in TNBS-induced colitis in WT rats. The incomplete understanding of mechanisms of gene expression led us to investigate the interaction between the inflammatory and neuronal responses affecting GLS in WT and GLS+/- animals. Experimentally, we induced colitis in Sprague-Dawley WT and GLS+/- rats by infusing TNBS into the colon and collected the colon and DRG (S1 and L6) at different time points. Immune hyperactivity in colon was evident in TNBS induced colitis rats with very inflamed colons. We examined miRNAs miR23b and miR-Let7a, which target GLS and nerve growth factor (NGF)-β respectively. TNBS-induced colitis decreased the expression of miR23b 5p as well as 3p in both WT and GLS+/- rats at day2. This decrease in miRNA levels corresponded with increase in GLS protein expression in TNBS-induced colitis. The expression of Let7a-5p on the other hand increased in this colitis model. We are currently investigating to find the NGF β protein expression levels to relate with Let7a results. Further, we investigated if the change in miRNA profile in colon affected the myenteric ganglia. Immunohistochemical analysis showed

that during TNBS-induced colitis there were visibly lower concentration and number of ganglia in WT animals and the ganglia were not as defined and structured as they were in control animals. GLS inhibitor, 6-diazo-5-oxo-L-norleucine (DON), pretreatment rescued the effect of colitis on these ganglia. Nevertheless, in GLS+/- animals, TNBS-induced colitis had very minimal effect on these myenteric ganglia. Their number and intensity did not change and the DON pretreatment had no effect at all on these myenteric ganglia in TNBS-induced colitis. Based on these results, it appears that GLS plays a very crucial role in TNBS-induced colitis and further investigation using different miRNA as a biomarker for colitis may be crucial for its potential role in pathogenesis, diagnosis and treatment.

Title: Understanding the role of mannose receptor activation in improved non-viral IL-10 gene therapy for peripheral neuropathic pain

Authors: *A. G. VANDERWALL[1,2], M. S. SUN[3], S. NOOR[3], J. J. SANCHEZ[3], X. O. YANG[4], L. L. JANTZIE[5,3], E. D. MILLIGAN[3,2];

Abstract: Intrathecal (i.t; peri-spinal) injection of non-viral plasmid DNA (pDNA) expressing the anti-inflammatory cytokine interleukin-10 (IL-10; pDNA-IL-10) reverses chronic pain in a variety of rat models of peripheral neuropathic pain. However, methods have required repeated i.t. injections or such large doses of pDNA &/or vehicle that clinical translation would be difficult. Our group reported that the mannose receptor (MR) agonist D-mannose (D-man)

improves therapeutic efficacy of non-viral IL-10 gene therapy in rats. MR is a scavenger receptor, but is also upregulated on anti-inflammatory glia and leukocytes (e.g. macrophages), with MR-activation possibly leading to increased anti-inflammatory signaling. The mechanisms by which MR mediates enhanced IL-10 gene therapeutic efficacy are yet unclear. To explore this further, we first tested if D-man improvement of non-viral IL-10 gene therapy requires endogenous IL-10 actions. Adult male C57BL/6 wild type (WT) and IL-10 knockout (KO) mice underwent either sciatic chronic constriction injury (CCI) or sham surgery. Baseline (BL) hindpaw response thresholds to light touch stimuli (von Frey assay for allodynia) were assessed prior to surgery and after surgery (1, 2, 3, 5, 7, and 10 days, then every 4-5 days) until allodynia resolved. Both IL-10 KO & WT mice exhibited similar levels of allodynia by day 3 post-surgery, which stably persisted until spontaneous reversal by day 45. Additionally, a single i.t. co-injection (10.5µl total) of pDNA-IL-10 (3µg) with D-man (25µg) on day 5 post-surgery produced complete and long lasting reversal from allodynia within 2 days in both IL-10 KO & WT mice. These results support that D-man is an effective adjuvant for non-viral transgene uptake and therapy in mice, and that these effects are independent of endogenous IL-10. To further test the role of MR activation in the absence of IL-10, IL-10 KO mice (CCI vs. Sham) were behaviorally verified and given i.t. co-injections (day 5 post-surgery) of either pDNA-IL-10 or a control plasmid (pDNA-GFP) with either D-man or saline. As before, CCI-treated mice given D-man/pDNA-IL-10 exhibited stable reversal from allodynia. Interestingly the mice given D-man/pDNA-GFP experienced transient pain reversal, achieving near BL levels by day 3 post-injection but returning to allodynia by day 12 post-injection. Overall these results point to an IL-10 independent mechanism of MR-mediated enhancement of initial transgene uptake, expression, and pain reversal. Ongoing studies will identify the anatomical region of transgene expression and the possible transcriptional regulation following MR-activation on glial-immune phenotypic profiles.

Title: The inhibitory effect of peripheral delta opioid receptors (dors) in knee joint on arthritis pain

Authors: *S. MOON, E. PARK, H. SUH, H. HAN;
Col. of Med. / Korea Univ., Seoul-City, Korea, Republic of

Abstract: Systemic opioid application can be used for its strong analgesic effect. However, extensive activation of opioid receptors (ORs) beyond the target can cause unwanted complications e.g. dysphoria, pruritis, respiratory depression and constipation. Therefore, the selective activation of peripheral ORs present in the afferent fibers of the targeted tissue can be considered a better strategy in opioid analgesia to avoid unwanted complications. The purpose of this study was to clarify the role of peripheral delta opioid receptors (dORs) in arthritic pain for the possible use of peripheral ORs in anti-nociception. We investigated whether the activation of peripheral dORs could reduce the nociceptive behavior and the response of sensitized primary mechanosensitive afferents (MSA) after carrageenan-induced arthritis in male Sprague-Dawley rat. Administering SNC80 (selective agonist of dOR) into the knee joint, we evaluated the nociceptive behavior by using dynamic weight bearing test which can measure the decreased weight load on affected side during freely walking, and recorded MSA activity (maximal spikes/second) in knee joint by using extracellular single nerve recording technique before and after the injection of SNC80. Four hours after the induction of arthritis, the intra-articular application of SNC80 (1μM, 100μM and 1mM) resulted in significant recovery in nociceptive behavior. Consistent with these behavioral results, we also found that the intra-articular application of SNC80 (1μM and 100μM) significantly decreased MSA activities stimulated by von Frey filaments (6 and 26g) 10 to 60 min post-drug injection. However, the application of 10nM SNC80 had no effect on MSA activities and nociceptive behavior. These results implicate that the activation of peripheral dOR in the knee joint can contribute to reducing the nociceptive behavior by decreasing the activity of MSA in inflamed knee joint.

Title: Red light (670 nm) reduces hypersensitivity and improves tactile pathway functional integrity that is preceded by decreased neuronal cell death and reactive astrocytes following a mild T10 spinal cord injury

Authors: *D. HU, J. R. POTAS;
Eccles Inst. of Neurosci., The Australian Natl. Univ., Acton, Australia

Abstract: Spinal cord injured patients often suffer from serious sensory deficits including neuropathic pain and/or loss of sensation. We investigated the effects of a 670 nm LED 30 min daily treatment on the development of neuropathic pain and tactile sensory pathway deficits in a hemi-contusion model in male Wistar rats. A spinal cord injury (hemi-contusion: 10 g, 25 mm height, diameter 1 mm) was induced on the right dorsal surface of the spinal cord at the T10 vertebral body and with the dura removed. We first assessed the development of hypersensitivity using a novel behavioural assessment assay applied to 6 regions over the rat dorsum at dermatomes above, at, and below the level of the injury and on ipsilateral and contralateral sides. Weights were applied to four behavioural categories to give a regional sensitivity score (RSS) to 10 consecutive innocuous mechanical stimulations (bending force: 2.86 ± 0.09 g) in each region. An accumulative sensitivity score (ASS) was then calculated by the sum of all 6 RSSs. Uninjured intact animals were assessed to define a hypersensitivity threshold (2 standard deviation above the mean). More than 50% of sham treated animals had ASS exceeding the hypersensitivity threshold between 1-5 days post injury (dpi) while this was reduced to 30% in 670 nm treated group. Treatment also decreased ASS in normosensitive animals compared to sham treated animals at 1-3 dpi. To study tactile pathway changes following spinal cord injury and treatment, local field potentials were measured from the brainstem surface by electrically stimulating sural nerves to ascertain the integrity of the dorsal column pathways. Sham treated animals displayed increased latency and decreased magnitude and duration of responses arising from the ipsilateral dorsal column pathway compared to the contralateral side. 670 nm treatment reversed these functional deficits, particularly at 7 dpi. Expression of astrocyte activation (GFAP) occurred from 1 dpi and was reduced by 670 nm from 3-7 dpi ipsilateral to the injury. The treatment however, did not affect IL-1β expression by astrocytes or microglia (IBA1) between 1-5 dpi. The density of iNOS containing microglia was reduced by 670 nm treatment at 7 dpi. While both groups showed reduced areas of myelination (MBP) and neurofilament density (NF200) ipsilateral to the injury, 670 nm treatment significantly reduced neuronal cell death (NeuN/TUNEL) at 1 dpi. We conclude that 670 nm reduces the early incidence of hypersensitivity, followed by improved tactile pathway integrity. Functional improvements are preceded by reduced astrocyte activation and neuronal cell death, and coincide with reduced iNOS secretion by microglia at 7 dpi.

Title: Stimulus-evoked and spontaneous pain in Complete Freund's adjuvant -induced arthritis in the rat

Authors: *S. WAGNER, J. BINDLER, L. BOURGOIN, E. ANDRIAMBELOSON; NEUROFIT, ILLKIRCH, France

Abstract: Intra-articular injection of complete Freund's adjuvant (CFA) in rodents is a well characterized model of monoarthritis and is routinely used for the screening of compounds targeting inflammatory pain. The injection of CFA usually results in an increased sensitivity to noxious stimuli such as heat or mechanical pressure. However, there is a paucity of data concerning the time course of spontaneous pain following CFA injection. In the present study, CFA was injected into the tibio-tarsal joint of the rat hindpaw. The time course of nociceptive responses to mechanical pressure applied to the hindpaw palm (Randall & Sellito paw pressure test) was assessed on days 0, 2, 4, 7, 10, 14, 21 and 28 post-CFA injection. In addition to measuring threshold to nociceptive challenge, spontaneous pain was assessed in parallel by changes in hindpaw weight bearing using pedobarography. Significant swelling indicative of inflammation was observed in the CFA-injected (ipsilateral) paw until day 28 post-CFA although the intensity of swelling was slightly reduced from day 10 onwards. When compared to the non-injected (contralateral) paw, a significant reduction (up to 80%) of mechanical nociceptive threshold was observed in the CFA-injected paw. However, the mechanical threshold of non-injected (sham control) animals also progressively decreased with successive paw pressure tests. By day 7 (after 4 measurements), the nociceptive threshold in sham animals was equal to the level in ipsilateral of CFA injected rats. Pedobarographic measurements indicated that there was a transfer of weight bearing from the CFA-injected paw to the non-injected paw during the 3 weeks following the injection of CFA. This postural imbalance in CFA rats was maximal 4 days after CFA injection and showed up to 75% weight transfer to the non-injected paw. Whilst the imbalance remained statistically significant until day 21, recovery was evident from day 7 and complete by day 28. In contrast to mechanically evoked pain using the paw pressure test, weight bearing was not altered in sham animals even after repeated measurements. Furthermore, the data indicates that acute treatment with morphine suppressed the postural imbalanced in the hindpaws of CFA rats. From these results, pedobarography appears as unbiased measure of pain in CFA rats as compared to the mechanical pressure test. Indeed, the perception of nociceptive stimulus is influenced by the learning of the test and also by the pain status of the animal. Thus,

pedobarography could be relevant for the profiling of analgesic drugs in this animal model of arthritis.

Title: Increased caspase1 activity in the DRG during inflammatory hyperalgesia

Authors: Y. MATSUOKA[1], K. OH-HASHI[2], *F. AMAYA[1];
[1]Kyoto Prefectural Univ. of Med., Kyoto, Japan; [2]Gifu Univ., Gifu, Japan

Abstract: Background
Caspase1, also known as interleukin1 beta converting enzyme (ICE), is the cysteine protease that mediates maturation and secretion of IL1 beta. Caspase1 is involved in the development of neuroinflammation in the central nervous system in the neurodegenerative disease. In the present study, we investigated the expression of Caspase1 and it adaptar protein ASC in the peripheral nervous system and Caspase1 activity during the inflammatory hyperalgesia.
Method
Male C57BL/6 mice (20-25g) were used for this experiments. All experimental procedures were approved by the animal ethics committee of the Kyoto Prefectural University of Medicine. Inflammatory hyperalgesia was produced by the intraplantar injection of complete Freund's adjuvant (CFA, 20μL) into the left hindpaw. Behavioral analysis including von Frey mechanical stimulation and hot plate testing were performed. For the immunohistochemistry analysis, mice treated with CFA or naïve controls were transcardially perfused with 0.9% NaCl followed by 4% paraformaldehyde in 0.1M PB under deep anesthesia. L4 and L5 DRGs were isolated and processed for immunohistochemistry. Visualization of Caspase1 and ASC was performed using fluorescent immunohistochemistry with antiCaspase1 and anti ASC antibody. For caspase1 activity measurement, mice L4 and L5 DRG were isolated Caspase1 activity was measured with the Fluorometric assay kit.

Result
In the DRG, caspase1 immunoreactivity was detected in neurons. Caspase1 expression in the DRG neurons significantly increased in CFA treated mice. Signal intensity analysis revealed that the percentage of neuron with intense signal for caspase1 significantly increased 2days after the CFA injection. The distribution of ASC was similar to Caspase1 in the DRG. Caspase1 activity of the DRG significantly increased in the CFA treated mice compared to the control.
Conclusion
Caspase1 activity in the DRG increased by the tissue inflammation. This is associated with increased expression of caspase1 in the primary afferent neurons. Caspase1 induced neuronal inflammation might be involved in the development of inflammatory hyperalgesia.

Title: Receptor specific activation of sensory neurons by cytokines

Authors: ***M. GUNASEKARAN**, B. STEINBERG, T. TSAAVA, S. CHAVAN, K. TRACEY; Lab. of biomedical science, Feinstein Inst. for Med. Res., Manhasset, NY

Abstract: Memory in immune cells and neurons develops in response to environmental changes. The central nervous system modulates immunity through reflexes to monitor and defend the organism. Threat from inflammation and infection are sensed by sensory neurons activated by cytokines and other messenger molecules. Here we have shown cytokine-specific receptor expression and cytokine-mediated activation of sensory neurons from nodose ganglia (NG). Pro-inflammatory cytokines, tumor necrosis factor (TNF) and interleukin 1 beta (IL-1b) induced activation of sensory neurons revealed by measuring intracellular calcium levels with fluorescence microscopy using fluo-4 AM. Exposure of neurons from wild type mice to TNF or IL-1b significantly increased intracellular calcium levels as compared to vehicle. TNF and IL-1b at concentrations up to 100 ng/ml activated 11 % and 6 % of NG sensory neurons. Neurons from TNFR1/TNFR2 and IL1 receptor knockout mice failed to develop increased calcium levels, indicating that TNF and IL-1b induced activation is receptor specific. Together, these observations reveal a cytokine-specific and receptor-mediated activation of sensory neurons. This is a mechanism by which peripheral neural circuits sense immunological threats in a mediator specific manner.

Title: Fab fragment of Nav1.7 monoclonal antibody inhibits sodium currents in mouse and human DRG neurons and suppresses inflammatory and neuropathic pain

Authors: *R.-R. JI[1], W. CHANG[1], J. YOO[2], Y. KIM[1], G. CHEN[1], T. BERTA[1], Y. HUH[1], S.-Y. LEE[2];
[1]Pain Res. Division, Anesthesiol., [2]Biochem., Duke Univ. Med. Ctr., Durham, NC

Abstract: The voltage-gated sodium channel subtype Nav1.7 plays an important role in pain sensation in rodents and humans. Our previous study (Lee et al., Cell, 2014) showed that a monoclonal antibody that targets a Nav1.7 channel voltage sensor (SVmab1) not only suppressed sodium currents in mouse DRG neurons but also inhibited inflammatory and neuropathic pain in mouse models, compared with the control antibody (CTmab). The Fab fragment of an antibody is smaller than the whole antibody and may have better tissue penetration in vivo. In this study, we generated a Fab fragment (SVfab) derived from hybridoma-produced SVmab1 and a Fab fragment (rSVfab) derived from recombinant SVmab1. Exposure of cultured mouse and human DRG neurons to SVfab (300 and 900 nM) reduced the amplitude of transient sodium currents in a dose and time-dependent manner, whereas CTmab had no effects. The inhibition reached a plateau at 10-20 min after the SVfab incubation in DRG neurons. Notably, the inhibitory effect of SVfab is enhanced in a chronic pain condition, in which mouse and human DRG neurons were treated with the chemotherapy agent paclitaxel (1 μM). Paclitaxel also increased Nav1.7 expression and neuronal excitability in mouse and human DRG neurons. RT-PCR analysis showed that the Nav1.7 expression ratio (vs. the expression of total sodium channels) is much larger in human DRG neurons than that in mouse DRG neurons. Intrathecal injection of SVfab

reduced the formalin-induced inflammatory pain and paclitaxel-induced neuropathic pain in mice. Finally, the recombinant SVfab (rSVfab) showed similar effects in reducing sodium currents in mouse and human DRG neurons and inflammatory pain in mice. Our data suggest that the Fab antibody fragments targeting Nav1.7 also have in vitro and in vivo activities inhibiting sodium currents and inflammatory pain in mice. Since human DRG neurons express higher levels of Nav1.7 and also respond to the Fab antibody fragments, these Fab antibody fragments have the potential to be developed to treat clinical pain.

Title: Antagonising LPA_1 receptor attenuates orofacial inflammatory pain in mice

Authors: ***M. SRIKANTH**, W. CHEW, S. LIM, D. R. HERR;
Dept of Pharmacol., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Lysophosphatidic acid receptor 1 (LPA_1) is one of six G-Protein Coupled Receptors (GPCRs) activated by the bioactive lipid, lysophosphatidic acid (LPA). It is highly expressed in the central and peripheral nervous systems and its signaling is essential for normal neurocortical development, among other physiological roles.
Recent studies have characterized the role of LPA_1 signaling in the pathophysiology of neuropathic pain. It has also been shown that inhibiting phospholipase A2, an enzyme that produces LPA and arachidonic acid, reduces mechanical allodynia in mice with inflammatory orofacial pain. This effect is not mediated by arachidonic acid, leading us to hypothesize that LPA via the LPA_1 receptor could be involved in mediating inflammatory orofacial pain. In our study, we used genetic and pharmacological approaches to block LPA_1 signaling and evaluate mechanical allodynia in a mouse model of carrageenan injection induced orofacial inflammatory pain. We found that LPA_1 -/- mice showed a significant reduction in pain response compared to wild type littermate controls. A similar significant reduction in pain response was observed in mice that were treated with a pharmacological LPA_1 antagonist. Interestingly, this effect was seen only when the antagonist was administered directly into the central nervous system.

Peripheral administration did not elicit any differences in pain behaviour. Taken together, our findings indicate that LPA_1 signaling in the central nervous system plays a key role in mediating orofacial inflammatory pain. Identifying LPA_1 as a potential therapeutic target for managing chronic pain could aid in the development of novel therapeutics with better efficacy and lesser adverse side-effects.

Title: A novel role of xist in mediating sex-specific difference in pain and inflammation

Authors: *B. B. SHENODA[1], G. M. ALEXANDER[2], E. ARADILLAS LOPEZ[2], S. K. AJIT[1]; [1]Pharmacol. and Physiol., [2]Neurol., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Epidemiological studies demonstrate that biological sex represents an important risk factor in the development of chronic pain and autoimmune disorders in women. However, the prevalence and severity of acute inflammatory diseases are more common in men. X-inactive specific transcript (XIST) is a long noncoding RNA that is crucial for equalizing expression of X-linked genes between females and males by randomly inactivating one of the two X-chromosomes in female cells. Our previous studies showed that specific microRNAs down regulated in complex regional pain syndrome (CRPS), a female-prevalent disorder characterized by inflammation and chronic pain, can target XIST. Using molecular, biochemical and imaging approaches, we investigated the role of XIST in regulating inflammation and pain in mouse macrophages, in blood samples from CRPS patients and a rodent model of inflammatory pain. Our findings indicate a novel role for XIST in female cells beyond X-chromosome inactivation. These studies provide insights on how sex-specific mechanisms may contribute to inflammation, pain and analgesia, and would be beneficial in developing sex-specific treatment strategies.

Title: Effects of alpha-7 nicotinic acetylcholine receptor positive allosteric modulator on proinflammatory cytokine expression and norepinephrine release following lipopolysaccharide-induced neuroinflammatory pain in mice

Authors: *M. ABBAS, S. RAHMAN;
Pharmaceut. Sci., South Dakota State Univ., Brookings, SD

Abstract: We have shown that alpha-7 nicotinic acetylcholine receptor positive allosteric modulator (PAM) controls neuroinflammatory pain (NP) phenotypes involving microglial activation in the hippocampus in lipopolysaccharide (LPS)-induced NP model in mice. Whether tumor necrosis factor (TNF)-alpha, a proinflammatory cytokine, and norepinephrine (NE) release is associated with NP phenotypes remains unknown. Here, we examined the effects of 3a,4,5,9b-Tetrahydro-4-(1-naphthalenyl)-3*H*-cyclopentan[*c*]quinoline-8-sulfonamide (TQS), an alpha-7 nAChR PAM, on microglial TNF-alpha expression and NE level following LPS-induced NP model in mice. Pretreatment of TQS (4 mg/kg) significantly reduced LPS-induced tactile allodynia and thermal hyperalgesia. Furthermore, pretreatment of TQS (4 mg/kg) reduced LPS-induced increased TNF-alpha mRNA and TNF-alpha expression in the hippocampus. Pretreatment of idazoxan, an alpha-2 adrenergic receptor antagonist, significantly reduced antiallodynic and antihyperalgesic effects of TQS. Moreover, TQS increased LPS-induced decreased NE level in the hippocampus. Taken together, these results suggest that TQS decreases LPS-induced NP by reducing TNF-alpha expression and increasing NE level in the hippocampus involving microglial alpha-7 nAChR positive allosteric modulation. Therefore, alpha-7 nAChR PAM such as TQS could be a potential drug candidate for the treatment of NP.

