Title: Clonally related interneurons disperse both within and across functional boundaries within the forebrain

Authors: *C. MAYER[1], X. H. JAGLIN[1], C. L. CEPKO[2], S. HIPPENMEYER[3], G. FISHELL[1]; [1]Physiol. & Neurosci., NYU Neurosci. Inst., New York, NY; [2]Harvard Med. Sch., Departments of Genet. and Ophthalmology and HHMI, Boston, MA; [3]IST Austria, Klosterneuburg, Austria

Abstract: The medial ganglionic eminence (MGE) gives rise to the majority of mouse forebrain interneurons. Here, we examine the lineage relationships among MGE-derived interneurons using a replication-defective retroviral library containing a highly diverse set of DNA barcodes. Recovering the barcodes from the mature progeny of infected progenitor cells enabled us to unambiguously determine their respective lineal relationships. We found that clonal dispersion occurs across large areas of the brain and is not restricted by anatomical divisions. As such, sibling interneurons can populate the cortex, hippocampus and striatum. Importantly, we also revealed that the majority of interneurons were generated from asymmetric divisions of MGE progenitor cells, followed by symmetric divisions within the subventricular zone. Altogether, our findings uncover that lineage relationships do not appear to determine interneuron allocation to particular regions. As such, it is likely that clonally-related interneurons have considerable flexibility as to the particular forebrain circuits to which they can contribute.

Title: Wide dispersion and diversity of clonally related inhibitory neurons

Authors: *C. C. HARWELL;
Neurobio., Harvard Med. Sch., Boston, MA

Abstract: A majority of GABAergic forebrain neurons are derived from the medial ganglionic eminence (MGE).MGE progenitors predominantly give rise to two functionally distinct subtypes of interneurons: parvalbumin (PV)-expressing fast spiking interneurons and somatostatin-expressing non-fast-spiking interneurons. MGE progenitors are molecularly defined by the expression of the homeodomain transcription factor Nkx2.1, which is required for the migration and specification of mature interneuron cell identities. Once cells have achieved their terminal division they migrate long distances to reach their final destination in the developing brain. The extrinsic signals involved in regulating the migration and positioning of newborn neurons have been extensively studied. However, the roles of intrinsic determinants, such as clonal lineage, and their relationships to the distribution of MGE derived interneurons remains poorly understood. Utilizing lineage-specific retroviral barcode labeling, we find that clonally related interneurons can be widely dispersed throughout the forebrain, and are composed of both parvalbumin and somatostatin interneuron subtypes. These data suggest that distinct functional interneuron subtypes can be derived from the same clonal lineage, and their distribution in distinct forebrain structures is not driven by their clonal relationships.

Title: Rewiring local inhibitory microcircuits by direct lineage reprogramming of neocortical projection neurons

Authors: *M. A. MOSTAJO RADJI[1], Z. YE[2], J. R. BROWN[3], C. ROUAUX[3], G. S. TOMASSY[3], T. K. HENSCH[2], P. ARLOTTA[3];

Abstract: We have previously demonstrated that overexpression of the master transcription factor Fezf2 is sufficient to reprogram postmitotic callosal projection neurons (CPNs) of cortical layers 2/3 to a corticofugal projection neuron (CFuPN) identity within a defined window of time. The reprogrammed neurons acquire molecular properties of CFuPNs and change their axonal connectivity from interhemispheric, intracortical projections to corticofugal projections directed below the cortex. Here, we sought to determine whether reprogramming projection neuron identity is sufficient to instruct the remodeling of their surrounding local inhibitory circuits. We first investigated the extent of reprogramming by performing single cell gene expression analysis of reprogrammed neurons. Our data showed that a subset of Fezf2-overexpressing cells significantly upregulated multiple molecular markers of CFuPNs compared to control CPNs. In agreement, we find that iCFuPNs acquire electrophysiological properties that are typical of CFuPNs. Notably, recordings of miniature inhibitory postsynaptic currents (mIPSCs) demonstrated that iCFuPNs receive increased inhibitory inputs, which resembled those of deep layer CFuPNs. In order to gain insight into this electrophysiological adaptation, we studied more specifically the contribution of Parvalbumin (PV) positive interneurons (INs). We found that PV positive INs form more perisomatic synapses onto reprogrammed neurons than onto CPNs, with levels indistinguishable from endogenous CFuPNs in layer 5. Optogenetic recordings and immunohistochemical analysis further confirmed an increased number of synapses by PV INs onto reprogrammed neurons. Furthermore, we demonstrate that reprogrammed projection neurons are not intrinsically more sensitive to inhibition and therefore the observed increase of inhibitory input likely reflects rewiring of the cortical circuit, rather than the expression of more GABA receptors. Altogether, our results indicate that reprogramming the identity of projection neurons is sufficient to reshape the local inhibitory circuitry and highlights the importance of projection neuron diversity in controlling this process.

Title: Genetic fate mapping of neocortical chandelier cell specification

Authors: *S. M. KELLY[1,2], M. MOISSIDIS[1], M. HE[1], Y. KIM[1], Z. HUANG[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Stony Brook Univ., Stony Brook, NY

Abstract: The diversity of GABAergic interneurons reflects a division of labor in regulating the balance, flexibility, and dynamic operations of cortical circuits, but the developmental processes that generate these diverse cell types are not well understood. Previous studies have identified embryonic neurogenic regions, such as the medial and caudal ganglionic eminence (MGE and CGE), which generate broad cohorts of GABA populations, but the progenitor mechanisms that give rise to distinct cell types remain unclear. In particular, it is unknown whether multipotent progenitors progressively generate multiple cell types or fate-restricted progenitors generate individual cell types. The chandelier cell (ChC) is one of the most distinctive GABA neuron types due to its axo-axonic synapses innervating the axon initial segment of pyramidal neurons, and thus provides a more tractable experimental system for the investigation of cell type specification. Here, we have taken an intersectional genetic approach to further define the progenitor types that give rise to ChCs and understand their temporal progression throughout embryogenesis. By combining Nkx2.1-FLP and Ascl1- or Dlx1- CreER drivers with a dual reporter, we have separately interrogated radial glia/apical progenitors (RGCs) and two types of intermediate/basal progenitor (IPC) within the MGE ($Nkx2.1^+/Asc1^+$ or $Nkx2.1^+/Dlx1^+$). This approach has revealed the birth pattern and progenitor origin of the laminar subtypes of ChCs, showing that unlike most MGE-derived interneurons, ChC production and laminar deployment do not follow an inside-out pattern: both L2 and L5/L6 ChCs are generated concurrently from mid- to late-gestation. Surprisingly, we found that $Ascl1^+$ RGCs are specified for production of L2 ChCs as early as E10, remaining latent for several days before completing the first wave of ChC neurogenesis (at ~E12). Subsequently, $Ascl1^-/Nkx2.1^+$ RGCs appear to produce the vast majority of L5 and L6 ChCs, while $Ascl1^+/Nkx2.1^+$ IPCs continue to produce L2 ChCs. Finally, at late embryonic timepoints, a pool of Ascl1+ intermediate progenitors becomes restricted for production of a burst of ChC between E16 and E18, which ultimately localize to all cortical layers and are particularly concentrated to medial prefrontal cortex. In contrast, $Nkx2.1^+/Dlx1^+$

IPCs generate few ChCs throughout the same period. Together these results implicate the role of fate-restricted progenitors in the generation of distinct cortical GABA interneurons.

Title: Study on lineage-specific gabaergic interneurons with brainbow vectors

Authors: ***M. WANG**, Y. H. FU, Y. C. YU;
Inst. of Brain Science, Fudan Univ., Shanghai, China

Abstract: Unlike simplex neocortical excitatory neurons, neocortical interneurons are various in types. Although the embryonic origins of diversity of interneurons have been examined in previous studies, little is known about the lineage development of interneurons at the single progenitor cell level, which would help explain the origin of multiple interneuron types. The traditional method to track lineage-specific neurons, low-titer injections of conditional reporter retroviral stocks, is hard to track single clone precisely or track different clones simultaneously. In order to solve the problem, we introduced a new method to label interneuron progenitors by electroporating the Brainbow vectors in Nkx2.1-creER mouse embryos. We found that the method help yield a sparse mosaic of color combinations in different clonal interneurons in MGE and POA of embryonic mice. Moreover, interneuron clones also could be identifiable on the basis of specific combinations of cytoplasmic and nuclear colors (up to 53 types) in adult stage, which make it more precise to label diversity of clones. In a word, it would be a great facility to study the clonal interneurons.

Title: T-box transcription factor Tbr2 controls multiple aspects of cortical projection neuron differentiation

Authors: *A. MIHALAS[1], R. DAZA[1], K. RAMOS[2], E. YOUNG[3], R. HEVNER[4];
[1]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., SEATTLE, WA; [2]Univ. of Washington, SEATTLE, WA; [3]Univ. of San Diego, San Diego, CA; [4]Ctr. for Integrative Brain Res., Seattle Children's Res. Institute; Univ. of Washington, SEATTLE, WA

Abstract: Cerebral cortex excitatory projection neurons are born from a common radial glial progenitor (RGP). RGPs produce neurons either directly, or indirectly, via intermediate progenitors (IPs), a process named indirect neurogenesis. IPs are thought to be essential for the evolutionary enlargement of the cortex in primates, where there is a great expansion of IP population. Tbr2 is a well-established marker for IPs. Tbr2-deficiency in humans is associated with developmental defects such as microcephaly, motor and cognitive delays. Initially, IPs were hypothesized to mainly produce late born, upper layer neurons. Consistent with this hypothesis, previous Tbr2-mutant models have shown reduced IPs, with a consequent decrease of upper layer projection neurons, but no detectable changes in deep layer neurons. Recent findings hint that IPs produce all cortical layer neurons. This study aims to clarify the laminar and molecular fate identity of IPs. Using a combination of Tbr2-CreER allele and Ai14-reporter we permanently labeled cohorts of IPs and their progeny systematically from the beginning until the end of neurogenesis (mouse embryonic day E11.5 to E16.5). Overall, our results indicate that IPs contribute to all layers and produce all types of cortical excitatory neurons, including Cajal-Retzius and subplate neurons. Unexpectedly, we find that IPs in the early cortex (E12.5) produce not only deep but also superficial layers, indicating that some early IPs are fated to undergo prolonged proliferation and produce upper layer neurons. Interestingly, laminar differentiation of Tbr2-deficient IPs is perturbed. In contrast to previous reports, we find increased abundance of IPs in Tbr2-mutant cortex; differentiation of these IPs is delayed and prolonged in the intermediate zone. The laminar cytoarchitecture of Tbr2-deficient cortex appears to be maintained, but contrary to previous reports, we find a large expansion of Ctip2+ layer 5, at the expense of Cux1+ upper and Tbr1+ deep layers. These changes in laminar identity are accompanied by severe dysregulation of molecular expression in Tbr2-deficient cortex, and are consistent with an initial burst of early-born cells, followed by a gradual decrease in mid and late-born cells in Tbr2-mutant cortex. Mechanistically, our data suggests that in the absence of Tbr2, IPs express aberrant levels of pro-IP transcription factors Pax6 and Insm1, and neuronal committed progenitor marker NeuroD, in an effort to compensate for the neuronal differentiation

defects. In all, our data provide support that Tbr2 is crucial for correct specification of laminar and molecular projection neuron identity in the cerebral cortex.

Title: Excessive Wnt/beta-catenin signaling promotes midbrain floor plate neurogenesis, but results in vacillating dopamine progenitors

Authors: *N. NOURI[1], M. PATEL[3], M. JOKSIMOVIC[4], J.-F. POULIN[1], A. ANDEREGG[1], M. M. TAKETO[5], Y.-C. MA[2], R. AWATRAMANI[1];

Abstract: The most debilitating motor symptoms of Parkinson's Disease (PD) result from the excessive loss of midbrain dopamine (mDA) neurons in the substantia nigra pars compacta, that transmit dopamine to the striatum. Recent protocols to convert human embryonic stem cells (hESC) or induced pluripotent stem cells (iPSC) to DA neurons have been generated for potential cell replacement therapeutics in PD patients and for PD modeling. However, further *in vivo* analysis of mDA specification is still needed to optimize these protocols for proper DA

neuron specification and differentiation. The floor plate (FP), a ventral midline structure of the developing neural tube, has differential neurogenic capabilities along the anterior-posterior axis. The midbrain FP, unlike the hindbrain and spinal cord floor plate, is highly neurogenic and produces mDA neurons. Canonical Wnt/beta-catenin signaling, at least in part, is thought to account for the difference in neurogenic capability. Removal of beta-catenin results in mDA progenitor specification defects as well as a profound reduction of neurogenesis. To examine the effects of excessive Wnt/beta-catenin signaling on mDA specification and neurogenesis, we have analyzed a model wherein beta-catenin is conditionally stabilized in the Shh+ domain. Here, we show that the Foxa2+/Lmx1a+ domain is extended rostrally in mutant embryos, suggesting that canonical Wnt/beta-catenin signaling can drive FP expansion along the rostrocaudal axis. Although excess canonical Wnt/beta-catenin signaling generally promotes neurogenesis at midbrain levels, less tyrosine hydroxylase (Th)+, mDA neurons are generated. This is likely because of improper progenitor specification. Excess canonical Wnt/beta-catenin signaling causes downregulation of net Lmx1b, Shh and Foxa2 levels in mDA progenitors. Moreover, these progenitors assume a mixed identity to that of Lmx1a+/Lmx1b+/Nkx6-1+/Neurog1+ progenitors. We also show by lineage tracing analysis that normally, Neurog1+ progenitors predominantly give rise to Pou4f1+ neurons, but not Th+ neurons. Accordingly, in the mutant embryos, Neurog1+ progenitors at the midline generate ectopic Pou4f1+ neurons at the expense of Th+ mDA neurons. Our study suggests that an optimal dose of Wnt/beta-catenin signaling is critical for proper establishment of the mDA progenitor character. Our findings will impact protocols that utilize Wnt pathway reagents to derive mDA neuron models and therapeutics for Parkinson's disease.

Abstract: The extensive neuronal diversity generated from neural stem cells in the mammalian CNS is an impressive feat of development, and also presents a significant challenge to dissect and understand. Ventral midbrain (vMB) dopaminergic neurons are a neuronal subtype that have been rigorously studied, strongly motivated by the interest in engineering stem cells into dopamine neurons for cell replacement in Parkinson's disease. However, classical approaches used to probe vMB neuron diversity and development are hampered by the presence of mixtures of different cell types and maturation stages in whole tissue dissections. To resolve this limitation, we have utilized single-cell RNA-sequencing to reconstruct the differentiation of neuronal lineages in the mouse vMB between embryonic day 10.5 and 13.5. Importantly, the analysis provided a robust genome-wide reconstruction of how neural stem cells expressing the transcription factor Lmx1a transition into postmitotic differentiating neurons. This approach also allowed rapid, comprehensive and unbiased identification of robust gene signatures represented in Lmx1a-expressing neuronal lineages. *In vivo* validation of one such signature has uncovered an unexpected similarity between developing dopaminergic neurons, and more rostrally developing glutamatergic neurons of the Subthalamic Nucleus. Single-cell RNA-seq thus proves an invaluable technique in successfully interrogating lineage diversity in the developing CNS.

Title: Role of retinoic acid receptor beta in development and homeostasis of mouse striatum

Authors: *W. KREZEL, M. RATAJ-BANIOWSKA, A. NIEWIADOMSKA-CIMICKA, A. PODLESNY-DRABINIOK, T. YE, D. DEMBELE, P. DOLLÉ;
IGBMC, ILLKIRCH, France

Abstract: Over the recent decade, retinoid signaling emerged as an important regulator of development and functions of the basal ganglia (Krezel et al. 1999; Maden 2001; Liao et al. 2005; Krzyzosiak et al. 2010), but to date little is known about the mechanisms underlying such activities, namely its genomic targets and the neuroanatomical pathways (striatonigral and/or striatopallidal output pathways) it may regulate. Signaling by retinoic acid (RA), an oxidative derivative and active form of vitamin A (retinol), is mediated by binding to RA receptors (RARα, β, γ), which form heterodimers with retinoid X receptors (RXRα, β, γ) and act as ligand-controlled transcription factors. Several lines of evidence indicate that RA is particularly important for striatal functions and pathology. Among different brain regions, the adult rodent striatum contains some of the highest levels of RA (Kane et al. 2005). The striatum is also a site of strong expression of two retinoid receptors, RARβ and RXRγ (Zetterstrom et al. 1994; Krezel et al. 1999). Genetic ablation of RARβ and/or RXRγ leads to abnormal striatal functions, revealed by deficits in motor coordination and depressive-like behaviors (Krezel et al. 1998; Krzyzosiak et al. 2010). Whereas some of these phenotypic abnormalities may have a developmental origin, post-natal (physiological) functions of these receptors have also been demonstrated (Krzyzosiak et al. 2010; Wietrzych-Schindler et al. 2011). We will present data from mice carrying null mutation of RARb receptor supporting role of RARb in control of development of striatonigral dopaminergic pathway through mechniams which may involve FGF and MEIS signaling. Deficits in the number of DRD1-positive striatonigral neurons may result from premature differentiation of progenitor cells, leading also to an overall reduction of proliferation index reported also previously by Liao and colleagues (Liao et al. 2005). In addition to its prenatal functions, RARb may also control a number of cell functions in the striatum as indicated by ChIP-seq, genome-wide identification of RARb binding sites and transcriptomic analyses of RARb-null mutant striatum, which will be presented. Such regulations may have direct relevance for pathophysiology of Huntington's disease.

Abstract: Developmental neurobiologists have defined how patterns of cell divisions in the ventricular zone change over time and how they help to specify the fate of daughter cells. So far, however, what factors control the number of cells that are generated remains a mystery. For any given lineage of cells, this numerical control could be intrinsic to the lineage itself or extrinsic (influenced by cells from other lineages). Early studies of mouse aggregation chimeras suggested a prominent role for intrinsic, lineage-autonomous regulation. The suggestion was that a small number of progenitor cells, selected early in development, serve as the sole source of an entire neuronal population (e.g., Purkinje cells, or facial nucleus neurons). A key feature of the model is that these progenitors, once specified, each go through the same specific number of cell divisions thus producing a quantum of cells. This hypothesis predicts that in normal wild type mice, quantitative variations in the determination of the number of the early progenitors should lead to large quantal variations in the total number of descendent cells. Thus, counts performed in a large enough number of brains should reveal a distribution that is not Gaussian, but rather multimodal, with each mode representing the addition or subtraction of a single quantum of cells. We report here that this prediction is born out. Using the isotropic fractionator to achieve high-throughput and quantitative reproducibility, we have counted the number of cells in 174 half cerebella from 47 males and 46 female C57BL/6J adult animals of similar age. The total number of cells in each hemisphere exhibits a multimodal distribution with peaks at 25, 28 and 31 million cells - consistent with the formation of each cerebellar half by 8, 9 or 10 quanta of slightly more than 3 million cells. We find no significant correlation between the numbers of cells in the left and right halves of the cerebellum across animals, which confirms earlier predictions that the progenitors of the left and right sides are specified independently. There is a significant bias towards a larger number of progenitors on the left side, and we observed a modest, but not significant ($p = 0.0686$) sexual dimorphism. In males the distribution is skewed towards the peaks at 28 and 31 million cells but towards the peaks at 25 and 28 million cells in females. The data confirm that the control of cell number in the mammalian CNS relies heavily

on intrinsic, lineage-based mechanisms. The use of genetically inbred, but otherwise normal animals to conduct this analysis allows the analysis of cells in a wide range of different brain regions.

Title: Role of intermediate progenitors in the specification of cortical pyramidal neuron subtypes

Authors: ***J. M. LEVINE**[1,2,3], D. HUILGOL[1], Z. HUANG[1];
[1]Cold Spring Harbor Lab., Cold Spring Harbor, NY; [2]Neurobio. and Behavior, [3]Med. Scientist Training Program, Stony Brook Univ., Stony Brook, NY

Abstract: Pyramidal neurons (PyNs) comprise ~80% of cortical neurons, constituting a myriad of inter-areal processing streams and cortical output channels. The progenitor cells that give rise to PyNs mainly include radial glial cells (RGCs) and intermediate progenitor cells (IPCs) located in the embryonic cerebral ventricle wall. RGCs divide asymmetrically to generate neurons either directly or indirectly through IPCs, which divide symmetrically to produce pairs of PyNs. It remains unclear how progenitor types (e.g. RGCs, IPCs), their lineage progression, and timing of neurogenesis contribute to the specification of diverse PyN subtypes, as defined by axon projection. In particular, the role of IPCs in the generation of PyNs is poorly understood. We have generated an inducible Cre mouse driver line, which allows comprehensive lineage tracing from IPCs. We have further developed a novel genetic method to fate map neurons according to their birth time. We are fate mapping IPC-derived PyNs throughout embryogenesis. In addition to assessing the laminar position of PyN subtypes, axon projections are analyzed with viral labeling of fate-mapped PyNs. Our latest results will be presented.

Title: GFAP+ and Oct4+ neural stem cells give rise to distinct neural progenitor cells in the perinatal mouse brain

Authors: *S. YAMMINE[1], J. GOSIO[2], D. VAN DER KOOY[1];
[1]Mol. Genet., [2]Human Biol., Univ. of Toronto, Toronto, ON, Canada

Abstract: There are at least two distinct types of neural stem cells (NSCs) in the developing mouse embryo that generate the diversity of neural progenitor cells (NPCs) that build the brain. Primitive NSCs form clonogenic neurospheres when grown in LIF and persist into the adult brain, where we have shown they express the pluripotency gene *Oct4* and give rise to the $GFAP^+$ definitive NSCs that form neurospheres in EGF and FGF2. We used the neurosphere assay *in vitro* to enrich for progenitor cells downstream either NSC type to characterize the functional differences between these two NSC populations. Here we show both NSCs derived from the E17.5 mouse brain give rise to many NPCs that are bipotent in the neuronal and glial lineages, though primitive NSCs give rise to more neuron-only NPCs and definitive NSCs give rise to many astrocyte-only NPCs. Most interesting, progenitor cells from either NSC that gave rise to both lineages generated significantly more progeny than those committed to either glial or neuronal fates. As primitive NSCs can give rise to definitive NSCs as well as neurons and glia, we asked whether primitive NSCs directly produce neurons and glia without a definitive NSC intermediate step. To test this, we grew spheres from early postnatal mice with herpes simplex virus thymidine kinase expression driven by the *GFAP* promoter, which causes *GFAP*-expressing cells (ie. definitive NSCs) to be killed upon division following administration of ganciclovir *in vitro*. There is a significant reduction in the number of neurospheres that form in EGF and FGF2 from definitive NSCs from the subependymal zone of early post-natal mice with this kill of *GFAP*-expressing cells, as expected. Results show primitive NSCs from these mice where *GFAP*-expressing cells were killed could still form $GFAP^+$ astrocytes, however the number of $BIII^+$ neurons was reduced. This suggests that astrocytes can be formed from progenitor cells that do not upregulate *GFAP* expression until after they are post-mitotic, and that neurons are made from mitotically active *GFAP*-expressing progenitors. By combining these data, we construct novel lineages for progenitor cells downstream primitive and definitive NSCs.

Title: Single-cell and bulk RNA-Seq reveal distinct cell states within the oligodendrocyte lineage in the mouse brain

Authors: *G. CASTELO-BRANCO[1], S. MARQUES[1], A. ZEISEL[1], D. VANICHKINA[2], S. SAMUDYATA[1], A. MUNOZ MANCHADO[1], R. TAFT[2], J. HJERLING-LEFFLER[1], S. LINNARSSON[1];

Abstract: Oligodendrocytes are glial cells that mediate myelination of neurons, a process that allows efficient electrical impulse transmission in the central nervous system. An autoimmune response against myelin triggers demyelination in multiple sclerosis (MS). Oligodendrocyte precursor cells (OPCs) can initially differentiate and promote remyelination in MS, but this process eventually fails in progressive MS. OPCs go through several cell states during development and disease, that ultimately define their potential to differentiate and myelinate. In order to clearly define distinct epigenetic states of OPCs and other oligodendrocyte lineage cells during development, we have performed single-cell and bulk RNA sequencing of cells of the oligodendrocyte lineage from mouse brain. We have found that FACS-sorted OPCs isolated from different locations in the central nervous system and developmental stages have distinct transcriptional profiles. Furthermore, by single-cell RNA-Seq of cells of the oligodendrocyte

lineage, we identified several sub-populations of cells, representing unique stages during the process of differentiation and myelination. We have further identified non-coding RNAs that are uniquely expressed in these distinct populations of the oligodendrocyte lineage. We are currently investigating if these non-coding RNAs play important roles in OPC differentiation and myelination.

Title: Neurotrophic factor-α1 (NF-α1): A key factor for down-regulating neural stem cell proliferation and promoting differentiation to astrocytes

Authors: *P. SELVARAJ[1], S. MURTHY[1], C. LEE[1], M. LANE[2], N. CAWLEY[1], I. MERCHENTHALER[2], S. AHN[1], P. LOH[1];
[1]Section of Cell. Neurobio., NICHD-NIH, Bethesda, MD; [2]Univ. of Maryland, Baltimore, MD

Abstract: Neurotrophic factor-α1 is a new neurotrophic factor shown to promote survival of embryonic hippocampal neurons. Our qRT-PCR (N=3) and *in situ* hybridization studies showed that NF-α1 mRNA is detectable as early as E5.5 in mouse embryos and increased significantly (p=0.01) in the brain from E10.5 to adulthood. Addition of recombinant NF-α1 (200nM) to E13.5 neocortex-derived neurospheres containing stem cells (5d culture), grown in the presence of FGF2 and EGF, reduced proliferation of the neurospheres by 37% (N=4; p=0.02). Since NF-α1 interacts with Wnt3a ligand binding receptor (Frizzled) and negatively regulates β-Catenin expression, we investigated whether β-Catenin and its downstream molecules known to regulate cell proliferation are involved. We found a 30% decrease in β-Catenin (N=3; p=0.01), 50-60%, decrease in Hes1 (N=3; p=0.01), and no change in CyclinD1 (N=3) protein levels in NF-α1 treated neurospheres compared to control, indicating that NF-α1 negatively regulates cell proliferation in neurospheres via Wnt signaling. Further, to assess the role of NF-α1 in neural

stem cell (NSC) differentiation, neurospheres from 7d cultures were dissociated and grown for 5d in the presence of NF-α1 and 1% FBS. Immunocytochemical analysis of differentiated cells labeled with specific antibodies against neurons (Tuj-1), astrocytes (anti-GFAP) and oligodendrocytes (anti-CNPase) showed a 17% (N=3; p=0.04) increase in GFAP+ in the presence of NF-α1, without altering the % of Tuj-1+ and CNPase + populations. Double immunostaining against nestin (anti-nestin) and astrocytes revealed increase of the GFAP+ population upon NF-α1 treatment comes from GFAP+ cells alone and not from intermediate glia population (GFAP+ nestin+, N=3; p=0.03). NF-α1-knockout & NF-α1-Wild type embryos were generated and their differentiation profile was checked. NF-α1-KO cells showed decrease in 15% GFAP+ cells (N=3; p=0.001) and increase in 18% Tuj-1+ cells (N=3; p=0.001), whereas it is opposite when compared to NF-α1-WT controls. This difference was rescued in NF-α1-KO cultures upon NF-α1 treatment. We also found NF-α1 significantly increased (N=3; p=0.01) phospho-ERK signaling and the downstream molecule Sox9 protein levels (N=3; p=0.01) which has been shown to be involved in astrocyte differentiation. Thus, we have uncovered an important factor, NF-α1 that modulates NSC differentiation into astrocytes.

Title: Exosomes derived from cerebral endothelial cells locally promote distal axonal growth

Authors: *Y. ZHANG[1], M. CHOPP[1,2], C. LI[1], X. LIU[1], X. WANG[1], L. ZHANG[1], Z. ZHANG[1]; [1]Neurol. Res., HENRY FORD HOSPITAL, Detroit, MI; [2]Dept. of Physics, OAKLAND UNIVERSITY, Rochester, MI

Abstract: Stroke induced angiogenesis promotes neuronal remodeling, and mechanisms underlying this neurovascular coupling have not been extensively studied. Exosomes are microvesicles which carry biological materials including RNAs and proteins, and play a pivotal role in the cell-cell communication. In the present study, we tested the hypothesis that exosomes derived from cerebral endothelial cells (CECs) promote distal axonal growth of cortical neurons.

Embryonic cortical neurons were cultured in a microfluidic culture device which separates somata and axons. Exosomes (3x107particles/ml) derived from primary cultured CECs of non-ischemic and ischemic rats were applied into the axonal compartment. During the 3 day culture, exosomes derived from non-ischemic CECs significantly increased distal axonal growth (24h, 528±24 μm; 48h 793±19 μm; 72h 1078±35 μm; $p<0.001$, n=3), compared to the axons of the non-exosome treatment group (24h, 378±10 μm; 48h, 567±14 μm; 72h 915±20 μm). Moreover, exosomes from ischemic CECs further increased axonal growth (24h, 611±23 μm; 48h 982±24 μm $p<0.001$, n=3) compared to exosomes from non-ischemic CECs. Confocal microscopic analysis showed that exosomes labeled with fluorescent siRNA internalized into the distal axons. Blockage of endocytosis with botulinum neurotoxin types A (BoNT/A) completely abolished exosome internalization and suppressed exosome-promoted axonal elongation, but did not induce cell death. We then examined whether internalized exosomes altered axonal miRNA profiles. Using miRNA PCR array, we found that exosomes contained abundant miRNAs and that 24 miRNAs in exosomes from ischemic CECs were significantly increased compared to exosomes from non-ischemic CECs. In the distal axons treated with exosomes from ischemic CECs, we detected significant increases in 8 out of these 24 miRNAs. One of the 8 increased miRNAs in the axon was miR-27a. Western blot analysis showed that Sema6A, one of verified targets of miR-27a, was significantly decreased in the axon treated with exosomes from ischemic CECs (0.3±0.1 vs 1 in exosomes from non-ischemic CECs, $p<0.05$, n=3). Using gain- and loss-of-function approach, we found that elevation and reduction of miR-27a in the distal axon by miR-27a mimics and inhibitors, respectively, increased and decreased axonal growth. Collectively, our data indicate that exosomes from CECs in particular from ischemic CECs robustly promote axonal growth, that the endocytosis process likely mediates exosomes internalization, and that miR-27a along with other miRNAs transferred by exosomes interact with their targets in the axons, leading to enhancement of axonal growth.

Title: Expression pattern of guidance cues and extracellular matrix molecules in the prosomere 1 during posterior commissure development

Authors: *K. STANIC[1], N. SALDIVIA[1], M. GONZALEZ[1], B. FÖRSTERA[3], J. R. BENITEZ[2], H. MONTECINOS[1], T. CAPRILE[1];
[1]Axon Guidance Lab., [2]Enzymology Lab., Univ. De Concepcion, Concepcion, Chile; [3]Dept. of Physiol., Univ. de Concepcion, Concepcion, Chile

Abstract: During development of the central nervous system (CNS) it is crucial for the axons of projecting neurons to reach their target structures. The successful establishment of these connections is pivotal for any process that involve more than one area of the CNS and disruption of these pathways can cause substantial impairments in brain structure and functionality leading to congenital disorders, such as holoprosencephaly, horizontal gaze palsy, congenital mirror movements and congenital fibrosis of the extraocular muscles, among others. The mechanisms which lead to these disorders are still poorly understood how ever it is known that in most of these cases axon guidance molecules are involved. Furthermore, these mechanisms could also be important to aim regeneration therapies after nerve injury in the future. Controlled spatio-temporal expression of guidance molecules during development of the CNS is essential for the ability of growing axons to reach their proper targets. Never the less guidance cues are not sufficient to achieve this process. For a long time extracellular matrix molecules (ECM) have not gained much attention, however resent findings support the idea that they have a pivotal role during axon guidance. This work provides important information regarding possible molecular pathways that pretectal axons from the prosomere 1 follow along basal-alar plate in order to reach the CNS midline and which molecules might be helping in their decision to cross to the contralateral side in the diencephalic roof plate area, leading to the formation of the posterior commissure (PC). All experiments where performed in chick embryos and different stages of development where investigated. Patterning analysis was held by immunohistochemical techniques for the following molecules: SCO-spondin, EphA7, Tenascin, Laminin, Chondroitin sulphate, Osteopontin, HNK-1 and Fibronectin in the PC region. Transcript analysis was carried out for EphA7 by *in situ* hibrydization as well as RT-PCR for different sets of EphA-EprhinsA family members. To identify axonal receptors that bind to these molecules we performed immunocytochemistry in primary culture of pretectal neurons. The results of this study draw a map of the investigated molecules in the prosomere 1 letting us know the molecular expression pattern related with pretectal axons route, and provides important data to elucidate possible mechanisms of how this process occurs. The understanding of how guidance cues act under different environments can contribute to ultimately develop more concrete tools for axon regeneration.

Abstract: Neuropathic pain is caused by primary lesions, dysfunction, or transient perturbation in the peripheral or central nervous system. Neuropathic pain is often chronic and analgesic agents are often used for treatment. Lidocaine relieves a variety of neuropathic pains but is reported to have neurotoxic effects. Neurotropin is an analgesic agent used for the treatment of various chronic pains and neuropathic pains. We hypothesized that neurotropin can provide neuroprotection and prevent neurotoxicity. To test our hypothesis, we examined the effects of neurotropin and lidocaine on neurite growth in cultured rat spinal neurons and how neurotropin interacts on lidocaine-induced neurotoxicity. Spinal neurons were identified by neurofilaments immunostaining and the length of the individual neurites of the neurons was measured using NIH Image software on the captured images. Neurotropin alone had no effect on neurite growth, whereas it protected against lidocaine-induced suppression of neurite growth in spinal neurons. These results suggested that neurotropin can protect against lidocaine-induced neurotoxicity.

Title: Development of an automated growth cone collapse assay

Authors: *P. JOYCE[1], M. MANGAN[1], A. CURNOCK[1], S. MEISLER[2];
[1]Vertex Pharmaceuticals (Europe) Ltd, Abingdon, United Kingdom; [2]Vertex Pharmaceuticals Inc., Boston, MA

Abstract: Analysis of growth cone dynamics has proved to be invaluable tool for the identification of axonal repellent components, leading to an extensive understanding of axonal guidance pathways in neuronal development and repair. Compounds that are able to preserve growth cones and promote axonal growth have been proposed as therapeutics for a number of neurological diseases. Growth cone collapse assays are associated with labour intensive, manual image capture and analysis. Consequently, they are useful for identifying compounds that influence growth cone morphology but lack the throughput required to support drug discovery. A reproducible growth cone collapse assay that is amenable to compound screening is therefore highly desirable. We have developed an automated growth cone collapse assay, which includes robotic and reproducible neuron plating in 96 well plates, automated image capture and tailored image analysis of growth cones. The assay was developed using primary rodent motor neurons but is adaptable to other neuronal cell types, and is responsive to multiple axonal repellent molecules. Importantly, the assay provides a quantitative measure of compound potency for inhibition of axonal repellent driven growth cone collapse.

Title: Nerve growth factor (NGF) facilitates innervation of perivascular nerves in tumor neovasculatures of mouse corneal

Authors: *H. KAWASAKI[1], S. TAKATORI[2], Y. SONE[3], E. OCHI[3], A. MATSUYAMA[3], M. GODA[3];
[1]Departmen of Clin. Pharm., Matsuyama, Ehime, Japan; [2]Departmen of Clin. Pharmacy, Matsuyama Univ., Matsuyama, Ehime, Japan; [3]Dept. of Clin. Pharmaceut. Sci., Grad Sch. Med. Dent. Pharm Okayama Univ., Okayama city, Okayama, Japan

Abstract: Background: The vascular tone and tissue blood flow are maintained and regulated by perivascular nerves. However, many studies have reported that tumor neovascular vessels have no innervation of perivascular nerves. We have shown that nerve growth factor (NGF) facilitated perivascular innervation and suppressed the tumor growth (1). From these results, we hypothesized that the neuronal regulation of blood flow toward tumors via perivascular nerves may lead suppression of the tumor growth. Therefore, the aim of this study is to investigate effect of NGF on distribution of perivascular nerves and neovessel form in tumor tissues, which were generated by mouse corneal micropocket method. Methods: Under pentobarbital anesthesia, a small incision was made in the center of eye ball. A gel, which contained DU145 prostate carcinoma cells or HT 1080 fibrosarcoma cells, was implanted into the mouse corneal micropocket. NGF or saline was subcutaneously administered using an osmotic mini-pump implanted the dorsal area. After 1 week, the distribution of perivascular nerves in mouse corneal were immunohistochemically studied. Also, the density of neovessels (immunocytochemically stained CD31) and smooth muscles (α-smooth muscle actin; SMA) in tumor tissues was quantified by the computer-assisted image processing. Results: Four days after implantation of tumor cells in mouse corneal, many neovessels generated from corneal limbal vessels were observed in DU145 and HT1080 tumor tissues. The bleedings around DU145 and HT1080 tumor tissues were observed in saline-treated control, while no bleeding was not found in tumor tissues of NGF-treated corneal. Treatment of mouse with NGF resulted in innervation of perivascular nerves around tumor neovessels, but not observed in saline-treated group. NGF treatment caused significant increase in SMA-, but not CD31-, immunopositive cells. Conclusion: These results suggest that NGF may facilitate innervations of perivascular nerve to regulate the blood flow in tumor neovessels. Title: Semaphorin 3C released by a biocompatible hydrogel guides and promotes axonal growth of rodent and human dopaminergic neurons

Authors: *O. A. CARBALLO MOLINA[1], A. SÁNCHEZ-NAVARRO[1], A. LÓPEZ-ORNELAS[1], A. CAMPOS-ROMO[2], I. VELASCO[1];
[1]UNAM, Distrito Federal, Mexico; [2]Periférica de Neurociencias de la Facultad de Medicina - UNAM en el Inst. Nacional de Neurología y Neurocirugía, Distrito Federal, Mexico

Abstract: The restoration of dopaminergic circuits could increase the effectiveness of the cell replacement therapy in Parkinson Disease (PD), in which dopamine neurons die. To achieve this goal, guidance of dopaminergic axonal (DAx) growth is desirable. Semaphorin 3C (Sema3C) is a molecule that participates in the formation of dopaminergic circuits during development. Sema3C attracts and causes enhanced DAx growth of rodent cells both *in vitro* and *in vivo*. In this work we used Puramatrix, a polypeptide hydrogel (Hyd) that polymerize at physiological ionic concentration and is compatible with the nervous tissue, as a protein carrier for Sema3C. We found that this Hyd is able to incorporate Sema3C and release it to the medium, after quantification by ELISA. We evaluated if Sema3C delivery by Hyd attracts DAx growth: cultured midbrain explants (MbE) of rat embryos were placed into collagen gel matrices, to allow axonal growth in all directions. MbE were placed close to explants of pretectum (PT), which is known to exert an attractive effect over DAx growth. In parallel experiments, MbE were exposed to Hyd coupled to Sema3C. We found that Sema3C released by Hyd induced an attractive effect over DAx growth similar to the PT explants, which was not observed with Hyd containing a control protein. To quantify the attractive effects, we used an index that was obtained by dividing the average DAx length of the proximal by the distal growth. We also analyzed if Sema3C released by Hyd was able to promote DAx growth using microfluidic devices, using cultured dissociated rat dopaminergic neurons or dopaminergic neurons differentiated from human embryonic stem cells. These devices contain microgrooves that are transversed by the growing axons in a linear trajectory, making easy to measure axonal length. The DAx growth of both rat and human dopamine neurons increased in response to soluble Sema3C, and also to Sema3C released by the Hyd. These results show that this Hyd is able to incorporate and release Sema3C, and such delivery guides and promotes DAx growth. This delivery system might be used as a Sema3C carrier for *in vivo* studies in PD animal models.

Title: Reaching new distances: extending neuronal regeneration with nanogrooves

Authors: *M. FORNARO[1], C. SIGERSON[1], H. SHARTHIYA[1], C. DIPOLLINA[2], D. GIAMBALVO[2], J. GASIOROWSKI[2];
[1]Dept of Anat., [2]Biomed. Sci., Midwestern Univ., Downers Grove, IL

Abstract: Peripheral nerve damage is a common result of many injuries and disease states. While the peripheral nervous system regenerates spontaneously, the extent to which it does is often insufficient to fully restore function. Such a loss can have a severe impact on quality of life for many patients. There is a great deal of research in increasing axonal growth using biochemical growth factors. While these growth factors may increase axonal development, it is often uncontrolled and random in direction. Such growth is inefficient in delivery of neurites to more distant structures. Therefore, the aim of this study is to control the direction of axonal growth using nano- to micron scale grooves as topographical cues. We believe organized and direct axonal growth will increase the effective reach of these neurites and could lead to a more functional recovery. Our hypothesis is that axons will use the biophysical signals as a guide and propagate parallel to them which will lead to a longer effective axonal length. For the purposes of this study, we used *ex vivo* explants of mouse dorsal root ganglia (DRGs) as our experimental model. Cervical and thoracic DRGs were harvested and cultured on varying sizes of anisotropic grooves. Three groove widths were tested: 200nm, 400nm, 700nm, and 2,000nm. A chemically identical flat surface was used as a control. All groups were maintained in Serum Free Medium (SFM) with 5ng/mL Nerve Growth Factor (NGF) for 6 days. They were then fixed, immunolabeled, and visualized using fluorescent confocal microscopy. Imaging and analysis demonstrated that axons align and grow in a linear fashion along the 700 and 2,000 nm grooves significantly more than the control. No significant difference was seen for the 200nm and 400nm grooves. This manner of direct propagation also significantly extended the average radius of growth of the axons in the 700 and 2,000 nm groups with a 50% increase in the average effective axonal length seen in the 700 nm group over the control. In conclusion, these results may translationally be applied toward novel treatments to directionally enhance spontaneous nerve regeneration across distances greater than those which occur naturally.

Title: Reelin control of retina ganglion cells synaptic lamination

Authors: ***F. DEL BENE**[1], T. O. AUER[1], N. TESTA[1], J.-P. CONCORDET[2], V. DI DONATO[1]; [1]Inst. Curie - Ctr. de Recherche, Paris, France; [2]INSERM U1154, CNRS UMR7196, MNHN USM503, Muséum Natl. d'Histoire Naturelle, Paris, France

Abstract: Neuronal connections in the retina as well as in the retino-recipient nuclei are arranged in layers. Understanding the basis of class-specific targeting of axons to appropriate regions of the brain is critical to gain deeper insights on how complex neural networks form. In the retino-tectal circuit of zebrafish larval brain, the retinal ganglion cells (RGCs) convey the visual information projecting their axons to different layers in the optic tectum (OT). We found that a specific type of inhibitory interneurons, the Superficial Inhibitory Neurons (SINs), located at the surface of the tectal neuropil, express the extracellular matrix protein Reelin. During the development of the central nervous system (CNS), the secreted Reelin controls the migration and laminar arrangement of neurons in various structures including the neocortex, hippocampus, cerebellum and spinal cord. In mammalian visual system few studies have addressed its role in axonal targeting. Here, we show that a gradient of Reelin is established along the neuropil, likely due to secretion by the SINs. TALENs- and CRISPRs-mediated gene disruption for reelin and dab1 (the intracellular mediator of the signaling pathway) revealed aberrant layering of RGCs axons without affecting the overall retino-tectal projection pattern. Furthermore, transplantation experiments of wild type RGCs into a reelin mutant genetic background indicates that Reelin acts non cell-autonomously to ensure proper axonal lamination. Finally, we show that the signaling cascade in the OT might be driven by the very-low-density lipoprotein receptor (VLDLR). In fact, we demonstrated that VLDLR is the only described canonical Reelin receptor expressed in the ganglion cell layer of the zebrafish retina and we show that it is transported anterogradely to the axonal branches. All together our findings elucidate a new role for the Reelin pathway in vertebrate visual system development, during which it acts as molecular cue

by imparting lamina-specific positional information on the ingrowing axons of retinal ganglion cells.

Abstract: Engineered 3D microenvironments are enabling the creation of designer neuronal networks that approximate the geometry of neuronal tissues. Here we use 3D alginate hydrogels functionalized with RGD (Arginine-Glutamate-Aspartate) peptides to direct the growth of neuronal processes and shape the formation of the developing networks. Through a glacier-moraine process of freezing-drying poly-lactic-co-glycolic acid (PLGA) microparticles, random and uniaxially aligned porous microchannels were created within the gels (Lee et al., Adv. Healthc. Mat., 2015). We grew early postnatal neurons from rat hippocampal and also adult rat dorsal root ganglion (DRG) neurons in these gels. Neurite processes were significantly more directed on the uniaxially aligned hydrogels compared to those grown in the random-pored gels. Using immunofluorescence imaging, we found that the morphologies of the neuronal networks grown in the uniaxial gels from hippocampal and DRG neurons are very similar to laminar neurite alignments in the CA1 region of the hippocampus as well as in nerves extending from

DRGs, respectively. To examine the functionality of the neuronal network, we used fluo-4 to monitor the intracellular Ca2+ dynamics in the neurons. After stimulating the non-conductive gel locally using a tungsten microelectrode, we observed sharp Ca2+ fluxes in the adjacent and downstream cells. This indicates that there was robust activation and communication between neurons within the hydrogel. Additionally, we measured the local field potential of the neuronal network within the gels and found activity characteristic of a communicating network. This study demonstrates the efficacy of porous 3D alginate hydrogels as scaffolds for developing neurons. Controlled growth of neurite processes using this scaffolding will be useful to better understand and direct cellular emergent behavior in differentiating and regenerating neurons.

Abstract: Substrate stiffness is an important mechanical cue affecting neuronal development and regeneration. Neurons of dorsal root ganglion (DRG) have been indicated owning potential to sense different rigidity of environment since peripheral nervous system is supported by a variety of tissue. Few investigations, however, have been conducted on the mechanism how peripheral neurons sense environmental rigidity. In this study, we applied polydimethylsiloxane with various types of stiffness responding to different tissue elasticity as culture substrates, and established the relationship between the substrate rigidity and the outgrowth pattern of DRG neurons. The results, similar to the phenomena in spinal cord, showed that neurite developed enriched branches on soft material. Furthermore, we found advillin, as a sensory neuron-specific and actin binding protein, regulated neurite processing in N2a cells, affected the morphology of growth cone and promoted the neurite branching in cultured DRG neurons. Proteomic approach

indicated advillin interacted with non-muscle myosin IIa and IIb, which have been reported modulating dynamics of growth cones and rigidity sensing. The subcellular distribution in growth cones revealed the interaction between advillin and myosin IIa/b affected by substrate stiffness. These observations implied that interaction of advillin and myosin II contributed to neurite outgrowth via mechanotransduction. Our work discovered the importance of actin-regulating protein on neuronal navigation on substrates with different elasticity, and could benefit future studies on neural tissue engineering.

Title: Slit-roundabout signaling during post optic commissure formation in zebrafish forebrain development

Authors: *N. E. WREN[1], J. M. SCHNABL[2], B. EDENS[1], E. DESCHENE[1], J. PARK[1], A. ANTOINE[1], K. ALLIGOOD[1], M. HARDY[1], C.-B. CHEN[3], M. J. F. BARRESI[1];

Abstract: During embryonic development, neurons send pioneering axons to make necessary connections, and establish the fundamental circuitry of the brain. With the help of environmental guidance cues, these axons navigate vast distances to reach and form synapses with target neurons. To connect both hemispheres of the brain, pathfinding axons lay the groundwork for the formation of commissures, tight bundles of axons that cross the midline of the brain. A substrate of astroglia cells, characterized as an ‘astroglial bridge’ in the zebrafish forebrain, provides adhesive support and directional guidance for midline crossing axons of the Post-optic commissure (POC). At the midline, axons are guided in part by Slits, extracellular signaling molecules, and their receptor, Roundabout, which is expressed at the growth cone of extending axons. In bilateral animals *slit* is known to act as an axon repellant, and prevent axons from wandering into regions of the brain they are not intended occupy. Preliminary data in the Barresi laboratory has suggested a previously uncharacterized role for Slit1a to positively mediate

growth-promoting interactions between axons and astroglia. To investigate this role, the Barresi laboratory uses a *gli2DR* (*you-too, yot*) zebrafish mutant that results in the loss of POC formation due to the expansion and upregulation of *slit2* and *slit3* expression and coincident downregulation of *slit1a*. In order to rescue POC commissure formation in *yot*, a transgenic heatshock promoter line [*tg(hsp70:slit1a-mCherry); yot*] was generated to return *slit1a* to the system. Transplants of gastrula stage *tg(hsp70:slit1a-mCherry* into the telencephalon of wild-type gastrula stage embryos were also used to assess the effect of local *slit1a* misexpression on POC axons. Additionally, hypothetical Roundabout mutants (*robo1 and robo4)* have been generated to investigate their roles as potential receptors for *slit1a*. Using Geographic Information System (GIS) spatial analysis tools, the Barresi laboratory further aims to more objectively define biological phenomena, including the characterization POC phenotypes. GIS tools are being used to calculate mean fluorescence values to determine spatial patterns, establish statistical significance of fluorescence clustering, calculate average axon movement to assess wandering or defasciculation of the POC, and measure sizes of anatomical structures in the forebrain. These tools will help further evaluate effects of Slit-Robo signaling on POC formation.

Title: Schwann cell-derived exosomes enhance neurite extension of adult sensory neurons via modulation of axonal guidance pathways

Authors: *F. PICOU[1], B. DIAZ[1], D. DIAZ DOMINGUEZ[2], P. MANQUE[2], F. A. COURT[1]; [1]Pontifical Univ. Catolica De Chile, Santiago, Chile; [2]Ctr. de Genómica y Bioinformática, Univ. Mayor, Santiago, Chile

Abstract: Nervous system function relies on the coordinated action of neurons and glial cells. Phenomena like synaptic activity, conduction of action potentials or axonal growth, to name a few, are fine tuned by glial cells. The mechanistic basis of glial cell-neuron communication is only partially understood. Recently, horizontal transfer between cells of proteins, lipids and nucleic acids through exosomes (40-100 nm vesicles) has been described. Our lab found that exosomes secreted by Schwann Cells (SC, peripheral nervous system glial cells) are able to increase neurite extension of embryonic dorsal root ganglion (DRG) sensory neurons *in vitro* and *in vivo*. We used purified primary SC culture and adult DRG neurons, SC-exosome function was studied using biochemistry and microscopy. Exosome RNA content was identified by next generation sequencing and qPCR. Bioinformatic analysis (IPA analysis) was used for network reconstruction and miRNA target gene prediction. SC-derived exosomes increase neurite extension in adult DRGs after 24 and 48 hours *in vitro*. Next generation sequencing of neuronal samples highlights an important modulation of axon guidance pathway in exosome-treated neurons. We also describe that SC-derived exosomes partially mimics a sciatic nerve conditioning lesion, a well-described paradigm to enhance neurite extension of adult DRG *in vitro*. Moreover, only few mRNA and miRNA carried by SC exosomes are able to efficiently modulate this axonal guidance pathways. Our results suggest that SC-derived exosomes tpartially recapitulates conditioning lesion effect on neuronal cells *in vitro* at the morphological and transcriptomic level. The underlying mechanism by which SC exosomes contribute to neurite outgrowth is a promising strategy to enhance axonal regeneration in both central and peripheral nervous systems.

Title: Nerve Growth Factor regulates TRPV2 via ERK signaling to enhance neurite outgrowth

Authors: *V. Y. MOISEENKOVA-BELL, M. R. COHEN, W. M. JOHNSON, J. M. PILAT, J. KISELAR, A. DEFRANCESCO-LISOWITZ, R. ZIGMOND;
Dept. of Pharmacol., Case Western Reserve Univ., Cleveland, OH

Abstract: Neurite outgrowth is key to formation of functional circuits during neuronal development. Neurotrophins including nerve growth factor (NGF) increase neurite outgrowth in part by altering the function and expression of Ca2+-permeable cation channels. Here we report that TRPV2 is an endosomal Ca2+-permeable transient receptor potential vanilloid (TRPV) channel that augments neurite outgrowth mediated by NGF, clearly indicating that the channel functions in intracellular membranes. TRPV2 protein levels increased after NGF treatment, suggesting that TRPV2 may be involved in NGF-induced neurite outgrowth. Overexpression of a Ca2+-impermeable TRPV2 mutant or TRPV2 knockdown significantly reduced neurite outgrowth in PC12 cells after NGF treatment. Pharmacological assays revealed MAPK signaling contributes to upregulation of TRPV2 in developing sensory neurons and PC12 cells. Furthermore, we show that TRPV2 acts as an ERK substrate in the processes of developing neurons and identify the structural elements necessary for the phosphorylation of TRPV2 by ERK, leading to enhanced TRPV2-mediated Ca2+ signals and neurite outgrowth. Based on these findings, we propose that TRPV2 is a component of the neuronal signaling endosomes and is directly modulated by ERK, altering Ca2+ signaling within neurites to enhance neurite outgrowth.

Title: Dystroglycan regulates visual circuit development

Authors: *K. WRIGHT, R. CLEMENTS;
Vollum Inst., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: The interpretation of cues in the extracellular environment by cell surface receptors is critical for proper neural circuit development. Dystroglycan is a transmembrane receptor that provides a link from the extracellular matrix (ECM) to the actin cytoskeleton. The ability of dystroglycan to bind to ligand requires its extensive glycosylation, and mutations that affect dystroglycan glycosylation lead to the development of congenital muscular dystrophy. Human patients with severe forms of dystroglycanopathy, including Walker Warburg Syndrome (WWS) and Muscle-Eye-Brain disease (MEB), present with severe neurodevelopmental defects, including type II lissencephaly, hindbrain malformations and retinal dysplasias. Using ISPDL79*/L79* mutant mice that lack glycosylated dystroglycan as a model system to study the mechanistic basis that underlie the neuropathological defects in WWS/MEB, we have identified a critical role for dystroglycan in regulating neuronal migration and axon guidance during the development of visual circuits. We find that in the absence of functional dystroglycan, the inner limiting membrane of the retina breaks down and neurons over-migrate, resulting in the formation of extensive neuronal ectopias in the vitreal space. The axons of developing retinal ganglion cells (RGCs) in ISPDL79*/L79* mutant mice exhibit guidance defects within the retina and at the optic chiasm, resulting in abnormal innervation of retinorecipient areas in the brain. We are using conditional deletion of dystroglycan to identify the specific cell types in which it functions, and to determine the role of dystroglycan in postnatal stages of visual circuit development, including laminar stratification within the retina, refinement of axonal targeting to retinorecipient areas of the brain and formation of functional synapses. Ultimately, these studies will define how dystroglycan regulates neuronal migration and axon guidance during neural circuit development, and provide mechanistic insight into the neuropathological defects observed in WWS/MEB.

Taiwan Univ., Taipei, Taiwan; [4]Dept. of Surgery, Natl. Taiwan Univ. Hosp. and Natl. Taiwan Univ. Col. of Med., Taipei, Taiwan; [5]Renal Div., Univ. Hosp. Freiburg, Freiburg, Germany

Abstract: Glutamatergic principal neurons, GABAergic interneurons and thalamocortical afferents (TCAs) are essential elements of the cerebrocortical network. Principal neurons originate locally from radial glia and intermediate progenitors (IPCs) whereas interneurons and TCAs are of extrinsic origin. Little is known how the assembly of these elements is coordinated. C-X-C motif chemokine 12 (CXCL12), which is known to guide axons outside the neural tube and interneurons in the cortex, is expressed in the meninges and IPCs. We dissected the influence of IPC-derived CXCL12 on TCAs and interneurons by showing that Cxcl12 ablation in IPCs, leaving meningeal Cxcl12 intact, attenuates intracortical TCA growth and disrupts tangential interneuron migration in the subventricular zone. Mechanistically, our data suggest that intracortical TCA growth is regulated by crosstalk between growth-promoting CXCL12 and repellent cortical plate-derived Slit1. Thus, a CXCL12 signal from IPCs links cortical neurogenesis to the progression of TCAs and interneurons spatially and temporally.

Title: The role of growth cone invadosomes in chemotrophic axon guidance within 3D collagen gels

Authors: *C. A. SHORT, S. M. O'TOOLE, M. SANTIAGO-MEDINA, T. M. GOMEZ; Univ. of Wisconsin, Madison, WI

Abstract: Invadosomes are specialized F-actin rich protrusions from the basal surface of cells that function to adhere to and degrade the extracellular matrix to allow cells to invade new tissues. Invadosomes have largely been studied in cancer and immune cells, but recently have been identified in migrating neural crest cells in zebrafish and in pathfinding growth cones of developing Xenopus laevis spinal neurons (Santiago, et al. Development). Similar to non-neuronal cells, our lab found that the formation of invadosomes in neuronal growth cones requires Tsk5 activity, however, the extracellular cues and intracellular signaling molecules that induce the formation of these protrusions in neural cells are unknown. However, our previous work largely examined invadosomes in 2D cell culture. Here, we employ confocal and structured illumination microscopy (SIM) of developing motoneurons (MN) in 3D collagen gel to investigate the roles of candidate morphogens for invadosome formation and function. We hypothesize that growth factors, such as BDNF and SDF-1, released from peripheral tissues during development, promote invadosome formation necessary MN guidance into the periphery. Preliminary data suggest that spinal neurons axons are guided up a gradient of BDNF in 3D collagen gels. Invadosome-dependent penetration of collagen gel and guidance toward local growth factor sources in 3D is being examined. Future studies will examine the molecular basis of invadosome formation and function *in vivo*.

Title: Molecular mechanisms of MAG and myelin-induced Smad2 phosphorylation

Authors: J. L. C. CADIEUX, S. SELAMAT, *S. S. HANNILA;
Human Anat. and Cell Sci., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Inhibitory proteins in myelin such as myelin-associated glycoprotein (MAG), Nogo-A, and oligodendrocyte myelin glycoprotein pose a significant barrier to axonal regeneration in the central nervous system (CNS) after injury. Previous studies have shown that all three proteins bind to Nogo receptor 1 (NgR1) and paired immunoglobulin receptor B (PirB) with high affinity, and MAG also binds to low-density lipoprotein receptor-related protein-1 (LRP1). In addition to these receptors, we now show that myelin-associated inhibitors can also activate the transforming growth factor β (TGFβ) receptor and Smad2/3 signaling pathway. For P6 rat cerebellar granule neurons (CGN), P1 cortical neurons, and P1 hippocampal neurons, treatment with 20 µg/ml MAG-Fc, Nogo-AP, or CNS myelin for 30 minutes strongly induced phosphorylation of Smad2. In our recent work, we have also shown that myelin basic protein (MBP), one of the most abundant proteins in myelin, does not induce Smad2 phosphorylation, which indicates that this effect is specific to myelin-associated inhibitors. To elucidate the role of the TGFβ receptor in this process, P6 CGN were treated with the TGFβ receptor inhibitors SB431542 and SB505124 for 1 hour, followed by the addition of 20 µg/ml MAG-Fc for 30 minutes. In samples from neurons that received SB431542 or SB505124, MAG-induced Smad2 phosphorylation was completely blocked, which suggests that MAG activates the TGFβ receptor. We are now characterizing the onset and duration of Smad2 activation by myelin-associated inhibitors and investigating whether the TGFβ receptor is being transactivated by the known MAG receptors NgR1, PirB, and LRP1. Elucidating the pathways involved in mediating inhibition of axonal growth is the first step towards developing therapies for enhancing functional recovery after spinal cord injury, and ultimately, we plan to test whether TGFβ receptor inhibitors are capable of overcoming inhibition by myelin and promoting axonal regeneration *in vivo*.

Title: A quantitative study of the locally synthesized proteins in the axons of rat cortical neurons in culture

Authors: *H.-W. CHUNG;
Dept. of Life Sci., Instituate of Mol. Medicine, Natl. Tsing H, Taoyuan City, Taiwan

Abstract: Local protein synthesis as enhanced by environmental stimulations may play important roles in neuronal growth, axonal guidance and synaptic plasticity[1]. Recently, it has been found that both glutamate and brain-derived neurotrophic factor (BDNF) treatments enhance protein translation not only in cell bodies but also in axons disconnected from their cell bodies of rat cortical neurons in culture. Here, we have used the bioorthogonal noncanonical amino acid tagging (BONCAT) [2], which has been widely used in studying nascent proteins, to label the newly synthesized proteins in the axons and whole cells of cultured rat cortical neurons. By quantitative Western blotting, we have compared the newly synthesized proteins in cell bodies and axons of cultured rat cortical neurons. The results indicate that the set of proteins whose syntheses are enhanced by BDNF is nearly identical to that as enhanced by glutamate, either in whole neurons or in severed axons. However, the sets of proteins whose syntheses are enhanced by BDNF and glutamate in whole neurons are respectively different from those in severed axons. In addition, we have also calculated the proportions of newly synthesized proteins in the total amounts of proteins in the axon in the basal level and those upon stimulation with glutamate and BDNF. The results will be presented. The results will help understand the mechanism(s) of how local protein synthesis may contribute to axon's functions. Reference:1. Kang, H., Schuman, E. Title: Long-term 2-photon imaging of thalamocortical connectivity refinement in the neonatal mouse barrel cortex

Authors: *S. NAKAZAWA[1,2], H. MIZUNO[1,2], T. IWASATO[1,2];
[1]Natl. Inst. of Genet., Mishima, Shizuoka, Japan; [2]Dept. of Genet., SOKENDAI (The Grad. Univ. for Advanced Studies), Mishima, Shizuoka, Japan

Abstract: Sensory information through the thalamus flows to the primary sensory cortex layer 4 (L4), and thalamocortical (TC) connectivity is refined by thalamic inputs during early postnatal period. In the mouse somatosensory cortex (barrel cortex) L4, there is an array of "barrels" that correspond to the arrangement of whiskers on the face. In barrel cortex L4, there are 2 types of excitatory neurons: spiny stellate neurons (barrel cells) and star pyramid neurons, which are distinguished by the absence and presence of apical dendrites, respectively. Barrel cells are located around the barrel edge, and their dendrites are asymmetrically oriented toward the barrel center, where TC axon termini are clustered. These unique morphological features of barrel cells allow single barrel cells to receive inputs from single whiskers. We are interested in how these barrel cell morphologies that are critical bases of precise TC connectivity are established during early postnatal period. To address this question, *in vivo* 2-photon time-lapse imaging should be a powerful approach. For the purpose, we labeled L4 excitatory neurons sparsely and brightly using the *in utero* electroporation-based "Supernova"-RFP (Mizuno et al., Neuron 2014), and visualized barrel center using the TCA-GFP Tg mouse (Mizuno et al., 2014). We then analyzed TC refinement by 18 hour-long *in vivo* imaging starting from postnatal day 5 (P5), and revealed that barrel cells reinforced their dendritic orientation toward the barrel center by moving dendritic branches dynamically (Mizuno et al., 2014). Our histological analyses demonstrated that most morphological features of barrel cells are apparent at P6 (and P5) but not at P3. To reveal dynamics and mechanisms of the initial phase of TC connectivity refinement, we here performed 3-day long *in vivo* imaging of L4 excitatory neurons starting at P3. In this meeting, we

will show how morphological differences between barrel cells and star pyramid neurons arise and how barrel cells acquire characteristic dendritic orientation bias during neonatal period.

Title: Activity-dependent controls over L4 glutamatergic interneuron identity

Authors: ***I. VITALI**[1], L. TELLEY[1], S. BARISELLI[2], N. HURNI[1], A. DAYER[1], C. BELLONE[2], D. JABAUDON[1];
[1]Fundamental Neurosci., Univ. of Geneva, Geneve, Switzerland; [2]Fundamental Neurosci., Univ. of Lausanne, Lausanne, Switzerland

Abstract: Neuronal circuits are thought to arise from a coordinated interplay between cell-intrinsic transcriptional programs, which form the backbone of the differentiation process, and superimposed input/activity-dependent programs, which act to refine neuronal identity in a circuit-specific manner. The whisker-to-barrel cortex pathway is ideally suited to study these hierarchical interactions in single neuron types during circuit assembly. We have recently shown that modality-specific thalamocortical input instructs the identity of their postsynaptic partner in layer 4 (Pouchelon et al., Nature, 2014), but whether L4 neuron activity is required for differentiation and circuit assembly is unknown. Here, using cell-type specific manipulations of L4 glutamatergic interneurons during development, we identify an activity-dependent control over the laminar, molecular, morphological and circuit identity of this cell type. Our experiments reveal an early and unexpected role for intrinsic activity on the functional differentiation of specific cortical neuron cell types, which suggests that cell-intrinsic and input/activity-dependent processes are tightly intermingled and regulated during early corticogenesis.

Title: Cortical feedback regulates feedforward retinogeniculate remodeling during a thalamic critical period

Authors: *A. THOMPSON[1,2], L. MIN[3], M. FAGIOLINI[4], C. CHEN[4];
[1]F.M. Kirby Neurobio. Dept., [2]BBS Program, [3]Neurobio., Harvard Univ., Boston, MA; [4]F.M. Kirby Neurobio. Dept., Harvard University, Children's Hosp. Boston, Boston, MA

Abstract: The development of sensory pathways has traditionally been thought to occur in a feedforward manner, such that local microcircuits refine and stabilize in isolation before directing the wiring of each subsequent layer. In the visual system, retinal circuits were thought to mature first and direct refinement in the visual thalamus (the lateral geniculate nucleus), after which cortical circuits would mature and incorporate visual experience during well-defined critical periods. Here we show that feedback from cortex to thalamus directly regulates the refinement of the retinal projection to thalamus during a discrete window in development. Disrupting cortical activity during this time frame leads to rewiring of the subcortical circuit characterized by an increase in the number of retinal ganglion cells innervating a given thalamic relay neuron. Both decreasing and increasing corticothalamic activity elicits this response, indicating that corticothalamic firing patterns may actively instruct the rewiring of the primary afferent input to thalamus. Our results demonstrate that primary sensory pathways develop through the concurrent and interdependent remodeling of subcortical and cortical circuits in response to sensory experience, rather than through a simple feedforward process. Moreover, our findings highlight an unexpected function for the corticothalamic projection.

Authors: *H. LI, K. JACKSON, N. SPITZER;
Neurobio. Section, Div. of Biol. Sciences, Kavli Inst. for Brain, UCSD, LA Jolla, CA

Abstract: The identity of the transmitters expressed by neurons has been thought to be fixed and immutable. However changes in electrical activity can reconfigure the transmitters and corresponding receptors that neurons express, both in the developing and adult brain (Borodinsky et al., 2004; Borodinsky & Spitzer, 2007; Dulcis & Spitzer, 2008; Demarque & Spitzer, 2010; Dulcis et al., 2013). Functionally, neurotransmitter switching in the adult rat hypothalamus has been shown to regulate behavior (Dulcis et al., 2013). The existence and behavioral consequences of neurotransmitter switching in other brain regions remain largely unknown. We thus began to search for activity-dependent neurotransmitter switching in motor circuitry where the mechanism underlying plasticity remains obscure. Our strategy is to compare the number of neurons expressing cFos in motor nuclei of mice with free access to running wheels to the number in nuclei of sedentary control mice. We found that mice exercised by running for one week showed a robust 5-fold increase in the number of cFos+ cells in the midbrain pedunculopontine nucleus (PPN) accompanied by a 33% decrease in the number of choline acetyltransferase-immunoreactive (ChAT+) neurons. Stereological counts showed that the decrease in number of ChAT+ neurons in the PPN occurred exclusively in the caudal region that projects to locomotor centers in the brain stem, to STN, VTA, and to the thalamus. There was no change in number of ChAT+ neurons in the rostral PPN that projects to other nuclei. The number of ChAT+ neurons in the adjacent laterodorsal tegmental nucleus was also unaffected. TUNEL staining revealed the absence of apoptosis. Moreover, nitric oxide synthase (NOS) is a marker for ChAT+ neurons and there was no change in the number of NOS+ neurons in the caudal PPN. The number of ChAT+ neurons was restored one week after mice had stopped running. These data are consistent with transmitter re-specification. To determine the consequence of ChAT loss in the caudal PPN, we performed behavioral analysis and found that runners progressively increased the duration of running episodes and acquired better motor control during training on running wheels. They also performed better than controls on the

rotorod motor learning and coordination test; no significant difference was seen in the locomotor activity test, the open field test, or metabolic analysis. To test for causal relationships, we are determining whether preventing ChAT loss can suppress the promotion of motor learning by running. This study is expected to be pertinent to understanding the mechanism underlying motor learning as well as neurological disorders of the motor system.

Title: Early BDNF signaling can substitute for visual experience in maintenance of receptive field refinement in dark-reared adults

Authors: D. B. MUDD[1], T. S. BALMER[2], *S. L. PALLAS[1];
[1]Neurosci. Inst., Georgia State Univ., Atlanta, GA; [2]Vollum Inst., Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Critical periods allow external information to shape sensory circuits during postnatal development, limiting plasticity in adulthood. Sensory deprivation interferes with this process, often leading to retention of the plastic state. Surprisingly, visual experience is not required for the refinement of retinocollicular or visual cortical receptive fields (RFs) (Balmer and Pallas, 2015). Instead, early light exposure protects against the deterioration of high acuity, refined RFs in adulthood (Carrasco et al., 2005). The failure to maintain refined RFs in dark-reared adults results primarily from a loss of inhibitory drive and thus a reduction in lateral inhibition (Carrasco et al., 2011). We sought to identify the experience-driven molecular trigger that stabilizes GABAergic synapses and maintains refined RF size. The neurotrophic factor BDNF and its receptor TrkB have been implicated as a link between visual experience, maturation of inhibition, and ocular dominance plasticity in visual cortex. We tested whether BDNF-TrkB signaling during the critical period also provides a mechanism for maintenance of RF refinement. If so, then TrkB activation during a critical period in dark-reared animals should substitute for light exposure and thus maintain refined RFs in adults. Pharmacological manipulation of TrkB signaling in an *in vivo* rodent model was used to generate an increase in TrkB phosphorylation during postnatal development. Syrian hamsters were dark-reared from birth to adulthood (>P90) and given daily IP injections of the TrkB agonist 7’8 Dihydroxyflavone or vehicle during the

critical period for RF refinement in the superior colliculus (SC) (P33-P37). Single unit *in vivo* extracellular recordings in superficial SC were used to compare adult RF sizes between treatment groups. We found that animals treated with the TrkB agonist (n = 26 units, mean RF diameter = 12.6 ± 0.81 deg), but not animals treated with vehicle alone (n = 16, mean = 17.9 ± 1.24 deg), maintained refined RFs into adulthood ($p<0.001$, t-test), suggesting that activation of the TrkB signaling pathway mimics visual experience. Thus, early, visually-driven activity appears to promote maintenance of RF refinement in SC via up-regulation of BDNF and subsequent TrkB phosphorylation. Our findings suggest that the SC and visual cortex share a common mechanism for experience-driven plasticity across distinct RF properties, despite differences in timing of their critical periods. The importance of TrkB signaling in modulating different critical periods across brain regions may facilitate investigation of pathological conditions in which maturation is governed by inhibitory plasticity.

Abstract: Very low birth weight (<1500 grams) prematurely-born infants, frequently experience periods of hypoxia due to immaturity of their respiratory system, that can severely affect brain development and result in lasting cognitive and behavioral impairments. In our study we used a mouse model of chronic postnatal hypoxia to examine the impact of hypoxic rearing (9.5-10.5% O2) from postnatal day 3 (P3) to P11. We previously showed that hypoxia transiently decreases the number of excitatory neurons and impairs the maturation of specific GABAergic interneuron populations together with a significant reduction of the mice cortical volume. Here, we investigated whether hypoxia may have also affected the maturation of synaptic connectivity in the neocortex of young adult mice. We found that there is a substantial decrease in presynaptic

inhibitory (vGAT) terminal boutons impinging onto pyramidal cell bodies in the layer 5 and layer 1 of the motor cortex in young adult hypoxic-reared mice. In the same layers, we detected a significant decrease in the number of presynaptic excitatory (vGlut1) terminal boutons impinging onto the soma of PV+ interneurons hypoxic-reared mice as compared to littermate controls. We identified similar patterns in the somatosensory cortex, where we also identified a decrease in thalamocortical excitatory (vGlut2) terminals. These findings were not reflected by a generalized loss of synaptic proteins, measured by western blot analysis. Moreover, using Golgi-cox impregnation, we detected a short-term decrease of both basilar and apical dendritic spines in cortical pyramidal neurons in the hypoxic motor cortex at P15 followed by normalization at P35, but persistent decreased dendritic branching and an immature morphology of the spines. All these results were paralleled by alterations in proteins downstream the mTOR pathway in the hypoxic cortex at young adulthood. Our data show that hypoxia disrupts the anatomical organization of cortical synapses with the molecular mechanisms behind this to being currently examined. To highlight these anatomical changes we are performing whole cell reconstruction of specific neuronal populations in hypoxia labeled with reporter AAV vectors, as well as electrophysiological *in vivo* recordings to understand the functional impact of these abnormalities.

Title: Investigating intracellular signaling events involved in neurotransmitter-receptor matching

Authors: *D. R. HAMMOND-WEINBERGER[1], N. C. SPITZER[1,2];
[1]Neurobio. Section, Div. of Biol. Sci., UCSD, La Jolla, CA; [2]Kavli Inst. for Brain and Mind, La Jolla, CA

Abstract: Matching the identity and location of postsynaptic neurotransmitter receptors to the transmitters released from presynaptic nerve terminals is a substantial challenge. The number of

neurotransmitters is large and the number of synapses most neurons receive is much larger. To begin to analyze the mechanism of neurotransmitter-receptor matching, we have focused on the developing *Xenopus* neuromuscular junction, where motor neurons normally express the neurotransmitter acetylcholine (ACh) and muscle cells express cognate ACh receptors. Changes in electrical activity of these immature motor neurons during a critical period drive a homeostatic shift to non-cholinergic neurotransmitters and the retention of matching receptors from the initially diverse receptor pool. Reduced activity results in a switch from ACh to combinations of cholinergic and glutamatergic phenotypes, with the retention and upregulation of both ionotropic ACh and glutamate receptors in the postsynaptic cell (Borodinsky & Spitzer, 2007). The mechanism of receptor matching remains elusive. Cultured *Xenopus* muscle cells are sensitive to exogenous glutamate, as assayed with the fluorescent Ca^{2+} indicator Fluo-4AM, and sensitivity increases when myocytes are grown in the presence of glutamatergic neurons or exogenous glutamate. This increase in glutamate sensitivity is prevented by growing cells in the presence of pharmacological ionotropic glutamate receptor inhibitors. Thus, although genetic factors are important for initial transmitter and receptor expression, the presence of glutamate appears to be both necessary and sufficient to drive enhanced glutamate sensitivity in myocytes. Use of specific agonists and antagonists demonstrates that metabotropic receptors do not mediate the increased sensitivity to glutamate. Application of pharmacological antagonists suggests that enhanced sensitivity to glutamate depends on activation of mitogen-activated protein kinases (MAPKs) but not protein kinase A or protein kinase C. We are currently conducting Western blot analysis to determine the phosphorylation status of JNK and p38 MAPKs when cells are exposed to exogenous glutamate. We are also evaluating the contributions of specific downstream signaling cascades via targeted gene knockdown with the intent to test the *in vivo* role of transmitter receptor activation in generating postsynaptic receptor clusters (Yamanaka et al., 2013). Understanding the mechanisms of neurotransmitter-receptor matching in the nervous system could form the basis for devising therapies aimed at promoting functional recovery to damaged circuits.

Title: The effects of post-pubertal aging on the juvenile-induced changes in the development of the prefrontal cortex

Authors: *B. T. HIMMLER, S. M. PELLIS, B. KOLB;
Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Juvenile social interactions have been shown to influence the dendritic complexity of neurons in the prefrontal cortex. Juvenile social play has been shown to induce pruning of the cells in the medial prefrontal cortex (mPFC), whereas interacting with multiple partners, whether those interactions involve play or not, increases the complexity of cells in the orbital frontal cortex (OFC). Previous studies suggest that the changes in these different areas of the prefrontal cortex are differentially stable during adulthood. In the present study, rats were reared in groups of either four (quads) or two (pairs) and the brains of the rats from each rearing condition were then harvested at 60 days (i.e., shortly after sexual maturity) and 100 days (i.e., fully adult). The rats housed with multiple partners had more complex neurons of the OFC at 60 days and this complexity declined to a comparable level to that of pair housed rats by 100 days. The play-induced pruning of the mPFC remained similar at both ages. These findings suggest that the changes in the prefrontal cortex induced by social experiences in the juvenile period differ in how long they are maintained in adulthood. The differences in the functions regulated by the OFC and the mPFC may account for these differences on the effects of age on neural complexity.

Title: Postnatal expression of Arx in GABAergic interneurons is critical for proper network function in the mouse hippocampus

Authors: *D. J. JOSEPH, A. J. MCCOY, R. RISBUD, E. D. MARSH;
Pediatrics Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Transcription factors (TFs) establish molecular codes that orchestrate early stages of interneuron development. Some TFs remain expressed in mature interneurons, suggesting a divergent, yet unknown, function. We previously showed that postnatal conditional ablation of one TF, the Aristaless Related homeobox gene (Arx), in parvalbumin (PV) positive interneurons resulted in learning deficits, alterations in intrinsic and synaptic properties, and electrographic seizures in some animals. These results suggest that Arx loss in all mature interneurons may have a more profound effect on network function. Thus, we studied the effect of postnatal ablation of Arx in all interneurons on the excitability of hippocampal networks. To temporally control Arx expression, we crossed a floxed Arx mouse (Arxfl/fl) with a tamoxifen-inducible CreER- mouse. Cre-mediated recombination induced by tamoxifen (Tam) injection in P35-40 male mice resulted in ablation of Arx in interneurons. Tam-induced (Arx-/y;CreER) and sham injected (Arx+/y;CreER) mice were sacrificed 10 days after the injections and processed for immunohistochemistry to assess the efficiency of Cre-mediated recombination. To determine the consequence on network activity, intracranial EEG and extracellular field recordings were performed ~21 days after the injections. Mice were monitored by video EEG continuously for 5 days. Field potentials were recorded at the hippocampal CA1 region in response to Schaffer collaterals (SC-CA1) stimulation. As an index of synaptic transmission, we examined the input-output (I/O) coupling of field excitatory postsynaptic potentials (fEPSPs). To examine the effect of Arx loss on synaptic plasticity, we recorded fEPSPs and measured the probability of release and long term plasticity (LTP). Preliminary results demonstrated that Tam injections resulted in nearly complete ablation of Arx in cortical and subcortical brain regions. Background EEG showed some irregular spikes, but no seizure was observed after Tam injections. Ablation of Arx postnatally resulted in a leftward shift of the I/O curve, suggesting a reduction in synaptic transmission. Paired-pulse stimulation of SC-CA1 was not affected by ablation of Arx, suggesting no change in release probability. However, both HFS and theta burst stimuli failed to induce robust LTP in the Arx-/y; CreER mice, indicating that loss of Arx in interneurons impaired LTP. Our preliminary study suggests that postnatal loss of Arx may alter network function via impairments of synaptic transmission and LTP. Therefore, postnatal expression of Arx may regulate the maturation of functional properties of inhibitory interneurons.

Abstract: MicroRNA-132/212 (miR-132/212) is an experience and cAMP response element-binding protein (CREB) dependent MicroRNA (miRNA) that acts in the central nervous system and in peripheral tissue regulating important biological processes, such as circadian clock, spine maturation and neural inflammation. Recently miR- 132/212 has been involved in Ocular Dominance (OD) plasticity during the critical period in mouse visual cortex. We have studied OD plasticity and binocular matching in MicroRNA-132/212 Knockout (miR-132/212 KO) mice, where the genomic locus of miR-132/212 is completely deleted. To examine the role of miR-132/212 in visual cortical function, we analyzed Local Field Potentials (LFP) responses to pattern Visual Evoked Potential (VEP) and measured single units activity to drifting sine gratings, in Wild Type (WT) and miR-132/212 KO mice. We found that the preferred orientations of individual cortical cells are mismatched through the two eyes at a significant higher level in animals that lack of miR-132/212 and monocularly deprived mice, respect to aged-matched WT subjects. Furthermore, as seen before, three days of Monocular Deprivation (MD) were not sufficient to induce OD shift during the critical period in miR-132/212 KO mice, assessed using pattern VEP responses. These results suggest a possible role of miR-132/212 in trigger adaptive rewiring of neuronal circuits following visually driven patterned activity.

Title: Developmental trajectories of parvalbumin-positive chandelier and basket cells in prefrontal cortex circuits

Authors: *T. MIYAMAE, O. KRIMER, D. A. LEWIS, G. GONZALEZ-BURGOS;
Dept. of Psychiatry, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA

Abstract: Parvalbumin (PV)-positive neurons regulate maturation of cortical circuit function. Moreover, PV neuron alterations, one of the best replicated findings in schizophrenia research, are thought to arise during development. Despite the relevance of PV neuron maturation for cortical development, the maturation trajectories of the PV neuron subtypes, chandelier and basket cells (ChCs and BCs), are poorly understood. We therefore assessed the maturation of ChCs and BCs during development of the prefrontal cortex (PFC), a cortical region that plays a crucial role in the development of cognitive function and its alterations in schizophrenia. We recorded from GFP+ PV neurons with soma localized near the layer 1/layer 2 (L1/L2) border in acute slices of the PFC of G42 mice (P12-P60). At P12, many GFP+ cells had BC-like axonal morphology, but some had markedly different axonal arbors in which we detected vertical cartridges of boutons, albeit in very small numbers, consistent with immature ChCs. At P14-15, the number of cartridges per ChC axon increased, and overall axon morphology was comparable to that of mature ChCs. As in other cortical regions, in PFC ChCs had asymmetric dendrites preferentially projecting to L1, while the L1/L2 dendrite distribution was more symmetric in BCs. These different L1/L2 dendrite distributions were also observed in cells classified as ChCs or BCs in slices from P12 mice. In both ChCs and BCs, firing properties changed gradually into a fast spiking (FS) phenotype during PFC development, as revealed by measurements of 10 electrophysiological parameters in 35 ChCs and 54 BCs (P12-P60). Seven parameters changed progressively with age, and the rate of change was well fit by single exponential curves. Interestingly, the time constants of the exponential curve fits indicated a slower development of FS properties in ChCs than BCs. Furthermore, the time to reach 95% of plateau (mature) value for the 7 curve fits was substantially longer for ChCs than BCs (29±2.9 vs 18±0.6 days), and the plateau values for most parameters differed between ChCs and BCs. Preliminary analysis of AMPA receptor-mediated EPSCs (P12-P30) suggests a different maturation of excitatory synaptic inputs in ChCs versus BCs. Our data suggest different trajectories of functional development in ChCs and BCs, consistent with the possibility that they play significantly different roles in regulating the activity and maturation of other circuit elements during PFC development. Their distinct developmental trajectories may determine a different sensitivity of

ChCs and BCs to the effects of environmental/genetic risk factors thought to disturb PV neuron development in schizophrenia.

Title: Expression of Npas4 mRNA in telencephalic areas of adult and postnatal mouse brain

Authors: *U. H. WINZER-SERHAN, J. C. DAMBORSKY;
Dept Neurosci & Exp. Therap., Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: The transcription factor neuronal PAS domain-containing protein 4 (Npas4) is an inducible immediate early gene which regulates the formation of inhibitory synapses. Npas4 could have a significant regulatory role during the development of cortical circuits and in shaping the excitatory/inhibitory balance. However, little is known about the expression of Npas4 mRNA under normal conditions, and no study has systematically evaluated the expression of Npas4 during postnatal development, when GABAergic synapses are formed. To address these questions, adult and postnatal mouse brain sections were processed for isotopic *in situ* hybridization using a Npas4 specific cRNA probe. The results show that adult expression of Npas4 is found in the telencephalon with very restricted or no expression in the diencephalon or and mesencephalon. In most telencephalic areas, including the anterior olfactory nucleus (AON), piriform cortex, neocortex, hippocampus, dorsal caudate putamen (CPu), septum and basolateral amygdala nucleus (BLA), Npas4 expression was found in scattered cells which exhibited strong hybridization signal. In the postnatal mouse brain, transcripts for Npas4 mRNA were detected in AON, CPu and piriform cortex at P5. At P8, additional Npas4 hybridization was found in CA1 and CA3 stratum pyramidale of dorsal and ventral hippocampus, and in primary motor cortex. By P13, robust mRNA expression was located in layers IV and VI of all sensory cortices and in cingulate cortex. The spatial distribution of postnatal mRNA expression was similar to that in

adults, except for the CPu, where Npas4 became gradually restricted to the most dorsal part. In conclusion, the spatial distribution of Npas4 expression was mostly restricted to telencephalic areas, and the developmental expression of Npas4 mRNA correlated with the maturation of excitatory synapses, when activity-driven formation of inhibitory synapses becomes more important. Understanding the temporal and spatial expression of Npas4 will serve as a foundation to explore the potential roles of Npas4 during development, and for the characterization of stimuli that could activate Npas4 expression.

Title: Short term potentiation induced by theta burst stimulation in CA1 pyramidal cells depends on activation of protein-G

Authors: *M. OUARDOUZ;
NRAC, Gatineau, QC, Canada

Abstract: As previously reported blocking G-protein by $GDP_{\beta s}$ induces an increase of EPSCs amplitude (Ouardouz, 2014). The increase in EPSCs amplitude by $GDP_{\beta s}$ may interfere with the expression of long term potentiation (LTP) of excitatory synapses in CA1 pyramidal cells. We used theta burst protocol (5 trains of 4 pulses at 100 Hz at 200 ms interval, 3 times at 30s interval) for LTP induction in CA1 pyramidal cells from P9-12 rat pups. In control condition theta burst protocol induces an increase of EPSCs amplitude which decay with time corresponding to short-term potentiation (EPSCs amplitude increases by 39.8 $\pm$ 4.5 %, n = 5, p = 0.0000004) flowed by a persistent increase that last for the duration of the recordings (30 minutes, EPSCs amplitude increases by 26.4 $\pm$ 4.4 %, n = 5, p = 0.00005). When $GDP_{\beta s}$ is included in the recording solution, theta burst stimulation induces a progressive EPSCs amplitude increase. The short term potentiation observed in control is not present. After 30 minutes recording the EPSCs amplitude was increased by 54.5 $\pm$ 4.6 % after theta burst stimulation compared to 25.7 $\pm$ 3.7 % without theta burst stimulation both in the presence of GDP_{β}. Paired pulse facilitation due to increase transmitter release at the presynaptic terminal was also explored. The increase of the amplitude of the second response compared to the first one is not different between control and in the presence $GDP_{\beta s}$ (% EPSCs amplitude increase in control

50.3 ± 9.8 %, n = 6 and in the presence of $GDP_{\beta s}$ 50.7 ± 7.6 %, n = 5, p = 0.98). However, after 30 minutes induction of LTP by theta stimulation, paired pulse facilitation is more pronounced in control group (90.7 ± 11.4 % after burst compared to 50.7 ± 7.6 % before Theta burst, P = 0.04 paired t-test) compared to cells recorded in the presence of $GDP_{\beta s}$ (45.5 ± 3.8 % after theta burst compared to 50.7 ± 7.6 % before Theta burst, P = 0.58). Those results show that short term potentiation was affected by intracellular application of $GDP_{\beta s}$ suggesting a role of G-protein activation in the expression of short-term potentiation. In addition, $GDP_{\beta s}$ block the increase paired pulse facilitation induced by theta burst stimulation in CA1 hippocampus suggesting the involvement of diffusing messenger from the post- to the pre-synaptic side.

Title: Activity-dependent dynamics of CREB in cortical neurons: a single-molecule imaging study

Authors: H. KITAGAWA, *N. SUGO, N. YAMAMOTO;
Osaka Univ., Suita, Osaka, Japan

Abstract: Activity-dependent transcription is essential for neuronal circuit formation and synaptic plasticity. An intriguing question is how neuronal activity affects dynamic interactions between sequence-specific transcription factors and their target sites. Here we investigated activity dependence of DNA binding and dissociation of cAMP-response element binding protein (CREB) in living cortical neurons. To visualize CREB at single molecule level, HaloTag-CREB was transfected into dissociated mouse cortical neurons, and was labeled with a single tetramethylrhodamine (TMR)-conjugated HaloTag ligand. Then, the individual TMR-CREB

molecules were observed in living cell nuclei by highly inclined and laminated optical sheet microscopy. At 5 DIV, when spontaneous firing activity is low, a significant fraction of TMR-CREB spots resided at restricted positions for several seconds (dissociation rate constant: 0.54 s^{-1}), but mutant CREB which lacks binding to its target sequence cAMP-response element (CRE) scarcely stayed at fixed locations for such a long period. To test the possibility that the residence time depends on neuronal activity, an optogenetic method with Channelrhodopsin-2 was applied to cultured cortical neurons. Although the photostimulation efficiently induced nuclear translocation of CREB-regulated transcriptional coactivator 1 (CRTC1), the residence time distribution of CREB was not changed before and after the photostimulation. However, we found that TMR-CREB spots with long residence times (> 1s) repeatedly emerged at highly restricted nuclear locations (0.8 × 0.8 μm) after the photostimultation. Quantitative analysis revealed that the number of the accumulation sites per optical section significantly increased in response to the optogenetic stimulation. Taken together, these results suggest that neuronal activity promotes CREB-dependent transcription by accelerating the frequency of CREB binding to particular CRE sites without altering the temporal binding property.

Abstract: Growth-associated protein 43 (GAP43) is a protein kinase C-dependent phosphoprotein known to promote activity-dependent presynaptic plasticity and axon growth. In this study, we revealed for the first time that phosphorylation of GAP43 at PKC phosphorylation

site Ser41 is pivotal for postsynaptic gephyrin clustering in developing cortical neurons. We found that GAP43 regulates the aggregation of gephyrin, a pivotal protein for clustering postsynaptic GABAA receptors (GABAARs), in developing cortical neurons. Pharmacological blockade of PKC and neuronal activity induced both GAP43-gephyrin association and gephyrin misfolding in the cytosol and aggresomes, suggesting the importance of PKC-dependent regulation of GABAergic synapses. Furthermore, we found that PKC phosphorylation-resistant GAP43S41A, but not PKC phosphorylation-mimicking GAP43S41D, interacted with gephyrin to trigger gephyrin misfolding and its sequestration into aggresomes. Interestingly, gephyrin clustering was greatly reduced by GAP43S41D, but not GAP43S41A. Surface GABAAR expression, which is highly dependent on gephyrin in developing neurons, were also reduced by GAP43S41D overexpression under physiological condition. In contrast, GAP43S41D can attenuate gephyrin misfolding under transient oxygen-glucose deprivation (tOGD) that mimics hypoxia-ischemic insult in neonatal brains. Calcineurin-mediated GAP43 dephosphorylation that accompanied tOGD also led to GAP43-gephyrin association and gephyrin misfolding/aggregation. Together, this study highlights the importance of GAP43 phosphorylation in the development of inhibitory synapses against hypoxic insult via a novel regulation of gephyrin aggregation.

Title: Transplantation of pro-oligodendroblasts, preconditioned by lps-stimulated microglia, promotes recovery after acute contusive spinal cord injury

Authors: ***X. LIN**[1], T. ZHAO[2], M. WALKER[3], A. DING[1], M. JIANG[1], J. CAO[1], S. LIN[1], X.-M. XU[3], S. LIU[1];

Abstract: Spinal cord injury (SCI) is a significant clinical challenge and, to date, no effective treatment is available. Oligodendrocyte progenitor cell (OPC) transplantation has been a promising strategy for SCI repair; however, the poor post-transplantation survival and deficiency in differentiation into myelinating oligodendrocytes (OLs) are two major challenges, which limit their use as donor cells. Here we report the generation of a relatively more mature OL lineage population, i.e. pro-oligodendroblast (proOL), than OPC, for transplantation after SCI. We found that proOLs responded to lipopolysaccharide (LPS)-stimulated microglia conditioned medium (L+MCM) by preserving toll-like receptor 4 (TLR4) expression, improving cell viability, and enhancing myelinating capability as compared to other OL lineage cells exposed to either LPS-stimulated or non-stimulated microglia conditioned medium (L-MCM). When stimulated proOLs were intrathecally delivered through a lumbar puncture after a T10 thoracic contusive SCI, they promoted behavior recovery assessed by Basso- Beattie-Bresnahan (BBB) locomotor rating scale, stride length, and slips on the grid tests. Histologically, transplantation of stimulated proOLs caused a considerable increase in axon growth and myelination, and less accumulation of macrophages at the lesion site when compared with the vehicle control or OPC transplantation group. Comparing with direct transplantation of OPCs, inducing these cells to a more mature proOL stage and stimulating them with L+MCM may be more advantageous since the proOLs may have already initiated the differentiation process towards OLs prior to transplantation. Thus, transplantation of proOLs, preconditioned by LPS-stimulated microglia conditioned medium, may offer a better therapeutic potential than OPCs for recovery after acute SCI.

Title: hiPSC-derived NSC grafting intervention early after hippocampus injury preserves memory and mood function and reduces the occurrence of seizures

Authors: *B. HATTIANGADY[1,2,3], A. BATES[1,2,3], S. SHIN[4], B. SHUAI[1,2,3], X. RAO[1,2,3], M. C. VEMURI[4], A. K. SHETTY[1,2,3];

Abstract: The hippocampus, a region of the brain vital for memory and mood function, exhibits its highest level of plasticity in response to injury. While some of these post-injury changes are reparative in nature, the other changes contribute to the development of aberrant synaptic reorganization and epileptogenesis. Hence, even a partial injury to the hippocampus may result in the occurrence of chronic temporal lobe epilepsy, typified by memory and mood impairments and spontaneous recurrent seizures (SRS). Here, we ascertained the efficacy of human induced pluripotent stem cell (hiPSC)-derived neural stem cell (NSC) grafts for restraining the evolution of unilateral hippocampal injury into conditions such as memory and mood dysfunction and chronic epilepsy. We first induced partial injury to the right hippocampus of young adult F344 rats through an administration of kainic acid (KA; 0.25 μg in 1 μl of saline) into the right lateral ventricle. Seven days after injury, a cohort of rats received grafts of hiPSC-derived NSCs expanded in xeno-free culture conditions (Life Technologies) into the injured hippocampus (~100,000 live cells to each of 3 sites) and another cohort received sham-grafting surgery. Animals in both groups received daily injections of an immunosuppressant drug cyclosporine until euthanasia. Animals that received sham-grafting surgery displayed spatial and recognition memory impairments in water maze and object recognition memory tests and increased depressive-like behavior in a forced swim test, when examined 3-4 months after injury. In contrast, animals that received hiPSC-derived NSC grafts displayed ability for formation of spatial and recognition memories and normal mood function at similar post-injury time-points. Measurement of SRS using chronic EEG recordings suggested that NSC grafting after injury decreased both frequency and duration of EEG Seizures by ~60%. Characterization of the grafted hippocampus using human nuclear antigen (HNA) revealed excellent survival and migration of graft-derived cells. Dual immunofluorescence analyses for HNA and neural cell markers revealed differentiation of a larger fraction (>80%) of graft-derived cells into NeuN+ mature neurons and smaller fractions of graft-derived cells into GABA+ inhibitory interneurons, S-100ß+ mature astrocytes and NG2+ oligodendrocyte progenitors. Analyses with Ki-67 revealed proliferative activity in only a minority of graft-derived cells (<1%). These results underscore that, early hiPSC-derived NSC grafting intervention into the injured hippocampus is effective for preserving memory and mood function and diminishing the occurrence of seizures.

Title: Effective transplantation of cones and cone-like cells into the diseased retina is dependent upon the recipient environment

Authors: *P. V. WALDRON[1,2], G. GRIMALDI[3,1], A. B. GRACA[2,1], F. DI MARCO[3,1], C. HIPPERT[2,1], J. CLAUDIO RIBEIRO[2,1], S. J. I. BLACKFORD[2,1], N. AGHAIZU[2,1], Y. DURAN[2,1], A. J. SMITH[2,1], J. W. B. BAINBRIDGE[2,1], J. SOWDEN[3,1], R. R. ALI[2,1], R. A. PEARSON[2,1];

Abstract: Replacement by photoreceptor (PR) transplantation represents a possible strategy for restoring vision in retinal degenerative diseases. We, and others, have shown that post-mitotic rod precursors can be transplanted into diseased adult eyes, where they functionally integrate within the recipient retina. Human vision is primarily dependent on cone PRs and the transplantation of cones is likely to be the most useful application of PR replacement. We previously provided proof of concept for cone transplantation. However, our data suggested that the adult retinal environment, while receptive to new cones, negatively impacts the number of integrating cone cells, favouring rod differentiation and integration. Transcription factors *Nrl* and *Nr2e3* act as co-activators of rod genes while suppressing cone gene expression. In *Nrl* and *Nr2e3* deficient retinae, rod development is impaired and a majority of cells develop as cones. We sought to use the plasticity of PR precursors by transplanting precursor cells genetically committed to a cone-like fate. Methods: 200 000 cone-like PR precursors were isolated from Nrl$^{-/-}$NrlGFP or Nr2e3^{rd7}CrxGFP mice and transplanted into recipient mice of several genotypes,

representing wild-type, cone-only (*Nrl*$^{-/-}$), cone functionless (*cpfl5*), cone depleted (*cpfl1*) and slowly degenerating (*Prph2*$^{rds/rds}$) retina. The R91W;Nrl$^{-/-}$ mouse was used as a non-degenerating cone-only phenotype. True cone precursors were also isolated from Chrnb4.eGFP mice and transplanted into wild-type and Nrl$^{-/-}$ retinae. Results: Cone and cone-like PR precursors integrated into all recipients and produced unambiguous examples of PR morphology. When transplanted into recipients with rod-rich environments (*wild-type, cpfl1, cpfl5*), the majority of integrated cells of either origin resembled rod PRs, although some resembled cones. In contrast, cells integrated into rod-depleted, cone-enriched environments (*Nrl*$^{-/-}$, R91W;Nrl$^{-/-}$, *Prph2*$^{rds/rds}$) more typically resembled cones. Significantly more cells integrated into *Prph2*$^{rds/rds}$ and *Nrl*$^{-/-}$ retinae than other recipients. Conclusions: The recipient environment affects the outcome of cone transplantation. Specifically, the rod/cone balance of the recipient retina affects the fate of integrated cells and their morphological features while factors within the recipient environment, including OLM integrity and degeneration, influence the efficiency of transplantation. Containing only cones, the Nrl$^{-/-}$ retina has similarities with the fovea of the human retina. Successful transplantation into this environment represents an important advance in the development of this technique.

Title: Dopamine neurons derived from human iPSCs retain midbrain phenotype in animal models of Parkinson's disease

Authors: *D. R. WAKEMAN[1], B. M. HILLER[1], D. J. MARMION[1], C. W. MCMAHON[2], G. T. CORBETT[1], J. MA[2], J. H. KORDOWER[1];

Abstract: Human induced pluripotent stem cells (iPSCs) are a promising source of autologous midbrain dopamine neurons for transplantation in Parkinson's disease (PD). Efficient differentiation of iPSCs into functional midbrain lineage dopamine neurons (iPSC-mDA) utilizing floor-plate induction has been shown to ameliorate functional deficits in animal models of PD. Cryopreservation of post-mitotic iPSC-mDA neurons represents a significant advancement towards translation of iPSC-mDA cell therapy for PD. Here, we demonstrate that cryopreserved iPSC-mDA neurons can be reliably thawed, allowing for rapid access to large numbers of highly pure neurons. Furthermore, we examined the engraftment potential of iPSC-mDA neurons after transplantation into both the rodent and nonhuman primate brain. Human iPSC-mDA neurons derived by episomal reprogramming were cryopreserved in master cell banks. Following thaw, iPSC-mDA neurons retained high viability for >1-month *in vitro* with gene and protein expression profiles consistent with the midbrain dopaminergic lineage. Electrophysiological recordings demonstrated both spontaneous and evoked action potentials, as well as functional Na^+ and K^+ ion channels with characteristic dose-dependent responses to pharmacological inhibition. Biochemical analysis of iPSC-mDA neurons indicated dopamine secretion. To determine *in vivo* survival, cryopreserved iPSC-mDA neurons were thawed and prepared for transplantation without additional subculturing. Cyclosporine immunosuppressed Sprague-Dawley rats received bilateral stereotactic injections of iPSC-mDA neurons ($4.5x10^5$ cells/hemisphere) into the striatum or substantia nigra and sacrificed 2- or 6-weeks post-transplantation. MPTP-treated cynomolgus macaques received three injections to the post-commissural putamen bilaterally ($3.75x10^6$ cells/hemisphere) and were sacrificed 4-weeks or 3-months post-transplantation. Immunohistochemical analysis demonstrated robust graft survival and maintenance of the midbrain dopaminergic phenotype with extensive fiber innervation into the host. We found no evidence of cell proliferation, indicating safety in our initial studies. Long-term functional studies are underway to ascertain whether cryopreserved iPSC-mDA neurons will provide functional benefit in the 6-OHDA-lesioned rat and MPTP-lesioned nonhuman primate models of PD. These results demonstrate excellent graft survival, maintenance of the midbrain dopaminergic phenotype, lack of neural overgrowth in parkinsonian rats and monkeys, as well as indicate considerable promise for the development of pluripotent cell-based therapies in PD.

Title: Embryonic stem cell-derived neural progenitors:interactions with the neurovasculature

Authors: *C. LASSITER, J. GAL, S. BECKER, L. GRABEL;
Biol., Wesleyan Univ., Middletown, CT

Abstract: Before we can safely use embryonic stem cell (ESC)-based cell replacement, we must characterize the behavior of these cells following transplant. We use embryonic stem cell-derived neural progenitors (ESNPs) to study the relationship between blood vessels and neural progenitors. The vasculature plays major roles in neural progenitor cell regulation, both during development and adulthood. Transplants of mouse ESNPs to the dentate gyrus region of the hippocampus are richly vascularized, and surprisingly, the ESNPs appear to migrate great distances from the original site of injection. Migrating ESNPs are found in close proximity to endogenous blood vessels, outside of the transplant area. Our data suggest that blood vessels and their associated astrocytes may provide a source of the chemokine CXCL12, which promotes cell migration in the brain. To test this model, we use organotypic hippocampal slice culture and find that human ESNPs are closely associated with blood vessels and this association increases over time. To directly study the interaction between ESNPs and endothelial cells and identify a molecular mechanism, we co-culture human ESNPs with mouse brain endothelial cells (BECs). We find the adhesive interaction between these two cell types involve an integrin-mediated binding. We examined the interaction of ESNPs with BECs *in vitro* and observe a dramatic morphological rearrangement leading to clusters of ESNPs between endothelial cells. Human ESNPs migrate towards BECs, in a Boyden chamber assay, likely due to factors secreted from the endothelial cells. These data suggest that the vasculature can promote ESNP migration and raise the concern that in a clinical application transplanted ESNPs will migrate away from the original transplant, and be disruptive at a distant site. On the other hand, understanding the signaling that directs neuronal migration may lead to more successful targeting of cells to areas of neurodegenerative damage.

Title: Construction of a spinal cord-like tissue *in vitro* to repair spinal cord injury

Authors: *B. Q. LAI, JR[1], Y. S. ZENG[2];
[1]Sun Yat-Sen Univ., Guang Dong, China; [2]Dept. of Histology and Embryology, Zhongshan Sch. of Med., Sun Yat-Sen Univ., Guang Zhou, China

Abstract: Recovery of damaged neural network after spinal cord injury is an unsettled scientific issue. Since the modern tissue engineering technology offer many powerful new tools for constructing engineered organoids *in vitro*. We herein attempt to take advantage of genetically modified neural stem cells (NSCs) and collagen sponge scaffolds, to generate a functional spinal cord-like tissue to reconstruct lesioned neural network of spinal cord through transplantation. The tissue is mimiced as real spinal cord containing white matter and grey matter. Our results showed, in white matter, many ciliary neurotrophic factor (CNTF) overexpressing oligodendrocytes forming thin myelin sheaths. In addition, NSCs transfected with either neurotrophin-3 (NT-3) or its high affinity receptor tyrosine kinase receptor type 3 (TrkC) genes tended to differentiate toward neurons which established synaptic connections between them in grey matter. When the white matter and grey matter tissues were assembled, we observed that axons from grey matter were attracted to white matter and enveloped by multilayered lamellae myelin. Furthermore, NSC-derived neurons in grey matter were revealed forming mature synaptic structures. Synapses of these neurons were found to be capable of releasing synaptic vesicles and to be able to record spontaneous post-synaptic currents. Our data suggest that the assembly of white matter and grey matter is expected to develop a functional spinal cord-like tissue and to offer insight into neural network reconstruction therapy after spinal cord injury.

Title: Enhanced GABAergic circuitry following Adeno-Associated Virus-Mediated Neuroligin2 overexpression in the hippocampus of adult mice

Authors: *M. A. VAN ZANDT[1], S. MAISEL[2], S. SHRESTHA[2], J. GUPTA[2], K. BUMSCH[2], F. HARRSCH[2], J. R. NAEGELE[2];
[1]Biol., Wesleyan, Middletown, CT; [2]Biol., Wesleyan Univ., Middletown, CT

Abstract: GABAergic interneuron dysfunction characterizes a number of neuropsychiatric disorders including autism and schizophrenia. Hippocampal GABAergic interneuron loss or dysfunction may also contribute to cognitive deficits or seizures in severe temporal lobe epilepsy (TLE). Stem cell therapy shows promise for treating interneuron dysfunction; GABAergic interneuron progenitor transplants in mice with TLE reversed cognitive deficits and ameliorated seizures after integrating synaptically into hippocampal circuitry (Henderson, Gupta et al; 2014, Hunt et al, 2013; Cunningham et al, 2015; Shetty et al, 2012). In the present study, we investigated whether Adeno-Associated Virus (AAV)-mediated overexpression of Neuroligin2 (NLGN2) in the hippocampus increased synaptic integration of endogenous or transplanted GABAergic interneurons. NLGN2 plays a pivotal role in forming and stabilizing GABAergic synapses during development, but little is known about its function in the adult brain. To overexpress NLGN2, we made stereotaxic injections into the hippocampus of AAV/DJ-CMV-mCherry-2a-mNLGN2 (titer: $6.4x10^{12}$ GC/mL; Vector BioLabs). Controls were injected with AAV/DJ-CMV-mCherry (Titer: 1.8×10^{13} GC/mL; Vector BioLabs). To observe the effects of NLGN2 overexpression on the structure of GABAergic synapses, we made stereotaxic injections of the virus into VGAT-ChR2(H134R)-eYFP adult male mice (Jackson Laboratories) and examined molecular components of GABAergic synapses 2-8 weeks later. The results showed that NLGN2 overexpression in principal cells in the adult hippocampus enlarges intracellular clusters of the post-synaptic scaffolding protein gephyrin, and they were apposed to GABAergic synaptic boutons. These findings suggest that AAV-mediated NLGN2 overexpression may be a powerful tool to manipulate the structure and location of GABAergic synapses in the adult brain. Current studies are testing the functional properties of these synapses using optogenetic approaches. Funding was provided by NIH Area #R15NS072879-01A1.

Title: Assessment of therapeutic efficacy and fate of GDNF expressing human induced pluripotent stem cell-derived neural precursor cells in cervical spinal cord injury

Authors: *M. KHAZAEI[1], N. NAGOSHI[1], H. NAKASHIMA[1], K. SATKUNENDRARAJAH[1], A. BADNER[1], A. MANN[1], M. SAYEG[1], M. G. FEHLINGS[1,2,3];
[1]Toronto Western Res. Inst., TORONTO, ON, Canada; [2]Dept. of Surgery, [3]Inst. of Med. Sciences,, Univ. of Toronto, Toronto, ON, Canada

Abstract: Spinal cord injury (SCI) is a common cause of disability and financial hardship that is currently without a cure. Cell therapies for treating SCI have shown great promise but are limited due to ethical concerns regarding cell source and challenges associated with the survival of graft cells. Human induced pluripotent stem cell derived neural precursor cells (hiPSC-NPCs) hold promise of being an autologous, patient-specific cellular therapy with less ethical concerns. The problems related to post transplantation survival of graft cells can be circumvented by GDNF, a neurotrophic factor that has been shown to promote survival of graft cells. However, delivery of GDNF *in vivo* is limited by its inability to cross the blood-brain barrier or penetrate gray matter, and by a relatively short half-life. To address this limitation we engineered the hiPSC-NPCs using piggyback vectors to express and secret GDNF. GDNF-expressing hiPSC-NPCs were transplanted into the spinal cords of a rodent model of cervical contusion SCI two weeks after injury and the involvement of these cells in neurobehavioural and neuroanatomical recovery was assessed. Our data suggest that the GDNF expressing cells significantly show higher survival and integration compared to control cell after transplantation and also protect host neurons resulting reduced cavity size, improved forelimb grip strength and better gait. In concordance, the amplitude of sensory evoked potential recordings was markedly higher in transplanted groups than in the medium-injected group.

Title: Human neural stem cells restore cognitive impairment through trophic support in the Q140 knock-in mouse model of Huntington's disease

Authors: *A. RELAÑO GINÉS[1], C. ZHU[1], A. GALSTYAN[1], K. MOWRIS[1], M. S. LEVINE[2], L. M. THOMPSON[3], M.-F. CHESSELET[1];
[1]Neurol., David Geffen Sch. of Medicine, Univ. of California, Los Angeles, Los Angeles, CA; [2]Semel institute for Neurosci. and Human Behavior, Univ. of California, Los Angeles, Los Angeles, CA; [3]Departments of Psychiatry and Human Behavior, and Neurobio. and Behavior, Univ. of California, Irvine, Irvine, CA

Abstract: Huntington's disease (HD) is an autosomal neurodegenerative disorder caused by an expanded CAG repeat in the huntingtin gene resulting in cognitive decline and motor dysfunction. No treatments currently exist for HD and there is an urgent need to develop new and effective therapies.The Q140 knock-in mouse model of HD displays early behavioral deficits in motor function and cognition as well as huntingtin aggregates, deficits in striatal transcripts and cortical brain-derived neurotrophic factor (BDNF).In this study, we assessed the therapeutic potential of a human neural stem cell line (ESI-017 NSC) (prepared by the UC. Davis GMP facility, Davis, CA) in the Q140 mouse model of HD. Littermates Q140KI and wild-type mice received vehicle instead of cells to be used as controls and all the mice in this study were immunocompromised by cyclosporine (2mg/Kg/day) that was administered by subcutaneous minipumps (Alzet#1004).After bilateral injection of 100,000 cells into the striatum, Q140 mice showed a transient improvement in motor function 3 months after transplantation, whereas notably, cognitive function was significantly improved as late as five months after cell transplantation. The cell transplants did not correct striatal transcripts anomalies measured 6 months after transplantation but levels of BDNF, as well as the levels of p-ERK, the downstream molecule of BDNF, were significantly increased and restored to wild-type levels in the striatum and cortex of the NSC treated mice.Our data suggest that the improved cognition may be mediated via a normalization of BDNF signaling and support the use of NSC for the treatment of HD.

Abstract: The cardinal motor symptoms of Parkinson's disease (PD) result from the progressive neurodegeneration of dopamine (DA) neurons in the substantia nigra and subsequent loss of dopaminergic tone in the striatum. Transplantation of dopaminergic neurons derived from pluripotent stem cells represents a viable therapeutic option to ameliorate motor complications and replenish the diseased brain with a renewable source of DA. Simulating normal developmental signaling, human embryonic stem cells were differentiated into midbrain dopamine neurons (hESC-mDA) following floor-plate induction and midbrain dopaminergic patterning (Kriks et al., 2011). In an attempt to enrich for the midbrain lineage, magnetic activated cell sorting (MACS) was applied for cell surface marker CD142 at day-25 of differentiation. CD142 MACS and unsorted hESC-mDA neurons were transplanted bilaterally into the striatum of unlesioned Cyclosporin immunosuppressed Sprague-Dawley rats, 6-hydroxydopamine (6-OHDA)-lesioned Athymic RNU NUDE rats, and 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-lesioned macaque monkeys immunosuppressed with CellCept, Prograf, and prednisone. Animals were sacrificed along multiple time points, and the survival of grafted cells was assessed using human specific antigens. The maturation of transplanted neurons and maintenance of midbrain floor-plate lineage (FoxA2+/TH+) were analyzed up to 1-year post-transplantation. In rodents, grafted neurons had an immature, bipolar morphology at 2-weeks post-transplantation and developed into highly arborized mDA neurons by 6-months post-transplantation. Human specific neural cell adhesion molecule (huNCAM)+ fibers were seen coursing white matter tracts rostrally into the forebrain and caudally into the midbrain from striatal grafts as early as 2-weeks post-transplantation. By 6-months,

huNCAM+/TH+ fibers had extensively innervated the rodent substantia nigra. Characterization of grafted neurons revealed Girk-2+/TH+ and Calbindin+/TH+ cells, indicating that grafts contained both A9 and A10 lineage mDA neurons. Using Ki-67 as a marker for dividing cells, we saw no evidence for tumor formation up to 6-months post-transplantation. Long-term survival of CD142 sorted and unsorted hESC-mDA neurons were found up to 1-year post-transplantation in the MPTP-lesioned nonhuman primate model of PD. Grafted (FoxA2+/TH+) mDA neurons matured and showed extensive innervation into the host striatum. Functional studies are in progress to assess the therapeutic value and safety of hESC-mDA transplantation for PD.

Title: Integration of human embryonic stem cell-derived retinal ganglion cells after *in vivo* transplantation

Authors: *X. ZHANG[1], P. VENUGOPALAN[1,2], K. TENERELLI[3], C. SUN[1], J. GALVAO[1], K. MULLER[2], J. L. GOLDBERG[1];

Abstract: Is it possible to repair retinas damaged by degenerative diseases like glaucoma, which injure and kill retinal ganglion cells (RGCs)? Cell therapies to replace RGCs will require a better understanding of both differentiation and integration. Human embryonic stem cells (hESCs) and human induced pluripotent stem cells (hiPSCs) may provide an unlimited source for cell transplantation therapy. We have developed a method of differentiating hESC/hiPSCs to RGCs using small molecules to inhibit BMP, Wnt and Notch signaling pathways. 30 days after

initiation of differentiation, RGC-like cells are generated from hESC/hiPSC culture that express RGC markers Brn3 and β-III-Tubulin and synapse marker synaptophysin. These cells respond to chemical stimulant KCl as determined by calcium imaging. Further, we have transplanted hESC-derived RGC like cells (hESC-RGCs) *in vivo* by intravitreal injection into young adult (1 month old) rat retinas, and studied the survival and integration of donor hESC-RGCs into host retinas. Our data suggest that donor hESC-RGCs integrate into the RGC layer as indicated by anti-human nuclei staining, with some transplanted cells co-labelled with RGC marker RBPMS and β-III-Tubulin. Second, we have transplanted primary mature RGCs *in vivo*. Donor RGCs from early postnatal transgenic GFP mice were transplanted into young adult rat eyes. Our data indicate that when transplanted intravitreally, the donor RGCs survive, extend neurites and functionally integrate into the host retina. Transplanted RGCs were observed to acquire the general morphology of endogenous RGCs with axons orienting towards the optic nerve head of the host retina as well as morphologic dendrites growing to the inner plexiform layer (IPL). GFP+ axons were also observed traversing the host optic nerves and optic tract to reach known RGC targets in the brain, e.g. the superior colliculus and lateral geniculate nucleus. Together these results indicate that RGC replacement therapy may be possible for diseases like glaucoma. Further experiments will compare the retinal transplant and integration of hESC/hiPSC-derived RGCs to primary RGCs and study their integration and function.

Abstract: The human motor functions can be permanently affected by the neuronal loss caused by a cerebral ischemic stroke or in association with neurodegenerative diseases such as Parkinson's disease (PD). Regenerative medicine supports the ability to restore the neuronal loss by using stem cells (SC). Pluripotent SC represent one of the most promising cell sources to achieve a successful treatment. However, until now there has not been systematically characterized the capacity of the adult brain to support neurogenesis of transplanted SC. It is unclear whether there are "silent" neurogenic niches or regions suitable for neuronal differentiation, in addition to the known areas of active neurogenesis. Considering the high neurogenic potential of embryoid bodies (EB) cells, derived from embryonic stem cells (ESCs), we used them as sensors to identify microenvironments in the adult rat brain with the capacity to support neuronal differentiation. We transplanted dissociated EB cells to conventional neurogenic and non-neurogenic regions and our results show a neuronal differentiation pattern of EB cells that was dependent on the host region. EB cell differentiation was initially patchy and progressed towards an even distribution along the graft by 15-30 days post-transplantation. The sequential expression of several differentiation markers along this time indicated: 1) EB cells transplanted into the striatum, a site conventionally considered non-neurogenic, showed a low level of neuronal differentiation while observing a significant number of astrocytes. 2) Remarkably, the EB cells shown that local ischemic stroke in the adult striatum promotes the formation of a favorable neuronal microenvironment, which increased the number of neuroblasts and neurons. 3) Unexpectedly, we found that the substantia nigra pars compacta (SNpc), a non-neurogenic region affected in PD, was highly permissive to the neurogenesis of EB cells. Therefore, our research validate the use of EB cells (SC uncommitted to the neural lineage) as biosensors of neurogenic environments in the adult brain. The relevance of this work is to point out by first time that the adult brain has favorable conditions for neuronal differentiation beyond the classic neurogenic sites, which not only helps to understand the limits of regeneration of mammalian brain, but also represents a fundamental step for the rational development of therapies with SC in neurodegenerative diseases.

Abstract: The integrity of spiral ganglion neurons (SGN) of the inner ear can be compromised by age, genetics, infection, noise, blast exposure and skull fractures. This can lead to progressive auditory neuron loss with or without associated hair cell loss and affect the success of cochlear implants. Efforts to restore hearing thus need to provide strategies to secure the presence of functional SGNs. In mammals, SGNs lack the ability to spontaneously regenerate, making it necessary to promote replacement. A major hurdle in replacement of SGNs remains the proper integration of introduced neural precursor cells (NPC) with the host tissue. Nanofibrous scaffolds can potentially both guide the integration of NPCs and improve the ease of interaction with novel cochlear biohybrid implants. We have previously demonstrated that nanofibrous scaffolds promote the neurodifferentiation of mouse embryonic stem cells (Purcell et al., 2012). Here, we applied the use of polycaprolactone (PCL) nanofibrous scaffolds to human embryonic stem cells (hESCs). Briefly, hESCs were predifferentiated to derive NPCs and plated on plasma treated PCL fibers with average diameters below 1 μm. For optimal adhesion the cells preferred Matrigel or fibronectin coating over laminin and poly-l-lysine. Next, NPCs were allowed to terminally differentiate for 2-6 weeks in Neurobasal-based media. Consistent with previous studies on the biocompatibility of this material, we did not find signs of toxic effects interfering with cell viability. The progression of neural differentiation was examined at different time points in culture for lineage, maturation, and transmitter phenotype. Both aligned and unaligned nanofibers promoted the growth of human NPCs, which showed development of cellular extensions alongside as well as across single fibers. We confirmed the acquisition of a glutamatergic fate and synaptic structures. While we continue to study the impact of structure

and material on the differentiation and functional abilities of neurons grown on nanofibers, we have modified the nanofibrous scaffolds to study the integration of the neurons with the cochlear tissue. Methods have been developed for forming nanofiber conduits in bundled and rolled configurations along with surgical strategies for implantation into the internal auditory meatus.

Abstract: We have investigated the therapeutic potential of mesenchymal stromal cells (MSC) transplanted after optic nerve crush (ONC), which causes retinal ganglion cell (RGC) death and optic nerve degeneration. Lister Hooded rats underwent unilateral ONC followed by an

intravitreal injection of 5 x 10^5 MSC (treated) or the vehicle (untreated). MSC were labeled with iron-oxide particles for cell tracking. Optomotor response was evaluated from 1 to 59 days after ONC. On the day before euthanasia, rats were kept for 24h in the dark and then exposed to light for 2h. The brains were analyzed for the expression of the immediate early gene NGFI-A in the SC. This gene is upregulated in neurons of the SC after activation of the NMDA receptor by RGC axons and it is downregulated in the absence of visual stimuli or connections from the retina to the SC. The retinas were immunostained for Tuj1 to estimate RGC number. Axons were anterogradely labeled with cholera toxin B (CTB). Tuj1-positive cell numbers in the central retina were increased from 88,88 ± 8,337 cells/mm^2 in the untreated group (n=9) to 260,4 ± 16,60 cells/mm^2 in the treated group (n=8, mean ± SEM, P<0.001), 28 days after injury. In addition, the number of CTB-positive axons 0.5 mm beyond the injury site was 2.7-fold increased in the treated group. MSC remained in the vitreous body for at least 18 weeks. Optomotor response was completely lost in the ipsilateral eye of treated and untreated groups, and it was not restored after 59 days. NGFI-A-positive cells in the contralateral SC were significantly increased from 0,1965 ± 0,02703 in the untreated group to 0,4059 ± 0,02377 in the treated group (% to ipsilateral SC, n=3, P<0,01). Cell counts 60 days after injury showed 67,98 ± 27,55 Tuj1-positive cells/mm^2 in the untreated group (n=3) and 104,1 ± 15,49 cells/mm^2 in the treated group (n=4). These preliminary results suggest that RGC degenerate overtime in both groups, but the number of cells is higher in the treated animals for at least 60 days after injury. Although this is not associated to the recovery of the optomotor response, NGFI-A expression was increased in the SC of treated animals, suggesting that axons regenerated and made synapses to their target cells in the brain. Further analysis of the visual response will be performed at 90 and 120 days after treatment.

Title: Chronic adolescent consumption of caffeine mixed alcohol significantly increases ΔFosB expression in the nucleus accumbens

Authors: *M. T. ROBINS, R. M. VAN RIJN;
Purdue Univ., West Lafayette, IN

Abstract: The last decade has seen a shift away from consumption of carbonated beverages to highly caffeinated energy drinks. This is particularly worrying in the adolescent population, where mixing of highly caffeinated beverages with alcohol occurs. As the adolescent brain develops, it is important to understand the potential long-term behavioral and neurochemical consequences of chronic exposure to caffeine mixed alcohol. Previously, we have found that, compared to exposure to caffeine or alcohol alone, adolescent mice exposed to caffeine mixed alcohol exhibit potentially worrying alterations in behavior, like increased locomotor sensitivity, blunted place preference, and impaired cognition. Drugs of abuse like cocaine, alcohol, and caffeine enhance dopamine release to neurons in the dorsal striatum and nucleus accumbens through mesolimbic and nigrostriatal projections. Chronic activation of these neurons can increase ΔFosB expression, a transcription factor implicated in long-term neuronal plasticity. It is unclear if the combination of caffeine and alcohol produces cumulative or synergistic release of dopamine and would cause significant increases in ΔFosB expression. We hypothesized that chronic adolescent exposure to caffeine mixed alcohol would increase ΔFosB expression in the dorsal and ventral striatum, similar to that observed for chronic cocaine exposure. To test our hypothesis, we chronically exposed mice to water, caffeine, alcohol, or caffeine mixed alcohol throughout adolescence. Afterwards, mice were sacrificed and immunohistochemistry was used to quantify ΔFosB expression in the dorsal striatum and nucleus accumbens. ΔFosB expression in the dorsal striatum increased in animals exposed to caffeine mixed alcohol compared to water treated mice, however no significant difference was observed between animals exposed to caffeine versus caffeine mixed alcohol. Yet, ΔFosB expression in nucleus accumbens was significantly increased in mice chronically exposed to caffeine mixed alcohol compared to caffeine or alcohol alone. How this increase in ΔFosB expression in the nucleus accumbens correlates with our behavioral data remains to be investigated. Overall, our data suggests that chronic exposure to caffeine mixed alcohol, unlike caffeine or alcohol alone, selectively increases ΔFosB expression levels in the nucleus accumbens and mimics cocaine-induced increases in ΔFosB expression in this particular brain area, known to be critical for drug reward behavior.

Title: The effects of amphetamine on synaptic plasticity in the medial prefrontal cortex are more pronounced in adolescent- compared to adult-exposed rats

Authors: *S. KANG[1,2], C. L. COX[4], J. M. GULLEY[2,3];
[2]Neurosci. Program, [3]Dept. of Psychology, [1]Univ. of Illinois At Urbana Champaign, Champaign, IL; [4]Dept. of Physiol., Michigan State Univ., East Lansing, MI

Abstract: High frequency stimulation (HFS) in superficial layers of the rat medial prefrontal cortex (mPFC) tends to induce long-term depression (LTD) *in vitro*. The mechanism for this may be a stimulation-induced increase in inhibitory transmission, rather than an attenuation of excitatory transmission. Moreover, it may be modulated by dopamine receptors that are known to be prevalent in the mPFC. In the current study, we investigated the mechanisms underlying HFS-induced LTD in the mPFC and whether amphetamine (AMPH) exposure would disrupt this plasticity. In experiment 1, naïve male Sprague Dawley rats were sacrificed during mid-adolescence [around postnatal day (P) 35] and young adulthood (around P70 and P125). Slices of their mPFC were prepared for *in vitro* field potential recordings. Four trains of 50-Hz HFS were delivered in the superficial layers of the mPFC to trigger LTD-like plasticity in deep layer neurons. Subsequently, we used various bath-applied drugs to examine the role of GABAA, dopamine, NMDA and metabotropic glutamate receptors in the formation of this plasticity. Our preliminary results suggests that HFS-induced LTD in the mPFC differs in adolescents compared to adults and is dependent on dopamine receptor activity. In experiment 2, rats were pre-treated with 3 mg/kg AMPH or saline (i.p.) every other day from P27 to 45 or P85 to 103 and HFS-induced plasticity was measured *in vitro* 3-4 weeks after the last injection. Our preliminary results suggest that HFS triggers LTD in controls, but it triggers LTP-like responses in AMPH-exposed rats. This effect was more pronounced in rats exposed during adolescence. These results are consistent with our previous finding that chronic AMPH exposure dampens inhibitory transmission in deep layer mPFC cells and further demonstrate a potential heightened vulnerability to drug-induced plasticity during adolescence. We hypothesize that this persistent AMPH-induced dysregulation of inhibitory tone in the mPFC may lead to a "noisy" PFC output and contribute to observed deficits in cognition in AMPH-exposed individuals.

Title: Age- and sex-dependent differences in acquisition and persistence of methamphetamine self-administration

Authors: *E. R. HANKOSKY[1], R. M. HAAKE[1], A. R. GOLD[1], E. C. KROEGER[1], J. M. GULLEY[1,2];
[1]Psychology, [2]Neurosci. Dept., Univ. of Illinois, Champaign, IL

Abstract: Individuals who initiate drug use during adolescence, and those who are female, tend to have more adverse long-term consequences than adult-onset users and males. Here, we used rats to investigate age- and sex-specific differences in acquisition and persistence of methamphetamine (METH) self-administration (SA). Male and female Sprague-Dawley rats were assigned to either adolescent- or adult-onset SA groups and implanted with an indwelling catheter in the right jugular vein [on postnatal days (P) 32 or 82, respectively]. Starting on either P40 or P90, rats began training and testing that lasted for 24 days. Acquisition of SA was assessed at 0.05 mg/kg/inf METH under fixed ratio 1 (FR1), FR3, and FR5 schedules, followed by FR5 testing with two within-session periods (15 min each) where illumination of the house light was used to signal that drug was not available (9 sessions total). Our preliminary results indicate that adult-onset females exhibit heightened acquisition of METH SA, but that adolescent- and adult-onset males are more persistent in METH seeking during periods of signaled non-availability. Control adolescent- and adult-onset counterparts that self-administered saccharin (SACC; 0.1%) demonstrated robust age- and sex-specific differences, such that adult-onset females acquired most readily and maintained the highest levels of responding. All groups learned to reduce responding when SACC was unavailable. These findings suggest that females and adolescents display heightened acquisition and persistence, respectively, which are distinct patterns of drug-seeking that may lead to poorer outcomes following repeated use. Furthermore, the age and sex-specific characteristics of non-drug reward seeking are considerably different than those observed for METH, which highlights the distinct aspects of METH SA in adolescent and adult rats.

Title: Can environmental enrichment protect against oxidative stress, parvalbumin loss, and behavioral deficits after early life stress? A preliminary study

Authors: V. THOMPSON[1], C. DO PRADO[3], H.-N. LEE[1], F. HOLLAND[1], *H. C. BRENHOUSE[2];
[2]Psychology, [1]Northeastern Univ., Boston, MA; [3]PUCRS, Porto Alegre, Brazil

Abstract: Exposure to early life stress (ELS) alters development, which purportedly yields behavioral deficits and vulnerability to mental illness in adolescence. For example, ELS causes cognitive deficits in adolescence that co-occur with loss of parvalbumin-expressing interneurons in the prefrontal cortex. Importantly, parvalbumin-expressing interneurons play an important role in cognitive function, and are particularly vulnerable to damage via oxidative stress early during early postnatal development. Environmental enrichment (EE) has been shown to buffer several effects of ELS, however the mechanism underlying the protective effects of EE is not well understood. Therefore, here we investigated whether ELS increases oxidative stress in the prefrontal cortex, and whether EE can prevent oxidative stress, parvalbumin loss, and cognitive deficits. Male rats (n=4) were exposed to control rearing or maternal separation ELS from postnatal days 2-20, followed by rearing from weaning through adolescence in either EE (large cage and social groups with novel objects and climbing opportunities) or standard housing. In adolescence (postnatal day 55), rats were tested for cognitive performance using the win-shift paradigm, followed by Western blot analysis of the prefrontal cortex for parvalbumin and for markers of oxidative stress. EE prevented increased errors on the win-shift paradigm after ELS. Preliminary data suggests that ELS also increased NADPH oxidase 2 (NOX2) in the adolescent prefrontal cortex. However, while EE protected ELS-exposed animals from deficits in win-shift performance, EE did not prevent ELS-induced PVB or NOX2 changes. Taken together, these data suggest that ELS yields increased enduring oxidative stress that likely contributes to parvalbumin loss in adolescence. EE appears to interfere with mechanisms other than oxidative

stress that contribute to cognitive deficits, since EE protected adolescents from cognitive, but not oxidative stress effects of ELS. Future investigations will determine whether EE protects against cognitive deficits via oxidative stress mechanisms in subcortical regions such as the hippocampus, which has been shown to be protected from ELS after EE rearing.

Title: The effects of unit dose on age- and sex-dependent differences in methamphetamine self-administration

Authors: *S. R. WESTBROOK, E. R. HANKOSKY, R. M. HAAKE, M. R. DWYER, J. M. GULLEY;
Univ. of Illinois Urbana-Champaign, Champaign, IL

Abstract: Recent work in our lab suggests there are age and sex differences in methamphetamine (METH) self-administration (SA) when rats are trained with a dose of 0.05 mg/kg/infusion. In this study, we extended these findings by utilizing different training doses in separate groups of rats and subsequently performing a dose-response analysis by changing the available unit dose across sessions. Male and female Sprague-Dawley rats were assigned to either adolescent- or adult-onset groups and implanted with an indwelling catheter in the right jugular vein on either postnatal day 32 or 82. Following 6-8 days of recovery, rats were trained for 15 days to self-administer METH at a dose of either 0.02 or 0.08 mg/kg/infusion. The acquisition period consisted of 7 days of responding on a fixed ratio (FR) 1 schedule of reinforcement followed by 4 days each of FR3 and FR5. Following acquisition, motivation to respond for 4 doses of METH (0.02, 0.05, 0.08, 0.1 mg/kg/infusion) was assessed in 4 separate sessions (5 h duration) using a progressive ratio (PR) schedule of reinforcement. Our preliminary results suggest that adolescent-onset females acquire METH SA more readily than adolescent-onset males at both training doses (0.02 and 0.08 mg/kg/infusion). However, rates of acquisition in adolescent-onset males and females were significantly lower at the 0.02 mg/kg/infusion dose

compared to the 0.08 mg/kg/infusion dose. Furthermore, adolescent-onset females worked significantly harder for METH under a PR schedule for all doses tested, regardless of training dose. Investigation of the adult-onset male and female groups is currently in progress. These preliminary findings suggest that at multiple doses, adolescent-onset females will work harder and self-administer more METH than their male counterparts. This heightened METH seeking could contribute to heightened vulnerability to METH addiction in females compared to males.