Title: Acute toluene exposure enhances hyperalgesia and allodynia in long lasting pain

Authors: *L. F. ORTEGA-VARELA[1], C. CERVANTES-DURÁN[2], M. A. TORRES-SANTANA[3], M. Y. GAUTHEREAU-TORRES[2];
[1]UMSNH, Lic. En Salud Publica, Morelia, Mexico; [2]Facultad de Ciencias Médicas y Biológicas "Dr. Ignacio Chávez", UMSNH, Morelia, Mexico; [3]Facultad de Químico Farmacobiología, Univ. Michoacana de San Nicolás de Hidalgo, Morelia, Mexico

Abstract: Toluene is a volatile solvent that can be found in products like thinner, paints and adhesives. Toluene misuse is an important public health problem in Mexico, mainly among street children and teenagers. Pharmacological studies indicate that this solvent produces pronociceptive effects in mice and rats, but the mechanisms involved are still unclear. On the other hand, chronic pain affects 25% to 29% of Mexican population. The purpose of this study was to evaluate the effect of acute toluene exposure on development of long-lasting secondary mechanical allodynia and hyperalgesia induced by formalin in rats. Formalin produces acute nociceptive behaviors (flinching and licking/lifting followed by long-lasting pain). Female Wistar rats (200-300 g) were placed in a static exposure chamber and exposed to toluene (6000 ppm) or air (control group) during 30 minutes. After acute exposure, rats were injected with 50 µl of 1% formalin in the dorsal surface of the right hind paw and 6 days later allodynia and hyperalgesia were evaluated in both paws. In control rats, formalin (1%), produced secondary mechanical allodynia and hyperalgesia in both paws. This was observed as a bilateral increase in paw withdrawal responses to the application of von Frey filaments (10 and 250 mN) that was significant one day after formalin injection and lasted for at least 12 days. In toluene-exposed rats, there was an increase of these nociceptive behaviors compared with control group ($P < 0.05$). These results suggest that toluene enhances secondary mechanical allodynia and hyperalgesia induced by formalin in rats, but further experiments are needed in order to elucidate the mechanisms involved in these effects.

Title: Epac-PKCalpha signaling in purinergic P2X3R-mediated hyperalgesia after inflammation

Authors: ***Y. GU**, G. LI, Y. CHEN, L.-Y. M. HUANG;
Univ. Texas Med. Br., Galveston, TX

Abstract: Sensitization of purinergic P2X3 receptors (P2X3Rs) is a major mechanism contributing to injury-induced exaggerated pain responses. In a previous study, we have showed that cAMP-dependent guanine nucleotide exchange factor 1 (Epac1) in rat sensory dorsal root ganglia (DRGs) is upregulated after inflammatory injury and plays a critical role in P2X3R sensitization by activating protein kinase C epsilon (PKCε) inside cells. In contract of PKCε, which has been established as the major PKC isoform mediating injury-induced hyperalgesic responses, the role of protein kinase C alpha (PKCα) in receptor sensitization was seldom considered. We therefore studied the participation of PKCα in Epac signaling in P2X3R-mediated hyperalgesia. Following complete Freund's adjuvant (CFA)-induced inflammation, we found that the expression of both Epac1 and Epac2 and the level of cAMP in DRGs are greatly enhanced. The expression of phosphorylated PKCα (pPKCα) is also upregulated. CFA-induced P2X3R-mediated hyperalgesia is not only blocked by Epac antagonists, but also by the classical PKC isoform inhibitors, Go6976, and PKCα-siRNA. These CFA effects can be mimicked by an application of the Epac agonist, CPT, in control rats, further confirming the involvement of Epacs. Since CPT can increase the expression of pPKCα and the application of Go6976 prior to CPT still reduces CPT-induced hyperalgesia, PKCα is downstream of Epacs to mediate the enhancement of P2X3R responses in DRGs. The pattern of translocation of PKCα inside DRG neurons in response to CPT or CFA stimulation is distinct from that of PKCε. Thus, in contrast to prevalent view, PKCα also plays an essential role in producing complex inflammation-induced receptor-mediated hyperalgesia.

Title: The chronic pain transcriptome: RNA-Seq profiling of dorsal spinal cord during persistent inflammatory hyperalgesia.

Authors: ***M. R. SAPIO**, M. J. IADAROLA, D. M. LAPAGLIA, A. J. MANNES;
NIH, Bethesda, MD

Abstract: Persistent pain states engage new gene expression programs in nociceptive circuits in the superficial laminae of the dorsal horn. These programs occur in concert with synaptic rearrangement and serve to protect injured body parts by changing the input-output functions of the spinal cord to respond appropriately to stimulation. In pain disorders these normally adaptive alterations create inappropriate and deleterious responses. Identifying the molecular processes that are engaged during this transition provides insight into intervention. RNA-Seq provides accurate quantitation and comprehensive assessment of transcript levels of all genes expressed in a cell or tissue. This provides a broad view of all biological processes that engage the transcriptional machinery, including the engagement of targetable receptors, and the regulation of signaling molecules altered by the remodeling of the spinal cord. We examined differentially expressed genes at 2, 24 and 48 hours after inflammation to characterize the transition from normal sensation to profound hyperalgesia. Elevated expression of multiple transcription factors occurred at 2hrs with return to control levels by 48 hrs. These included known transcription factors c-Fos, the Fos paralog Fra2, and JunB, and 3 paralogs of NGFI-B (nuclear receptor family). Several neuropeptide transcripts displayed long-term increases including prodynorphin, proenkephalin and protachykinin, as expected. In addition, many of the most highly expressed and highly differential genes are immune-like and are part of the microglial complement system, which engages in degrading synaptic connections to change the circuitry of the spinal cord. This induction occurs in the absence of other inflammation markers, and is long-lived. We further examined to what extent these genes are expressed in different cell types and tissues, incorporating additional information from large public datasets. We conclude that neuronal activity is accompanied by complement-dependent synaptic rearrangement by microglia, and that a relatively discrete set of receptors and their ligands are regulated by peripheral inflammation.

The data demonstrate that a cadre of state-dependent drivers and downstream effector molecules are induced to control nociceptive primary and secondary sensitization processes that occur in persistent pain states, and describe in a comprehensive fashion the cascade of signals involved in the transition to persistent pain.

Title: Gender influences efficacy of tetracycline derivative at relieving formalin and alcohol-induced mechanical and cold allodynia

Authors: *H. BLANTON[1], D. HUNTER[1], C. SHERFEY[2], C. BEZBORUAH[1], J. MARINEZ[1], S. BERGESON[1], J. GUINDON[1];
[1]Texas Tech. Univ. Hlth. Sci. Ctr., Lubbock, TX; [2]Texas Tech. Univ., Lubbock, TX

Abstract: Tetracycline and its synthetic and semi-synthetic derivatives were developed as broad-spectrum antibiotics that were later experimentally demonstrated to possess anti-inflammatory activity. This anti-inflammatory action suggests potential application of tetracycline derivatives as novel alternatives for the treatment of inflammatory pain. Our study investigates the effect of a synthetic tetracycline compound on formalin-induced and chronic alcohol-induced mechanical and cold allodynia in male and female wild-type C57BL/6 mice. First, we evaluated the effect of the tetracycline compound on mechanical and cold allodynia in formalin-naïve mice with results indicating no difference from control. We then repeated the mechanical and cold allodynia tests at 60 minutes following the formalin test in control and tetracycline-treated mice. Our results demonstrated an antinociceptive effect in the mechanical and cold allodynia test values when pre-treated with the tetracycline compound, with values returning to baseline levels 2 hours after formalin injection. Finally, we evaluated the effect of chronic alcohol consumption using the DID model on mechanical and cold allodynia in control and tetracycline pre-treated mice. Our

results demonstrated gender related differences in both alcohol's effect on mechanical and cold thresholds as well as the efficacy of the tetracycline compound at mediating the alcohol-induced mechanical and cold allodynia. Further studies are needed to investigate what mechanisms, whether gender or otherwise, underlie these differences.

Title: The effect of cutaneous inflammation on subsets of satellite glial cells in mouse dorsal root ganglion

Authors: *B. KNIGHT[1], R. M. RITZEL[2], E. R. JELLISON[2], E. E. YOUNG[3], K. M. BAUMBAUER[3];
[1]Neurosci., [2]UCONN, Farmington, CT; [3]UCONN, Storrs, CT

Abstract: Peripheral inflammation and tissue injury causes alterations in nociceptor activity and contributes to the development of normal and pathological pain states. Primary afferent nociceptors have been extensively characterized, and like central neurons, neurons that exist within the DRG do not appear to act in isolation in the peripheral pain circuitry. A resident population of peripheral glial cells, satellite glial cells (SGCs), appears to influence nociceptive activity, but the precise mechanisms by which SGCs alter neuronal function is not well understood because of difficulty in isolating adult cells without their neuronal counterparts. Ultimately, in order to understand the role of SGCs in nociceptive processing we must develop a basal cellular profile by which SGCs can be identified. To accomplish this, we used fluorescence activated cell sorting (FACS) to identify neuronal and non-neuronal cell populations in mouse DRG using CD200 and CD45, respectively. Using this broad gating strategy, we identified putative neurons (CD200+ high/CD45-), a non-neuronal cell type (CD200+ intermediate/CD45-) and two immune-related cells. We then FACS sorted SGCs based on GFAP, S100, and glutamine synthetase (GS) immunofluorescence, and found that the majority of sorted cells were GFAP+ (56.3%), while S100+ (31.3%) and GS+ (12.5%) cells constituted a lower percentages, respectively. GFAP+/S100+ and GFAP+/S100+ each represented 50% of the overlapping cell populations. Next, we examined the impact of cutaneous inflammation on SGC protein expression by injecting mice with 20 uL of CFA into the dorsal surface of one hindpaw. L2 and

L3 DRG were collected 24 hr later and cells were FACS sorted based on GFAP, S100, and GS immunofluorescence. We found that inflammation increased the the percentage of S100+ cells by 23.2%, while the percentage of GFAP+ and GS+ cells slightly decreased by 16.7% and 6.5%, respectively. When GFAP+/S100+ and GFAP+/GS+ cell populations were examined we found that inflammation caused a 50% decrease in both the GFAP+/S100+ and GFAP+/GS+ cell populations. Our data suggest the presence of a heterogeneous population of SGCs, and given the divergent regulation of SGC markers following inflammation our results further suggest there may be functional differences between the various populations of cells. Ongoing experiments are developing gene expression profiles for naïve and inflamed SGCs and are aimed further characterizing the role of SGCs in pain processing.

Title: Regulation of peripheral opioid receptor-mediated signaling and antinociception by 12- and 15-hydroxyeicosatetraenoic acid

Authors: *K. A. BERG[1], L. C. SULLIVAN[1], T. A. CHAVERA[1], M. PANDO[1], X. GAO[2], W. P. CLARKE[1];
[1]Pharmacol., Univ. of Texas Hlth. Sci. Ctr. at San Antonio, San Antonio, TX; [2]Metabolomics Core, Univ. of Texas Hlth. Sci. Ctr., San Antonio, TX

Abstract: Delta opioid receptors (DOR) expressed by peripheral pain-sensing neurons (nociceptors) are regulated by both cyclooxygenase (COX)- and lipoxygenase (LOX)-dependent arachidonic acid (AA) metabolites (Sullivan, Berg and Clarke, JPET 353:44-51, 2015). Whereas COX metabolites induce functional competence (i.e., responsiveness to agonist) for antinociception, LOX metabolites induce a non-responsive state of the receptor that is refractory to re-induction of functional competence. In this study, using high performance liquid

chromatography tandem mass spectrometry analyses, we have found that the 12/15-lipoxygenase AA metabolites, 12-HETE and 15-HETE, are elevated following treatment of adult rat primary sensory neuron cultures with AA. Exogenously applied 12-HETE and 15-HETE blocked DOR-mediated inhibition of PGE_2-stimulated adenylyl cyclase (AC) activity in primary sensory neuron cultures as well as DOR-mediated reduction of PGE_2-evoked thermal allodynia in the rat hindpaw. In addition, treatment of primary cultures of peripheral sensory neurons with 12- and 15-HETE blocked kappa opioid receptor-mediated inhibition of PGE_2-stimulated AC but had no effect on the responsiveness of $5\text{-}HT_{1B/1D}$ receptors for inhibition of PGE_2-stimulated AC. Further, pretreatment with 12- and 15-HETE had no effect on either DOR- or KOR-mediated extracellular signal-regulated kinase (ERK1/2) activation. Taken together, these data suggest that 12- and 15-HETE selectively induce a non-responsive state of opioid receptors for antinociceptive signaling. These results exemplify the differential regulatory control of opioid receptors expressed by peripheral nociceptors and suggest that the duration of opioid receptor responsiveness under inflammatory conditions may be increased by inhibition of 12/15-lipoxygenase.

Title: 12- and 15-hydroxyeicosatetraenoic acid promote a non-responsive signaling state of delta opioid and kappa opioid receptors, but not for delta-kappa heteromers, in peripheral nociceptors

Authors: ***M. M. PANDO**, T. A. CHAVERA, W. P. CLARKE, K. A. BERG;
Univ. of Texas Hlth. Sci. Ctr. San Anto, San Antonio, TX

Abstract: Opioid receptor systems expressed by peripheral pain-sensing neurons (nociceptors) are under dual regulatory control by cyclooxygenase (COX) and lipoxygenase (LOX) dependent arachidonic acid (AA) metabolites. Neither DOR nor KOR are functionally active for

antinociception under basal conditions, but become responsive following exposure to inflammatory mediators (e.g., carrageenan, bradykinin (BK) or AA) that produce COX-dependent AA metabolites. However, opioid receptors revert to a non-signaling state due to production of LOX-dependent AA metabolites, 12- and 15-HETE (see Berg et al., this meeting). Here we sought to examine the effects of LOX-dependent regulation of DOR-KOR heteromer signaling and antinociception in primary cultures of adult rat peripheral sensory neurons (ex vivo model) and in the carrageenan model of inflammation (in vivo). Ex vivo, we compared the effects of 12- and 15-HETE on inhibition of PGE_2-stimulated cAMP accumulation by the DOR agonist, DPDPE, the KOR agonist, U50488 and the DOR-KOR heteromer agonist, 6'-GNTI. Addition of 12- and 15-HETE blocked DPDPE- and U50488-mediated inhibition of PGE_2-stimulated cAMP accumulation. By contrast, 12- and 15-HETE had no effect on 6'-GNTI-mediated inhibition of PGE_2-stimulated cAMP accumulation. We next compared the abilities of DPDPE, U50488 and 6'-GTNI to inhibit carrageenan induced thermal allodynia in the rat hind paw. When administered 15 min after intraplantar (i.pl) injection of carrageenan (500 ug), all agonists completely reduced carrageenan-induced thermal allodynia. When injected (i.pl.) 3h or 24h after carrageenan administration, neither DPDPE nor U50488 produced antinociceptive responses. However, responsiveness was restored following i.pl. injection of the 12/15-LOX inhibitors, baicalein and luteolin. Interestingly, the heteromer agonist, 6'-GNTI, completely inhibited the nociceptive response when administered (i.pl.) 3h or 24h (longest period tested) after carrageenan. Taken together, in striking contrast to DOR and KOR, DOR-KOR heteromers appear to remain functionally competent for a prolonged period of time under inflammatory conditions, suggesting that they may be suitable targets for development of peripherally restricted pain medications.

Title: Role of inhibitory g proteins in opioid-induced hyperalgesia and tolerance

Authors: ***L. LI**, S.-R. CHEN, H.-L. PAN;
MD Anderson Cancer Ctr., Houston, TX

Abstract: Opioids are commonly used to treat patients with moderate and severe pain. However, opioid-induced hyperalgesia and tolerance (OHT) largely limit the opioid efficacy and lead to opioid dose escalation. Although the analgesic action of opioids is mediated by inhibitory Gαi/o-type G proteins, it is unclear whether Gαi/o proteins at the spinal cord level play a role in OHT development. To study the role of individual Gαi/o proteins at the spinal cord level in OHT, we used intrathecal injection of siRNAs targeting specific Gαi/o proteins in rats. Morphine was injected systemically, and nociception was tested with a radiant heat and a noxious pressure stimuli applied to the hindpaw. We found that treatment with Gαi1-specific and Gαi3-specific siRNA did not significantly affect the morphine analgesic effect and OHT development. In contrast, intrathecal treatment with Gαi2-specific or Gαo-specific siRNA significantly diminished the acute analgesic effect of morphine. Mechanical and thermal hyperalgesia and the reduction in the analgesic effect after 5 days of morphine treatment were significantly greater in Gαi2 siRNA-treated rats than in control siRNA-treated rats. Gαo knockdown unexpectedly increased the baseline heat, but not mechanical, nociceptive threshold following daily morphine treatment. Furthermore, the analgesic effect of morphine was completely lost after 5 days of treatment in Gαo siRNA-treated rats. These results suggest that Gαi2 and Gαo at the spinal cord level play a critical role in mediating the opioid analgesic effect. Gαi2 is also involved in attenuation of OHT development. Supported by NIH grant NS073935.

Title: Development of selective peptide antagonists to the mu-delta opioid receptor heterodimer

Authors: K. OLSON[1], V. J. HRUBY[2], *J. M. STREICHER[3];
[1]Pharmacology; Chem. and Biochem., [2]Chem. and Biochem., [3]Pharmacol., Univ. of Arizona, Tucson, AZ

Abstract: The opioid receptors are a family of G protein coupled receptors crucial for the neuromodulation of important brain states including pain, reward, memory, and food intake. While the family is composed of three main members, mu (MOR), delta (DOR), and kappa, it has long been appreciated from pharmacological and other experiments that more than three

forms of these receptors likely exist. These identified forms include splice variants as well as heterodimerization between the opioid receptor family members as well as with non-opioid receptors. One such identified heterodimer is the mu/delta (M/DOR) heteromer. Using in vitro models, the heterodimerization binding site of the M/DOR has been identified, and it has been shown that the M/DOR invokes different signal transduction cascades than either monomer. Recently an M/DOR selective antibody was developed, which demonstrated that the M/DOR is upregulated in the brains of chronic morphine treated mice, and may mediate opioid tolerance, among other potential effects. Despite these advances however, there are very few tools to selectively target the M/DOR, and no selective antagonists that we could find, making it difficult to determine the role of the M/DOR in opioid and pain physiology. To address this lack we synthesized a series of potential selective peptidic M/DOR antagonists by coupling two moderate to low affinity MOR and DOR antagonist pharmacophores with a flexible and variable-length linker (15-42 atoms in the initial series), hypothesizing that we could attain high selectivity for the M/DOR by using two moderate/low affinity pharmacophores that would have an avidity induced improvement in M/DOR potency. We then characterized this antagonist series in vitro using competition radioligand binding and ^{35}S-GTPγS coupling in antagonist mode using CHO cells expressing the MOR or DOR homomers, or the M/DOR heteromer. Our initial results demonstrate a linear relationship between the linker length and the antagonist potency at the M/DOR, with the 15 atom linker compound having the best potency to date (5.1 nM, 5.1-187 nM range). We also demonstrate at least a 30 fold selectivity with the 15 atom linker compound between the M/DOR and either the MOR or DOR homomer, validating our strategy. Beyond these initial results, we will also explore shorter linker lengths, alternate pharmacophores, and varying the rigidity of the linker. After completion of in vitro characterization and the selection of the highest selectivity and potency M/DOR antagonist, we will explore the ability of our antagonist to reverse chronic morphine induced tolerance in vivo, among other potential effects of the M/DOR in vivo.

Abstract: Due to their limited adverse effects, delta opioid receptors (DOPrs) represent a promising target for the treatment of chronic pain and emotional disorders. Although DOPr agonists produce only weak analgesic effects in healthy animals and in acute pain models, we and others have previously shown an increased in their potency to relieving chronic pain (e.g. inflammatory, neuropathic, and bone cancer-induced pain). Interestingly, we observed that this increase in the analgesic effects of DOPr agonists is paralleled by a translocation of DOPr from the intracellular compartment to the plasma membrane. In order to study the roles of DOPr *in vivo* and to study the molecular and cellular mechanisms regulating its trafficking, we have generated a genetically-engineered mouse in which a Flag epitope has been introduced between the first and second amino acids of DOPr. A floxed translational stop cassette was also introduced upstream of the initiation codon. In the absence of recombination, these mice (STOP::Flag-DOPr) behave as DOPr knockout mice. We first bred the STOP::Flag-DOPr mice with Zp3-Cre mice to generate mice (Flag-DOPr knockin) expressing a Flag-tagged DOPr in place of the endogenous receptor. A thorough characterization of these mice reveal that the Flagged receptor is expressed at similar levels and in the same areas as its endogenous counterpart. We also observed that DOPr agonists produces similar behavioral effects in the Flag-DOPr knockin mice and in wildtype animals. Therefore, these mice display pharmacological and behavioral properties similar to mice expressing endogenous DOPr. In the human lumbar spinal cord, DOPr is primarily expressed in the terminals of primary afferents. To specifically study the role of DOPr in these neurons, we infected newborn STOP::Flag-DOPr mice with a rAAV2/9-CBA-Cre-GFP adenovirus. The virus was injected at P5 in the hindpaws of the animals. Two months after the injection, GFP is expressed in the nuclei of approximately 60% of the lumbar dorsal root ganglia neurons. No GFP staining was observed in the spinal cord nor in the brain, indicating that the infection was restricted to the primary afferent. When these mice were injected with the Complete Freund's adjuvant in one hindpaw, we found that the intrathecal administration of deltorphin II produces analgesia in the thermal plantar test, indicating that presynaptic DOPr are able to inhibit heat-induced pain. These results are important since they support a role for DOPr-expressing nociceptors in heat-induced pain, a dogma that was recently challenged.

Title: Bold imaging in awake wild-type and mu-opioid receptor knock-out mice reveals on-target activation maps in response to oxycodone

Authors: *K. MOORE[1], D. MADULARU[2], S. IRIAH[1], J. YEE[1], P. KULKARNI[1], E. DARCQ[2], B. KIEFFER[2], C. FERRIS[1];

Abstract: Blood oxygen level dependent (BOLD) imaging in awake mice was used to identify differences in brain activity between wild-type, and Mu (μ) opioid receptor knock-outs (MuKO) in response to oxycodone (OXY). Using a segmented, annotated MRI mouse atlas and computational analysis, patterns of integrated positive and negative BOLD activity were identified across 122 brain areas. The pattern of positive BOLD showed enhanced activation across the brain in WT mice within 15 min of intraperitoneal administration of 2.5 mg of OXY. BOLD activation was detected in 72 regions out of 122, and was most prominent in areas of high μ opioid receptor density (thalamus, ventral tegmental area, substantia nigra, caudate putamen, basal amygdala and hypothalamus), and focus on pain circuits indicated strong activation in major pain processing centers (central amygdala, solitary tract, parabrachial area, insular cortex, gigantocellularis area, ventral thalamus primary sensory cortex and prelimbic cortex). Importantly, the OXY-induced positive BOLD was eliminated in MuKO mice in most regions, with few exceptions (some cerebellar nuclei, CA3 of the hippocampus, medial amygdala and preoptic areas). This result indicates that most effects of OXY on positive BOLD are mediated by the μ opioid receptor (on-target effects). OXY also caused an increase in negative BOLD in WT mice in few regions (16 out of 122) and, unlike the positive BOLD response the negative BOLD was only partially eliminated in the MuKO mice (cerebellum), and in some case intensified (hippocampus). Negative BOLD analysis therefore shows activation and deactivation events in the absence of the μ receptor for some areas where receptor expression is normally extremely low or absent (off-target effects). Together, our approach permits establishing opioid-induced BOLD activation maps in awake mice. In addition, comparison of WT and MuKO mutant mice reveals both on-target and off-target activation events, and set an OXY brain signature that should, in the future, be compared to other μ opioid agonists.