Title: DCC receptors control the development of fine axonal structure of mesocortical dopamine neurons and determine behavioral inhibition in adult mice

Authors: *L. M. REYNOLDS[1,3], M. WODZINSKI[3], C. MANITT[3], E. NESTLER[4], C. FLORES[3,2];
[1]Integrated Program in Neurosci., [2]Psychiatry, McGill Univ., Montréal, QC, Canada; [3]Douglas Mental Hlth. Univ. Inst., Montréal, QC, Canada; [4]Fishberg Dept. of Neurosci., Icahn Sch. of Med. at Mount Sinai, New York, NY

Abstract: The guidance cue netrin-1 and its receptor, DCC, are highly and conspicuously expressed in the mesocorticolimbic dopamine system throughout life. We have recently shown that DCC signaling within dopamine neurons controls the extent of dopamine input to the medial

prefrontal cortex (mPFC) during adolescence. In turn, DCC organizes mPFC local circuitry, significantly influencing cognitive flexibility in adulthood. How precisely DCC receptors control mPFC dopamine input expansion remains to be determined. Here, we used cre-lox recombination to induce *dcc* haploinsufficiency selectively in dopamine neurons ($dcc^{lox/+}DAT^{Cre}$ mice). We then performed quantitative analysis of the architecture of individual mPFC dopamine axons across cingulate 1 (Cg1) and prelimbic (PrL) subregions. To this end, we injected bilaterally an AAV-DIO-eYFP viral vector in the ventral tegmental area (VTA) of adult $dcc^{lox/+}DAT^{Cre}$ or control $dcc^{+/+}DAT^{Cre}$ littermates to label small subsets of mPFC-projecting dopamine axons with eYFP. We find that mPFC dopamine axons of $dcc^{lox/+}DAT^{Cre}$ mice have less complex arbors than those of $dcc^{+/+}DAT^{Cre}$ mice. Furthermore, dopamine axon arbors of $dcc^{lox/+}DAT^{Cre}$ mice are significantly shorter and have fewer varicosities than dopamine axon arbors of $dcc^{+/+}DAT^{Cre}$ littermates. We are now examining whether these less complex dopaminergic axons were destined to innervate limbic regions, but instead were rerouted to the mPFC due to changes in DCC signaling. To assess whether altered organization of mPFC dopamine connectivity is associated with changes in behavioral inhibition, we tested adult $dcc^{lox/+}DAT^{Cre}$ mice in a go/no-go behavioral task we adapted for use in mice. We find that $dcc^{lox/+}DAT^{Cre}$ and wild-type mice show similar acquisition of the go/no-go task and similar number of omission errors. However, $dcc^{lox/+}DAT^{Cre}$ mice have improved behavioral inhibition, indicated by fewer commission errors than wild-type controls.

Title: Caffeine potentiates cocaine effects on dopamine signaling more in adolescent than adult rat ventral striatum

Authors: *Q. D. WALKER, M. PUSTJOVESKY, C. M. KUHN;
Pharmacol. and Cancer Biol., Duke Univ., Durham, NC

Abstract: Caffeine use rates by adolescents is concerning and little is known about whether they are particularly sensitive to caffeine effects. Caffeine's psychostimulant effects are mediated primarily via antagonism of adenosine receptors. Adenosine A1A and A2A receptors densely populate the striatum in a variety of loci, usually in combination with DA receptors. Adenosine A1A receptors are located on presynaptic dopamine (DA) terminals where they couple with D2 receptors and inhibit DA release. We have observed that caffeine increases locomotor behavior more in adolescent than adult male rats. To resolve a presynaptic contribution to this effect these studies have examined A1A dependent DA release regulation using voltammetry. DA transient frequencies were the same at baseline in adolescent and adult male rats (15.5 and 17.5/min, respectively.) but became significantly greater in adolescents than adults (22 vs. 14/min) from 15 to 30 min following 25 mg/kg caffeine. DA transient duration and amplitude were the same before and after caffeine. Caffeine potentiated the effects of 15 mg/kg cocaine injected 30 mins following caffeine. Caffeine doubled the cocaine-induced increase of transient amplitude in adult rats but the increase in adolescents was almost 6-fold over baseline amplitude. Caffeine enhanced the cocaine-induced increase of DA transient duration by about 2-3 fold in adults and adolescents, respectively. Concurrent changes in tonic extracellular DA concentrations were also determined using principal components analysis. Caffeine decreased tonic DA in both age groups at 5 mins post injection; the decrease was brief in adolescents but sustained in adults. Subsequent injection of cocaine produced greater increases in tonic DA than cocaine alone. Cocaine-induced increases in tonic DA were sustained longer following caffeine in both ages. In contrast to these age differences in adenosine regulation of DA release, D2 autoreceptor antagonism with raclopride induced greater effects on phasic and tonic DA in adults. Thus, DA release autoregulation shifts developmentally from primarily adenosine A1 in adolescence to DA D2 in adulthood. Human adolescents may be particularly vulnerable to the ability of caffeine to increase the rewarding value of other drugs of abuse.

Title: Transient NMDAR blockade during adolescence selectively disrupts the frequency-dependent heterosynaptic inhibition of basolateral amygdalar transmission in the adult prefrontal cortex

Authors: *D. R. THOMASES[1], S. BELTON[2], K. Y. TSENG[1];
[1]Cell. and Mol. Pharmacol., Rosalind Franklin Univ. of Med. and Sci., North Chicago, IL;
[2]Depaul Univ., Chicago, IL

Abstract: While much of the brain is mature by the time of adolescence, the prefrontal cortex (PFC) continues to undergo major functional changes during this transitional period that depend upon NMDAR-mediated transmission. We have recently shown that adolescent exposure to the non-competitive NMDAR antagonist MK-801 produces an enduring frequency-dependent disruption of prefrontal local field potential (LFP) responses to ventral hippocampal drive that was not seen when MK-801 was given during adulthood. Here we examined whether a similar age-dependent PFC dysregulation occurs with other inputs such as those originated from the basolateral amygdala (BLA). We found that the overall pattern of BLA-evoked LFP facilitation and inhibition in the PFC remains unaltered following adolescent MK-801 treatment (0.1 mg/kg, i.p., from postnatal day 35 to 40). Both saline and MK-801-treated rats exhibited similar degrees of BLA-evoked paired-pulse facilitation of the homosynaptic response at 10 and 20 Hz, and LFP suppression at 40 Hz. Interestingly, a disruption of the heterosynaptic regulation of BLA-evoked LFP emerged following adolescent MK-801 treatment. Typically, the pattern of LFP facilitation and inhibition in saline controls is no longer present when the BLA-evoked LFP is preceded by a heterosynaptic response elicited from the ventral hippocampus. While the hippocampal-induced heterosynaptic modulation of the BLA response was not apparent at 10 Hz, it did suppress the amplitude of BLA-evoked LFP at 20 Hz and increased the degree of LFP suppression at 40 Hz. Such frequency-dependent inhibitory regulation of the BLA response by the ventral hippocampus is lacking in the PFC of adult rats that received MK-801 treatment during adolescence. Collectively, these results point to an interesting possibility that NMDAR-mediated function during adolescence is essential for the functional maturation of a heterosynaptic mechanism of inhibitory control in the PFC that can be driven by the ventral hippocampus to suppress BLA inputs. A disruption of PFC afferent processing could extend to impair the inhibitory regulation of other inputs and contribute to widespread and enduring prefrontal-dependent cognitive deficits later in life.

Title: Effects of amphetamine exposure during adolescence on orbitofrontal cortex neurons that encode goal-directed and habitual behaviors

Authors: *L. R. HAMMERSLAG[1], A. J. CONTRERAS-ROGERS[2], P. B. SHAH[2], A. N. MARKS[2], J. M. GULLEY[2];
[2]Psychology and Neurosci. Program, [1]Univ. of Illinois - Urbana Champaign, Champaign, IL

Abstract: Human drug users characteristically engage in habitual behavior, such as continuing to seek and use drugs in the face of diminished value. Similarly, animals that have been exposed to psychostimulants display more rapid development of habits as well as deficits in adapting to new information about reward contingencies and value. The orbitofrontal cortex (OFC) may mediate the effects of drug exposure on habit formation, as OFC-lesioned animals resemble drug-exposed animals in tests of habitual responding. Here, we used *in vivo* electrophysiology to examine OFC activity following outcome devaluation in rats exposed to amphetamine (AMPH) or saline during adolescence. Male and female Sprague-Dawley rats were exposed to AMPH every other day during adolescence (postnatal days 27-55). After a 3-week withdrawal period, microwire electrodes were surgically implanted into the OFC and recordings were obtained during behavior sessions where rats responded for a reinforcer under random interval (RI) 30 schedule and during extinction sessions that followed 1-h ad libitum access to the reinforcer (outcome devaluation). Neurons that displayed lever press (LP)-related activity were characterized as up- or down-modulated and a modulation rate (maximum difference from baseline) was calculated for each period of LP-related activity. Preliminary results suggest that the majority of LP-related neurons are up-modulated during RI30 training sessions and when the reinforcer is devalued. Furthermore, up-modulated neurons have a greater positive modulation rate during the devalued test relative to the RI30 sessions. During the valued test, however, the majority of lever-press related neurons are down-modulated, resulting in a negative modulation rate. Data collection is ongoing but we hypothesize that AMPH-exposed animals will be more habit-based compared to controls and that OFC neurons will encode this drug-induced change in behavior. It is important to clarify the relationship between habitual behavior and OFC function in drug-exposed animals as it is currently unclear if drug-exposure alters how the OFC responds to changes in value, or if drug-exposure simply reduces OFC activity non-specifically.

Title: Effect of peridolescent dopaminergic perturbation on adult dopamine circuit activity and dopamine-regulated behaviors

Authors: *D. SURI[1], N. CHUMA[2], M. ANSORGE[3];
[1]Developmental Neurosci., NYS Psychiatric Inst., New York, NY; [2]Psychiatry, [3]Developmental Neurosci., Columbia Univ., New York, NY

Abstract: Peridolescence (PA) constitutes a vulnerable period in humans, during which a range of psychiatric disorders as well as drug abuse emerge. We have identified a dopamine (DA) sensitive period in PA that alters aggression and behavioral response amphetamine (AMPH) in rodents. Specifically, enhanced DA levels during P32-P41 achieved by transient blockade of the dopamine transporter (DAT) result in enhanced adult aggressive behavior and sensitized response to AMPH challenge. Hyperactivity of the DA system is associated with increased impulsive aggression, and altered amphetamine response is an indication for perturbed DAergic function. We therefore examined how PA DAT blockade impacts adult DAergic activity and DA-regulated behaviors namely, impulsivity, motivation and working memory. We find that in animals with PA DAT blockade VTA but not SNc DA neurons exhibit enhanced excitability in slice recordings, and increased population activity and burst firing *in vivo.* These results support our hypothesis of a hyper-DAergic phenotype evoked by PA DAT blockade. Concomitant with increased VTA DAergic activity we also note enhanced motor impulsivity in the go-nogo task. These behavioral changes are however not accompanied by alterations in motivation or working memory. This study furthers our knowledge of how perturbed DAergic function during PA impinges on adult DAergic circuit activity to impact complex behaviors implicated in psychiatric disorders and drug abuse.

Title: Mouse strain differences in midbrain dopamine neuron firing during adolescence

Authors: ***A. PLACZEK**, J. LOGUE, M. SIMMONS;
Mercer Univ. Sch. of Med., Macon, GA

Abstract: In humans, adolescence is a developmental period of increased vulnerability to substance abuse and drug addiction. Those who use drugs and alcohol during adolescence are more likely to develop lifelong problems with addictive substances when compared to adult users. Human data have been consistently supported by animal models which have identified a role for ongoing neuronal development as a key component of the adolescent critical period for drug and alcohol addiction. The mesocorticolimbic dopamine (DA) systems are particularly important in the brain's response to addictive drugs, and all known addictive substances increase DA release from neurons originating in the ventral tegmental area (VTA). Action potential firing is probabilistically coupled to neurotransmitter release, and both *in vivo* and *ex vivo* studies have shown an important relationship between action potential firing patterns in VTA DA neurons and the release of DA in the nucleus accumbens (NAc). Our previous work has shown that direct depolarization of ventrolateral VTA DA neurons leads to greater sustained action potential firing in adolescent C57BL/6J mice compared to adults. Given the fact that C57BL/6J mice are known as an "alcohol-preferring" strain, and that these mice are also known to engage in binge-like alcohol consumption during adolescence, we wondered if an "alcohol non-preferring" strain (FVB/NJ) showed similar firing patterns during adolescence. We conducted patch-clamp recording in horizontal brain slices containing the VTA, measuring depolarization-induced burst durations in current-clamp mode of periadolescent (5 week old) and adult (3-6 month old) mice of both strains. We found again that the VTA DA neurons of periadolescent C57BL/6J mice fired significantly longer action potential trains than those of adults, however, this was not the case for those of FVB/NJ mice. In fact, adolescent FVB/NJ neuronal firing was not significantly different from adults, suggesting that the adolescent firing difference may be linked to alcohol preference and possibly binge-like consumption. We previously showed that increased activity of

small-conductance calcium-activated potassium (SK) channels was responsible for increased action potential firing durations in adolescent C57BL/6J mouse VTA DA neurons. We therefore examined apamin-sensitive, SK-mediated tail currents in adolescent FVB/NJ mice, and compared them to those of adults. Our findings suggest that decreasing SK channel function may reduce binge-like alcohol consumption in adolescent, alcohol-preferring mice, while increasing SK channel activity may have the opposite effect in alcohol non-preferring mice.

Title: Communication during a dyadic social interaction in school-age children with high functioning autism and children with williams syndrome

Authors: ***P. T. LAI**[1], M. IGNACIO[2], M. B. KIM[3], U. BELLUGI[3], J. REILLY[2];
[1]Salk Inst. LCN-B, La Jolla, CA; [2]Psychology, San Diego State Univ., San Diego, CA; [3]Lab. for Cognitive Neurosci., Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: Social communication is central to the human experience and affects all aspects of one's life. Lacking the ability to convey social information can lead to deficits in maintaining relationships and academic problems in school. The majority of studies investigating how children communicate have focused on children under the age of 7. The goal of this study is to better define the communicative phenotype of school age children in typically developing (TD; n = 26) children, children with High Functioning Autism (HFA; n = 23), and children with Williams Syndrome (WS; n = 14), by analyzing linguistic output during an interaction with an adult. Language was examined by assessing morphological proficiency and syntactic complexity. The social elements of language were assessed through the Reilly Evaluation Coding System (Reilly et al.,1998; 2004). Specifically, social evaluations (i.e., attributing emotions, building suspense, intensifiers, etc.) are measures used to attract and maintain the listener's attention through the narrator's attitude or perspective. Finally, a specific social aspect of the interaction was examined through questions that are asked by the child towards the experimenter. For the rates of morphsyntactic errors, differences were observed ($p<.001$); the HFA and WS groups

produced more morphosyntactic errors than the TD group. Next, differences were observed for syntactic complexity (p=.006); the TD group produced more complex syntax than both HFA and WS groups. However, to assess how children use language for social purposes, the HFA group produced fewer of these evaluations (p=0.09) than either the WS or TD groups. Finally, children asking questions were examined. This behavior was observed in 2 out of 26 TD children, 12 out of 23 HFA children, and 10 out of 14 WS children. A content analysis was then completed. For the TD group, only 2 questions were asked. Of the 29 questions asked by the HFA children, 8 were personal and 21 were on the topic of discussion. The WS group posed 25 questions, 12 personal and 13 on the topic of discussion. An example of a question asked from a WS child: "where did you go to dinner". Taken together, the language results suggest the structure and quality of language in both the HFA and WS children are not on par with their TD peers. When examining evaluative devices that serve social purposes, the WS group are more expressive followed by the TD group then HFA group. Asking questions during the interaction was a rare behavior in the TD group, while the HFA and WS groups posed numerous questions, but their content differed. These specific behaviors may suggest the WS individuals are trying to engage the experimenter into the conversation.

Title: Evidence that behavioural phenotypic effects of increased 5-HT transporter expression are mediated by a neurodevelopmental mechanism

Authors: *A. SENGUPTA[1], S. MCHUGH[2], A. TAYLOR[2], T. SHARP[3], D. BANNERMAN[2]; [2]Dept. of Exptl. Psychology, [3]Dept. of Pharmacol., [1]Univ. of Oxford, Oxford, United Kingdom

Abstract: Variation in the expression of the 5-HT transporter (5-HTT) has been linked to altered emotionality. For instance, prior research has shown that both humans and rodents with higher levels of the 5-HTT exhibit a phenotype of reduced anxiety and fear, though the mechanisms through which this is mediated remain unclear. One theory suggests that altered 5-HT

transmission specifically during development gives rise to the adult phenotype. To investigate this hypothesis, we studied ethological unconditioned anxiety and fear learning in early adolescent (P25 - P40) 5-HTT overexpressing (5-HTTOE) mice. We used a battery of tests including the elevated plus maze, hyponeophagia, successive alleys, black-white alley, open field test, and a standard cue-based fear-conditioning paradigm. The results taken across a range of tests indicated that young 5-HTTOE mice already have an established phenotype of reduced anxiety and fear, which is similar to that observed previously in adult 5-HTTOE mice. This phenotype could be driven either by discrete developmental changes in 5-HT signalling or by the ongoing activity of the 5-HTT at the time of the behaviour. To test the latter, citalopram (10 mg/kg) was administered acutely during the training session of the fear conditioning task. It was confirmed that fear learning was decreased in early adolescent 5-HTTOE mice compared to wild-type mice. Moreover, the deficit in fear learning of 5-HTTOE mice was not rescued by the acute dose of citalopram. Thus, the phenotype in the 5-HTTOE mice does not appear to be mediated solely by overexpression of the 5-HTT at the time point at which the behavioural task is performed. These findings support the idea that developmental events, rather than ongoing activity of the 5-HTT, are the underlying mechanism for the phenotype of reduced fear observed in 5-HTTOE mice.

Title: An investigation into the effects of developmental exposure to Bisphenol-S on anxiety in rats

Authors: *H. A. MOLENDA-FIGUEIRA, R. S. KLISH, S. F. KREUL, T. R. BECKER, K. L. FLETTY, S. N. HASEKER;
Psychology Dept., Univ. of Wisconsin-Stevens Point, Stevens Point, WI

Abstract: It has been suggested that developmental exposure to endocrine disruptors may play a role in the development of a diverse group of maladies, ranging from cancers to attention deficit hyperactivity disorder, neurodegeneration and Schizophrenia. This has prompted the removal of some of these chemicals, such as Bisphenol-A (BPA) from commonly-used plastic products.

However, BPA has been replaced with a similar chemical, Bisphenol-S (BPS), which is also known to alter hormone actions in a variety of tissues, potentially leading to illness. Little is currently known about the impact of BPS on health or behavior. We investigated the impact of developmental BPS exposure on anxiety-like behaviors in rats, and whether sex differences in response to BPS treatment are present. Pregnant Sprague-Dawley rats were exposed to BPS in drinking water (1mg/L of water) beginning on gestational day 12. This resulted in a BPS dose of approximately 15µg/kg/day. Control dams received plain water. At 1 day of age, the sex of rat pups was determined and litters were culled resulting in a 2-cohort final total of 10 rats/sex/water treatment group. Exposure to BPS through drinking water continued until 45 days of age. Beginning at 21 days of age (juvenile test), rats received one of 3 anxiety tests: the elevated plus maze (EPM), light-dark box (L-D Box) or open field test (OF). Rats received 1 type of test on alternate days until all 3 tests were completed. Each test was conducted for 5 minutes, and behavior was recorded using video cameras. Rats were again tested for anxiety beginning at 37 days (peripubertal test) and finally beginning at 60 days of age (adult test). Females were monitored for estrous cycle stage via appearance of vaginal cytology, and anxiety tests were only administered on the day of estrus. Duration of time spent in the open versus closed arms for the EPM, in the light versus dark compartments for the L-D Box and time spent in corners, center or sides of the OF test was quantified using a MS-DOS computer program. Preliminary results of Cohort 1 demonstrate an interaction between Sex and Treatment for the EPM, suggesting that control male rats were the most anxious. However, during the peripubertal tests, there was a trend for BPS-treated animals to spend more time in the corners of the OF test, indicating higher levels of anxiety compared to controls. Because BPS treatment was ongoing during the peripubertal time point, this could indicate that while BPS may have organizational effects on the brain early on in development, as has been shown for BPA, puberty may be another sensitive time for not only organization of circuits mediating anxiety but also manifestations of anxious behaviors.

Title: Developmental and sex-dependent effects of early life stress on glutamate receptor expression

Authors: *P. GANGULY[1], H. C. BRENHOUSE[2];
[1]Psychology, [2]Northeastern Univ., Boston, MA

Abstract: Exposure to early life stress increases vulnerability to psychiatric disorders such as depression and anxiety, which often develop in adolescence or young adulthood and manifest in a sex-dependent manner. Numerous studies have shown that ELS disrupts normal development of prefrontal cortex (PFC) receptor expression and functional connectivity to the limbic system. ELS may also disrupt glutamate receptor trafficking and mobility, which play an important role in stress and behavior adaptation. However, the mechanisms by which ELS impacts glutamatergic receptor expression in males and females are still relatively unknown. PFC AMPA and NMDA receptors mediate excitatory synaptic transmission and behavior through tightly regulated post-translational trafficking to the membrane. Previous studies have indicated that ELS in the form of maternal separation (MS) leads to overexpression of NMDA receptor (NMDAR) subunit NR2A within the medial PFC. Membrane density of GluR2-containing AMPA receptors (AMPARs) in the PFC is also substantially elevated after acute stress, further suggesting that stress can affect trafficking of NMDARs and AMPARs. Here we compared plasma membrane and cytoplasmic expression of NR2A and GluR2 subunits in the PFC of male and female rats, either reared under control (CON) conditions or exposed to MS. Western blot analyses of membrane or cytoplasmic fractions were performed on animals sacrificed on postnatal day 25 (juvenility) or 40 (adolescence). We observed sex- and developmental related changes in membrane expression of NR2A and GluR2. Specifically, males expressed less NR2A and GluR2 in both cytoplasmic and membrane fractions compared to females. However, MS caused increased membrane NR2A in male adolescents but not female adolescents. These results suggest sex and rearing condition effects on AMPA and NMDA receptor trafficking. One interpretation is that increased insertion of AMPARs and NMDARs during early adolescence in females could facilitate resilience in females, while the absence of such a mechanism could yield males more susceptible to some ELS effects. However, the age-dependent expression of these receptors, along with their subunit composition, will shed further light on possible developmental influences on sex-dependent ELS effects.

Title: Behavioral alterations induced by adolescent chronic social instability stress are correlated with downregulation of nectin-3 in medial PFC in mice

Authors: *J.-T. LI[1], X. WANG[2], H. WANG[1], Y.-A. SU[1], T. SI[1];
[1]Inst. of Mental Health, Peking Univ., Beijing, China; [2]Dept. of Neurobio., Zhejiang Univ. Sch. of Med., Hangzhou, China

Abstract: Background: Adolescence is a critical developmental period witnessing substantial remodeling of neural circuits, especially the prefrontal cortex. Chronic social instability stress in adolescence has been known to induce persistent alterations in a variety of behaviors. However, it remains to be determined how the prefrontal cortex is affected by this paradigm. Methods: Male mice were exposed to chronic social instability stress from postnatal day 28 to 77. One week after treatment, they were tested for anxiety-related behaviors in the open field, social behaviors (including social preference and recognition) and spantaneous alternation in Y maze. At the end of behavioral testing, animals were sacrificed and we measured the expression levels of several synaptic proteins in medial PFC, including synaptophysin, PSD-95, nectin-1 and nectin-3. Result: Social stressed mice exhibited increased anxiety levels, impaired performance in social recognition and spontaneous alternations, whereas social preference and novel object recognition were not affected. Among several synaptic proteins of mPFC, only nectin-3 was found to be significantly decreased in stressed animals. Moreover, the downregulation of nectin-3 significantly correlated with behavioral alterations. Conclusion: These findings add to evidence that chronic social stress during adolescence modifies the PFC development, which may serve as the underlying mechanisms for stress-induced behavioral deficits.

Title: Consumption of a high-fat diet during adolescence results in long-lasting impairments in sensorimotor gating and stress reactivity

Authors: *P. KALYAN-MASIH, J. VEGA-TORRES, T. HEERS, J. D. FIGUEROA;
Loma Linda Univ. Sch. of Med., Loma Linda, CA

Abstract: Adolescence is a critical period in the neurobiological programming of lifelong stress coping mechanisms. The brain undergoes extensive rearrangement during this maturation period, which underscores a unique sensitivity to environmental factors. Dietary-essential omega-3 polyunsaturated fatty acids (n-3 PUFAs) are gaining recognition as potent nutritional factors underpinning optimal brain development and function. However, their consumption is not sufficient in the reported typical "Western" dietary patterns, in particular during adolescence. This study investigates the impact of a Western diet (WD) on stress responses and sensorimotor gating behaviors using the elevated plus maze, the acoustic startle reflex (ASR) and the prepulse inhibition (PPI) of the ASR. Adolescent Lewis rats (PND 28; $n = 36$) were fed *ad libitum* during four weeks in either experimental WD (42% kcal from fat; $n = 18$) or control diet (7 % kcal from fat; $n = 18$). During early adulthood (PND 58), all rats received the same control diet for four additional weeks before behavioral testing. We found that the rats that consumed the WD during adolescence exhibited reduced ASR and PPI responses (approximately 30% reduction) when compared to control animals ($p < 0.05$). The WD had no effect on body weight in the adult rats ($p > 0.05$) Notably, we show that the WD impaired the ability of these animals to cope with stress, as evidenced by a significant increase in anxiety-like behaviors (elevated plus maze, open field test) following exposure to social isolation and predatory threat stress. Collectively, this study shows that the neurobehavioral responses to stress are sensitive to WD intake during adolescence. Understanding how nutrition affects the adolescent brain is critical, as alterations during this period impose vulnerability to stress-associated disorders, including PTSD.

Title: DISC1 mutation in astrocytes synergistically interacts with adolescent cannabis exposure to affect cognitive function in adult mice

Authors: *S. ABAZYAN, B. ABAZYAN, O. MYCHKO, A. SHEVELKIN, C. YANG, A. KAMIYA, M. PLETNIKOV;
Psychiatry, Johns Hopkins Univ., Baltimore, MD

Abstract: Marijuana use during adolescence has been linked to the increased risks for psychoses and long-term cognitive impairment. The literature supports a multi-factorial view of the liability to psychiatric and cognitive disorders. Thus, we assess the effects of adolescent cannabis exposure on cognitive dysfunction in mice expressing mutant Disrupted-In-Schizophrenia-1 (DISC1) in astrocytes that have been recently implicated in the cognitive effects of cannabis. Control and mutant DISC1 mice were treated with saline or tetrahydrocannabinol (THC) (8.0 mg/kg) for 21 days during postnatal days (P) 32-52; and three weeks later mice were tested for novelty-induced hyperactivity in open field, anxiety in elevated plus maze, spontaneous alteration in Y maze, spatial recognition memory in Y maze, novel object recognition, place preference test and fear conditioning. Compared to all other groups, THC-treated DISC1 mice exhibited impaired spatial, object recognition and place recognition memory. These effects of THC were dependent on expression of mutant DISC1 during adolescent exposure and were not observed after adult THC exposure or adolescent exposure to amphetamine. Our findings indicate that chronic adolescent THC exposure leads to cognitive deficits in mice carrying DISC1 mutation in astrocytes and suggest that genetically predisposed individuals are more sensitive to adolescent marijuana use to develop cognitive impairment.

Title: Age related differences in the neural representation of magnitude discrimination and cognitive impulsivity in the orbitofrontal cortex

Authors: *L. R. AMODEO, J. D. ROITMAN;
Psychology, Univ. of Illinois, Chicago, Chicago, IL

Abstract: The underdevelopment of the prefrontal cortical system in adolescents is thought to explain a relative increase in maladaptive decisions during this period. Specifically, the orbitofrontal region of prefrontal cortex (OFC) has been shown to play a central role in guiding goal-directed decisions. The aim of this research is to assess, across the lifespan, how OFC encodes the cues that predict reward availability and the receipt of immediate and delayed rewards. To this end, microwire electrode arrays were implanted into the OFC of both adolescent and adult rats so that activity of multiple single-neurons could be recorded during behavioral performance. Long-Evans rats were trained to perform a Magnitude Discrimination (MD) task where a choice was given between a small reinforcement lever and a large reinforcement lever, with both rewards delivered immediately. After five sessions of the MD task, rats began a progressive Delay Discounting task (DD), where they were given the choice between two levers: one leading to a smaller sooner (SS) reward and the other to a larger later (LL) reward. The delay to the larger reward for LL presses increased daily from 1s to 5s, 10s, 15s, 20s, 50s, 70s and 90s. We found no behavioral differences between age groups on DD performance. While inconsistent with prior research, this discrepancy may be due to differences in age-dependent learning and engagement in the task. Using the MD task, we matched learning for both ages so that both groups begin the DD task with an equivalent preference for the large reward. Further, animals are required to attend to the task by initiating each trial via center port response. While adolescent and adult rats performed the MD and DD tasks, we recorded the activity of OFC neurons. Despite a lack of behavioral effects, reward and temporal processing during decision-making were neurologically different in adolescents compared to adults. While the behavioral responses follow the same general pattern in adolescents as adults, adolescent rats do not exhibit a phasic response at the time of the behavioral choice and have an overall blunted response at the time of the later reward. Overall, this research provides a novel insight into how orbitofrontal cortex executes impulse control across development, and suggests that adults and adolescents may leverage different neurological mechanisms during impulse control.

Title: Adult mesocorticolimbic tyrosine hydroxylase activity is increased by adolescent social defeat

Authors: *M. A. WEBER[1], J. L. SCHOLL[1], R. T. PAULSEN[1], G. L. FORSTER[1], K. J. RENNER[2], M. J. WATT[1];
[1]Div. of Basic Biomed. Sci., [2]Biol. Dept., Univ. of South Dakota, Vermillion, SD

Abstract: Adolescent social defeat in rats, a model of teenage bullying, results in decreased medial prefrontal cortex (mPFC) dopamine (DA) activity in early adulthood. Precise mechanisms influencing the defeat-induced decrease in mPFC DA activity are not fully understood, but may involve altered tyrosine hydroxylase (TH; rate-limiting enzyme in DA synthesis) activity. We used two experimental approaches to examine TH activity in specific regions of the young adult brain after adolescent defeat. First, brain tissue collected from previously defeated and control rats in early adulthood (postnatal day [P]56) was processed using western immunoblot for total and phosphorylated serine 40 (pSer40) TH expression. Second, previously defeated and control rats received acute injections of the amino acid decarboxylase (AADC) inhibitor NSD-1015 (100 mg/kg, ip.) at P56. Brain tissue DOPA (DA precursor) accumulation served as a measure of *in vivo* TH activity. Adult mPFC TH activity was increased after adolescent defeat, as indicated by both increased pSer40 TH expression and greater DOPA accumulation 30 min after AADC inhibition. Within subcortical regions, AADC inhibition elicited greater DOPA accumulation after 180 min in the striatum of previously defeated rats, indicating higher *in vivo* TH activity, with a similar effect in the nucleus accumbens (NAc) core after 30 min. No differences in DOPA accumulation as a result of adolescent defeat were evident in the NAc shell or the ventral tegmental area. Increased adult mPFC TH activity after adolescent defeat is contrary to our initial hypothesis that TH activity would be decreased to result in lower mPFC DA activity. We speculate that increased mPFC TH activity may be acting as a compensatory mechanism attempting to raise mPFC DA synthesis. Current studies are examining TH activity 180 min after AADC inhibition, along with western immunoblots to measure total and pSer40 TH expression in the affected subcortical regions. Findings to date suggest that adolescent defeat has long-lasting effects on TH activity in distinct cortical and

subcortical regions, implying alterations to DA synthesis. However, the functional significance of the subcortical changes to TH activity is unknown.

Title: The novel endocannabinoid degradation inhibitor, MJN110, dose-dependently alters social behavior and medial prefrontal cortex activation in adolescent male rats

Authors: *R. L. JONSCHER[1], E. E. BOXER[2], E. C. LOETZ[2], A. ALESSI[2], M. T. ISHIKI[3], S. T. BLAND[2];
[2]Psychology, [3]Biol., [1]Univ. of Colorado-Denver, Denver, CO

Abstract: The endocannabinoid (eCB) system of the brain is involved in many social behaviors and cognitive processes, and may be involved in mood disorders including anxiety. Here, we tested the hypothesis that enhancing the eCB 2-arachidonylglycerol (2-AG) would increase pro-social behavior in the social interaction test, suggesting decreased anxiety. Furthermore, we proposed that the decrease in anxiety would be associated with altered activation of parvalbumin-expressing GABAergic interneurons in the basal-lateral amygdala (BLA) and medial prefrontal cortex (mPFC). We administeredMJN110, which inhibits monoacylglycerol lipase, the enzyme that degrades 2-AG. After 2 hr, adolescent male rats were exposed to a 15 min encounter with a novel conspecific. 90 min later brains were removed and processed for immunohistochemistry (IHC). We observed dose-dependent alterations in social behaviors produced by MJN110. Low doses of MJN110 significantly increased play behaviors in adolescent male rats during a social encounter, whereas a high dose produced a significant reduction in total social interaction. These observations suggest that increased 2-AG signaling may elicit an anxiolytic response at a low dose and sedative effects at a high dose. Double-label IHC for Fos and parvalbumin revealed that MJN110 leads to dose-wise, regionally specific alterations in the activation of parvalbumin-positive cells. At a high dose (5mg/kg), double labeled cells were reduced in the mPFC, but not the BLA. These results suggest that mPFC, but

not BLA mediates 2-AG's effects on play and anxiety-like behaviors, and imply that the behavioral effects of MJN110 may be due to dose-dependent disinhibition of the mPFC.

Title: Monoacylglycerol lipase (MAGL) inhibition differentially alters phosphorylation of mTOR in medial prefrontal cortex neurons and astrocytes in adolescent rats

Authors: *E. C. LOETZ[1], R. JONSCHER[2], E. BOXER[2], Z. NARROWE[2], B. GREENWOOD[2], S. T. BLAND[2];
[2]Psychology, [1]Univ. of Colorado Denver, Denver, CO

Abstract: The mammalian target of rapamycin (mTOR) is a protein kinase that has been identified in neurons and glial cells and has a role in plasticity through regulation of protein synthesis. Activation of mTOR through phosphorylation (pmTOR) can be mediated through numerous extracellular signals, but it is unknown what the endocannabinoid (eCB) system's effect on mTOR phosphorylation might be. 2-arachidonoylglycerol (2-AG) is one of the primary eCBs present in the brain, and is broken down largely by the enzyme MAG-L. The novel compound MJN110 is a potent MAG-L inhibitor capable of increasing central 2-AG levels. We have observed that MJN110 dose-dependently alters social behavior and neuronal activation in the medial prefrontal cortex (mPFC). Here, differing doses of MJN110 were administered systemically to adolescent male rats prior to a single social encounter. pmTOR expression was assessed in neuronal and glial cell types (based on cell morphology) using immunohistochemistry (IHC) in both the prelimbic (PL) and infralimbic (IL) regions of the mPFC. Similar patterns of pmTOR expression were observed in PL and IL. In vehicle-treated rats only, a social encounter increased glial pmTOR expression. A high dose of MJN110 produced a robust decrease in glial pmTOR expression, while neuronal pmTOR expression increased approximately twofold in neurons at this dose. Double-label fluorescent IHC revealed

that pmTOR was expressed in astrocytes but not microglia. These results suggest that 2-AG has opposite and dose-dependent effects on mTOR phosphorylation in neurons and astrocytes.

Title: Effect of monoacylglycerol lipase (MAGL) inhibition on aggression in female rats after postweaning social isolation

Authors: J. FONTENOT[1], H. HAMIDU[2], M. ISHIKI[2], E. LOETZ[1], *S. T. BLAND[1];
[1]Dept of Psychology, [2]Dept of Biol., Univ. of Colorado, Denver, Denver, CO

Abstract: Early life adversity, including during adolescence, can lead to alterations in normal brain development and can increase susceptibility to behavioral disorders in adulthood. Post-weaning social isolation (PSI) is a model of early life adversity in social animals, and previous work has shown that after PSI, female rats display increased aggression during a social encounter with a novel conspecific. The endocannabinoid system, which includes 2-arachidonoyl glycerol (2-AG), is known to regulate central pathways that are important for emotional regulation. The novel drug MJN110 increases the concentration of 2-AG by inhibiting MAGL, the enzyme responsible for its breakdown. The present study examined the impact of MJN110 on PSI-induced aggression in female rats. Female rats were either group housed (GP) or isolation housed (PSI) for 3 weeks between postnatal days 21 and 42. MJN110 (1 or 5 mg/kg IP) or vehicle was administered 2 hr prior to a single social encounter. Social behaviors and total social interactions were assessed. PSI females displayed more aggressive grooming and more social interaction than GRP females. Both doses of MJN110 decreased aggressive grooming regardless of housing conditions but did not significantly decrease overall social interaction. Thus, 2-AG may selectively modulate aggressive behavior in female rats.

Title: Effects of paradoxical sleep deprivation on adolescent mice

Authors: *L.-H. TUAN[1], L.-J. LEE[1,2,3];
[1]Grad. Inst. of Anat. and Cell Biol., [2]Grad. Inst. of Brain and Mind Sci., [3]Neurobio. and Cognitive Sci. Ctr., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Sleep insufficiency has become a serious health issue. In modern society, the majority of citizen, including the adolescence, do not obtain enough sleep. Since adolescence is a critical period for brain development, the consequences of insufficient sleep during adolescence should be concerned. In this study, we used five weeks old male C57/BL6 mice to examine the acute effects of 72-hour paradoxical sleep deprivation (SD). The modified multiple platform method was adopted. For mice kept in the home cage and on big platforms, sleep time was not limited and used as controls. Mice of SD and control groups were examined in behavioral, neurochemical and histological aspects. Unlike the results of SD in adult animal models, our results showed minimal changes in adolescent mice immediately after 72-hour SD.

Title: Altered plasma sulfate and eaat3 expressions in a mouse model of autism, BTBR T+Itpr3tf/J (BTBR)

Authors: *S.-H. KIM, M. HILGART, A. WADOOD, R. SHYTLE;
Dept. of neurosurgery and brain repair, Univ. of South Florida, Tampa, FL

Abstract: Etiology of autism is unknown due to heterogeneity of the disorder, it has been suggested that genetic variations and various environmental factors may play a synergistic role in autism manifestation. Sulfate may be an important element promoting autism phenotype, especially during early development. Sulfate conjugation of hormones and neurotransmitters is necessary for normal growth and development as well as detoxification of xenobiotics. Recently, it has reported that autistic children have lower sulfate levels and increased oxidative stress markers, suggesting that lower plasma sulfate levels may lead to accumulation of toxins and decreased antioxidant capacity in this population. Increased oxidative stress in autistic individuals has been reported. Glutathione (GSH) plays essential roles in detoxification and balancing redox homeostasis in brain. Cysteine (Cys) is the rate limiting factor in GSH de novo synthesis, thereby performing an essential role in cellular protection against oxidative stress. In neurons, the majority of Cys is transported from extracellular space via excitatory amino acid transporter 3 (EAAT3), one of the glutamate transporters. Studies have suggested that disrupted EAAT3 expression resulted in neuronal death due to the excessive oxidative stress; furthermore, EAAT3 has been implicated in neurodegenerative diseases. Accordingly, our group hypothesize that autistic children may have lower detoxification capacity, and therefore are more prone to drug induced toxicity and oxidative stress. In our study, we determined if a mouse model of autism, the BTBR line, exhibits differences when compared to C57BL/6J (B6) in plasma sulfate levels, EAAT3 expression, as well as GSH levels. Plasma sulfate levels, GSH levels in plasma and brain, and EAAT3 expression in frontal cortex were measured in BTBR and B6 mice (6 weeks old, male, n=8). Our data showed that plasma sulfate levels were significantly lower in BTBR than B6 mice which have been reported. BTBR mice showed significantly lower EAAT3 expression levels in the prefrontal cortex. On the other hand, GSH and GSSG levels were similar between BTBR and B6 mice. Our findings suggest that lower plasma sulfate levels and lower EAAT3 expression in neurons may increase vulnerability to oxidative stress due to the diminished detoxification capacity and Cys availability, leading to GSH depletion in response to environmental toxins. The role of EAAT3 during development needs to be investigated in depth and BTBR mice may be a favorable animal model to study the mechanism of EAAT3 modulation. Furthermore, how altered sulfate physiology affects in normal brain development needs to be elucidated.

Title: Exercise in adolescent rats reduces renewal of extinguished instrumental behavior

Authors: *M. C. EDDY, J. T. GREEN;
Psychological Sci., Univ. of Vermont, Burlington, VT

Abstract: Conditioned instrumental behaviors are voluntary actions that are controlled by their outcomes. Animals readily acquire behaviors (e.g., lever pressing) to obtain a desirable outcome (e.g., food pellet, drug delivery) and likewise learn to suppress behavior when the reinforcer is withheld. Extinction of instrumental responding is an important component of behavioral change. Extinguished behaviors can re-emerge through several associative mechanisms, including renewal. Renewal occurs when an animal is exposed to a context different from the extinction context (Bouton & Bolles, 1979), resulting in a return of extinguished responding. This return of responding demonstrates that extinction is not erasure of the original learning, but rather new inhibitory learning. Additionally, it appears that extinction learning is particularly sensitive to context (Bouton, Todd, Vurbic, & Winterbauer, 2011), a feature that presents a major challenge in treating addiction disorders clinically. Reducing renewal, therefore, is an important avenue of study. Our lab has previously demonstrated that voluntary exercise improves extradimensional set-shifting in adolescent (PD30-45) rats, which is dependent upon medial prefrontal cortex (mPFC). Because the mPFC has been suggested to underlie extinction and renewal, we asked whether exercise during adolescence (i.e., PD30-45) might affect renewal. Using a sucrose pellet reinforcer, rats with an unlocked (exercising) or locked (non-exercising) running wheel in their home cage were trained to lever press over 6 sessions in context A, and then were extinguished (lever press no longer resulted in pellet delivery) in context B. During test, rats were returned to context A (in extinction_no pellet was available; ABA renewal). No differences between groups were observed across acquisition or extinction trials. As predicted, renewal of responding occurred in non-exercising rats. Rats that had exercised also showed renewal, but responding in context A was significantly lower than non-exercising rats. Similarly, using an AAB preparation (acquisition and extinction in the same context, test in a novel context) non-exercising rats showed renewal when removed from the extinction context, while exercising rats did not show a significant increase in responding in context B. Exercise may have eliminated AAB renewal, or we may have observed a floor effect, as AAB renewal is typically of lower magnitude than ABA renewal. ABC renewal (all three

contexts novel) is currently being investigated to further explore how exercise is modifying operant renewal (and possibly mPFC function) in adolescent rats.

Title: The endocannabinoid system is altered in mice bred for high voluntary wheel running

Authors: ***Z. THOMPSON**[1], D. ARGUETA[2], J. KAUR[3], T. GARLAND, Jr.[4], N. V. DIPATRIZIO[3];
[1]Neurosci. Grad. Program, [2]Bioengineering, [3]Biomed. Sci., [4]Biol. Dept., Univ. of California, Riverside, Riverside, CA

Abstract: Endocannabinoids have many roles, including in aspects of energy balance, food reward, and voluntary locomotion. Signaling at the cannabinoid type 1 (CB1) receptor has been specifically implicated in motivation for voluntary movement, including wheel running. We studied 4 replicate lines of high-runner (HR) mice that have been bred for 75 generations based on total number of wheel revolutions on days 5 & 6 of a 6-day period of wheel access. Four replicate control (C) lines are bred without regard to wheel running. HR mice voluntarily run ~3 times as much as C, primarily by running faster. When given a CB1 receptor antagonist (SR141716; Rimonabant), HR female mice decreased their running more than C female mice, while male HR and C mice did not show a differential response. Both female and male HR mice showed a differential decrease in running (compared to C mice) when given a CB1 receptor agonist (WIN 55,212-2). We hypothesized that circulating levels of endocannabinoids (specifically, anandamide and 2-arachidonoylglycerol) differ between HR vs C mice, possibly in a sex-specific manner. 50 male and 50 female mice (half HR and half C) were allowed access to wheels for 6 days, while another 50 males and 50 females (also half HR and half C) were kept without access to wheels. Blood samples were taken during the 6th night of wheel access or no wheel access, centrifuged at 1500 g, and plasma stored at -80 C. Brains, livers, and jejunum were

also dissected. Lipids, extracted from plasma or tissue, were processed through an LCMS. Based on the previous pharmacological data, we predict higher levels of plasma endocannabinoids in the HR mice, especially in females. We also expect that mice with access to wheels for 6 days will have higher plasma levels of endocannabinoids.

Title: GABAergic transmission and reduced modulation by endocannabinoids in adult rat rostral ventromedial medulla (RVM) neurons following persistent inflammation

Authors: *M.-H. LI, K. L. SUCHLAND, S. L. INGRAM;
Neurolog. Surgery, Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Chronic pain is a major health issue that affects ~ 20% of the population worldwide and has an estimated cost of >$500 billion a year in medical treatments and lost productivity. Recently, an *in vivo* study showed that activity of rostral ventromedial medulla (RVM) neurons changes in rats pretreated with complete Freund's adjuvant (CFA), an agent that induces persistent inflammatory pain. Using whole-cell patch-clamp recordings from *adult* rat RVM slices, we find that GABA release in the RVM is significantly increased in rats pretreated with CFA. Endocannabinoids normally inhibit presynaptic GABA release in adult RVM so that superfusion of the cannabinoid receptor 1 (CB1) selective inhibitor rimonabant (SR141716, 3 μM) increases GABAergic miniature inhibitory postsynaptic currents (mIPSCs) by 88 ± 31%. Interestingly, the ability of endocannabinoids to inhibit GABA release is reduced following CFA treatment so that SR141716 increases GABA mIPSC frequency by 13 ± 9% ($p<0.05$ compared to naive). Further, we find that the inhibition of GABA release by the CB receptor agonist Win55,212-2 is reduced in CFA-treated (11 ± 6%) compared with naïve rats (40 ± 5%; $p<0.05$).

Different from cannabinoids, opioid inhibition of GABA release was not different in naïve (52 ± 6%) compared to CFA-treated (52 ± 10%; p>0.05) RVM neurons. Increased GABA release in the RVM reduces activation of descending pain inhibitory fibers resulting in increased nociceptive transmission from primary afferent inputs to the dorsal horn of the spinal cord.

Title: CB1R activation enhances hippocampal excitatory neurotransmission in female adolescent rats

Authors: *C. G. REICH;
SSHS/Psychology, Ramapo Col. of New Jersey, Mahwah, NJ

Abstract: A previous study demonstrated that hippocampal CB1 receptor (CB1R) levels are lower in female adolescent animals compared to males (Reich et al., 2009). Following 21 day exposure to chronic mild stress, CB1 increased in females while decreasing in males; thus suggesting that hippocampal CB1 responds differentially to stress depending on sex. Several other lines of converging evidence clearly indicate a functional sex difference in the endocannabinoid system and behavioral reactions to exogenous cannabinoids in both human and animals (Rubino and Paralaro, 2011). However, there remains a paucity of data how these sex differences are manifested physiologically. We, therefore, begun a series of neurophysiological investigations on the endocannabinoid system in female adolescent rats. Preliminary studies show that exogenous activation of CB1 (WIN 55-212-2) enhances excitatory neurotransmission in the CA1 of female animals, while it classically decreases excitatory transmission in males. The latter is due to a CB1-mediated suppression of glutamate release. The mechanism of the observed enhancement in females is presently being investigated.

Abstract: The second messenger hydrogen peroxide transduces changes in cellular redox state by reversibly oxidizing protein cysteine residues to sulfenic acid. This signaling event regulates many cellular processes, but has been never shown to occur in the brain. Here we report that hydrogen peroxide heightens endocannabinoid signaling in brain neurons through sulfenylation of cysteines C201 and C208 in monoacylglycerol lipase (MGL), a serine hydrolase that deactivates the endocannabinoid 2-arachidonoyl-sn-glycerol (2-AG) in nerve terminals. The results suggest that MGL sulfenylation may provide a presynaptic control point for 2-AG-mediated endocannabinoid signaling.

Abstract: The endogenous endocannabinoid system plays a crucial role in regulating appetite and feeding behavior in mammals as well as working memory and reward mechanisms. In order to elucidate the possible role of cannabinoid type-1 receptors (CB1Rs) in the regulation of hippocampal plasticity in animals exposed to food restriction (FR), we limited the availability of food to a 2-h daily period for 3 weeks in Sprague Dawley rats. FR rats showed a higher LTP at hippocampal CA1 excitatory synapses with a parallel increase in the probability of presynaptic glutamate release when compared to animal fed ad libitum. FR was also associated with a decreased inhibitory effect of the CB1R agonist win55,212-2 on glutamatergic fEPSPs, together with a decrease in hippocampal CB1R protein expression. In addition, hippocampal brain derived neurotrophic factor (BDNF) protein levels and mushroom dendritic spine density were significantly enhanced in FR rats. The present data underscore the important role of CB1R signaling in the regulation of glutamate release from presynaptic terminals in CA1 hippocampal field and, in turn, the increase in hippocampal excitability, long-term synaptic plasticity and dendritic spine remodeling of CA1 excitatory synapses. Our results are consistent with the hypothesis that FR in rats could have ameliorating effects on hippocampal function, and support previous published data showing increased levels of neurotrophic factors and LTP formation.

Title: Diacylglycerol lipase is a substrate for PKA: examining the role of dopamine and PKA in 2-arachidonoylglycerol mobilization

Authors: *B. C. SHONESY[1], J. R. STEPHENSON[1], C. R. MARKS[1], S. PATEL[2], R. J. COLBRAN[1];

Abstract: The endocannabinoids (eCBs) 2-arachidonoyl glycerol (2-AG) and anandamide (AEA) are retrograde modulators of striatal synaptic transmission that have been implicated in multiple striatal-based psychiatric and neurological disorders. The identification of mechanisms regulating eCB synthesis is key to understanding the synaptic roles of eCBs in the normal and pathophysiological state. Dopamine (DA) is a crucial regulator of striatal synaptic function, and interactions between the DA and eCB signaling pathways appear to be critical in the dynamic regulation of striatal output. Although the intersection of DA and eCBs has been shown at the circuit level, the molecular mechanisms that underlie these events are still unknown. Although activation of D2-DA receptors is necessary for AEA-mediated striatal LTD, little is known about the effects of DA on 2-AG mobilization at striatal synapses. To address this, we examined the importance of D1 and D2 receptors on depolarization induced suppression of excitation (DSE) at direct and indirect pathway synapses, a form of short-term 2-AG mediated plasticity. In contrast to what is known about AEA, we found that the D1R agonist SKF-81297 enhances DSE in D1R-expressing medium spiny neurons (MSNs). Interestingly, the D1R or D2R antagonists SCH23390 and sulpiride do not significantly affect DSE in either D1R-MSNs or D2R-MSNs. 2-AG is primarily synthesized by diacylglycerol lipase alpha (DGLα) in the striatum, and we have previously shown that DGLα activity can be regulated by CaMKII phosphorylation to inhibit 2-AG synthesis (Shonesy et al., 2013. Nat Neurosci **16**:456). Therefore, since PKA is the canonical downstream target of D1 receptors, we tested whether DGLα was a substrate for PKA. These studies revealed that PKA phosphorylates DGLα at distinct sites from CaMKII. Preliminary studies indicate that PKA phosphorylation stimulates DGLα activity *in vitro*, which would be consistent with our finding that D1 receptor activation can enhance 2-AG release at striatal synapses. Moreover, initial data suggests that the enhancement of DSE by SKF-81297 in D1-MSNs can be blocked by the application of a PKA inhibitor peptide. Given the segregation of D1 and D2 receptors in direct and indirect striatal circuits, the involvement of D1 receptors in the regulation of 2-AG synthesis may be important in controlling information flowing through the striatum to modulate multiple behavioral outcomes.

Title: Far-reaching effects of fatty acid amide hydrolase knock out on the lipidome

Authors: *H. B. BRADSHAW[1], E. LEISHMAN[2], K. MACKIE[2], B. CORNETT[1];
[2]Psychological and Brain Sci., [1]Indiana Univ., Bloomington, IN

Abstract: Endogenous cannabinoids 2-arachidonoyl glycerol (2-AG), N-arachidonoyl ethanolamine (AEA), and the AEA metabolite N-arachidonoyl glycine (NAGly) are all derivatives of arachidonic acid (AA), a polyunsaturated fatty acid that is also a substrate for the production of prostaglandins (PGs). The directionality of the relationship among these lipids is an important biochemical factor in how enzymes that regulate each of the classes of lipids that potentially affects the available pools of the others. Fatty acid amide hydrolase (FAAH) is hypothesized to be responsible for the majority of the brain's AEA hydrolysis; although it can also hydrolyze other N-acyl amides. Therefore, deleting FAAH may also have effects on other bioactive lipids than AEA. This study aims to elucidate the effects of genetic deletion of FAAH on the N-acyl amide, 2-acyl glycerol, and PG lipidome in the mouse striatum, hippocampus, cerebellum, thalamus, cortex, hypothalamus, midbrain and brainstem. Six FAAH knockout (KO) mice were compared to age and sex matched wild-type mice from the same C57 genetic background. Animals were sacrificed, brains were removed and targeted areas were dissected and stored at -80C. Methanolic extracts were partially purified on C-18 solid-phase extraction columns. Eluants were analyzed with high-pressure liquid chromatography coupled to tandem mass spectrometry using an API 3000 triple quadrupole MS. Results here highlight those AA derivatives and metabolites; however, many differences were observed in other lipids. Replicating previous studies, levels of AEA were higher in FAAH KO mice across all eight brain regions. N-arachidonyl serine was likewise increased, but only in the striatum, thalamus, and brainstem. Interestingly, 2-AG levels were significantly reduced with regional specificity in the cerebellum, thalamus, and cortex of FAAH KO mice. FAAH KO mice displayed lower levels of NAGly and N-arachidonyl GABA in all brain regions, and levels of 6 additional N-arachidonyl acyl amides were significantly lowered by FAAH deletion as well. However, deleting FAAH had no impact on levels of PGE2 or free AA. These data replicate and greatly extend the finding that deletion of FAAH drives changes in a range of AA metabolites and extends this to a wider range

of N-acyl amides. This pattern of shifts in substrates and products appears largely unique to AA derivatives, demonstrating that FAAH has differential effects on lipid biosynthetic and metabolic pathways that are dependent on the specific fatty acid derivatives that are interacting with the enzyme.

Title: A pro-nociceptive phenotype revealed in mice lacking fatty-acid amide hydrolase

Authors: *L. M. CAREY, IV, R. SLIVICKI, E. LEISHMAN, B. CORNETT, K. MACKIE, H. BRADSHAW, A. G. HOHMANN;
Indiana Univ., Bloomington, IN

Abstract: The endocannabinoid system represents an emerging target for pharmacotherapies aimed at treating pathological pain. Inhibition of the enzyme fatty-acid amide hydrolase (FAAH) has been proposed to enhance endocannabinoid signaling for therapeutic benefit. FAAH catalyzes metabolism of a class of biologically active lipid signaling molecules called the N-acyl amides. FAAH is the primary catabolic enzyme that degrades the endocannabinoid anandamide but it also degrades other N-acyl amides that do not bind to cannabinoid receptors. Thus, genetic deletion of FAAH is likely to produce widespread changes in the lipidome involving many bioactive lipids, in addition to anandamide. Anandamide acts as an endocannabinoid to produce antinociception at cannabinoid receptors but has also been postulated to act as an endovanilloid to produce hyperalgesia at vanilloid TRPV1 receptors. We examined the impact of genetic deletion of FAAH on pain responsiveness evoked by intradermal injection of capsaicin, the pungent ingredient in hot chili peppers. We compared capsaicin-induced mechanical allodynia, heat hyperalgesia, and nocifensive behavior in age-matched FAAH knockout (KO) and wild type

(WT) mice. Alterations in the lipidome in paw skin ipsilateral and contralateral to the site of capsaicin injection were measured using high-pressure liquid chromatography tandem mass spectrometry. Capsaicin-evoked mechanical and heat hypersensitivity and nocifensive behavior were increased in FAAH KO mice relative to WT mice. In FAAH KO mice, capsaicin-evoked hypersensitivity was blocked by the TRPV1 antagonist AMG9810. In paw skin samples derived from FAAH KO mice, profound alterations in the profiles of several lipid signaling molecules were observed ipsilateral to intradermal capsaicin injection including marked decreases in levels of 2-acyl glycerols, arachidonic acid, N-stearoyl GABA, N-acyl serines, N-acyl alanines, N-acyl ethanolamines and prostaglandin F2alpha. By contrast, in WT mice, such changes were absent; intradermal capsaicin increased levels of prostaglandin F2alpha only in paw skin samples ipsilateral to capsaicin injection. Our studies identify a previously unrecognized pro-nociceptive phenotype in FAAH KO mice challenged with capsaicin. These effects were blocked by a TRPV1 antagonist and associated with profound alterations in the lipidome that were not observed in WT animals under comparable conditions. More work is necessary to understand the mechanism underlying this pro-nociceptive phenotype if FAAH inhibition is to be employed as a therapeutic strategy for treating chronic pain in human patients.

Title: Opposing effects on the arachidonic acid derivative lipidome in ABHD12 and MAGL knock outs

Authors: *E. LEISHMAN, K. SPORK, A. STRAIKER, K. MACKIE, H. BRADSHAW; Psychological and Brain Sci., Indiana Univ., Bloomington, IN

Abstract: The enzymes monoacylglycerol lipase (MAGL) and α,β-hydrolase domain 12 (ABHD12) are responsible for approximately 85% and 10% of the endogenous cannabinoid (eCB) 2-arachidonoyl glycerol's (2-AG) hydrolysis, respectively, in the rodent brain. The eCBs 2-AG, N-arachidonoyl ethanolamine (AEA), and the AEA metabolite N-arachidonoyl glycine (NAGly) are all derivatives of arachidonic acid (AA), a fatty acid (FA) that is also a substrate for the production of prostaglandins (PGs). However, other FAs undergo similar enzymatic reactions

as AA to make structural analogs (e.g. 2-linoleoyl glycerol); therefore, enzyme deletion or blockade may have broader lipidomic effects. This study aims to elucidate the effects of genetic deletion of MAGL and ABHD12 on the N-acyl amide, 2-acyl glycerol, and PG lipidome in the mouse striatum, hippocampus, cerebellum, thalamus, cortex, hypothalamus, midbrain and brainstem. 6 MAGL and 6 ABHD12 knockout (KO) mice were compared to 12 wild-type (WT) mice from the same genetic background. Animals were sacrificed, brains were removed and targeted areas were dissected and stored at -80C. Methanolic extracts were partially purified on C-18 solid-phase extraction columns. Eluants were analyzed with high pressure liquid chromatography coupled to tandem mass spectrometry using an API 3000 triple quadrupole MS. Although ABHD12 and MAGL share a common substrate, the lipidomics profiles of the KO mice drastically differ. Results here highlight AA derivatives and metabolites; though many additional classes of lipids were affected. As predicted, MAGL KO caused elevated 2-AG levels throughout the brain; however, in ABHD12 KO mice 2-AG was only elevated in the cerebellum, thalamus and midbrain. Interestingly, levels of AEA were elevated in most regions of the ABHD12 KO mice; whereas, AEA levels were lower in selected regions of the MAGL KO mice. NAGly levels followed a similar pattern to those of AEA, with region-specific increases in ABHD12 KO and decreases in MAGL KO. One of the most striking differences between the KO mice was with COX2 metabolites wherein there was a marked decrease in PGE2 and PGF2alpha in MAGL KO; conversely, there was a significant elevation in these PGs in the ABHD12 KO. Following the effects on PGs, levels of AA decreased in all regions of the MAGL KO mice, whereas, levels of AA increased in most regions of the ABHD12 KO mice. These data replicate and greatly extend the finding that deletion of MAGL drives changes in a range of AA metabolites and extends this to N-acyl amides as well as providing a novel dimension to our understanding of the roles of ABHD12.

Title: Endosomal adaptor protein APPL1, a new player in signaling from synapse to nucleus

Authors: *Y. WU, Y. YAN, X. LV, J. LUO, S. QIU;
Sch. of Med., Zhejiang Univ., Zhejiang, China

Abstract: Activity-dependent modification of gene expression is a powerful means by which the neurons builds up long-term modification. Local signaling events at synapses or axon terminals are communicated to the nucleus to elicit transcriptional responses, and thereby translates information about the external environment into internal neuronal representations. This retrograde signaling is critical to dendritic growth, synapse development, and neuronal plasticity. However, the lengths of neuronal processes pose a significant challenge for such intracellular communications. Here, we found that synaptic activity induced nuclear translocation of an endosomal adaptor protein APPL1 in the excitatory neurons. Nuclear translocation of APPL1 requires calcium influx from NMDA receptors or L-type VGCC. Futhermore,. a peptide against the NLS of APPL1 blocked synaptic activity-dependent nuclear translocation of APPL1, as well as the upregulation of CREB phosphorylation at Ser133 site in the nucleus. These data indicate that APPL1 is a key player transducing signals from synapse to nucleus and modulating gene transcription.

Title: Endocannabinoids in excitatory synaptic scaling

Authors: *Y. SONG, J. ZHANG, C. CHEN;
LSUHSC, New Orleans, LA

Abstract: Synaptic scaling is a form of homeostatic plasticity, which plays an important role in stabilizing the excitability of neural circuits in response to the deprivation of excitatory or inhibitory neurotransmission. However, the mechanism of homeostasis regulation of synaptic activity is not fully understood yet. The endocannabinoid 2-arachidonoylglycerol (2-AG) functions as a retrograde signaling molecule mediating synaptic transmission and plasticity.

However, little is known about whether 2-AG signaling is involved in homeostatic regulation of miniature synaptic events at excitatory synapses in response to activity deprivation. Here, we report that chronic blockade of firing by tetrodotoxin (TTX), a sodium channel blocker, for two days resulted in increases both in the frequency and amplitude of spontaneous miniature excitatory postsynaptic currents (mEPSCs) in cultured hippocampal neurons. However, treatment with 2-AG alone or JZL184, a potent and selective inhibitor for monoacylglycerol lipase (MAGL) that hydrolyzes 2-AG, induced a CB1 receptor-dependent reduction of the frequency of mEPSCs, but not the amplitude in cultures. The TTX-increased frequency was blunted by 2-AG or JZL184 and this effect was eliminated by pharmacological or genetic inhibition of CB1 receptors. In addition, the frequency and amplitude of mEPSCs were still increased by TTX in the presence of CB1 receptor inhibition. Our results suggest that endocannabinoid signaling does not significantly contribute to the mechanism by which the strength of excitatory glutamate synapses is scaled up after chronic activity deprivation.

Title: TRPV1 and CB1 receptors in the vMPFC modulate autonomic responses in rats submitted to acute restraint stress

Authors: *T. B. MORAES NETO, A. FASINI, F. M. A. CORRÊA, L. B. M. RESSTEL; Univ. of Sao Paulo - Sch. of Med. of Ribeirao Preto, Ribeirao Preto, Brazil

Abstract: Goals: Acute restraint is an unavoidable stress situation that evokes autonomic changes, characterized by elevated mean arterial pressure (MAP), intense heart rate (HR) increases and decrease in the tail skin temperature. The ventral portion of medial prefrontal cortex (vMPFC) is a limbic structure and can modulate autonomic responses caused by stress and it can be divided in two portions, the prelimbic cortex (PL) and the infralimbic cortex (IL).

The vMPFC glutamatergic system is involved with modulation of autonomic responses evoked by restraint stress (RS). Moreover, the CB1 receptors activation reduces the local vMPFC glutamate release. Moreover, the activation of TRPV1 receptors increases the local vMPFC glutamate release. Therefore, the objective of the present work was to investigate the involvement of TRPV1 receptors and CB1 receptors in the modulation of autonomic responses evoked by RS in rats. Methods: Male Wistar rats (250-270g) had guide cannulae bilaterally implanted in the PL or IL for drug injection and a polyethylene catheter was implanted in the femoral artery for MAP and HR recording. Tail skin temperature (TST) was measured using a thermal camera. The animals were submitted to restraint, which was initiated by introducing animals into a small plastic cylindrical restraining tube (diameter =6.5cm and length =15cm) and lasted for 60 minutes. The TRPV1 antagonist 6-iodonordihydrocapsaicin (6-IODO, 3 nmol/ 200 nL) was administrate 10 minutes before the RS. The CB1 antagonist AM251 (1 pmol/ 200 nL) was administrate 5 minutes before the enzyme fatty acid amide hydrolase (FAAH) inhibitor URB597 (100 pmol/ 200 nL), that was administrate 10 minutes before the RS. Results: The RS increase both MAP ($F_{35, 350} =20.48$, $P<0.05$) and HR ($F_{35, 350} =17.44$, $P<0.05$) and decrease the TST ($F_{17, 170} =35.08$, $P<0.05$). The microinjection of 6-IODO (n=6) decrease PAM (PL: $F_{1, 350} =7.609$, $P<0.05$; IL: $F_{1, 350} =6.503$, $P<0.05$) and HR response (PL: $F_{1, 350} =16.66$, $P<0.05$; IL: $F_{1, 350} =14.59$, P0.05; IL: $P>0.05$) associate to RS when compared with vehicle treated animals (n= 6). The microinjection of AM251 and URB597 (n=6) decrease PAM ($F_{3, 700} =5.580$, $P<0.05$) and HR response ($F_{3, 700} =3.979$, $P<0.05$) and the TST drop ($F_{3, 340} =4.752$, $P<0.05$) when compared with vehicle treated animals (n= 6). Conclusion: The present results shown that vMPFC endocannabinoid system through TRPV1 receptors activation has an excitatory influence in the cardiovascular responses and the CB1 receptors activation has an excitatory influence in the cardiovascular responses and an inhibitory influence in the TST responses evoked by RS.