Title: Inhibition of regulator of G-protein signaling proteins enhances morphine but not fentanyl antinociception in the rat.

Authors: *A. T. TRAN[1], S. M. SCHOO[2], M. M. MORGAN[2];
[2]Psychology, [1]Washington State Univ., Vancouver, WA

Abstract: Although opioids are the most effective treatment for chronic pain, their use is hindered by many negative effects (e.g. analgesic tolerance, dependence, respiratory depression). An important goal is to develop treatments that enhance opioid analgesia while diminishing side effects. Opioid antinociception is mediated through the mu-opioid receptor (MOR), a seven-transmembrane G-protein coupled receptor (GPCR). Regulator of G-protein signaling (RGS) proteins interact with the Gα-subunit of GPCRs and catalyzes the hydrolysis of GTP to GDP, rapidly terminating G-protein signaling. We hypothesize that the inhibition of RGS proteins will prolong G-protein signaling and enhance opioid-mediated antinociception. This hypothesis was tested by microinjecting an opioid (morphine or fentanyl) simultaneously with the small molecule RGS inhibitor CCG-63802 into the ventrolateral periaqueductal gray (PAG) of awake rats. The PAG is a midbrain structure known to contribute to opioid antinociception. Both morphine and fentanyl produced dose-dependent antinociception when microinjected into the ventrolateral PAG. Administration of CCG-63802 enhanced morphine potency as indicated by a leftward shift in the dose response curve compared to control animals, but had no effect on fentanyl antinociception. This selective enhancement of morphine but not fentanyl antinociception is consistent with other ligand biased signaling at the MOR and indicates that morphine, but not fentanyl antinociception is mediated by G-protein signaling.

Title: Oxycodone, hydrocodone, and morphine differentially affect gene expression

Authors: ***C. T. HORRAX**[1], M. A. EMERY[1], M. L. S. BATES[1], P. J. WELLMAN[2], S. EITAN[2];

Abstract: Opioid drugs remain the gold standard in pain treatment, and are regularly prescribed. However, the chronic use of these medications is known to lead to complications such as the development of tolerance, hyperalgesia, allodynia, dependence, and addiction. Additionally, the use of opioids, both medical and nonmedical, has been shown to increase the risk of developing comorbid mental disorders such as anxiety, depression, and alcoholism. This implies a shared mechanism underlying these disorders, and indeed recent research has revealed that the D2DR plays a role in all three. Recent research revealed that opioids disturb the signaling of the D2DRs, which may partially account for this association. Importantly, we recently observed that various opioids differentially modulate the responses of the D2DRs. Specifically, at equianalgesic doses, various opioids have differential effects on the responses of D2DRs to dopamine agonists. Moreover, at equianalgesic doses, various opioids have differential effects on the activity of signaling molecules. Additionally, these drugs have been shown to differ in their efficacy in the treatment of both acute and chronic burn pain. Thus, in the current study we examined the differential effects of oxycodone, hydrocodone, and morphine on striatal gene expression. Specifically, mice were administered with saline or the various opioids for 6 days. Twenty four hours after the final injection, striatal tissue was dissected. Following this, RNA was extracted and high throughput next generation sequencing was used to examine the mouse genome. Subsequently, we used RT-PCR to confirm the results for selected candidate genes. In mice given morphine, the expression of 79 genes was dysregulated, 33 of which were unique to morphine, 15 of which were shared with oxycodone, 9 of which were shared with hydrocodone, and 22 of which were shared with both oxycodone and hydrocodone. In mice given hydrocodone, 71 genes were dysregulated, 27 of which were unique to hydrocodone, and 13 of

which were shared with oxycodone. Most surprisingly, in mice given oxycodone, 179 genes were dysregulated, 158 of which were unique to oxycodone. These data provide strong evidence that there are differences between opioid drugs with regard to their effects on opioid receptors, D2DRs, intercellular signaling, and the dopamine reward system. This information should be considered by physicians when deciding which opioid medication is most efficacious in specific clinical scenarios, and least likely to have harmful effects.

Title: A minimally brain-penetrant, biased μ-opioid receptor (MOR) agonist that is an effective analgesic with a reduced side effect profile

Authors: *S. M. GOEBEL-GOODY[1], A. PIKE[2], S. HUMPHREYS[3], R. TORELLA[4], E. DUNN-SIMS[1], C. HSU[1], C. TYSZKIEWICZ[1], N. NAWREEN[1], D. HORTON[1], R. SUZUKI[3]; [1]Global Safety Pharmacol., Pfizer Inc., Groton, CT; [2]Pharmacokinetics Dynamics & Metabolism, [3]Neurosci. & Pain Res. Unit, [4]Worldwide Medicinal Chem., Pfizer Inc., Cambridge, United Kingdom

Abstract: Conventional μ-opioid receptor (MOR) agonists, such as morphine, oxycodone, and fentanyl, are among the most efficacious and widely-prescribed analgesics for moderate to severe pain. Despite their robust efficacy, they elicit a variety of prohibitive adverse side effects including constipation, nausea, respiratory depression, and sedation. They also induce a state of euphoria and physical dependence that can lead to misuse or abuse. MORs are G protein-coupled receptors (GPCRs), where activation is primarily mediated via dissociation of the G protein complex and production of downstream signaling molecules, such as cAMP. On the other hand, desensitization of MORs upon ligand binding is mediated by β-arrestin recruitment and subsequently clathrin-mediated endocytosis. Converging lines of evidence have demonstrated that at least some of the side effects associated with MOR agonists may be mediated by the β-arrestin pathway. The objective of these studies was to investigate a structurally novel biased MOR agonist with minimal brain penetration, Compound A. Compound A was administered subcutaneously and evaluated in male Sprague Dawley rats in the acetic acid-induced writhing pain model to confirm analgesic efficacy and in the charcoal transit model to assess

gastrointestinal (GI) function. Given that the subjective or perceived effects of a drug can greatly influence propensity for abuse, Compound A was also assessed in a two-lever food-reinforced drug discrimination procedure to determine if it shares similar discriminative stimulus effects with morphine. Compound A induced a dose-dependent decrease in the number of writhes induced by acetic acid, with >90% efficacy achieved. Doses for the charcoal transit and drug discrimination studies were selected to target efficacious exposures achieved in the acetic acid-induced writhing model. The effect of Compound A on GI motility was less than that of morphine at similar levels of analgesic efficacy. Furthermore, administration of Compound A produced an increase in morphine-appropriate responding that resulted in only a partial generalization to the morphine cue when compared with vehicle. Taken together, these data support the hypothesis that a biased MOR agonist is an effective analgesic with reduced effects on GI function and yet still shares some, but not complete overlap in the discriminative stimulus properties with morphine, despite minimal brain penetration.

Title: Morphine-induced analgesia on sensory and affective components of complete freund's adjuvant (CFA)-induced inflammatory pain.

Authors: *A. ARMENDARIZ[1], A. NAZARIAN[2];
[2]Pharmaceut. Sci., [1]Western Univ. of Hlth. Sci., Pomona, CA

Abstract: The experience of pain is characterized by the presence of an aversive sensory stimulus combined with negative affect, which is often mediated clinically through administration of analgesics such as morphine or other prescribed opioids. Although an extensive body of work has elucidated much of the physiological mechanisms involved in the sensory

component of pain, many questions regarding the affective component of pain remain elusive. The present study investigates the effects of morphine on sensory and affective components of pain following administration of Complete Freund's Adjuvant (CFA), a model of inflammatory pain. An intraplantar injection of CFA was administered into the left hind paw of male and female Sprague-Dawley rats. Hargreaves tests for thermal nociception and conditioned place preference (CPP) data were obtained following subcutaneous administration of varying morphine doses (0, 1, 4, 8 mg/kg). Hargreaves Test results revealed sex differences in paw withdrawal latencies (PWL) in a dose dependent manner, with females being less sensitive to morphine than males. CPP results revealed sex differences in the preference for the morphine-paired chamber after one-day post-CFA, but not seven days post-CFA. These results reveal sexually dimorphic properties of morphine analgesia on the affective and sensory components of pain. Considering these findings, further investigation into the underlying mechanisms of morphine analgesia in the affective and sensory component of inflammatory pain is needed.

Title: Cb_1 cannabinoid and delta opiod receptor heteromers in neuropathic pain

Authors: *S. SIERRA SAN NICOLAS[1], A. GUPTA[2], I. GOMES[2], L. DEVI[2];
[1]Icahn Sch. of Med. At Mount Sinai, New York City, NY; [2]Dept. of Pharmacol. Systems, Icahn Sch. of Med. at Mount Sinai, New York City, NY

Abstract: Opioid and cannabinoid receptor function is modulated by multiple mechanisms and both receptors are critical to a number of physiological processes in health and disease including nociception. We have previously reported that CB_1 and delta receptors associate to form heteromers that exhibit distinct pharmacological properties and disease-specific dysregulation including during neuropathic pain. Hence these receptors have been posited as desired targets for pain relief; however, the in vivo consequences of heteromer signaling or their specific location along the pain circuit is not fully explored. Towards this end, we have initiated studies using the cancer chemotherapy drug paclitaxel-induced allodynia (mechanical allodynia) as a model of neuropathic pain. Mice (C57BL/6J mice; 10/group) were treated with vehicle or paclitaxel on

alternate days (cumulative doses 16 mg/kg); paclitaxel-induced (mechanical) allodynia was assessed on days 0, 4, 7 and 15. On day 16, tissues were collected and levels of CB_1 and delta receptors in spinal cord and brain regions were assessed using a receptor-selective or heteromer-selective antibodies and proximity based techniques. We find a significant increase in the abundance of CB_1-delta receptor heteromers in the spinal cord and basolateral amygdala of animals with allydonia. There were no changes in heteromer levels in a number of other regions including cortex, nucleus accumbens, hippocampus, or periaqueductal gray. Studies to characterize the cell types that show increased heteromer levels and to delineate the differential signaling pathway driven by this heteromer are underway. Together, these results suggest an important role for pain in orchestrating the regulation of CB1-DOR heteromer levels and signaling in specific pain related pathways. Title: Peripherally restricted opioid combination therapy synergizes in multiple pain states

Authors: *D. J. BRUCE[1], C. D. PETERSON[2], K. F. KITTO[3], C. A. FAIRBANKS[4], G. L. WILCOX[5];
[1]Pharmacol., [2]Exptl. and Clin. Pharmacol., [3]Neurosci., [4]Neurosci., Pharmacol., Exptl. and Clin. Pharmacology, Pharmaceutics, [5]Neurosci., Pharmacol., Dermatol., Univ. of Minnesota, Minneapolis, MN

Abstract: Background: The adverse effects of opioid pharmacotherapy are largely mediated by the activation of mu-opioid receptors (MORs) in the central nervous system. However, opioid receptors also mediate analgesia on the peripheral terminals of primary sensory afferents. Despite more than a decade of research directed at developing peripherally restricted opioids, no opioid analgesic to date has delivered pain control without the risk for addiction and diversion. We recently published that morphine and agonists at delta-opioid receptors (DORs) synergized

in spinal cord, and that this interaction was dependent on Protein Kinase C epsilon (PKCε). We interpreted this finding to mean that the synergy occurs on the central terminal of primary afferents, and reasoned that this MOR-DOR synergy should generalize to the peripheral terminals of those same nociceptors. For this study, we chose loperamide (Lo), a highly efficacious MOR agonist that is excluded from the CNS, and oxymorphindole (OMI), a DOR agonist that was shown to synergize with morphine spinally.
Methods: Using the Hargreaves and tail flick thermal nociception assays, we evaluated the analgesic effect of loperamide, OMI, or their 1:1 combination in naive mice. Drugs were delivered by spinal (intrathecal, i.t.), local (intraplantar, i.pl.) or systemic (subcutaneous, s.c.) injections. We also examined the anti-hyperalgesic effect of the drugs or their combination in the mouse model of Freund's Complete Adjuvant (FCA)-induced chronic inflammatory pain (subjects injected i.pl. with FCA 3-6 days earlier). Finally, the efficacy of a transdermal formulation of OMI-Lo was tested in the FCA model by applying drugs in an ethanol solution directly onto the hindpaw.
Results: Our initial efficacy studies show that when combined in a 1:1 dose ratio—either locally or systemically—OMI-Lo produces analgesia (naïve subjects) at 4- to 10-fold lower doses or anti-hyperalgesia (inflamed subjects) at 50- to 100-fold lower doses than either agent given alone. This synergy is blocked by the peripherally restricted opioid antagonist, naloxone methiodide, reinforcing the peripheral localization of the effect. Lastly, OMI-Lo is able to produce potent anti-hyperalgesia when delivered as a transdermal solution.
Conclusions: MOR agonists significantly synergize with DOR agonists at peripheral sites of action, providing strong evidence in support of peripherally restricted combination therapy. The systemic and transdermal efficacy of the combination, along with loperamide's extremely low abuse liability, suggests that this combination therapy might be therapeutically useful to control inflammatory pain in the clinic.

Title: Home cage wheel running as a method to assess morphine side effects, tolerance, and withdrawal

Authors: *J. J. CALSBEEK[1], A. T. LEE[1], R. KANDASAMY[2], M. M. MORGAN[1]; [1]Psychology, Washington State Univ. Vancouver, Vancouver, WA; [2]Integrative Physiol. and Neurosci., Washington State Univ., Vancouver, WA

Abstract: Although opioids are the most effective treatment for pain, the use of opioids is limited because of unpleasant side effects and the development of tolerance and dependence. We recently have shown that home cage wheel running is an effective method to assess nociception (Kandasamy et al., 2016) and may be a useful way to assess opioid side effects, tolerance, and dependence. We tested this hypothesis by measuring home cage wheel running before and following repeated injections of morphine into male Sprague-Dawley rats. Rats were individually housed in a cage with a running wheel for 7 days prior to morphine (5 mg/kg, s.c.) or saline administration. Rats received two more injections on each of the next three days. Naltrexone (2 mg/kg, s.c.) or saline was administered 30 min after the last morphine/saline injection to precipitate withdrawal. Administration of morphine caused a complete cessation of wheel running that recovered to baseline levels by the third hour after the injection. Tolerance was evident to morphine-depressed wheel running as was evident by a reduction in the magnitude of depressed wheel running on subsequent days. Administration of naltrexone following the seventh morphine injection induced mild signs of physiological withdrawal and produced a significant decrease in wheel running that persisted for over 2 hrs. Administration of naltrexone also depressed wheel running in control rats not given morphine, but this decrease was only evident for the first hour after the injection. These data indicate that home cage wheel running is a useful method to assess opioid side effects and withdrawal in the rat.

Title: Mu-opioid receptor signaling mechanisms: role of kinetics in biased agonism

Authors: *S. SIANATI[1], A. YOUSUF[1], M. CHRISTIE[1], M. CANALS[2];
[1]Sydney Univ., Sydney, Australia; [2]Pharm. and pharmaceutical science, Monash, Melbourne, Australia

Abstract: Opioid analgesics are the most efficacious drugs for treatment of acute and chronic pain and hold the major market share of pain medications. However, the clinical utility of opioids is limited by development of tolerance and physical dependence during long-term administration. Improving the effectiveness and safety profile of opioids have remained major goals in drug discovery.
The notion of biased signaling offers a new perspective as a means to separate therapeutic effects from unwanted side effects. This concept refers to the ability of different agonists to distinctively activate different signaling pathways while binding to the same receptor. Recent studies have indicated that G-protein versus βarrestin (and endocytosis) bias influences opioid tolerance and other side effects of opioids; suggesting bias towards G-protein improves safety profile. However the molecular basis underlying bias is not resolved yet.
The aim of this study was to determine the mechanisms behind bias at MOR by considering the kinetic properties of agonist. Efficacy, bias and kinetics were determined in G-protein signal, Ser^{375} phosphorylation, βarr2 recruitment and internalization (signaling cascades triggered by activated MOR) for a series of widely used, potent opioids having a large range of G-protein versus endocytosis bias. The present study illustrated that opioid kinetic is agonist dependent. Inactivation of each pathway depends on ligand dissociation (residence time) rather than biochemical kinetics. Off-rate kinetics for G-protein were highly correlated with Ser^{375} and βarr2 off-rates (r_{xy} = 0.96 and 0.91 respectively). Most importantly, biased efficacies were strongly correlated with the off-rate kinetics for each pathway (r_{xy} = 0.93, 0.96 and 0.98 for G-protein, Ser^{375} and βarr2 off-rate respectively). These results indicating that bias towards endocytosis at opioids requires sustained agonist occupancy. Slowly dissociating agonists such as endomorphins with long residence time develop endocytosis versus G-protein bias, suggesting for the first time that the residence time of an agonist at MOPr controls bias.

Title: Constitutive internalization of delta opioid receptors

Authors: *S. GRASTILLEUR[1], J. SIMARD[1], J.-L. PARENT[2], C. LAVOIE[1], L. GENDRON[1];
[1]Pharmacologie-Physiologie, [2]Médecine, Univ. De Sherbrooke, Sherbrooke, QC, Canada

Abstract: Agonist-induced activation of G protein coupled receptors (GPCRs) produces their internalization followed by their recycling or degradation. In addition to the agonist-induced internalization, the delta opioid receptor (DOPr) was shown to be constitutively internalized through a clathrin-dependent pathway. However, to date the characterization of this mechanism is poorly described in the literature. Here, we used the proximity-dependent biotin identification (Bio-ID) coupled to mass-spectrometry to identify novel putative DOPr interacting partners. The biotin ligase Bir A* was fused to the carboxy-terminal tail of the rat DOPr and transfected in NG108-15 cells. Following incubation of cells stably expressing DOPr-Bir A* with biotin, the biotinylated proteins were isolated using sepharose-streptavidin beads then identified by mass spectrometry analysis.
193 of 1557 proteins were considered as being specific and potentially interacting with DOPr. These proteins belong to 21 different families (examples are cell adhesion molecules, membrane receptors, transporters, trafficking, chaperones, and signalling molecules). Some proteins of the endocytic pathway have also been identified (including AP-2, clathrin heavy chain 1, clathrin interactor 1, various Rab). Immunofluorescence experiments performed on stable HEK cells expressing Flag-DOPr revealed that the constitutive internalization of DOPr was Rab5-dependent. Most interestingly, we failed to observe a significant accumulation of DOPr in the lysosomes in the presence of chloroquine, suggesting that the agonist-independent internalized DOPr is primarily recycled back to the plasma membrane. Whether constitutively internalized DOPr is trafficked via the fast recycling pathway (Rab4 dependent) or the slow recycling pathway (Rab11 dependent) remains to be determined.
Regulating the level of constitutive internalization of DOPr represents an opportunity to control the level of DOPr expressed at the cell surface and, by way of consequence, the level of analgesia induced by delta agonists. Therefore, a better knowledge of the mechanisms involved in the regulation of DOPr trafficking may lead to the development of new strategies to increase the analgesic potency of delta agonists.

Title: Kappa opioid receptor activation in neuropathic pain regulates reward

Authors: S. LIU[1], L. XUE[3], M. C. OLMSTEAD[3], F. M. LESLIE[1], F. I. CARROLL[4], *C. M. CAHILL[2];
[1]Pharmacol., [2]Anesthesiol. & Perioperative Care, Univ. of California Irvine, Irvine, CA;
[3]Queen's Univ., Kingston, ON, Canada; [4]Res. Triangle Inst. Intl., Research Triangle Park, NC

Abstract: The kappa opioid receptor (KOR) is known to regulate mood, motivation and reward pathways in the brain. It has been shown that activation of KORs at the nucleus accumbens (NAc) leads to a decrease in dopamine neurotransmission. Antagonists for this receptor have anxiolytic and anti-depressant effects in preclinical animal models, which are possibly due to the inhibitory tone of KOR on dopamine release. Chronic pain leads to anxiety and depression in patients, which negatively impacts their quality of life. Previous studies in acute pain models have determined that KOR activation does not alter anxiety and depression; however, it is unknown if KOR function alters motivation or negative affect in chronic pain states. It is hypothesized that chronic neuropathic (NP) pain leads to a decreased dopaminergic tone within the mesocorticolimbic pathway. In this study, we aimed to determine whether KOR activity is increased in NP pain and whether blockade of this receptor recovers reward in this chronic pain state. We induced NP pain in adult male C57/BL6 mice or Long Evans rats by implanting a polyethylene cuff around their sciatic nerve of the left hind limb. Using [35S]-GTPγS autoradiography, we found that NP pain mice exhibited significant increases KOR activation and/or availability in the NAc and ventral tegmental area (VTA) when compared to sham surgical controls. Conversely, we observed decreased MOR activation in the VTA of NP pain mice, suggesting either receptor down-regulation or desensitization. Previous studies in our lab identified that NP pain caused a blunting of reward circuitry where intra-VTA injection of MOR agonist DAMGO failed to produce a place preference. These data can be explained by a decrease in MOR function (possibly desensitization) as evidenced by [35S]-GTPγS autoradiography data. However, because KOR system is upregulated in NP pain conditions, we asked whether blockade of KOR could restore DAMGO-induced reward in NP pain. Pretreatment of the KOR antagonist JDTic prior to conditioning with intra-VTA DAMGO had no effect on place preference in sham animals but restored reward in NP pain animals. These results demonstrate

that NP pain increases the expression and activation of KOR as well as a corresponding decrease in the expression and function of MORs in the dopaminergic reward pathway. Long-term KOR signaling may be regulating the functional effects of MORs in reward. This interaction provides insight to understanding why mu-opioid-based therapeutics to treat chronic pain in the clinic become less effective over time. This study also confirms the importance of KOR function with regard to reward in the chronic pain state.

Title: Knockout of r7bp suppresses somatosensory itch perception by enhancing kappa opioid mediated inhibition

Authors: ***M. PANDEY**[1], J.-H. ZHANG[1], P. ADIKARAM[1], W. SIMONDS[1], M. HOON[2], S. MISHRA[3], R. NEUBIG[4];
[1]Metabolic Dis. Br., NIH, NIDDK, Bethesda, MD; [2]Lab. of Sensory Biol., Natl. Inst. of Dent. and Craniofacial Res., Bethesda, MD; [3]Lab. Of Sensory Biol., (National Inst. of Dent. and Craniofacial Res., Bethesda, MD; [4]Dept. of Pharmacol. and Toxicology, Univ. Michigan, Ann Arbor, MI

Abstract: R7-binding protein (R7bp) facilitates the G i//o-directed GTPase activating protein (GAP) activity of complexes containing Gbeta5 and a regulator of G protein signaling protein belonging to the R7 subfamily (R7-RGS), thereby accelerating the termination of Gi/o signaling. We discovered that mice lacking R7bp have an abnormal somatosensory phenotype manifest by diminished scratching responses to a variety of pruritogens administered intradermally or intrathecally. In contrast, most of the nociceptive modalities tested were not different in R7BP knockout (KO) mice as compared to wild type. The pruriceptive defect in *R7bp* KO mice was abolished in double KO mice also lacking *Oprk1*, encoding the G protein-coupled kappa opioid receptor whose activation inhibits itch sensation. The anti-pruritic effect of kappa opioid agonists was potentiated in *R7bp* KO mice. Taken together, our results indicate that R7bp normally enhances pruriception by inhibiting G protein signaling coupled to, or downstream of, the kappa-

opioid receptor and suggest the potential targeting of R7bp-dependent GAP activity as a novel therapeutic strategy for pathological itch.