Title: Estradiol rapidly attenuates ORL-1 receptor-mediated inhibition of proopiomelanocortin neurons via Gq-coupled, membrane-initiated signaling

Authors: *K. M. CONDE[1], C. MEZA[2], M. KELLY[3], K. SINCHAK[4], E. WAGNER[2];
[1]Grad. Col. of Biomed. Sci., [2]Col. of Osteo. Med. of the Pacific, Western Univ. of Hlth. Sci., Pomona, CA; [3]3 Dept. of Physiol. & Pharmacol., Oregon Hlth. and Sci. Univ., Portland, OR; [4]California State University, Long Beach, Long Beach, CA

Abstract: Ovarian estrogens act through multiple receptor signaling mechanisms that converge on hypothalamic arcuate nucleus (ARH) proopiomelanocortin (POMC) neurons. A subpopulation of these neurons project to the medial preoptic nucleus (MPN) to regulate lordosis. Orphanin FQ/nociception (OFQ/N) via its opioid-like receptor (ORL-1) regulates lordosis through direct actions on these MPN-projecting POMC neurons. Based on an ever-burgeoning precedence for fast steroid actions, we explored whether estradiol excites ARH POMC neurons by rapidly attenuating inhibitory ORL-1 signaling in these cells. Experiments were carried out in hypothalamic slices prepared from ovariectomized female rats injected one-week prior with the retrograde tracer Fluorogold into the MPN. During electrophysiologic recordings, cells were held at or near -60 mV. Post-hoc identification of neuronal phenotype was determined via immunohistofluorescence. In vehicle-treated slices OFQ/N caused a robust outward current/hyperpolarization via activation of GIRK channels. This OFQ/N-induced outward current was attenuated by 17-β estradiol (E2, 100nM). The 17α enantiomer of E2 had no effect. The OFQ/N-induced response was also attenuated by an equimolar concentration of E2 conjugated to BSA. In addition, the ability of E2 to diminish OFQ/N responsiveness was blocked by the co-administration of the estrogen receptor (ER) antagonist ICI 182,780 (1μM). The attenuating effect of E2 was mimicked by the membrane ER (mER) ligand STX (10nM) and the ERα agonist PPT (1μM), but not the GPR30 agonist G1 (3μM) or the ERβ agonist DPN (3μM). Moreover, the phospholipase C (PLC) inhibitor U73122 (20μM) restored the OFQ/N-induced outward current in the presence of E2, whereas the inactive analog U73343 (20μM) was without effect. Finally, the protein kinase C (PKC) inhibitor NPC 15437 (30μM) abrogated the estrogenic impairment of the OFQ/N-induced outward current, whereas the PKC activator PDBu (1μM) per se attenuated the OFQ/N response. These collective actions were observed in a substantial number of MPN-projecting ARH neurons positive for various markers of POMC neurons. The results reveal an ORL-1 receptor mediated inhibition of POMC neurons that is negatively modulated by estradiol. The estrogenic attenuation is stereoselective; membrane delimited, mediated via the Gq-coupled mER and ERα activation, and involves signaling through PLC and PKC. This disinhibition of POMC neurons is critical for the subsequent expression of sexual behavior in the female.

Title: Inhibition of c-Src blocks morphine analgesic tolerance

Authors: ***F. BULL**[1], D. BAPTISTA-HON[1], S. KING[1], W. WALWYN[2], T. G. HALES[1]; [1]Univ. of Dundee, Dundee, United Kingdom; [2]UCLA, Los Angeles, CA

Abstract: A major limitation of morphine analgesia is the development of tolerance, which leads to the requirement for increasing doses for the treatment of persistent pain. Morphine tolerance is attenuated in βarr2-/- mice that lack β-arrestin2, which participates in mu opioid receptor (MOP) endocytosis and signaling through MAP, Akt and c-Src kinases. We previously demonstrated that βarr2-/- mice exhibit a sustained increase in MOP-mediated basal analgesia and constitutive inhibition of voltage-activated Ca^{2+} channels in DRG neurons. The latter was mimicked by inhibition of c-Src. In this study we examined whether c-Src participates in morphine analgesic tolerance and/or reinforcement. Tail withdrawal from noxious heat and conditioned place preference (CPP) were used to assess morphine analgesia and reinforcement, respectively. The reinforcing effects of morphine have been attributed to disinhibition of dopaminergic neurons of the VTA. We used the whole-cell patch-clamp technique to establish the effect of morphine on spontaneous inhibitory postsynaptic currents (sIPSCs) recorded from neurons in VTA slices. We examined several C57BL/6 strains including WT, MOP+/-, MOP-/- and βarr2-/- mice. PP2 was used to inhibit c-Src in slices, with PP3 as a control. The anti-leukaemia drug dasatinib administered ip to mice crosses the blood-brain barrier and was used to examine the behavioural effects of c-Src inhibition. Morphine caused a negligible inhibition of sIPSC frequency in VTA neurons of MOP-/- mice and was less potent in MOP+/- compared to WT neurons. A lack of βarr2 reduced morphine's inhibition of sIPSCs frequency, as did PP2, while PP3 had no effect. A lack of βarr2-/- caused a reduced locomotor response to morphine compared to WT mice, while dasatinib had no effect. βarr2-/- mice exhibited morphine (10 mg/Kg) CPP similar to WT mice. Similarly, dasatinib treated WT mice exhibited morphine CPP similar to that of controls. Morphine did not prolong MOP-/- tail withdrawal from noxious heat and had a reduced analgesic

potency in MOP+/- mice. Morphine analgesic tolerance developed faster and to a greater extent in MOP+/- mice than in WT mice. As previously reported, tolerance was reduced in βarr2-/- mice, which also exhibited basal analgesia. Dasatinib prevented morphine tolerance in WT and MOP+/- mice and caused recovery from tolerance in the latter. Our data suggest that the β-arr2/c-Src signalling system can be targeted to produce sustained morphine analgesia without affecting the drug's psychomotor effects.

Abstract: Neuropeptides exert specific, coherent effects on formation and rewiring of neural circuits. Coordinated production of these signaling molecules and their receptors under resting conditions and upon stimulation may be a prerequisite for efficient regulation circuit's functions and connectivity. To test this hypothesis, we examined whether expression of the endogenous

opioid system (EOS) genes is co-regulated within and between three CNS areas including striatum, and dorsal and ventral cervical spinal cord. The left and right parts of these areas were analyzed separately to assess the bias associated with possible lateralization. Unilateral traumatic brain injury (CCI, controlled cortical impact centered on forelimb representation area of the motor cortex) was used as a model to impact the EOS in spinal and brain circuits, whereas unilateral sham operation (SO) was applied to control for CCI. Five groups of rats (N=10/group) including the right- and left-hemisphere CCI, right- and left-side SO rats, and naïve animals were analyzed. Analysis of variances demonstrated no significant effects of the CCI and SO on the expression of the EOS genes in the spinal cord. Interestingly, the expression was lateralized in the dorsal (Oprk1, Pdyn, Penk) and ventral (Oprd1, Oprk1, Oprm1) spinal domains. The asymmetry was also evident for the ratio of opioid receptor levels (for the Oprk1 / Oprm1 ratio in dorsal part, and for the Oprk1 / Oprm1 and Oprk1/ Oprd1 ratio in the ventral part). Left- but not right-hemisphere CCI affected Oprd1and Oprm1 expression in striatum. Analysis of the intra-area correlations identified strong, highly significant correlations between the five EOS genes in each spinal domain in both naïve group and the pooled sample of 5 groups. Right-side but not left-side surgery (each SO and CCI) reduced correlation strength in the dorsal spinal cord. Analysis of correlations between all areas / sides revealed strong highly significant positive interactions between left dorsal and left ventral spinal domains, and strong highly significant negative interactions between left dorsal and right ventral spinal domains. Network analysis confirmed these findings and identified co-regulated gene networks in the spinal cord that were specific for the left and right domains, and differentially responded to the left- and right-hemisphere CCI. The area- and side-specific co-regulation of the EOS genes may be a general principle relevant for shaping of functional connectivity within and between neural circuits in the spinal cord.

Title: Synapse-specific persistent activation of VTA kappa opioid receptors following acute stress

Authors: *A. M. POLTER[1], R. CHEN[1], R. M. ST. LAURENT[2], J. A. KAUER[1];
[1]Mol. Pharmacology, Physiology, and Biotech., [2]Neurosci., Brown Univ., Providence, RI

Abstract: Stressful experiences drive many adaptive and maladaptive behaviors, and even acute stressors can have lasting behavioral consequences. Emerging evidence shows that dopaminergic neurons in the ventral tegmental area (VTA) are an important locus in stress. We previously identified a long-term potentiation of GABAergic synapses onto these neurons (LTP_{GABA}) that is blocked by acute stress (Graziane et al, Neuron, 2013). Administration of a kappa opioid receptor (KOR) antagonist (norBNI) *in vivo* prevents the block of LTP_{GABA}. Intra-VTA injection of the KOR antagonist also prevents reinstatement of cocaine seeking by acute stress, suggesting that KOR-mediated regulation of VTA inhibitory plasticity may play a role in stress-induced drug seeking. Our recent work shows that a single five minute cold water swim stress blocks LTP_{GABA} for at least five days. Surprisingly, blocking KORs with norBNI even well after stress restores LTP_{GABA}, and cocaine self-administration is prevented even when norBNI is administered after stress (Polter et al, Biological Psychiatry, 2014). Here we show that the long-lasting block of LTP_{GABA} by stress is due to changes in the KOR itself. While bath application of an inverse agonist (norBNI, 100 nM) rescues LTP_{GABA} in slices from stressed animals, bath application of a neutral antagonist (6--naltrexol, 10 μM) does not (LTP magnitude: norBNI after stress=144± 18% of baseline, 6--naltrexol after stress=99±8% of baseline; $p<0.05$). These results suggest that LTP_{GABA} is blocked by constitutive activation of KORs rather than by persistently elevated dynorphin, which would be blocked by both drugs. Transient activation of KORs was sufficient to induce a lasting blockade of LTP_{GABA}, as a KOR agonist (U50488, 5 mg/kg) blocked LTP_{GABA} for 5 days (LTP: saline=140±10% of baseline, 1 day post U50488=108±5% of baseline, 5 days post U50488=99±9% of baseline). The activation of KORs by stress is synapse specific, as bath application of norBNI did not potentiate excitatory synapses on either dopaminergic (IPSC amplitude after norBNI: control=92±6% of baseline, FSS=94±2% of baseline) or GABAergic VTA neurons (IPSC amplitude after norBNI: control=109±4% of baseline, FSS=112±3% of baseline). Our results show that a single exposure to acute stress or KOR activation both cause long-lasting changes in activity of KORs specifically at GABAergic synapses in the VTA.

Title: Variable sensitivity to morphine mediated Ferritin Heavy Chain upregulation in cortical neuronal subpopulations

Authors: *B. S. NASH[1], K. TARN[2], J. H. PITCHER[2], O. MEUCCI[2];
[2]Pharmacol. and Physiol., [1]Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Current HIV therapies have dramatically improved patients' disease progression and quality of life, but HIV-associated neurocognitive disorder remains a prevalent and challenging problem to address in the clinic. Many HIV+ patients also abuse drugs, with opioid use being particularly common as sharing needles represents an important avenue of infection. These patients can show accelerated progression of cognitive impairment, the mechanism of which is currently under investigation. Our lab has shown that morphine and other mu-opioids upregulate Ferritin Heavy Chain (FHC) in CNS neurons, which is associated with reduction of downstream signals of the homeostatic chemokine receptor CXCR4 via its natural ligand CXCL12. This results in a host of adverse effects including reduced dendritic spine density and is correlated with enhanced cognitive decline in humans and animal models of HAND. Our experiments aim to gain insights into this novel mechanism of mu-opioid mediated CXCR4 regulation, and thereby potential future targets for novel HAND therapies. Morphine upregulates FHC in cortical neurons in a mu-opioid/g-protein dependent manner, while astrocytes seem to be unaffected *in vitro* even though they express the mu-opioid receptor. This suggests exclusivity for particular CNS cell types in their ability to upregulate FHC via opioids. FHC upregulation specifically occurs in the cytoplasm of neuronal cells as demonstrated by fractionation and confocal imaging studies, which allows it to potentially interact with CXCR4 on the cell membrane. Preliminary imaging studies show that certain neurons are more susceptible to FHC upregulation than others, and that GABA transporter-1 expressing neurons represent one of these susceptible populations. Current work is focused on exploring FHC expression after morphine treatment in inhibitory and excitatory neuronal subpopulations both *in vitro* and *in vivo*. Pilot studies suggest variability amongst neuronal subpopulations in that calretenin expressing interneurons do not upregulate

FHC after morphine, but interestingly have higher basal levels of FHC compared to calretenin negative cortical neurons. Future studies will characterize additional neuronal populations. These experiments suggest that mu-opioid usage may cause specific deficits in inhibitory neuronal circuits via FHC upregulation and subsequent CXCR4 blockade, which may induce or sustain particular features of HAND such as excitotoxicity, or other neurochemical adaptations leading to cognitive impairment.

Title: Enkephalin-evoked catecholamine secretion in adrenal tissue

Authors: ***L. DUNAWAY**[1], L. SOMBERS[2];
[1]Chem., [2]North Carolina State Univ., Raleigh, NC

Abstract: The adrenal glands regulate physiological responses to stressors by secretion of the catecholamines, epinephrine and norepinephrine. A variety of peptides, including opioid peptides, are thought to be co-stored with the catecholamines in dense core vesicles in adrenal cells. The opioid system is strikingly complex, and the precise interaction between opioid peptides and the catecholamines has not been investigated in the adrenal gland. We have used fast-scan cyclic voltammetry coupled to carbon-fiber microelectrodes to quantify secretion of catecholamines (epinephrine and norepinephrine) in response to application of met-enkephalin, (M-ENK), and its synthetic mu opioid receptor specific analog, DAMGO, in a rat adrenal slice preparation. An acute application of M-ENK evokes catecholamine release that is sensitive to blockade by naltrexone, a non-selective opioid receptor antagonist. DPDPE, a delta opioid receptor agonist, does not elicit a physiological response. These results demonstrate that M-ENK acts in the adrenal medulla to evoke catecholamine secretion by binding to mu opioid receptors on the cell membrane, providing a specific chemical mechanism by which opioid peptides can regulate an organism's response to physiological and environmental demands.

Title: A novel rabbit monoclonal antibody against the N-terminus of the rat mu-opioid receptor (MOR): selectivity for rat but not mouse MOR

Authors: *M. RAMSDEN[1], S. SCHNELL[2], M. WESSENDORF[2], A. KALYUZHNY[1]; [1]R&D Systems Inc., Minneapolis, MN; [2]Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: In many immunofluorescent studies of the mu-opioid receptor, antisera directed against the carboxy terminal region, developed by us and others, have been successfully used to localize MOR in tissue sections. These antisera share common epitopes, are usually not species-selective and no labeling is observed with them in mice that do not express functional MOR. We have developed an antisera directed against the rat MOR amino-terminal sequence that appears not to recognize mouse MOR. We used two-color immunofluorescence to determine the spatial relationships in brain and lumbosacral spinal cord between MOR labeling obtained with the amino- and carboxyl-terminal epitopes in rats and mice. Animals were perfused with 4% formaldehyde and then sections were stained using a monoclonal rabbit anti-MOR directed at the N-terminus (R&D Systems) and a polyclonal guinea pig anti-MOR directed at the C-terminus (Arvidsson et al., 1995). These were followed by Cy2-labeled donkey anti-rabbit and Cy3-labeled donkey anti guinea pig. We observed that virtually all cell bodies, fibers and puncta were double-labeled in rat brain and spinal cord. In addition, we observed that in rats the two antibodies appeared to label identical subcellular structures. In contrast, only the C-terminal antibody stained cell bodies, fibers and puncta in tissue sections of mouse CNS. With both antibodies, staining was abolished in tissue sections where the antisera was pre-incubated with their respective immunizing peptides. The basis for this species-specificity is unclear since the amino acid sequences of the N-terminal region of rat and mouse MOR are nearly identical. These studies were supported by R&D Systems and the Department of Neuroscience, Univ. of Minnesota.

Title: β2-AR antagonist ICI 118,551 reduces OIH after chronic opioids administration in mice

Authors: *A. SAMOSHKIN[1], O. KAMBUR[4], J. WIESKOPF[2], J. MOGIL[2], E. KALSO[5], L. DIATCHENKO[3];

Abstract: Opioid analgesics are used in the treatment of moderate to severe pain, but their chronic administration of these drugs leads to unwanted adverse effects such as analgesic tolerance, dependence and opioid-induced hyperalgesia (OIH), limiting their clinical utility. A truncated 6-transmembrane (TM) isoform (lacking of the first TM and extracellular domains) of mu-opioid receptor (MOR) has been associated with high pain sensitivity and poor response to morphine. However, a newly developed potent 6TM-MOR ligand, IBNtxA, lacks the traditional adverse effects associated with classical opioids, like morphine. Moreover, recently we discovered strong evidence of 6TM-MOR coupling with β2-adrenoreceptor (AR; unpublished data). In this study we have explored these receptors interaction in reversal of OIH in mice. Chronic morphine (20-40 mg/kg) and IBNtxA (2-4 mg/kg) administered twice a day, produced hyperalgesia that manifested as sensitivity to mechanical and thermal stimuli (hot or cold). Treatment with β2-AR selective antagonist ICI 118,551 (3.25mg/kg) restored nociceptive responses to thermal stimuli back to the baseline levels. Interestingly, we also observed that ICI 118,551 produces robust synergy in analgesic efficacy upon co-administration with morphine or IBNtxA. These results further confirm the concept of β2-AR and 6TM-MOR interaction *in vivo*. We suggest that co-administration of β-blockers with opioids might be a way to achieve effective levels of analgesia while minimizing the possibility of adverse effects.

Title: CRF-BP and $CRF_{2\alpha}R$ interact primarily in the endoplasmic reticulum

Authors: P. SLATER[1], M. ANDRES[1], *K. GYSLING[2];
[1]Cell. and Mol. Biol., [2]Pontificia Univ. Catolica de Chile, Santiago, Chile

Abstract: The corticotrophin-releasing factor (CRF) family plays pivotal roles on drug addiction and stress. Intra ventral tegmental area injections of CRF, as well as stressful stimuli, induce potentiation of glutamatergic synapses onto VTA dopaminergic neurons leading to relapse to drug seeking in cocaine-experienced rats. This potentiation of glutamatergic synapses depends on CRF binding protein (CRF-BP) and type-2 CRF receptor (CRF2αR). However, the molecular mechanism underlying this functional interaction is presently unknown. We have observed that CRF-BP and CRF2αR can physically interact. We hypothesize that this interaction allows regulation of the subcellular localization of the proteins. Thus, we studied the subcellular localization of CRF-BP and CRF2αR in transfected PC12 cells, using Van Steensel co-localization analysis. The results showed that CRF-BP is localized primarily in secretion granules and CRF2αR in the endoplasmic reticulum. Interestingly, when CRF-BP and CRF2αR are co-expressed a high degree of co-localization in the endoplasmic reticulum is observed, evidencing that CRF2αR pulls CRF-BP towards the endoplasmic reticulum. This interaction and subcellular localization change are isoform-specific since it is not observed when CRF-BP is co-expressed with the CRF2βR isoform. In summary, our results show that CRF-BP and CRF2αR form a protein complex allowing modification of CRF-BP subcellular localization.

Title: Interaction between dopamine D1 and type-2β corticotropin releasing hormone receptors

Authors: *H. E. YARUR, M. ANDRES, K. GYSLING;
Cell. and Mol. Biol., Pontificia Univ. Católica de Chile, Santiago, Chile

Abstract: G-protein coupled receptors (GPCR) are involved in many physiological responses and are the target of more than 50% of the drugs present in the market. Heteromerization of GPCRs is a phenomenon known as the interaction of at least two GPCRs with functional consequences distinct from individual receptors. In our laboratory, we have shown that D1 dopamine receptors (DAD1) are capable of heteromerizing with type-2α corticotropin releasing hormone receptors (CRH-R2α) when both receptors were heterogeneously co-expressed in HEK293 cells. Interestingly, CRH-R2 have three spliced variants, CRH-R2α, CRH-R2β and CRH-R2γ. CRH-R2α and CRH-R2β only differ in their N-terminal, suggesting that CRH-R2β could also interact with DAD1 Thus, we evaluated the interaction between CRH-R2β and DAD1 by co-immunoprecipitation, immunofluorescence and with the heteromer mobilization strategy (O'Dowd et al, 2005). We observed that CRH-R2β can establish an interaction with DAD1. A recombinant DAD1 with a nuclear localization sequence (DAD1-nls) is able to change the cellular localization of CRH-R2β. Our data indicate that CRH-R2β physically interacts with DAD1.

Abstract: The mammalian neuropeptide FF (NPFF, FLFQPQRF-NH2) belongs to the family of RF-amide neuropeptides, characterized by a conserved Arg-Phe-NH2 COOH-terminal sequence. NPFF and NPFF-related peptides are the endogenous ligands of two G protein-coupled receptors named NPFF1-R (GPR147) and NPFF2-R (GPR74), and have been linked to various physiological activities including modulation of nociception and morphine analgesia. We describe here the characterization of the first orally available NPFF receptor antagonist, RF313. This compound displayed a slightly better affinity for NPFFR1 than for NPFFR2 and a potent antagonist activity at NPFFR1 receptor subtype *in vitro*. In mice, this compound had no effect by itself but prevented the hyperalgesic effect of neuropeptide VF, the endogenous agonist of NPFF1R, demonstrating its antagonist activity *in vivo*. We further showed that RF313 potentiated opiate analgesia and prevented the development of secondary hyperalgesia as well as analgesic tolerance when it was co-administered subcutaneously or orally at low doses (0.5 to 5mg/kg) in rats and mice. We also showed that this compound displayed no affinity toward the other RF-amide receptor GPR10, GPR54 and GPR103 as well as 50 different receptor targets. Moreover, RF313 displayed low toxicity when administered in mice at doses at least 10 times higher than the effective dose used to prevent the development of opioid-induced hyperalgesia and tolerance. Altogether, these data indicate that RF313 could represent a potential lead compound for the development of novel drugs that will improve opiate analgesia and reduce adverse side effects associated with chronic opiate administrations. Title: Signaling cascades of Humanin and the derivatives through Folmyl peptide receptor like-1 (FPRL-1) : Possibility of EGFR involvement

Authors: *Y. KITA[1], N. HARADA[2], H. INUI[1,3], T. ARAKAWA[4], T. NIIKURA[5];
[1]Osaka Prefecture Univ., Osaka, Japan; [2]Applied Life Sci., Osaka Prefecture Univ., Sakai, Osaka, Japan; [3]Col. of Hlth. and Human Sci., Osaka Prefecture Univ., Habikono, Osaka, Japan; [4]Alliance Protein Labs., San Diego, CA; [5]Information and Communication Sci., Sophia Univ., Chiyoda-ku, Tokyo, Japan

Abstract: Humanin (HN), an identified cell survival factor, protects neurons from amyloid beta (Abeta) *in vitro* and reduces amyloid burden in AD model mice. To explore the functional mechanism of HN, we investigated signaling cascades activated by FPRL-1, a receptor of HN as well as cytotoxic Aβeta. FPRL-1 and the murine counterpart FPR2 are G protein-coupled receptor (GPCR) which activates extracellular signal-regulated kinase (ERK)1/2 by the ligands, Abeta, HN or Wpeptide (FPRL-1 specific agonist) etc.. The ERK1/2 phosphorylation is inhibited significantly by PTX, suggesting the involvement of Gi protein in the activation. The changes of cAMP level were also obtained upon ligand treatments. Activations of signaling molecules such as ERK, p38, JNK, and Akt were quantitatively analyzed by detecting their phosphorylation in cells expressing FPRL1 using immunoblotting. The similar levels of ERK phosphorylation were observed among the different HN derivatives, unlike with previous findings that neuroprotective activity of S14G-HN was about 1000 fold more potent than authentic HN while S7A- and C8A-HN were not neuroprotective. HN and its derivatives did not activate such signaling molecules, as p38, which were shown to be activated by FPRL-1 agonist, W peptide. Furthermore, HN seemed to activate molecules which were detected by anti-phospho EGFR antibody suggesting the so-called receptor cross-talk between FPRL-1 and EGFR. Thus, The ERK-mediated signal pathway seems not essential for the neuroprotective action of HN. These findings suggested that HN evokes signaling cascades distinct from that of natural FPRL-1 ligands, and HN activates specific signaling cascades via FPRL-1, which are relevant to HN's functions.

Title: Interactions between vasoactive intestinal polypeptide and dopamine in the olfactory bulb

Authors: *K. S. KORSHUNOV[1], P. Q. TROMBLEY[2];
[2]Biol. Sci., [1]Florida State Univ., Tallahassee, FL

Abstract: The olfactory bulb (OB) receives afferent input from olfactory sensory neurons (OSNs) and uses its distinct laminar circuitry and neuronal subtypes to process odor information. The activity of the OB is circadian, and it is one of two brain regions that contains independent circadian neuronal clocks outside of the suprachiasmatic nucleus of the hypothalamus (the other is the retina, a structure in vision parallel to the OB in olfaction) (Miller et al. 2014; Ruan et al. 2008). Circadian OB activity manifests as rhythms in gene expression, neuronal activity, and odor detection. However, almost nothing is known about the cellular mechanisms that underlie the OB's circadian rhythms. A prominent cell type of the OB's circuitry is dopamine (DA) neurons found within the glomerular layer (GL) of the OB (Halasz et al. 1981; Berkowicz and Trombley 2000; Ennis et al. 2001; Davila et al. 2003). DA is implicated in sharpening odor sensation and discrimination by presynaptically inhibiting the release of glutamate from OSNs (Berkowicz and Trombley 2000; Ennis et al. 2001) and OB neurons (Davila et al., 2003). It has been shown recently that OB DA content and release varies with the time of day (Corthell et al. 2013). A second known endogenous regulator of the OB is vasoactive intestinal polypeptide (VIP), which has been implicated in regulating circadian activity within the OB (Miller et al. 2014). Unlike DA neurons, the circuitry of VIP neurons is not well established and is highly variable among mammalian species. Also, it is unknown whether VIP and DA are co-expressed by neuronal subpopulations and/or interact with each other to modulate OB activity. Hence, the goal of the present study is to test the hypothesis that subpopulations of OB neurons express DA, VIP, or both, and that VIP regulates DA neurons (as it does in the hypothalamus) and/or that DA regulates VIP neurons. To that end, we have immunohistochemical data that suggest that a subpopulation of rat DA neurons may also express VIP and VIP receptors. VIP receptors also appear to be highly expressed by neurons in the GL that are not dopaminergic. We are currently examining whether DA modulates VIP neurons and whether VIP modulates DA neurons. Such interactions may contribute to the cellular mechanism underlying circadian activity of the OB.

Title: Localization of AGRP immunoreactivity in the mouse hippocampus that expresses eGFP-tagged GHSR1a

Authors: B. GONZALEZ, *M. ISOKAWA;
Dept. of Biomedicine, Univ. Texas-Brownsville, Brownsville, TX

Abstract: The ghrelin receptor (GHSR1a) is expressed highly in the hippocampus (Mani et al., 2014) and contributes to learning and memory (Diano et al., 2006). However, in spite of intense investigation with immunohistochemical techniques and transgenic eGFP expression, what types of hippocampal neurons express GHSR1a is not well understood. Available evidence suggests hippocampal principal neurons (glutamatergic pyramidal cells and dentate granule cells) are likely the target of ghrelin (Diano et al., 2006; Cuellar and Isokawa, 2011). However, in the hypothalamus, GHSR1a is specifically localized in AgRP/NPY/GABA-containing neurons (Wang et al., 2013). Since AgRP, NPY, and GABA are all well-acknowledged neuropeptides and neurotransmitters in the hippocampus, this evidence suggests the possibility that a subset of hippocampal GABAergic interneurons that co-express AgRP and/or NPY could be the target of ghrelin. In the present study, localization of NPY and AgRP are assayed immunohistochemically in the brain of a transgenic mouse strain where GHSR1a-expressing cells are reported with eGFP. Identification of GABAergic neurons are accomplished by the immunohistochemical detection of GAD, an enzyme to synthesize GABA. Cardially-perfused brains are cryo-sectioned into 50 micrometer thick. Brain sections that contained the hippocampus and the hypothalamus (as a positive control) are collected and processed for immunohistochemistry. NPY, AgRP, GAD, and eGFP signals are visualized using a confocal microscope and the results are quantified for analysis. We observed AGRP immunoreactivity at cell soma and processes in the dentate gyrus where eGFP signals for GHSR1a were also detected. AGRP immunoreactivity was particularly dense at the inner (hilar) edge of the dentate granule cell layer, supporting our hypothesis that AGRP neurons could be the target of ghrelin in the hippocampus. We propose a novel cellular mechanism for hippocampal learning and memory that involves AGPR/GHSR1a interactions.

Title: Structure based design of dual orexin receptor antagonists with a differentiated kinetic profile from suvorexant

Authors: K. A. BENNETT, S. J. AVES, J. A. CHRISTOPHER, M. CONGREVE, A. S. DORE, J. C. ERREY, J. C. PATEL, R. MOULD, B. G. TEHAN, A. ZHUKOV, F. MARSHALL, *A. BROWN;
Heptares Therapeut. Ltd, Welwyn Garden City, United Kingdom

Abstract: The orexins (orexin A and orexin B) are two neuropeptides produced by a small population of neurons in the hypothalamus which bind to G protein-coupled receptors (GPCRs) orexin-1 (OX_1) and orexin-2 (OX_2) The orexin system is a key regulator of behavioral arousal, sleep and wakefulness. There is a clear link between the orexin system and sleep modulation with loss of orexin neurones (but not receptor expression) leading to narcolepsy in humans (Tsujino N & Sakurai, 2009). Over the past decade, there has been significant drive to develop selective orexin receptor antagonists (SORAs) and dual orexin receptor antagonists (DORAs) to investigate the potential for treatment of numerous disorders including addiction and insomnia. In 2014 Merck's suvorexant (Belsomra) was approved for use in adults with insomnia. Heptares specialize in GPCR structure-based drug design. A small number of point mutations are incorporated into the receptor, increasing thermostability and creating stabilized receptors (StaR® proteins). These can be used for biophysical and structural techniques that are not usually amenable to wild-type GPCRs due to their instability when removed from the membrane. OX_1 and OX_2 StaR® proteins were purified and immobilised on biosensor chips allowing fragment screening and characterisation of receptor kinetics using surface-plasmon resonance. We identified a novel series of potent, selective, and orally efficacious dual antagonists of the orexin OX_1 and OX_2 receptors which were optimised resulting in the selection of HTL6641 as a pre-clinical candidate molecule. HTL6641 showed fast receptor kinetics (OX_1 half life ($t_{1/2}$) = 0.8 min; OX_2 $t_{1/2}$ 4.2 min) in contrast suvorexant showed significantly longer residency time (OX_1 $t_{1/2}$ = 24 min, OX_2 $t_{1/2}$ = 79 min). Fast receptor kinetics may be beneficial in reducing the potential of next day effects associated with prolonged receptor blockade, such as somnolence and driving impairment. Such observations have been noted with high doses of suvorexant (Sun et al., 2014). During the medicinal chemistry programme multiple co-crystal structures of OX_1 and OX_2 with internal series and literature compounds (such as suvorexant and SB-334867) were solved. These structures reveal, in fine detail, the binding mode of various compounds. This has

provided a detailed understanding of the similarities and differences in the ligand binding sites between the orexin receptors and is aiding the structure-based design of several series of selective OX_1 antagonists for the treatment of addiction disorders. *Sun H, Kennedy WP, Wilbraham D et al. Title: Latrophilin1 adhesion GPCR signals through G protein coupling

Authors: *O. V. NAZARKO, A. KIBROM, D. ARAÇ;
Biochem. and Mol. Biol., Univ. of Chicago, Chicago, IL

Abstract: G protein-coupled receptors (GPCRs) are integral membrane proteins that play a central role in signaling pathways being key intermediaries between external stimuli and the intracellular signaling cascades and involved in regulation of nearly all processes in human body. GPCRs are essential mediators for neuronal transmission, they regulate neuronal function, modulate neuronal survival and plasticity of neuronal circuits in the nervous system and disorders in GPCR signal transduction are connected with the pathogenesis of several prominent neurodegenerative conditions including stroke, Alzheimer's, Parkinson's, and Huntington's diseases. GPCR's are today's favorite therapeutic drug targets and are studied intensively. Latrophilins (Lphn1-3) are cell-surface molecules that belong to the adhesion-type G-protein coupled receptor (GPCR) family. Lphn1 was identified as the calcium-independent receptor for α-latrotoxin, a black widow spider toxin that triggers massive neurotransmitter release from neurons and neuroendocrine cells. Mutations of Lphns have been linked to attention deficit hyperactivity disorder as well as numerous cancers. Lphns are highly expressed in the brain, and were shown to function as heterophilic cell adhesion molecules in processes such as synapse formation or maintenance. However, their signaling pathways and which effector molecules they are coupled to are not known. In our study, we demonstrated that Lphn1 signals via the inhibitory Gα (Gαi**)** G-protein. A decrease in intracellular cyclic AMP level in response to Gαi coupled signaling was shown in HEK293 cells transfected with full length LPHN1 after activation with synthetic agonist peptide. The N-terminus deletion led to constitutively more active truncated LPHN1 receptors (enhanced basal signaling) which strongly supports the idea that a tethered agonist peptide within the receptor sequence is the agonist for activation of the receptor. As an indication of Gi coupling, cAMP levels were reversed to initial level by treatment with Gi inhibitor pertussis toxin. We also designed point mutations in LPHN1 and tested their impact on constitutive or agonist induced signaling. This study could be important for further investigation of GPCR signaling modulation, which is of high significance in light of

possible treatment of different pathological conditions connected with receptor malfunctioning including neurological diseases.

Title: Conserved expression of the gpr151 receptor in habenular axonal projections of vertebrates

Authors: *B. ANTOLIN-FONTES[1], J. BROMS[2], A. TINGSTRÖM[2], I. IBAÑEZ-TALLON[1]; [1]The Rockefeller Univ., New York, NY; [2]Lund Univ., Lund, Sweden

Abstract: The habenula is a phylogenetically conserved brain structure in the epithalamus. It is a major node in the information flow between fronto-limbic brain regions and monoaminergic brainstem nuclei, thus anatomically and functionally ideally positioned to regulate emotional, motivational and cognitive behaviors. Consequently, the habenula may be critically important in the pathophysiology of psychiatric disorders such as addiction and depression. Here we investigated the expression pattern of GPR151, a G coupled-protein receptor (GPCR), whose mRNA has been identified as highly and specifically enriched in habenular neurons by *in situ* hybridization and Translating Ribosome Affinity Purification (TRAP). In the present immunohistochemical study we demonstrate a pronounced and highly specific expression of the GPR151 protein in the medial and lateral habenula of rodent brain. Specific expression was also seen in efferent habenular fibers projecting to the interpeduncular nucleus, the rostromedial tegmental area, the rhabdoid nucleus, the raphe nuclei and the dorsal tegmental nucleus. Using confocal microscopy and quantitative colocalization analysis we found that GPR151 expressing axons and terminals overlap with cholinergic, substance P-ergic and glutamatergic markers. Virtually identical expression pattern was observed in rat, mouse and zebrafish brains. Our data demonstrate that GPR151 is highly conserved, specific for a subdivision of the habenular neurocircuitry, and constitutes a promising novel target for psychiatric drug development.

Title: CGRP mediated neuroprotection against homocysteine-induced neurotoxicity in rat central and peripheral neurons

Authors: P. A. ABUSHIK[1], G. BART[2], D. A. SIBAROV[1], *S. M. ANTONOV[1], R. GINIATULLIN[2];
[1]Sechenov Inst. of Evolutionary Physiol. and Biochem., Saint-Petersburg, Russian Federation;
[2]Univ. of Eastern Finland, Kuopio, Finland

Abstract: The neuropeptide calcitonin gene-related peptide (CGRP), which is expressed in the central and peripheral nervous system plays a crucial pro-nociceptive role in migraine. Migraine, especially migraine with aura, is likely associated to a hyper-activation of glutamate receptors which can eventually lead to neurotoxic events. Some forms of migraine are linked to the disturbed metabolism of an endogenous amino acid: homocysteine (HCY). HCY is known a neurotoxic compound which effects are mediated by several pathways, including the activation of glutamate NMDA receptors (Abushik et al., 2014). The aim of this project was to study the role of CGRP in excitotoxicity induced by HCY in rat cultured trigeminal ganglion (TG), cerebellar and cortical neurons. D,L-HCY (100 or 500 μM) applied for 24 h induced a significant amount of cell death in all type of neurons. However, co-application of HCY together with 1 μM CGRP significantly increased the number of live TG, cerebellar and cortical neurons. A similar effect was observed with 1 μM forskolin suggesting a role for cAMP signalling in neuroprotection. Moreover, we found that CGRP signalling involves also CaMKII whereas the role of PKC was less evident. In TG neurons (rich in CGRP receptors) CGRP increased transcriptional factors Nor1 and Nur77 mRNA levels, these members of the NR4A family of orphan nuclear receptor are also known to have neuroprotective functions. Thus, the neuropeptide CGRP, apart from its pro-nociceptive role in migraine, promotes a wide ranging

protection of sensory, cerebellar and cortical neurons against the neurotoxicity induced by HCY via signalling cascades involving cAMP, CaMKII and NR4A family members.

Title: Stress-induced analgesia: a sequential cascade involving neuropeptide s, orexins, substance p, glutamate and endocannabinoids

Authors: *L.-C. CHIOU[1,3], Y.-T. CHIU[2], G. CALO'[4], R. GUERRINI[5];
[2]Pharmacol., [1]Natl. Taiwan University, Med. Col., Taipei, Taiwan; [3]Grad. Inst. Brain and Mind Sci., Taipei, Taiwan; [4]Dept. of Med. Sci., [5]Dept. Chem. and Pharmaceut. Sci., Univ. of Ferrara, Ferrara, Italy

Abstract: Neuropeptide S (NPS), when given by *i.c.v.* injection, is antinociceptive in mice and activates hypothalamic orexin neurons. During stress, both NPS- and orexin-containg neurons in the hypothalamus are activated. We have previously shown that stress-induced analgesia (SIA) is mediated by orexins released from the hypothalamus, acting at the OX1R in the ventrolateral periaqueductal gray (vlPAG) to release substance P that produces disinhibition via NK1Rs through releasing glutamate that activates the $mGluR_5$-endocannabinoid(eCB)-CB1R signaling cascade. Here, we further validated a hypothesis that during stress, NPS is released to activate the orexin neurons in the hypothalamus, releasing orexins that induce analgesia through the OX1R-substance P-$mGluR_5$-eCB-CB1R sequential cascade in the vlPAG, leading to analgesia using the hot-plate test in C57BL/6 mice (male, 8-12 weeks). NPS (0.1, 0.3, 1 nmol, *i.c.v.*) significantly increased the paw withdrawal latency in mice. The antinociceptive effect of NPS (0.3 nmol) was significantly prevented by *i.c.v.* injection of [^{t}Bu-D-Gly^5]NPS (10 nmol), an NPS receptor antagonist, and by intra-vlPAG injection of the specific antagonists of NK1 (L-703,606,

0.3 nmol), OX1 (SB 334867, 15 nmol), and CB1 (AM251, 30 nmol) receptors, respectively. Importantly, a 30-min restraint stress significantly decreased the hot-plate nociceptive response in mice, and this SIA was prevented by *i.c.v.* injection of [^{t}Bu-D-Gly^{5}]NPS (10 nmol). These results suggest a novel SIA mechanism that is initiated by NPS in the hypothalamus, following by a sequential cascade in the vlPAG mediated by orexins, substance P, mGluR5 and endocannabinoids; i.e., during stress, NPS is released and activates hypothalamic orexin neurons, releasing orexins that activate the OX1R on the substance P-containing neurons in the vlPAG, releasing substance P that activates NK1 receptors on glutamatergic neurons to release massive amount of glutamate that activates perisynaptic mGluR5, generating endocannabinoids that produce retrograde inhibition of GABAergic transmission, leading to analgesia.

Title: Delta-opioid receptor recycles from late endosomal compartments

Authors: *I. CHARFI[1,2], G. PINEYRO[1,2];
[1]Sainte-Justine Res. Ctr., Montreal, QC, Canada; [2]Univ. of Montreal, Montreal, QC, Canada

Abstract: Delta opioid receptors (DORs) are an involved in multiple brain functions and their agonists are currently considered as promising therapeutic alternatives for a variety of disorders including chronic pain, mood and learning. Substantial evidence indicates that the duration of DOR-mediated responses is very much influenced by the trafficking route these receptors follow upon activation. Classically, DORs had been considered as highly internalizing and poorly recycling receptors, but more recent evidence indicates that these trafficking patterns are also influenced by the activating ligand. Here we have characterized the post-endocytic itinerary of followed by DORs after internalization by DPDPE, an agonist that supports DOR recycling. We found that once internalized, DORs travel through compartments labeled by early-endosome antigen (EEA) and SNX1 (sorting endosomes) to accumulate in Rab9/manose-6-phospate receptor (M6PRs) positive structures, corresponding to late-endosomes and multivesicular bodies (MVBs). Interfering with transport machinery that allows retrograde recovery of M6PRs from

late endosomes to the trans-Golgi network (TGN) interfered with DOR recycling, as did blockade of TGN to membrane transport. This itinerary was confirmed both in HEK293 cells and neurons, indicating that internalized DORs can return to the membrane from late endosomal compartments where they have been classically considered as committed for degradation.

Title: Control of neuronal excitability by glycogen synthase kinase 3 in the nucleus accumbens

Authors: *M. N. NENOV[1], F. SCALA[2,1], E. CROFTON[1], Y. ZHANG[1], N. PANOVA[1], T. GREEN[1], M. D'ASCENZO[2], F. LAEZZA[1];
[1]Pharmacol. and Toxicology, Univ. of Texas Med. Br., Galveston, TX; [2]Inst. of Human Physiology, Med. School, Univ. Cattolica, Rome, Italy

Abstract: Susceptibility to psychiatric disorders is associated with gene and environment interactions that can predispose or protect individuals against these brain pathologies. Enriched environmental conditions (EC) can exert protective effects opposing maladaptive neuronal plasticity of the brain circuit that underlies these aberrant behaviors. Using unbiased transcriptomic analysis in the nucleus accumbens (NAc) of EC rats mRNAs coding for glycogen synthase kinase 3 (GSK3) and the voltage-gated Na+ channel Nav1.6 were identified as part of a protective genetic program against addiction and psychiatric disorders. Using *in vivo* Adeno-Associated Virus (AAV) vector expression for selective genetic silencing and acute brain slice patch-clamp electrophysiology, we found that silencing of either GSK3 or Nav1.6 with selective AAV short hairpins leads to a reduction in maximum firing frequency and increased in the action

potential threshold. Accordingly, we show that application of GSK3 inhibitor CHIR99021 in medium spiny neurons in both the NAc core and shell significantly suppresses maximum firing frequency and reduces Na+ persistent currents compared to vehicle treated cells. In complementary studies in HEK293 cells stably expressing Nav1.6 channels, we show that either CHIR99021 or GSK3 inhibitor XIII induce a significant reduction of Na+ peak current density compared to control along with significant changes in the voltage-dependence of the channel activation and/or steady-state inactivation that are inhibitor-specific. Based on this evidence, we propose that changes in GSK3 and Nav1.6 expression might coordinate rewiring of the NAc with effects on depression-, anxiety- and addiction-related behaviors.

Title: Multi-electrode array (MEA) analysis of disease-causing Nav1.7 A1632G mutation in inherited erythromelalgia, a chronic pain syndrome

Authors: *Y. YANG[1], J. HUANG[2], M. ESTACION[3], D. B. HORTON[4], S. D. DIB-HAJJ[3], S. G. WAXMAN[3];
[1]Neurol., VA CT Healthcare Syst., West Haven, CT; [2]VA healthercare, west haven, CT; [3]VA healthercare, West Haven, CT; [4]Nemours A.I. duPont Hosp. for Children, Wilmington, DE

Abstract: Voltage-gated sodium channel Nav1.7 is a central player in human pain. Mutations in Nav1.7 produce several human pain syndromes including inherited erythromelalgia (IEM), a syndrome in which patients suffer from episodes of intense burning pain that are often triggered by warmth. Patch-clamp studies show that gain-of-function Nav1.7 mutations from patients with IEM increase DRG neuron excitability. However, the long-term effects of expression of Nav1.7

mutations in cultured DRG neurons are not known, and the response of DRG neurons expressing mutant Nav1.7 channels to thermal stimuli has not been well-documented. Multielectrode arrays (MEA) provide a non-invasive extracellular recording approach, typically having ~64 micro-electrodes engineered on the bottom of a culture dish, which can continuously record action potentials from a population of neurons over a period of up to several weeks. Using MEA and traditional patch-clamp, we have studied a newly-identified Nav1.7 mutation, A1632G, from a patient with IEM. This mutation shifts fast-inactivation of the channel in a depolarized direction and significantly increases spontaneous firing in a population of transfected DRG neurons. We are studying the effect of physiologically relevant variations of temperature on the firing of these neurons. Through MEA and traditional electrophysiologic approaches, we have better characterized the pathophysiology of a novel disease-causing Nav1.7 mutation expressed in DRG neurons.

Title: Identification of new druggable pockets at the FGF14: Voltage-gated sodium channel 1.6 complex

Authors: ***S. R. ALI**, Z. LIU, A. K. SINGH, M. N. NENOV, J. ZHOU, F. LAEZZA;
Dept. of Pharmacol. & Toxicology, Univ. of Texas Med. Br., Galveston, TX

Abstract: Voltage-gated sodium (Nav) channels are responsible for the initiation and propagation of transient depolarizing currents that control neuronal excitability. Dysregulation of specific Nav channel isoforms is found across a wide range of brain disorders associated with motor and cognitive disabilities. Unfortunately, currently available drugs targeting Nav channels

are directed against highly conserved domains of the protein and as such lack isoform specificity. The macromolecular complex of Nav channels is a source of less conserved protein-protein interaction (PPI) interfaces that represent a unique opportunity for the design of isoform-specific chemical leads against Nav channelopathies. The intracellular fibroblast growth factor 14, FGF14, is a biologically relevant component of the neuronal Nav channel complex controlling gating, stability and trafficking of native Nav channels. Through a monomeric interaction with the intracellular C-terminal tail of Nav channel α subunits, FGF14 binds and modulates the activity of Nav channels in an isoform-specific manner with potency and affinity unique to any other identified interactors. Here, we have reconstituted the FGF14:Nav1.6 complex in live cells using the split-luciferase complementation assay (LCA) and through site-direct mutagenesis identified "hot-spots" at the FGF14 surface critical for binding to Nav1.6. By patch-clamp electrophysiology, we have further identified that Y158 and V160 located in the β8/9 of FGF14 are required to modulate Nav1.6-encoded current. Subsequently, we have designed short peptide fragments that targeted of β12-strand and β8-β9 loop of FGF14 and validated their in-cell activity as inhibitors of the FGF14:Nav1.6 complex. These breakthrough results identify the FGF14 β8-β9 as part of potential druggable pocket against the FGF14:Nav1.6 complex. Small molecules including short peptides and peptidomimetics targeting this pocket might give rise to a new class of unconventional PPI-based allosteric modulators of Nav channels that could restore malfunction of neuronal excitability and plasticity. These results provide fundamental new knowledge for the design of new leads targeting the Nav channel macromolecular complex. We expect our studies to have a broad impact in the drug design against a wide range of still untreatable brain disorders. Title: The background sodium channel NALCN regulates basal excitability of chemosensitive retrotrapezoid nucleus neurons and stimulation of breathing by CO2

Authors: *Y. SHI, C. ABE, B. HOLLOWAY, S. SHU, E. PEREZ-REYES, R. STORNETTA, P. GUYENET, D. BAYLISS;
Univ. of Virginia, Charlottesville, VA

Abstract: CO2/H+-sensitive neurons of the retrotrapezoid nucleus (RTN) are a nexus for integration of multiple respiratory-related inputs in service of homeostatic regulation of the rate and depth of breathing, blood gases, and arterial pH. The spike firing activity of RTN neurons controls respiratory output. Using a transgenic mouse line in which RTN chemosensory neurons are marked with GFP, we identified two populations of RTN neurons -- Type I and Type II -- with different firing activities evident over distinct pH ranges. The higher baseline firing rate in Type II cells is associated with greater inward current at -60 mV and larger NMDG-sensitive, TTX-resistant current. We hypothesized that NALCN, a “leak” Na+ channel might underlie this RTN current. Single cell RT-PCR (scPCR) and *in situ* hybridization showed that NALCN is expressed in nearly all RTN neurons (>90%), and quantitative scPCR revealed that NALCN expression is highest in Type II cells. Using viral-mediated shRNA knockdown of NALCN, we found that NALCN depletion favors Type I properties *in vitro* and blunts ventilatory responses to CO2 *in vivo*. Therefore, NALCN plays an important role in establishing baseline excitability of RTN neurons and contributes to control of breathing by these cells.

Title: FHF2A negatively regulates resurgent currents in sensory neurons

Authors: *C. M. BARBOSA NUNEZ, T. R. CUMMINS;
Dept. of Pharmacol. and Toxicology, Indiana Univ., Indianapolis, IN

Abstract: Resurgent sodium currents (INaRs) are an atypical sodium current that is mediated by an alternate mechanism of inactivation termed open channel block. Increased INaRs in sensory neurons have been implicated in different pain pathologies. However, our ability to selectively target INaRs is hindered by our lack of knowledge on how INaRs are modulated. In this study we investigated the potential regulation of INaRs in sensory neurons by Fibroblast Growth Factor Homologous Factor 2A (FHF2A). FHF2A variant contains a long N-terminus sequence that can interact with sodium channels and induce long-term inactivation. Previous studies with Navβ4 derived peptide (open channel blocker) and FHF2A derived peptide (long term inactivation particle) suggest that these factors compete for the open channel state. Therefore, we hypothesized that FHF2A limits sensory neurons capacity to generate resurgent current by outcompeting the open channel blocker. To test this hypothesis we overexpressed FHF2A or chimeric constructs of FHF2A and Navβ4. The FHF2A-(β4) chimera was generated by substituting the long term inactivation particle sequence (F2A) with the open channel particle sequence (β4) and vice-versa for the Navβ4-(F2A) chimera. Overexpression experiments were performed using recombinant expression in primary cultured DRG neurons. Nav1.6r was biolistically transfected with tagged constructs of FHF2A, FHF2A-(β4), Navβ4-(F2A) or vector (tag only). Endogenous currents were eliminated and whole-cell patch-clamp recording were obtained. Overexpression of the FHF2A decreased INaR positive neurons and INaR amplitude relative to control. FHF2A overexpression increased the fraction of channels in long-term inactivated states and slowed channel recovery relative to control. In contrast, overexpression of FHF2A-(β4) chimera increased resurgent current amplitude and INaR positive neurons. Recovery from inactivation was enhanced in FHF2A-(β4) group relative to control. The fraction of channels in long-term inactivated states was not different between FHF2A-(β4) and control. Overexpression of Navβ4-(F2A) abolished resurgent current generation. However, the fraction of channels in long-term inactivated states was not different than control suggesting that inhibition of INaR observed in this group may be due to a dominant negative effect of an inactive Navβ4. Overall, our results suggest that FHF2A negatively regulates INaRs in sensory neurons by mediating long-term inactivation. Interestingly, Navβ4-(F2A) data supports that NavB4 open channel blocker sequence is important for mediating INaR.

Abstract: The electrophysiological and morphological phenotyping of human neurons was performed on resected cortical and hippocampal tissue from cases of Communicating Hydrocephalus, Epilepsy, Normal Pressure Hydrocephalus as well as primary and secondary brain tumors. The differences in electrophysiological properties of adult human neurons are being correlated to the single-cell analysis of the mRNA transcriptome. With IRB approval 79 patients were enrolled with informed consent. For each enrolled patient, a case report form was populated with the subject information, which includes cortical location of the tissue as well as past medical history, all current medications and pathology reports (25-86 years old). Brain tissue that would otherwise be discarded was collected into ice-cold oxygenated artificial cerebrospinal fluid to preserve the necessary cellular and cortical circuitry components. Spontaneous and induced action potentials (APs) as well as concurrent field potentials were recorded from 350um thick cortical and hippocampal slices using intracellular sharp electrodes. Dissociated adult human neurons survived in culture for up to 6 months. Using whole-cell patch-clamp technique, ionic currents and changes in membrane potentials were analyzed. Resting membrane potential, amplitude of currents through voltage-gated channels, as well as consequent APs generation was monitored over time (days) in culture. The associated differences in electrophysiological properties of adult human neurons will be correlated to the single-cell transcriptome throughout various stages of culture. In order to develop a better understanding of the variability of the mRNA profile of individual cells, as well as in various disease states, identified correlations will be compared among different patient diagnoses.

Title: Triciribine potentiates Nav1.6-encoded currents and increases excitability of medium spiny neurons in the nucleus accumbens

Authors: *F. SCALA[1,2], M. N. NENOV[2], M. A. ALSHAMMARI[2], T. F. JAMES[2], N. I. PANOVA[2], C. GRASSI[1], M. D'ASCENZO[1], F. LAEZZA[2];

Abstract: Evidence indicates that dysfunction of the Akt/protein kinase B pathway correlates with the phenotypic manifestation of psychiatric disorders and neurodegenerative diseases. Yet, the molecular endpoints of this pathway in neurons remain poorly understood. Recent studies from our group identified glycogen synthase kinase 3 (GSK3), a well characterized downstream target of AKT as a modulator of the voltage-gated Na+ (Nav) channels. Here, we posited that inhibition of AKT might exert effects on Nav channel function and excitability in neurons. Using whole-cell patch-clamp recordings in HEK293 cells stably expressing Nav1.6 channels we show that pharmacological inhibition of AKT (triciribine 20 uM) induces a significant potentiation of Nav1.6 peak current density with no changes in the channel biophysical properties. Accordingly, prolonged application of triciribine (12-24 h) in mature primary hippocampal neurons leads to increased firing frequency and decreased action potential threshold. We then examined the effect of triciribine in acute brain slices from the nucleus accumbens (NAc), a brain area associated with high expression of Nav1.6. Whole-cell patch clamp recordings from medium spiny neurons revealed that triciribine increases repetitive firing, decreases action potential threshold and potentiates persistent Na+ current, a functional signature of Nav1.6 channels. Taken together, these findings provide evidence for a molecular target of the AKT pathway that effect on Nav1.6

channels. Thus, suppression of the AKT pathway might promote a hyper excitable state that could contribute to neuronal circuit dysfunction associated with brain disorders.

Title: What is the high sodium channel density in the axon initial segment good for?

Authors: ***A. NEEF**[1,2], E. LAZAROV[1,3], M. DANNEMEYER[4], M. J. GUTNICK[3], F. WOLF[1,2]; [1]MPI For Dynamics and Self-Organization, Goettingen, Germany; [2]Bernstein Ctr. for Computat. Neurosci., Goettingen, Germany; [3]Koret Sch. of Vet. Med., Hebrew Univ., Jerusalem, Israel; [4]Georg August Univ., Goettingen, Germany

Abstract: In many types of neurons, the density of sodium channels is higher in the axon initial segment (AIS) as compared to the soma. The AIS is also the place of action potential (AP) initiation and the high local density of sodium channels is often seen as a crucial requirement for axonal AP initiation. On the other hand, recent theoretical [1] and experimental[2] studies suggest that other parameters, such as the electrotonic distance from the soma, contribute significantly to the excitability of an axonal segment. We studied AP initiation in cultured hippocampal neurons at different stages of maturation with patch clamp and by immuno-histochemistry and fluorescence microscopy to visualize molecular components of the AIS. For voltage gated sodium channels a pan-antibody, recognizing all neuronal subtypes, was used. Beginning at 7 days *in vitro* (DIV), we recorded somatic AP waveforms. They had a biphasic shape due to non-local drive by lateral current that preceded local, somatic sodium channel

activation. This indicates that APs were initiated in the axon. Over the next 3 weeks, the channel densities in soma and axon increased and the somatic AP shape matured to a form tat closely resembled APs recorded from hippocampal neurons in tissue slices. In neurons derived from mice with the qv3J mutation of beta-IV-spectrin [3], we observed that the sodium channel immuno-staining in the AIS failed to increase while somatic and dendritic channel densities developed normally. Consistent with a reduced axonal sodium channel density, the amount of lateral current that drove early somatic depolarization was decreased in the mutants, while the somatic voltage threshold for AP initiation was increased. At DIV 21 to 28, the sodium channel immuno-staining in the axon was often as weak as the somatic staining, however, AP initiation still occurred in the axon. Preliminary data suggests, that part of the remaining axonal sodium channels are of the subtype NaV1.6, featuring a slightly lower activation threshold. Beyond DIV 21, an increasing fraction of the neurons displayed monophasic AP-shapes consistent with somatic AP initiation. Additional experiments are now performed to determine the initiation site in those cases. We conclude that high axonal sodium channel densities are not required to shift the action potential generation into the soma. Numerical simulations of multi-compartment neuron models using realistic sodium channel densities and properties support the notion, that axonal AP initiation can be achieved without a high density ration between soma and axon. Title: The effect of NKCC1 on aquaporin-4 induced astrocyte swelling

Authors: *R. KATADA, K. SUGIMOTO, K. NAKAMA, H. YOSHIZAWA, H. MATSUMOTO;
Osaka Univ. Fac. of Med., Suita, Japan

Abstract: Brain edema is the cause of poor prognosis after traumatic brain injury (TBI). Aquaporin-4 (AQP4), an water channel, is related to brain edema formation after TBI under ethanol consumption (Katada et al, Am J Pathol 2012). Sodium ion concentration in blood is decreased after TBI in rat under ethanol exposure. In fresh water drowning case (hyponatremia), brain AQP4 expression is increased, on the other hand, it is decreased in salt water drowning case (hypernatremia). AQP4 is regulated by or co-expressed with sodium channel, Na(+)-K(+)-2Cl(-) co-transporter-1 (NKCC1). From these findings, we hypothesized that the interaction between AQP4 and sodium channel may affect AQP4 expression change by sodium ion. In the present study, rat primary astrocytes were obtained from rat pup cortices. Astrocytes were incubated in iso-sodium MEM (NaCl: 680 mg/dl), hypo-sodium (NaCl: 410 mg/dl) or hyper-sodium MEM medium (NaCl: 950 mg/dl) with 10% calf serum in 2 hr with or without ethanol. NKCC1 siRNA was used for checking whether NKCC1 expression would affect AQP4 expression or not. Astrocyte AQP4 and alpha-syntrophin, an AQP4 anchor protein, expressions were checked by western blotting and immunohistochemistry. And immunoprecipitation for AQP4 and NKCC1 in cytosol or membrane extracts was performed. AQP4 expression was increased in 3 hr hypo-sodium medium exposure. However, Hyper-sodium did not change AQP4 expression significantly. NKCC1 knockdown decreased AQP4 expression under hypo-sodium condition. Alpha-syntrophin was increased by AQP4 knockdown under ethanol and hyper-sodium condition. The binding activity for AQP4 and NKCC1 was changed by each extract. These findings suggest that brain edema increasing by AQP4 and sodium ion was involved in the interaction between AQP4 and NKCC1.

Abstract: Painful peripheral neuropathy often occurs without identifiable causes, but no systematic genetic studies have been performed in patients with this disorder. We sought to identify a genetic basis for painful peripheral neuropathy by screening these patients for mutations in the SCN9A, SCN10A and SCN11A genes, encoding voltage-gated sodium channels Nav1.7, Nav1.8, and Nav1.9 which are preferentially expressed in small-diameter peripheral sensory neurons. Patients referred with painful neuropathy and no underlying etiology for SFN, were screened for mutations in SCN9A, SCN10A, and SCN11A and functional analyses were carried out. Here we report the identification of a new mutation in SCN11A, and no mutations in SCN9A or SCN10A, in an individual with painful peripheral neuropathy. This variant encodes a missense substitution in SCN11A resulting in a change of the Phenylalanine at position 1689 to Leucine (F1689L) in the C-terminus of human Nav1.9. Functional analysis using current-clamp revealed gain-of-function changes at the neuronal level. The effect of the mutation on the channel properties are being evaluated by voltage-clamp recordings. These findings provide new evidence supporting the contribution of Nav1.9 to pain associated with painful neuropathy, and widens the spectrum of gain-of-function mutations in Nav1.9 to include substitutions within the C-terminus of the channel.

Title: Sodium channel accessory β4 subunits control long-term depression in nucleus accumbens medium spiny neurons

Authors: *S. SAHA, X. JI, G. E. MARTIN;
Psychiatry, Brudnick Neuropsychiatric Res. Inst., Worcester, MA

Abstract: Voltage-gated sodium channels are essential for generating the initial rapid depolarization of neuronal membrane potential known as action potentials that enable cell-to-cell communication, propagation of signals throughout the brain, and control the induction of synaptic plasticity. Although all brain neurons express one or several variants coding for the core pore-forming α subunit, the expression of the β1 to β4 auxiliary subunit varies greatly. Of particular interest is the β4 subunit, also called Scn4b, whose expression in the dorsal and ventral (i.e. nucleus accumbens - NAc) striatum is much higher compared to other brain regions. Scn4b confers sodium channels unique gating properties, yet its role on neuronal activity and synaptic plasticity remains poorly understood. Combining whole-cell patch-clamp recordings and two-photon calcium imaging in Scn4b knockout and knockdown mice, we found that down regulation of Scn4b altered the properties of action potentials (APs) in core accumbens medium spiny neurons (MSNs). These alterations resulted in a strong reduction of spike-timing-dependent long-term depression (tLTD) in MSNs. In contrast, long-term potentiation (tLTP) remained unaffected. Finally, it reduced the ability of backpropagating action potentials to evoke calcium signals in dendrites of MSNs. Taken together, these data indicate that the Scn4b subunit selectively controls tLTD by modulating dendritic calcium transients evoked by backpropagating action potentials.

Title: Evaluation of Cacna1g as a candidate modifier of epilepsy in the Scn2aQ54 mouse model

Authors: *J. CALHOUN, N. A. HAWKINS, N. J. ZACHWIEJA, J. A. KEARNEY; Northwestern Univ., Chicago, IL

Abstract: Epilepsy is a common neurological disorder characterized by recurrent seizures. Mutations in genes encoding voltage-gated sodium channels are responsible for several types of human epilepsy. More than 1000 mutations in the neuronal sodium channels *SCN1A* and *SCN2A* have been identified in human patients with several epilepsy syndromes, including Genetic Epilepsy with Febrile Seizures Plus, Dravet Syndrome, and Benign Familial Neonatal-Infantile Seizures. A common feature of genetic epilepsies is variable expressivity in family members with the same mutation. We generated mouse models with mutations in voltage-gated sodium channels *Scn1a* and *Scn2a* that cause epilepsy phenotypes with different underlying mechanisms. Both mouse models show strain-dependent differences in phenotype severity. These observations demonstrate that genetic modifiers act to influence the expressivity of epilepsy. *Cacna1g*, encoding the Cav3.1 voltage-gated calcium channel subunit, was identified as a candidate modifier of epilepsy in the $Scn2a^{Q54}$ mouse model using genetic mapping and RNA-seq transcriptome analysis. In this study, transgenic mice were generated with increased expression of *Cacna1g* in order to test the hypothesis that elevated expression of *Cacna1g* will increase the severity of the epilepsy phenotype in the $Scn2a^{Q54}$ mouse model. We observed increased seizure frequency in $Scn2a^{Q54}$ mice with elevated *Cacna1g* expression relative to wildtype littermates. This demonstrates that *Cacna1g* is a modifier of the $Scn2a^{Q54}$ epilepsy phenotype and suggests that *Cacna1g* may be a potential therapeutic target for epilepsy. The identification of genetic modifiers that influence susceptibility and disease progression will provide insight into the etiology of epilepsy and suggest novel therapies for improved treatment of human patients.

Title: Gain-of-function mutation in voltage-sensing domain of $Na_v1.8$ associated with idiopathic small fiber neuropathy

Authors: *J. HUANG[1], P. ZHAO[1], J. G. J. HOEIJMAKERS[2], M. M. GERRITS[3], G. P. LAURIA[4], C. G. FABER[2], I. S. J. MERKIES[2,5], S. D. DIB-HAJJ[1], S. G. WAXMAN[1]; [1]Dept. of Neurol. and Ctr. for Neurosci. and Regeneration Res., Yale Univ. Sch. of Medicine/Veterans Affairs Med. Ctr., West Haven, CT; [2]Neurol., [3]Clin. Genet., Univ. Med. Ctr. Maastricht, Maastricht, Netherlands; [4]Headache and Neuroalgology Unit, Fondazione IRCCS Inst. Neurologico 'Carlo Besta', Milan, Italy; [5]Neurol., Spaarne Hosp., Hoofddorp, Netherlands

Abstract: Variants of sodium channel $Na_v1.8$, a critical molecule for repetitive firing in dorsal root ganglion (DRG) neurons, were previously identified in patients diagnosed with idiopathic painful small fiber neuropathy (I-SFN), providing an association with human pain disorders. Four of these $Na_v1.8$ variants (L554P, A1304T, I1706V, and G1662S) have been shown to manifest gain-of-function attributes that render DRG neurons hyperexcitable. These mutants alter biophysical properties of the $Na_v1.8$ channel, including hyperpolarizing activation, depolarizing fast-inactivation, facilitating recovery from fast-inactivation and enhancing ramp current. We have now evaluated additional I-SFN patients and report a novel *SCN10A* variant occurring in a voltage-sensing domain of the channel. Current-clamp studies in adult rat small DRG neurons (< 30 μm) revealed that this mutation significantly increases action potential-firing frequency and the population of repetitively firing neurons as compared to wild-type channel. The percentage of spontaneous firing neurons did not differ between neurons expressing wild-type or mutant channels. Mutant channels reduced current threshold for firing an all-or-none action potential by approximately 50%, hyperpolarized the voltage threshold by 5.6 mV, increased the spike height by 11%, and prolonged the action potential duration by 25%. However, the mutant did not affect resting membrane potential, input resistance or after-hyperpolarization potential. The effects of the mutation on gating properties of $Na_v1.8$ are being evaluated. These observations suggest that expression of this novel *SCN10A* variant enhances the response of small DRG neurons to external stimuli compared with wild-type $Na_v1.8$, which contributes to the pain phenotype in this individual, and enlarges the spectrum of mutations in $Na_v1.8$ that are linked to human pain disorders.