Title: Brain plasticity changes by playing wind instruments and piano

Authors: ***Y.-W. SUNG**, D. KANG, Y. KAWACHI, S. OGAWA;
Kansei Fukushi Inst, Tohoku Fukushi Univ., Sendai-Shi, Japan

Abstract: Neuroimaging studies have showed plasticity changes in the human brain by training or learning. For musical training the plasticity change was observed in musical genres such as piano playing, violin playing or singing. However, when one person has experiences playing several musical instruments, differences in the plasticity change between musical instruments is not yet known well. In this study, we compared plasticity changes in the brain by musical training in piano and wind instruments by voxel-based morphometry (VBM) and resting state fMRI (rs-fMRI) signals. Twenty-four college students who were playing wind instruments and also had experiences of piano playing were participated. All subjects were scanned by 3T MRI (Siemens) in two sessions of structural (T1) and functional imaging (resting-state fMRI). The training period (years) for wind instruments showed a positive correlation with VBM data at a brain area, the left superior temporal gyrus (anterior of BA22). But the training period of the piano did not show correlation with any brain area at the same significance level. A seed-based analysis with the postcentral gyrus (Post-CG) as the seed was performed in correlation with the training period for wind instruments and piano respectively. Post-CG had more significant correlation with pre-center gyrus (Pre-CG) for the training period of wind instruments than for that of piano. Another seed-based analysis with STG as the seed revealed that many brain areas had significant correlation between STG and the training periods of wind instruments or piano experiences. The areas shown correlation with the wind instrument training only were the left supramarginal gyrus (SMG), the left frontal pole (FP) and the bilateral paracingulate cortices

(Para-CC). The areas shown correlation with the piano training only were the superior division of the right lateral occipital cortex and caudate nucleus. SMG is part of the somatosensory association cortex, which interprets tactile sensory data. The core function of the FP is known as processing of the cognitive branching that enables multiple tasks. Para-CC is involved in social cognition. These suggest that the training of wind instruments affects brain functions related to somatosensory, multiple tasks and social cognition. The caudate nucleus and lateral occipital cortex are known to be involved in working memory, and the caudate nucleus is also known to be involved in motor processing. These suggest that piano training affects working memory and motor function. Those results, together, indicate that brain plasticity change is related specifically to the playing styles as well as the musical instrument per se.

Title: Aesthetic appreciation and perception of 3D shapes through the sense of touch in the blind and the sighted: on the properties of contour curvature and symmetry of 3D tactile shapes

Authors: *A. KARIM[1], L. LIKOVA[2];
[1]Envision Res. Inst., Wichita, KS; [2]The Smith-Kettlewell Eye Res. Inst., San Francisco, CA

Abstract: Whether blind people are different from the sighted in perceiving the world is a long-standing question. Research has shown that sighted people prefer a curved visual object over a sharp one (Bar & Neta, 2007), and a symmetric visual object over an asymmetric one (Shepherd & Bar, 2011). However, it has rarely been studied how people perceive 3D tactile objects, how they characterize them, and whether the appreciation of 3D tactile objects can be affected by early visual experience. In order to fill this gap, we investigated tactile discrimination, and appreciation and preference for 3D tactile shapes in congenitally blind, late-onset blind and blindfolded sighted participants.
Method: 15 congenitally blind, 13 late-onset blind and 11 blindfolded sighted adults were tested in two different experiments. Nine pairs of 3D tactile geometric shapes (sharp vs curved) were presented in Experiment 1, and ten pairs of 3D tactile shapes (symmetric vs asymmetric) were presented in Experiment 2. Participant's task was to explore and compare the members of each

stimulus pair with two hands, and respond to a set of 14 questions (using a 2AFC paradigm) designed to measure their tactile discriminability, tactile preference, and aesthetic appreciation. Results and Discussion: Analysis of data in MANOVA revealed that there was no difference in tactile discrimination (sharpness, symmetry) between the three groups of participants. On average, they exhibited significantly more preference or aesthetic bias for a curved 3D tactile shape over a sharp one and for a symmetric 3D tactile shape over an asymmetric one. These findings are in line with previous findings in the visual modality (Bar & Neta, 2007; Shepherd & Bar, 2011). Though we did not find any overall difference between the groups we did observe that the proportion of individuals making a preference or aesthetic bias for a sharp or asymmetric 3D tactile shape were greater in the blind than the sighted. More interestingly, both the blind and sighted participants characterized the sharp or asymmetric 3D tactile shapes by more emotionally intense attributes as compared to the curved or symmetric shapes. This suggests that sharp or asymmetric 3D tactile shapes may have inherent capacity to produce a greater response in the brain areas engaged in emotion processing as compared to the curved or symmetric shapes. This is partly supported by the finding that sharp visual objects produce an increased activation of the amygdala as compared to the curved visual objects (Bar & Neta, 2007). All these findings are very informative and lead to further research on the underlying brain mechanisms or neural correlates of tactile shape and aesthetic processing.

Title: Second-order spinal cord pathway contributes to cortical reactivation in New World monkeys after long recovery times from incomplete dorsal column lesions

Authors: *C.-C. LIAO, H.-X. QI, J. L. REED, J. H. KAAS;
Dept. of Psychology, Vanderbilt Univ., Nashville, TN

Abstract: After long recovery times (> 6 months) from dorsal column lesions (DCLs), rewiring of neuronal connections in the somatosensory system underlies the cortical reactivation of somatosensory areas 3b and 1. The second-order spinal cord projections from below the lesion level could contribute to the functional recovery after DCLs because these neurons convey tactile inputs to the ipsilateral cuneate nucleus (Cu) through the cuneate fasciculus and lateral funiculus. We tested this hypothesis by comparing the distributions of second-order spinal cord neurons in the cervical spinal cord in normal monkeys and monkeys after short and long-term recovery periods after DCLs. Nine New World monkeys (*Saimiri boliviensis*; 5 male and 4 female) were used in this study. In 2 normal monkeys, a retrograde tracer, cholera toxin subunit B (CTB), was injected into the digit representation in the Cu to label the second-order spinal cord neurons. In 7 monkeys, unilateral DCLs were made at the C4 level. After 2 weeks (short-term; n=3) or after 7-9 months (long-term; n=4), CTB was injected into the Cu ipsilateral to the lesion site. We mapped hand representations in the contralateral areas 3b and 1 by microelectrode multiunit recordings to investigate the cortical reactivation after injuries. The labeled neurons in the cervical spinal cord were plotted and quantified. Our results revealed that: 1) in normal monkeys, the labeled neurons were extensively distributed in the cervical spinal cord ipsilateral to the tracer injections site in the Cu. 2) After short recovery periods in monkeys with extensive DCLs (91-100% complete), the hand representations in contralateral areas 3b and 1 remained unresponsive or only weakly responsive to touch on hand. The proportions of labeled spinal cord neurons in the ipsilateral C5-C8 below the lesion (8.3% -14.8%) were greatly decreased compared to the normal monkeys (54.4% and 56.5%). 3) After long recovery times, the deafferented somatosensory cortex of 2 monkeys with complete DCLs responded weakly to touch on face and forelimb, and occasionally on the hand. The proportions of labeled neurons in the ipsilateral spinal cord below the lesion were only 3.6% and 5.0%. In 2 monkeys with large but incomplete DCLs (87% and 72% complete), the hand cortex in areas 3b and 1 responded well to touch on hand in a roughly somatotopic organization. The proportions of labeled neurons below the lesion in the ipsilateral cervical spinal cord (22.2% and 39.0%) were increased over neurons labeled in the short-term cases. Accordingly, we suggest that the second-order spinal cord pathway contributes to cortical reactivation, especially after incomplete DCLs and long recovery times.

Title: Correlates of recovery after sensory loss with and without treatment in monkeys with dorsal column lesions

Authors: *J. L. REED[1], H.-X. QI[1], C.-C. LIAO[1], M. M. PAKULSKA[2], M. S. SHOICHET[2], J. H. KAAS[1];
[1]Psychology, Vanderbilt Univ., Nashville, TN; [2]Chem. Engin. and Applied Chem., Univ. of Toronto, Toronto, ON, Canada

Abstract: In a nonhuman primate model of spinal cord injury, unilateral lesions of the dorsal column (DC) disrupt sensory input from one hand to impair sensation and motor control. Task-specific rehabilitation (Rehab) to encourage hand use may promote functional recovery, and combining Rehab with appropriate interventions may further enhance recovery. Treatments incorporating the chondroitinase ABC (ChABC) enzyme to digest chondroitin sulfate proteoglycans in the extracellular matrix are studied for the potential to reduce barriers that prevent axons at the lesion site from growing to their targets. Rodent models yield promising results, and we collaborate here to investigate ChABC treatment using an affinity release hydrogel (Pakulska et al. 2015) in nonhuman primates to provide valuable information for clinical studies. We hypothesized that ChABC-hydrogel + Rehab would improve sensorimotor function sooner, and would result in more neurons with useful response properties in the cortex. Because the ChABC-hydrogel has been studied in rodents but not primates, we delivered the hydrogel alone to the cervical spinal cord in 1 adult male squirrel monkey (*Saimiri*) without inducing a DC lesion. Behavioral observations and histological processing of tissue for structural markers and microglia/macrophages indicated that the hydrogel was safe and did not produce undesirable side effects. We then obtained preliminary results from 2 adult male squirrel monkeys that received ChABC-hydrogel at the time of experimentally induced DC lesions. Promising data suggest that use of the impaired hand in the Rehab task occurred earlier with ChABC-hydrogel treatment than with Rehab only. After a 12-week Rehab period, we assessed neuron responses and topographic organization in both hemispheres of primary somatosensory cortex area 3b. Reactivation of the deprived area 3b was incomplete and retained abnormalities typically found after DC lesions. After single electrode mapping, we implanted microelectrode arrays into both hemispheres of 1 monkey and recorded responses to tactile stimulation. In our preliminary sample, responsive neurons had faster latencies and higher response rates after ChABC + Rehab compared to cases without treatment. These findings suggest that the ChABC treatment did not promote detrimental changes; however, and we found no evidence that ChABC-hydrogel healed the lesion within the 12 weeks studied. The spinal cord in both monkeys sustained extensive lesions of segment C5. By evaluating multiple measures, these

results represent initial studies to employ combination treatments with Rehab in a nonhuman primate model of spinal cord injury and sensory loss.

Title: Reorganization of cuneate nucleus in macaque monkeys following chronic partial spinal cord injuries

Authors: *P. HALDER, N. JAIN;
Dept. of Systems Neurosci., Natl. Brain Res. Ctr., Gurgaon, India

Abstract: Cortical and sub-cortical somatosensory areas undergo large-scale reorganization following deafferentations. As a result of chronic unilateral dorsal column lesions, neurons in the deafferented hand region of cortical area 3b, secondary somatosensory area (SII), parietal ventral area (PV), and ventroposterolateral nucleus (VPL) of the thalamus respond to touch on the chin. However, extent and nature of reorganization of the brainstem dorsal column nuclei were not well understood. Here we determined the somatotopy of the cuneate nucleus, which normally receive afferent connections from the hand, in monkeys with chronic unilateral dorsal column injuries at cervical levels. We first mapped the somatosensory area 3b using multiunit mapping techniques. As expected, the chin representation showed an expansion into the hand area. Chin representation expanded medially up to a region where arm or occiput representations are found. Few hand-responsive neurons were found at some recording sites inside hand cortex due to minor sparing of dorsal column fibres. In the same monkeys, we mapped the dorsal column nuclei on the deprived side. Neurons showed responses to tactile stimulations to the chin throughout the cuneate nucleus. Few neurons in pars rotunda responded to touch on the hand as seen in area 3b. In addition, neck, shoulder, occiput and arm representations, which are normally confined to the dorsal and lateral parts of the cuneate nucleus, expanded into the ventral and

medial part of the nucleus. Normally inputs from digits and glabrous hand region are present in this region. Neurons at many recording sites had dual receptive fields either on chin and arm, or on chin and neck, shoulder or occiput. The present findings show that following dorsal column lesions, cuneate nucleus also undergoes large-scale reorganization, with expansion of chin representation, as well as of arm, neck, shoulder and occiput representation.

Title: Receptive fields and response properties of neurons in the S1 whisker representation of early blind short-tailed opossums

Authors: *D. L. RAMAMURTHY, L. A. KRUBITZER;
Ctr. for Neurosci., UC Davis, Davis, CA

Abstract: The mammalian neocortex has a remarkable capacity to alter its functional organization and connectivity in response to changing patterns of sensory input. In animals and humans deprived of visual input early in development, cortical areas normally associated with vision are recruited by spared sensory modalities. Further, there is also compensatory plasticity in the cortical areas associated with spared sensory modalities. Most previous studies examining cross-modal plasticity following blindness have examined plasticity within the auditory system. However, there have been a few reports of changes within the somatosensory cortex following blindness including the expansion of the S1 barrel fields in bilaterally enucleated rats. Previous studies in our laboratory have shown that there is an increase in the percentage of neocortex dedicated to S1 in bilaterally enucleated short-tailed opossums, and in some cases alterations in overall functional organization. The short-tailed opossum, *Monodelphis domestica*, provides a tractable animal model in which to investigate early cortical development because the immature state of the nervous system at birth allows for targeted manipulations to be performed *ex utero* very early in development. We used single-unit extracellular recording techniques to examine the

receptive fields and response properties of neurons in the S1 whisker representation of short-tailed opossums that were bilaterally enucleated at P4 (P0 in *Monodelphis domestica* is equivalent to E11 in the mouse and E12 in the rat). Preliminary data indicate that compared to sighted controls, S1 neurons in the whisker representation of these animals display lower stimulus-evoked firing rates and smaller receptive fields. These differences in S1 suggests that there is compensatory plasticity in primary somatosensory cortex of these early blind animals, which could either be a direct consequence of the early loss of visual input, or due to an differences in the extent to which early blind animals rely on whisker-mediated touch in the absence of vision.

Title: The role of CaMKII in spine dynamics and experience-dependent structural plasticity of L2/3 cortical neurons

Authors: *G. SEATON, A. M. DE HAAN, K. D. FOX;
Cardiff Univ., Cardiff, United Kingdom

Abstract: Functional plasticity studies to date in cortical layer 2/3 (L2/3) have demonstrated robust experience dependent potentiation (EDP) and long-term potentiation (LTP), whilst structural plasticity in these layers remains largely uncharacterized. Here we investigated the relationship between functional and structural plasticity in barrel cortex L2/3 neurons, by exploiting the CaMKII-T286A (T286A) mouse model, which lacks EDP and LTP, but retains LTD. Spines of T286A L2/3 basal dendrites were compared to those of wild-type animals (WT) for baseline turnover, formation and elimination in response to whisker deprivation, stability of newly formed spines and existing spine size fluctuations. In vivo 2-photon microscopy was used to image dendritic spines both before and after chessboard whisker deprivation. Baseline condition imaging (when animals are not whisker deprived) revealed T286A mutant mice have higher spine turnover rates compared to wild-type controls. However, T286A mutant mice

formed fewer new spines in response to whisker deprivation compared to WT mice. Furthermore, in T286A mice, new spines were less likely to persist beyond 8 days, which would suggest the probability of stable synapse formation may be reduced, in the absence of CaMKII autophosphorylation. (K. Svoboda 2006). Indeed T286A mice exhibit fewer "always persistent spines" (spines present throughout the entire imaging protocol), compared to WT controls. In comparison, following deprivation, WT control animals showed increased spine formation, destabilization of previously stable spines, and an increased number of new spines that persisted. Comparisons between pairs of dendrites at bifurcation points revealed that spines were specifically added to high formation branches in WT animals, whilst in T286A mutant mice, the few new spines that were formed in response to whisker deprivation showed no preference for dendrite branch. Increased baseline turnover and deficits in experience dependent new persistent spine formation in T286A animals coincided with a smaller range of spine size fluctuations compared to WT controls. In particular, large spines in T286 mice tended to be less extreme in size than in WT mice, which may be related to the T286 deficit in LTP. These results suggest CaMKII autophosphorylation plays a significant role in experience dependent dendritic spine restructuring in L2/3 neurones.

Title: Environmental enrichment increases whisker responsiveness and alters somatotopy in L/3 of somatosensory cortex

Authors: ***A. M. LEMESSURIER**, S. CHEN, K. M. MCCLAIN, D. E. FELDMAN;
Helen Wills Neurosci. Inst., UC Berkeley, Berkeley, CA

Abstract: The whisker map in L2/3 of mouse primary somatosensory cortex has very high local scatter, such that neighboring neurons, intermixed within a column, are often tuned to different nearby whiskers (Sato & Svoboda 2010; Clancy et al., 2015). This "salt and pepper" organization was discovered in mice housed in standard laboratory conditions, which may represent a deprived environment. Here we test how sensory experience regulates this micro-organization within L2/3. We raised C57BL/6 mice with environmental enrichment (EN),

including tactile objects and 2-3 littermates, or in normal housing (NH), with 1 littermate but no other objects. Objects were introduced at weaning (P21) and were exchanged regularly to encourage whisker exploration. At age P50 ± 10 days, we measured whisker responses and 9-whisker tuning curves (somatotopic tuning) in L2/3 using 2-photon imaging of virally expressed GCaMP6s through a chronic cranial window. We observed robust changes in whisker-responsiveness and local somatotopy with enrichment. In EN mice, spontaneous activity was increased over NH mice, and cells showed stronger dF/F responses to their best whisker. In NH mice, neurons were not spatially clustered by whisker tuning—neurons tuned to the same whisker were not closer together than random pairs of neurons in the imaging field, which was roughly the area of one column. However, in EN mice, co-tuned neurons were significantly spatially clustered relative to randomly chosen neurons ($p<0.01$). This suggests either more accurate columnar somatotopy, or more homogeneous tuning neighborhoods within the column. To measure these effects specifically in pyramidal neurons, we repeated the experiments in 45 ± 5 day old Drd3-Cre mice, which expressed GCaMP6s in a subset of L2/3 pyramidal neurons. In NH Drd3-Cre mice, only 6.6%± 2.7% of GCaMP6-expressing pyramidal neurons were responsive to any whisker, whereas 51%± 13% were responsive in EN littermates. In enriched Drd3-Cre mice, co-tuned pairs of cells were more spatially clustered than random pairs ($p<0.01$), similar to the C57BL/6 cohort. These findings demonstrate a strong impact of sensory experience on the spatial organization of the L2/3 whisker map.

Title: Toward a murine model to image the remapping of synaptic inputs after stroke

Authors: *M. LEVY, R. I. GRANT, C. BURTON, A. Y. SHIH;
neurosciences, MUSC, Charleston, SC

Abstract: After a stroke in the somatosensory cortex, the function of tissues lost to injury will remap into regions surrounding the infarct. This remapping forms the basis for functional recovery after stroke, but its mechanism remains poorly understood. Anatomical studies have shown that dendritic spines in layer 1 become more labile during the period of remapping, suggesting that the cortex is a locus of plasticity (Brown et al. J Neurosci 2007). However whether these anatomical changes correspond to new sensory inputs has not been demonstrated. Following recent advances in subcellular calcium imaging (Chen et al. Nature 2013; Varga et al. PNAS 2012), we developed a murine model where post-stroke remapping can be imaged longitudinally *in vivo* at the level of individual spines. Neurons in all layers of the barrel cortex except layer 4 were sparsely labeled with a genetically-encoded calcium sensor (GCaMP6s) using adeno-associated viruses. Spine calcium responses to stimulations of the barrel's principal whisker or of surrounding whiskers were imaged over multiple days using two-photon microscopy. In each imaging session (typically lasting 2h), we could sample the activity of ~100 spines on a single neuron. We focused on pyramidal neurons in layer 2 and 5 which were brightly labeled. At the spine level, spontaneous as well as sensory-evoked calcium transients were sparse. Approximately 1/10 spines displayed reliable responses to whisker stimulation. In agreement with previous results, most responsive spines preferred stimulation of the barrel's principal whisker, while the remainder responded to both whiskers or to the surrounding whisker alone. We are currently studying the stability of spine whisker preference over the course of several weeks. We will next examine the plasticity of synaptic inputs in peri-infarct tissue after a barrel is deleted by photothrombotic stroke.

Title: LTP in the mouse barrel cortex driven by cooperative lemniscal and paralemniscal pathway activity

Authors: *L. E. WILLIAMS, A. HOLTMAAT;
Fundamental Neurosci. and Ctr. for Neurosci., Univ. of Geneva, Geneva, Switzerland

Abstract: Long term potentiation (LTP) is thought to underlie changes in synaptic efficacy as observed during cortical synaptic network plasticity and learning. Our lab has previously demonstrated *in vivo* that repeated sensory input, in the form of 8-Hz rhythmic whisker stimulation (RWS), induces synaptic LTP in layer (L) 2/3 pyramidal cells of the somatosensory barrel cortex (BC) [Gambino et al., Nature, 2014. 10.1038/nature13664]. Whisker sensory information is primarily processed by the lemniscal pathway, which comprises neurons in the ventral posteromedial (VPM) thalamus that mainly project to BC L4 and L5B. L4 cells in turn synapse on L2/3 pyramidal cells. Whisker stimuli also recruit activity in paralemniscal circuits, which contain projections from the posteromedial complex of the thalamus (POm) to BC L1 and L5A. Our lab has found that RWS evokes prolonged coactivity of these two pathways, which is necessary to drive sensory-evoked LTP in the absence of somatic spikes. However, the exact nature of the synaptic circuits remains elusive. Here, using whole-cell patch clamp recordings in thalamocortical slices we tested if repeated coincident activity of L4 and POm synapses onto L2/3 pyramidal cells is sufficient to drive LTP. Activity of L4 and POm synapses was paired by electrical stimulation of L4 and optical stimulation of channelrhodopsin-2 (ChR2) expressing POm axons. Rhythmic (8Hz) coincident pairing of activity in these two circuits efficiently induced LTP of postsynaptic potentials (PSPs) in the L4-to-L2/3 synapses. Paired stimulation while suppressing POm neurotransmission using Designer Receptors Exclusively Activated by Designer Drugs (DREADDS) pharmacogenetics, or while blocking NMDA receptors, failed to induce LTP. We are currently testing to what extent GABAergic inhibition on L2/3 dendrites regulates this form of LTP. L2/3 pyramidal dendrites are efficiently inhibited by somatostatin (SST) expressing interneurons, which in turn are inhibited by vasoactive intestinal peptide (VIP) expressing interneurons. Thus, VIP cells are thought to disinhibit L2/3 pyramidal dendrites, which could gate activity- dependent synaptic plasticity. We find that optical stimulation of ChR2-expressing POm axons evokes PSPs in VIP neurons. Preliminary data suggest that inhibition of VIP or SST interneuron activity using DREADDS in VIP-CRE and SST-CRE mouse transgenic lines bidirectionally alters LTP. Our data identifies excitatory and disinhibitory microcircuits whose synergistic activity may facilitate sensory-driven LTP in the barrel cortex.