Title: Hlf is a genetic modifier of epilepsy caused by sodium channel mutation

Authors: *N. HAWKINS, J. KEARNEY;
Pharmacol., Northwestern Univ., Chicago, IL

Abstract: In the United States, nearly 3 million people have epilepsy. Several types of human epilepsies, including Dravet syndrome, can be attributed to mutations identified in voltage-gated sodium channel genes. Genetic epilepsy pedigrees illustrate how the same sodium channel mutation can result in heterogeneous phenotypes. This suggests that other factors, possibly genetic, modify the primary mutation and alter disease severity. The genetic basis of epilepsy can be studied using mouse models. Frequently, the genetic strain background can change the disease phenotype, supporting a contribution of genetic modifiers in epilepsy. The Scn2aQ54 (Q54) transgenic mouse model has a strain-dependent epilepsy phenotype. Q54 mice on the C57BL/6J strain exhibit delayed seizure onset and improved survival compared to [B6xSJL/J]F1-Q54 mice. We mapped two dominant modifier loci the influence Q54 seizure susceptibility. Hlf (hepatic leukemia factor) was identified as a strong candidate modifier gene at one locus by RNA-Seq analysis. Hlf was hypothesized to modify the Q54 seizure phenotype by contributing to strain-specific variation in PDXK and PLP levels, enzymes involved in the pyridoxine pathway and neurotransmitter metabolism. An Hlf targeted knockout mouse model assessed the modifier potential. Hlf KO/+ was crossed with Q54 to generate Hlf KO/+;Q54 mice, which were then crossed with Hlf KO/+ to generate Hlf KO/KO;Q54 test mice and controls. Spontaneous seizure frequency was measured during 30 minute observations at 3 and 6 weeks of age and survival was monitored until 9 weeks. We observed a significant difference in seizure frequency ($p<0.0236$) and survival ($p<0.002$) between Hlf KO/KO;Q54 mice and controls. To determine if direct

modulation of the pyridoxine pathway could alter their phenotype, Q54 mice were fed a pyridoxine deficient diet for 6 weeks. At 3 weeks of age, mice were randomly assigned modified or control diet for 6 weeks. At 9 weeks, spontaneous seizure frequency was determined, as described above. Q54 mice maintained on a pyridoxine deficient diet exhibited elevated seizure frequency ($p<0.0120$) and decreased survival ($p<0.002$) compared to controls. To determine if Hlf could modify other epilepsies, Hlf KO/+ mice were crossed with the Scn1aKO/+ Dravet syndrome mouse model to examine the effect on the early lethality phenotype. Hlf KO/+;Scn1aKO/+ offspring exhibited a significant lifespan reduction ($p<0.0001$) compared to Scn1aKO/+ controls. Together these results demonstrate that Hlf is a genetic modifier of epilepsy caused by voltage-gated sodium channel mutations and that modulation of the pyridoxine pathway can also influence phenotype severity.

Title: Nav1.7 selective sodium channel inhibitor CNV1014802 attenuates stimulus-evoked action potential activity in hyperexcitable DRG neurons expressing inherited erythromelalgia mutations

Authors: ***S. D. DIB-HAJJ**[1], M. ESTACION[1], D. DERJEAN[2], V. MORISSET[2], S. TATE[2], S. G. WAXMAN[1];
[1]Dept Neurol, Neurosci & Regen Res. Ctr, Yale Sch. Med., West Haven, CT; [2]Convergence Pharmaceuticals an affiliate of Biogen Idec, Cambridge, United Kingdom

Abstract: Genetic and functional studies have shown that sodium channel Nav1.7, which is highly expressed in dorsal root ganglion (DRG) neurons, is an important player in pain signaling in humans; gain-of-function mutations of Nav1.7 are known to underlie pain syndromes such as inherited erythromelalgia (IEM) and paroxsysmal extreme pain disorder (PEPD), and loss-of-function mutations cause channelopathy-associated congenital indifference to pain (CIP). This suggests that selective pharmacological blockade of Nav1.7 could result in significant reduction of pain. CNV1014802 is a novel small molecule state-dependent blocker that preferentially inhibits Nav1.7 sodium channels. Here we report the effects of CNV1014802 on rat DRG

neurons expressing the hNav1.7-F1449V mutant channel which has been identified in IEM patients. CNV1014802 had a clear effect on action potential current threshold in DRG neurons expressing F1449V mutant channels, which increased from a mean of 134 pA (pre-drug) to 203 pA during exposure to 1 uM drug. We also evaluated the effect of CNV1014802 on the response to 1000 msec stimuli in the subpopulation capable of firing at a high rate (>5Hz). Treatment of transfected DRG neurons with CNV1014802 reduced the firing frequency of these neurons. The increase of threshold and the reduction of peak firing rate in response to CNV1014802 suggest favorable clinical responses to this compound in patients with IEM.

Title: Isoform- and age-dependent effects of deltamethrin on voltage-gated sodium channel expression and function

Authors: ***T. F. JAMES**[1], J. P. MAGBY[2], F. LAEZZA[1], J. R. RICHARDSON[2];
[1]Univ. of Texas Med. Br., Galveston, TX; [2]Rutgers Univ., Piscataway, NJ

Abstract: Pyrethroids have become the most common class of insecticides in the past decades, and their primary mode of action is to prevent inactivation of opened voltage gated sodium channels (Na_v), which results in increased excitability that can lead to permanent illness or even death. However, the details of acute and chronic exposure to pyrethroids remain poorly understood—effects beyond the delay of inactivation remain to be explored. Here we present

data demonstrating that acute exposure to the pyrethroid insecticide deltamethrin in developing Long-Evans rats induces down-regulation of voltage-gated sodium channel expression that is associated with increased calpain cleavage or 20S proteasomal processing based on age. Further, repeated exposure of postnatal rats to deltamethrin resulted in decreased sodium channel levels and hippocampal glutamate release in an age- and isoform-dependent manner. Furthermore, electrophysiological data demonstrate an isoform-specific effect of acute deltamethrin exposure on Na_v function in human embryonic kidney cells (HEK293) with variances between the magnitudes of induced persistent current and directionality of peak current densities mediated by the neuronal $Na_v1.1$ and $Na_v1.6$ channels. Some properties, such as the voltage-dependence of activation, remain identical across the two isoforms, indicating that deltamethrin may have multiple binding sites and/or is dependent on differences in Na_v primary sequences in order to exert its effect. Collectively, these data indicate that deltamethrin has differential effects depending on Na_v channel type, which may have implications for certain isoforms known to be involved in neuropsychiatric disorders. Additionally, these data have implications for reported age-related susceptibility to pyrethroid neurotoxicity. Title: Nav1.7 inhibitor reduces stimulus-evoked action potential activity from small diameter trigeminal ganglion neurons

Authors: *M. R. ESTACION[1,2], D. DERJEAN[3], S. TATE[3], V. MORISSET[3], S. WAXMAN[1,2]; [1]Neurol, Yale Univ. Sch. of Med., New Haven, CT; [2]Ctr. for Neurosci. and Regeneration Res., Veteran Affairs Med. Ctr., West Haven, CT; [3]Convergence Pharmaceuticals, Cambridge, United Kingdom

Abstract: Genetic and functional studies have shown that Nav1.7 is an important player in pain signaling in humans. Nav1.7 is highly expressed in sensory neurons of dorsal root ganglion and trigeminal ganglion (TG) neurons and sets the gain on firing, and is considered an attractive target for development of next-generation analgesics. Here we report the effects of a novel state-

dependent Nav1.7 selective blocker, CNV1014802, in rat TG neurons. We evaluated the effect of CNV1014802 on TG neuron excitability by assessing the effect of graded concentrations of the compound on threshold and evoked spiking activity of small diameter TG neurons. CNV1014802 increased current threshold in all neurons. There was a clear dose-response effect on threshold, with 1 uM of CNV1014802 increasing threshold by 90 pA, 10uM increasing threshold by 130 pA and 100 uM increasing threshold markedly so that most cells did not fire even at 1000 pA stimulus current. While most small TG neurons fire one or two action potentials in response to a 1000 msec stimulus, a subpopulation of cells fire at a higher rate (>5Hz). CNV1014802 reduced the firing frequency of these neurons. The inhibitory effect of CNV1014802 on excitability of TG neurones provides a potential mechanism supporting the recent efficacy of the compound demonstrated in a trigeminal neuralgia phase II clinical study.

Title: DV21 decreases excitability of cortical pyramidal neurons and acts in epilepsy

Authors: *P. SUN[1], X. LI[2];
[1]Zhejiang Univ., Zhejiang, China; [2]Zhejiang Univ., Hangzhou Zhejiang, China

Abstract: Epilepsy is a disabling neurological disorder and affects about 1% of the population of all ages and often requires lifelong medication. However, nearly 30% affected individuals are refractory to current pharmacological treatment, so, it is necessary to develope new antiepileptic drugs. As we all know, natural products are important source of new drugs (about 60% drugs come from natural molecules directly or indirectly). We extracted a small natural molecule from plants in our country, which is named DV21 and detected to have remarkable antiepileptic activity. First, in the individual level, we find DV21 can decrease the onset time, latency of death time, and also decrease the mortality in the mouse model of epilepsy. Then, to prove it in the cell level, we find the number of action potential are reduced in the pyramid neuron after applying

the DV21 in acute cortical slices. Now we are investigating the mechanisms underlying the antiepileptic activity of DV21.

Title: Strain-dependent differences in voltage-gated sodium currents in the Scn2aQ54 mouse model of epilepsy

Authors: C. H. THOMPSON, *J. A. KEARNEY, A. L. GEORGE, Jr.;
Pharmacol., Northwestern Univ., Chicago, IL

Abstract: A spectrum of genetic epilepsy is associated with mutations in genes encoding voltage-gated sodium channels. Mouse models have been valuable for elucidating mechanisms of epileptogenesis associated with sodium channel mutations. In the *Scn2a*^{Q54} model, a severe seizure phenotype is caused by increased persistent sodium current conferred by transgenic expression of an engineered mutation in $Na_V1.2$. Importantly, epilepsy severity in *Scn2a*^{Q54} mice exhibits a strong strain-dependence. When bred congenically onto the C57BL/6J background, *Scn2a*^{Q54} (B6.Q54) mice have a mild phenotype compared to animals that have been intercrossed for a single generation with SJL/J mice (F1/Q54), which are more severely affected. We used a combination of whole-cell voltage and current clamp recording on acutely dissociated hippocampal pyramidal neurons to investigate the basis for this strain dependence. Whole-cell voltage clamp recordings of voltage-gated sodium channels revealed that neurons from F1.Q54 animals exhibited a larger persistent current (expressed as a % of peak sodium current) compared to B6.Q54 animals (1.1 ± 0.2% vs 0.4 ± 0.1%, n = 6-10), while there was no differences in whole-cell current density. Additionally, neurons from F1.Q54 animals showed a more depolarized voltage dependence of inactivation compared to neurons from B6.Q54 animals, suggesting that these channels are more resistant to inactivation. Neither voltage-dependence of

activation, nor recovery from inactivation showed any strain-dependent differences. No differences were observed between the biophysical properties of sodium currents measured from wild-type mice of the two background strains. Finally, whole-cell current clamp recording revealed that neurons from both B6.Q54 and F1.Q54 animals show spontaneous action potential firing, but F1.Q54 neurons exhibited a higher level of activity compared to B6.Q54 neurons (6.5 ± 1.5 Hz vs 2.5 ± 0.5 Hz, n = 8-9). Neurons from F1.Q54 animals also showed greater evoked activity compared to B6.Q54 neurons. These data suggest that the strain-dependent phenotype observed for the *Scn2a*^{Q54} model is driven, at least in part, by divergent levels of sodium channel dysfunction between strains that confer different levels of neuronal hyperexcitability.

Title: Biophysical and pharmacological properties of human Nav1.9 stably expressed in HEK 293 cells

Authors: *Z. LIN, S. SANTOS, K. M. PADILLA, D. PRINTZENHOFF, N. A. CASTLE; Biol., Pfizer Inc., Durham, NC

Abstract: Recent human genetic studies have identified gain of function mutations of the sensory neuron expressed voltage dependent sodium channel Nav1.9, which are associated with either complete insensitivity or hypersensitivity to pain. Thus, Nav1.9 is as an attractive target for development of new pharmacological treatments for pain. Despite its pathophysiological importance, little is known about Nav1.9, partly due to the historical difficulty of achieving functional expression of the recombinant channel. Here we report the generation, biophysical and pharmacological characterization of a HEK-293 cell line stably expressing the recombinant human Nav1.9 alpha subunit along with beta1 and beta2 accessory subunits. Examination of cell line using whole cell patch clamp revealed a slowly inactivating tetrodotoxin insensitive inward current (29 ± 9 pA/pF) with midpoint voltages of activation (-56.6± 0.5 mV) and inactivation (-46.7 ± 0.9 mV) following 100 ms voltage steps. Nav1.9 current density increased in the presence of GTP-gamma-S in the pipette solution, which is inconsistent with previous reports that Nav1.9 can be regulated by G protein coupled receptor modulation. Nav1.9 currents were inhibited by

established sodium channel blockers, but potency was considerably less than reported for other sodium channel subtypes. For example, IC_{50} (midpoint inhibition ± 95% CI in μM) for amitriptyline = 30 ± 5; lidocaine = 377 ± 56; mexiletine = 271 ± 36 and tetracaine = 38 ± 5. In other sodium channel subtypes, these inhibitors have been shown to interact with the local anesthetic binding (LA) site in the pore. We mutated the equivalent LA site residues of Nav1.9 (F1592A/Y1599A) and found that potencies for the inhibitors were reduced by 3 to 15 fold. This suggests that the inhibitors interact with the local anesthetic binding site, despite their low potencies observed for inhibition of wild type Nav1.9. The results from this study show that stable expression of Nav1.9 in HEK cells is possible, and the resulting cell line recapitulates the properties of native Nav1.9 currents in sensory neurons.

Title: Interplay between CRMP2 phosphorylation and SUMOylation determines NaV1.7 trafficking

Authors: *A. MOUTAL, E. T. DUSTRUDE, X. YANG, Y. WANG, M. KHANNA, R. KHANNA;
pharmacology, Univ. of Arizona, Tucson, AZ

Abstract: Trafficking of voltage-gated sodium channel NaV1.7 remains poorly understood. Post-translational modifications of NaVs and/or auxiliary subunits and protein-protein interactions have been posited as NaV-trafficking mechanisms. We recently reported that modification of the axonal collapsin response mediator protein 2 (CRMP2) by a small ubiquitin-like modifier (SUMO) controls both NaV1.7 trafficking and currents (Dustrude et al., J. Biol. Chem. 288: 24316-31 (2013)). Because CRMP2 functions are regulated by its phosphorylation state, we investigated the possible interplay between phosphorylation and SUMOylation of CRMP2 on NaV1.7. Phosphorylation of CRMP2 by cyclin dependent kinase 5 (Cdk5) was necessary for maintaining NaV1.7 surface expression and current density. Loss of either CRMP2 SUMOylation or phosphorylation decreased binding to NaV1.7. Preventing both CRMP2

modification events simultaneously was not synergistic, suggesting that NaV1.7 co-opts both pathways to be functional. However, CRMP2 phosphorylation was obligatory for its SUMOylation. Loss of either CRMP2 SUMOylation or phosphorylation triggered NaV1.7 internalization in a clathrin-dependent manner involving the HECT domain-containing E3 ubiquitin ligase Nedd4-2 as well as other endocytosis adaptor proteins. Our findings identify a novel mechanism for selective regulation of NaV1.7.

Title: Disease mutations affecting calmodulin and FGF13 interaction with Nav1.2 voltage-dependent sodium channel increase persistent sodium current

Authors: *H. YAN, C. WANG, G. S. PITT;
Dept. of Medicine, Ion Channel Res. Unit, Duke Univ. Med. Ctr., Durham, NC

Abstract: Whole exome sequencing studies have identified SCN2A, which encodes the neuronal voltage-gated Na+ channel NaV1.2, as one of the most commonly mutated genes associated with autism and intellectual disabilities. Several of the mutations cluster within the intracellular C terminal domain (CTD), the binding site for calmodulin (CaM) and members of the fibroblast growth factor homologous factor (FHF) family. Both CaM and FHFs are potent modulators of various aspects Na+ channel currents. Whether disease mutations within the NaV1.2 CTD affect Na+ currents because of disruption of interaction with (and consequent modulation by) CaM or FHFs is not known. Here, we tested the consequences on voltage-gated Na+ currents and on in the interaction with CaM or FHFs of several disease mutations (H1853R and R1918H associated with epilepsy; and R1902C associated with familial autism) within the NaV1.2 CTD. Binding studies with recombinant proteins showed that all three mutations reduced the affinity of the CTD for CaM and/or FGF13 (one of four FHF family members). Using a heterologous expression system, we showed that all three mutations affect various Na+ current

parameters_including steady-state inactivation the amount of the persistent “late” Na+ current. The reduced affinity for CaM and/or FGF13 appeared to be causative for the effects on Na+ currents since over-expression of the CaM and/or FGF13 “rescued” the disease-associated defect. Thus, our data suggest that CaM and FHFs are essential components of neuronal voltage-gated Na+ channels and that disease mutations may lead to altered Na+ currents through reduced interaction with the critical channel modulators.

Title: Modulation of the cardiac sodium channel Nav1.5 by the antiepileptic agent lacosamide

Authors: N. ELIA, X. XIONG, S. DHILLON, P. CHEN, A. MONTALVO, S. TANG, D. H. FELDMAN, *C. LOSSIN;
Neurol., UC Davis - Sch. of Med., Sacramento, CA

Abstract: Sodium channel blockers are the first line of defense in controlling seizures, but inhibition of voltage-gated sodium (Nav) channel activity may have undesired effects throughout the nervous system, heart, and muscle, due to the similarity of structure and function in all Nav variants of excitable tissues. Lacosamide (LCM) is approved therapy for adult partial seizures and its likely mechanism of action is the enhancement of Nav channel slow inactivation. The literature contains electrophysiological characterizations of LCM’s effect on neuronal Nav such as Nav1.2, Nav1.3, Nav1.7, etc., but the impact on cardiac Nav1.5 is mentioned only anecdotally. To get a better understanding of LCM action in the heart, we tested LCM (Ontario Chemicals) on whole-cell voltage-clamped HEK cells stably transfected with human Nav1.5. Our data show that, in presence of the drug, Nav1.5 entered slow inactivation much more readily, requiring less and shorter depolarization, and it recovered at a significantly slower pace than when LCM was absent. At high concentrations, the shift in the voltage dependence of slow inactivation was dramatic, effectively disabling approximately half of all Nav1.5 channels, even without depolarization. Contractility assays on cardiomyocytes showed complete but reversible

cessation of rhythmic beating between 30 and 100 μM LCM. Since pharmacokinetic studies suggest a patient serum concentration nearing 30 μM, our results indicate that LCM-induced enhancement of Nav1.5 slow inactivation is a plausible contributor to the observed cardiac effects, and suggests that there may be a narrow window of dosage safety, which if exceeded, may precipitate cardiac events.

Title: Modulation of hyperpolarization-activated cation currents (Ih) by ethanol in rat hippocampal CA3 pyramidal neurons and influence on neuronal excitability

Authors: V. LICHERI[1], G. TALANI[2], A. A. GORULE[1], L. FIRINO[1], L. COCCO[1], G. BIGGIO[1], *E. SANNA[1];
[1]Univ. Cagliari, Monserrato 09042, Italy; [2]of Neurosci., Natl. Res. Council, Monserrato, Italy

Abstract: Hyperpolarization-activated and cyclic nucleotide-gated channels (HCN) are expressed in different neuronal populations where they play a crucial role in fundamental neurophysiologial functions including neuronal pacemaker activity, dendritic integration, and membrane excitability. Recent studies have reported that ethanol (EtOH) is able to modulate Ih mediated by HCN in VTA and hippocampal interneurons. Because robust Ih are also present in CA3 pyramidal neurons, we here investigated whether the action of EtOH on CA3 excitability could be correlated with its possible interaction with HCN. To evaluate whether Ih were altered by EtOH, we initially tested a low (20 mM) and higher (60 and 80 mM) concentrations of EtOH which were bath applied for 10-15 min under voltage-clamp conditions in acute hippocampal slices from Sprague Dawley rats. Bath perfusion of 20 mM EtOH induced a significant increase in Ih amplitude with respect to control, whereas, 60 and 80 mM produced an opposite effect, with a significant reduction of Ih amplitude. Because the activity of HCN is considered a contributing factor in the fine-tuning of neuronal excitability, we also studied the effect of EtOH

on action potential firing in hippocampal CA3 pyramidal neurons. Firing in CA3 pyramidal cells is regulated by an intrinsic cellular mechanism, and recently, it was shown that the majority of pyramidal cells in the hippocampal CA3 field support persistent firing only in the presence of the muscarinic receptor agonist carbachol. Carbachol-induced firing in CA3 pyramidal neurons was increased following perfusion of 20 mM EtOH, while 80 mM reduced the frequency of action potentials. In addition, bath perfusion of ZD-7288 (20 μM), selective HCN blocker, as well as the non-selective blocker CsCl (5 mM), completely suppressed action potential firing. Overall these findings suggest that the biphasic modulatory action of EtOH on HCN-mediated Ih may contribute to the effects of EtOH on the excitability of CA3 pyramidal cells. Title: Changes in Ih current channel's subunits 2 and 4 during the expression of cocaine sensitization

Authors: *C. E. MARÍA-RÍOS[1,2], A. MONTIEL-RAMOS[1,2], B. SANTOS-VERA[1], A. VAQUER-ALICEA[1], R. VÁZQUEZ-TORRES[1], C. A. JIMÉNEZ-RIVERA[1];
[1]Physiol., Univ. Of Puerto Rico Med. Sci. Campus, San Juan, Puerto Rico; [2]Biol. Dept., Univ. of Puerto Rico Río Piedras Campus, San Juan, Puerto Rico

Abstract: Cocaine abuse is known to induce neurobiological adaptations in the Mesocorticolimbic (MCL) system; a brain reward circuit composed of interconnected regions

that regulate pleasure and motivation. Some of these adaptations include changes in the excitability of the neurons in the MCL system, which can contribute to the development and expression of cocaine sensitization. Cocaine sensitization is the progressive escalation of psychomotor responses that results with repeated cocaine administration. The Hyperpolarization-Activated Cyclic-Nucleotide Current (Ih), is a pronounced mixed cation current present in MCL neurons. The potential regulatory role of Ih current in neuronal excitability is subjected to the expression of Hyperpolarization-Activated Cyclic-Nucleotide gated channel (HCN) subunits. Ih may play a significant role in the behavioral responses to cocaine. Previously, our laboratory demonstrated that protein expression of the HCN_2 subunit, was increased in the Ventral Tegmental Area (VTA), Nucleus Accumbens (NAcc), Hippocampus (HIP), and Prefrontal Cortex (PFC) after the development of cocaine sensitization. However, protein expression of the HCN_4 subunit was significantly decreased only in the VTA. The purpose of the present study was to elucidate if protein expression levels of HCN_4 and HCN_2 subunit observed during the development of cocaine sensitization persist after a 7-day cocaine-withdrawal period, or if normal expression was reinstated. Sprague Dawley male rats (250g) received intraperitoneal cocaine (15mg/kg) or 0.9% saline injections for 7 days. Locomotor activity was recorded for one hour. Following a 7-day cocaine withdrawal period, rats were sacrificed and tissue micro-punches from VTA, NAcc, HIP and PFC collected and put through protein extraction and western blot analysis. Our results show a significant 61% decrease in protein expression of HCN_4 subunit in the HIP (sample T-test; $p< 0.05$). In addition, preliminary data shows a 71% decrease in protein expression of HCN_4 in PFC (n=4). These results may suggest possible changes emerging during the cocaine-withdrawal period that could be essential for the maintenance of the neuroadaptations that are present during cocaine addiction. Protein expression of the HCN_2 subunit during the expression of sensitization is still being explored.

Title: Determining the distribution and functional role of HCN channels in a collision sensitive neuron

Authors: *E. SUNG[1], R. B. DEWELL[2], S. J. COX[1], F. GABBIANI[2];
[1]Computat. and Applied Mathematics, Rice Univ., Houston, TX; [2]Neurosci., Baylor Col. of Med., Houston, TX

Abstract: The Lobula Giant Movement Detector (LGMD) neuron in locusts is an identified visual neuron that responds vigorously to approaching objects on a collision course with the animal. The LGMD serves as a strong model to study single neuron computations. It has been studied extensively for the past 50 years, and its role in locust escape behavior has been well characterized. The LGMD consists of three dendritic subfields denoted as subfields A, B, and C. Subfield A receives ~15,000 retinotopic excitatory inputs whereas subfields B and C receive inhibitory inputs. Current clamp recordings with pharmacological manipulations have revealed the presence of the inward-rectifying current Ih mediated by HCN channels. However, the distribution and functional role of these HCN channels in the LGMD has yet to be fully characterized. To study such questions, we use computational methods to model the membrane dynamics and to ascertain the role of the HCN channels. We perform 3D morphological reconstructions of the LGMD to better characterize the size and geometry of the LGMD. We repeat this procedure over several LGMD neurons from different animals. Then, we incorporate these reconstructions into a Hodgkin-Huxley type multi-compartmental model. Using this model, we first investigate how the HCN channels are distributed in the LGMD's dendritic subfields. We do this by fitting our model to dual potential experimental recordings in order to recover an estimated guess of the HCN channel distribution. To study the functional role of the HCN channels in the LGMD, we simulate incoming retinotopic synaptic inputs in the presence and absence of HCN channels, and observe the change in response of the LGMD. We show that the HCN channels play a role in shaping LGMD responses to incoming synaptic inputs.

Title: Influence of active dendrites on membrane resonance and temporal synchrony in a looming sensitive neuron

Authors: *R. B. DEWELL[1], F. GABBIANI[1,2];
[1]Dept of Neurosci., Baylor Col. of Med., Houston, TX; [2]Rice Univ., Houston, TX

Abstract: How a neuron integrates complex spatial and temporal patterns of synaptic inputs is critical for the computations it performs. Synaptic integration depends in turn on the active conductances localized within a neuron's dendritic arbor. We use a well-studied looming sensitive neuron in the locust that integrates ~15,000 retinotopically organized excitatory synaptic inputs as a model system. This neuron, the lobula giant movement detector (LGMD) responds to approaching objects or their two dimensional analogues, called looming stimuli, in a manner that is largely invariant to the object's shape, texture, contrast and approach angle. Experimental evidence suggests that both I_h and I_M contribute to complex, nonlinear processing within the LGMD, which allows reliable detection of approaching objects. These currents can produce resonance within single neurons that results in increased responses to inputs within a particular frequency range. In addition to this ability to band-pass filter synaptic inputs, I_h has also been shown to increase the temporal synchrony of inputs, by reducing the phase lag of signals as they propagate from distal dendrites toward the site of spike initiation. As the spatio-temporal pattern of synaptic inputs into the LGMD is important both for the computations carried out within the neuron and the animal's escape behavior, this neuron represents an attractive model to investigate the influence of active conductances on the resonance and temporal filtering of synaptic inputs. To study these questions, we used chirp currents in single and dual recording experiments *in vivo* combined with pharmacological manipulations of M and h currents. This system allows us to not only investigate the role of active conductances for dendritic integration, but also to ground these data in the context of an ecologically important neural computation.

Title: Alterations in cerebellar stellate cell hyperpolarization-activated currents following fear learning

Authors: *K. L. CARZOLI, J. LIU;
Cell Biol. and Anat., LSUHSC, New Orleans, LA

Abstract: Along with its canonical role in motor coordination, the cerebellum has been shown to be involved in associative learning. One form of associative learning, fear conditioning, has been found to alter synaptic transmission and connectivity in a cerebellar lobule-specific manner. Most studies of fear conditioning have focused on how learning alters synaptic transmission, but few reports have actually investigated the influence of learning on membrane excitability. A neuron's intrinsic properties are determined by ion channels in the membrane, the alteration of which can affect neuronal activity and output. Unlike most voltage-gated channels, hyperpolarization activated cyclic nucleotide-regulated (HCN) channels are nonselective cation channels that activate with hyperpolarization and deactivate with depolarization. Furthermore, these channels can produce a small inward current near a neuron's resting membrane potential, and thereby influence intrinsic membrane properties. After fear leaning, it has been shown that there is an increase in inhibitory transmission in the cerebellum. Cerebellar stellate cells are inhibitory interneurons that express HCN channels, an alteration of which could influence their membrane excitability and the activity that they output onto their principal Purkinje cells. Here, we investigated the effects of fear learning on hyperpolarization-activated currents (Ih) using voltage clamp recordings. We found that fear conditioning reduced the amplitude of Ih in cerebellar stellate cells. Moreover, we found that this reduction in Ih resulted in an increase in neuronal input resistance. These learning-induced changes were specific to vermal lobules V/VI, and changes in Ih were reversed following extinction. We concluded that changes in Ih were due to associative fear learning because when mice underwent a control procedure in which conditioned and unconditioned stimuli were explicitly unpaired, these leaning-induced changes did not occur. Together, our findings aid in our understanding of how learning can alter membrane excitability in the cerebellum.

Title: The supramammillary-dentate gyrus pathway: evidence for a unique glutamate and gaba co-transmission

Authors: L. CASTILLO[1,2], A. IVANOV[1,2], A. GHESTEM[1,2], E. KROOK-MAGNUSON[3], I. SOLTESZ[4], C. BERNARD[1,2], *M. ESCLAPEZ[1,2];

Abstract: The supramammillary nucleus (SuM) provides substantial projections to the hippocampal formation. This hypothalamic structure is involved in the regulation of hippocampal theta rhythm and therefore plays a crucial role in the control of several hippocampal-dependent cognitive functions as well as emotional behavior. In rat previous studies demonstrate that neurons from the lateral region of the SuM (SuML) which innervates the supragranular layer of the dorsal dentate gyrus (DG) and, to a much lesser extent the ventral DG co-express markers for both glutamatergic (vesicular glutamate transporter 2; VGluT2) and GABAergic (glutamate decarboxylase 65, GAD65 and the vesicular GABA transporter, VGAT) neurotransmission and establish asymmetric and symmetric synapses on dentate granule cells. In this study, we examine the physiological features of this potential co-transmission using an *in vitro* optogenetic experimental approach performed in VGLUT2-Cre mutant mouse (Jackson's Laboratory) expressing Chanelrhodopsin (ChR2, excitatory opsin) within SuML neurons and their axon terminals after stereotaxic injection of an AAV5 cre-dependent ChR2 viral vector (UNC Vector Core, Desseroth's laboratory) into the SuML. We confirm in this mutant mouse, the dual neurotransmitter phenotype of SuML neurons, described in rat. We then demonstrate in hippocampal slices, that light activation of SuML axon terminals expressing channelrhodopsin2 induced simultaneously a fast glutamate postsynaptic current (PSC) and a slower GABA PSC onto a single granule cell. The GABA-A receptor antagonist gabazine (10 μM) blocked light-evoked GABA PSC and increased (or reveal) the glutamate PSC. The AMPA-receptor antagonist NBQX (10 μM) selectively blocked the light-evoked glutamate current without modifying the GABA PSC. Our findings indicate that Glutamate and GABA are co-released monosynaptically from SuML axon terminals. The functional role of such unique glutamate and

GABA co-transmission by SuML neurons that could simultaneously depolarize and hyperpolarize dentate granule cells remains to be demonstrated.

Title: Presynaptic NMDA receptors act via RIM1αβ to control the readily-releasable pool in layer-5 pyramidal neurons

Authors: ***T. ABRAHAMSSON**[1], R. P. COSTA[2], K. BUCHANAN[3], D. ELGAR[3], A. BLACKMAN[3], J. OYRER[3], A. TUDOR-JONES[3], M. VAN ROSSUM[2], P. J. SJÖSTRÖM[1,3]; [1]Neurol. and Neurosurg., The Res. Inst. of the McGill Univ. He, Montreal, QC, Canada; [2]Inst. for Adaptive and Neural Computation, Univ. of Edinburgh, Edinburgh, United Kingdom; [3]Univ. Col. London, London, United Kingdom

Abstract: Presynaptic NMDARs (preNMDARs) of unclear function have been found at several central synapse types. Although it is known that they increase vesicle release probability, precisely how is unknown. We recorded evoked release onto layer-5 pyramidal cells (PCs) using paired recordings in acute slices of juvenile mouse visual cortex. PreNMDARs could affect evoked release in several different ways: by directly altering release probability, by increasing the readily releasable vesicle pool (RRP) size, or by upregulating RRP replenishment rate. We used Schneggenburger-Neher's approach to examine the RRP, depleting it with 14 spikes at 30 Hz every 80 seconds. We first compared preNMDAR blockade to external [Ca2+] reduction.

The GluN2B-specific NMDAR blocker Ro25-6981 (Ro) reduced both RRP size (-36% ± 7%, n = 11 vs. controls -7.1% ± 5%, n = 11, $p < 0.05$) and replenishment rate (-31% ± 7% vs. 18% ± 7%, $p < 0.001$). However, lowered [Ca2+] decreased RRP size (-27% ± 4%, n = 9, $p < 0.05$ vs. controls) but not replenishment rate (7.8% ± 7%, $p = 0.33$). Next, we extended the Tsodyks-Markram short-term plasticity model to include preNMDARs and tuned it to control and Ro conditions. The model indicated that both vesicle usage and recovery from depression were downregulated by Ro, and that preNMDARs improve signal-to-noise ratio during high-frequency firing.Finally, we explored how preNMDARs signal by hypothesizing a need for RIM1. In slices from heterozygote RIM1αβ conditional KO mice, we found decreased EPSC amplitudes (32 ± 4 pA, n = 36 vs. controls 54 ± 10 pA, n = 22, $p < 0.01$) and increased paired-pulse facilitation (-0.30 ± 0.05 vs. controls -0.47 ± 0.03, $p < 0.001$), consistent with a low baseline release probability. Ro blockade left EPSC amplitude in RIM1αβ KO indistinguishable from mock wash-in (96% ± 4%, n = 12 vs. 98% ± 10%, $p = 0.88$), but reduced it in RIM1αβ flox controls (52% ± 10%, n = 6, ANOVA $p < 0.01$). Similarly, Ro had no distinguishable effects on RRP size ($p = 0.68$) or replenishment rate ($p = 0.83$) in KO mice vs. mock wash-in (pooled: 1.6% ± 10% and -9.8% ± 4%), but reduced both in RIM1αβ flox controls (-69%±5%, $p < 0.001$ and -42% ± 9%, $p < 0.01$, ANOVAs). Cortical preNMDARs thus need RIM1αβ to regulate the RRP. We conclude that during high-frequency firing, preNMDARs signal via RIM1αβ to upregulate the RRP replenishment rate, thereby increasing the release probability indirectly. As a consequence, preNMDARs boost high-frequency neurotransmission and improve the signal-to-noise ratio.

Title: Investigation of calcium currents upon overexpression of αCav2.1 in the Calyx of Held

Authors: ***M. LUEBBERT**[1], B. DAS[1,3], W. DONG[1], K. GOFF[1], R. RICHARD[1], N. KAMASAWA[2], S. M. YOUNG, Jr.[1];

[1]Mol. Mechanisms of Synaptic Function, [2]Electron Microscopy Core, Max Planck Florida Inst. For Neurosci., Jupiter, FL; [3]Florida Atlantic Univ., Jupiter, FL

Abstract: Previous studies on cultured hippocampal neurons proposed the existence of voltage-gated Ca2+ channel (VGCC) subtype preferring slots at the active zone (AZ). It was proposed that these slots are binding sites with different capacities for each VGCC subtype that interact with the α-subunit of VGCCs. Two different kinds of slots are expressed at the AZ: 1) Cav2.2 (N-type) channel slots exclusively binding Cav2.2 VGCCs with an unlimited capacity and 2): Cav2.1 (P/Q-type) preferring slots with limited capacity that still accept Cav2.2 VGCCs (Cao et al., 2004; Cao et al., 2010). The calyx of Held is a giant presynaptic terminal, forming a glutamatergic axosomatic synapse with the principal cells of the medial nucleus of the trapezoid body (MNTB) in the auditory brainstem. During development (P7-P11) the composition of VGCCs at the calyx consists of R, N, and P/Q-type. However, by hearing onset (mice ~P11) the calyx exclusively expresses P/Q at the synaptic terminal. Recently, it was shown that the number of P/Q-type channels in calyx of Held AZs varies strongly (2-73; Nakamura et al., 2015), implying that AZs themselves have variable slots for P/Q-type VGCCs. However, it remains unclear if AZs have variable numbers of slots or if AZs express similar numbers of slots that remain unsaturated. To answer this question, we used a helper-dependent adenoviral vector (HdAd) to overexpress αCav2.1 in the calyx. Expression was driven by the high level expression cassette pUNISHER. Subsequently, we conducted whole-cell patch clamp recordings to investigate the effect of αCaV2.1 overexpression on presynaptic Ca2+ currents. The results obtained from these recordings will be discussed.

Title: Artificial nanostructures mimicking the extracellular environment: sculpting neurotransmission during maturation of hippocampal synapses

Authors: *N. P. PAMPALONI[1], D. SCAINI[2], S. BOSI[2], M. PRATO[2], L. BALLERINI[3]; [1]SISSA, Trieste, Italy; [2]Univ. of Trieste, Trieste, Italy; [3]sissa, Trieste, Italy

Abstract: Neurons sense physical and chemical features of the extracellular environment that are then translated into appropriate actions. This ability has been exploited in modern neuroscience to manufacture nanostructured growth scaffolds with biomimetic cues useful for enabling key biological tasks in cultured tissues (Dvir et al, 2010; Shao and Fu, 2014; Battiston et al, 2014). Multi-walled carbon nanotubes (MWCNT) are nanostructures constituted by sheets of graphene rolled up to form hollow tubes (Iijima 1991). Over the last decade MWCNTs were shown to be an ideal interface to grow excitable cells such as neurons and cardiomiocytes (Mattson et al, 2000; Dvir et al, 2010; Fabbro et al, 2013). The extracellular environment when artificially reconstructed by MWCNTs induces synaptogenesis in cultured neurons (Lovat et al, 2005; Mazzatenta et al, 2007; Cellot et al, 2009, 2011). In practice, the physical and chemical properties of MWCNTs provide potent biomimetic signals to neurons and significantly favor the construction of monosynaptic connections among pairs of neurons when synaptic networks mature *in vitro* (Cellot et al, 2011). There are currently no reports on the effects that immobilized MWCNTs exert on the cell membrane equilibria, however several studies targeted the interaction between lipidic membrane and MWCNTs in suspension (Monticelli et al, 2009). Here we investigate the impact of MWCNTs meshwork on the synaptic homeostasis of cultured neurons at different stages of growth. By patch-clamp and immunofluorescence microscopy we investigated whether the ability of such nanomaterials to modulate excitatory synaptic transmission was related to alteration in cell membrane lipids, in particular we focused on cholesterol, known to balance presynaptic vesicle release (Wasser et al, 2007; Ramirez and Kavalali, 2011). We exclude the presence of major MWCNT-induced cholesterol changes in the membrane of cultured neurons. However, we unmasked MWCNT ability to shape synapse formation and the synaptic mode of transmission of glutamatergic connections during *in vitro* development. Finally, we described for the first time network activity homeostasis upon long term MWCNT interfacing. Battiston, Biomaterials (2014) 35:4465. Cellot, J.Neurosci. (2011) 31:12945. Title: Disturbances in presynaptic active zone structure-function relationships in Lambert-Eaton myasthenic syndrome

Authors: *T. B. TARR[1], J. MA[2], M. DITTRICH[2], S. D. MERINEY[1];
[1]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [2]Pittsburgh Supercomputing Ctr., Carnegie Mellon Univ., Pittsburgh, PA

Abstract: Although the mammalian neuromuscular junction (NMJ) is normally a very reliable synapse, there are disease states in which this reliability can be drastically reduced. One such example is Lambert-Eaton myasthenic syndrome (LEMS), an autoimmune disease that reduces neurotransmitter release at the NMJ and leads to muscle weakness in patients. The reduction in neurotransmitter release is thought to occur because of an autoantibody-mediated removal of a fraction of the presynaptic voltage-gated Ca2+ channels (VGCCs) that trigger release of neurotransmitter-containing vesicles. Despite the well accepted theory that a reduction in the number of presynaptic VGCCs causes the physiological properties observed in LEMS NMJs, large LEMS-induced changes in short-term plasticity at mouse-model synapses led us to examine this hypothesis in greater detail. To explore this issue, we used a combination of electrophysiological recording, calcium imaging, and MCell modeling techniques. We find that changes in short-term plasticity cannot be explained by a simple reduction in the number of VGCCs. First, we pharmacologically blocked neurotransmitter release to a similar extent as observed in our LEMS model (~75% reduction in quantal content) using ω-agatoxin IVA, but this pharmacological block did not generate short-term plasticity characteristics that matched those of LEMS NMJs. Second, we conducted computer modeling studies based on our previously developed 3-dimensional reaction-diffusion MCell computer model of the mouse NMJ that accurately predicts experimentally observed quantities, such as quantal content, release latency and short-term plasticity characteristics. Using this MCell model we tested the hypothesis that removal of VGCCs can predict the short-term plasticity observed at LEMS model NMJs. As with our physiological recordings, we find that simple VGCC removal is not sufficient to explain the experimentally observed changes in facilitation under LEMS conditions. Therefore, using this model we are currently testing the functional role of additional changes to

active zone organization in the observed LEMS NMJ physiology. These changes include alterations in the distance between VGCCs and synaptic vesicles and the LEMS-induced up-regulation of additional VGCC types that might not be positioned within the highly organized active zone structure. Lastly, we have used our newly developed VGCC gating modifier (GV-58) as an experimental tool to test these short-term plasticity mechanisms both physiologically and in our MCell model.

Title: Reduced endogenous calcium buffering speeds active zone calcium signaling

Authors: *S. J. HALLERMANN[1], I. DELVENDAHL[1], J. LUKASZ[1], C. BAADE[1], V. MATVEEV[2], E. NEHER[3];
[1]Univ. Leipzig, Leipzig, Germany; [2]New Jersey Inst. of Technol., Newark, NJ; [3]Max-Planck-Institute for Biophysical Chem., Goettingen, Germany

Abstract: Fast synchronous neurotransmitter release at the presynaptic active zone is triggered by local calcium signals, which are confined in their spatio-temporal extent by endogenous calcium buffers. However, it remains elusive how rapid and reliable calcium signaling can be sustained during repetitive release. Here, we established quantitative two-photon calcium imaging in cerebellar mossy fiber boutons, which fire at exceptionally high rates. We show that endogenous fixed buffers have a surprisingly low calcium-binding ratio (~15) and low affinity, whereas mobile buffers have high affinity. Experimentally constrained modeling revealed that the reduced endogenous buffering accelerates the clearance of calcium at the active zone during repetitive firing. Measuring calcium signals at different distances from active zones with ultra-highresolution confirmed our model predictions. Our results lead to a novel concept that reduced calcium buffering speeds active zone calcium signaling, suggesting that the strength of endogenous calcium buffering limits the rate of synchronous synaptic transmission.

Title: Novel functions of ADF/cofilin-dependent actin dynamics in neurotransmitter release and mouse behavior

Authors: *M. B. RUST[1,2], A. GÖRLICH[2], M. WOLF[2], A.-M. ZIMMERMANN[2], C. GURNIAK[3], M. SASSOÈ-POGNETTO[4], E. FRIAUF[2], W. WITKE[3];

Abstract: Actin depolymerizing proteins of the ADF/cofilin family are essential for actin dynamics, which is critical for synaptic function. Two ADF/cofilin family members, namely ADF and cofilin1, are highly abundant in the brain and present at excitatory synapses. By exploiting gene-targeted mice we have shown previously that cofilin1 is critical for dendritic spine morphology, synaptic plasticity, associative learning, and anxiety (Rust et al., EMBO J, 2010; Goodson et al., PLoS Genet, 2012). Conversely, inactivation of ADF in mice did not interfere with synapse morphology or physiology and mutant mice performed normal in paradigms of associative learning (Görlich et al., PLoS One, 2011). Interestingly, we found elevated cofilin1 levels in synaptic structures from ADF mutant mice suggesting i) that cofilin1 can compensate for the loss of ADF and ii) that ADF and cofilin1 have overlapping synaptic functions. To test these suggestions, we genetically removed ADF together with cofilin1 from synapses. In double mutant mice, synaptic actin dynamics was impaired and more severely affected than in single mutants (Wolf et al., Cereb Cortex, 2015; Rust et al., Exp Cell Res, 2015). The resulting cytoskeletal defects affected the organization and mobilization of synaptic vesicles

and thereby impaired neurotransmitter release. Enhanced glutamate release in the striatum caused attention deficit/hyperactivity disorder (ADHD)-like behavioral abnormalities in double mutants that were not present in single mutants, including hyper-locomotion and a calming effect of psychostimulants (Zimmermann et al., Biol Psychiatry, 2015). Together, our data revealed novel and redundant functions for ADF and cofilin1 in neurotransmitter release and mouse behavior. Moreover, they highlight the relevance of actin dynamics for presynaptic mechanism and associated defective actin dynamics with the etiology of ADHD.

Title: Distinct molecular signatures of NE and ATP containing vesicles in vascular sympathetic nerves

Authors: ***J. WALIA**[1], B. LI[1], C. GERSHOME[1,2], D. POBURKO[1,2];
[1]Biomed. Physiol. and Kinesiology, SFU, Burnaby, BC, Canada; [2]Ctr. for Cell Biology, Development, and Disease, SFU, Burnaby, BC, Canada

Abstract: Sympathetic vericosities release neurotransmitters including ATP and NE into the neuroeffector junction to regulate vascular smooth muscle cell contraction and ultimately blood pressure. Despite advances in our knowledge of presynaptic signalling and organization in cultured sympathetic neurons, few studies have characterized presynaptic molecular details in the sympathetic terminals in intact blood vessels. Our work focuses on whether ATP and norepinephrine (NE) are co-stored in the same vesicles or in distinct pools of vesicles and/or varicosities. Using immunohistochemistry (IHC) and epifluorescence microscopy, we previously found that the vesicular monoamine transporter 2 (VMAT2) and vesicular nucleotide transporter (VNUT), which load NE and ATP in to vesicles respectively, are segregated within varicosities. Here we report IHC analyses to characterize the association of VNUT with other vesicular proteins: Synaptic Vesicle 2A (SV2A), Synaptophysin (Syp) and Synaptotagmin-1 (Syt1), the Ca2+ sensor for NE containing vesicles. Reports studying vas deferens suggested that SV2A

localizes to all vesicles of sympathetic nerve terminals, whereas Syp might preferentially associate with VNUT-containing vesicles. Clusters (fluorescent puncta) of labelled vesicles were analyzed for fluorescent intensity and their distance to neighbouring puncta of other proteins using ImageJ. Morphologically, VNUT labelled small and highly punctate pools of vesicles that were smaller than typical varicosities (typically <500 nm), whereas Syt1 labelled pools of vesicles roughly the same size as vericosities. Syp- and SV2A-labelled vesicle pools were of intermediate size between VNUT and Syt1, with labelling consisting of small, round puncta within a varicosity. Visually, VNUT was anti-colocalized with all but a small subpopulation of vesicles labelled by Syt1, SV2A and Syp. In contrast, Syp and SV2A extensively colocalized with Syt1, but they also labelled small pools of vesicles lacking Syt1. The separation between the perimeters of VNUT and Syp, SV2A or Syt1 puncta averaged 0.1 μm, whereas Syt1 and SV2A or Syp consistently overlap by at least 0.1 μm. Correlations in puncta intensities for Syt1 and SV2A (r=0.23) or Syp (r=0.36) and VNUT-Syp (r=0.29) were high relative to VNUT and SV2A (r=0.02) or Syt1 (r=-0.05). Thus we conclude that Syp and SV2A are preferentially localized with Syt1 to NE containing vesicles, but also associate with a small subpopulation of ATP containing vesicles. Moreover, ATP containing vesicles appear to lack Syt1, which may contribute to differential sympathetic release of ATP and NE as a function of stimulation frequency and duration.

Title: All-or-none axonal Ca^{2+} dynamics in recurrent circuits of the hippocampus

Authors: ***I. RAN**[1], R. W. TSIEN[2];
[1]NYU Neurosci. Inst., NYU Langone Med. Ctr., New York, NY; [2]NYU Neurosci. Inst., NEW YORK, NY

Abstract: An action potential (AP) is assumed to travel actively and reliably along axons and trigger Ca2+ entry into nerve terminals without fail, leaving all-or-none regulation of release probability (Pr) in the hands of downstream SNARE proteins. Using viral delivery in mature

hippocampal slice cultures and two-photon imaging of fast genetically-encoded Ca2+ sensor, GCaMP6f, we explored the dynamics of axonal Ca2+ transients (CaTs) evoked by single AP stimulation of CA3 pyramidal neurons in organotypic slices studied at 30°C. CaT amplitudes followed a right-skewed distribution (>700 boutons). Strikingly, 1AP CaTs imaged along single axons failed intermittently on repeated (30) trials at neighbor boutons. Conservative histogram analysis of CaT amplitude revealed a bimodal distribution with clear separation of CaT successes and failures. CaT failures rarely spread across an entire branch, suggesting that they were not due to conduction failure. Notably, prolonging AP duration with the K+ channel blocker 4-aminopyridine (100 μM) reduced CaT failure rate and increased both their amplitude and duration. Finally, a subset of axons exhibited functionally silent boutons that were unresponsive to single trial AP stimulation but responded to a stronger 50 AP train pattern. In these silent boutons, a visible CaT signal evolved within 5-10 APs, possibly due to recruitment of Ca2+ channels or build-up of residual Ca2+. Altogether, our finding uncover large all-or-none variations in axonal CaT dynamics and leave ample room for Pr regulation, upstream of SNAREs, via Ca2+ channel modulation.

Title: Impaired endosomal system mediated by Cathepsin D produces defects in GABAergic synaptic transmission

Authors: *X. LI[1,2], Y. LI[1], H. YU[1], Z. ZHANG[1], Y. LIU[1], L. QIN[1], Z. XU[1], Z. GAO[1], S. DUAN[1];
[1]Zhejiang Univ., Zhejiang, China; [2]Nantong Univ., Nantong, China

Abstract: The role of endosomal/lysosomal system for proper brain function is underscored by many neurological disorders. Cathepsin D (CathD, ctsd, EC 3.4.23.5) is a soluble aspartic endopeptidase in this system, that mediates the cleave of structural and functional proteins and

peptides. However, how Cathepsin D affects the function of neurons and synapses remains unknown. Here we show that Cathepsin D deficiency mice recapitulated hyperactivity with the absence of anxiety by the open field (OF) and elevated plus maze (EPM) tests. Increased pentylentrazol (PTZ) induced epilesy seizure susceptibility was measured in knock out mice. Loss of ctsd also demonstrated the degenerative loss of neurons and proliferation of reactive astrocytes with increased levels of GFAP in the cotex and hippocampus using immunocytochemistry. Cultured hippocampal neurons lacking ctsd showed reduced GABAergic synapses and inhibitory/excitatory synaptic ratio while Glutamergic synaptic marker did not affected.Cathepsin D deficiency is accompanied by significant changes in hippocampal synaptic plasticity, due to reduced GABAergic synaptic strength and impaired GABAergic synapses RRP. FM4-64 dye staining and destaining in micro-island cultured GAD-GFP neuron revealed specifically inhibition effects on GABAergic synaptic vesicle exocytosis pathway. These data suggested that Cathepsin D may be critical for normal function of GABAergic neurons and subtle imbalance between GABAergic and Glutamergic synaptic circuit may contribute to numerous neurological phenotypes.

Title: Hydrogen peroxide modulates synaptic transmission in ventral horn neurons of the rat spinal cord

Authors: M. OHASHI, *T. KOHNO, N. OHASHI, T. HIRANO, K. WATANABE, H. SHOJI, N. ENDO;
Niigata Univ. Grad Sch. Med. & Dent. Sci., Niigata, Japan

Abstract: Excessive production of reactive oxygen species (ROS) is a critical component of the cellular and molecular pathophysiology of many central nervous system (CNS) disorders, including trauma, ischemia-reperfusion injury, and neurodegenerative diseases. Hydrogen peroxide (H2O2), an abundant ROS, modulates synaptic transmission and contributes to neuronal damage in the CNS; however, the physiological role of H2O2 in spinal cord ventral horn (VH) neurons remains poorly understood, despite reports that these neurons are highly vulnerable to oxidative stress and ischemia. This was investigated in the present study using a whole-cell path-clamp approach in rats. We found that elevated H2O2 levels increased the release of glutamate and γ-aminobutyric acid (GABA) from excitatory and inhibitory presynaptic terminals, respectively, of VH neurons. The former was induced in part by an increase in Ca2+ influx through N-type voltage-gated calcium channels (VGCCs) as well as by ryanodine receptor (RyR)- and inositol triphosphate receptor-mediated Ca2+ release from the endoplasmic reticulum (ER); in inhibitory presynaptic neurons, increased IP3R-mediated Ca2+ release from the ER increased GABAergic transmission, which served to rescue VH neurons from excessive release of glutamate from presynaptic terminals. These findings indicate that inhibiting N-type VGCCs or RyRs may attenuate excitotoxicity resulting from increased glutamatergic activity while preserving the neuroprotective effects of GABA, and may therefore represent a novel and targeted strategy for preventing and treating H2O2-induced motor neuron disorders.

Title: Synaptic functions of γRIM proteins

Authors: *S. FERRANDO-COLOMER[1], K. MICHEL[2], D. DIETRICH[1], S. SCHOCH[2]; [1]Exptl. Neurophysiology, Dept. of Neurosurg., Univ. Bonn Med. Sch., Bonn, Germany; [2]Inst. of Neuropathology and Dept. of Epileptology, Univ. Bonn Med. Sch., Bonn, Germany

Abstract: The large members of the RIM protein family, RIM1α/β and RIM2 α/β, are centrally involved in the cytomatrix of the presynaptic active zone. Through multiple interactions with other active zone proteins as well as synaptic vesicle proteins they are involved in several steps of presynaptic neurotransmitter release. αRIMs are important for maintaining sufficient and localized calcium entry to trigger fast release of vesicles and for maintaining synaptic vesicles in a release-ready state. The RIM protein family contains two additional small isoforms, RIM3γ and RIM4γ, which are composed of only the RIM-specific C-terminal C2B domain and an isoform specific N-terminus. The C2B domain of all RIM proteins has been suggested to bind to the β subunit of the presynaptic N- and P/Q-type voltage gated Ca2+-channels and to modulate their opening times. However, the synaptic function of γRIMs in neurons has not been studied in detail up to now. We addressed this question by analyzing glutamatergic synaptic transmission in native brain slices of newly generated RIM3γ and RIM4γknockout (KO) mice. Field potential recordings of Schaffer collateral-evoked synaptic activity of CA1 pyramidal neurons indicate reduced paired-pulse facilitation (PPF) in RIM4γ KO mice which is in contrast to the previously reported increase in PPF in RIM1α KO mice. The function of the presynaptic release machinery is assessed by an approach that allows us to quantitatively estimate calcium binding properties of the release machinery and the relative release probability. We use ω-conotoxin GVIA, an N-type calcium channel blocker, to reduce presynaptic calcium entry to a certain and constant fraction and to quantify the resulting relative decrease in synaptic transmission while varying the extracellular calcium concentration. The differential sensitivity of field potentials to the ω-conotoxin GVIA suggests a differential contribution of N- and P/Q-type calcium channels at the

active zone of RIM1α and RIM4γ KO mice. Furthermore, RIM4γ KO mice develop a strong phenotype of episodic ataxia and seizure-like episodes at around P21, accompanied by reduction in weight and body size. In contrast, RIM3γ KO mice do not exhibit an overt phenotype. In summary, the data point at a prominent role of RIM4γ for maintaining normal neuronal network function.

Title: α-Synuclein interacts with Hsc70: a possible mechanism underlying the synaptic vesicle recycling defects in Parkinson's disease models

Authors: *S. M. BANKS[1], D. J. BUSCH[2], P. A. OLIPHINT[3], R. B. WALSH[4], J. M. GEORGE[5], E. M. LAFER[6], J. R. MORGAN[1];

Abstract: Overexpression and abnormal aggregation of α-synuclein is linked to neurodegeneration in Parkinson's disease (PD). A growing body of evidence suggests that α-synuclein aggregation is prevalent at synapses, disrupting synaptic function in PD and other synucleinopathies. However, the underlying mechanisms causing the synaptic defects remain unclear. To address this, we utilize lamprey giant reticulospinal synapses, which are ideal for studying the acute effects of excess human α-synuclein on synaptic structure and function. Using this model, we previously showed that excess human α-synuclein causes an inhibition of synaptic vesicle recycling that affects both clathrin-mediated and bulk endocytosis. Here, we test the hypothesis that excess α-synuclein causes these recycling defects by binding to other core components of the endocytic pathway, thus inhibiting their function. Using GST-pull downs, we

tested for α-synuclein interactions with well-characterized proteins involved in clathrin-mediated endocytosis: AP2, clathrin, dynamin, synaptojanin, auxilin and Hsc70. The only interaction observed was a direct and specific interaction between α-synuclein and Hsc70, the clathrin uncoating ATPase at synapses. Hsp70 did not bind under the same conditions. PD-linked α-synuclein mutants A30P and A53T also bound to Hsc70. Mapping of the interaction revealed that the N-terminal domain of α-synuclein (a.a. 1-102) was sufficient for the interaction and the C-terminal 10kD of Hsc70 was required. The interaction is evolutionarily conserved, because lamprey γ-synuclein also bound to Hsc70. The N-terminal domain of α-synuclein folds into an alpha helix and readily binds to small vesicles containing acidic phospholipids such as phosphatidic acid (PA). Interestingly, α-synuclein binding to PA-containing vesicles was reduced in the presence of Hsc70, and Hsc70 recruitment to PA-containing vesicles was significantly increased in the presence of α-synuclein. These data suggest that the Hsc70-synuclein interaction also occurs on membranes and that the two proteins may affect each other's localization and function. As a preliminary test of this model, we evaluated whether excess α-synuclein affects clathrin uncoating at synapses, a process that is attributed to Hsc70 function. After treatment with excess human α-synuclein, synapses exhibited nearly a 4-fold increase in the number of clathrin-coated vesicles, suggesting that α-synuclein may bind Hsc70 and disrupt its function during vesicle recycling. Taken together, these findings provide one possible mechanism for how excess α-synuclein leads to synaptic defects in PD.

Title: Distinct functional roles for P/Q- and N-type voltage-gated calcium channels in synchronous glutamate release

Authors: *S. CHAMBERLAND, A. EVSTRATOVA, K. TÓTH;
Cell. and Mol. Neurosci., CRULRG, Quebec, QC, Canada

Abstract: In presynaptic terminals, calcium elevations are shaped by several key parameters, including the properties, density, combination and the spatial location of VGCCs. These features allow presynaptic terminals to translate complex firing frequencies to postsynaptic signals by regulating the amount of neurotransmitter released. For example, the number of vesicles fusing to the membrane can be amplified through mechanisms such as synchronization of multivesicular release or recruitment of additional release sites. While synchronous release relies on both P/Q- and N-type VGCCs at hippocampal MF-CA3 synapses, the contribution of individual types of VGCCs to the mechanisms controlling neurotransmitter release remains unknown. To dissect the roles of P/Q and N-type VGCCs, we used random-access two-photon calcium imaging and electrophysiology in combination with electron microscopy. Our results show that calcium influx through P/Q- and N-type VGCCs differently influence glutamate release during a single action potential firing and repetitive activity through specialized calcium dynamics. First, two-photon calcium imaging in giant mossy fiber terminals revealed that P/Q-type VGCCs mediated a larger fraction of calcium elevations than N-type VGCCs for a single action potential. Consistent with calcium imaging data, P/Q-type VGCCs showed a significantly larger contribution to glutamate release than N-type VGCCs. However, this difference was dependent on the external calcium concentration, as decreasing the aCSF calcium concentration to 1.2 mM revealed a similar effect for both toxins. To investigate how calcium entry through N-type VGCCs can mediate a larger fraction of EPSCs in conditions of low release probability without changes in presynaptic calcium entry, we used a coefficient of variation (CV) analysis of single and train of stimuli. While blocking N-type VGCCs decreased the quantal size of EPSCs, blocking P/Q-type VGCCs reduced EPSC amplitude by reducing the number of active release sites. Furthermore, CV analysis revealed that application of ω-Agatoxin IVA or EGTA-AM had similar effects on short-term facilitation by eliminating the recruitment of additional release sites. Altogether, our results demonstrate the highly specialized roles of P/Q- and N-type VGCCs in neurotransmitter release. While N-type VGCCs are tightly coupled to calcium sensors and provide local calcium elevations, P/Q-type VGCCs are strategically involved to support global calcium elevations and recruit additional release sites during trains of activity.

Title: Ultrastructural and functional fate of recycled vesicles in hippocampal synapses

Authors: ***S. REY**[1], C. SMITH[1], M. W. FOWLER[1], F. CRAWFORD[1], J. J. BURDEN[2], K. STARAS[1];

Abstract: There is substantial interest in understanding the mechanisms of vesicle recycling that support sustained transmission at size-limited central synapses. The readily releasable pool (RRP) defines the population of synaptic vesicles that undergo privileged fusion, but the long-term fate of the vesicles recovered after endocytosis and their contribution to future RRP composition is not clearly established. Here, we exploit time-stamped electron microscopy approaches in native hippocampal synapses, as well as novel fluorescence methods, to track the positional and functional destiny of vesicles retrieved after RRP stimulation. We show that most vesicles are endocytosed near the active zone but are subsequently inserted randomly in the cluster volume with time, losing their preferential re-use status. These vesicles non-selectively queue, advancing towards the release site with further stimulation in a process that depends on actin turnover. However, a subset of the retrieved vesicle population operates differently, selectively re-clustering near the active zone and undergoing privileged re-release as part of the future RRP. We use a variety of protocols to examine the rules that underpin this differential behaviour. Heterogeneity in the fate of vesicles retrieved after RRP stimulation provides new understanding of the mechanisms that govern vesicle recycling at small central synapses and the origins of future pool composition.

Title: Role of reduced synaptobrevin 2 levels in age-related cognitive decline

Authors: *A. OROCK[1,2], S. LOGAN[2,3], W. E. SONNTAG[1,2,3], F. DEAK[1,2,3];

Abstract: Introduction: One of significant socio-economic impacts from the rise of the elderly population worldwide is age related cognitive decline. Synaptic dysfunction is emerging as the major cause of cognitive impairment and dementia as synaptic plasticity is a central mechanism in learning and memory. Our laboratory and others have identified synaptobrevin-2, a SNAP Receptor (SNARE) protein as a key player in synaptic transmission and plasticity. Synaptobrevin-2 (syb2) is the major SNARE protein of synaptic vesicles (SV) which is highly expressed in the cerebral cortex and hippocampus, essential brain centers for spatial learning. Syb2 protein levels have also been shown to decrease with age but functional consequences of this lower expression are still elusive. We hypothesize that reduction of syb2 protein levels with age mediates age related cognitive decline. **Methods:**We have been using heterozygous syb2 knock-out mice which express syb2 at about the same level at 6 month-of-age as old (24 mo) wild-type animals. This is 50-60% of the protein levels found in young wild-type littermates ($p<0.01$, Student t-test). As a proof of concept, we are also using aged (>24 months) TgV2 animals which overexpress syb2 in this study. This will enable us know if overexpressing syb2 will rescue the phenotype seen in old animals with reduced syb2. We performed behavioral tests for spatial learning and memory using the radial-arm water maze (RAWM) and a complex cohabitate environment called Intellicage. Neuronal plasticity was assessed by long-term potentiation (LTP) assays on hippocampal slices. We used live fluorescence microscopy to measure the SV release rate in neuronal cultures. **Results:** The behavioral test with syb2 heterozygous resulted in maintained basic spatial memory acquisition for simple place finding (RAWM) but impaired learning in complex tasks in Intellicage. This impaired spatial memory was reflected in reduced CA1 hippocampal LTP and Syb2 heterozygous neurons have reduced SV release rates (~35% in 15 seconds, $p<0.01$ compared to wild-type controls). Importantly, aged animals overexpressing syb2 performed better in the RAWM task than wild-type suggesting that syb2 plays a major role in age related cognitive decline. **Conclusions:** To our best knowledge, this is the first study to demonstrate that syb2 levels have a causative role in synaptic failure and dementia, and our results suggest syb2 reduction with age mediates age-related cognitive decline.

Title: Examining the role of Neurexins in the Formation and Maturation of Synapses between Hippocampal Neurons

Authors: D. P. QUINN[1], A. KOLAR[1], J. P. FAWCETT[2], *S. R. KRUEGER[3];
[1]Dept Physiol. & Biophysics, [2]Pharmacol., [3]Dept Physiol & Biophysics, Dalhousie Univ., Halifax, NS, Canada

Abstract: Neurexins are a diverse family of cell adhesion molecules that are expressed in CNS neurons and localize to presynaptic specializations. Neurexins mediate synaptic cell contact through extracellular interactions with postsynaptic adhesion molecules of the Neuroligin and LRRTM families. Studies suggest that neurexins have important roles in synapse formation and neurotransmitter release. To further investigate the role of neurexins in synaptic physiology, we used two approaches to disrupt neurexin function: 1) Overexpression of a dominant negative neurexin construct which lacks the extracellular domain necessary for trans-synaptic adhesion and 2) shRNA knockdown of all neurexins. By using a genetically encoded optical sensor for synaptic vesicle exocytosis called synaptophysin-pHluorin, we were able to examine the effect of neurexin perturbation on synaptic release at single synapses in dissociated hippocampal culture. We found that neurexin perturbation resulted in smaller readily releasable pool sizes at presynaptic compartments as well as a decrease in the likelihood with which individual vesicles in the pool undergo fusion in response to an action potential. We also find that neurexin disruption caused a decrease in active zone protein content and synaptic density; an effect that could be due to a decrease in synapse formation or an increase in synapse elimination. To address these possibilities we used time-lapse imaging of tagged pre- and postsynaptic proteins to assess the effect of neurexin perturbation on synapse formation and synapse stability. We found that axons with perturbed neurexin function retain the ability to form synapses, though these synapses were transient in nature and are eliminated at a much higher rate. Taken together, these experiments suggest that neurexins may be dispensable for synapse formation, but needed for the stabilization and maturation of functional synaptic contacts.