Title: Brain-derived neurotrophic factor and caspase activity in mouse barrel cortex following whisker plucking

Authors: *S. A. MARIK, C. D. GILBERT;
Rockefeller Univ., New York, NY

Abstract: Brain-derived neurotrophic factor (BDNF) plays a key role in development and plasticity of the central nervous system. We previously reported that death receptor 6 (DR6) and amyloid precursor protein (APP) are required for axonal pruning in adult somatosensory cortex following manipulation of sensory experience (e.g. whisker plucking). While neurotrophin withdrawal leads to activation of the DR6/APP pathway in the developing brain, the link between neurotrophins and the DR6/APP pathway in adult plasticity has not been determined. Here we confirm previous reports that an elevation in BDNF within the lesion projection zone (LPZ) occurs following sensory deprivation. Furthermore, we directly tested if artificially increasing BDNF levels would result in the expression of key members of the DR6/APP pathway by injecting a CMV.GFP.2A.GFP AAV into mouse somatosensory cortex. Immunohistochemical labeling of components of the apoptotic pathway showed upregulation of proBDNF, DR6 and APP in neurons surrounding BDNF expressing cells. APP was upregulated mainly in layer 2. As expected, proBDNF expression occurred in BDNF infected neurons; however, unexpectedly neurons neighboring GFP positive neurons also expressed proBDNF. Caspase 3 expression was observed within in a small population of BDNF expressing neurons throughout the injection. We examined expression of cleaved caspase 3 in WT and CREmKI mice, which contain a mutation in promoter IV of the BDNF gene. Two days following whisker plucking cleaved caspase 3 is detectable within the barrel cortex of WT mice but not detected in CREmKI mice. Taken together these results suggest a role for BDNF in the DR6/APP pathway and the resultant experience dependent axonal pruning in the adult.

Title: Neuroplasticity in the primary sensory cortical neurons following facial nerve reconstruction in adult rats

Authors: *J.-J. HUANG[1,4,2], J.-L. CHEN[4,1], C.-H. LIN[3,2], Y.-C. PEI[1,4,2];
[1]Dept. of Physical Med. and Rehabil., [2]Ctr. for Vascularized Composite Allotransplantation, [3]Dept. of Plastic and Reconstructive Surgery, Chang Gung Mem. Hosp., Taoyuan, Taiwan; [4]Sch. of Med., Chang Gung Univ., Taoyuan, Taiwan

Abstract: Sensory-motor recovery is a spontaneous phenomenon that occurs after peripheral nerve injuries, such as cutting, blunt, laceration injury and nerve transplantation, and is mediated by neuroplasticity. Even though the return of neuronal activities in peripheral nerves and trigeminal ganglia have been observed, the neuronal mechanisms mediated by the thalamus and cerebral cortex remain unknown. To this end, we used whisker-to-barrel model in rodents to evaluate the alteration of neuronal tuning following a neurotomy and neurorrhaphy surgery, an approach that is analogous to a nerve reconstruction surgery in patients. We used a piezo-actuator-based whisker stimulator to bend the whisker at a variety of directions and speeds. We applied extra-cellular recording using micro-wire electrode arrays to record neuronal spiking activities in the barrel cortex in response to whisker stimulation in adult rats. The recording was performed before and after the neurotomy and neurorrhaphy surgery with a follow-up period up to 4 to 6 weeks post-surgery. The results showed that all units lost their sensory responses immediately after the surgery and, surprisingly, the sensory responses could recover as early as 7 days post-surgery. Further follow-up showed that one third of the units regained their whisker tuning that is analogous to that before the surgery. The onset latency of neuronal responses to whisker stimulations prolonged in the early recovery period and gradually decreased in the late recovery period. In conclusion, the present study reveals the neuronal mechanisms that account for the functional recovery following nerve reconstruction in the whisker-to-barrel model.

Title: Physiological and morphological roles of endocannabinoid 2-arachidonoylglycerol in the developing neuronal circuit in the mouse barrel cortex

Authors: *C. ITAMI[1], K. SAKIMURA[2], M. KANO[3], F. KIMURA[4];
[1]Saitama Med. Univ., Saitama, Japan; [2]Dept of Cell Neurobiol, Brain Res. Inst, Niigata Univ., Niigata, Japan; [3]Dept of Neurophysiol, Grad Sch. of Med, Univ. of Tokyo, Tokyo, Japan; [4]Dept of Mol Neurosci, Grad Sch. of Med, Osaka Univ., Osaka, Japan

Abstract: Recent studies indicated that endocannabinoids play important roles in the development of neuronal circuits both physiologically and morphologically. In the rodent barrel cortex, we have shown that type 1 cannabinoid receptors (CB1R) cause the long-term depression (LTD) component of spike timing-dependent plasticity (STDP) at the thalamocortical as well as L4-L2/3 synapses. We also demonstrated that CB1R knockout (CB1R-KO) mice show disorganized thalamocortical projections. Thus, endogenous CB1R signalling is important in translating physiological changes into morphological consequences. Anandamide and 2-arachidonoylglycerol (2-AG) are regarded as two major endocannabinoids, but to what extent each substance is involved in the cerebral cortex is still obscure. We show here that observed physiological and morphological effects are accounted for by 2-AG as the major endocannabinoid, using mutant mice lacking a 2-AG synthesizing enzyme, diacylglycerol lipase α (DGLα). We found that timing-dependent LTD (tLTD) was completely absent at L4-L2/3 as well as thalamocortical synapses in DGLα KO mice. Rather, KO animals and heterozygotes showed slight potentiation, possibly revealing occluded tLTP. In addition, we observed morphological abnormality in the thalamocortical projections stained by DiI at P12 in DGLα KO mice. Individual axons did not terminate within barrels as in wild type mice; instead, there were significant invasions of thalamocortical afferents into L2/3 as in CB1R KO mice. From theses results, we conclude that 2-AG works as a major endogenous ligand to produce physiological and morphological effects acting on CB1R in the mouce barrel cortex.

Title: Effectiveness of a robot-aided proprioceptive training program with vibro-tactile feedback on proprioception in chronic stroke participants

Authors: *I.-L. YEH[1], N. ELANGOVAN[1], J. HOLST-WOLF[1], A. CUPPONE[3], J. KONCZAK[1,2];
[1]Human Sensorimotor Control Lab, Sch. of Kinesiology, [2]Program of Neurosci., Univ. of Minnesota, Minneapolis, MN; [3]Dept. of Robotics, Brain and Cognitive Sciences,, Inst. Italiano di Tecnologia, Genoa, Italy

Abstract: Proprioception refers to the perception of limb motion or position and the orientation of one's body in space. Nearly 50% of stroke survivors showed proprioceptive deficits (e.g. Carey & Matyas 2011), which is associated with poor upper limb motor function impairing many activities of daily living. Thus, improving proprioception could be an additional route to enhance motor recovery. We designed a robot-aided training regimen that required users to make active wrist movements without vision. User grasped the handle of the robot and performed wrist adduction/abduction movements to tilt a virtual board on which a ball rolled. Aim was to roll the ball to a target on the board. Real-time, vibro-tactile feedback about joint position and velocity was provided to the forearm. METHODS: Two functionally independent yet with limited affected arm use, chronic stroke participants were recruited (Fugl-Meyer Assessment: 65/66 & 27/66). Four healthy participants (mean age ± SD: 26.4 ± 3.3 years) served as controls. Participants completed two training sessions on two consecutive days (total training time: 1 hour). A familiarization phase with vision was completed prior to training, while training was performed without vision. Task difficulty increased as the participants succeeded. Assessment was conducted before, immediately after, and two days after the intervention. Outcome measures were 1) wrist position sense acuity defined as the just-noticeable-difference threshold of wrist abduction/adduction and 2) the latency (time to peak) of a somatosensory-evoked potential proprioception-related component (N30). Controls were assessed only before and after the intervention. RESULTS: The more severely impaired stroke participant improved and maintained his wrist position acuity (Pretest: 5.4°; Day 2 (End of training): 3.3°; Day 5: 2.3°). The less affected stroke participant did not show proprioceptive deficits but performed within the range of the control group (Pretest: 0.8°; Day 2: 0.8°, Day 5: 1.2°; Control group: Pretest mean ± SD: 2.0° ± 1.2°; Day 2 mean ± SD: 1.4° ± 0.5°). The N30 latencies were within the known

normal range throughout the tests in both groups. CONCLUSION: Robot-aided proprioceptive training may improve proprioceptive acuity in chronic stroke participants with known proprioceptive impairment. If the effectiveness on improving the proprioceptive and motor function is substantiated in a larger population, the proposed training could be a treatment approach for clinical practice. Title: A comparative study of genital representation in the primary somatosensory cortex of mammals

Authors: *S. LAUER[1], C. LENSCHOW[2], M. BRECHT[2];
[1]Bernstein Ctr. For Computat. Neurosci., Berlin, Germany; [2]Bernstein Ctr. for Computat. Neurosci., Berlin, Germany

Abstract: Mammals show sexually dimorphic external genitalia. Little is known about the representation of these in the primary somatosensory cortex (S1). Recent anatomical and physiological studies in the rat have identified a region in S1, which responded to genital stimulation (Lenschow et al., 2016). In rats genital cortex was sexually monomorphic and showed expansion during puberty. In the current study, we addressed the following questions: (i) Is the distinctive representation of penis/clitoris conserved across species? (ii) Is genital representation sexually monomorphic across species? (iii) Can growth of genital cortex also be observed in other species? (iv) Is there a correlation between socio-sexual behavior and genital

representation? To answer these questions, we performed cyotchrome oxidase staining of the flattened cortex and identified a distinctive genital representation in eight further species (Mouse, Mongolian Gerbil, Syrian Hamster, Degu, Guinea Pig, American Chipmunk, Chinchilla, Rabbit). Genital cortices were sexually monomorphic. Four species (Mouse, Hamster, Rabbit, Gerbil) were investigated for puberty related expansion of the genital cortex and we observed a 1.4 fold to 3.1 fold increase, similar to that reported in rats (Lenschow et al., 2016). The relative size of genital cortex varied between the species (0.41 to 1.73% of the area of somatosensory cortex), with monogamous animals typically exhibiting a smaller genital cortex compared to polygamous animals. Comparisons between solitary and social living species did not reveal any differences. Remarkably, relative testicle size (a robust evolutionary indicator of sperm competition) and relative size of genital cortex area was highly correlated. Our results identify conserved features of genital cortex (position, sexual monomorphism, pubertal expansion, erect posture of the penis). Species differences point to an important role of sexual selection in the evolution of genital cortex - to our knowledge this is the first time that effects of sexual selection on a cortical region have been documented.

Title: Intrinsic harmonics in the human cochlea revealed by 7 Tesla MRI

Authors: K. SUZUKI[1], M. WATANABE[1], H. MATSUZAWA[1], K. NAKADA[1], I. L. KWEE[2], *T. NAKADA[1,2];
[1]Brain Res. Inst, Univ. of Niigata, Niigata, Japan; [2]Univ. of California, Davis, Davis, CA

Abstract: The classical model of the cochlea views it as a “spectral analyzer” made of a “dispersive transmission line” where different frequency components travel at different speeds (travelling wave). The basilar membrane (BM) is topographically organized so that the BM at the specific location resonates with its characteristic frequency. Although this linear concept and model has provided a powerful approximation, modern investigations revealed that the behavior of the cochlea is highly non-linear on which its functionality appears to be strongly dependent. Since, in principle, activities of the inner hair cell (IHC) and, hence, spiral ganglionic acoustic

neuron linearly correlate with the BM displacement, the non-linear behavior of the BM with respect to auditory input primarily is believed to arise from active outer hair cell (OHC) modification on passive responses of endolymph towards input signals. Currently, there are two leading hypotheses related OHC function, referred to as the non-linear resonant tectorial membrane (NL-RTM) and the cochlear amplifier (CA) model. Unfortunately, they still remain far from providing a perfect description of cochlear functionality; especially when one considers the significance of formants in human language processing. Using functional magnetic resonance imaging (fMRI), we have previously demonstrated that behavior of the human primary motor cortex can be effectively modeled by ensemble behavior of limit cycle oscillators and entrainment (Entropy 17: 7596-7607, 2015). Should OHC possess properties of a self-excited van der Pol (limit-cycle) oscillator, it could help the BM to synchronize with subharmonic driving forces passively brought about by auditory stimuli by the entrainment mechanism. To test this hypothesis, we performed *in vivo* analysis of the BM response in the human cochlea using 7 Tesla MRI. Endolymphatic fluid motion concomitant with BM displacements was detected as signal alteration of steady-state free precession imaging technique. The results unequivocally exhibited that stimulus sounds (pure tone and narrow-band chirp, centered at 3 kHz or 4 kHz) introduced the BM response not only at the location corresponding to the characteristic frequency but also those for its overtones. The study strongly indicated that human cochlea has an intrinsic sensitivity to pure tone harmonics, which is likely driven by BM resonance with subharmonics (1/2, 1/3, 1/4, ⋯) of its characteristic frequency inherent to non-linear dynamics.

Title: Spiral ganglion in an aged adult human cochlea

Authors: C. KAUR[1], T. G. JACOB[1], T. C. NAG[1], A. THAKAR[1], D. BHARDWAJ[1], *T. ROY[2]; [1]Dept. of Anat., All India Inst. of Med. Sci. New Delhi, New Delhi, India; [2]All India Inst. Med. Sci., New Delhi, India

Abstract: Constant exposure to occupational and environmental noise impairs the hearing ability and degree of impairment and its prevalence increases with age. One major cause of age related hearing loss is the loss of Spiral Ganglion Neurons (SGNs) that convey nerve impulses from the hair cells of the cochlea to the cochlear nucleus for audition. Two important neurotransmitters that are involved in the auditory pathway are the inhibitory GABA and the excitatory Glutamate (one of its common receptors being NMDAR-2B in SGN). Earlier, we had estimated that the young adult (between 21-30 years) have on an average 27,485 ± 3251.3 neurons, and that there were an equivalent number of GABA and NMDAR-2B positive neurons in the same cases.In this study, we estimated the total number of SGNs in the cochlea of an elderly adult and also studied the expression of GABA and NMDAR-2B in the same case. Temporal bone specimen of a 70 year old individual was obtained from the mortuary at All India Institute of Medical Sciences, New Delhi, with approval from the Institute's Ethics committee. It was fixed in buffered formalin, dissected, decalcified, cryoprotected and serially sectioned (30µm) in the coronal plane. Every 7th section was stained by cresyl violet, immunostained with GABA (Abcam, ab86186; 1:1000), NMDAR 2B (Abcam, ab93610; 1:1000) using standard protocol. The total number of SGNs (Optical Fractionator), SG volume (Cavalieri) and the volume of soma and its nucleus (Nucleator) were estimated with the StereoInvestigator software (Microbrightfield Inc. VT, USA).The estimated total number of neurons was 14730, total volume of the SG was 1.32 mm^3, and the volume of the soma and its nucleus were 2913µm^3 and 144µm^3 respectively. The expression of GABA and NMDAR 2B was reduced when compared to its expression in younger adults. Hence, we show that in the elderly, there is a significant reduction in the number of SGNs and a decreased expression of GABA and NMDAR-2B in the SGNs. These findings need to be confirmed in a larger population, but these preliminary results suggest that aging probably causes a reduction in the number of SGNs and also the efficacy of the surviving cells, since their functioning is dependent on the availability of the neurotransmitters GABA and glutamate.

Title: Significantly improved recovery of severe noise-induced hearing loss by the orally available, clinical drug candidate SENS-401

Authors: *J. DYHRFJELD-JOHNSEN, M. PETREMANN, L. BEYNAC, A. BROUSSY; Sensorion SA, Montpellier, France

Abstract: Sensorineural hearing loss through acoustic damage to the sensory hair cells, synapses and neurons of the cochlea is among the most common types of permanent hearing loss for adults (American Speech-Language-Hearing Association - ASHA; Hearing Loss Association of America - HLAA). Currently no approved pharmaceutical treatment exists for sudden hearing loss and recent meta-analysis of the standard-of-care, off-label use of corticosteroid therapy have concluded that neither systemic nor intratympanic administration has any significant treatment effect (Crane et al. 2015, Laryngoscope 125(1):209-17).

SENS-401 is small molecule, clinical drug candidate which can be administered orally and achieves significant local exposure (50-250 nM) in perilymph and inner ear tissue lasting at least 6 hours after a single oral administration in naïve rats.

Following baseline audiometry (ABRs at 8/16/24 kHz; DPOAEs at 4/8/16/24/32 kHz), 7 week old awake and behaving male Wistar rats were exposed to 120 dB octave band noise (8-16 kHz) for 2 hours on a slowly rotating platform in a sound-attenuating cubicle. SENS-401 at doses of 5 mg/kg, 10 mg/kg and 20 mg/kg or placebo treatment was initiated after the end of acoustic trauma exposure using oral gavage continued daily for 14 days.

In animals suffering initial severe hearing loss (ABR threshold shifts > 55 dB or otoacoustic emissions detectable only at 2 or fewer test frequencies at t=24h), daily SENS-410 treatment dose-dependently reduced permanent ABR threshold shifts from baseline to D14 from 52.1-59.3 dB in the placebo group down to 33.3-49.2 dB in the 2 highest dose SENS-401 treated groups. This corresponds to an improvement from “moderately severe” to “mild/moderate” hearing loss according to ASLHA criteria. ABR threshold recovery from 24h to D14 was also dose-dependently improved from 7.1-12.9 dB in the placebo group to up to 20.8-29.2 dB in the 2 highest dose SENS-401 treated groups. DPOAE amplitude recovery from 24h to D14 was similarly dose-dependently improved, with placebo treated animals particularly showing near complete and permanent loss of otoacoustic emissions at the most sensitive, higher tested frequencies (16/24/32 kHz), while SENS-401 treated animals showed partial recovery in the 2 highest dose groups.

These results demonstrate that daily, oral administration of the small molecule clinical candidate drug SENS-401 leads to significant local drug exposure and strongly enhances recovery in rats suffering from severe, acute noise-induced hearing loss.

Title: LMO4 downregulation is a critical factor in cisplatin-mediated ototoxicity

Authors: *S. JAMESDANIEL[1], R. RATHINAM[1], W. NEUMANN[2];
[1]Inst. of Envrn. Hlth. Sci., Wayne State Univ., Detroit, MI; [2]Dept. of Pharmaceut. Sci., Southern Illinois Univ. Edwardsville, Edwardsville, IL

Abstract: Ototoxicity is a major side-effect of cisplatin, a highly effective anti-cancer drug. Several studies have indicated that oxidative stress plays a causal role in mediating cisplatin-induced ototoxicity. We reported that cisplatin treatment leads to nitration and downregulation of a transcription regulator, Lim domain only 4 (LMO4), in the cochlea. To evaluate the critical role of LMO4 in cisplatin ototoxicity we genetically manipulated the expression levels of LMO4 in UBOC1 cells, which are immortalized auditory sensory epithelial cells derived from C57BL/6 mice. Transient overexpression of LMO4 using the mammalian expression vector pRK5, significantly attenuated cisplatin-induced decrease in cell viability ($p<0.0001$), as indicated by the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay. CRISPR/Cas9 knock-out of LMO4 significantly worsened cisplatin-induced cytotoxicity ($p<0.01$), as indicated by the cell counts using trypan blue stain. Furthermore, auditory brainstem responses of CBA/J mice indicated that co-treatment with a peroxynitrite decomposition catalyst (SRI110), which attenuated cisplatin-induced decrease in LMO4 and apoptosis in UBOC1 cells, mitigated the cisplatin-induced shift in hearing thresholds ($p<0.01$, at 8 kHz). These data suggest that LMO4 probably has a protective role in the organ of Corti at normal or higher levels. However, cisplatin-induced decrease in LMO4 protein levels compromises the anti-apoptotic cellular defenses thereby facilitating cochlear apoptosis. We conclude that cisplatin-induced nitration and downregulation of LMO4 plays a critical role in facilitating the ototoxic effects. Title: FGF-dependent otic induction in inner ear organoid derivation from $Pax2^{EGFP/+}$ mouse embryonic stem cells

Authors: *S. A. SCHAEFER, R. K. DUNCAN;
Univ. of Michigan, Ann Arbor, MI

Abstract: Stem cells represent a potential source of cell types that are difficult to obtain for study in the lab. The sensory hair cells of the inner ear present a particular challenge: they are relatively scarce and concealed by the temporal bone. Therefore, a major goal of hearing research is the efficient production of hair cells for downstream applications such as replacement therapy, developmental studies, and drug discovery. Recently, a method for producing inner ear organoids from aggregates of mouse embryonic stem (ES) cells was established. This method recapitulates basic signaling events of otic development (Koehler et al., 2013). A key event is otic induction, when progenitors upregulate Pax2 in response to fibroblast growth factors (FGFs) and commit to otic fate. This event is mediated by the ERK pathway downstream of FGF receptors in chickens and zebrafish (Wang et al., 2015; Yang et al., 2013). However, this has not been shown in mammals, and FGFs are known to signal through additional pathways including AKT and PLCγ. Understanding the mechanism of otic induction would permit more efficient recapitulation of mammalian inner ear development. To study otic induction in a mammalian model, we adopted the inner ear organoid method. We used $Pax2^{EGFP/+}$ mouse ES cells with EGFP inserted upstream of one Pax2 allele. This provided a report of Pax2 upregulation during FGF-driven otic induction. FGF2 was applied at 0, 5, 25, and 100 ng/mL, and ERK phosphorylation was assayed in some aggregates via Western blotting. Others were observed over several days as they developed internal $EGFP^{+}$ otic vesicle-like structures, which pushed outward and expanded into large protrusions. $EGFP^{+}$ cells became concentrated at the organoid regions (i.e., the protrusion-aggregate borders). Organoids were fixed with 4% PFA and stained by immunofluorescence to confirm presence of hair cell-like cells at day 20. Finally, the effect of Pax2 dose on organoid formation was examined using $Pax2^{EGFP/EGFP}$ mouse ES cells, which express a lower amount of Pax2. The degree of ERK phosphorylation correlated positively with FGF2 dose within 3 hours of application. In addition, the formation of organoids correlated positively with both FGF2 and Pax2 dose. Organoids contained $Myo7a^{+}$ cells with F-actin^{+}

stereocilia-like structures. These cells were able to rapidly uptake the styryl dye FM4-64, indicating functional mechanotransduction channels. These results suggest that FGF2 drives Pax2 expression and otic induction through the ERK pathway in a mammalian system. Inhibition of other FGF-driven pathways may promote otic induction, facilitating higher yields of hair cells.