Title: The PXDLS-binding cleft of Ribeye is required for normal synaptic ribbon function

Authors: C. LV, E. PRESCOTT, S. VIVIANO, J. SANTOS-SACCHI, *D. P. ZENISEK;
Yale Univ. Sch. Med., New Haven, CT

Abstract: Tonic non-spiking cells of the retina and inner ear release neurotransmitter from vesicles tethered to specialized protein structures known as synaptic ribbons. The most abundant protein in the synaptic ribbon is Ribeye, but its role in synaptic ribbon formation and function is poorly understood. Ribeye arises from an alternative start site to the transcriptional co-repressor gene CtBP2, with the C-terminal half of Ribeye nearly identical to CtBP2. CtBP2 interacts with many proteins via its PXDLS-binding cleft. We investigated the importance of the PXDLS-binding cleft in retinal ribbon synapse function using zebrafish as a model system. To do so, we generated transgenic zebrafish overexpresssing wild-type Ribeye(a)-YFP and Ribeye(a)-YFP with a mutation to the PXDLS-binding cleft. Zebrafish overexpressing Ribeye(a) with a mutation to the PXDLS-binding domain exhibited a reduction in the electroretinogram (ERG) b wave, which was not observed in fish overexpressing wild-type Ribeye(a). Zebrafish *in vivo* hair cell recordings show that overexpressed Ribeye(a)-YFP cells exhibit no significant differences in exocytosis as measured by membrane capacitance changes. By contrast, PXDLS-binding cleft mutants exhibit an approximately 50% reduction in exocytosis in response to 3s step depolarizations to -10 mV. Electron microscopy of neuromast hair cells revealed that animals overexpressing binding-cleft mutant Ribeye exhibit morphologically normal ribbons. Together, our results suggest that the PXDLS-binding cleft is necessary for proper ribbon function.

Title: Sparse SCN VIP projections to the PVN consistent with paracrine signaling

Authors: *J. M. WEBB[1], C. MAZUSKI[2], E. HERZOG[2], C. WEICHSELBAUM[2], D. CAI[3], D. ROOSSIEN[3];
[1]Washington Univ. In St. Louis, University City, MO; [2]Washington Univ., St. Louis, MO; [3]Univ. of Michigan Med. Sch., Ann Arbor, MI

Abstract: The mammalian suprachiasmatic nucleus (SCN), the body's master circadian pacemaker, consists of approximately 20,000 neurons in the ventral hypothalamus. Neurons within the SCN have been categorized into more than 20 cell types based on their neuropeptide expression. Among these, vasoactive intestinal polypeptide (VIP) neurons have been identified as critical for coordinating circadian rhythms within the SCN and body. VIP receptor 2 (VPAC2R) is known to be widely expressed in the paraventricular nucleus of the hypothalamus (PVN), an upstream regulator of circadian glucocorticoid release. However, little is known about the anatomy or physiology of VIP projections outside of the SCN. We hypothesized, based on the broad distribution and low expression of VPAC2R in the PVN, that VIP neurons would have large, divergent projections in the PVN. We injected Cre-dependent Brainbow mTFP/mCherry and TagBFP/eYFP viruses into the right SCN of VIP-Cre knockin mice. After two weeks, the brains were harvested, sectioned at 100μm and processed for 3-color immunohistochemistry using chicken anti-GFP, rabbit anti-mCherry, and guinea pig anti-mKate2 antibodies. Sections were imaged on a confocal microscope with 0.5μm optical sections, and traced using a novel ImageJ plugin. Preliminary results from ~600 reconstructed neuronal processes indicated that nearly 100% of VIP axons could be discriminated in the PVN and subPVN. We found that, of all the VIP neurons entering the PVN, about 20% have terminals within the PVN. Of these VIP neurons that synapse in the PVN, the majority typically have a single terminal within the PVN with a maximum of 10 terminals within the PVN per SCN VIP neuron. These synapses are evenly distributed across the PVN. In addition, SCN VIP neurons appear to make similar numbers and distributions of terminals in the ipsilateral and contralateral PVN. Our findings support the conclusion that VIP neurons form sparse terminals in the PVN and likely communicate through a paracrine signal. Supported by NIGMS.

Title: The structural basis of priming of docked synaptic vesicles at the frog's neuromuscular junction

Authors: *J. JUNG, J. A. SZULE, U. J. MCMAHAN;
Biol., Texas A&M Univ., College Station, TX

Abstract: Docked synaptic vesicles undergo priming before fusing with the presynaptic membrane to mediate synaptic impulse transmission. We searched by electron tomography for structural correlates of priming at active zones on the presynaptic membrane of axon terminals at frog neuromuscular junctions. In resting terminals, the contact area between docked vesicles and the presynaptic membrane varied >10-fold. Evoked synaptic transmission selectively reduced the frequency of vesicles having a large contact area. Contact area correlated with the force-dependent eccentricity of vesicle shape and the shortness of the active zone material macromolecules linking vesicles to presynaptic membrane components that include Ca^{2+}-channels. The findings lead to the conclusions that priming is a variable continuum of events imposing on each vesicle variable fusion probability and that it is regulated by force-generated shortening of active zone material macromolecules in dynamic equilibrium. These conclusions are consistent with the findings of others indicating that the SNARE core complex and its auxiliary proteins regulate priming as well as docking. Our approach may provide a way of establishing the degree of priming of any docked vesicle at any synapse under normal, experimental and disease conditions.

Title: Interaction of inputs in hippocampal granule cells with inhibitory connections

Authors: N. NAKAJIMA[1], H. HAYAKAWA[2], T. KITAJIMA[3], *T. AIHARA[1];
[1]Tamagawa Univ., Tokyo, Japan; [2]Kyoto Inst. of Technol., Kyoto, Japan; [3]Universiti Teknologi Malaysia, Johor Bahru, Malaysia

Abstract: The hippocampus integrates non-spatial information (such as objects and odors) and spatial information (places). The dentate gyrus is the gate for input-information to the hippocampus. Non-spatial information and spatial information are independently transported from the entorhinal cortices to separated sites, the distal dendrite and the medial dendrite of granule cells (GCs) within the molecular layer in the dentate gyrus, respectively. To investigate the interaction of those two inputs, response characteristics of distal and medial dendrites of GCs were independently measured at 0.1-40Hz of input frequency in a rat hippocampal slice where inhibitory input was blocked by application of picrotoxin, GABAergic receptors antagonist. From those experimental data, a multi-compartment GC model with dynamic synapses was developed using NEURON simulator. Model simulations were performed using the model which reproduced the response characteristics of the dendrites of a GC. As the results, when the random and theta burst inputs were simultaneously applied to the respective dendrites, the pattern discrimination for theta burst input to medial dendrites that caused slight GC activation was enhanced in the presence of random input to distal dendrites. These results suggest that the temporal pattern discrimination of spatial information is originally involved in a synaptic characteristic in GCs and is enhanced by non-spatial information input to distal dendrites. Furthermore, to investigate a role of inhibitory neurons for the interaction between medial and distal inputs in the dentate gyrus, response characteristics were also physiologically measured in the presence of inhibitory inputs, without picrotoxin. In addition, model simulation was also performed. It was found that the local inhibitory network played to maintain magnitudes of EPSP for successive inputs to distal dendrite at high-frequency (25-40Hz). The result suggests that inhibitory inputs may support the enhancement of input information to medial dendrites by sustaining responses for input sequence to distal dendrites.

Title: High frequency filters with variable gain in the dentate gyrus generated by differential inhibition onto developing and mature granule cells

Authors: M. B. PARDI[1], M. B. OGANDO[1], A. F. SCHINDER[2], *A. MARIN-BURGIN[1]; [1]Ibioba-conicet-Partner Inst. of the Max Planck, Buenos Aires, Argentina; [2]Fundacion Inst. Leloir, Buenos Aires, Argentina

Abstract: Adult neurogenesis generates pools of constantly renewing immature granule cells (GC) with unique processing properties. We have previously showed that immature GC have lower thresholds of activation than the rest of the GC from the circuit, already mature. In the present work we address the question of how immature and mature granule cells process complex stimuli in the form of trains of pulses at different frequencies, and how activation profiles are determined by the recruitment of inhibitory and excitatory circuits. To study activation of immature newly born cells in the adult hippocampus, we inject a retrovirus in the dorsal hippocampus of adult mice to label dividing cells. Four weeks later, we prepare acute hippocampal slices from the injected mice, where we can recognize the immature four week old adult born granule cells (4wpiGC). By simulating the afferent medial perforant path with a monopolar electrode and recording from 4wpi GC and mature GC with loose-patch and whole-cell configurations we studied spiking and evoked excitatory and inhibitory currents after 1 Hz, 10 Hz, 20 Hz and 40 Hz trains of stimulation. Results show that 4wpi GC are activated at higher levels than mature GC at every frequency of stimulation. Moreover, 4wpiGC are more efficient in reproducing the frequency of stimulation with their spiking. Activation levels strikingly diminish at higher frequencies, showing that both populations of GC act as low-pass filters. Main

differences in the activation profiles are dictated by the inhibitory circuits. Inhibition determines activation by affecting the excitation/inhibition balance the GC receives after the stimulation. Thus, activity arriving to the hippocampus at different frequencies activates two populations of neurons with variable frequency filters, immature cells, with wide range of responses, that are reliable transmitters of the incoming frequency, and mature neurons, with narrow responses to frequency and sparse activity.

Title: Balance between excitatory and inhibitory synaptic inputs in principal neurons in the hippocampal CA1 and Dentate Gyrus regions resulting from electrical stimulation in an *ex vivo* mouse model

Authors: *S. D. DE KNECHT[1], P. CHAMEAU[2], W. WADMAN[2];
[1]Swammerdam Insitute of Life Sci., [2]Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Afferent electrical stimulation of Schaffer collaterals (SC) evokes a combination of excitatory and inhibitory synaptic responses in pyramidal neurons (PYRs) of the CA1 region. Afferent stimulation of the perforant path (PP) evokes a similar response in granule cells (GCs) of the DG region. These principal neurons were recorded under voltage clamp and linear decomposition was used to separate the excitatory and inhibitory conductance. The excitatory response preceded the inhibitory response in PYRs (Δt: 3.8 ± 1.1 ms) as well as in GCs (Δt: 3.9 ± 0.8 ms). In GCs the peak amplitude of the inhibitory conductance was smaller (47%) than that of the excitatory conductance, while these values were not different in PYRs. In GCs the rise time of the excitatory conductance was faster (78%) than that of the inhibitory conductance. Inhibitory conductance in GCs also had a larger decay time (time constant 17 ± 2 ms) than can be explained by the kinetics of the IPSC, suggesting population recruitment. This observation also explains the short duration of the reconstructed post synaptic potential in GCs. The I-E balance was defined as the fractional inhibition calculated from each conductance integrated over

the first 50 ms. This balance was slightly larger in PYRs (53 ± 3 %) than in GCs (43 ± 3%). Increasing stimulus intensity shifted the balance in both regions towards inhibition, suggesting a stronger recruitment of interneurons. Repetitive stimulation (5 - 20 Hz) gradually reduced the excitatory conductance in GCs, but not in PYRs. The inhibitory conductance decreased with each stimulus in both neuron types. Thus repetitive stimulation results in a stronger reduction in balance in PYRs than in GCs, with potential consequences for the stability of the circuit. Our results indicate that activation of a single afferent pathway recruits a circuit response in the targeted neurons with distinct dynamics with at least two different time scales. Most neuronal networks seem to maintain a well-defined balance between excitation and inhibition. However, the detailed kinetics of the underlying conductances and intensity dependent circuit recruitment shape the fast synaptic response, while differences in use-dependent adaptation shape the time course of the I-E balance at a larger time scale. The two regions studied play a sequential role in hippocampal signal processing; the clear differences in dynamics has consequences for the overall characteristics of signal processing in this region.

Title: Frequency-dependent input processing in hippocampal CA1 pyramidal neurons

Authors: *C. L. COMBE[1], R. TIKIDJI-HAMBURYAN[2], C. C. CANAVIER[3], S. GASPARINI[4];
[1]Neurosci. Ctr., [2]Dept. of Cell Biol. and Anat., [3]Dept. of Cell Biol. and Anatomy, Neurosci. Ctr., [4]Neurosci. Center, Dept. of Cell Biol. and Anat., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA

Abstract: Gamma oscillations (25-100 Hz) are thought to coordinate activity within brain regions. Two frequency bands, slow (25-50 Hz) and fast (65-90 Hz) gamma, have been

identified in the CA1 region of the rodent hippocampus. Slow gamma is phase-locked to slow gamma activity in area CA3 and presumably driven by the Schaffer Collaterals (SC), whereas fast gamma is phase-locked to fast gamma activity in the medial entorhinal cortex and presumably driven by the Perforant Path (PP). We used a combination of computational modeling and *in vitro* electrophysiology to test the hypothesis that CA1 pyramidal neurons preferentially respond to slow gamma in response to SC input activation and to fast gamma in response to PP input activation. Repetitive activation of proximal synapses of a CA1 model neuron (to mimic SC input) elicited firing in the slow gamma range, whether the stimulation was at slow or fast gamma. Action potentials were generated after each pulse in a ten-pulse, 40 Hz-train, but only after every other pulse for 100 Hz-trains. Activation of distal synapses to mimic PP input, however, elicited a single action potential for 100 Hz-trains, but not for 40 Hz. Whole-cell patch clamp recordings from CA1 pyramidal neurons in hippocampal slices *in vitro* showed that trains of 10 stimuli resulted in 8.1 ± 0.2 action potentials when SC fibers were stimulated at 40 Hz, but only 5.8 ± 0.2 at 100 Hz (n = 31), indicating a tendency to reliably follow slow, not fast gamma. This low-pass filtering tendency was greatly reduced in the presence of apamin, which blocks small conductance Ca^{2+}-activated K^{+} (SK) channels. In 10 neurons, the number of action potentials generated by trains of 10 stimuli at 100 Hz increased from 5.6 ± 0.4 under control conditions to 7.6 ± 0.5 in the presence of apamin (100 nM). On the other hand, when electrical stimulation was delivered to PP fibers, 100 Hz-trains were more effective at generating spikes than 40 Hz-trains (1.2 ± 0.2 and 0.3 ± 0.1 action potentials evoked per 10 stimuli at 100 Hz and 40 Hz, respectively; n = 11). Perfusion of the NMDA receptor antagonist APV (50 μM) decreased the number of action potentials generated in response to stimulation at these distal inputs to 0.4 ± 0.2 for 100 Hz-trains. These results suggest that CA1 pyramidal neurons might behave as low-pass filters in response to Schaffer Collateral activation and high-pass filters in response to Perforant Path activation, due to a combination of intrinsic and synaptic mechanisms.

Title: Regulation of entorhinal cortical input to hippocampal granule cells by local inhibitory network in the dentate gyrus

Authors: *Y. MIRCHEVA, K. TOTH;
Ctr. De Recherche De L'Institut Universitaire En, Quebec City, QC, Canada

Abstract: Interneurons in the molecular layer of the dentate gyrus play a crucial role in the integration of entorhinal cortex (EC) input to the hippocampus. EC inputs will trigger complex network responses via the activation of various types of locally interconnected neurons such as fast-spiking basket cells and neurogliaform cells. The resulting network response will shape the firing pattern of granule cells via fast and slow inhibitory responses. In this study we aimed to determine the effect of perforant path (PP) stimulation on the firing pattern of dentate granule cells (GC). Our results show that activation of PP inputs can trigger a prolonged inhibitory response that can abolish granule cell firing for duration of 1-2 seconds. This mechanism may be involved in shaping the preferential "burst" firing pattern of GCs, information transfer at the EC-dentate gyrus gate as well as responses during periods of hyperactivity. Given the importance of this slow inhibition in information transfer and processing, we investigated the detailed properties of PP-evoked slow hyperpolarization and its physiological importance. In *in vitro* whole cell patch clamp recordings from GCs, stimulation of the perforant path with single or multiple (1 - 5) pulses evoked slow IPSPs (from ~958 ms ±34 to ~1732 ms ±182, n=10) with the potential to alter their firing pattern for an exceptionally extended period of time. This hyperpolarization was dependent on the activation of postsynaptic GABAA, GABAB and mGluR 1 receptors. Longest lasting responses were evoked when PP input was stimulated at 200 Hz. This long lasting response is specific for the feed-forward inhibitory circuit as similar response could not be evoked with the stimulation of feed-back inhibitory cells. This long lasting hyperpolarization developed in an age-dependent manner. In animals from 3 age groups (15-20 days old, 21-30 days old, 31 days and older) showed significant differences in the lengths and the amplitude of PP-evoked responses (15-20 days: mean length = 393 ms ±67.9, mean amplitude = 1.9 mV ±0.2, n = 6; 21-30 days: mean length = 1623 ms ±212, mean amplitude = 4.5 mV ± 0.7, n=6 ; 31 days and older: mean length = 2047 ms ±68, mean amplitude = 7.3mV ±0.9, n = 4). These results demonstrate the presence of an exceptionally slow IPSP in GCs in response to short train stimulation of the PP that is evolving with age. It specifically involves the feed-forward inhibitory circuit. Further investigation of the mechanism and the origin as well as the relevance for information transfer and processing of this prolonged inhibitory response, will improve our current understanding of the complex interactions at the EC-dentate gyrus gateway.

Title: Knockout of CRMP-1 diminished intracellular calcium signal and decreased colocalization of synaptophysin and PSD-95 in primary hippocampal neurons

Authors: *Y.-C. TSAI[1], S.-R. LIN[2], T.-Y. CHIN[2], S.-M. HUANG[1];
[1]Grad. Inst. of Life Sci., Natl. Def. Med. Ctr., Taipei, Taiwan; [2]Dept. of Biosci. Technol., Chung Yuan Christian Univ., Chungli, Taiwan

Abstract: Collapsing response mediator protein-1 (CRMP-1) belongs to a family of cytosolic phosphorproteins that mediate the extracellular signals from semaphorin 3A. It was initially identified in brain and has been implicated in plexin-dependent neuronal function. In order to study the physiological function of CRMP-1 in hippocampus, primary cultured hippocampal neurons were prepared from wild-type (WT) and crmp-1 knockout (KO) neonatal mice respectively. The variation in the intracellular calcium concentration ([Ca2+]i) of cultured cell was measured using Fura-2, and colocalization of pre- and post-synaptic markers was measured by immunostaining. In the studies of pre-synaptic functions, KCl caused the similar [Ca2+]i at the initial, transient stage both in WT and crmp-1 KO neurons, but at 150 seconds, crmp-1 KO neurons exhibit a higher [Ca2+]i than WT neurons. This result indicate the activation of voltage-sensitive Ca2+ channel in the initiation stage is similar in both genotypes, but after a few seconds, crmp-1 KO neurons still maintain in a higher activation of voltage-sensitive Ca2+ channel. In the studies of post-synaptic functions, glutamate caused a higher [Ca2+]i was detected in WT neurons than in crmp-1 KO neurons. On the other hand, the colocalizaton of synaptophysin and PSD-95 was decreased in crmp-1 KO neurons. Our results implied knockout of CRMP-1 influenced the pre- and post-synaptic function, and even decreased the synaptogenesis. However, the mechanisms for explaining the difference phenotype between WT and crmp-1 KO neurons need further investigations.

Title: The parasubiculum heterosynaptically modulates the strength of piriform cortex inputs to the medial entorhinal cortex

Authors: *D. W. SPARKS, C. A. CHAPMAN;
Psychology, Concordia Univ., Montreal, QC, Canada

Abstract: The hippocampus receives the majority of its sensory input from the entorhinal cortex, and the entorhinal cortex receives dense sensory input from the piriform cortex. Layer II of the entorhinal cortex also receives the single major output projection of the parasubiculum, which receives projections from multiple hippocampal subfields and subcortical areas. Previous research in our lab found that stimulation of the parasubiculum can enhance entorhinal responses to piriform inputs *in vivo*, suggesting that the parasubiculum modulates sensory input to the hippocampus via the entorhinal cortex. Spatial and mnemonic processes in these brain areas are modulated by cholinergically-induced rhythmic activity, and our lab has also found that synaptic responses in the entorhinal cortex *in vitro* during trains of theta- and gamma-frequency stimulation of the parasubiculum are enhanced following application of the cholinergic agonist carbachol via effects on the non-specific cationic channel Ih. The purpose of the current study was to investigate how parasubicular inputs modulate the responsiveness of individual entorhinal cortex cells to piriform cortex stimulation *in vitro*. We also assessed if rhythmic stimulation of the parasubiculum could heterosynaptically modulate synaptic input to the entorhinal cortex from the piriform cortex, and assessed the contribution of Ih. Patch-clamp recordings from layer II medial entorhinal neurons were obtained in slices from four to eight-week old male Long-Evans rats, and bipolar tungsten stimulating electrodes were placed in the parasubiculum and piriform cortex. Single pulses and trains of stimulation at theta-frequency were delivered to the parasubiculum, followed by single pulses to the piriform cortex at various intervals. Consistent with previous *in vivo* findings, parasubicular stimulation enhanced responses to piriform cortex stimulation at a 25ms interval. This effect, however, was only found following theta-frequency trains of parasubicular stimulation, as opposed to single pulses. This suggests that rhythmic depolarizing drive from the parasubiculum can enhance incoming sensory input to the entorhinal cortex. Bath application of the Ih blocker ZD7288 caused an enhancement of this effect, suggesting that cholinergic inhibition of Ih may facilitate heterosynaptic modulation of piriform inputs to the entorhinal cortex by the parasubiculum. These findings provide further evidence that theta activity in the entorhinal cortex is associated with short-term heterosynaptic facilitation effects that may play a role in the parasubicular modulation of sensory inputs to the entorhinal cortex.

Title: Synaptic integration gradients in dendrites of hippocampal CA1 interneurons reflect heterogeneity of the local excitatory input

Authors: ***O. CAMIRÉ**[1,2], I. LAZAREVICH[3], V. KAZANTSEV[3], L. TOPOLNIK[2]; [1]IUSMQ, Quebec, QC, Canada; [2]Biochemistry, Microbiology and Bio-informatics, Univ. Laval, Québec City, QC, Canada; [3]Nizhny Novgorod State Univ., Nizhny Novgorod, Russian Federation

Abstract: Two structurally and functionally distinct subtypes of pyramidal neurons(superficial and deep PYRs) have been identified along the radial axis of the PYR layer in the hippocampal CA1 region. These cells can be further distinguished by differential recruitment of CA1 inhibitory interneurons. But the mechanisms that control the integration of inputs from different PYRs in interneuron dendrites remain unknown. Here, we addressed this question using a combination of two-photon microscopy, whole-cell patch-clamp recordings and computational simulations in basal dendrites of CA1 parvalbumin-positive (PV+) basket and bistratified cells. We first examined the mechanisms of synaptic integration along a somatodendritic axis of interneurons. We found significant fluctuations in the mechanisms of postsynaptic Ca2+ influx and in summation of Ca2+ signals at excitatory synapses formed on PV+ cells by CA1 PYRs, indicative of the synapse-specific dendritic integration. Analysis of computational simulations showed that, as a rule, the activation of 7 to 8 synapses was sufficient for the initiation of dendritic Ca2+ nonlinearities, which at distal synapses relied mostly on Ca2+ influx through activation of Ca2+ -permeable AMPA receptors and Ca2+ release from the internal stores. However, a higher NMDA:AMPA receptor ratio detected experimentally at more proximal synapses slowed the decay of Ca2+ nonlinearities with a direct impact on somatic input. In

particular, a higher slope of the voltage derivative and, accordingly, a larger number of action potentials was associated with Ca2+ nonlinearities induced at synapses with higher NMDA receptor content, leading to the interneuron bursting. As these synapses could be primarily formed by the superficial PYRs, the latter may play a preferential role in driving the interneuron recruitment. These data indicate that heterogeneity of hippocampal PYRs may be encoded in interneuron dendrites, thus determining their input-specific recruitment and firing behaviour during different brain states.

Title: Increased dosage of high affinity kainate receptor gene grik4 alters synaptic transmission and produces autism spectrum disorders features

Authors: *M. I. ALLER, V. PECORARO, A. V. PATERNAIN, S. CANALS, J. LERMA; Inst. de Neurociencias, San Juan de Alicante, Spain

Abstract: The GRIK4 gene, coding for the high affinity kainate receptor (KAR) subunit GluK4, has been associated with several mental disorders and intellectual disability. This gene maps in the human chromosomal band 11q23.3. This region seems to be an instable region that in some cases may undergo translocation. For instance, the Enmanuel syndrome is characterized by a duplication of this region which translocate in the chromosome 22, generating a complex set of symptoms, including intellectual disability. Although not definitively documented, the GRIK4 gene has been involved in mental diseases such as depression, bipolar disorders, and more recently a duplication of this gene has been found in a patient of autism. KARs play an important role in synaptic transmission, particularly in the hippocampus. To understand which are the physiological consequences of a gain of function of this gene, we developed a new transgenic mouse overexpressing the GluK4 subunit in the forebrain. To this end, the expression

of exogenous grik4 tagged with 5 myc was driven by the CaMKII promoter. These mice showed a 25% increase in the body weight. Western blot studies revealed that the transgene gave rise to the overexpression of GluK4 30-100% above the endogenous levels. Inmunocytochemical data indicated the presence of exogenous GluK4 in the hippocampus, especially in CA3 and DG regions, that normally express this subunit, at pre and postsynaptic sites. Spontaneous EPSCKAR recorded in CA3 pyramidal cells presented 38% larger amplitude than in normal mice and faster deactivation times, indicating that exogenous protein was correctly inserted at synaptic sites. Surprisingly, AMPA receptor-mediated mEPSC had both larger frequency and amplitude in the GluK4over mice. Behavioral studies in these mice revealed high levels of anxiety, less social interaction, anhedonia and depression, similar symptoms as can be found in autism and depressive patients.. By using *in vivo* electrophysiology we observed augmented information transfer through the trisynaptic hippocampal circuit, which was indicative of altered synaptic transmission. In conclusion these data show that increased levels of GluK4 subunits alter synaptic transmission and generates behavioral symptoms compatible with those seen in autism spectrum disorders, demonstrating a clear link of KARs with mood disorders and revealing new targets for their treatments.

Title: Role of neurexin 2 (nrxn2) in cortex and hippocampus: synaptic analysis of conditional nrxn2 knockout mice

Authors: *L. Y. CHEN, P. ZHOU, A. ORTIZ, T.-L. HUYNH-TRAN, T. C. SUDHOF; Stanford Inst. for Neuro-innovation & Translational Neurosciences, Stanford Univ., Stanford, CA

Abstract: Increasing evidence suggests that neurexins (Nrxns) are presynaptic cell adhesion molecules that are critical for maintaining synaptic function. NRXN genes have been linked to autism spectrum disorders (ASD) and schizophrenia. In particular, recent studies identified patients with ASDs that have a truncating mutation of NRXN2. However, due to the lacking of fundamental understanding of Nrxn2 function, it remains unknown why Nrxn2 is associated with these disorders. Here, we made, characterized, and used conditional knockout (cKO) mice in which both the α- and β-forms of NRXN2 can be deleted by Cre recombinase. These mice allow us to investigate the synaptic function and requirements for NRXN2. The design and creation of this cKO NRXN2 mouse was confirmed by genotyping and quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) to measure mRNA levels. We tested our hypothesis that Nrxn2 is required for normal synaptic function and synapse formation in both hippocampus and cortex. Analysis of spontaneous miniature postsynaptic currents, evoked responses and synaptic morphology of Cre-induced knockout neurons (or with overexpression of specific Nrxn2 isoform for rescue) in comparison with control neurons (a mutated version of Cre: ΔCre). This study will address the precise contributions of specific NRXN isoforms to synaptic transmission and identify pathways relevant to synapse development that give rise to cognition and brain function.

Title: Input-specific synaptic differences in hippocampal CA1 parvalbumin-positive fast-spiking basket cells

Authors: *J. CORNFORD, D. KULLMANN;
UCL, London, United Kingdom

Abstract: Although PV+ interneurons make up <3% of interneurons in the CA1 region of the hippocampus, they are fundamental for a range of functions, from basic circuit processes to more complex network operations such as place cell field regulation (Hu et al., 2014). The importance of PV+ basket cells is partly explained by their specialised input co-incidence detection mechanisms, which allow them to convert asynchronous input into precisely timed output (Bartos & Elgueta, 2012). Recent work has suggested that basket cells express synaptic receptors

in an input specific distribution: local feedback excitatory synapses onto oriens dendrites display a much larger NMDA receptor component than synapses in the stratum radiatum, which are dominated by calcium permeable (CP) AMPA receptor currents (Le Roux et al., 2013). This raises the possibility that PV+ basket cells integrate afferent activity in different ways, as in contrast to radiatum inputs, synaptic connections from local pyramidal cells could co-operate via NMDA receptors (Branco & Häusser, 2011). In order to investigate the distinct expression of rectifying glutamate receptors and its functional implications, we used a combination of neuronal modelling, multi-photon imaging, and glutamate uncaging. We first looked for structural differences between basket cell dendrites in the CA1 stratum oriens and the stratum radiatum. We found that dendrites in the oriens express spines in a sparse distribution, whereas dendrites in the radiatum are smooth. Hypothesising that these spines might be the location of postsynaptic sites containing both NMDA and AMPA receptors, we modelled how dendrites expressing synapses with different properties might behave when presented with various input patterns. We show that CP-AMPA receptors enhance the detection of input coincidence, whereas NMDA receptors promote input co-operation. Further experiments employing glutamate uncaging onto smooth dendrites in stratum radiatum, and spiny dendrites in stratum oriens, will seek to further clarify differential input processing mechanisms by fast spiking PV+ basket cells. Title: Gap junction channels in the hippocampal plasticity in an *in vivo* model of high neuronal activation

Authors: *E. R. KINJO[1], B. A. SANTOS[1], G. S. V. HIGA[1,3], M. M. G. AGUIAR[1], É. SOUSA[2], A. H. KIHARA[1];

[2]UNIVERSIDADE FEDERAL DO ABC, SÃO BERNARDO DO CAMPO, Brazil;
[3]UNIVERSIDADE DE SÃO PAULO, São paulo, Brazil

Abstract: Gap junction channels (GJC) are intercellular conduits that enable the exchange of small molecules such as second messengers and ions between two adjacent cells, allowing the occurrence of electrical synapses. These channels are composed by protein subunits called connexins (Cx). So far, at least 20 Cx genes were described in human and mouse genome, and Cx36 and Cx45 were identified in neuronal cells. The involvement of these channels in the synchronization of neuronal oscillations has been increasingly demonstrated, which in turn are important for processes regarding synaptic plasticity. While most efforts have been dedicated to the understanding of chemical synapses, less is known regarding the plastic properties of electrical synapses. By using an *in vivo* model of neuronal activation induced by pilocarpine, our goal was to evaluate the expression of the neuronal Cxs 36 and 45 in the hippocampus of rats combining real time PCR and western blot analysis. Male wistar rats were previously treated with methyl scopolamine (1 mg/kg; subcutaneous) followed by intraperitoneal pilocarpine (360 mg/kg) injection. Control animals received saline instead of pilocarpine. Thirty minutes after the establishment of status epilepticus, the animals were sacrificed and the hippocampi removed for real time PCR and western blot analysis. Pilocarpine application promptly induced changes in rat electrocorticogram, particularly in fast-beta range (21-30 Hz), demonstrating high neuronal activation. Real time PCR analysis showed no significant changes in Cx36 mRNA levels after neuronal activation, while increase in Cx45 gene expression ($p<0.01$) was detected. The western blot analysis revealed no significant alterations in Cx36 protein levels, in contrast to an increase of 23% ($p<0.05$) in Cx45 protein levels in the hippocampi of animals submitted to intense neuronal activation. These data suggest modulation of GJC in the activity-dependent plasticity, favoring the idea that electrical synapses can be modulated and play important role in shaping the neuronal electrical activity.

Title: Short-term potentiation of dendritic Na^+ spikes and action potentials after high frequency stimulation at Schaffer collateral-CA1 synapses

Authors: W. YU[1], J. KWON[1], J.-W. SOHN[2], S.-H. LEE[1], *W.-K. HO[1];
[1]Seoul Natl. Univ. Col. Med., Seoul, Korea, Republic of; [2]KAIST, Daejeon, Korea, Republic of

Abstract: Active properties of dendrites are important in the process of how local synaptic inputs are integrated and transmitted to the soma to generate propagating action potentials. In particular, Na^+-dependent dendritic spikes play crucial roles in the amplification of synaptic potentials to increase the efficacy of axosomatic action potential initiation and modulation of synaptic plasticity. In this study, we demonstrated that after high frequency stimulation (HFS, 50 stimuli at 100 Hz) to the Shaffer collateral pathway near proximal apical dendrites of pyramidal cells in the CA1 hippocampus (CA1-PCs) EPSP-spike coupling was potentiated significantly (E-S potentiation), which lasted for about 2 min. Dendritic patch recordings revealed that probability of the generation of dendritic spikes was increased significantly after HFS. We further investigated ion channel mechanism and found that inhibition of persistent Na^+ current ($I_{Na,P}$) using riluzole abolished E-S potentiation and increased dendritic spikes after HFS. As underlying signaling mechanisms, we found that E-S potentiation was abolished by inhibiting mGluR5 (MPEP or mGluR5 knock-out) or inhibiting mGluR5-dependent Ca^{2+} release using cADP ribose blockers (8-NH2-cADPR and nicotinamide) or ryanodine. Voltage clamp analysis confirmed that group I mGluR agonist, DHPG, increased $I_{Na,P}$, especially when DHPG was applied locally to the apical dendrites, and that DHPG-induced $I_{Na,P}$ potentiation was abolished by inhibiting mGluR5-dependent Ca^{2+} release or calmodulin. These results provide a novel insight into how the activity-dependent regulation of dendritic ion channels by metabotropic receptor signaling leads to the regulation of action potential outputs.

Title: Determinants of synaptic heterogeneity at the mature calyx of Held synapse

Authors: *A. FEKETE, L.-Y. WANG;
Program in Neurosci. and Mental Hlth., The Hosp. for Sick Children, Toronto, ON, Canada

Abstract: The heterogeneity of release probability (Pr) and short-term plasticity (STP) among synapses on the same population of neurons is a fundamental feature of the central nervous system, and thought to be important for underlying different dynamic range of information coding. However, the origin of synaptic heterogeneity remains largely unknown. We addressed this issue by taking advantage of the large size of the mouse calyx of Held synapse, where the morphological variability strongly correlates with, and predicts the differences in Pr, polarity of STP and fidelity of spiking (Grande and Wang, 2011). We have examined single and high-frequency train stimuli-evoked Ca2+ dynamics mediated solely by P/Q-type Ca2+ channels in distinct compartments of different types of calyces with two-photon laser scanning microscopy of high- and low-affinity Ca2+-indicators and the morphological tracer Alexa 594. We found Ca2+ transients throughout the entire calyceal arborization, being the largest in the smallest compartments (swellings). Application of potassium channel blocker TEA increased the Ca2+ transients throughout the calyx, suggesting that APs can successfully propagate into distinct compartments and recruit increasing number of calcium channels to boost Ca2+ transients. AP propagation into small and large compartments was independently validated by direct cell-attached recordings at different sites of the same calyx. Patch-clamp recordings showed a significantly higher Ca2+ channel density in complex calyces than that in simple ones. Presynaptic injections of slow Ca2+ buffer EGTA attenuated Pr and RRP more robustly in complex calyces. Our data implicate differences in the density of Ca2+ channels and their spatial coupling distance to synaptic vesicles as key elements underpinning the heterogeneity of presynaptic Ca2+ transients and quantal parameters, ultimately leading to functional diversity of central synapses.

Title: Influence of a single session of maximal intensity aerobic exercise on the post-translational modification and trafficking of plasticity-related receptor proteins within the motor cortex

Authors: *J. S. THACKER[1], W. R. STAINES[1], J. G. MIELKE[2,1];
[1]Kinesiology, [2]Sch. of Publ. Hlth. & Hlth. Systems, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: A substantial body of research has focused on developing techniques that enhance the recovery of motor function after injury by priming neural plasticity. A recent focus in the area has involved using multiple sessions of aerobic exercise as a variety of evidence has indicated that exercise can stimulate the expression of proteins thought to play a role in plasticity. For example, the interaction of brain derived neurotrophic factor (BDNF) and its receptor tropomyosin kinase B (TrkB), which have been linked to various features of plasticity, are clearly affected by aerobic training. Notably, while the effects of multiple bouts of exercise training are becoming established, comparatively less is known about the effects that may result from a single session of exercise. As a result, the aim of the current investigation was to explore the influence that a single session of maximal intensity aerobic exercise could have on a set of proteins previously identified as being both influenced by exercise and important for plasticity. We hypothesized that a single session of maximal aerobic exercise would lead to changes in BDNF-TrkB signal transduction, as well as altered trafficking of glutamate receptor proteins, in the motor cortex. Young (post-natal day 60), male Sprague-Dawley rats (n = 20) on a reverse light cycle (12 h/12 h) were exposed to a treadmill acclimatization procedure that consisted of 8 days of increasing exercise intensity (speed = 10 m/min up to 25 m/min) for 10 minutes at the same time (10 am) each day. The acclimatization period was followed by 2 days of rest to reduce the possibility of carryover effects from the treadmill training. On testing day, rats were separated into either a maximal intensity aerobic exercise group (VO2 max test), or a non-exercising group. Immediately following the bout of maximal intensity aerobic exercise (or a sedentary period of a similar length), rats were sacrificed and brains were dissected into varying regions (motor cortex, prefrontal cortex, cerebellum, and brainstem) and either homogenized, or flash frozen at -80°C. Brain homogenates were probed for all proteins of interest using Western blotting. Preliminary results suggest no significant differences in either the expression, or phosphorylation level (Y813) of TrkB receptor in motor cortex following a single session of intense aerobic exercise. However, further analysis of other plasticity-related proteins, including Calcium-calmodulin kinase II, insulin-like growth factor and its receptor, as well as the synaptic trafficking of NMDA and AMPA receptors, remain to be explored.

Title: Effects of dopaminergic D2 receptor activation on layer I and layer V evoked excitatory synaptic responses in mouse medial prefrontal cortex

Authors: *J. M. LEYRER[1], M. P. THOMAS[2];
[1]Univ. Of Northern Colorado, Greeley, CO; [2]Sch. of Biol. Sci., Univ. of Northern Colorado, Greeley, CO

Abstract: In humans, prefrontal cortical areas are known to support executive functions. In mice, these functions are mediated by homologous regions in the medial prefrontal cortex (mPFC). While it is well established that executive processes are critically dependent on optimal levels of dopamine (DA) in the PFC, the cellular mechanisms of DA modulation are incompletely understood. Stable patterns of neuronal activity may be sensitive to frequency dependent changes in inhibitory and excitatory transmission. In this study, we characterized the effects of D2 receptor (D2R) activation on short-term excitatory postsynaptic potential (EPSP) dynamics evoked at varying frequencies (10Hz-50Hz) in layer V pyramidal neurons in mouse mPFC. We isolated NMDA receptor (NMDAR) and non-NMDAR receptor mediated components of EPSP trains evoked by stimulating fibers within layer V or layer I (tufts). D2R activation had no effect on non-NMDAR mediated EPSPs with layer V or layer I stimulation, while decreasing the amplitude of NMDAR mediated EPSP trains with both layer V and layer I stimulation. These results suggest that D2R activation acts by restricting synaptic plasticity at both layer V and layer I excitatory synapses, stabilizing existing connectivity patterns. Our previous studies demonstrate that D1R and D2R activation have similar effects on layer I excitatory synapses. However, with layer V stimulation, D1R activation enhanced both NMDA and non-NMDA EPSPs, which suggests that when D1R activation predominates, plasticity is promoted; and when D2R activation predominates, plasticity is suppressed. These data provide further insight into mechanisms of dopamine's bidirectional modulation of executive functions.

Title: Effects of irregular (Poisson) conditioning trains on synaptic plasticity between individual neurons in layer 4 of mouse visual cortex

Authors: *J. WU, M. J. FRIEDLANDER;
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: Mammalian primary visual cortex Layer 4 (L4) neurons receive monosynaptic excitatory input from the dorsal lateral geniculate nucleus, from layer 6 and from adjacent L4 cells. Synaptic integration with layer 4 has considerable effect on visual information processing and has been hypothesized to act as an amplifier of thalamocortical inputs. Though the thalamocortical pathway has been extensively studied, less is known about the functional properties and synaptic plasticity between individual L4 neurons. To better understand plasticity of synaptic connections between individual L4 neurons, and the effect of different conditioning patterns on plasticity, we performed dual and triple whole cell patch clamp recording from L4-L4 pairs (n=17) in visual cortical slice of P25~35 C57B1/6 mice. A pair of action potential was elicited in the L4 presynaptic neuron with a pair of square depolarizing pulses (5ms duration, 600~800pA, 30ms inter spike) at 0.1Hz, the unitary postsynaptic currents were recorded from the postsynaptic neuron under voltage clamp. In some case (n=6), a 15min 10Hz conditioning protocol was applied with a Poisson distribution of interstimulus intervals having a coefficient of variation (CV) = 1.0 to induce synaptic plasticity. The synaptic strength, potency, failure rate and paired pulse ratio were calculated before and after conditioning. The pre-conditioning control L4 baseline synaptic strength varied from 0.64 to 71.6 pA with an average of 19.2 ±3.7pA (n=17). 13 pairs of connection were reliable, the failure rate ≤ 30% and the other 4 unreliable pairs failure rate >50%. The low failure rate is correlated with paired pulse depression (PPD), while the high failure rate is correlated with paired pulse facilitation (PPF). Short term plasticity (PPD and PPF) was heterogeneous - 9 pairs of connection exhibited PPD (0.69±0.04), 6 pairs exhibited PPF (1.61±0.25) and 2 pairs exhibited no short term plasticity (1.01±0.01). After conditioning, net synaptic strength decreased (7.4±2.8 *vs* 12.0±4.2 pA, $p<0.05$, paired t-test) and failure rate increased (35.3±15.7 *vs* 16.5±5.8%, n=6); one pair switched from PPF (1.40) to PPD (0.67); one pair remained unchanged; in the remaining 4 pairs, PPD increased (0.81±0.4 *vs* 0.65±0.32

,p<0.01 paired t-test). Among the 6 pairs that underwent 10 Hz Poisson distributed conditioning, 3 underwent LTD (0.40 ±0.13, p<0.05), and one underwent LTP (1.28, p<0.01, KS-test).

Title: A role for hippocampal PSA-NCAM and NMDA-NR2B receptor in flavonoid-induced spatial memory improvements in young rats

Authors: *C. RENDEIRO[1], A. FOLEY[2], C. M. WILLIAMS[3], C. REGAN[2], J. P. E. SPENCER[3];
[1]Beckman Inst., Univ. of Illinois, Urbana, IL; [2]Berand Neuropharmacology, NovaUCD, Belfield Innovation Park, UCD, Belfield, Dublin, Ireland; [3]Univ. of Reading, Reading, United Kingdom

Abstract: The increase in incidence and prevalence of neurodegenerative diseases highlights the need for a more comprehensive understanding of how food components may affect neural systems. In particular, flavonoids have been recognized as promising agents capable of influencing different aspects of synaptic plasticity resulting in improvements in memory and learning in both animals and humans. Our previous studies highlight the efficacy of flavonoids in reversing memory impairments in aged rats, yet little is known about the effects of these compounds in healthy animals, particularly with respect to the molecular mechanisms by which flavonoids might alter the underlying synaptic modifications responsible for behavioral changes. We demonstrate that a 3-week intervention with two dietary doses of flavonoids (Dose I: 8.7 mg/day and Dose II: 17.4 mg/day) facilitates spatial memory acquisition and recall (24 h) ($p < 0.05$) in the Morris Water Maze in young healthy rats. We show for the first time that these behavioral improvements are linked to increased levels in the polysialylated form of the neural adhesion molecule (PSA-NCAM) in the dentate gyrus (DG) of the hippocampus, which is known to be required for the establishment of durable memories. We observed parallel increases in hippocampal NMDA receptors containing the NR2B subunit for both 8.7 mg/day ($p < 0.05$) and

17.4 mg/day ($p < 0.001$) doses, suggesting an enhancement of glutamate signaling following flavonoid intervention. This is further strengthened by the simultaneous modulation of hippocampal ERK/CREB/BDNF signaling and the activation of the Akt/mTOR/Arc pathway which are crucial in inducing changes in the strength of hippocampal synaptic connections that underlie learning. Through these mechanisms, the consumption of flavonoid-rich foods throughout life holds the potential to limit neurodegeneration and to prevent or reverse age-dependent loses in cognitive performance.

Title: Short-term facilitation is predominantly mediated by presynaptic Ca^{2+} current facilitation at Purkinje cell - Purkinje cell synapses

Authors: *F. DÍAZ-ROJAS, T. SAKABA, S.-Y. KAWAGUCHI;
Doshisha Univ., Kyotanabe, Japan

Abstract: Short-term facilitation (STF) of synaptic transmission plays a critical role in neural information processing. Several hypotheses have been proposed to explain this process: temporal summation of residual Ca^{2+}, modulation of action potential (AP) waveform, saturation of Ca^{2+}

buffer protein, facilitation of Ca^{2+} current (I_{Ca}^{2+}) through voltage-gated Ca^{2+} channels, and Ca^{2+}-dependent positive modulation of vesicle release machinery. We attempted to clarify the mechanism mediating STF at GABAergic synapses between cerebellar Purkinje cells (PCs) using dissociated rat cerebellar cultures. We performed fluorescent imaging of residual Ca^{2+} increase upon an action potential in PC axon terminals using OGB-1 or OGB-6. PC terminals exhibited only a tiny increase in the fluorescence intensity upon stimulation single AP. With this information, we estimated the residual Ca^{2+} concentration, which could explain only 1% of the facilitation. Alternatively, direct patch-clamp recording from a PC axon terminal showed that presynaptic I_{Ca}^{2+} was facilitated depending on the intracellular Ca^{2+} concentration upon paired pulses of AP-like waveforms. Application of BAPTA but not EGTA suppressed the facilitation of I_{Ca}^{2+} suggesting that this facilitation is tightly coupled with Ca^{2+} influx. Taking it into consideration that synaptic transmission shows about 4^{th} power dependency on the presynaptic Ca^{2+} concentration, the I_{Ca}^{2+} facilitation almost completely explained the facilitation of IPSC at PC-PC synapses. Importantly, suppression of the I_{Ca}^{2+} facilitation by modulation of the AP waveforms eliminated the facilitation of IPSCs. Our data suggests that the Ca^{2+}-dependent facilitation of the presynaptic I_{Ca}^{2+} fully accounts for the facilitation observed at the PC-PC synapse.

Title: Acute presynaptic loading of α-syunclein impairs synaptic fidelity by slowing vesicle endocytosis at glutamatergic synapses

Authors: ***K. EGUCHI**, Z. TAOUFIQ, T. TAKAHASHI;
Okinawa Inst. of Sci. and Technol. Grad. Univ., Onna-Son, Kunigami, Okinawa, Japan

Abstract: α-Synuclein is a small protein highly localized in presynaptic terminals. In sporadic and familial Parkinson's diseases (PDs), its expression is found to be elevated by several-fold. To address how the elevation of α-synuclein can influence neurotransmission, we loaded recombinant human α-syunclein directly into the calyx of Held presynaptic terminals in

brainstem slices of rats, using whole-cell patch-clamp method.α-Synuclein loaded at 3.6 μM had no effect on basal synaptic transmission, but slowed the recovery of EPSCs from synaptic depression, and impaired the fidelity of neurotransmission during high frequency stimulation. Membrane capacitance measurements from presynaptic terminals indicated that α-synuclein slowed endocytosis of synaptic vesicles with no effect on calcium currents or vesicle exocytosis. In contrast to wild-type α-synuclein, its A30P mutant had no significant effect on the endocytic rate. Strikingly, co-loading with α-synuclein of the microtubules depolymerizing drug nocodazole rescued the inhibitory effects of α-synuclein on vesicle endocytosis, recovery rate of EPSCs after synaptic depression, and synaptic fidelity. We conclude that excess α-synuclein primarily targets vesicle endocytosis and impairs precision of fast neurotransmission via aberrant assembly of microtubules in the mammalian glutamatergic nerve terminals.

Title: Stress contagions at glutamate synapses in the paraventricular nucleus of the hypothalamus

Authors: *T.-L. STERLEY, D. BAIMOUK, J. BAINS;
Univ. of Calgary, Calgary, AB, Canada

Abstract: Experiencing a stressor causes short and long-term changes at synapses in various brain regions. We have previously shown that exposure to a single acute stress ‘primes’ glutamate synapses in the paraventricular nucleus of the hypothalamus - the brain region at the apex of the hypothalamic-pituitary-adrenal axis. This priming of glutamate synapses allows them to undergo short-term potentiation following a burst of high-frequency afferent activity. A

number of reports have shown that rodents exposed to specific stimuli can transfer information that alters the behavior of cagemates not exposed to the stimulus. Whether this transfer can be detected at the level of individual synapses is not clear. Here we housed male mice (Crh-IRES-Cre, tdTomato) in pairs and subsequently exposed one of the pair to a stressor (5 minute footshock, 0.5 mA for 2 seconds every 30 seconds). We then allowed the pair to interact for 30 minutes. During this period, the pair engaged in social interactions including sniffing and grooming as well as self-grooming. We then anaesthetized both animals and prepared coronal brain slices to conduct electrophysiological experiments in the PVN. Glutamate synapses on CRH neurons from mice exposed to footshock were potentiated is response to bursts of afferent activity (single housed: 160 ± 12.91, n = 24; with littermate: 126.28 ± 12.08, n = 14) compared to single housed naïve animals (99.66 ± 15.06, n = 11). In addition, we observed the same synaptic phenotype in the naïve conspecific littermate (141.55 ± 14.43, n = 19). This synaptic phenotype was not evident in male littermates only separated for 5 minutes without footshock (107.25 ± 7.83, n = 30). These observations demonstrate that the impact of acute stress on one animal can manifest as synaptic changes in another animal. This is, to the best of our knowledge, the first demonstration of stress contagions at the level of the synapse.

Title: An event-driven model of short-term presynaptic dynamics based on detailed molecular simulations with MCell

Authors: ***J. W. GARCIA**[1], T. M. BARTOL[1], D. J. SPENCER[1], T. J. SEJNOWSKI[2];
[1]Salk Inst. for Biol. Studies, La Jolla, CA; [2]Howard Hughes Med. Inst., La Jolla, CA

Abstract: Chemical synapses enable information transmission between neurons throughout the brain and are generally considered fundamental to learning and memory. We propose a novel model designed to efficiently reproduce their short-term dynamics. In biological synapses, action

potentials trigger an influx of calcium ions through voltage-gated channels. These ions stochastically bind with the vesicular release machinery with some delay, causing probabilistic release of neurotransmitter that occurs asynchronously with incoming spikes. Nonlinear calcium binding and unbinding kinetics both determine the timing of neurotransmitter release and enable facilitation of release probability between spikes, while depletion of the finite vesicle pool in the presynaptic space depresses the release probability. Although many synaptic models implement probabilistic release and some form of short-term plasticity, most of them do not take asynchronous release into account. Detailed molecular models of the presynaptic machinery, on the other hand, achieve all these features but with huge cost in computational efficiency. To investigate the significance of these dynamics in the context of larger networks, we designed our presynaptic model to capture the phenomenology of the molecular models while maintaining the speed and efficiency of the simpler models. The model achieves both probabilistic, asynchronous release and facilitation by matching the release profiles from detailed molecular simulations in MCell, and the time course for depression is implemented with exchanges between vesicle pools. The model treats spikes, releases, and vesicle exchanges as point events, allowing it to skip over intervening time without computational overhead by asynchronously calculating the timing of future events. It thus has significant advantages in biological realism, efficiency, and scalability.

Title: Post-synaptic Pannexin-1 alters synaptic fidelity in the CA3-CA1 synapse of the hippocampus

Authors: ***J. BIALECKI**[1], N. L. WEILINGER[2], M. N. HILL[3], R. J. THOMPSON[3];
[2]Neurosci., [3]Cell Biol. and Anat., [1]Hotchkiss Brain Inst., Calgary, AB, Canada

Abstract: Pannexin-1 is a large pore ion channel that is capable of passing molecules up to 1 kilodalton. It is ubiquitously found in the brain and is highly expressed in post-synaptic hippocampal pyramidal neurons. Pannexin-1 is known to play a role in pathological conditions such as stroke, where the activation of Panx1 leads to ionic dysregulation and the anoxic depolarization. However, possible physiological roles of Panx1 are not well understood. We

hypothesize that Panx1 plays a role in synaptic physiology under physiological conditions. Using whole- cell patch clamp electrophysiological recordings of CA1 pyramidal neurons and through the use of various pharmacological blockers of Panx1, we observed that blocking Panx1 leads to an up-regulation of pre-synaptic glutamate release. When post-synaptic Panx1 is blocked through the use of anti-Panx1 in the patch pipette, a large increase in sEPSP frequency was detected. Increased glutamate release is also seen with other Panx1 antagonists including ^{10}Panx, and this increase is not seen when using a scrambled version of ^{10}Panx. Interestingly, increased glutamate in the presence of anti-Panx1 or ^{10}Panx does not occur under baseline recording conditions, but required stimulation of the Schaffer Collaterals. Various stimulation paradigms were assessed to determine the intensity and frequency of stimulation necessary to excite the synapse. We are now working towards the synaptic mechanism by which Panx1 is able to alter pre-synaptic transmission. Retrograde transmitters such as 2-AG and nitric oxide have been tested and did not alter the change in synaptic fidelity seen with Panx1 blocking. Other potential retrograde signals are under investigation. We conclude that postsynaptic Panx1 are intimately linked to pre-synaptic glutamate release through an, as yet, unidentified mechanism.

Title: Differences in short-term plasticity cause a reduction in excitatory drive onto CA1 interneurons relative to pyramidal cells during temporally complex input patterns

Authors: *L. E. DOBRUNZ[1], Q. LI[1], A. F. BARTLEY[1], H. SUN[2];
[1]Dept. of Neurobio., Univ. of Alabama @ Birmingham, Birmingham, AL; [2]Dept. of Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: Target-cell specific short-term plasticity enables Schaffer collateral (SC) synapses onto CA1 interneurons to have different dynamic properties than SC synapses onto CA1

pyramidal cells. We have previously shown that SC synapses onto CA1 interneurons have less paired-pulse facilitation than SC synapses onto pyramidal cells, and there is even a subset of interneurons that express paired-pulse depression. In contrast, there is little difference in the amount of steady-state high frequency depression between cell types. SC synapses onto pyramidal cells have robust facilitation in response to temporally complex stimulation patterns such as these synapses receive *in vivo*. However, little is known about how SC synapses onto interneurons respond to these patterns, or how short-term plasticity alters the relative amount of excitatory input onto interneurons compared to pyramidal cells. Here we compared SC synapses onto s. radiatum interneurons and CA1 pyramidal cells in acute hippocampal slices from juvenile rats in response to a physiologically derived Natural Stimulus Pattern (NSP). We find that SC synapses onto interneurons have less short-term facilitation and operate over a narrower dynamic range than synapses onto pyramidal cells, and a subset of interneurons has short-term depression. This causes a large reduction in the strength of the SC input onto interneurons relative to pyramidal cells, and of depression interneurons relative to facilitation interneurons, during high frequency periods of the NSP. This occurs to a similar extent at 25 °C and at 32 °C, but is even greater at a lower, more physiological relevant extracellular calcium level. We developed a simple mathematical model of short-term plasticity, which can fit this temporally complex data for all three cell groups at both temperatures and calcium concentrations. The model shows that target-cell specific differences in short-term plasticity can be accounted for by only a difference in the initial release probability between the three cell groups. Target-cell specific differences in initial release probability therefore enable SC synapses to have different temporal filtering characteristics, which may help to dynamically regulate the balance of inhibition and excitation in CA1.

Title: feedforward SHORT-TERM memory in Hippocampus: spine to network

Authors: ***S. YANG**[1], S. YANG[2], C.-M. TANG[3];
[1]Nano-bioengineering, Incheon Natl. Univ., Incheon, Korea, Republic of; [2]Ctr. for Integrative

Neurosci., University of California at San Francisco, CA; [3]Univ. of Maryland Sch. of Med., Maryland, MD

Abstract: The cellular mechanism underlying short term memory is a fundamental but poorly understood in neuroscience. Until now, synaptic modulation and reverberating activity within a feedback network have been the dominate models of short-term memory. Recently, a feedforward short-term memory (fSTM) model has been proposed which does not involve massive repetitive inputs. While mechanisms supporting fSTM was found at the level of the dendrite, they have not yet been demonstrated at the level of the spine and network. Here, using powerful techniques, including 3D digital holography with uncaging, voltage-sensitive dye imaging, two-photon calcium imaging, we show that a memory trace of past excitation can be held in the spines where this memory trace can be read-out at a later time in the form of calcium-delivering dendritic spikes. Such a sequence of events can mediate signal propagation throughout the whole hippocampal network. Our data thus provide a more thorough account of fSTM from spine to system in the hippocampus.

Title: Short-term plasticity as a homeostatic mechanism in the lateral amygdala

Authors: *A. E. FINK, T. J. MADARASZ, J. E. LEDOUX;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The lateral amygdala (LA) is an area that combines sensory information to produce both aversive and appetitive associative learning. Normally a quiet brain region, activity in the LA is thought to be dysregulated in disorders such as anxiety and PTSD. Short-term plasticity (STP) in the normally functioning LA might therefore be a crucial physiological mechanism for

maintaining amygdala homeostasis. STP (plasticity lasting from milliseconds to tens of seconds) modulates online processing in neuronal networks, and could also determine both the type of information that is passed through the circuit, as well as whether or not synaptic inputs can be incorporated into a memory engram. Nevertheless, little is known about short-term plasticity in the LA, whether it differs by input, and how it differs by frequency. These questions are important for understanding the LA microcircuit in health and disease, and we have conducted patch-clamp recordings in acute brain slices from adult male mice to identify properties of STP in the LA. We show that during trains of synaptic stimulation at theta (5 Hz), beta (30 Hz), or gamma (100 Hz) frequencies, synaptic inputs onto LA cells undergo a rapid, transient depression that varies both by frequency and by input. This depression is increasingly pronounced at higher frequencies of stimulation. Most importantly, our data suggest that these forms of STP arise from a combined modulation of excitatory input, inhibitory input, and biophysical properties of LA principal cells. We furthermore demonstrate that STP is robust to noradrenergic modulation. Specifically, we find that alpha1 and beta1-adrenergic agonists act primarily through changing excitatory-inhibitory balance, without interfering with frequency-dependent forms of STP.

Title: Paired-pulse modulation of axonal spikes at the hippocampal mossy fibers

Authors: *H. KAMIYA;
Hokkaido Univ. Grad. Sch. of Med., Sapporo, Hokkaido, Japan

Abstract: Use-dependent modification of synaptic strength is caused by changes in the probability transmitter release from the presynaptic terminals or in the responsiveness of the postsynaptic neurons. Axonal spike is the important upstream process of synaptic transmission which directly impacts the presynaptic release probability. However, its activity-dependent modulation has been less studied experimentally. Direct recordings from single axon enable testing possible use-dependent modification of axonal spikes. In acute hippocampal slices, the glass recording pipette was placed on the visually identified giant mossy fiber boutons located in the stratum lucidum of the CA3 region. Using a loose-patch clamp configuration from single presynaptic boutons, stimulation of the granule cell layer of the dentate gyrus elicits spikes

which occur in all or none fashion. This response was recorded also in the calcium free perfusing solution, confirming that they originated in the presynaptic component of the mossy fiber synapses. Unexpected from the digital nature of action potential, the peak amplitude of the second spikes in response to paired stimuli at ~50 ms interval was slightly but reproducibly smaller than the first spikes. This paired-pulse depression of the amplitude of axonal spikes may cause reduction of presynaptic calcium influx, and thereby reduce the transmitter release from the presynaptic terminals. Hippocampal mossy fiber boutons are reported to express highly abundant voltage-dependent sodium channels, although the density may not be sufficient to support fully digital signaling of axonal spikes.

Title: CaMKIIβ is localized in dendritic spine in a drebrin-dependent and drebrin-independent manners

Authors: *H. YAMAZAKI[1], T. SHIRAO[2];
[2]Dept. of Neurobio. and Behavior, [1]Gunma Univ. Grad. Sch. of Med., Maebashi, Japan

Abstract: Dendritic spines are actin-rich small protrusions that contain postsynaptic components of excitatory synapse. Many actin-binding proteins have been identified as spine-resident protein, and they regulate actin-cytoskeleton through diverse processes. Drebrin is a major F-actin binding protein in neurons, and is localized in the center of dendritic spines. Drebrin regulates dendritic spine morphogenesis and spine targeting of synaptic proteins such as spikar, PSD-95 and NMDA receptors. Moreover, drebrin is involved in neurological diseases (eg., Alzheimer's disease and schizophrenia). Although increasing evidences show that drebrin plays pivotal roles in neurons, how drebrin interacts with other proteins in spines is much less known. In this study, we isolated CaMKIIβ as a drebrin-binding protein by yeast two-hybrid screen and investigated the interaction of drebrin-CaMKIIβ in dendritic spines. CaMKIIβ is localized in dendritic spines more than in dendritic shaft. However, drebrin knockdown (KD) caused diffuse localization of CaMKIIβ in dendrites, suggesting that drebrin anchors CaMKIIβ in dendritic

spines. To analyze drebrin-dependence of CaMKIIβ stability in dendritic spine, we performed fluorescence recovery after photobleaching (FRAP) experiments on individual dendritic spines. We calculated the stable fraction from the time-series of fluorescence intensity of GFP-CaMKIIβ before and after photobleaching. The stable fraction of GFP-CaMKIIβ in drebrin-KD neurons was greater than that of control neurons. In addition, NMDA receptor stimulation increased the stable fraction of CaMKIIβ in parallel with drebrin-dislocation from dendritic spines. These results suggest that drebin-loss increases the stable fraction of CaMKIIβ in dendritic spines. Therefore, we think that drebrin-independent stable pool became dominant in drebrin-KD neurons and synaptic activity regulates the accumulation of drebrin-independent CaMKIIβ in dendritic spines. Taken together, our study suggests that there are two stable pools of CaMKIIβ in dendritic spines, drebrin-dependent and drebrin-independent pools.

Title: Microglial amylin receptors: a novel target for the actions of beta amyloid (Aβ) protein

Authors: *J. H. JHAMANDAS, V. VUKOJEVIC, D. MACTAVISH, W. FU;
Univ. of Alberta, Edmonton, AB, Canada

Abstract: Alzheimer’s Disease (AD) pathology is characterized by amyloid deposits, neurofibrillary tangles, and activation of microglia. Our laboratory has shown that the toxic effects of amyloid beta (Aβ) protein on neurons are expressed, in part, through the amylin receptor, that is comprised of dimers of calcitonin receptor (CTR) and receptor activity modifying protein 3 (RAMP3). We have identified the presence of amylin receptors on human fetal microglia (HFMs) that are key immune cells in the CNS. In this study, we sought to identify a functional role for these microglial amylin receptors. Purified HFM cultures were first incubated with an *in vivo* microglial marker, DyLight 594 conjugated tomato lectin and loaded

with 5μM of the membrane-permeant green fluorescent dye, Fluo-8L-AM for measurements of intracellular calcium [Ca2+]i. Acute applications of human amylin (1μM) or Aβ1-42 (1μM) resulted in an increase in intracellular calcium levels that could be blocked by either the amylin receptor antagonist, AC253 (1μM) or pramlintide (1μM). RT-PCR measurements on HFMs exposed to either human amylin (1 μM) or Aβ1-42(1 μM) for 24 hours revealed an increase in the release of cytokines TNFα, IL-1β and IL-10, effects that could be blocked with AC253. Finally, application of either human amylin or Aβ1-42 resulted in an activation of the NLRP3 inflammasome complex (comprising of NLRP3, ASC and caspase-1), that was diminished by AC253 pretreatment of HFMs. This study provides first evidence for the presence of amylin receptors on microglia and identifies a functional role for these receptors in mediating human amylin or amyloid-evoked release of inflammatory mediators. Blockade of microglial amylin receptors with antagonists offers an attractive therapeutic target for intervention in AD on account of their anti-inflammatory effects identified in the present study.

Title: T-cell mediated inflammation is involved in pathogenesis in Alzheimer’s disease mouse model

Authors: ***J. BLOEMER**, M. AHUJA, E. ABDEL-REHMAN, D. BHATTACHARYA, S. BHATTACHARYA, A. ALHOWAIL, F. ALJADANI, D. KATZ, R. AMIN, V. SUPPIRAMANIAM, M. DHANASEKARAN;

Abstract: Alzheimer’s disease (AD) is a progressive neurodegenerative cognitive disorder, which is an increasing problem in the aging population. Although amyloid-beta theory is considered a cornerstone of AD pathogenesis, it does not explain all the aspects of AD and thus the exact cause of AD remains elusive. Inflammation is considered to be one of the pathological factors associated with AD, however there is a lack of experimental evidence on the mechanisms involved. Therefore, this study was carried out to better understand and establish the pathophysiological involvement of chronic inflammation in AD. Ten-month-old mutated APΔE9

mice, along with wild type control C57BL/6 mice, were assessed for behavioral, biochemical, and synaptic deficits. Amyloid-beta (Aβ) levels and beta sectretase (BACE) activity was assessed biochemically. Synaptic plasticity was assessed by extracellular field recordings, and changes in synaptic excitatory receptors were evaluated by western analysis. We also analyzed the pro-inflammatory cytokines, chemokines, and T-cells in different regions of the brain through various immunological and biochemical techniques. Substantial increase in Aβ levels together with increased BACE activity was observed in 10 month old transgenic mice as compared to age matched control. Marked elevations in pro-inflammatory cytokines in cortical and whole brain lysates were observed. Robust T-cell infiltration and activation in the transgenic mice brains were observed as evidenced by higher frequency of CD4+ IL-17a secreting T-cells. Behavioral deficits in learning and memory tasks, specifically Y-maze and novel object recognition, were also exhibited along with impaired long-term potentiation (LTP) in APΔE9 mice compared to WT mice. Taken together, the current study establishes the presence of T-cell mediated neuroinflammation associated with increased Aβ deposition in the APΔE9 mouse model, which may be the cause of cognitive decline and behavioral deficits in these mice.

Title: Inflammation alters APP glycosylation relevant to Alzheimer’s disease

Authors: ***T. JEAN-LOUIS**[1,2], P. ROCKWELL[1], M. FIGUEIREDO-PEREIRA[1];
[1]Biol. Sci., Hunter Col., New York, NY; [2]The Grad. Center, CUNY, New York, NY

Abstract: Senile plaques are important pathological hallmarks of Alzheimer disease (AD). The main component of senile plaques is Aβ, a polypeptide generated via the sequential cleavage of the amyloid precursor protein (APP) by β- and γ-secretases in the amyloidogenic pathway. Alternatively, APP processing by α-secretase in the non-amyloidogenic pathway, which prevents Aβ formation. The upstream events that regulate APP processing by both the amyloidogenic and non-amyloidogenic pathways are poorly defined. We propose that inflammation is a mechanism that shifts the balance towards APP processing by the amyloidogenic pathway. Inflammation plays a major role in AD. Investigating how specific factors of inflammation mediate the neurodegenerative processes in AD is crucial. Our studies focus on prostaglandin products of cyclooxygenases, which are key enzymes in inflammation and highly relevant to AD. In particular, we are investigating how the neurotoxic prostaglandin J2 (PGJ2) alters the processing, trafficking, and post-translational modifications of APP. Here we report that PGJ2 affects the post-translational glycosylation of APP in rat cerebral cortical neuronal cultures. Investigating APP glycosylation in neurons is important because (1) glycosylation deficits in APP have been detected in brains of AD patients, and (2) changes in APP glycosylation may trigger a shift from the non-amyloidogenic to the amyloidogenic pathway. Neuronal APP occurs as a mature form, exhibiting both N- and O-glycosylation, as well as an immature form, displaying only N-glycosylation. APP processing seems to be affected by glycosylation, as secretases preferentially cleave APP once it is O-glycosylated. In our studies, we established that PGJ2 decreases the levels of APP O-glycosylation in a time and concentration-dependent manner. The levels of N-glycosylated APP were not affected by the PGJ2 treatment. The finding that N-glycosylation is not changed and O-glycosylation is significantly decreased may indicate that immature APP is sequestered in the ER and unable to translocate to the Golgi for O-glycosylation. Furthermore, this PGJ2-induced blockade of APP translocation to the Golgi is likely to induce the ER stress (UPR) response. In conclusion, alterations in APP glycosylation induced by the endogenous product of inflammation PGJ2 is likely to have an impact on the intracellular sorting, processing and export of APP that are affected in AD.

Title: Gender related cognitive differences in response to chronic inflammation and passive immunotherapy in an Alzheimer's disease mouse model

Authors: *L. EUGENIN-VON BERNHARDI[1,2], A. PEÑAILILLO[2], N. SALGADO[2], R. VON BERNHARDI[1,2];
[1]Neurología, [2]Lab. de Neurociencias, Pontificia Univ. Católica de Chile, Santiago, Chile

Abstract: Alzheimer's disease (AD) is the most common dementia among the elderly, with increasing prevalence over the last years. Despite all the research directed to understand this pathology and generate effective therapies, its molecular mechanisms have not been fully understood and no therapeutic target has been proven useful. Presently, the most accepted hypothesis for AD, the "amyloid cascade hypothesis", coexists with a new proposal, progressively empowered, the "dysfunctional glial cell hypothesis". Our laboratory has worked on this second proposal over the last eight years, showing that microglia and astrocytes have a key role in the pathogenesis of AD. Age-related inflammatory state - via redox imbalance and innate immunity activation- ultimately results in a cytotoxic activation of glia and neurodegeneration. Chronic inflammation in APP/PS1 mice is associated with impaired Aβ-plaques clearance by microglia, a central feature of Alzheimer's disease histopathology. Here, immunotherapy and inflammatory treatment consisted in consecutive biweekly i.p. injections of APP/PS1 (APPswe, PSEN1dE9) mice with anti-Aβ antibodies and/or LPS for 3 months. After treatment, mice were trained in the Morrison's water maze neurobehavioral tasks. We observed that APP/PS1 mice exposed to chronic inflammatory states had worst cognitive performance in reference and episodic memory tasks (traduced as an increased latency duration) in comparison with APP/PS1 mice receiving saline injections and wild type mice under similar conditions. In contrast, APP/PS1 mice receiving anti-Aβ passive immunotherapy performed better than those without anti-Aβ antibody treatment. Furthermore, we observed a gender difference among all the subgroup treatments. Female mice appeared to learn faster to recognize the platform than males, but did not improve their latency times as males did. These differences were enhanced in APP/PS1 female mice that received chronic inflammatory treatments. We have also shown that immunotherapy affects microglial cell activation, improving their phagocytic activity on Aβ. Our work is coherent with cognitive changes observed in other mice models although human patients have failed to show improvement in response to immunotherapy. By means of this *in vivo* study on cognitive function, and our results on the effect of immunotherapy on the activation pattern of glia, we propose to correlate neurobehavior with pathophysiological mechanisms related with microglial cell activation.

Title: Effect of inflammation and anti-Aβ immunotherapy on the pattern of microglia activation and their association with β amyloid plaques in an Alzheimer's disease animal model

Authors: *R. VON BERNHARDI, N. SALGADO, G. RAMÍREZ, P. NAVARRO;
Pontificia U Catolica De Chile, Fac Med., Santiago, Chile

Abstract: β-amyloid (Aβ) immunotherapy has beneficial effects on Alzheimer disease (AD) mice models. However, immunotherapy trials in AD patients have mostly failed. We propose that AD depends on age-related dysregulation of microglia resulting in a cytotoxic environment and impairment of scavenger functions. We assessed the effect of passive immunotherapy on neuroinflammation, changes on microglia activation and the association with Aβ plaques of microglia. Immunotherapy and inflammatory treatment consisted in biweekly i.p. injections of APP/PS1 (APPswe, PSEN1dE9) mice with anti-Aβ antibodies and/or LPS for 3 m. Microglia activation was assessed by ELISA of inflammatory cytokines (IL1β, TNFα and TGFβ) in brain tissue, and the expression pattern of various activation markers (CD68, FcR, Iba-1, MHC-I and MHC-II) in hippocampal microglia, by immunohistochemistry and stereology. Aggregation of microglia in proximity to Aβ plaques labeled with thioflavin was also assessed. Stereological analysis showed that the density of cells with the constitutive marker Iba-1(+) was similar for WT and APP/PS1 mice, indicating that the number of microglia was unaffected. In contrast, CD68(+), MHC-I(+) and MHC-II(+) cells showed a 100% increase in APP/PS1 mice. In un-stimulated APP/PS1 mice predominated CD68(+) cells, whereas MHC-II(+) was nearly absent. Treatment with LPS and immunotherapy did not affect CD68 expression. However, both Inflammation and immunotherapy resulted in a 50% increase of MHC-I(+) cells, whereas MHC-II(+) cells showed a 3-fold decrease for the immunotherapy plus LPS treatment. APP/PS1 mice that received anti-Aβ immunotherapy showed a 30% reduction on total Aβ deposition in the hippocampus. However, there was only a mild effect on microglia associated plaques, which varied depending on their activation pattern. Iba-1(+) and FcR(+) cells increased after immunotherapy, but that population was reduced in response to LPS, whereas MHC-I(+) cells increased after immunotherapy plus LPS and MHC-II(+) cells were increased under inflammatory conditions. Finally, the association of CD68(+) microglia with plaques was reduced by both immunotherapy and LPS. It was especially interesting the increase of MHC-I(+) and the decrease of MHC-II(+) cells induced by both immunotherapy and systemic inflammation. However, MHC-II(+) cells showed a 3-to-10 fold higher association with plaques

than MHC-I(+) cells, which was increased by the inflammatory stimulation. Our results suggest that passive immunotherapy can immunomodulate microglia, leading to changes in their activation pattern and decrease in the number and size of amyloid plaques.

Title: The role of the TRIF-dependent pathway in β-amyloidosis and neuroinflammation in a mouse model of Alzheimer’s disease

Authors: J.-E. LIM[1], J. YANG[1], J. KOU[1], R. LALONDE[2], *K.-I. FUKUCHI[1];
[1]Cancer Biololgy and Pharmacol., Univ. of IL Col. of Med. At Peoria, Peoria, IL; [2]Dept. of Psychology, Univ. of Rouen, Rouen, France

Abstract: Toll-like receptors (TLRs) are a class of pattern-recognition receptors in the innate immune system. One of the important roles of TLRs is to activate phagocytes/microglia in response to pathogens and damaged host cells, and to clear pathogens, damaged tissues, and accumulated wastes. Some TLRs, including TLR2, TLR4, and TLR6, have been shown to be essential components of the receptor complexes for microglial activation by Aβ. All TLRs use MyD88 as an adaptor except TLR3. The ligation of TLR2 and TLR4 culminates in activation of transcription factors, NF-κB and AP1, through the MyD88-dpendent pathway that is essential for expression of cytokines, chemokines and co-stimulatory molecules, such as TNF-α, IL-1β, IL-6, IL-8, IL-12 and MIP1α. TLR3 and TLR4 ligation can signal via the TRIF-dependent pathway, leading to the activation of interferon regulatory factor 3 (IRF3) that induces expression of type I interferon (IFN) genes such as IFNβ and IFN-inducible genes. It remains to be determined which TLR signaling pathways and effectors are involved in modulation of Aβ deposition and clearance in the brain. In this study, we tested whether activation of the TRIF-dependent pathway is involved in Aβ accumulation and neuroinflammation because TLR4 is an essential component

of the cell surface receptor complex for fibrillar Aβ recognition by microglia. Polyadenlyic-polyuridylic acid, poly(A:U), is a synthetic double stranded RNA molecule that signals only through the TRIF-dependent pathway. We intraperitoneally injected poly(A:U) into an AD mouse model. Currently, we are investigating Aβ load and inflammatory responses in experimental animals to determine the role of the TRIF pathway in the AD pathogenesis.

Title: Acceleration of amyloidosis by inflammation in the amyloid-beta marmoset monkey model of Alzheimer’s disease

Authors: *I. H. PHILIPPENS;
Biomed. Primate Res. Ctr. (BPRC), Rijswijk, Netherlands

Abstract: Background: A pro-inflammatory state is increasingly associated and mentioned for its therapeutic potential to target amyloidopathy that characterizes Alzheimer’s disease (AD). The common marmoset monkey has potential as an AD model due to its natural amyloidosis. Moreover, the marmoset shows a human-like immune system and aging phenotype, which is partly due to exposure to environmental pathogens causing transient or chronic latent infections. Aim was to investigate the effect of inflammation on amyloidopathy in the marmoset AD model. Methods: Four middle aged (5-8y) and two aged (13-14y) common marmoset monkeys (Callithrix jacchus) of both sexes were intracranial injected with amyloid-beta (Aβ) fibrils at three cortical locations into the right hemisphere (frontal, parietal, and sensorimotor cortices) and both hemispheres were injected with PBS (n=3) or LPS (n=3). The effect of inflammation on amyloidopathy was also investigated in an animal that died due to a systemic inflammatory condition, marmoset-wasting syndrome (MWS), which is associated with chronic colitis. The pro-inflammatory effect of LPS and Aβ was also tested in an ex vitro blood analysis (flow cytometry) for immune cell biomarkers (CD45RA and CD95). Campbell-Switzer silver staining and IHC analyses (Aβ, Aβ42, Aβ43, Iba1, and GFAP antibodies) were used on mirror sections to

assess amyloidopathy and immune reaction. Results: The MWS and two LPS+Aβ monkeys developed plaques within 5 months and all LPS+Aβ animals had an early-AD immune blood cell expression profile as seen in human AD patients. Conclusion: A pro-inflammatory condition accelerates amyloidopathy in the marmoset, which indicates the possible importance of immune modulation to decrease the susceptibility for AD. Title: Changes in amyloid deposition and neuroinflammation with age and its relationship with learning deficits in a mouse model of Alzheimer’s disease

Authors: *S. ZHU[1], J.-F. WANG[2], X.-M. LI[3];
[1]Dept. of Pharmacol. and Therapeut., [2]Pharmacol. and Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada; [3]Psychiatry, Univ. of Alberta, Edmonton, AB, Canada

Abstract: The pathology of Alzheimer’s disease (AD) includes amyloid plaques and neurofibrillary tangles as well as chronic neuroinflammation characterized by frank microglial/astroglial activation and subsequent upregulation of proinflammatory cytokines. Both amyloid deposition and neuroinflammation appear in the early course of AD and become notably conspicuous as disease progresses. However, the progression of neuroinflammation and its relationship with amyloid deposition and behavioural changes have not been characterized as many underlying mechanisms rarely occur in isolation. The present study will thoroughly characterize the behaviour of the APP/PS1 mouse model of AD, using a comprehensive test battery designed to assess a variety of behaviours including: working memory, reference memory, long-term memory, anxiety, and motor ability. Using a cross-sectional design, these behaviours will be assessed in mice aged 2-3 months, 6-7 months, 9-10 months, 12-13 months,

and 15-16 months. Brain pathology measures for amyloid deposition and neuroinflammation are done post-mortem. APP/PS1 mice exhibited significant learning deficits from the age of 6 month, which were aggravated at the later stages of life. However, the degree of memory impairment plateaus after 12 months. Histological analyses showed that an early appearance of amyloid plaques at 3 months of age with a linear progressive increase up to 22 months. This pronounced amyloid deposition was accompanied by a steady increase of the glial fibrillary acidic protein (GFAP) positive astrocytes and CD11b positive microglia up to the age of 9-12 months. Interestingly the expression levels of GFAP rose steeply from the age of 5 months to the age of 9 months and then stabilized at the age of 12 months which coincided with the observed pattern of learning deficits in the APP/PS1 mice. This work aims to provide advances in the knowledge of the neuroinflammatory changes and its relationship with amyloid deposition and behavioural changes that occur in AD patients.

Title: Oleamide identified in a fermented dairy product activates microglial phagocytosis via peroxisome proliferator-activated receptor γ and suppresses inflammatory response via cannabinoid receptor type 2

Authors: *Y. ANO[1], T. KUTSUKAKE[1], M. KITA[1], K. UCHIDA[2], H. NAKAYAMA[2]; [1]Central Lab. for Key Technologies, Kirin Company, Limited, Yokohama-Shi, Japan; [2]Dept. of Vet. Pathology, the Univ. of Tokyo, Tokyo, Japan

Abstract: Despite the ever-increasing number of patients with dementia worldwide, fundamental therapeutic approaches to this condition have not been established. Epidemiological studies suggest that intake of fermented dairy products prevents cognitive decline in the elderly. We, previously, reported that in a mouse model of Alzheimer's disease (5xFAD) intakes of camembert cheese reduce the accumulation of amyloid β (Aβ) and hippocampal inflammation. In the present study, we searched the responsible components in dairy products with primary microglial phagocytosis and anti-inflammatory assay systems. As a result of screening, oleamide was identified as a novel dual-active component in camembert cheese that enhanced microglial Aβ phagocytosis and suppressed TNF-α and MIP-1α production and MHC class II and CD86

expression towards lipopolysaccharide (LPS) stimulation. Orally administered oleamide (10 and 50 mg/kg) also enhanced microglial Aβ phagocytosis in hippocampus, and reduced TNF-α production after LPS i.c.v. injections. Oleamide is also known as an endogenous substance that binds to cannabinoid (CB) receptors as an agonist and known as a sleep-inducing property. In this study, we elucidated novel oleamide functions modulating microglial activities. As a result of GC/MS analysis, oleamide was identified in various fermented products such as gorgonzola cheese, cheddar cheese, and aging beef, as well as camembert cheese. Oleamide is the amide of oleic acid abundant in milk, and is synthesized from oleic acid and ammonia by enzymatic amidation during fermentation. We also elucidated that enhancement of microglial Aβ phagocytosis by oleamide was diminished by the treatment of an antagonist of peroxisome proliferator-activated receptor γ (PPAR-γ) and that suppression of microglial TNF-α production by oleamide was partly diminished by the treatment of an antagonist of CB receptor type 2 (CB2) *in vitro*. Therefore, the activation of oleamide, enhanceing microglial phagocytosis and anti-inflammatory activity, may be mediated via the PPAR-γ and CB2 receptor, respectively. The present study demonstrated that oleamide is an active component of fermented dairy products that reduces the Aβ accumulation via enhanced microglial phagocytosis and suppresses microglial inflammation after the Aβ deposition. Oleamide contained in fermented foods such as cheese is easy to intake as a daily meal, and would be an effective prevention against dementia.

Title: Glial cells mediate cell cycle-related neuronal death induced by inflammatory challenge: evidence from a pure neuronal culture model

Authors: *Y. ZHANG, C. HUI, K. HERRUP;
Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong

Abstract: Chronic inflammation characterized by activated microglia and reactive astrocytes plays an important role in the pathogenesis of neurodegenerative diseases, especially in Alzheimer's. Previous studies in our lab have demonstrated that beta-amyloid activated microglia or THP-1 monocytes secrete diverse bioactive molecules, most probably cytokines to induce cell cycle-related death in cultured mouse cortical neurons. In order to investigate the role of other glial cells, especially astrocytes in establishing this effect, we developed a modified method to remove the glial cells in primary culture from E16.5 mouse cortex. We use a brief treatment of the thymidine analog, 5-fluorodeoxyuridine (FdU), to kill the proliferating cells in culture. Two weeks later, cell cycle and glial markers confirmed the loss of ~99% of all microglia, astrocytes and NG2 glia. More importantly, no morphological defects were observed at DIV15-21; both pre- and post-synaptic markers were retained in the purified neuron culture. FdU-treated culture maintained responsiveness to excitotoxicity induced by L-glutamate application, and presumably had normal synaptic function. By applying individual cytokines or conditioned medium from THP-1 cells stimulated by beta-amyloid, we showed that the absence of glial cells dramatically attenuated cell cycle related death in cultured neurons. This observation could be explained by altered immunobiology in FdU culture. Compared with mixed culture, both protein levels and activity of NFκB p65 were decreased, suggesting a reduced NFκB activity. Besides, the gene expression of several cytokine receptors in FdU culture was significantly altered. Thus, we have developed a modified FdU protocol to obtain purified neuronal cultures. With this model, we demonstrate that the presence of glial cells, most probably astrocytes, are required for cell cycle-related neurodegeneration induced by certain inflammatory challenges, including individual cytokines or a mixture of different cytokines and chemokines. We propose to further investigate how astrocytes mediate cell cycle-related death this process. Whether biochemical or physical neuron-glial interaction was required will be determined in the future.

Title: Distribution of glia maturation factor and mitochondrial uncoupling protein-2 and -4 in neuronal degeneration

Authors: *A. ZAHEER[1,3], R. THANGAVEL[2], D. KEMPURAJ[3], S. ZAHEER[1];
[1]Neurol., [2]Univ. of Iowa, Iowa City, IA; [3]VAHCS, Iowa City, IA

Abstract: Alzheimer's disease (AD) is characterized by the presence of neuropathological lesions containing amyloid plaques (APs) and neurofibrillary tangles (NFTs). AD is associated with mitochondrial dysfunctions, neuroinflammation and neurodegeneration in the brain. Our previous immunohistochemical staining in temporal cortex showed enhanced expression of proinflammatory protein glia maturation factor (GMF) in glial cells at the vicinity of APs and NFTs in AD brains. Parahippocampal gyrus consisting entorhinal and perirhinal subdivisions of temporal cortex is the first brain region affected during AD pathogenesis. In the present study, we have analyzed the expression of GMF and mitochondrial proteins (UCP) 2 and 4 in the parahippocampal gyrus of AD and non-AD brains by immunostaining techniques. APs were detected by thioflavin-S fluorescence staining or 6E10 antibody. Results showed down-regulation of UCP2 as well as UCP4, and upregulation of GMF expression in the parahippocampal gyrus of AD brains when compared to non-AD brains. GMF expression is associated with up-regulation of inducible nitric oxide synthase (iNOS), the enzyme that induces the production of nitric oxide, as well as nuclear factor kB (NF-kB p65) expression. In conclusion, increased expression of GMF may down-regulate UCP2 and UCP4 in AD. Increased GMF and its co-localization with iNOS and NF-kB suggest that GMF may play proinflammatory role in the pathogenesis of AD.

Title: Investigating the role of glia in the amyloid beta-associated pathogenesis of Alzheimer's disease using *Drosophila* as a model system

Authors: *A. RAY, E. J. MUENZEL, S. D. SPEESE, M. A. LOGAN;
Jungers Center, Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Glial cells are tightly coupled to the onset and progression of many neurodegenerative diseases. In the context of Alzheimer's disease (AD), glia play a protective role by engulfing and digesting neurotoxic amyloid-β (Aβ) peptides and eventually clearing degenerating neurons that succumb to disease, but the precise molecules that regulate glial responses to Aβ remain unclear. Glial cells likely express a repertoire of cell surface receptors involved in recognition, internalization, and clearance of Aβ. Although glial responses to Aβ have been extensively examined *in vitro*, the complexity of the CNS has hindered our understanding of how glia might recognize and destroy Aβ *in vivo*. Using *Drosophila melanogaster* as a well-established system to investigate amyloid proteinopathies, we find that transgenic expression of the neurotoxic human $A\beta42^{arc}$ fragment in neurons results in age-dependent Aβ accumulation, neurodegeneration and locomotor defects, as well as reduced lifespan. Interestingly, electron microscopy reveals that Aβ aggregates are present in *Drosophila* glia following neuronal expression of Aβ, suggesting that fly glia internalize secreted Aβ peptides (Iijima et al, 2008), but the molecules involved in glial clearance of Aβ in flies are unknown. Draper/MEGF10 is a highly conserved receptor required for phagocytosis of apoptotic cells and degenerating neuronal projections (MacDonald et al, 2006; Wu et al, 2009; Chung et al, 2013). Based on an *in vitro* study, the mammalian homolog MEGF10 may also be involved in Aβ internalization (Singh et al, 2010). Thus, we hypothesize that Draper is required for glial engulfment of Aβ in the fly CNS. Interestingly, by performing anti-Draper immunostaining we find that glial Draper is significantly increased ($p<0.05$) in the central brain following neuronal expression of $A\beta42^{arc}$. Also, since the transcription factor STAT is a known regulator of *draper* expression (Doherty et al, 2014), we asked if STAT activity was upregulated in Aβ-expressing flies. Indeed, our preliminary data using an *in vivo* reporter for STAT function suggest that Aβ expression triggers STAT transcriptional activity, although the cell autonomy of this response remains to be determined. Currently, we are using genetic strategies to perturb glial phagocytic function *in vivo* (e.g. *draper* null mutants, RNAi knockdown of additional scavenger receptors, etc) to determine how Aβ aggregation, neurodegeneration and longevity are affected. This work will provide important molecular insight into how glia recognize and destroy Aβ and also allow us to explore the protective role that glia play in delaying Aβ-mediated neurodegeneration *in vivo*.

Title: Determining the neuroinflammatory phenotype in a model of amyloid deposition and vascular cognitive impairment after anti-Aβ immunotherapy

Authors: *C. N. CAVERLY, E. M. WEEKMAN, T. J. KOPPER, T. L. SUDDUTH, D. M. WILCOCK;
Physiol., Univ. of Kentucky, Lexington, KY

Abstract: Alzheimer's disease (AD) and vascular contributions to cognitive impairment and dementia (VCID) are the two most common forms of dementia and it is estimated that 40% of AD patients also have VCID. Several studies have described the heterogeneity of neuroinflammatory phenotypes in AD and the effects of these states on the pathologies of the disease. Our laboratory has recently shown an M1 phenotype dominates when VCID is co-morbid with amyloid deposition in a mouse model. Due to the disappointing outcomes of anti-Aβ immunotherapy clinical trials, and the significant vascular adverse events in these trials we hypothesized that anti-Aβ immunotherapy could result in an adverse neuroinflammatory response when AD and VCID are co-morbid leading to adverse events and reduced efficacy. To model AD-VCID co-morbidity we use the APP/PS1 mouse model of amyloid deposition and induced hyperhomocysteinemia (HHcy) via diet, which models a form of VCID. For this study, we placed 9 month old wildtype or APP/PS1 mice on a control diet or the HHcy diet. After 3 months on diet, when cerebrovascular pathology is induced by the HHcy, the mice received weekly intraperitoneal injections of a control antibody (IgG2a) or N-terminal anti-Aβ antibody (3D6). The neuroinflammatory phenotype was assessed by qPCR for gene markers specific for inflammatory phenotypes. Protein levels via ELISA and microglial activation via CD11b immunohistochemistry are currently in progress. We found that the APP/PS1 mice on control diet with 3D6 treatment were polarized towards an M1/M2b phenotype. Interestingly, of the genes tested, the APP/PS1 mice on the HHcy diet with 3D6 treatment showed significant exacerbation of many neuroinflammatory markers and we are continuing to assess these more carefully. Overall, we found that anti-Aβ immunotherapy in a model of amyloid deposition and VCID results in a different neuroinflammatory response than in a model of amyloid deposition alone.

Title: Molecular interaction between naturally secreted Amyloid β oligomers, GLT-1 downregulation and NF-kB activation in astrocytes

Authors: *J. M. ZUMKEHR, M. KITAZAWA;
Natural Sci., UC Merced, Merced, CA

Abstract: The excitatory amino acid transporter 2 or its mouse homologue glutamate transporter 1 (GLT-1, herein collectively referred to as GLT-1) is a major transporter responsible for regulating glutamate levels in the brain. We and others have suggested that its impairment can exacerbate pathology in many neurodegenerative diseases including Alzheimer's disease (AD). We recently reported that global GLT-1 levels significantly decrease when exposed to naturally secreted Amyloid β (Aβ) species in the conditioned media (CM) of 7PA2 Chinese hamster ovary (CHO) cells that express the human APP751 containing the V717F AD mutation in APP751 (7PA2-CM) *in vitro*. To further understand the underlying molecular mechanism, we examined the altered activation of several transcription factors responsible for Aβ -induced GLT-1 downregulation in the murine primary astrocyte and neuron co-culture system. Interestingly, we found that NF-κB p65/RelA nuclear translocation significantly decreased after forty eight hours of 7PA2-CM compared to CHO-CM (control). In addition, EMSA revealed less NF-κB activity in the nuclear fraction of astrocytes when exposed to 7PA2-CM compared to CHO-CM. These results suggest that NF-κB upregulates GLT-1 transcription under normal conditions while exposure to 7PA2-CM containing Aβ species counteracts this process. Our findings show a relationship between Aβ and GLT-1 downregulation mediated by NF-kB which may be a potential pathway target to prevent glutamate dyshomeostasis and thus prevent further exacerbation of Alzheimer's disease pathology.

Title: C5a enhances the injury to primary neurons elicited by fibrillar amyloid beta

Authors: *M. X. HERNANDEZ, P. NAMIRANIAN, E. NGUYEN, A. J. TENNER; Pathology and Lab. Med., UC-Irvine, Irvine, CA

Abstract: Previous work demonstrated the C5aR1/CD88 antagonist, PMX205, decreased amyloid pathology and suppressed cognitive loss in two Alzheimer Disease (AD) mouse models. However, the molecular mechanism of this protection has not been definitively demonstrated. C5aR1 is expressed on microglia, and has also been reported to be expressed on endothethial cells and neurons in some environments. Others have demonstrated that C5a leads to injury to primary neurons using the trypan blue exclusion assay. Here, exogenous C5a is shown to lead to a dose-dependent loss of MAP-2 staining in primary murine neuron cultures within 24 hours of treatment, indicative of injury to neurons. This injury is prevented by the C5aR1 antagonist PMX53, a close analog of PMX205. To determine the influence of C5a in brain with accumulating fibrillar amyloid beta plaques (fAβ), we tested if C5a can enhance the injury to neurons initiated by fAβ *in vitro*. Primary neurons from C57B6 at E14.5 were cultured on glass coverslips for 7 days and treated with C5a with or without fAβ. PMX53 was added 30 minutes prior to addition of C5a to block C5aR1. After twenty four hours, cells were fixed and MAP-2 staining was used as a marker of injury to the primary neurons. Data shows low levels (1nM) of C5a can enhance the damage to neurons treated with 5uM fAβ. Blocking C5aR1 with the receptor antagonist PMX53 (100nM) blocked the loss of MAP2 in these primary neurons treated with fAβ and C5a. The data further adds to the growing literature on the contribution of C5a in neuroinflammation and the beneficial effects of C5aR1 antagonists as a therapeutic candidate for neurodegenerative diseases, particularly Alzheimer’s.

Title: Elevated homocysteine results in activation of microglia and pro-inflammatory cytokine production both *in vitro* and *in vivo*

Authors: F. GONZALEZ OREGON[1], T. L. SUDDUTH[1], E. M. WEEKMAN[1], *D. M. WILCOCK[2];
[1]Sanders-Brown Ctr. on Aging, Dept Physiol., [2]Univ. of Kentucky, Lexington, KY

Abstract: Homocysteine is a non-protein forming amino acid that is generated as a result of the methionine metabolism. It is a by-product that is normally maintained at low concentrations in the body through enzymatic clearance and recycling. Accumulation of homocysteine in the plasma, termed hyperhomocysteinemia (HHcy) is a risk factor for a vast array of conditions including cardiovascular disease, cerebrovascular disease and stroke, Alzheimer's disease (AD), and diabetes. Induction of HHcy in wildtype mice models vascular cognitive impairment and dementia (VCID). The exact mechanism by which HHcy increases risk for these conditions is unknown but a common pathology of all of these conditions is inflammation. We hypothesized that homocysteine activates microglia resulting in pro-inflammatory responses in the brain and therefore increasing susceptibility to diseases including AD and VCID. We treated BV2 microglial cells with increasing concentrations of homocysteine and examined their responses 24 hours after treatment. We found that the most robust changes were increased pro-inflammatory cytokine expression, specifically IL-1β, TNFα and IL6. M2-type markers of inflammation including IL1Ra and YM1 were also increased to a lesser extent. In wildtype mice, when HHcy is induced over several months we find that there is a significant inflammatory response characterized by increased expression of IL-1β, TNFα and IL6, as well as activation of the microglia as assessed by cell surface markers CD45 and CD11b. We have found, in a time course of pathology, that the inflammatory changes in the mouse model precede any pathological changes in the cerebrovasculature, perhaps suggesting a causal role of the neuroinflammatory changes in the onset and progression of VCID. Future studies include testing compounds for inhibition of homocysteine effects on BV2 *in vitro* and then taking these into the mouse model to assess their efficacy in ameliorating VCID pathologies.

Title: Identifying stimulators of TYROBP-associated M2 microglial phagocytosis of amyloid beta *in vitro*

Authors: *J. DE VRY[1,2], P. VANDORMAEL[2,3], T. VANMIERLO[3], J. HENDRIKS[3], B. BRÔNE[2], J. PRICKAERTS[1];
[1]Maastricht Univ., Maastricht, Netherlands; [2]Dept. Physiol., [3]Dept. Immunol., Univ. Hasselt, Hasselt, Belgium

Abstract: Accumulation of neurotoxic extracellular amyloid beta (Aβ) in the brain is a major pathological hallmark of Alzheimer's disease (AD). Microglia are key players involved in Aβ phagocytosis and clearance, and alternatively activated microglia (M2) do this without provoking an inflammatory response. M2-associated TYRO protein tyrosine kinase-binding protein (TYROBP) regulation of phagocytosis was found to be hampered in AD, suggesting that reduced M2 microglial activity is implicated in AD. We hypothesize that stimulating M2 microglial phagocytosis specifically decreases plaque load in the AD brain without inducing detrimental immune responses. In this study, the relative contribution of TYROBP and non-TYROBP associated regulators in the internalization of Aβ by microglia is assessed *in vitro* in a BV-2 microglial cell line and in primary mouse microglia. For this purpose, phagocytosis of fluorescent Aβ42 is measured using flow cytometry and microscopy, following reduced or enhanced expression of key players from TYROBP-associated (e.g. TREM2, SIRPβ1 and CR3) and non-TYROBP (e.g. CD14, LRP, RAGE, SRs) receptor signaling cascades. At the same time, the microglial phenotype is determined to check for differentiation towards anti-inflammatory M2 microglia. The most efficient regulators of M2 microglial phagocytosis will be validated *in vivo* in transgenic AD mice.

Abstract: Neuroinflammation is one of the hallmarks of Alzheimer's disease (AD). Increasing levels of the inflammatory cytokine Tumor Necrosis Factor-alpha (TNFα) have been observed to correlate with disease progression. TNFα has a dual function in neuronal cells: it activates apoptosis by the extrinsic pathway and protects neurons against amyloid-β (Aβ) toxicity. We have examined the actions of a death receptor antagonist, FAIM-L, in the regulation of TNFα roles in AD. FAIM-L protein levels were reduced in the hippocampi of patients with AD, and also in the entorhinal and hippocampal cortex of a mouse model of AD (APP/PS1) before the onset of neurodegeneration. *In vitro*, cultured neurons treated with the cortical soluble fractions of these animals showed a decrease in endogenous FAIM-L, an effect that is also observed by the treatment with Aβ-derived diffusible ligands (ADDLs). The protection afforded by TNFα against Aβ toxicity ceases when endogenous FAIM-L is reduced by short hairpin RNA (shRNA) or by treatment with ADDLs, but FAIM-L protein levels do not modify Aβ toxicity. FAIM-L levels are thus associated with the progression of the neurodegeneration by changing the inflammatory response mediated by TNFα in neurons. We are at present further characterizing this effect in an *in vivo* model of FAIM-L overexpression in neurons by a Tet-Off system.

Title: Changes in SR-A expression in aged APP/PS1 mice: their dependence on activation of the TGFβ pathway and their consequence in inflammatory activation of glia

Authors: *F. A. CORNEJO, N. SALGADO, M. ANDRÉS, R. VON BERNHARDI; Pontificia Univ. Católica De Chile, Santiago, Chile

Abstract: Scavenger receptors (SR) are responsible for most of the clearance of cellular debris in the central nervous system. Recent studies have shown that SR not only have a role removing waste from our brain, but they also participate in the inflammatory activation of glial cells. One of the most studied SR is the Class A Scavenger receptor (SR-A), since it has been associated with the pathophysiology of Alzheimer's disease (AD). Here, we show that SR-A expression in microglia and astrocytes of APP/PS1 mice is significantly reduced as animals age, in contrast with the mild increase observed in their wild type counterparts. SR-A expression has been shown to be modulated by the activation of the TGFβ pathway in macrophages, and our group has also reported that TGFβ1-treated microglia had increased expression of SR-A, by a mechanism that is mediated by the transcriptional co-factor Smad3. According to this evidence, in this work we attempted to determine how the TGFβ pathway could modulate SR-A expression in glial cells, and if this cytokine signaling could be related to the reduced expression of SR-A in APP/PS1 aged mice. By using immunofluorescence, here we report that TGFβ1 treatment induces Smad3 activation and its fast translocation to the nucleus in microglia and astrocytes from WT neonatal mice. On the other hand, we observed an altered expression pattern of the TGFβ1 receptor TβRII in APP/PS1 mice by western blot; an effect that could partially explain the impaired expression of SR-A in this animal model. In addition, we developed a triple congenic mouse derived from the transgenic APP/PS1 that overproduces Aβ and mice knockout for SR-A (APP/PS1/SR-A-/-) to analyze the consequences of age-reduced SR-A expression on the behavior and the activation response of the AD mouse model. We have observed altered cytokine profiles in plasma and in the hippocampus of APP/PS1/SR-A-/- mice as they age. Memory impairments were assessed by the Morris water maze neurobehavioral test. Our results suggest that the impairments of the

TGFβ pathway could affect the correct expression of SR-A in the aged APP/PS1 mouse brain, inducing inflammatory and cognitive alterations.

Title: Comparison of cell culture systems for the study of microglial biology in Alzheimer's disease

Authors: N. TAUB, E. GROSS, M. FROSCHAUER, *B. HUTTER-PAIER;
QPS Austria Gmbh, Grambach, Austria

Abstract: Besides amyloid plaques and neurofibrillary tangles, chronic inflammation has been identified as another pathological hallmark of Alzheimer's disease (AD). Microglia - brain resident macrophages - are likely to play a key role in the release of inflammatory mediators and in the efficient clearance of amyloid beta, thereby maintaining amyloid plaque homeostasis. Over the years many cell culture systems were developed to examine different aspects of neuroinflammation. In this study, we aimed to compare the advantages and disadvantages of high-through put cell systems as activated murine (BV-2) and human (HMO6) microglial cell lines and more complex systems as stimulated organotypic brain slices by determining cytokine release (TNF-alpha, IL-1beta, IFN-gamma, IL-6, IL-10, KC and IL-12p70), nitrosative stress and amyloid beta clearance. While microglial cell lines allow studying functional aspects of microglia, organotypic brain slices mimic the more complex brain milieu. However, both cell systems are suitable screening tools to identify novel compounds interfering with AD associated inflammation.

Title: Type 2 diabetes mellitus is associated with alterations in astrocyte and neuronal metabolism

Authors: *H. S. WAAGEPETERSEN, J. V. ANDERSEN, M. HOHNHOLT;
Univ. of Copenhagen, Copenhagen, Denmark

Abstract: Type 2 diabetes mellitus (T2DM) is a metabolic disorder characterized by an abnormal and persistent increase in blood sugar. A correlation between T2DM and the development of an Alzheimers-like dementia has been shown in animal models and human patients. Impaired cerebral glucose utilization and mitochondrial dysfunction has been reported, but the specific roles of neurons and astrocytes in relation to T2DM remains to be elucidated. In these studies we used a frequently used animal model of T2DM; the db/db mouse. Acutely isolated cortical slices, from 14 week old db/db mice, were incubated with either [U-^{13}C]glucose or [1,2-^{13}C]acetate. Glucose is metabolized by both neurons and astrocytes, whereas acetate is selectively metabolized in astrocytes. The formation of ^{13}C-labeled metabolites was assessed by gas chromatography and mass spectrometry. Preliminary experiments suggest that [U-^{13}C]glucose metabolism was reduced in cortical slices from db/db mice in comparison to control mice. In contrast, the labeling from [1,2-^{13}C]acetate was increased indicating an increased TCA cycle metabolism in astrocytes of cortical slices from db/db mice compared to control mice. Our data suggest an augmentation of mitochondrial metabolism in astrocytes but a general decrease in glucose metabolism in the db/db mouse model of T2DM.

Abstract: There is an increasing support for the hypothesis that microglia participate in Alzheimer's disease (AD) pathogenesis. Despite the extensive neuropathological, genetic, and biochemical characterization of microglia in AD little is known about microglial morphology in other common forms of age-related dementia: particularly, dementia with Lewy bodies (DLB) and hippocampal sclerosis of aging (HS-Aging). The clinical disease formerly referred to simply as "Alzheimer's disease" is, at the population level, a complex manifestation of many different brain conditions. These age-related brain pathologies include AD (characterized by amyloid plaques and neurofibrillary tangles), as well as cerebrovascular disease, DLB, and HS-Aging. Here we studied cases with pathologically-confirmed AD (n=7), HS-Aging (n=7), AD + HS-aging (n=4), DLB (n=12), and normal (cognitively intact) controls (NC) (n=9) from the University of Kentucky Alzheimer's Disease Center autopsy cohort. The Aperio ScanScope digital neuropathological tool was used along with two well-known microglial markers: IBA1 (a marker for both resting and activated microglia) and CD68 (a lysosomal marker in macrophages/microglia associated with phagocytic cells). Hippocampal staining analyses included studies of subregions within the hippocampal formation and nearby white matter. In addition, we defined and quantified, in the CA1 region, five microglia morphological phenotypes in the autopsy samples: ramified, hypertrophic, dystrophic, rod-shaped, and amoeboid. Using these tools and methods, we describe variation in microglial characteristics that show some degree of disease specificity, including, (1) increased microglia density and number in HS-aging and AD + HS-aging; (2) low microglia density in DLB; (3) increased number of dystrophic microglia in HS-aging; and (4) increased proportion of dystrophic to all microglia in DLB. We conclude that variations in morphologies among microglial cells, and cells of macrophage lineage, can help guide future work connecting neuroinflammatory mechanisms with specific neurodegenerative disease subtypes.

Title: Trem2 has age-dependent effects on myeloid cell activation and pathology in Alzheimer's disease mouse models

Authors: *T. R. JAY[1], S. BEMILLER[2], A. HIRSCH[1], M. BROIHIER[1], C. MILLER[2], B. T. LAMB[2], G. E. LANDRETH[1];

Abstract: Alzheimer's disease (AD) is characterized by aberrant neuroinflammation. The integral role of inflammation in AD pathogenesis was highlighted by studies which identified variants in Trem2, an important modulator of myeloid cell activation, which confer high risk for developing AD. We have recently shown that Trem2 deficiency reduces myeloid cell activation and accumulation around plaques and ameliorates AD pathologies in 4-month-old APPPS1-21 mice. However, others have shown that Trem2 increases pathology in 8-month old 5XFAD mice. One possible explanation for these divergent findings is that Trem2 has differential affects early and late in pathology. Here we assess whether Trem2 has an age-dependent role in myeloid cell activation and amyloid pathology by examining 2- and 8-month-old APPPS1;Trem2-/- mice. We also examine possible mechanisms by which Trem2 deficiency prevents myeloid cell activation and accumulation. We further confirm that Trem2 expressing cells are peripherally-derived using radiation chimeras, and examine proliferation and cell death of resident and peripherally-derived myeloid cell populations in Trem2 deficient APPPS1 mice. These data further our understanding of how Trem2 loss affects myeloid cell function, which will be important to more fully understand the role of inflammation in AD.

Title: Diabetes mellitus induces vascular damage, inflammation and neuronal loss in a murine model of Alzheimer’s disease

Authors: *J. RAMOS RODRÍGUEZ, C. INFANTE-GARCIA, L. GALINDO-GONZALEZ, M. GARCIA-ALLOZA;
Sch. of Medicine. Univ. of Cadiz, Cadiz, Spain

Abstract: Alzheimer’s disease (AD) and vascular dementia (VaD) are the most common forms of dementia, clinically characterized by cognitive decline. Whereas the ultimate causes remain largely unknown, many studies support the relationship between AD-VaD and metabolic disorders. Among these, diabetes mellitus (DM) seems to be of special relevance and it is a risk factor to develop dementia, although the mechanisms implicated have not been elucidated. In order to further explore the relationship between DM and AD-VaD, as well as the effects of a mixed pathology on the central nervous system we induced hyperglycemia in APP/PS1 mice. Animals were i.p. treated with streptozotocin (STZ), 40 mg/Kg for 5 consecutive days, at 4 months of age. Mice were then aged up to 6 months, when AD features are already established in this mouse model. At 6 months of age, STZ-wildtype and STZ-APP/PS1 mice showed high glucose and low insulin plasma levels, as typical metabolic alterations observed in type 1 DM. Both, widltype and AD mice, treated with STZ presented severe brain atrophy, that preferentially affected the cortex, while the hippocampus was spared. Further inmunohystochemical studies revealed significant neuronal loss in STZ-treated mice, that worsened in the proximity of senile

plaques in case of APP/PS1-STZ animals. Microglia activation, indicative of the inflammatory processes, was significantly increased in all STZ-treated mice, and this effect was worsened in APP/PS1-STZ animals. To deepen in the study of central disorders, we used Prussian blue staining to detect spontaneous hemorrhages. We observed that cortical hemorrhage burden was increased in STZ mice, and significantly worsened in APP/PS1-STZ mice. These data suggest a synergistic effect of APP/PS1 transgenes and STZ treatment, and it remains feasible that increased bleeding in APP/PS1 mice may underlie observed neuronal loss. Altogether, our data support a direct relationship between DM and brain atrophy, neuronal loss and vascular damage. DM might be more than a risk factor to develop dementia, and synergistically contribute to the degenerative process observed in AD and VaD. Our data provide new insights into the causes of late-life AD and may set the basis to develop novel strategies to prevent dementia.

Title: Interleukin 1: A major player in Alzheimer-related autophagic dysfunction

Authors: *P. A. PARCON[1], L. LIU[2], R. A. JONES[2], R. E. MRAK[3], W. T. GRIFFIN[2]; [1]RIOA, [2]Reynolds Inst. on Aging, UAMS, Little Rock, AR; [3]Dept. of Pathology, Univ. of Toledo Hlth. Sci. Campus, Toledo, OH

Abstract: Neuroinflammation is recognized as a major player in Alzheimer (AD) pathogenesis. Here we extend its influence to include autophagy, in particular with regard to APOE genotype. Firstly, we report that the AD-related nuclear-to-cytoplasmic translocation of NEDD8 in

hippocampal neurons is mimicked by treatment of primary rat neurons treated with IL-1β. Secondly, we show in the PD-APP mouse model of AD that an elevation of IL-1α and IL-1β mRNA at 2 months of age - one month prior to cognitive deficits and 4-7 months before plaque deposition - that is even greater at 17 months, and is accompanied by a marked elevation in the E3 ubiquitin-ligase parkin. This, together with the increase in colocalization of parkin and NEDD8 in primary rat neurons treated with IL-1β and the increase in both total parkin protein and NEDD8-conjugated parkin in NT2 cells treated with IL-1β, suggests that IL-1β facilitates parkin-dependent ubiquitination via upregulation of both parkin protein and parkin neddylation. Thirdly, we find similar relationships between the levels of IL-1 and autophagy-related mRNAs in hippocampal tissue homogenates from AD compared to age-matched control patients. Moreover, such changes were influenced by APOE genotype with an increasing trend in protein levels of autophagy substrate SQSTM1/p62: AMC 3,3 < AD, and AD 3,3 < AD 3,4< AD 4,4. Interestingly, while mRNA levels of p62, LC3, and LAMP2 did not differ between AD 4,4 carriers and AMC 3,3 carriers, those with AD 3,3 showed a marked elevation, suggesting that inheritance of APOE ε4 alleles is associated with a weakened autophagy system in which p62 protein levels build up despite transcriptional down-regulation. Taken together with previous reports of elevated expression of IL-1α and β in AD, the data reported here is consistent with the idea that IL-1β is a major player in protein degradation pathways associated with Alzheimer pathogenesis. Supported in part by NIA AG12411 and the Windgate Foundation.

Title: Restoration of the peripheral immune/inflammatory response correlates with brain injury recovery in a murine model of Alzheimer’s disease

Authors: G. DI BENEDETTO, G. FUCCIO SANZÀ, G. CANTARELLA, *R. BERNARDINI; Univ. Catania Sch. of Med., Catania, Italy

Abstract: Alzheimer disease (AD) related inflammation is triggered concomitantly with deposition of amyloid beta in the brain and is characterized by increased expression of inflammatory/immune mediators, including cytokines belonging to the TNF superfamily such as

TNF-Related-Apoptosis-Inducing-Ligand (TRAIL). Accumulation of activated microglia producing TNF-α and MCP has been reported either in AD animal models as well as in the human AD brain. However, little is known about changes occurring in peripheral immune response in AD. Here, we investigated the inflammatory/immunological abnormalities occurring in the spleen of a murine model of AD, and whether treatment with a TRAIL neutralizing antibody, known to exert neuroprotective effects in similar animal model, could also be related to improvement of peripheral inflammatory/immunological parameters. The effects of TRAIL neutralization on the morphology of the spleen as well as the expression of TRAIL, DR5, and inflammatory mediators were studied in 3xTg-AD mice. Treatment with the TRAIL neutralizing antibody resulted in improvement of morphology of spleens, as well as in decreased expression of inflammatory molecules. Finally, neutralization of TRAIL resulted in restrained peripheral immune/inflammatory response, which correlates with CNS functional and tissue parameters of 3xTg-AD mice. Thus, it is plausible to propose the peripheral immune system as a target for innovative treatment of neuroinflammatory disorders.

Title: Oxidative damage and antioxidant response during the progression of Alzheimer’s pathology in Tg2576 mouse neocortex

Authors: A. FRACASSI[1,2], G. TAGLIALATELA[2], *S. MORENO[1];
[1]Univ. Roma Tre, Rome, Italy; [2]Univ. of Texas Med. Br., Galveston, TX

Abstract: Alzheimer’s Disease (AD) is the most common form of dementia, characterized by progressive neurodegeneration of cortical structures. Neuropathological changes include the formation of extracellular senile plaques and intracellular neurofibrillary tangles, followed by inflammation and massive neuronal loss [1]. The mechanisms underlying AD pathogenesis,

triggered by amyloid beta (Aβ) peptide accumulation, include oxidative stress, deriving from deregulation of energy homeostasis and involving mitochondria and peroxisomes [2,3]. We here addressed the oxidative stress status and the elicited cellular response at the onset and during the progression of Aβ pathology. As a suitable model for this purpose, and consistent with our previous investigations, we chose the Tg2576 mouse model [4], displaying a slowly progressive Aβ pathology. We focussed on the neocortex of mice aging 3, 6, 9, 12, and 18 months to study age-dependent changes of oxidative modification markers, antioxidant enzymes and related transcription factors. The expression of these molecules was analysed in relation to the distribution of Aβ peptide and oligomers, by a combined molecular/morphological approach. Nucleic acid oxidative damage in the cytoplasm and mitochondria, accompanied by defective antioxidant defences and decreased PGC1α expression are already detected in 3-month-old Tg2576 neurons. Conversely, peroxisome proliferator-activated receptor α is increased in these cells. The predominantly cytoplasmic immunostaining found in Tg neurons possibly reflects a nongenomic action of this redox sensor molecule, leading to inhibition of inflammatory gene expression. At 6 months, concominant with Aβ intracellular accumulation, PMP70 is downregulated, indicating impaired peroxisomal translocation, and consequent harmful accumulation, of fatty acids. In 9-month-old Tg neocortex, Aβ oligomers and acrolein deposition positively correlates with GFAP, GPX1 and PMP70 increases, supporting a compensatory response, involving astroglial peroxisomes. At severe AD stages, when senile plaques disrupt cortical cytoarchitecture, antioxidant capacity is gradually lost. Overall, our study suggests that therapeutic intervention targeting peroxisomes in AD should be considered. References 1.Querfurth, HW, LaFerla, FM. Abstract: Alzheimer's disease (AD) is a neurodegenerative disease characterized by a marked decline in cognition and memory function. One of the major pathological hallmarks of AD is the progressive accumulation and deposition of amyloid beta (Aβ) peptides in the brain. Importantly, increased Aβ toxicity and pathology is accompanied by alterations in parallel mechanisms and responses that regulate brain homeostasis and function. Increasing evidence highlights the essential role of neuroinflammatory and immune-related molecules, including those produced at the brain barriers, on brain immune surveillance, decreased Aβ clearance from the brain and increased brain cell dysfunction and pathology in AD. Therefore, understanding the response at the brain barriers may unravel novel pathways of relevance for the pathophysiology of AD. Herein, we focused on the study of the choroid plexus (CP), which constitutes the blood-cerebrospinal fluid barrier, in aging and in AD. Specifically, we used the PDGFB-APPSwInd (J20) transgenic mouse model of AD, which presents early memory decline and progressive Aβ accumulation in the brain, and littermate age-matched wild-type (WT) mice, to characterize the CP transcriptome at 3, 5-6 and 11-12 months of age. The most striking observation was that the CP of J20 mice displayed an overall overexpression of type I interferon (IFN) response genes at all ages. Moreover, J20 mice presented a high expression of type II IFN genes in the CP at 3 months, which became lower than WT at 5-6 and 11-12 months. Importantly, along with a marked memory impairment and increased glial activation, J20 mice also presented a similar overexpression of type I IFN genes in the dorsal hippocampus at 3 months. Altogether, these findings provide new insights on a possible interplay between type I and type II IFN responses in AD and point to IFNs as targets for modulation in cognitive decline.

Title: Repeated exposure to poly i:c leads to elevations in hippocampal amyloid-beta, cognitive dysfunction, and sustained deficits in burrowing

Authors: *J. D. WHITE[1], M. J. EIMERBRINK[2], A. D. HARDY[3], D. KRANJAC[4], K. C. PAULHUS[3], G. W. BOEHM[2], M. J. CHUMLEY[3];
[1]Dept. of Psychology, [2]Psychology, [3]Biol., Texas Christian Univ., Fort Worth, TX; [4]Psychiatry and Behavioral Sci., Stanford Univ. Sch. of Med., Stanford, CA

Abstract: Current global statistics estimate that 44.4 million people are afflicted with dementia, and that 50–75% of these patients suffer from Alzheimer's disease (AD), a progressive disorder categorized by neuronal and behavioral deterioration (Prince et al. 2013). One hallmark of AD neuropathology is the accumulation of the amyloid-beta (Aβ) peptide, that is known to inhibit cell-to-cell communication, and lead to cognitive deficits and neuronal cell death. Our lab has previously shown that repeated bouts of peripheral inflammation are sufficient to significantly increase the amount of Aβ in the hippocampus of treated animals, and cause deficits in cognition. The goal of the present research was to extend the duration of inflammatory immune challenges to monitor the corresponding changes in sickness behaviors, central Aβ accumulation, and cognitive deficits induced by said Aβ accumulation. All experiments utilized polyinosinic:polycytidylic acid (poly I:C), a viral mimetic, as an immune challenge to induce an inflammatory response, and subjects were compared to saline treated controls. We tested the influence of daily injections of poly I:C, over a 21 day period, on sickness behaviors, using a burrowing paradigm. Results indicate that the inflammatory response to poly I:C over this duration is sufficient to consistently induce sickness behaviors across all days of testing. Next, we examined the effect of poly I:C on cognitive deficits and central Aβ accumulation, over three treatment durations: 7, 14, and 21 days. Forty-eights hours after the final injection, animals were trained in a contextual fear conditioning paradigm, and tested 24 hours later. The hippocampus was then collected and Aβ levels were quantified. Results show that poly I:C can disrupt cognition after both 14 and 21 days of administration, while at all time points, a significant elevation in Aβ within the hippocampus was found. These results demonstrate that peripheral injections of poly I:C are a reliable means to induce sickness behaviors over an extended duration. Moreover, repeated poly I:C exposure is capable of inducing a significant elevation in central Aβ after 7 days, which can be maintained with consistent injections. Finally, we identified that Aβ accumulation can disrupt cognition after 14 and 21 days, but not after 7 days, despite a significant increase in Aβ. This may indicate the presence of a physiological threshold for Aβ that must be exceeded to disrupt cognition. In addition, these results suggest that long

term administration of poly I:C may provide a model to investigate the effects that chronic inflammation has on the development of Alzheimer's-like pathology.

Title: Tau oligomers co-localize with inflammatory markers in Frontal Temporal Lobe dementia

Authors: *A. N. NILSON[1], K. ENGLISH[2], J. E. GERSON[1], R. KAYED[3];
[1]Neurosci. and Cell biology, [2]Med., [3]Neurol., Univ. of Texas Med. Br., Galveston, TX

Abstract: Inflammation plays a large role in age-related diseases including tauopathies such as Frontal Temporal Lobe dementia (FTLD). Neurodegenerative diseases exhibit inflammation and cell death before larger aggregates form. Tau aggregates in neurodegenerative disease into large aggregates called neurofibrillary tangles. However, smaller soluble aggregates -oligomers-are formed prior to tangles and evidence suggests that they are actually the most toxic species. Thus we decided to investigate a connection between tau oligomers and inflammation. Human cortex samples from control and FTLD brains were sectioned. The sections underwent immunohistochemistry using two fluorescent stains and DAPI nuclei stain. The antibodies included both oligomer-specific and total tau, as well as various inflammation markers such as GFAP (astrocyte marker), Iba1 (microglia marker), and HMGB1 (inflammation marker). Additionally, homogenates were prepared for ELISA to determine levels of inflammatory proteins. There was co-localization seen with tau and several of the inflammation markers. GFAP showed changes in number of cells and morphology. T22 also co-localized with Iba1 and HMGB1. The ELISA showed an increase in GFAP. Oligomeric tau co-localizes with inflammatory markers indicating it may stimulate the neuroinflammation seen in FTLD. These preliminary results indicate oligomeric tau is associated with the inflammatory response in FTLD subjects. Further investigation of this response to oligomeric tau could provide insight for developing treatments for FTLD. Furthermore, oligomeric tau plays a role in other diseases such as Alzheimer's and Parkinson's and deserves further investigation. Anti-inflammatory drugs may play an important role in the treatment of these diseases by decreasing the inflammation and cell death due to oligomeric tau.

Title: m6a regulatory proteins in human Alzheimer's disease neurons

Authors: *A. LICHT-MURAVA[1], S. ILYAS[1], P. KATSEL[1], P. ROUSSOS[1], M. BERRI[2], G. RECHAVI[2], V. HAROUTUNIAN[1];
[1]Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Sheba Med. Ctr., Ramat Gan, Israel

Abstract: Epigenetic modification of RNA is another layer of regulation between DNA and protein translation. N(6)-methyladenosine (m^6A) is one of the most common RNA modifications. A Methyltransferase complex for m^6A, containing: methyltransferase like 3 (METTL3) and methyltransferase like 14 (METTL14) proteins, has been identified. In addition, two demethylases: Fat mass and obesity-associated protein (FTO), and AlkB family member 5 (ALKBH5) have been shown to dynamically regulate m^6A. A growing body of evidence is beginning to identify specialized cell-type specific alteration and regulation of gene and protein expression in health and disease. Human brain function depends not only on different cell types but also on contacts between them. The current study aimed to determine if the regulation of m^6A changed in different brain cell types and whether these changes exist in Alzheimer disease (AD). Laser capture microdissection was used to isolate endothelial cells and neurons near blood vessels from the hippocampus of healthy individuals and those with varying severities of AD. This study shows that FTO, ALKBH5, METTL3 and METTL14 were abundant specifically in neurons and were decreased significantly with AD severities. Moreover, total RNA and protein expression show significant decrease of FTO levels in the superior temporal cortex of individuals with different degrees of dementia or different severities of AD associated neurofibrillary (NFT) pathologies (Braak stage >0). The most significant decrease in FTO RNA and protein levels were in the first stages of neurofibrillary tangle pathology development where NFTs are confined to the transentorhinal region. Studies have shown that FTO decrease leads to m^6A increase and that m^6A modifications contribute to the regulation of translation and lifetime of mRNA.

Collectively, this study suggests that epigenetic regulation of RNA expression in neurons may play a significant role in the development of dementia and AD.

Title: Association of Alcadein alpha with kinesin light chain is regulated by phosphorylations at cytoplasmic acidic region

Authors: *Y. SOBU, S. HATA, T. SUZUKI;
Grad. Sch. of Pharm.Sci. Hokkaido Univ., Sapporo/Hokkaido, Japan

Abstract: Alcadeins(Alc) / Calsyntenins are type I membrane proteins consisted of Alcα, Alcβ and Alcγ, which express predominantly or exclusively in neuron (J. Biol. Chem. [2003] 278, 49448). Alcs are found as molecules suppressing the cleavage of amyloid precursor protein (APP) by forming a complex with cytoplasmic X11L adaptor protein. As is APP, Alcs are primarily cleaved by ADAM10/17 at jaxtamembrane region and then subject to the intracellular cleavage by γ-secretase (J. Biol. Chem. [2004] 279, 24343). This is mentioned as the regulated intramembrane proteolysis (RIP) to release intracellular cytoplasmic domain (ICD) fragment into cytoplasm (J. Biol. Chem. [2009] 284, 36024). Moreover, Alcα is known to function as a cargo receptor of kinesin-1. Kinesin-1, a heterotetramer composed of two heavy chains (KHC) and two light chains (KLC), is an anterograde molecular motor transporting cargos toward nerve terminus. Alcα binds to KLC through the WD motif in the cytoplasmic region. This binding activates kinesin-1, then vesicles containing Alcα are transported from cell body to nerve end in axon (EMBO J. [2007] 26, 1475; Traffic [2012] 13, 834). However, it remains unclear how Alcα vesicular transport is regulated. Here, we focused our analysis on the regulation of Alcα association with kinesin-1. We found that the cytoplasmic domain of Alcα includes many consensus sequences for phosphorylation, especially by casein kinase I and/or II. Because we found that the cytoplasmic sequence of Alcα is phosphorylated in brain *in vivo*, we investigated the function of Alcα phosphorylation in the interaction with kinesin-1. Alcα-FLAG expressed in N2a cell are recovered with anti-FLAG antibody and dephosphorylated with λPPase. The dephosphorylated Alcα-FLAG was mixed with N2a cell lysate expressing HA-KLC1 to examine

a binding ability to KLC. Dephosphorylation of Alcα-FLAG decreased the binding with HA-KLC1. Then we tried to determine the phosphorylable residues which regulate the interaction with KLC by the procedures using deletion constructs and the alanine-scanning mutagenesis into the candidate sites. We detected the phosphorylation sites in the acidic region of Alcα. These results suggest that transport of Alcα vesicle by kinesin-1 is regulated by phosphorylation of Alcα intracellular domain.

Title: Assessment of Parkinson’s disease specific microRNA in Alzheimer’s disease

Authors: *S. MUKHOPADHYAY;
Grand Valley State Univ., Grand Rapids, MI

Abstract: Alzheimer’s Disease (AD) and Parkinson's Disease (PD) are distinct conditions. However, mounting evidence shows possible links between the genetics and brain changes associated with them such as cognitive impairment and aggregation of misfolded proteins, suggest cross disease association. Previous research has identified a panel of plasma based PD specific microRNA biomarkers. The pathway analyses of these microRNAs target genes showed enrichment in the neuron differentiation/projection and synaptic pathways, which are also important signaling pathways in AD. Here we find novel evidence that shows the presence of PD specific microRNA in AD brain samples. There was up regulation of all microRNA in mid stage and late stage of AD samples compared to the healthy control samples. In general, inferior temporal cortex of hippocampus showed higher microRNA expression compared to the frontal cortex of the same patient. We identified that microRNA cross-talk is present between PD & AD. This study is essentially an important first step towards future functional studies of microRNA analyses for potential therapeutic targets for AD.

Title: A role of aquaporine-4 in immune responses in Alzheimer's disease model mice

Authors: *T. NIIKURA[1], H. WADA[1], M. YASUI[2], Y. ABE[2];
[1]Sophia Univ., Tokyo, Japan; [2]Dept. of Pharmacol., Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: Astrocytes have essential roles in maintaining stable physiological conditions in the brain. In addition, astrocytes are implicated in specific neuronal functions such as the facilitation of learning and memory. Aquaporin-4 (AQP4) is the major water channel in the CNS and enriched in the subpial and perivascular endfeet of astrocytes. The AQP4 expression is up-regulated in the injured brain and the astrocytes migrate to the injured site in an AQP4-depepndent manner. In the AQP4-deficient (AQP4/KO) mice, the up-regulation of pro-inflammatory cytokines induced by brain injury is significantly attenuated, suggesting that AQP4 has an essential role in immunological function under pathological conditions in the CNS. Multiple studies have demonstrated that inflammatory cytokines are up-regulated and reactive astrocytes and activated microglia accumulate surrounding the amyloid plaques in brains of Alzheimer's disease (AD) patients and AD model mice. To clarify the effect of astrocyte dysfunction in the AD pathogenesis, we established AQP4-deficient AD mouse model (AQP4/KO-5xFAD) with C57BL/6J background by crossing AQP4/KO mice and amyloid overproducing AD model mice, B6-Cg-Tg (APPSwFlLon,PSEN1*M146L*L286V)6799Vas (5xFAD). At six months of age, behavioral tests were performed and brains were subjected to the immunohistological analysis. In the behavioral tests, no significant difference was observed between 5xFAD and AQP/KO-5xFAD female mice in both open field and Y-maze tests. Contrary to our expectation, amyloid plaque formation or reactive astrocytosis was not altered by AQP4 deficiency. However, microgliosis was significantly attenuated in the AQP4/KO-5xFAD mice as compared with 5xFAD mice. These findings suggest that AQP4 is involved in the induction of microgliosis underlying AD pathogenesis.