Abstract: Sensorineural hearing loss (SNHL) stems primarily from by disorder of the cochlea of the inner ear, and this disease provides a social impact due to lack of effective medical therapies. In the cochlea, mechanical energy of sounds is converted to electrical signals by sensory hair cells and thereafter the information is transmitted to the brain through the auditory nervous system. The mechanoelectrical transduction is greatly enhanced by an endocochlear potential (EP) of +80 mV in a K^+-rich extracellular fluid, endolymph. Hair cells expose their

mechanoelectrical apparatus to the endolymph. The positive potential of the endolymph depends on membrane potentials of the stria vascularis, an epithelial-like tissue in the cochlear lateral wall. Disorders of the stria are suggested to be involved in various idiopathic SNHL such as sudden deafness and Ménière's disease. These diseases are characterized by sudden onset and/or short-term hearing fluctuation. Such phenotypes in human have not been reproduced in animals by pharmacological methods and conventional gene-targeting techniques. Here we have applied optogenetical approach to the stria vascularis. We analyzed the mice that express channelrhodopsin-2 (ChR2), a blue light-gated nonselective cation channel, under the control of proteolipid protein promoter. A blue-light illumination to the cochlea of ChR2-expressing mice resulted in moderate elevation of auditory brainstem response (ABR) thresholds throughout the audible frequency range by ~20 dB in 3 min. After cessation of the illumination, the hearing recovered to the initial level in 5 min. Immunolabeling assays revealed that ChR2 occurred in intermediate cells (ICs) of the stria as well as glial cells in the nervous system. Whole-cell patch-clamp experiments showed that the illumination rapidly depolarized that membrane potential of IMs by approximately 20 mV. In *in vivo* electrophysiological recordings, the EP was reduced by roughly 20 mV in response to the optical stimulation. These two photoreactions were reversible and repetitive. Finally, electrical ABR measurements, which can assess function of the nervous system, ruled out the involvement of photoactivated glial ChR2 in the hearing loss. Taken together, because ICs' membrane potential strongly correlates with the EP, the change of the former underlay the reduction of the latter and thereby the impairment of hearing. This mouse model can represent short-term hearing fluctuation with the sudden onset and may contribute to translational medicine of SNHL.

Title: Effect of temperature on exocytosis at the bullfrog hair cell ribbon synapse

Authors: *M. CHEN[1], H. VON GERSDORFF[2];
[2]Vollum Inst., [1]Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Synaptic transmission from the auditory hair cell to afferent fiber is a fundamental step in hearing. Synaptic release and endocytosis have been shown to be highly temperature sensitive in many preparations, but there is no study in amphibian hair cell ribbon synapse. To investigate the effect of temperature on exocytosis from hair cell ribbon synapse, we performed whole-cell patch-clamp recordings of Ca^{2+} current and exocytic membrane capacitance changes in semi-intact preparations of bullfrog hair cell and also recorded excitatory postsynaptic current (EPSC) of afferent fibers at room (22-24°C) and high (32-34°C) temperature. Temperature was adjusted by flow-heating with a temperature controller. Temperature was measured by a miniature thermistor close to the amphibian papillae that was recorded. An increase of temperature within this range increased Ca^{2+} influx of hair cells during 200-ms depolarization from -90 mV to -30 mV (e.g., Ca^{2+} current amplitude at room temperature: 604.5 ± 42.7 pA vs. high temperature: 756.6 ± 56.6 pA, n = 11, $p < 0.0001$, paired t test; Ca^{2+} charge transfer at room temperature: 80.8 ± 6.8 pC vs. high temperature: 109.0 ± 10.0 pC, $p = 0.0001$, n = 11). Activation of Ca^{2+} current was also accelerated by high temperature (Ca^{2+} current latency to peak at room temperature: 1.54 ± 0.09 ms vs. high temperature: 1.08 ± 0.12 ms, $p < 0.0001$, n = 11). Synaptic release triggered by 200-ms depolarization from -90 mV to -30 mV was enhanced at high temperature (ΔCm at room temperature: 84.8 ± 13.1 pF vs. high temperature: 136.2 ± 21.4 pF, $p = 0.0004$, n = 11). However, the increase of capacitance change triggered by depolarization was disproportionately to the increase in Ca^{2+} influx ($\Delta Cm/QCa^{2+}$ at room temperature: 1.06 ± 0.15 vs. high temperature: 1.25 ± 0.15, $p = 0.0236$, n = 11), indicating the release efficiency is increased at high temperature. We also recorded the EPSC of postsynaptic afferent fibers. We found that the amplitude and frequency of EPSC increased at high temperature. Furthermore, the high temperature also quickened the time to peak and fastened the decay of EPSC, which suggest that release is more synchronized at high temperature. Altogether, our results suggest that the increased synaptic release at high temperature is not only a result of increase of Ca^{2+} influx but could also involves other mechanisms, such as more readily releasable vesicles available at the active zone at high temperature, increased Ca^{2+} influx at high temperature induces more Ca^{2+} release from intracellular Ca^{2+} stores and enhances release efficiency.

Title: Berbamine derivatives protect against aminoglycoside induced hair cell damage in the zebrafish lateral line

Authors: *A. M. CAMINO[1], R. D. L. BONEY[1], B. E. BLOUGH[2], A. B. COFFIN[1]; [1]Washington State University-Vancouver, Vancouver, WA; [2]Res. Triangle Inst., Research Triangle Park, NC

Abstract: Our hearing depends on sensory hair cells that transduce mechanical stimulation into electrical stimuli, which are then perceived by the brain. When hair cells are damaged- from, aging, noise exposure and medications such as aminoglycoside antibiotics, hearing loss is often the result. Further, hearing loss affects approximately 360 million people globally. Although aminoglycosides are efficacious in treating bacterial infections in life threatening diseases such as cystic fibrosis and sepsis, they often result in the adverse side effect of hair cell damage. In fact, 20% of patients consuming these antibiotics develop some degree of hearing loss. To date, there are no FDA-approved drugs that prevent damage from aminoglycosides. Our goal is to develop a drug that prevents aminoglycoside-induced hearing loss, using a natural product as the chemical scaffold. Natural compounds represent a strong source of novel molecular scaffolds due to their enormous structural and chemical diversity, making them a rich fountainhead for drug leads. A previous study by our lab conducted a blind drug screen in the zebrafish lateral line and identified four natural compounds that share a modified quinolone scaffold and strongly protect hair cells by attenuating aminoglycoside uptake. The present study builds on this previous work, investigating analogs of our protective compounds to determine the core protective structure and the specific molecular targets. Analogs containing a phenyl functional group were found to robustly protect hair cells. Based on this data we now have promising lead compounds for further optimization to meet the therapeutic goal of developing a protective hearing loss drug candidate.

Lab., Woods Hole, MA

Abstract: This study provides the first report of gap-junction proteins expressed in mechanosensory receptors of fishes. Prior work suggests that fast copulatory movements of the male Mosquitofish, *Gambusia affinis*, are controlled by a motor circuit containing mixed (chemical and electrical) synapses rather than chemical synapses only. A gap-junction protein, connexin 35, has been identified in dye-coupled motor neurons in spinal segments innervating skeletal muscles that move the gonopodium (a modified anal fin as functional copulatory organ) of adult male Mosquitofish. In our recent work characterizing the sensory circuit activating these motor neurons, we found positive immunolabeling of connexin 26, a gap-junction protein, in superficial neuromasts from the base of the anal fin of adult male and female Mosquitofish. Data analyses of male and female neuromast surface area and number of spots containing connexin 26 showed no significant differences. In addition, results showed that although the percent of relative frequency of spots was similar in males and females, females showed an increase in spot frequency in relation to the surface area. Finally, analysis showed a tendency of sexually dimorphic spatial distribution of connexin 26 within superficial neuromasts, with connexin 26 being more localized among female neuromasts than male neuromasts. Future research is focused on determining the spatial localization and functionality of these connexin 26-containing gap junctions in fish neuromasts.

Title: The effect of glucose-6-phosphate dehydrogenase on cochlear and auditory function

Authors: *K. WHITE, M.-J. KIM, C. HAN, H.-J. PARK, Z. MENESES, L. GRANTGES, P. LINSER, S. SOMEYA;
Aging and Geriatric Research/ Speech, Language, and Hearing Sci., Univ. of Florida, Gainesville, FL

Abstract: Currently, there are no treatments or preventions of sensorineural hearing loss due to the lack of knowledge regarding the molecular mechanisms of this disorder. A large body of evidence suggests that oxidative stress plays a key role in progressive sensorineural hearing loss. Glucose-6-phosphate dehydrogenase (G6PD) is the first rate-limiting enzyme in the pentose phosphate pathway that converts glucose-6-phosphate into 6-phosphogluconate and $NADP^+$ into NADPH in the cytosol. Antioxidant enzymes such as glutathione reductase and thioredoxin reductase require NADPH in order to reduce oxidized glutathione to reduced glutathione and oxidized thioredoxin to reduced thioredoxin, that in turn protect cells from oxidative stress and cell death. **Therefore, we hypothesize that *G6pd* plays an important role in protecting cochlear cells from oxidative stress and maintaining hearing by supplying NADPH to the cytosolic antioxidant defense under normal conditions.** To investigate whether G6PD plays a key role in auditory function, we performed Auditory Brainstem Response (ABR) tests to measure hearing sensitivity in *G6pd* wild-type and *G6pd* deficient mice at 3-5 months of age. Our results showed no significant changes in ABR thresholds at 4, 8, 16, 32, 48 or 64 kHz between wild-type and *G6pd* deficient male or female mice at 3-5 months. To confirm these results, we counted the numbers of spiral ganglion neurons and hair cells in the cochlea from young wild-type and *G6pd* deficient males. There were no differences in the mean number of cochlear spiral ganglion neurons, inner hair cells or outer hair cells between wild-type and *G6pd* deficient mice. Taken together, these results suggest that *G6pd* deficiency does not affect cochlear histology or auditory function and that loss of *G6pd* is likely compensated by other NADPH-producing enzymes. We are currently investigating whether *G6pd* deficiency affects auditory function in middle-aged and old wild-type and *G6pd* deficient mice. Measurement of oxidative stress and antioxidant defense parameters are currently ongoing.

Title: Effect of direction-dependent envelope coding on the representation of sound location in the owl's midbrain

Authors: ***M. V. BECKERT**[1], B. J. FISCHER[2], J. L. PENA[1];
[1]Neurosci., Albert Einstein Col. of Med., Bronx, NY; [2]Mathematics, Seattle Univ., Seattle, WA

Abstract: Two primary features of sounds encoded by the auditory system are the sound's identity and location. We investigated how these two features are represented in parallel in the auditory midbrain of the barn owl, *Tyto alba*. In the brainstem of the barn owl the primary sound localization cues, interaural time (ITD) and level difference (ILD) are computed along two parallel pathways. It has been previously shown in our lab that the ILD pathway is better suited to encode sound identity by examining the locking of spikes to the sound's envelope across repeated trials of identical noise. We recorded neurons in the first midbrain structure that receives input from both of these pathways, the lateral shell of the inferior colliculus (ICls). We tested the ability of ICls neurons to lock to the envelop of repeated presentations of frozen noise by calculating the area under the curve of their shuffled autocorrelograms (SAC), which is a measurement of how reproducible is the spiking pattern for a given stimulus. We found that in ICls reproducibility is directly related to how far in space the sound is from the neuron's preferred sound direction. This is true for both ITD and ILD; however ILD appears to have a stronger influence on this direction-dependent representation of the envelope. We hypothesized that the direction-dependent reproducibility in ICls has an effect on the representation of sound location and identity in downstream structures by affecting population responses. To test this hypothesis we performed tetrode recordings in the optic tectum (OT), which contains a map of auditory space. We found that pairs of neighboring neurons are more likely to fire synchronously at their preferred direction and this synchrony drops off as a function of distance, thereby adding a temporal element to the representation. Finally, we tested whether this direction-dependent synchrony could influence the decoding of sound location and identity using a computational model. We found that synchrony can affect decoding of ambiguous stimuli by selectively

weighting neurons that respond to the dominant stimulus. In conclusion, we found a source of co-dependency between the encoding of sound identity and location through spike timing in the midbrain of the barn owl. This emphasizes how important spike timing can be, even in structures classically considered not to utilize a temporal code.

Title: Dysfunctional myelin affects neural processing, neurochemistry and behavior

Authors: ***K. MAHERAS**[1], S. PERRINE[2], F. GHODDOUSSI[2], M. GALLOWAY[2], A. GOW[3,4,5];
[2]Psychiatry and Behavioral Neurosci., [3]Ctr. for Mol. Med. and Genet., [4]Carman And Ann Adams Dept. of Pediatrics, [5]Dept. of Neurol., [1]Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: In the current study, we have generated mutant mice that lack Claudin 11 (Cldn11) in CNS myelin sheaths. In this compartment, Cldn11 forms tight junctions located along the outer and inner edges of the membrane spiral, preventing ions and small molecules from entering the intramyelinic space. The function of Cldn11 tight junctions is to improve the passive properties of the myelin membrane, by increasing membrane resistance and reducing capacitance, thereby boosting the speed of saltatory conduction. In the absence of Cldn11, myelin is dysfunctional and conduction velocity is slowed, most dramatically in small diameter myelinated fibers. Importantly, the absence of Cldn11 does not induce degenerative myelin pathology, enabling direct study of the impact of dysfunctional myelin on neuronal circuit properties such as neural processing.
Undoubtedly, slowed conduction velocity along myelinated axons increases temporal dispersion and, consequently, degrades information transfer between neural circuits. Herein, we explore the impact of dysfunctional myelin on neural processing in the conserved integration circuit of the auditory brainstem. We find that dysfunctional myelin perturbs neural processing and may

diminish the ability of mice to lateralize sound sources on the azimuth plane. Extrapolating this finding to higher order circuitry within the cortex, dysfunctional myelin may also disconnect distributed neural circuits across brain regions. Currently, we are functionally characterizing this type of behavioral deficit using auditory operant chambers.
Further investigation into the neural circuitry of the auditory brainstem reveals increased steady state levels of the neurotransmitters, glutamate and glutamine, which may exacerbate neural processing deficits or may be an attempt by neurons in the brainstem to compensate for increased temporal dispersion. In either case, our data are significant in two ways. First, they represent the first demonstration that non-degenerative changes in myelin membrane passive properties can lead to neurochemistry changes that perturb behavior/perception. Second, they have important implications for the etiology of behavioral disorders in general, and more specifically for the behavioral components of hypomyelinating and demyelinating diseases like multiple sclerosis.

Title: sound localization performance to variations in spectral contrast.

Authors: *B. YOOSEFIZONOOZ, P. DE VETH, J. VAN OPSTAL;
Biophysics, Donders Cntr Neurosci, Radboud Univ., Nijmegen, Netherlands

Abstract: The acoustic spectral pinna cue-to-elevation mapping, is an ill-posed problem for the auditory system, as the spectral sensory input to the eardrum is always a convolution of the HRTF, H(f,E) (unknown) with the sound-source spectrum, X(f) (also unknown): S(f,E) = H(f,E)*X(f). The brain, therefore, should employ clever strategies to estimate source-elevation angle E. Our spectral correlation model may account for such a strategy with two prior assumptions: (1) HRTFs are unique, and (2) source spectra and HRTFs are uncorrelated: C[(X,H)]~0. Correlations between S(f,E) and all HRTFs are determined over a certain bandwidth, and elevation E is found at max[C(S,H)]. However, it is not well known which parts

of the acoustic spectrum dominate the mapping: the entire spectrum, vs. particular spectral bands? As the most prominent spectral cues lie within the 5-10 kHz band, we tested whether perhaps only this part of the spectrum matters. We systematically manipulated spectral contrast of broadband sounds in the 6-9 kHz band with the remaining frequencies (0.2-6 kHz and 9-20 kHz) over a 35 dB range (25 different spectra), and measured sound-localization performance of 8 participants over a wide range of locations in the 2D frontal hemifield. Our results indicate a systematic influence of spectral contrast on gain and bias of the stimulus-response relationships, suggesting that the elevation percept relies on the spectral content across the entire audible frequency domain.

Title: Altered balance of excitation and inhibition in the auditory brain stem of Fragile X mice

Authors: E. MCCULLAGH[1], S. MINKOWICZ[2], M. HUNTSMAN[3], *A. KLUG[4];
[1]Physiol. and Biophysics, Univ. of Colorado Sch. of Med., Aurora, CO; [2]Florida Gulf Coast Universty, Fort Myers, FL; [3]Pharmaceut. Sci., [4]Physiol. & Biophysics, Univ. of Colorado, Aurora, CO

Abstract: Virtually all forms of autism involve some sort of auditory dysfunction, which points to the auditory system as one of the key systems involved in the physiology of autism. This autism related auditory dysfunction is most noticeable as impairments in communication skills, social difficulties and sound localization. Sound localization impairments include the ability to establish and separate between various competing sound sources, such as in a crowded noisy room. A recent theory posits that autism spectrum disorders may be caused by an imbalance in the ratio of excitation to inhibition, particularly in sensory systems.
Since sound localization relies heavily upon the synaptic ratio of excitation and inhibition (E/I ratio) in the auditory brainstem, we hypothesized that these neural circuits, may be altered in a mouse model of autism, the Fragile X mouse (Fmr1-/-).
We investigated differences in presynaptic and postsynaptic markers for the neurotransmitters glutamate, glycine and GABA in the nuclei of the mammalian sound localization pathway,

specifically the medial nucleus of the trapezoid body (MNTB) and the lateral superior olive (LSO). Both of these centers receive substantial excitatory and inhibitory inputs. Additionally, MNTB is a major source of inhibition to the sound localization pathway and projects to LSO. Recently it has been shown that there are more presynaptic GABAergic synapses in the MNTB of Fragile X mice (Fmr1-/-) as indicated by vesicular GABA transporter (VGAT). This study, however, did not investigate the effect of glycine, which, in the MNTB, becomes the primary inhibitory neurotransmitter in adulthood. The main reason why glycine has not been studied in the context of Fragile X is that the current E/I model of Fragile X assumes mostly changes occur in GABAergic inhibition. Here we address the role of glycine in Fmr1-/- mice by anatomical studies examining changes in number and organization of glycinergic neurons and synapses in the MNTB. Our results suggest that the glycinergic E/I ratio in Fmr1-/- mice is altered, suggesting that not only GABAergic but also glycinergic inhibition may play an important role in Fragile X.

Title: Processing of binaural cues conveyed by temporal fine structure and envelope in human auditory cortex

Authors: *Q. WANG[1], T. LI[1], G. LUAN[1], L. LI[2];
[1]Beijing Key Lab. of Epilepsy, Beijing Sanbo, Beijing City, China; [2]Dept. of Psychology and Beijing Key Lab. of Behavior and Mental Hlth., Peking University, Beijing, China

Abstract: In our auditory system, the peripheral system firstly filters broadband signals into narrowband waves, and then decomposes narrowband waves into quickly-varying temporal fine structures (TFSs) and slowly-varying envelopes. Whether TFS and envelope play critical roles in

music perception, sound localization, and speech recognition in complex environment has been under debated. Although previous neurophysiological studies discuss the temporal processing mechanisms in various levels of auditory system, how TFS and envelope are processing in auditory cortex is still unclear. With temporal fluctuations, both TFS and envelope could convey binaural cues, but the neural mechanisms of processing different binaural cues and their interactions in human auditory cortex is rarely discovered. In this study, using stereo-electroencephalographic (sEEG) with both highly temporal and spatial resolutions, we obtained electrophysiological data directly from primary auditory cortex (PAC) and non-primary auditory cortices (non-PAC) in epilepsy patients when they were listening to narrowband noises with different interaural correlations (IAC: +1, -1) and interaural time differences (ITD: 0,±0.2,±0.4,±0.6,±0.8 ms). The results showed that the TFS-sensitive responses (difference between IAC = +1 and IAC = -1) were shown in alpha-beta (8-13 Hz) band within PAC and non-PAC areas, but were shown in high-gamma (60-120 Hz) band only within non-PAC areas. On the other hand, both the PAC and non-PAC were sensitive to the ITD cues conveyed by both temporal fine structures and envelopes. PAC, but not non-PAC, showed a preference of the ITD sensitivity conveyed by envelope, with a significant correlation with the ITD sensitivity conveyed by TFS. Furthermore, a more robust correlation between temporal fine structure and envelope were shown in non-PAC. In conclusion, the binaural cues conveyed by TFS and envelope were processed hierarchically and built up gradually in human auditory cortex.

Title: Differential tuning of the low- and high-frequency components of the neurophonic spectrum reveals the spike contribution of barn owl's nucleus laminaris neurons.

Oldenburg, Oldenburg, Germany

Abstract: In-vivo neural activity gives rise to trans-membrane currents that can be recorded as an extracellular field potential. These potentials are often challenging to interpret due to thousands of contributing sources. We aim at revealing the neural sources of the “neurophonic”. The neurophonic is a frequency-following extracellular potential that can be recorded in the network formed by the nucleus magnocellularis (NM) and the nucleus laminaris (NL) in the brainstem of the barn owl. NL anatomy is well understood, and putative generators of the neurophonic are the activity of afferent axons from NM, the synaptic activation onto NL neurons, and spikes of NL neurons.
We recorded the neurophonic in response to binaural high-frequency tones (3-7 kHz) close to the recording site's best frequency, and we varied the interaural time difference (ITD). The mean activity of the monaural inputs to NL does not change with ITD. However, their relative phase does, causing cancellation or summation of input signals. The activity of the binaurally-sensitive output of NL, i.e., firing rate of NL neurons, strongly depends on ITD. Our recordings contained both of these signals, and we analyzed the broad-band power spectrum of the response (0.1-8 kHz).
The low-frequency component (LFc, 200-700 Hz) of the neurophonic spectrum depended on ITD. The spectrum of extracellularly recorded NL neurons' action potentials closely resembled this component. Thus, the LFc reflects the contribution of action potentials initiated in NL neurons. The spectral component at the stimulus frequency (SFc) was much stronger than the LFc. The SFc also depended on ITD, reflecting the activity of the inputs and their relative phase change with ITD. The power spectrum at other frequencies did not depend on ITD.
We used the LFc as a proxy for NL neurons' local population activity, and the SFc as a proxy for NM axons' local population activity. We compared the ITD and frequency tunings of these proxies at each recording site. The best ITDs of the LFc and the SFc were independent. Also the tuning to stimulus frequency was different: LFcs showed typically a 400 Hz lower best frequency than SFcs. Both findings indicate that the LFc might originate from NL neurons' axons in the vicinity of the electrode. Related NL neurons can be located tens to hundreds of micrometers away. The findings are consistent with the known anatomy of NL. Our analysis thus reveals the small contribution of NL neurons to the neurophonic, improving our understanding of the extracellular field potential in the auditory brainstem.

Title: Decoding the cortical representation of acoustic space using EEG

Authors: *A. BEDNAR, E. C. LALOR;
Trinity Col. Dublin, Dublin, Ireland

Abstract: The human ability to localize sound is essential for monitoring the environment and helps us to analyze complex auditory scenes. Sound localization in the horizontal plane is mainly based on binaural acoustic cues: interaural time and level differences. Monaural (spectral) cues are crucial for sound localization in the vertical plane and when binaural cues are ambiguous. Although the acoustic cues mediating localization have been established behaviorally, it remains unknown how these cues are represented in human cortex. In particular, it is still a point of contention whether binaural and monaural cues are processed by the same or distinct cortical networks.

In this study, participants listened to a sequence of spatial sound stimuli while we recorded their neural activity using electroencephalography (EEG). The stimuli were presented over a loudspeaker array, which allowed us to deliver realistic, free-field stimuli in both the horizontal and vertical planes. Using a multivariate classification approach, we showed that it is possible to decode sound source azimuth and elevation from scalp-recorded EEG. Notably, the spatio-temporal pattern of EEG features that facilitated decoding differed based on the availability of binaural and monaural cues. In particular, we identified neural processing of binaural cues at around 120 ms post-stimulus and found that monaural cues are processed later at between 150 and 200 ms. Furthermore, different spatial activation patterns emerged for binaural and monaural cue processing. These spatio-temporal dissimilarities suggest the involvement of separate cortical mechanisms in monaural and binaural acoustic cue processing. In addition, our results did not reveal any differences in decoding performance between hemispheres, contradictory to the often reported right hemispheric dominance in sound localization.

The finding that we can decode sound source location using EEG has potential applications in the development of brain-computer interfaces, future hearing aids, and in measuring the fidelity of virtual acoustic environments.

Title: Spatial encoding of speech in human auditory cortex

Authors: P. PATEL[1], L. K. LONG[1], J. HERRERO[2], A. D. MEHTA[2], *N. MESGARANI[1]; [1]Columbia Univ., New York, NY; [2]Feinstein Inst. for Med. Res., Manhasset, NY

Abstract: Sound localization is an important ability that allows an organism to monitor its surroundings. While the neural mechanisms of sound localization have been well characterized in nonhuman mammals, auditory spatial selectivity in human primary and non-primary brain areas has not been adequately characterized. Moreover, it remains unclear how the auditory cortex jointly encodes spatial cues with the spectrotemporal features of speech that carry linguistic and non-linguistic information. In this study, we used invasive neurophysiological recordings in humans while they listened to speech from five different directions to study the spatial selectivity in human auditory cortex. We found differential responses to spatial cues at the level of single electrodes in primary cortical areas, clearly revealing a spatially selective organization of responses. Moreover, a linear decoder was able to predict the direction of speech stimuli based on neural population data with accuracy as high as 80%. Furthermore, we characterized the joint encoding of spectrotemporal and spatial information. We found an orthogonal encoding of these cues, meaning that spectrotemporal feature selectivity was largely independent of the direction of the sound. Instead, we observed that the stimulus direction modulates the gain of the spectrotemporal tuning properties. These findings characterize the spatial encoding of speech sounds in the human auditory cortex, with implications for neurophysiological models of speech processing in the auditory pathway.

Title: *In vivo* intracellular recordings from neurons of the lateral superior olive show narrow time windows of effective inhibition and high sensitivity to interaural time differences of transient sounds

Authors: *T. P. FRANKEN[1], P. H. SMITH[2], P. X. JORIS[1];
[1]KU Leuven, Leuven, Belgium; [2]Univ. of Wisconsin, Madison, WI

Abstract: The lateral superior olive (LSO) in the superior olivary complex contains binaural neurons that receive excitatory inputs from the ipsilateral ear relayed in the cochlear nucleus, and inhibitory inputs from the contralateral ear relayed in the medial nucleus of the trapezoid body. This interaction results in output sensitivity to interaural level differences (ILDs). This circuit also features large axosomatic synapses (such as the calyx of Held) and other specializations suggestive for timing, which are not easily reconciled with the proposed role of these neurons as ILD detectors. To study the computation performed by these neurons, we recorded from 29 cells in the LSO in the Mongolian gerbil using patch clamping in vivo. We presented monaural and binaural tones, at several ILDs, and monaural and binaural clicks, at several ILDs and interaural time differences (ITDs). We compared these responses to responses from medial superior olive (MSO) neurons. We labeled many of the LSO neurons with biocytin and studied the anatomy at the light and electron microscopic level. Our data represent the first retrieved neurons of the lateral superior olive that were recorded in vivo. Study of the soma location, somatodendritic anatomy and synaptic coverage allowed us to confirm the tonotopy of the lateral superior olive and classify the neurons as principal, type 5, marginal or multiplanar cells. The spontaneous intracellular activity showed EPSPs and IPSPs. All anatomical cell types received inhibition from the contralateral and excitation from the ipsilateral ear. We observed that, for simultaneous bilateral stimulation at the same sound level, contralaterally driven IPSPs often arrive earlier than ipsilateral EPSPs, even though they have to take a longer anatomical route through an extra

synapse. The responses to binaural clicks at different ITDs showed that the time window of effective inhibition is generally narrow and restricted to the initial, descending slope of the IPSP waveform. Click-ITD functions of LSO neurons showed steep ITD-sensitivity, as opposed to MSO neurons. We propose that inhibitory-excitatory interactions in the LSO, combined with the temporal specializations in the circuit, enable steep sensitivity to ITDs of transient sounds, unlike excitatory-excitatory interactions in the MSO.

Title: The effect of spectral mismatch on binaural fusion in vocoder simulations of cochlear-implants for single-sided deafness

Authors: *J. WESS[1,2], J. G. W. BERNSTEIN[2];
[1]Univ. Of Maryland, College Park, MD; [2]Walter Reed Natl. Military Med. Ctr., Bethesda, MD

Abstract: Cochlear implants (CIs) can restore some degree of spatial hearing for individuals with single-sided deafness, SSD. However, there is a large amount variability in outcomes among those with SSD. One possible cause is spectral mismatch between the acoustic and electric ears. Standard frequency-to-electrode maps are programmed to provide the full speech bandwidth to a CI patient. This approach might be sub-optimal for a SSD-CI user, limiting the ability to fuse the very different auditory inputs from the two ears into a single fused sound. Fusion of signals across the ears is an integral step in enabling listeners to hear effectively in cocktail party environments. The goal of this study was to measure perceptual binaural fusion of speech stimuli. Vocoder simulations of SSD-CI listening were used to investigate the effect of spectral mismatch on subjective fusion in normal-hearing listeners. A virtual cocktail party was created by presenting combinations of one or more concurrent talkers to the left ear (normal unprocessed speech), to the right ear (vocoded speech) or to both ears (normal speech and vocoded speech). Each trial was 2 seconds long and the total number of concurrent talkers varied from one to six. The positions of individual electrodes along the cochlear array were simulated by adjusting the frequencies of the vocoder synthesis filters based on existing published data of average CI electrode insertion depth. In the “standard” condition, the analysis filters were set based on a standard clinical CI frequency allocation table. In the “place-matched” condition, the analysis filters were set to the same frequencies as the synthesis filters. After each trial, the

listener was asked how many total voices were heard. If listeners were able to perceptually fuse the voices that were presented to both ears, they should be more likely to report the correct number of total talkers in the scene. Conversely, if the signals were not fused between the ears, then listeners should report more total talkers then were actually presented. The results showed that listeners reported more total talkers when the vocoded speech was processed with a standard map then with the place-matched map. These data suggest that place-matched CI mapping has the potential to provide SSD-CI listeners with more opportunity for binaural fusion and subsequent improvements in spatial hearing. This paradigm provides a way to measure binaural fusion in a fast, straightforward way using speech signals representative of everyday listening environments. This method could be applied to the SSD-CI population to compare mapping strategies and outcomes after implantation.

Title: Representing space in 3D: Response profiles of midbrain neurons in the free-flying bat

Authors: *N. B. KOTHARI, M. WOHLGEMUTH, C. F. MOSS;
Johns Hopkins Univ., Baltimore, MD

Abstract: Past research on the mammalian superior colliculus (SC) has elucidated its role in encoding 2D sensory space (azimuth and elevation) to guide species-specific orienting behaviors. In their natural environment, most animals, however, orient in 3D space, which requires sensory representation of not only the direction bat also the distance/depth of objects. Echolocating bats, for example, probe the environment with sonar signals and determine 3D object locations by processing acoustic information carried by echo returns. Here, we report on SC recordings from the free-flying echolocating big brown bat (*Eptesicus fuscus*) and present evidence demonstrating 3D spatial response areas in SC neurons. We used a 16 channel silicon probe to collect extracellular, single unit activity across laminae of the bat SC, using a telemetry system while the bat flew across an experimental room with objects positioned along its flight path. Synchronized high-speed audio and video recordings were used to quantify echolocation signals, head direction and flight trajectory data. From audio and 3D video position data, we built an

'echo model' to determine the arrival time and 3D location of acoustic stimuli arriving at the bat's ears. Combining the output of the echo model with synchronized neural recordings, we were able to reconstruct 3D spatial response profiles of SC neurons from free-flying echolocating bats. Importantly, multi-channel recordings across the dorsal-ventral axis of the SC allows us to investigate the relative timing of activity in sensory, sensorimotor and pre-motor layers. The results of this study reveal specializations for acoustic orienting by sonar and serve to advance a broader understanding of SC function in the context of species-specific orienting behaviors.

Title: Laminar specific, orientation selective current source density response in cat area 18

Authors: M. Y. VILLENEUVE, P. KROPF, Z. YAO, V. M. MOCANU, *A. SHMUEL; McGill Univ., Montreal, QC, Canada

Abstract: Orientation selectivity shown by neurons in the visual cortex is considered to be the result of thalamo-cortical input and intra-cortical processing. Although much effort has been devoted to understanding the emergence of orientation selectivity, the exact mechanisms are still incompletely understood. In particular, it is still unclear how orientation specific signals are selectively relayed across cortical layers. Lamina-resolved current-source density (CSD) is hypothesized to mainly reflect synaptic activity. It should therefore be well suited to further our understanding of the role of intra-cortical signal processing in the emergence of orientation selectivity. Surprisingly, previous studies reported that the spatiotemporal CSD pattern is virtually invariant to the orientation of grating stimuli. Here we revisit this paradox by comparing 1-D laminar CSD in cat visual area 18 in response to gratings varying in contrast and orientation. Contrary to previous reports, we found a clear orientation selective component in the CSD responses. In particular, the primary sink in layer IV was found to extend from layer IV to supra-granular layers (Figure 1A, bottom, dark rectangle) when the preferred orientation (157.5

degrees), determined according to the rate of action potential response (Figure 1A, top), was presented. In contrast, no similar extension of the primary sink was observed in response to the non-optimal orientation (67.5 degrees; Figure 1A, bottom, red rectangle). We observed this orientation-dependent modification in the pattern of the CSD not only in response to high-contrast oriented grating (Figure 1A), but also at lower contrast (Figure 1B). This suggests that the observed effect is not due to a difference in overall amplitude of the neural activation but rather reflects differences in cortical signal processing. Hence, we present evidence that feature selection in early cortical processing can be achieved by selective information transfer between cortical laminae.

Title: Spatial asymmetry and amplitude-dependent suppression: a novel mechanism for generating direction selectivity

Authors: *Y.-T. LI[1], Q. FANG[2], L. I. ZHANG[2], H. W. TAO[2];
[1]Caltech, Pasadena, CA; [2]USC, Los Angeles, CA

Abstract: Direction selectivity (DS) of neuronal responses is important for motion detection. Two models, spatially offset inhibition and temporally offset excitation, have been proposed for the generation of DS. While mouse primary visual cortex (V1) has become an important model, the mechanisms for DS there, in particular in the thalamo-recipient layer 4, remain obscure. In this study, we investigated this issue with in vivo whole-cell recordings and neuron modeling. For both membrane depolarization and excitatory synaptic responses, we found that the preferred direction and degree of direction tuning under moving-bar stimulation strongly correlated with the spatial skewness of input strengths evoked by stationary stimuli (flash bars) across the receptive field. Modeling revealed that this correlation cannot be accounted for by a simple linear summation of flash-bar evoked inputs. Sequential-bar stimulation revealed a forward suppression of the excitatory response to the second bar by the first bar, with the suppression level depending on the relative amplitude of the first-bar evoked response. By incorporating such amplitude-dependent suppression into our summation model, we could then successfully predict DS of the excitatory response under moving-bar stimulation. Our results suggest that DS in the mouse visual cortex can be generated via short-term plasticity on excitatory inputs whose strengths form an asymmetric spatial distribution. Such mechanism is distinct from those previously proposed in other species.

Title: Orientation discrimination depends on co-activation of on- and off-dominated visual channels

Authors: *A. W. FREEMAN[1], G. LUO-LI[1], D. ALAIS[2];
[1]Sch. of Med. Sci., Univ. of Sydney, Lidcombe, Australia; [2]Sch. of Psychology, Univ. of Sydney, Sydney, Australia

Abstract: Introduction. Visual responses to light increments and decrements are not symmetrical: both behavioural and neural data show that responses to darks are stronger and faster than to lights. Given the evidence that on- and off-centre subcortical inputs converge onto orientation-selective cortical neurons, we aimed to see whether the light/dark asymmetry influences orientation discrimination. **Methods.** We separated Gabor patches into light bars and dark bars, and presented the two components asynchronously. Bars were tilted 2° left or right of vertical but the tilt on any one trial was the same for light and dark bars. Adult human subjects indicated whether the tilt was leftward or rightward; response correctness and reaction time were both recorded. **Results.** The proportion of correct responses was measured as a function of stimulus contrast. Contrast sensitivity, calculated as the reciprocal of the contrast required to obtain 75% correct responses, was plotted against the asynchrony between light and dark bars. As shown in the figure, contrast sensitivity is optimal when light bars precede dark bars by 13 ms (one video frame), and the 95% confidence intervals show that this effect is significant. A similarly lop-sided tuning curve was found for reaction time. **Conclusion.** Given that on-pathways have a longer response latency than do off-pathways, this result suggests that orientation discrimination is optimal when on- and off-signals reach cortex at about the same time.

Title: Quantitative analysis of excitatory-inhibitory dynamics in the thalamocortical network of awake mice

Authors: ***I.-C. LIN**, M. OKUN, M. CARANDINI, K. D. HARRIS;
Univ. Col. London, London, United Kingdom

Abstract: While each region of cortex contains many cells, the bulk structure of local cortical activity can be summarized by a small number of "macroscopic variables", such as the summed activity of excitatory (E) and inhibitory (I) neuronal populations. It has been hypothesized that these macroscopic variables obey quantitative laws (e.g., the Wilson-Cowan equations), similarly to how statistical mechanics governs the macroscopic variables of physical systems.
To measure, manipulate, and model E-I dynamics, we combined large-scale electrophysiological recordings with independent optical stimulation of pyramidal (E) and parvalbumin-expressing

(*Pvalb*; I) neurons in primary visual cortex (V1) of quietly awake mice. The mice harbored a Thy18 allele (expressing ChR2 in a subpopulation of E neurons) and *Pvalb-Cre* allele, and expressed the red-shifted opsin C1V1(E122T/E162T) in *Pvalb* neurons via a conditional virus. E and I neurons were activated by brief blue (445 nm) and green (561 nm) laser pulses. Network activity at each moment was summarized by two variables: the total firing rates of all recorded wide-spiking (putative E) and narrow-spiking (putative I) cells.
A single blue pulse briefly activated the E population then the I population, followed by prolonged suppression of both populations, then a rebound in activity. Similarly, a green pulse increased the activity of the I (but not E) population, followed by shorter, less noticeable suppression of both populations. When pairs of pulses were presented to successively activate the two populations, the timing of the rebound after prolonged suppression was time-locked to the activation of E cells, rather than I cells.
To investigate potential mechanisms underlying this prolonged suppression, we recorded neural activity in the lateral geniculate nucleus (LGN) while activating cortical E/I populations. A blue pulse caused prolonged suppression in LGN, while a green pulse had little effect. These results suggest that the suppression generated by E activation involves a substantial thalamic contribution, while the suppression generated by I activation is due to the cortical network only. Moreover, as the suppression evoked by I activation exceeds that expected from synaptic $GABA_A$ activation alone, additional "slow" GABA components might be involved.
Finally, we asked whether these dynamics could be summarized by a set of equations. The Wilson-Cowan equations were insufficient, owing to their inability to predict prolonged suppression. We are currently developing a dynamical system model that includes variables representing slow GABA inhibition and LGN activity to summarise the observed population dynamics.

Title: The affiliation of individual cortical neurons with global cortical networks

Authors: *K. CLANCY, I. ORSOLIC, T. MRSIC-FLOGEL;
Biozentrum, Univ. of Basel, Basel, Switzerland

Abstract: The neocortex is richly interconnected, and different cortical areas exhibit shifting affiliations with one another depending on behavioral state or context. This coupling is subserved in part by the excitatory long-range projections between cortical areas. Neighboring neurons may send projections to and receive input from local and distant areas. In addition to their heterogeneous connectivity, cortical neurons fall along a spectrum of engagement with shared local activity—while some are preferentially co-active with their neighbors, others are not functionally coupled to the local network. This response heterogeneity might reflect the variety of global influences on individual cells. We therefore undertook to map the relationship between the activity of individual neurons and the activity in distant areas, and sought to relate these functional maps to the strength of a cell's coupling to shared local activity.
In order to probe the affiliation of individual cells with distant networks, we recorded extracellularly from single units in visual cortex while simultaneously imaging cortex-wide activity in transgenic mice expressing the calcium indicator GCamp6s in CaMKII+ neurons. We made maps of the strength of correlation between individual units and various cortical areas. While many neurons shared similar cortex-wide correlation maps, a small proportion had unique affiliations, and these were often the cells most negatively coupled to local activity. Given that activity in primary sensory cortices not only reflects the occurrence of a sensory stimulus, but information about the animal's behavioral state and stimulus context, this method might be used to relate dynamic long range influences on the spiking of individual cortical neurons during different behaviors.

Title: VIP interneurons mediate cortical phenotypes in a genetic model of schizophrenia

Authors: *M. VINCK, R. BATISTA-BRITO, K. FERGUSON, J. A. CARDIN;
Yale Univ., New Haven, CT

Abstract: Schizophrenia is associated with altered cognitive and perceptual processing, as well as dysregulation of normal brain rhythms such as gamma oscillations (30-80Hz). Current evidence suggests that dysregulation of GABAergic interneurons contributes to neural and behavioral deficits in this disease. However, the roles of diverse interneuron populations in psychiatric disease remain poorly explored. Neuregulin 1 (*NRG1*) and its interneuron-specific receptor *ERBB4* are risk genes for schizophrenia. Using a conditional ErbB4 deletion model, we used awake behaving animals to test the role of distinct interneuron populations in disease-related deficits. In contrast to the prevailing view, which supports a role for parvalbumin (PV)-expressing interneurons in the pathophysiology of schizophrenia, we find that deletion of ErbB4 specifically from vasoactive intestinal peptide (VIP)-expressing interneurons mediates many observed phenotypes. ErbB4 removal from VIP interneurons during development leads to changes in their activity, along with elevated cortical firing rates and severe dysregulation of the fine temporal organization of excitatory and inhibitory activity patterns. ErbB4 deletion from VIP interneurons abolishes the normal behavioral state-dependence of excitatory cortical activity. As a result of these alterations, animals in which VIP interneurons lack ErbB4 exhibit reduced visual cortical responses and impaired learning on a visual task. Our data support novel roles for VIP interneurons in cortical circuit development and the pathophysiology of schizophrenia, and provide a new perspective on the disruption of cortical circuit function in this complex disease.

Title: Inhibition and synaptic integration in simple cell receptive fields in cat V1

Authors: *M. M. TAYLOR, L. A. PALMER, D. CONTRERAS;
Neurosci., Univ. of Pennsylvania Perelman Sch. of Med., Philadelphia, PA

Abstract: Simple cells in primary visual cortex (V1) are sensitive to the orientation of visual stimuli. This property arises because their receptive fields (RFs) consist of side by side elongated subregions of opposite contrast preference. A bright bar presented in a bright subregion (sign-matched) drives the cells output while presented in a dark subregion (sign-mismatched) suppresses output. We found that sign-matched stimuli evoke not only an excitatory synaptic conductance but also an inhibitory conductance. We termed this "sign-matched inhibition" to distinguish it from the expected and established inhibition triggered by a sign-mismatched stimulus (that we call "sign-mismatched inhibition"). We find that sign-matched inhibition is comparable in magnitude to sign-mismatched inhibition. Therefore, inhibition is widespread in space across the RF.

Do both types of inhibition serve the same function? We test the role of sign-mismatched inhibition by pairing a sign-matched stimulus with sign-mismatched stimulus while recording intracellularly from simple cells in vivo. We examine the time-dependent properties of combinations of sign-matched and sign-mismatched inhibition. For three delays between the two bar onsets (-8, 0, and 8 ms), we examine the peak amplitude of the evoked PSP and the dV/dt of the PSP onset. Inhibition from a sign-mismatched stimulus reduces the amplitude and dV/dt of the excitatory response to a sign-matched stimulus, when the sign-mismatched bar is presented before or concurrently with the sign-matched bar. This suggests that the onset timing of sign-matched and sign-mismatched inhibition is not the same, which in turn suggests two functionally distinct cellular sources of inhibition. Surprisingly, we also find in a subset (~30%) of simple cells, presentation of a sign-mismatched bar had no effect on the PSP evoked by the sign-matched bar, indicating that a sign-mismatched stimulus does not always evoke an inhibitory response.

Our results suggest that while inhibition concurrent with an excitatory response limits its time course, inhibition triggered from an inhibitory response (sign-mismatched) contributes to the spatial integration of inputs within the RF of simple cells.

Title: Dopamine elicits lamina- and frequency-specific increase of information in the local-field-potentials of the macaque V1

Authors: *D. ZALDIVAR[1], J. GOENSE[2], S. LOWE[3], N. LOGOTHETIS[4], S. PANZERI[5]; [1]Physiol. of Cognitive Processes, Max Planck Inst. For Biol. Cybernetics, Tuebingen, Germany; [2]Inst. of Neurosci. and Psychology, Univ. of Glasgow, Glasgow, United Kingdom; [3]Sch. of Informatics, Inst. of Adaptive and Neural Computation, Edinburgh, United Kingdom; [4]Max Planck Inst. for Biol. Cybernetics, Tuebingen, Germany; [5]Inst. Italiano di Tecnologia, Rovereto, Italy

Abstract: Purpose: Local field potentials (LFPs) reflect the aggregate activity of neural populations generated by different neural mechanisms and expressed in different frequency domains. Each frequency range reflects, at least in part, different aspects of neural activity and capture the activity expressed by different processing pathways[1]. In particular, previous studies showed the activity reflected in the low (< 20 Hz) and high-frequencies (> 50 Hz) dissociate from the activity of the middle-frequency band (18 – 38 Hz). It has been proposed, based on statistical considerations, that this middle frequency band reflects the influence of neuromodulation pathways[1]. However, it is not know whether and how this middle-frequency band reflects neuromodulation and whether it relates to stimulus encoding.
Methods: We recorded LFPs in four anesthetized non-human primates (*macaca mulatta*), during spontaneous activity and presentation of movie clips, using 16-contact laminar probes (NeuroNexus) on a single shank of 3 mm long (50 µm thick) and with electrode-sites spaced 150 µm apart spanning the entire cortical depth of V1. We pharmacologically mimicked dopaminergic (DAergic) neuromodulation, by systemically applying L-DOPA+Carbidopa. L-DOPA is metabolic precursor of dopamine (DA) and once it crosses the blood-brain-barrier, is immediately metabolized into DA[2].
Results and Conclusions: DAergic neuromodulation elicited frequency- and stimulus dependent power changes in the recorded LFPs. During spontaneous activity, we observed a remarkable increase specific to the middle-frequency (18 – 38 Hz) band power accompanied by a decrease of gamma (50 – 150 Hz) power. In contrast, during visual stimulation with movie clips DA increased both the power of gamma and of the middle frequency band. Moreover, DA increased the information in LFP power, particularly superficial and deep layers and in the gamma (50 – 100 Hz) frequency band. Overall, our results show that the middle-frequency band captures endogenous non-stimulus driven oscillations that are modulated by dopamine, and that dopamine regulates gamma-range information coding in visual cortex.

Abstract: Orientation selectivity, the hallmark property of neurons in mammalian primary visual cortex (V1), is invariant to stimulus luminance and contrast, which are two basic properties of visual stimuli in the natural world. Under low light or contrast levels (e.g., in fog), driving and games involving hand-eye co-ordination become more difficult. We wondered how the time-course of neuronal orientation processing was affected by luminance and contrast, and whether it could account for the observed perceptual effects. Here, we characterised the dynamics of orientation selectivity in V1 neurons (N=286) of halothane-anaesthetized rats, using a reverse correlation method. Stimuli comprised a sequence of sinusoidal gratings (each visible for 33 ms) with continually changing orientation, phase, and spatial frequency. We varied luminance and contrast in four different stimulus blocks: 1) high contrast; 2) low contrast; 3) high luminance; 4) low luminance. Averaged across all conditions, orientation selectivity was evident from 60±23 ms, with peak selectivity at 80±20 ms post stimulus onset. Consistent with previous reports using forward correlation, orientation selectivity did not vary with luminance contrast, and we now show that the mutual information between neuronal activity and stimulus orientation is the same under all conditions. Although neurons responded earlier with higher luminance stimuli, the response latency to high-contrast gratings was surprisingly longer than to low-contrast stimuli. Based on our computer simulations, we suggest that the longer latencies in high-contrast conditions are due to membrane hyperpolarization after prolonged exposure to high-contrast stimuli. The hyperpolarization at high-contrast may increase signal-to-noise ratios while a more depolarized membrane under low-contrast may lead to greater sensitivity to weak stimuli.

Title: The neuronal and perceptual effects of visual masking

Authors: ***K. L. RICHARDS**[1], D. S. ALWIS[2], E. ARABZADEH[3], N. S. C. PRICE[4]; [1]Clayton, Australia; [2]Florey Inst., Melbourne, Australia; [3]Australian Natl. Univ., Canberra, Australia; [4]Physiol., Monash Univ., Melbourne, Australia

Abstract: The perception and neural representation of a stimulus are influenced by other stimuli that occur nearby in space or time. The phenomenon of visual masking describes the reduction in the perception of a target stimulus by a preceding (forward masking) or succeeding (backward masking) stimulus. In this way, masking illustrates a disconnect between the physical stimulus, its neuronal representation, and its percept. To understand the neural correlates of masking, we examined how visual masks affect orientation discrimination in awake rodents, and separately examined neuronal responses to similar stimuli in the primary visual cortex (V1). Long-Evans rats (n=6) were trained to discriminate the orientation of a Gabor patch presented for 42 ms. These target stimuli were presented at stimulus onset asynchronies (SOA) of –250 to 250 ms relative to an uninformative mask. In a separate cohort of halothane-anaesthetised animals (n=28) neuronal responses to target and mask stimuli were recorded from all layers of V1 using a 32-channel linear array. Early and late components of the neuronal response were analyzed separately. Behaviourally, for both forward and backward masking conditions, discrimination performance was impaired when the target and mask occurred close in time (i.e. short SOAs). Similarly, across all cortical layers, neuronal firing rate and orientation selectivity decreased monotonically with shorter SOAs. However, within early and late response components the reductions in orientation selectivity were not reliably predicted by changes in firing rate. Collectively, our data suggests that changes in V1 activity are responsible for the impairment in perceptual discrimination during masking. Based on the weak, non-selective responses to our mask stimuli, we suggest that both forward and backward visual masking may develop throughout the visual processing hierarchy through cumulative normalization computations.

Title: Correlations of interneuron populations with Pyramidal cells in mouse primary visual cortex

Authors: ***M. DIPOPPA**, M. CARANDINI, K. D. HARRIS;
Univ. Col. London, London, United Kingdom

Abstract: Different classes of GABAergic interneuron are thought to play different roles in cortical function. Interneurons expressing Parvalbumin (Pvalb) are thought to provide inhibition that is proportional to local excitation (Xue et al., Nature 2014). Interneurons expressing somatostatin (*Sst*) are thought to integrate excitatory activity over larger regions and inhibit Pyramidal (Pyr) neurons, playing a role in computations such as surround suppression (Adesnik et al., Nature 2012). Interneurons expressing vasoactive intestinal peptide (*Vip*) are thought to disinhibit Pyr cells via their strong inhibition of *Sst* cells (Fu et al., Cell 2014).
To test these proposal, we used 2-photon imaging to measure the activity of these interneuron types together with Pyr cells, in layers 2/3 of V1 of head-fixed mice that were free to run while viewing drifting gratings of various sizes. We identified interneuron types in transgenic mice expressing tdTomato in *Sst*, *Vip*, or *Pvalb* neurons, and measured Ca^{2+}-related fluorescence with unconditional viral expression of GCaMP6m. We identified putative Pyr by the sparseness of their neural activity.
The three interneuron types showed different relationships to Pyr activity. The *Pvalb* population had strong positive spontaneous correlations with the Pyr population, in running or stationarity. *Vip* cells showed similar behavior to *Pvalb* cells, but their correlations with Pyr cells were less prominent in stationarity, when their firing was overall weaker. The *Sst* population had negative correlations with Pyr cells during running, but these were also substantially weakened in

stationarity. Noise correlations showed similar structure to spontaneous correlations.
Signal correlations revealed a more complex picture. For small stimuli (between 5 and 30 deg), signal correlations showed a similar organization to spontaneous and noise correlations. For larger stimuli, however, signal correlations were less reliable between experiments, with *Sst* cells often showing positive correlations with Pyr activity.
These results indicate that the nature and even the sign of interneuron-Pyr correlations strongly depend on sensory and behavioral context. The predictions of the disynaptic inhibitory circuit involving *Vip* and *Sst* cells appear to be correct only for some of these sensory and behavioral contexts.

Title: Estimating simple and complex cell properties using a convolutional model with parameterized rectifiers

Authors: P. M. T. NGUYEN, *C. L. BAKER;
Ophthalmology, McGill Vision Res. Unit, Montreal, QC, Canada

Abstract: Neurons in the early visual cortex have often been classified into two types based on their receptive field (RF) properties. Simple cells have RFs with segregated excitatory and inhibitory zones, and phase-dependent responses (F1/F0 ratio > 1) to sinewave gratings. Complex cells' RFs have mixed excitatory and inhibitory responses, with F1/F0 < 1. The behaviour of simple cells can be understood in terms of linear-nonlinear (LN) models, and readily estimated with simple system identification methods such as spike-triggered averaging. Due to the phase invariance, complex cells are much harder to estimate, requiring heavily parameterized models.
Here we present a new 2-layer convolutional neural network model, with a parameterised rectifier between layers, which allows us to capture the responses of both simple and complex cells with only a single additional parameter, "alpha". The optimization of model parameters is

achieved through a backpropagation algorithm using gradient descent.
We recorded the extracellular single-unit responses of neurons in Areas 17 and 18 of anesthetised, paralyzed cats using 32-channel multielectrodes. Natural image stimuli were used to estimate and predict the neurons' responses, while sinewave gratings were used to estimate F1/F0 ratios. We collected neuronal responses to separate sets of stimuli. One dataset was used for model estimation, and a separate holdback dataset was used solely to score the performance of the estimated model. Model performance was measured as the "variance accounted for" (VAF) in the model's prediction of the holdback dataset.
The convolutional network method yields higher VAFs than previous methods of receptive field estimation, such as spike-triggered average and spike-triggered covariance, for both simple and complex cells. Furthermore we show that the alpha parameter is predictive of a neuron's F1/F0 ratio. Also we show how the parameterised rectifier unit may be used to estimate the degree of push-pull imbalance between excitatory and inhibitory inputs.
This work suggests that convolutional neural networks may be a fruitful approach to characterizing receptive fields of early visual cortex cells.

Abstract: Visual perception and behavior are mediated by a network of cortical areas that have been distinguished using architectonic and retinotopic criteria. We employed fluorescence imaging and GCaMP6 reporter mice to generate retinotopic maps of visual areas in the mouse. Changes in GCaMP6 fluorescence were >2 orders of magnitude larger and 5 times faster than intrinsic optical signals, the standard imaging technique for mapping visual areas. The resulting high signal-to-noise map includes new retinotopically-organized regions medial and anterior to

known visual areas. To compare the borders of cortical areas identified using different techniques, we registered functional and projection-based retinotopic maps to borders identified with chemo- and cytoarchitectonic markers. This comparison revealed that retinotopic organization extends into barrel cortex and retrosplenial cortex and that the locations of borders between visual areas identified with different techniques differed by several hundred micrometers, which is on the order of size of some of the smaller visual areas. We also assessed the representation of visual space within each visual area, showing that four higher visual areas bordering V1 (LM, P, PM and RL) display complementary representations, with overlap primarily at the central hemifield. Our results extend our understanding of the organization of mouse visual cortex to include up to 16 retinotopically distinct maps. To identify the sources of wide field signal, further experiment will align wide field retinotopic maps with receptive field locations of cellular structures recorded by 2-photon imaging.

Title: Inactivation mapping of mouse cortex during a visual detection task

Authors: ***M. VALLEY**, D. R. OLLERENSHAW, J. MILES, S. OLSEN, J. WATERS; Allen Inst. for Brain Sci., Seattle, WA

Abstract: The degree to which the mouse cortex is necessary for performing highly-trained and repetitive laboratory behaviors remains controversial. Cortical lesions have been shown to result in little or no decrement in behavioral performance in a variety of sensory modalities. However, recent work using temporally-focused optogenetic lesions have renewed interest in defining exactly how cortical circuits participate in trained behaviors. Here, we systematically inactivate regions of cortex in VGAT-ChR2 mice during performance of a visual detection task. Our procedure allows for arbitrary targeting of cortical regions using guidance relative to retinotopic maps, intrinsic stimulus maps, and stereotaxic coordinates. Using targeted inactivation in a variety of cortical locations, we map the involvement of these regions in visual detection, lick-

based behavioral report, locomotion, and in the modulation of arousal as measured by pupillary diameter.

Title: Mesoscale cortical dynamics measured with wide-field calcium imaging during a visual detection task in mice

Authors: ***D. R. OLLERENSHAW**[1], M. T. VALLEY[2], J. ZHUANG[2], N. H. CAIN[2], P. A. GROBLEWSKI[2], M. E. GARRETT[2], B. DANSKIN[2], J. WATERS[2], S. R. OLSEN[2]; [1]Allen Inst. For Brain Sci., Seattle, WA; [2]Allen Inst. for Brain Sci., Seattle, WA

Abstract: Sensory guided behaviors involve a dynamic interplay of many distributed cortical areas to process an external stimulus and choose an appropriate motor response. Here, we characterize mesoscale cortical activity in mice engaged in a visually guided detection task. We use wide-field imaging of transgenic mice expressing the calcium indicator GCaMP6 in genetically defined cell populations. Our imaging preparation permits the simultaneous measurement of population activity from multiple visual areas through a cranial window or multiple brain regions across the entire dorsal surface of the cortex through the intact skull. In the behavioral task, head-fixed mice are trained to respond to briefly flashed visual stimuli with contrasts spanning the detection range. Using traditional signal detection theory metrics, we describe the coding of stimulus information in V1 and higher visual areas. We extend this analysis across the dorsal surface of the cortex to map a distributed network of cortical regions that predict the animal's behavioral choice at the contrast detection threshold. These experiments help to further elucidate the cortical network involved in a sensory task, while also provide a map for targeting future spatially and temporally restricted optogenetic perturbation experiments.

Title: Functional magnetic resonance imaging (fMRI) - guided single unit recordings reveal first order disparity selectivity in area PIP of the macaque brain.

Authors: *A. ALIZADEH[1], P. JANSSEN[2];
[1]Katholieke Univ. Leuven, Leuven, Belgium; [2]KU Leuven, Leuven, Belgium

Abstract: Binocular disparity provides a strong, unambiguous cue for depth perception in primates. Several cortical areas in both the dorsal and the ventral visual pathways are involved in the processing of depth from binocular disparity. Previous functional magnetic resonance imaging (fMRI) studies in monkeys (Van Dromme et .al, PloS Biol, 2016) revealed stronger activations in the medial bank of the caudal intraparietal sulcus (IPS, area PIP) in response to higher-order (curved and slanted) disparity stimuli compared to zero-order (flat) stimuli. The current study was carried out to investigate the higher-order disparity selectivity in area PIP at the single-cell level. The search test consisted of 32 second-order stimuli in addition to 8 first-order stimuli (2 vertical and 2 horizontal linear disparity gradients, square shape, 4 of which were 8.4° and the other 4 were 18.75° in diameter). We tested for both second- and first-order disparity selectivity (including monocular controls) and selective cells were additionally tested with preferred and non-preferred stimuli at 5 different positions in depth (mean disparity from -0.5 to 0.5). In total, we recorded from 207 PIP neurons showing significant visual responses to the stimuli of the search test presented at the fixation point in 3 monkeys. A large fraction of all visually-responsive neurons (87 neurons, 42%) exhibited significant selectivity for first- or second-order stimuli which could not be explained by the monocular responses. More than half of these selective neurons (43/79, 54%) preserved their selectivity across positions in depth when tested with first-order (slanted planar) stimuli. However, contrary to the predictions of the previous fMRI studies, none of the PIP neurons tested (N=56) maintained its selectivity across different positions in depth for second-order (curved) stimuli. The average response to the preferred second-order stimuli at three positions in depth (mean disparity -0.25 to +.25) was significantly larger than the response to zero-order stimuli at the same positions in depth, which could explain the fMRI activations. In general, PIP neurons preserved their 3D selectivity across different stimulus sizes (ranging from 3.1° to 18.8°). Disparity-selective PIP neurons usually had large receptive fields in the contralateral hemifield, frequently including the fovea. Thus, the

fMRI activation elicited by curved surfaces in area PIP is primarily based on a neural selectivity for first-order stimuli.

Title: Dynamics of "population coupling" between synaptic inputs and local cortical activity during visual processing

Authors: ***N. WRIGHT**, M. S. HOSEINI, R. WESSEL;
Physics, Washington Univ. In St. Louis, Saint Louis, MO

Abstract: The spiking activity of a cortical neuron is coordinated with that of its neighbors. This "population coupling" has significant implications for sensory coding, and is thought to represent the effects of both anatomical and emergent network properties on cortical function. Here, we investigate two questions vital to a better understanding of cortical sensory processing. (1) How strongly-coupled are the synaptic inputs (g) to a neuron with the local population activity (LFP), and how does this change with sensory stimulation? (2) To what degree are the dynamics of g-LFP coupling determined by the network, and what are the relevant network parameters?
To address the first question, we simultaneously recorded the membrane potential (V) and the nearby LFP in the visual cortex of the turtle eye-attached wholebrain *ex vivo* preparation, during ongoing and visually-evoked activity. We then applied a recently-developed algorithm to infer g from V, and calculated the g-LFP coupling. We found that during ongoing activity, g-LFP coupling differed from neuron to neuron. Moreover, coupling during (the highly-variable) evoked activity was not static, but transiently increased following stimulation, before relaxing to intermediate values. Comparison with a parallel study suggests coupling falls off very gradually with cortical distance. That is, global fluctuations strongly influence the sensory-evoked inputs to individual neurons.
To address the second question, we implemented a small-world network of leaky integrate-and-fire neurons, subject to Poisson external inputs and synaptic depression with recovery. This

model reproduces two experimentally-observed aspects of evoked activity: large across-trial response variability, and the g-LFP coupling dynamic. Importantly, it does so despite the fact that external inputs are uncorrelated across pairs of neurons. Instead, these response properties are largely determined by the network state, which is highly sensitive to such network parameters as spatial clustering, synaptic time constants, and adaptation. We are currently investigating the ability of the model to reproduce other experimental results.
Together, our results provide a clearer picture of the subthreshold coordination dynamics corresponding to suprathreshold population coupling in cortex. Moreover, they implicate specific network properties that shape cortical coordination during sensory processing.

Title: Evaluating network criticality with membrane potentials

Authors: *J. K. JOHNSON[1], N. C. WRIGHT[2], R. WESSEL[2];
[1]Washington Univ. Physics, University City, MO; [2]Physics, Washington Univ., Saint Louis, MO

Abstract: Membrane potentials (Vm) are a well-established observable in neural systems that are also used for carrying information by the brain itself. Recordings from intact functional networks are becoming increasingly accessible with recent advances in experimental automation and in-vivo techniques. Subthreshold Vm fluctuations are primarily driven by synaptic inputs via the dendritic arbor of a neuron. This constitutes a subsampling of the spiking activity of the network to which that neuron belongs, with the caveat that such post-synaptic-potentials are non-linear transformations**.** Therefore, it makes sense to test the extent to which Vm fluctuations can contain information about network variables. We addressed this with a combined experimental and modeling approach. We recorded ongoing activity from pyramidal neurons in turtle visual cortex, and found that distributions of subthreshold fluctuations displayed size and duration power laws with a scaling relation consistent with the critical point of a second-order phase transition. Our modeling results suggest that we can expect analysis of neural inputs to be

consistent with results that are normally attained via multi-electrode array recordings or calcium-fluorescent imaging. Values from input fluctuations were found to be systematically offset from network values and also to co-vary with changes in connectivity and inhibition that affect network state. This has never previously been demonstrated using single-unit recordings of any kind. Thus this work is important for two reasons. First it expands the tools available to researchers looking for behavior or other properties concomitant with a near-critical state (presumably emergent properties suggestive of self-organized criticality). Finally, it also supports and extends the use of subthreshold membrane potential fluctuations as a carrier for some kinds of network state information.

Title: Spatial spread of local field potential is band-pass in the primary visual cortex

Authors: *A. DUBEY, S. RAY;
Ctr. For Neurosci., Indian Inst. of Sci., Bangalore, India

Abstract: In recent years, local field potential (LFP), which is obtained by low-pass filtering the raw signal from a microelectrode inserted in the brain, has emerged as a promising candidate in understanding brain functions and in brain-machine interface (BMI) applications. However, there is no consensus about the cortical area which contributes to the LFP, known as its "spatial spread", with different studies reporting values between a few hundred micrometers[1] to several millimeters[2]. Further, dependency of spatial spread on frequency is also not well known, with previous modelling and theoretical studies predicting either "all-pass" (all frequencies spread equally) or "low-pass" (lower frequencies spread farther than higher frequencies) behavior.
We recorded brain signals from the primary visual cortex of two awake male rhesus monkeys using a 10x10 microarray. A small Gabor stimulus was flashed at different locations on the screen in a random order to estimate the visual spread for each recording site. The spatial spread

(measured in micrometers) was computed from the visual spread by using a model proposed by Xing and colleagues (2009)[1]. To estimate the spatial spread as a function of frequency, we first obtained the time-frequency spectrum of the signal using a signal processing technique called "Matching Pursuit", and subsequently estimated the visual spread at each frequency. Surprisingly, we found the LFP spread to be "band-pass", with frequencies in the high-gamma (60-150 Hz) range spreading significantly more than both lower (20-40 Hz) and higher (>250 Hz) frequencies. This was mirrored by an increase in phase coherence across neighboring sites in same frequency range, providing experimental evidence to a recent model[3] that reconciles different studies by showing that spatial spread depends on the extent of neuronal correlations. Our results are useful in understanding cortical architecture and communication, as well as in BMI applications.

Title: Critical network dynamics determines the variability of neural activity

Abstract: A rigorous understanding of brain dynamics and function requires a conceptual bridge between multiple levels of organization, including neural spiking and network-level population activity. Among the vast spectrum of spatial and temporal scales of brain activity, two experimentally accessible levels of brain organization are (i) the single-neuron spiking and (ii) the population activity of the network in which the neurons are embedded to various degrees.

Single-neuron spiking in cerebral cortex is characterized by statistical properties, such as irregular spiking and reduced variability during sensory stimulation. Population activity is characterized by complex spatiotemporal activity, including scale-free activity, which is predicted to occur for a network state near criticality. These observations at two adjacent levels of brain organization raise the question, to what extent the network state controls the variability of single-neuron spiking?
To explore impact of the network state on the statistics of neuronal spiking, we used a model of binary probabilistic integrate and fire neurons. We simulated the network activity for different states, for which we quantified spiking irregularity in terms of *coefficient of variation* (CV) of the inter-spike-intervals and the variability of spike trains in terms of average Fano factor (FF) over a sliding time window. In our computational model we show that two prevalent features of cortical single-neuron activity, irregular spiking (CV>1) and the decline of response variability at stimulus onset, could both arise as emergent properties of a recurrent network operating near criticality. Importantly, our work reveals that the relation between the irregularity of spiking and the number of input connections to a neuron, i.e., the in-degree, is maximized at criticality. This relation establishes a valuable conceptual link between criticality and the important field of network theory. Furthermore, as the observed decline in response variability is regarded as an essential mechanism to enhance response fidelity to stimuli, our discovery of its relation to network criticality offers a starting point toward unraveling the possible roles of critical dynamics in neural coding.
It will be interesting to see to what extent the presented findings will generate a paradigm shift in the study of criticality of neural systems, as our results also provide novel and robust measures to test the criticality hypothesis. Overall, our findings establish criticality as a unifying principle for the variability of single-neuron spiking and the collective behavior of recurrent circuits in cerebral cortex.

Title: Computational model on spatial-temporal response of primary visual cortex to contour stimuli

Abstract: Experimental study showed that population activities of primary visual cortical neuron encode the information of contour. Here we applied a physiology plausible computational model to explore the spatial-temporal dynamics of these population activities. We model a patch of neurons in V1 including 10*10 orientation hypercolumns. Excitatory (75%) and inhibitory (25%) neurons are randomly arranged in the plane and their preferred orientation forms a spinwheel structure. The short-range connections are isotropic among nearby neurons and mediated by AMPA or GABA receptors depending on the type of presynaptic neuron. The long-range connections are orientation-specific and mediated by NMDA receptors. We employ Wilson-Cowan model to describe the dynamics of single neuron. We apply the first order equation to model the fast synapse mediated by AMPA and GABA receptors and the second-order equation to model the slow synapse mediated by NMDA receptors. Given an image, we obtain the signal strength by filtering the image using steerable filters and the signal strength determines the input to a neuron according to its preferred orientation and spatial location.
Our model demonstrates typical spatial-temporal population activity of V1 upon orientation and contour stimuli. Given a stimulus with a single long straight line, the population activity pattern is consistent with classic image observations. Given a contour formed by five colinear bars with random background, the activation of neurons whose receptive field is on the contour are enhanced while the activities in the other areas are suppressed comparing with given stimulus of random bars (Fig). Comparing with the spiking neuron models, our firing rate model enables us to simulate large-scale cortical circuit efficiently and investigate the spatial temporal dynamics of large-scale network.