Title: Differential associations between retinal ganglion cell thickness and white matter integrity among healthy normal, cognitive impairment, and Alzheimer's disease

Authors: *S. LIU[1], Y. ONG[3], S. HILAL[2], Y. LOKE[1], C. CHEN[2], C. CHEUNG[3], J. ZHOU[1]; [1]Ctr. for Cognitive Neuroscience, Neurosci. and Behavioral Disorder Program,, [2]Dept. of Pharmacol., Natl. Univ. of Singapore, Singapore, Singapore; [3]Singapore Eye Res. Inst., Singapore Natl. Eye Ctr., Singapore, Singapore

Abstract: Introduction: Alzheimer's disease (AD) is associated with disrupted brain white matter integrity [1]. Recently, our group reported thinning of macular ganglion cell-inner plexiform layer (GC-IPL) measured by spectral-domain optical coherence tomography (SD-OCT) in patients with AD and mild cognitive impairment [2]. However, the link between GC-IPL thickness and brain white matter integrity in normal and pathological ageing remains unknown. Here, using SD-OCT and Diffusion Tensor Imaging (DTI) techniques in subjects with no cognitive impairment (NCI), cognitive impairment without dementia (CIND) and AD, we hypothesized that a thinner GC-IPL, reflecting retinal ganglion cell loss in retina, would be associated with reduced white matter integrity. **Methods:** 180 subjects (65 NCI, 68 CIND, and 47 AD) underwent DTI scans (Siemens Tim Trio, 3T, 61 diffusion directions at b=1150 s/mm^2 and 7 b0 maps) and SD-OCT (Cirrus OCT, Carl Zeiss Meditic) scans. After retina image quality control, 124 subjects remained (47 NCI, 50 CIND, and 27 AD). After standard preprocessing using TBSS [3], group differences in fractional anisotropy (FA) and mean diffusivity (MD) were examined across the three groups using pairwise two-sample t-tests. Whole-brain skeletonized voxelwise regression of two DTI indices (FA and MD) against GC-IPL thickness performed across and within each of the groups. All analyses were controlled for age, gender, handedness, and ethnicity. **Results:** We observed that white matter integrity deteriorated (evidenced by FA decrease and MD increase) as with increasing severity of cognitive impairment from NCI to CIND and AD (FWE corrected $p<.005$). Furthermore, the GC-IPL thickness was correlated with FA positively and MD negatively (FWE corrected $p<.05$) in NCI, mainly in anterior thalamic radiations, corticospinal tracts, cingulum cingulated and hippocampus, forceps minor, inferior fronto-occipital fasciculus, and superior longitudinal fasciculus. At the same threshold, no correlations were found in CIND or AD. However, there was a trend of positive (negative)

correlation between FA (MD) in the fornix and the cingulum cingulate and GC-IPL thickness (uncorrected p<.05) for the CIND, and positive correlation between FA in the fornix and the GC-IPL thickness for the AD. **Conclusion:** Our findings suggest that thinning GC-IPL may be associated with deterioration of white matter integrity in normal aging. Though AD affects both retinal ganglion cell and white matter integrity, the correlation between these markers are altered, suggesting a disruption of normal physiological age-related relationships due to disease-induced changes.

Title: A role for the Alzheimer’s disease risk factor CD2AP in mediating blood-brain barrier integrity in mice

Authors: ***J. COCHRAN**, T. RUSH, S. C. BUCKINGHAM, E. D. ROBERSON;
Ctr. for Neurodegeneration and Exptl. Therapeut., Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: CD2-associated protein (CD2AP) is a leading genetic risk factor for Alzheimer’s disease, but little is known about the function of CD2AP in the CNS. We used CD2AP -/- mice to determine the role of CD2AP in the CNS. Because CD2AP -/- mice normally die by 6 weeks of age from nephrotic syndrome, we used mice that also express a CD2AP transgene in the kidney, but not brain, to attenuate this phenotype. We found that CD2AP-deficient mice did not exhibit abnormalities in behavior, including learning and memory, except for motor deficits in a subset of CD2AP -/- mice exhibiting severe nephrotic syndrome. This suggests that CD2AP does not overtly affect behavior in mice, and that the motor deficits we observe in a subset of CD2AP -/- mice are due to systemic illness. We also observed more severe pentylenetetrazol-induced seizures in CD2AP -/- mice, but characteristics of these seizures on EEG were not altered. As CD2AP is known to be expressed in brain-adjacent endothelial cells, we speculated that the increased susceptibility to seizures without detectably different seizure characteristics may be

due to increased availability of pentylenetetrazol due to compromised blood-brain barrier integrity. Using sodium fluorescein extravasation, we found that CD2AP -/- mice had reduced blood-brain barrier integrity, suggesting that increased seizure susceptibility in these mice may depend simply on the availability of pentylenetetrazol. Neither seizure measures nor blood-brain barrier integrity were correlated with a marker of nephrotic syndrome, suggesting that these measures are dissociable from the systemic illness present with CD2AP -/-. Taken together, our results suggest a new role of CD2AP in mediating blood-brain barrier integrity and indicate that further investigation of non-neuronal roles of CD2AP relevant to the CNS is justified.

Title: Proteasome and autophagic degradation in an *in vitro* model of Alzheimer's disease

Authors: *R. C. CHANG[1,2], S. S. Y. CHENG[1], C. H. L. HUNG[1];
[1]Lab. of Neurodegenerative Diseases, LKS Fac. of Medicine, Univ. of Hong Kong, Hong Kong, China; [2]State Key Lab. of Brain and Cognitive Sciences, The Univ. of Hong Kong, Hong Kong SAR, China

Abstract: Alzheimer's disease (AD) is the leading cause of dementia, affecting about 44 million people worldwide and amounting to over $605 billion in healthcare costs. Therefore, it is important to understand the initiation and pathogenesis of AD in hopes of finding a cure. Since AD is classified by the accumulation of β-amyloid (Aβ) and hyperphosphorylated tau protein, it has been speculated that impairments in key protein degradation systems such as the ubiquitin-proteasome system (UPS) or autophagy-lysosomal pathway (ALP) may be important contributors to AD pathology. Also, both of these pathways have been found to be affected in postmortem brain of AD patients. Therefore, we hypothesize that dysfunctions in the UPS and

ALP play an important role in AD pathogenesis. Using primary culture of cortical neurons treated with oligomeric Aβ as an *in vitro* model of AD, biochemical and imaging techniques were employed to investigate changes in UPS and ALP activity after exposure to Aβ peptide. Our data showed an initial impairment proteasome activity followed by an induction of autophagy at later time points. Different isoforms of tau were found to accumulate and aggregate at different time points in neurons exposed to Aβ where protein degradation impairments were found. The accumulation in phosphorylated tau was not due to changes in kinase or phosphatase activity but likely due to impairments in protein degradation signaling. Consequences of impaired protein degradation in neurons were also investigated by examining changes in synaptic integrity and function. As tau is a microtubule stabilizing protein, impairments in tau turnover after exposure to Aβ peptide will affect microtubule stability, resulting in disturbances in axonal transport and synaptic function, ultimately resulting in neuronal loss. Therefore, the effects of tau accumulation and phosphorylation on synaptic protein expression and function were examined. To date, our data suggest that the UPS is affected at early time points, resulting in the accumulation and subsequent aggregation of tau within neurons exposed to Aβ peptide. The presence of tau aggregates initiates the ALP to promote the removal of these aberrant proteins, to bring neurons back to protein homeostasis. With the accumulation and aggregation of tau, other factors contributing to neuronal cell death such as a loss in synaptic protein expression may also be affected

Title: Long-term brain pathology in a mixed model of Alzheimer’s disease and type 2 diabetes

Authors: *C. INFANTE GARCIA, J. RAMOS-RODRIGUEZ, A. GARCIA-ALCINA, M. GARCIA-ALLOZA;
Div. of Physiology. INBIO, Sch. of Medicine. Univ. De Cadiz, Cadiz, Spain

Abstract: Alzheimer's disease (AD) is the leading cause of dementia worldwide. Neuropathological features include: 1) neurofibrillary tangles with abnormally phosphorylated tau protein, 2) senile plaques (SP), mainly composed of amyloid-beta peptide (Aβ), and 3) neuronal loss. Whereas aging remains the main risk factor to suffer dementia, hyperinsulinemia and type 2 diabetes mellitus (T2D) are also relevant risk factors to develop dementia. Since the EA and DM2 are chronic diseases closely associated with aging, we have explored this relationship in the long term. We have characterized a mixed model of T2D and AD, resulting from crossing an AD model (APP/PS1 mice) with a classical model of T2D, the db/db mouse. Pathological hallmarks were assessed at 36 weeks of age, when both pathologies have chronified. In APP/PS1xdb/db mice body weight, postprandial blood glucose and insulin levels were followed at 4, 18 and 36 weeks of age. Our studies revealed an overall increase of glucose levels in APP/PS1xdb/db mice. On the other hand, insulin levels were reduced with aging, showing premature exhaustion of beta-pancreatic cells in the mixed model. Learning and memory were assessed by the Morris water maze and new object discrimination tests and cognitive compromise observed in APP/PS1 and db/db animals was significantly worsened in APP/PS1xdb/db mice. Postmortem studies revealed a shift in Aβ profile, and whereas insoluble Aβ was reduced in our mixed model, soluble more toxic species were significantly favoured. We also observed that tau phosphorylation was increased in APP/PS1xdb/db mice. Central atrophy was detected in db/db mice and a worsening effect was observed in the APP/PS1xdb/db group. Further the assessment of dendritic complexity revealed a relevant compromise in diabetic mice, that was worsened in the APP/PS1xdb/db mice. Altogether, our data suggest that T2D and AD have a synergistic effect, both at metabolic and central level, leading to a worsened version of AD pathology and memory dysfunction in the long term. Therefore, it remains possible that tight control of T2D could slow central pathology progression in AD. Abstract: Alzheimer's disease (AD) is associated with an increased incidence of seizures, and recent evidence suggests that such neuronal hyperexcitability in AD may actively contribute to cognitive decline. Therefore, understanding the mechanisms by which seizures contribute to cognitive decline may enable the discovery of novel therapeutic targets. Our studies of seizure-related changes in the hippocampus of a transgenic mouse model of AD have revealed that expression of the transcription factor ΔFosB is markedly increased by seizures. Unlike other leucine zipper transcription factors, ΔFosB has an unusually long half-life, and this unique property may explain how even a few intermittent seizures can cause long-lasting changes in gene expression that affects cognition. Our studies demonstrate that viral overexpression of ΔFosB in the hippocampus of wildtype mice is sufficient to alter hippocampal gene expression and cause cognitive deficits similar to those we observe in AD transgenic mice. Therefore, further delineation of ΔFosB's functions and identification of its targets in the hippocampus may provide critical insight into the mechanisms by which seizures induce synaptic dysfunction and cognitive impairment in neurological conditions such as epilepsy and AD.

Title: Quantification of cytosine modifications in Alzheimer's disease

Authors: E. M. ELLISON, M. A. BRADLEY-WHITMAN, *M. A. LOVELL;
Chem/Sanders-Brown Ctr. Aging, Univ. Kentucky, Lexington, KY

Abstract: DNA methylation of the fifth position of cytosine is a key epigenetic modification regulating gene transcription. Although epigenetic modifications to cytosine have been extensively studied in embryonic development and cancer, there has been little study of epigenetics as it relates to neurodegeneration, particularly Alzheimer's disease (AD). Studies of global levels of 5-methylcytosine (5-mC) and 5-hydroxymethylcytosine (5-hmC), as well as gene modifications in target brain regions, could provide insight regarding neurodegeneration and dysfunction as it relates to AD. Bulk level changes to modified cytosine could suggest changes in epigenetic marks on the genetic level, giving insight to possible altered transcriptional states. Analysis of global cytosine modifications, as well as genetic levels of cytosine, 5-mC, and 5-hmC, would give a more comprehensive picture of epigenetic modification as it relates to AD. To determine global modified cytosine profiles in the brain of AD and age-matched normal control (NC) subjects, a GC/MS method was developed using stable labeled standards of cytosine, 5-mC, and 5-hmC. Bulk levels of epigenetic marks were quantified in key brain regions of AD and NC subjects, expressed as percent of control values. Preliminary data show elevated levels of 5-mC in AD subjects compared to NC in disease associated brain regions. To determine if 5-mC oxidation is altered in target genes associated with AD, specific restriction endonuclease cleavage at target CCGG sequences, paired with quantitative polymerase chain reaction (q-PCR), was used to quantify sequence specific levels of cytosine, 5-mC, and 5-hmC in a subset of AD relevant genes. DNA samples were isolated from the hippocampus/parahippocampal gyrus (HPG) of AD and NC subjects. To correlate epigenetic modification to transcriptional regulation, changes in protein levels were determined using Western blot analysis. Our data suggest significantly altered levels of epigenetic marks in genes relevant to AD in the HPG of AD subjects compared to NC subjects. Collectively, these studies suggest epigenetic modifications to cytosine may be associated with AD and potentially play a role in neurodegeneration and dysfunction.

Title: Clusters of damaged neuronal terminals (dystrophic neurites) form around ruptured capillaries in Alzheimer's disease

Authors: *G. K. HANSRA, K. M. CULLEN, G. POPOV, P. O. BANCZEK;
Anat. and Histology, The Univ. of Sydney, Sydney University, Australia

Abstract: Rationale: Growing evidence suggests that vascular pathology may be important in the pathogenesis Alzheimer's disease (AD). Cerebrovascular abnormalities are common with increasing age and have been associated with cognitive impairment in AD. Previously, we showed that all amyloid-containing plaques are found at sites of capillary damage. These plaques colocalise with haemorrhage markers and inflammatory cells. We now have substantial evidence that senile plaques are, in fact, microhaemorrhages of 100-200μm. Linking the neuritic degeneration to these microstrokes would provide a unifying hypothesis for the vascular aetiology of the hallmark AD lesions. **Objective:** To correlate the location of neuritic plaques (clusters of hyperphosphorylated tau dystrophic neurites) to the microvascular network in *post mortem* brain tissue from AD and neurologically normal patients. **Methods and Results:** Blocks of formalin fixed human brain tissue were obtained from the Australian Brain Bank Network. This study was approved by the Human Research Ethics Committee (HREC), University of Sydney. Cases were chosen with a range of neuritic pathology using the Braak and Braak stageing criteria ranging from stages 0 to VI. Cases included 5 neurologically-normal individuals. Blocks of hippocampus, superior frontal and cingulate cortices were cryosectioned at 50-200μm and fluorescently labeled for tau (AT8) and collagen IV (for blood vessels). Entire neuritic plaques contained within the depth of the section were optically sectioned. Each plaque was then examined for the presence of a microvessel. Imaris and Fiji applications were used to measure features of the microvessels including length density, tortuosity, diameter, branch density as well as, distance to lesions. We find that neuritic plaques encircle capillaries in all stages of disease. We also find that neuritic plaques frequently appear around collapsed vessels and near capillary branches. Moreover, dystrophic neurites within the microhaemorrhages are iron-positive, suggesting iron uptake from the haemorrhage site. We also note iron-positive neurites emanating from the microstroke region. We suggest that this iron is derived from the leakage of blood into the parenchyma. **Conclusion:** This study provides evidence that the clinically-significant neuritic lesions of AD form at sites of microhaemorrhage, which strengthens the notion, that vascular breakdown is the proximal cause of AD. Therapeutic and preventative strategies aimed at vascular health have potential to delay or slow the progression of this disease.

Inst., Grand Rapids, MI; [5]Dept. of Pathology, [6]Dept. of Neurol., Univ. of Michigan, Ann Arbor, MI; [7]Mercy Hlth. St. Mary's, Grand Rapids, MI

Abstract: Longer life expectancies have contributed to an increased prevalence of dementias in the aged population. The two most prevalent causes of dementia are Alzheimer's disease (AD) and vascular dementia (VaD). However, the pathogenic mechanisms that differentiate these two diseases are unclear. To begin to understand these differences, we used Agilent Human 8x60K v2 microarrays to profile gene expression in frozen frontal cortex tissue samples (BA 10) harvested postmortem from individuals who died with probable AD, VaD (multi-infarct subtype), or no dementia (n = 11-12/group). The cases were matched for age, postmortem interval, and gender. Of the 24,127 genes featured on the microarray platform, 3495 genes were uniquely dysregulated in AD (1344 up; 2151 down). Notably, preliminary network and pathway analyses revealed that the genes specifically downregulated in AD but not in VaD were heavily enriched for synaptic function (e.g., synapsin I, rab3a), axonal transport (e.g., dynein, bassoon), and glutamatergic signaling (e.g., NR2, mGluR5). Hence, the molecular pathogenic mechanisms leading to VaD may be different from AD. In this regard, microarray analysis revealed that 413 genes were uniquely dysregulated in VaD (221 up; 192 down). Preliminary network analysis revealed a prominent hub centered on the small GTPase Rac1, a critical negative regulator of epithelial antioxidant and neurotrophic activities. Rac1 was significantly down-regulated in VaD

compared to AD and controls (log fold change = -0.4, FDR adjusted $p < 0.01$). Likewise, several Rac1 inhibitors (e.g., RalBP1) were upregulated whereas Rac1 activators (e.g., puratrophin-1) were downregulated in VaD. Taken together, these results suggest a compensatory pathway is activated in VaD that inhibits Rac1-mediated oxidative stress and pro-apoptotic function. This pathway may be amenable to therapy for early intervention in VaD. In addition, we found that the histone acetyltransferase CREB-binding protein (CREBBP) was significantly upregulated in VaD samples (log fold change = 0.4, FDR adjusted $p < 0.02$). Network analysis revealed CREBBP to be a modulatory hub for several upregulated genes encoding core histones (e.g., H2, H4) and regulators of chromatin remodeling (e.g., SATB1), indicating that distinct epigenetic programs are activated in VaD compared to AD. These findings provide insight into the differential pathogenic mechanisms underlying the two most prevalent dementias. These differences could prove vital for driving dementia-specific treatments and prevention strategies.

Title: Generation of isogenic iPS cells to address the effects p25/Cdk5 activity on AD pathology

Authors: *J. SEO, Y.-T. LIN, R. MADABHUSHI, L.-H. TSAI;
Picower Inst. for Learning and Memory, Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Aberrant activity of cyclin-dependent kinase 5 (Cdk5) has been observed in Alzheimer’s disease (AD), and this is associated with increased p25, the proteolytic fragment of p35. Previously, we showed that the blockade of p25 generation attenuates AD pathological phenotypes including gliosis and synaptic dysfunction in 5XFAD mice. However, because of the lack of tauopathy phenotypes in most of AD mouse models harboring mutations in amyloid beta precursor protein (APP) or presenilin 1 (PSEN1) locus, and the biochemical and physiological differences between mouse models and humans, further investigation on the effects of p25 on

tauopathy and the beneficial effects of p25 inhibition on AD pathology in human systems are required. To address this, we take advantage of induced pluripotent stem cells (iPSCs) derived from fibroblasts of healthy donors or AD patients with the pathogenic M146I mutation or the deletion of exon 9 in PSEN1 locus. We first differentiated iPSCs to neural progenitor cells (NPCs), and observed more DNA damages and increased levels of histone deacetylase 2 (HDAC2) in NPCs harboring PSEN1 mutations compared to controls. To address whether inhibition of p25 generation is beneficial, we utilized the CRISPR/Cas9 genome editing tool to created isogenic lines in which the endogenous p35 is replaced with a cleavage-resistant p35. We also created isogeneic iPSC lines with PSEN1 mutations corrected. We are currently investigating neuronal differentiation, synaptic function and pathology exhibited by neurons derived from these multiple pairs of cells.

Title: Phosphorylation of FGF14 at S226 in the tg2675 mouse model of Alzheimer’s disease is rescued by PPAR-gamma agonist RSG

Authors: *W.-C. HSU[1], E. WOLD[2], A. OCON[2], S. ALI[3], N. PANOVA[3], J. HAIDACHER[4], L. DENNER[4], K. T. DINELEY[5], F. LAEZZA[3];
[2]Summer Undergraduate Res. Program, [3]Pharmacol., [4]Endocrinol., [5]Neurol., [1]UTMB Galveston, Galveston, TX

Abstract: Recent research has suggested that cognitive impairment associated with Alzheimer’s disease (AD) in humans, as well as Aβ pathology associated with animal models such as Tg2576 can be ameliorated with treatments that target the nuclear receptor peroxisome proliferator-activated receptor-gamma (PPAR-gamma), such as the PPAR-gamma agonist rosiglitazone (RSG). Previously, we have demonstrated that RSG treatment of the Tg2576 animal model normalizes hyperactivity of granule neurons in the dentate gyrus (DG), the brain area critical for memory formation, and rescues cognitive deficits. We now show through LC-MS/MS that phosphorylation of fibroblast growth factor 14 (FGF14), an accessory protein of the voltage-

gated Na+ complex (Nav) critical for neuronal firing, at S226 is reduced following treatment of Tg2576 mice with RSG. Using the split-luciferase assay to screen for FGF14:Nav1.6 complementation in recombinant cells treated with kinase inhibitors revealed that the effects of PKC and Wee1 inhibitors were abrogated by the phosphosilent mutation S226A. Pathway analysis suggests that PKC forms a PPAR-gamma-centered network of kinases sensitive to RSG. In total, these results suggest a novel role of FGF14 as a PPAR-gamma-sensitive target controlling Aβ-induced dysfunctions of neuronal activity of DG, leading to memory impairment in early AD.

Title: Ubiquitin specific protease (USP)-13 regulates Parkin function and modulates intracellular Aβ and extracellular plaque levels in AD models

Authors: ***M. HEBRON**, I. LONSKAYA, Y. FENG, M. IBA, C. MOUSSA;
Georgetown Univ., Washington, DC

Abstract: Parkin is an E3 ubiquitin ligase that tags specific protein substrates with ubiquitin and targets them for degradation. Parkin is usually auto-inhibited and inactive, but self-ubiquitination leads to Parkin activation, which can be regulated by de-ubiquitinases (DUBs). De-ubiquitination de-activates Parkin and may reduce its recognition by the proteasome, leading to accumulation of insoluble aggregates reminiscent of PD and AD pathologies. Our new data show increased USP13 levels (2-fold) in post-mortem AD and PD brains, along with increased insoluble Parkin levels. Cell culture studies show that USP13 over-expression de-ubiquitinates Parkin, leading to soluble and insoluble protein accumulation and decreased proteasome activity. Conversely, USP13 knockdown via shRNA reverses these effects. Lentiviral USP13 was injected into the hippocampus of 4-6 months old transgenic APP mice, harboring Swedish, Iowa and Dutch mutations (TgAPP). USP13 expression altered soluble and insoluble Parkin levels, suggesting regulation of Parkin stability, and thereby activity. USP13 overexpression reduced intracellular

Aβ42 but led to more plaque deposition, while USP13 knockdown via shRNA decreased both intracellular Aβ42 and extracellular plaques, suggesting that USP13 plays a role in intracellular degradation of Aβ42. Consistently, USP13 overexpression increased p-Tau, but USP13 shRNA reduced p-Tau levels. Taken together these data suggest that an increase in USP13 leads to Parkin de-ubiquitination, affecting its stability to facilitate intracellular Aβ42 and p-Tau clearance. These studies suggest that USP13 may be a drug target that regulates Parkin activity to induce autophagic protein clearance in neurodegenerative diseases.

Title: Aldehyde dehydrogenase 2 null mice as an oxidative stress-based model of cognitive impairment and sporadic Alzheimer’s disease that displays both neuronal and vascular pathologies

Authors: A. ELHARRAM, Y. D'SOUZA, R. D. ANDREW, *B. BENNETT;
Biomed. and Mol. Sci. and Ctr. for Neurosci. Studies, Queen's Univ., Kingston, ON, Canada

Abstract: The study of late-onset/age-related Alzheimer’s disease (AD)(sporadic AD, >95% of AD cases) has been hampered by a paucity of animal models. Oxidative stress is considered a causative factor in late onset/age-related AD, and aldehyde dehydrogenase 2 (ALDH2) is important for the catabolism of toxic aldehydes associated with oxidative stress. One such toxic aldehyde, the lipid peroxidation product 4-hydroxynonenal (HNE), accumulates in the brains of AD patients and is associated with AD pathology. Given this linkage, we hypothesized that in mice lacking ALDH2, there would be increases in HNE and the appearance of AD-like pathological changes. Accordingly, changes in relevant AD markers in Aldh2 null mice and their wildtype littermates were assessed over a 1 year period. Marked increases in HNE protein adducts arise in hippocampi from Aldh2 null mice as early as 3 months, and there were age-

related increases in amyloid-beta (Aβ), phospho-tau protein, and activated caspases 3 and 6. Also observed were age-related decreases in PSD95 and synaptophysin (indicating synaptic loss), pGSK3β, and total and phosphorylated CREB. Aldh2 null mice exhibit a graded, age-related decrease in performance in the novel object recognition and Y maze tasks beginning at 3 months and maximal at 6-7 months. There was decreased performance in the Morris Water Maze task in 6 month old Aldh2 null mice. Differences in locomotor activity and coordination, as well as behavioural phenotype using the open field test, balance beam and SHIRPA standardised battery were not observed, suggesting that diminished cognitive performance was the result of impaired memory and not due to confounding changes in motor function. These mice also exhibit dystrophic neurites and loss of dendritic spines, brain atrophy, defects in cholinergic agonist-induced CREB and ERK phosphorylation, endothelial dysfunction, increased monomeric and oligomeric Aβ in cerebral microvessels, and cerebral vascular microbleeds. Additionally, chronic administration of the novel nitrate, 4-methyl-5-(2-nitroxyethyl) thiazole, a neuroprotectant that targets synaptic failure via activation of NO/cGMP/pCREB signaling, or of the HNE scavenger, histidine hydrazide, reverses the progressive memory deficits and biochemical changes that occur in these mice. The presence of AD-like pathologies and the reversal of memory and biochemical deficits by pharmacological intervention suggests that Aldh2 null mice represent a new model of age-related cognitive impairment and sporadic AD that may prove useful both for assessing AD therapeutics and for gaining better insight into the pathogenesis of AD.

Title: The effects of metabolic syndrome in the brain structures and its implications in the pathogenesis of neurodegenerative disease

Authors: *L. PEREIRA[1], J. J. MELOT[1], E. CASTRO[2], C. M. MORÁN[3];
[1]Dept. of Anat. and Neurosci., San Juan Bautista Sch. of Med., Caguas, PR; [2]Biol., Univ. del Turabo, Gurabo, PR; [3]Biol., Univ. de Puerto Rico - Cayey, Cayey, PR

Abstract: Metabolic syndromes have been recently identified as a group of signs and symptoms that greatly increase the risk for many conditions later in life such as diabetes, cardiovascular diseases, and steatosis among others. Some of these metabolic changes, include insulin resistance

and high cholesterol, have been shown to cause defects in the neurochemistry and influence neurologic diseases such as Alzheimer's disease. Given that such metabolic disturbances might contribute to neurodegenerative disease, it opens up a novel field of study. Apolipoprotein E (ApoE) catabolizes lipids and cholesterol, and ε4 allele is associated to Alzheimer's disease. Objective: Identify brain structures directly affected by high fat diet (HFD)-induced metabolic syndrome and in genetically predisposed ApoE-/- mice. Methods: C57BL/6 wild-type and ApoE-/- mice were HFD (41% fat, 17% protein and 43% carbohydrate) fed for 12 weeks. All animals had a metabolic panel examination in order to quantify metabolic disturbances, and presented hyperlipidemia, hyperglycemia, glucose intolerance, and steatosis. Brains from mice were extracted. Two groups were examined: control (wild-type) and experimental (ApoE -/-). Sagittal sections of 8µm and H&E stained were prepared and neurologic comparisons were made between the groups. Results: In comparison with wildtype (Wt), ApoE-/- group had an increase number of xanthomas (lipid aggregates) within the cerebral cortex [Wt = 7 aggregates per field view (SD +/-2), ApoE-/- = 19 aggregates (SD +/-2]; and hippocampi [Wt = 10 aggregates per field view (SD +/-3), ApoE-/- = 37 aggregates (SD +/-2]. Increased number of immune cells concentrated within the brain blood vessels was observed. Remarkably, cerebellar changes were detected in ApoE-/- mice under HFD such as decreased number of Purkinje cells [Wt = 131 cells counted (SD +/-14), ApoE-/- = 62 cells (SD +/-2]; and reductions within the molecular layer length [Wt = 68.75 length (SD +/-4), ApoE-/- = 47.75 length (SD +/-6]. Conclusions: Lipid aggregations resemble the amyloid plaques found in Alzheimer's brains. These xanthomas may disrupt the neuronal signaling within the cerebrum. Linking metabolic alterations to the onset of neurodegenerative disorders, such as Alzheimer's disease, is an important scientific advancement. In the cerebellum, damage to Purkinje and molecular layers might lead to loss of body balance and posture, and degeneration of motor learning and gait. The overall outcomes of these studies will contribute to understand the impact of nutrition on the neuroanatomy and its potential consequences on cognition, motor functions and pathogenesis of neurological diseases.

Title: An insight on new roles of the proteasome complex on organelle axonal transport

Authors: *M. G. OTERO[1], T. M. M. SAEZ[2], M. ALLOATTI[1], L. E. CROMBERG[1], T. FALZONE[1,2];

Abstract: Axonal transport is the neuron mechanism that ensures the correct delivery and positioning of different organelles and vesicles. Impairments of the transport machinery at different levels have been associated with abnormal protein accumulation in Alzheimer disease (AD). The observation in AD of abnormal protein accumulation at confined intracellular regions of the neuron suggests local defect in protein degradation. The ubiquitin-proteasome system (UPS) is the major route for cytosolic protein degradation and proteasome distribution throughout the neuron is necessary for normal physiological neuronal functions and is abnormal in disease. We have recently demonstrated using a novel high spatial- and temporal-resolution analysis that proteasomes have 3 different motion regimes in axons. We described the active transport of proteasomes that is dependent on motor function and association of membrane organelles. These novel and important results position the axonal transport of the proteasome as a relevant intracelluar mechanism that can be impaired during the progression of neurodegenerative diseases. Here we tested a pathway to improve the axonal transport of proteasomes by the overexpression of the adaptor proteasome protein ECM29 that has affinities for proteasome, motor and membranes. In addition, the role of proteasome activity in the regulation of the axonal transport dynamics of other axonal cargos was tested in condition of short proteasome inhibitions with MG132. ECM29 overexpression is capable to improve the anterograde segmental velocities of proteasomes. Moreover, Proteasome inhibition revealed a great impact on transport dynamics inducing specific reduction in proportions and velocities of movement for different cargos. Taken together, our results reinforce the relevance of our recent demonstration of the axonal transport regimes that ensure the homogenous distribution of proteasomes in neurons and suggest that proteasome activity impacts on the regulation of the axonal transport dynamics. Interestingly, we propose a mechanism to improve the distal distribution of proteasomes in synapses that can be a novel mechanism to recover the local synaptic defects in protein degradation that have been described in neurodegenerative diseases such as AD.

Title: Streptozotocin-induced neurodegeneration involves NADPH oxidase activation

Authors: *K. G. RAVELLI, B. A. ROSÁRIO, M. S. HERNANDES, L. R. G. BRITTO; Dept. of Physiol. and Biophysics of the Inst. of Biomed. Sci., Univ. of São Paulo, São Paulo, Brazil

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by the progressive loss of memory, disordered cognitive function, decline of the language function, and behavioral changes, including paranoia, delusions and loss of social adequacy. The neuronal degeneration in the nervous system of patients with AD has been linked to oxidative damage to several types of biomolecules. Some studies have suggested the involvement of NADPH oxidase (Nox), a multisubunit enzyme that catalyzes the reduction of oxygen, in the physiopathology of neurodegenerative diseases. The main purpose of this study was to investigate the involvement of NADPH oxidase in memory, inflammation and neuronal death in the hippocampus in the streptozotocin(STZ)-induced AD mouse model by comparing the effects of that drug on mice lacking gp91phox-/-, the catalytic subunit of Nox2, and wild type mice (C57BL/6). The AD-like condition was induced by intracerebroventricular stereotaxic injections of streptozotocin in male mice (25-30g) (Committee for Ethics in Research no 098/2012). In control animals we injected citrate buffer. The animals were subjected to behavioral testing or were euthanized for analysis 14 days after the surgery. In addition to the behavioral analysis, using the object recognition test, immunoblotting techniques were used to determine the protein expression of astrocyte and microglia markers and caspase-3, and immunohistochemical methods were used to assess the activation of astrocytes and microglia in the CA1 and CA3 areas of the hippocampus. Wild-type animals injected with STZ showed a reduction of 26% and 29% in the short and long term memories, respectively. Furthermore, they showed increased expression of astrocyte markers (58%), microglial markers (76%) and caspase-3 (690%). The increased expression of astrocyte and microglia markers occurred in both hippocampal regions studied. The knockout mice treated with STZ showed no change in any of those analyses, when compared to the respective control group. These data suggest that NOX2 - mediated oxidative stress contributes to neurodegeneration that occurs in AD, since the knockout animals showed a resistance to STZ-induced processes in the nervous system.

Title: Small Rho GTPases affect production and localization of Alzheimer's disease proteins: APP, Aβ, and Tau

Authors: ***R. CHABAYTA**, P. MODY, J. REDDY, D. L. HYNDS;
Texas Woman's Univ., Denton, TX

Abstract: Alzheimer's disease (AD) is a fatal neurodegenerative disorder that is histopathologically characterized by the formation of amyloid plaques and neurofibrillary tangles in the brain. Aberrant cleavage of the amyloid precursor protein (APP), a transmembrane protein, produces beta amyloid plaques. hyperphosphorylation of a microtubule associated protein, tau, forms the neurofibrillary tangles. Defects in the Rho family GTPases (small guanosine triphosphatases) signaling pathways have been implicated in many neurological diseases, including Alzheimer Disease. Rho proteins (Rho, Rac, Cdc42) regulate a wide variety of cellular functions and play key roles in actin cytoskeletal rearrangements. In this study, we determined the effects of manipulating activity of the Rho GTPases, Rho, Rac, Cdc42, on the production of Alzheimer's disease proteins. For that purpose, B-35 cells were treated with the Rho GTPase inhibitors and activators. The levels of APP, Aβ, and tau were determined by western blotting and immunocytochemistry. Toxin A, a Rho/Rac/Cdc42 inhibitor, increased the levels of Aβ and tau as expected and decreased the levels of APP. Rho inhibitor I and Rho/Rac/Cdc42 activator treatments significantly decreased APP levels, but increased the high and low molecular weight levels of tau. Rac I Inhibitor II decreased the levels of APP, suggesting that disruption or manipulation of Rho GTPases affect APP, Aβ, and tau production. To further investigate the role of Rac in AD pathology, cytosolic and membrane lysates from cells transfected with EmGFP (without Rac1), EmGFP-Rac1 and EmGFP-Rac1^{C196A} were used to detect changes in APP and tau levels in the cytosol and at the membrane. High molecular weight of APP increased and tau

levels decreased in the cytosol when transfected with EmGFP-Rac1 and EmGFP-Rac1C196A. While low molecular weight of APP decreased in the cytosol only when transfected with EmGFP-Rac1. Our data support a role for Rho GTPases in the classic hallmarks of AD pathology and suggest targeting Rac as a possible AD therapy.

Title: Kir6.2 is increased in astrocytes of the 3xtg mouse hippocampus

Authors: ***C. M. GRIFFITH**[1,3], A. A. SHARP[1,2,3], X. X. YAN[4], P. R. PATRYLO[1,2,3]; [1]Physiol., [2]Anat., Southern Illinois Univ. Sch. of Med., Carbondale, IL; [3]Ctr. for Integrated Res. in Cognitive and Neural Sci., Southern Illinois Univ., Carbondale, IL; [4]Anat. and Neurobio., Central South Univ. of Xiangya Sch. of Med., Changsha, China

Abstract: KATP channels are inwardly rectifying potassium channels composed of 4 pore-forming subunits (Kir6.1 or Kir6.2) and 4 sulphonylurea regulatory subunits (SUR1, SUR2A, or SUR2B). These channels couple neuronal activity with metabolism. One of the hallmarks of Alzheimer’s disease (AD) is brain hypometabolism and recent data (Liu et al. JAD, 2010) show that treating the 3xTg mouse model of AD with diazoxide (a KATP channel agonist) improves memory and reduces β-amyloid plaques and neurofibrillary tangles. Whether AD is associated with a change in KATP channels is unknown. To test this hypothesis we examined Kir6.1 and Kir6.2 in the hippocampi of aged male 3xTg and C57/129 control mice using western blots and immunohistochemistry. For immunoblots, the plasma membrane fraction was separated from total membrane using differential centrifugation. Protein concentrations were determined using the Bradford assay and 50µg were loaded on 10% SDS-Page gels, transferred to PVDF membranes and probed for Kir6.1 or Kir6.2. Appropriate secondary antibodies were used for densitometric quantification of protein bands using the Odyssey Licor system. This revealed no change in total or plasma membrane Kir6.1 but a significant increase in plasma membrane Kir6.2

(wild type NOD = 1 ± 0.06 n = 12, 3xTg NOD = 1.60 ± 0.24, n = 11; $p < 0.05$ student's t-test). To then assess regional and cell specific differences in Kir6.2, immunohistochemistry was used. Mice were perfused intracardially with 4% paraformaldehyde, brains were extracted, post-fixed overnight and cryoprotected in 30% sucrose. 30µm coronal sections were then processed for DAB staining or immunofluorescence. DAB staining was done via normal procedures. Immunoreactive product (IR) was visualized using 0.003% H2O2 and 0.05% DAB. This revealed an increase in Kir6.2 IR in "presumptive astrocytes" in 3xTg mice. To verify the localization of Kir6.2 in astrocytes and semi-quantify astrocytic and neuronal Kir6.2 IR triple immunofluorescence was used. Sections were blocked for 1 hour in 5% rabbit serum in PBS and then incubated in primary antibody overnight with an appropriate secondary used for Kir6.2 visualization. Immunofluorescence confirmed that Kir6.2 was present in GFAP-IR astrocytes. While the physiological consequences of an increase in Kir6.2 expression in reactive astrocytes is unclear, it is possible that this change could affect K+ and glutamate buffering. Future electrophysiology experiments will be used to assess these possibilities.

Title: Reduction of Alzheimer's disease beta-amyloid pathology in the absence of gut microbiota

Authors: *T. HARACH;
EPFL STI IMT LOB, EPFL, Lausanne, Switzerland

Abstract: Alzheimer's disease (AD) is the leading cause of dementia in western societies that features tremendous societal and personal cost and burden. To date, there is no early diagnosis or cure for this devastating neurodegenerative disorder. Gastro-intestinal microbiota is an essential factor to many physiological processes including nutrition, inflammation, vitamins synthesis, drug processing, but also defense against pathogens. A growing body of evidence suggests that gastro-intestinal microbiota impacts on brain disorders such as autism and Parkinson's disease. However, the role of the intestinal microbiota in AD has never been investigated. Our preclinical results using axenic mouse models of AD indicate that gastro-intestinal microbiota is involved in

the development of AD and supports the view that neurodegenerative disorders may be tackled by gastro-intestinal modulation.

Title: Decline in central cholinergic activity alters central and peripheral immune response

Authors: *B. KORIN[1], T. BEN-SHAANAN[1], H. AZULAY-DEBBY[1], F. HAKIM[2], A. ROLLS[1];
[1]Immunol., Technion, Haifa, Israel; [2]Pediatric Pulmonary Unit, Rambam Hlth. Care Campus, Haifa, Israel

Abstract: The tight link between Alzheimer's disease (AD) and aging suggests that processes occurring in the aging brain promote AD initiation and progression. Understanding the transition from normal aging to AD pathology is crucial for early detection, prevention and treatment of the disease. Studies suggest that the immune system is involved in this process, as activated immune cells, including microglia/macrophages, are evident in diseased brains. Others argue that these immune cells act to restore tissue homeostasis, activated in response to the age-related changes in the neural tissue. Among those changes is the decrease in cholinergic activity and shrinkage of cholinergic neurons in the basal forebrain (BF). Previous lesion-based studies linked the activity of BF cholinergic neurons with immune changes, however, this research direction is very limited. We utilized the newly developed engineered GPCRs (DREADDs), to specifically attenuate the activity of these neurons in mice, simulating the decline in their activity with age. Subsequently, we characterized the effects of this neuronal manipulation on the immune system. Using high-throughput analysis of the immune system, we discovered that inhibition of BF cholinergic neurons activity resulted in significant changes in monocytes/macrophages phenotype and phagocytic activity in the periphery and changes in monocytes/microglia activity in the brain. Taken together, we establish a new experimental paradigm to study the effects of BF cholinergic neurons activity on aging and AD, and demonstrate that changes in the cholinergic activity of the brain can affect the peripheral and central immune response.

Title: Neuronal cell cycle re-entry and mTOR: how insulin resistance promotes Alzheimer's disease

Authors: A. NORAMBUENA[1], H. WALLRABE[1], L. MCMAHON[1], E. SWANSON[1], S. THOMAS[1], D. BAERTHLEIN[1], A. SILVA[1], E. KODIS[1], J. W. MANDELL[1], S. ODDO[2,3], *G. S. BLOOM[1];
[1]Univ. of Virginia, Charlottesville, VA; [2]Banner Sun Hlth. Res. Inst., Sun City, AZ; [3]Univ. of Arizona Col. of Med., Phienix, AZ

Abstract: Brain insulin resistance is a characteristic feature of Alzheimer's disease (AD), but how it leads to specific AD phenotypes has not been determined. Mechanistic target of rapamycin (mTOR), a protein kinase subunit of the mTORC1 and mTORC2 multiprotein complexes, plays a major role in cell proliferation, and is hyperactivated in AD. Insoluble aggregates of amyloid-β (Aβ) and tau respectively accumulate as plaques and tangles in AD brain, where ectopic neuronal cell cycle re-entry (CCR) leads to massive neuron death, which along with synaptic dysfunction, underlies memory and cognitive loss. We previously showed that CCR entails soluble Aβ oligomers (AβOs) activating fyn, PKA and CaMKII, which respectively phosphorylate soluble tau at Y18, S409 and S416. Now we report that Rac1-mediated mTOR dysregulation is also essential for AβO-induced CCR, which furthermore is insulin-sensitive. Inhibition or reduction of mTORC1, mTORC2 or Rac1 in cultured neurons

blocks AβO-induced CCR, which requires mTORC1-dependent tau phosphorylation at S262. In human brain, plaques and tangles strongly correlate with CCR, and with tau phosphorylation at S262, S409 and S416. CCR can be prevented in cultured neurons by reducing Rac1-dependent targeting of mTOR to the plasma membrane, forcing mTORC1 onto lysosomes, knocking down the lysosomal mTORC1 inhibitors, Nprl3 or Tsc2, or by insulin, which activates mTORC1 at lysosomes to inhibit autophagy. In AD model mice, genetic reduction of mTOR suppresses CCR and tau phosphorylation at S262, the latter of which is also reduced by rapamycin. Collectively, the data presented here establish mTORC1 activation at the plasma membrane, but not at lysosomes, as essential for AβO-induced, tau-dependent CCR. Because AβOs also trigger insulin resistance in AD, the new data suggest that AβOs dysregulate mTOR signaling by promoting mTORC1 activation at the PM while preventing insulin from stimulating mTORC1 at lysosomes. These dual effects of AβOs provide a mechanistic explanation at the cell biological level for classifying AD as type 3, or brain-specific, diabetes.

Title: 17 KDa and 23 KDa FGF-2 affect astrocyte proliferation and survival differentially

Authors: *Y. CHENG[1], Z. LI[2], P. Y. LOH[2];
[1]Developmental Neurobio., [2]NIH/NICHD, Bethesda, MD

Abstract: Astrocytes are the most abundant type of glial cells in the brain, and they play a key role in Alzheimer’s disease (AD). Amyloid beta (Aβ) toxicity is thought to be the cause of neuronal death and astrocyte dysfunction in AD brain. In the present study, we investigated the protective effects of low molecular weight (17 KDa) and high molecular weight (23 KDa) Fibroblast Growth Factor-2 (FGF-2) on Aβ-induced toxicity, and also the effects of FGF2 on astrocyte proliferation. Our results demonstrated that both isoforms of purified recombinant

FGF-2 had similar protective effects against Aβ1-42 induced toxicity in hippocampal neurons and cortical astrocytes as measured by LDH release assay. We then showed that the low molecular weight FGF-2 significantly promoted astrocyte proliferation as measured by Trypan Blue and DRAQ5 staining. In contrast, the high molecular weight FGF-2 did not have a significant effect on astrocyte proliferation. Furthermore, results from western blot suggested that both forms of FGF-2 activated ERK and AKT in a similar way within 30 min in astrocytes. Using specific inhibitors, we found that AKT signaling pathway but not ERK signaling pathway was required for the protective effects of FGF-2. Taken together, our findings revealed differential effects of 23 kDa and 17 kDa isoforms of FGF-2 on neuron/glial cell protection against Aβ toxicity and astrocyte proliferation, thus providing important information in tailoring the forms of FGF-2 to use as a potential therapeutic agent for treatment of AD.

Title: Sex biases in susceptibility and severity of neurological disorders

Authors: *R. S. NOWAKOWSKI, J. L. BUNDY, C. M. VIED;
Biomed. Sci., FSU Col. of Med., Tallahassee, FL

Abstract: Sex differences in the brain are critical to understanding multiple neurological and behavioral disorders that differentially affect males and females, such as autism and Schizophrenia (more common in males), Alzheimer’s Disease and depression (more common in females). We generated transcriptomic data from the mouse hippocampus of six inbred strains of mice (129S1/SvImJ, A/J, C57BL/6J, DBA/1J, DBA/2J and PWD/Ph) that provide a novel and deep perspective on the issue of differences between males and females. Our data show that: 1) gene expression in male versus female mouse brains varies significantly, 2) there are 12 core genes that are differentially expressed across a diverse set of inbred strains, and 3) there are >2,500 non-core differentially expressed genes (DEGs) that vary from one inbred strain to another. To examine the diversity between the six strains, we categorized the DEGs in each strain according to sex-biased expression (a gene that is more highly expressed in males or

females). This analysis shows that DBA/2J is unique in having a majority of DEGs that are higher in females than in males, with 89% of all DEGs being female-biased. 129 is strongly male-biased, 69% of DEGs are more highly expressed in males. C57BL/6J and A/J are slightly male-biased. This diversity in sex-biased expression indicates that different genetic controls exist that regulate sex differences. This is significant and exciting because the existence of the non-core DEGs provides a basis for a mechanism to explain sex biases in disease susceptibility and severity. To gain insight into the function of the sex-biased DEGs, we have examined gene ontology (GO), pathway and phenotype enrichment. When analyzing all of the non-core DEGs from the six strains we found significant enrichment in phenotypes related to abnormal nervous system morphology and physiology, among others. In addition, several pathways were enriched significantly in the list of DEGs. Of particular interest was Alzheimer's disease (AD) enrichment, with 32 genes implicated in AD. Separate analysis of the male-biased and female-biased DEGs showed that 24 of the genes related to AD were female-biased and 8 were male-biased. Three of the male-biased genes have been implicated in a neuroprotective role in AD. These data suggest a genetic basis for the female-bias in AD that is independent of female longevity. To further elucidate the sex bias in AD we have, in progress, a transcriptomic analysis in an AD mouse model (5XFAD; Familial Alzheimer's Disease). Taken together, our transcriptomic data provides new insight into understanding the possible genetic bases for sex-specific susceptibility and severity of brain disorders.

Title: miR-146a dysregulates mitochondrial function and glycolysis

Authors: *S. JUN, S. N. SARKAR, J. W. SIMPKINS;
Physiol. and Pharmacol., West Virginia Univ. Hlth. Sci. Ctr., Morgantown, WV

Abstract: Mitochondrial dysfunction is associated with the aging process and with the pathogenesis of a variety of disorders such as metabolic syndrome and neurodegenerative diseases including Alzheimer's disease. MicroRNAs (miRNAs) are endogenous small RNAs of 21-25 nucleotides that post-transcriptionally regulate various gene expressions. Interestingly, miRNAs can modulate mitochondrial activity, and a discrete miR set has recently been identified in mitochondria of different species and cell types (mitomiRs) . Also, Ingenuity Pathway Analysis (IPA) of aging-related mitomiR targets has disclosed a number of resident mitochondrial proteins playing large roles in energy metabolism, mitochondrial transport and apoptosis. Among them, miR-146a, miR-34a, and miR-181a are involved in important cell functions (growth, proliferation, death, survival, maintenance) and age-related diseases. Furthermore, miR-146a was found to be significantly up-regulated in the temporal cortices of patients with AD. It was shown to function in the AD inflammatory and oxidative stress pathways, as it was shown to be up-regulated by NF-κB in response to Aβ42 in cultured human neuronal glial cells. However, the impact of miR-146a on mitochondrial function and glucose metabolism has not been analyzed. Since a single microRNA (miRNA) is capable of deregulating many genes' function, we hypothesized that increased miR-146a by Aβ may influence mitochondrial function and glucose metabolism, especially glycolysis through regulating multiple target proteins involved in these process in AD. We found that the level of miR-146a was significantly associated with Braak stage not only in temporal cortex but also in frontal cortex and cerebellum of AD patients. Through bioinformatic analysis study, we identified 4 putative target genes related to mitochondrial electron transport chain as well as 2 glycolysis related genes. Furthermore, overexpression of miR-146a significantly decreased ATP production, spare capacity, and maximum respiration measured in rat primary glial cell, and also significantly decreased glical glycolysis and glycolytic reserve that was measured by Seahorse assay. Our results indicate that increased level of miR-146a in brain cells may play a direct role in controlling mitochondrial function and energy metabolism by regulating mitochondrial protein expression as well as proteins regulating glycolysis. The modulation of miR-146a could thus mediate the loss of mitochondrial integrity and function in aging cells, inducing or contributing to the inflammatory response and to age-related diseases especially in AD.

Title: The relationship between proteasome activity and changes in cellular levels of atp in a *Drosophila* model of Alzheimer's disease

Authors: *T. SCHMIDT-GLENEWINKEL[1,2], M. JANSEN[1], A. RASHID[1], J. NETHERCOTT[1], I. ONYEJIUKWA[1], S. BENNETT[1], A. KLEIN[1];

Abstract: Many neurodegenerative diseases are associated with the formation of protein aggregates. The accumulation of aggregated proteins in form of neurofibrillary tangles and senile plaques in Alzheimer disease (AD) suggests that inability to turnover or degrade certain proteins might be a key factor in the etiology of certain neurodegenerative disorders, like Alzheimer disease. Degradation of most proteins is normally carried out via ubiquitination followed by degradation by the proteasome. Impairment of the ubiquitin proteasome pathway (UPP) may therefore be a contributing factor in the etiology of neurodegeneration. Several lines of evidence suggest that declining ATP levels as a consequence of deteriorating mitochondrial function may be relevant to the pathology of neurodegenerative diseases. To investigate the role between energy metabolism and proteasome function we will use the inducible GeneSwitch system to inhibit specific enzymes in energy metabolism via RNAi. Using the GeneSwitch system we also explore the relationship between impaired ATP synthesis and protein aggregation in a fly model of Alzheimer Disease. This approach allows us to study the interaction between reduced energy metabolism, reduced proteasome activity, and protein aggregation.

Title: Preliminary investigation on the antidepressive effect of chronic oxotremorine treatment in a rodent model of Alzheimer's disease

Authors: *D. V. NAIR, M. M. AL-BADRI, H. PENG, J. PACHECO-QUINTO, C. B. ECKMAN, D. IACONO, E. A. ECKMAN;

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disease and the rate of progression varies from individual to individual. A great deal of evidence supports the idea that depression and other neuropsychiatric conditions co-exist with cognitive decline. However, the neurobiological basis of these symptoms and their influence on the clinical course of AD remain unclear. Our lab has shown previously that the 192-IgG saporin rat model of AD-like basal forebrain cholinergic cell loss exhibits a depression-like phenotype that develops months after the well-described impairment in spatial working memory. Furthermore, we have shown that chronic intracerebroventricular administration of the muscarinic agonist oxotremorine reverses both spatial working memory deficits and the depression-like behavior triggered by cholinergic denervation, and induces hippocampal neurogenesis. Current experiments are focused on determining additional pathological correlates of depression in this model and how they may be modulated by muscarinic agonists. To induce AD-like basal forebrain cholinergic cell loss, adult female Sprague Dawley rats were injected intracerebroventricularly (icv) with the immunotoxin 192-IgG-saporin (SAP) or saline as control (SHAM). After a 5 week recovery period, the rats received either 2 or 6 weeks of icv infusion of either oxotremorine or vehicle (saline) via osmotic minipump. Behavioral testing to assess the depressive phenotype was carried out using the sucrose consumption test every 2 weeks during oxotremorine treatment. The phenotype was further confirmed by forced swim test. The levels of ChAT, tryptophan hydroxylase (TPH), muscarinic receptors and FosB and ΔFosB were assessed in the hippocampus, basal forebrain, and orbitofrontal cortex by western blot and immunohistochemistry. Our preliminary results show increases in TPH, M1 receptors and FosB in the hippocampus, basal forebrain, and orbitofrontal cortex of a subset of treated animals, but no changes ChAT or ΔFosB. Further experiments are in progress to determine if there are changes in the expression of these and additional proteins in other brain regions including the nucleus accumbens, an area involved in activational aspects of motivation which also contributes to behavioral disorders such as to depression. The results of these studies may provide new insight in understanding the molecular basis of depression and antidepressant action of oxotremorine thereby defining new targets for possible therapeutic intervention for depressive symptoms in AD.

Title: Impaired alpha synuclein membrane interaction promotes aggregation and neurotoxicity in Parkinson's disease

Authors: *D. YSSELSTEIN[1], M. JOSHI[1], V. MISHRA[1], A. M. GRIGGS[1], G. P. MCCABE[2], L. A. STANCIU[3], C. B. POST[1], J.-C. ROCHET[1];

Abstract: Oligomerization of the protein alpha-synuclein (aSyn) is a critical factor in the onset of both genetic and sporadic Parkinson's disease (PD). In healthy individuals aSyn exists in a number of conformations, including a membrane-bound state which displays resistance to aggregation. How this aggregation-resistant state is altered is significant in PD research as a better understanding of the events that initiate aSyn aggregation is critical for designing neuroprotective strategies. We hypothesize that disruption of interactions between aSyn and phospholipid membranes leads to a shift to a conformation which is more susceptible to the formation of neurotoxic aSyn oligomers due to exposure of the central hydrophobic NAC region. Therefore, stabilization of membrane bound aSyn should prevent membrane-induced aggregation and alleviate aSyn neurotoxicity. We generated aSyn variants predicted to disrupt aSyn-membrane interactions including the genetic mutants A30P and G51D and a designed variant A29E. We characterized the variants' association with synthetic phospholipid vesicles and their ability to undergo membrane-induced aggregation. Dopaminergic neurotoxicity was examined using adenoviral-mediated expression in a primary midbrain culture model system. To examine

the potential protective effects of stabilization of aSyn-membrane interactions, we investigated the impact of endosulphine alpha (ENSA), a protein found to interact with membrane-bound aSyn, on membrane-induced aSyn aggregation and aSyn neurotoxicity. We found that the familial mutants A30P and G51D displayed increased exposure of the NAC region at the membrane surface, and this effect correlated with enhanced accumulation of potentially toxic, SDS-resistant aggregates at the membrane. Although A29E adopted a similar exposed conformation, this variant had a reduced propensity to undergo membrane-induced aggregation and also did not elicit neurotoxicity. Upon co-incubating aSyn with ENSA in the presence of vesicles, we observed a reduction in membrane-induced aggregation of A30P and G51D aSyn. Co-expression of ENSA with A30P in primary midbrain cultures rescued A30P-induced dopaminergic toxicity. Our findings suggest a novel therapeutic strategy to prevent formation of neurotoxic aSyn aggregates through stabilizing membrane-bound aSyn. These results have led us to initiate a search for "membrane stabilizers" of aSyn via high-throughput screening. We have identified several exciting leads that inhibit membrane-induced aggregation. These membrane stabilizers could be a powerful tool to examine how membrane-induced aggregation plays a role in aSyn neurotoxicity.

Title: Reduced cytosolic calcium caused by SERCA activation is an early and pathogenic event in the cellular stress caused by alpha-synuclein oligomers

Authors: *C. BETZER[1], L. BERKHOUDT LASSEN[1], M. BRINI[3], T. CALI[3], A. OLSEN[2], W.-P. GAI[4], J. ANDERSEN[1], P. JENSEN[1];

Abstract: Accumulation of aggregated alpha-synuclein (AS) in degenerating neurons in Parkinson's disease (PD) represents the patho-anatomical hallmark. Epidemiological studies demonstrate a protective effect of brain penetrating calcium channel antagonists against development of sporadic PD in patients treated for hypertension, suggesting that aggregated AS leads to alterations in calcium homeostasis. We analyzed the cellular calcium levels in cell based models of AS aggregation dependent degeneration. The cytosolic calcium levels were measured in live cells by use of Fura-2 and high-content-fluorescence microscopy. The cell lines used were differentiated human neuroblastoma cells, rat oligodendroglia cells, and primary mouse hippocampal neurons. Measurement of cytosolic calcium in these cell models revealed an early decrease and a later increase in cellular calcium when degeneration occurs. Endoplasmic calcium ATPase, SERCA plays a critical role in maintaining normal cytosolic calcium by pumping excess cytosolic calcium into the endoplasmic reticulum. We demonstrate that soluble AS oligomers, in contrast to monomers, bind SERCA and activate the pump as measured *in vitro* by increased ATPase activity and transport of calcium. We hypothesize that the increased ATPase activity causes the early decrease in cellular calcium level in our cell models. To test this, we treated the cells with low doses of a reversible SERCA inhibitor, cyclopiazonic acid (CPA). This treatment normalized both the initial reduction in cellular calcium, but also the later increase, suggesting that there is a direct link between the two phenomena. Furthermore, we found that CPA treatment improved the viability in the cell based models, strengthening our hypothesis that the early decreased cellular calcium is harmful and if untreated will lead to increased cellular calcium and cellular degeneration. In conclusion, decreased cytosolic calcium is an early disease-propagating event in the course of AS oligomer cytotoxicity that can be pharmacologically targeted by inhibitors of SERCA and represents a novel therapeutic strategy to be tested in synucleinopathies like PD, multiple system atrophy, and dementia with lewy bodies.

Title: The hyperpolarization-activated current as a determinant of selective nigrostriatal degeneration in Parkinson's disease

Authors: *G. MANNAIONI, R. NARDUCCI, F. RESTA, C. CARBONE, G. PROVENSI, A. COSTA, A. MASI;
Univ. of Florence, Firenze, Italy

Abstract: Parkinson's Disease (PD) is caused by massive, selective degeneration of dopaminergic (DA) neurons in the Substantia Nigra pars compacta (SNc). In contrast, DA neurons in the neighbouring Ventral Tegmental Area (VTA) are much less affected. The bases of this peculiar aspect of the disease are still unclear, as the two populations share all the neurochemical and biophysical properties deemed critical in PD pathogenesis. Increasing evidence suggests that a complex SNc-specific interplay of pathogenic determinants, rather than individual factors, underlies selective vulnerability. We recently demonstrated that MPP+, a neurotoxin able to cause selective nigrostriatal degeneration in rodents and primates, alters the electrophysiological properties of SNc DA neurons *in vitro* by inhibiting the Hyperpolarization-activated current (Ih). In midbrain DA neurons from TH-GFP mice, we found that pharmacological suppression of Ih increases the amplitude and duration of evoked Excitatory Post-Synaptic Potentials (EPSP). Moreover, Ih suppression leads to temporal summation of multiple EPSPs, a result of the impaired ability to resolve individual excitatory synaptic inputs at somatic level. The extent of this response depends on postsynaptic Ih magnitude and is significantly greater in SNc compared to VTA DA neurons. These results indicate that Ih regulates dendritic excitability differentially within midbrain DA neurons and suggest that differential impact of MPP+-mediated Ih suppression may underlie selective vulnerability. In this respect, we have obtained preliminary experimental evidence that intranigral injection of Ih blockers recapitulates the DA degeneration pattern generated by MPP+. Overall, these findings support the hypothesis that Ih loss of function, possibly caused by PD-trigger mechanisms such as mitochondrial failure and oxidative stress, may act in concert with SNc-specific synaptic connectivity to promote selective vulnerability.

Abstract: The factors leading to onset of Parkinson's disease (PD) are unknown, although there is strong evidence linking environmental toxins and genetic factors to individual susceptibility. Zinc dimethyldithiocarbamate (ziram), a widely used fungicide, has been shown to increase the risk of PD in exposed farm workers and nearby residents (Wang et al. 2011). We previously found that mammalian neurons in primary culture display an increase in the frequency of miniature EPSCs and IPSCs following acute exposure to ziram. As ziram has been found to directly inhibit E1 ubiquitin activating enzyme, and thus indirectly the 20S proteasome, we examined whether other pesticides with links to PD or the ubiquitin signaling system could cause similar changes in synaptic transmission. Amongst the tested compounds, Maneb, also a dithiocarbamate, had effects similar to ziram and appeared to disrupt the E1 enzyme. We examined the intrinsic excitability of neurons acutely exposed to ziram and discovered changes in neuronal firing patterns and excitability. Intriguingly, using the *Drosophila* NMJ as a model, we found that aminergic neurons - which may be susceptible in PD - respond differently to ziram than do glutamatergic neurons. Our findings demonstrate that exposure to this class of drug causes robust changes in synaptic transmission, leading to neuronal dysfunction and possibly excitotoxicity.

Title: Glycosylation of synaptic vesicle glycoprotein 2C (SV2C) affects vesicular packaging of dopamine

Authors: *K. STOUT[1], M. OZAWA[2], A. DUNN[2], C. HOFFMAN[2], M. WANG[2], G. MILLER[2]; [1]Envrn. Hlth., [2]Emory Univ., Atlanta, GA

Abstract: An isoform of the synaptic vesicle glycoprotein 2 (SV2A, B, or C) localizes to every neurosecretory vesicle. Though the exact function of these proteins remains unclear, it is postulated that they stabilize neurotransmitter packaging via chemiosmotic stabilization, a process in which glycan chains on the intraluminal loop bind neurotransmitter. This interaction is thought to reduce the neurotransmitter concentration gradient and allow increased vesicle packaging. While SV2A and B are ubiquitously expressed throughout the brain, SV2C has a distinct basal ganglia expression and co-localizes strongly with tyrosine hydroxylase, the rate-limiting enzyme of dopamine synthesis. Given these data, we hypothesized that glycosylation of SV2C increases vesicular packaging of dopamine. To address this hypothesis, we generated site-directed mutants of each of the five N-glycosylation sites of SV2C and expressed them in human embryonic kidney (HEK) cells. We thoroughly characterized glycosylation via western blotting and immunocytochemistry. As certain forms of glycosylation are indispensible for protein trafficking, we visualized protein localization via total internal reflection fluorescence microscopy of immunolabelled cells. No individual glycan mutation affected protein localization. To address the functional changes of the mutated proteins we used false fluorescent neurotransmitter 206 (FFN206). FFN206 is a pH-sensitive fluorophore with affinity for the vesicular monoamine transporter 2 (VMAT2). HEK cells stably expressing human VMAT2 were transfected with pcDNA, SV2C, or site-directed mutants and the resulting uptake of FFN206 measured. Fluorescence experiments were confirmed with radioactive dopamine uptake assays. These data provide the first evidence of SV2C induced modulation of dopamine packaging.

Title: SSAO/VAP-1 is altered in Parkinson's disease: possible role of the vascular system

Authors: ***M. SOLE**[1], M. UNZETA[1], T. VALENTE[2];
[1]Inst. de Neurociences/Universitat Autonoma de Barcelona, Cerdanyola del Valles, Spain;
[2]Dptm. Cerebral Ischemia and Neurodegeneration. Inst. of Biomed. Res. of Barcelona (IIBB)-Spanish Natl. Res. Council (CSIC). Inst. d'Investigacions Biomèdiques August-Pi i Sunyer (IDIBAPS), Barcelona, Spain

Abstract: Increasing evidences suggest that cerebrovascular system dysfunction may play a role in the onset and progression of neurological diseases. Semicarbazide-sensitive amine oxidase (SSAO) is an enzyme highly expressed in brain vasculature and also released into blood. Its expression and activity are altered in neuropathological conditions, in which progression it is believed to contribute by releasing toxic products through its catalytic activity (Solé et al., Biochim Biophys Acta 2008), and by promoting the leukocytes binding and transmigration to inflamed tissues, acting as vascular adhesion protein 1 (VAP-1) (Jalkanen and Salmi, Blood 2007). Actually, an increase of its soluble plasmatic form is observed in multiple sclerosis (MS) (Airas et al., J Neuroimmunol 2006), in stroke, where it predicts the neurological outcome (Hernandez-Guillamon et al., Stroke 2010; Hernandez-Guillamon & Solé et al., Cerebrovasc Dis 2011), and in severe Alzheimer's disease (AD) (del Mar Hernandez et al., Neurosci Lett 2005), where it reflects the elevated membrane-bound form (Ferrer et al., Neurosci Lett 2002). Some pathological markers are shared among neurodegenerative diseases, and there is nowadays a great interest in identifying them for therapeutic purposes. In this regard, it is known that Parkinson's disease (PD) patients have vascular risk factors and display cerebrovascular abnormalities including microbleeds and white matter lesions, which is classified as vascular parkinsonism (VP) (Korczyn, Nat Rev Neurol 2015). These evidences suggest that vascular lesions can contribute to cognitive impairment in PD. However, this is a poorly studied issue, and precise changes in blood vessels have not yet been described in detail. In addition, there exists a clear inflammatory component in PD including peripheral immune cell infiltration (Chao et al., Biomed Res Int 2014). Therefore, our objective has been to determine the levels of SSAO/VAP-1 expression and activity in samples from PD patients in order to evaluate it as possible biomarker, pathologic mechanism and/or therapeutic target overlapping between several neurological disorders. We have observed an altered expression of SSAO/VAP-1 in different brain regions of PD patients compared to control samples. These results suggest the involvement of the vascular system in PD, although more studies should be performed to determine if this is a consequence of the neurodegeneration (cerebrovascular dysfunctions and/or pathologic

alterations in the blood-brain barrier) or could also contribute to the disease progression. These results will allow designing new SSAO inhibitors for therapeutic purposes.

Abstract: A feature common to many neurodegenerative diseases is the disruption of protein homeostasis. HSP90 co-chaperone complexes stabilize protein interactions in many cells and adapt to different signaling events during disease progression. However, changes in protein homeostasis during early neurodegenerative events have not been elucidated. Neurons differentiated from induced pluripotent stem cells (iPSCs) make it possible to directly examine the cells involved in neurodegenerative diseases. Here, we leverage iPSC technology and chemical tools to investigate how HSP90 complexes could propagate Parkinsonian-relevant signaling cascades. We examine global HSP90 complex changes in iPSC-derived midbrain neurons in response to Parkinson's-relevant stress. We identified HSP90 complex alterations that resulted in increased oxidative stress and neurodegeneration. Hsp90 inhibition partially reversed this cascade. Our findings suggest a mechanism by which dysfunctional chaperone protein-mediated "stress" networks can inflict and perpetuate cell-type specific damage in Parkinson's disease.

Title: Disruption of the synaptic vesicle glycoprotein 2C (SV2C) in Parkinson's disease

Authors: ***A. DUNN**, K. A. STOUT, A. BERNSTEIN, M. WANG, Y. LI, W. CAUDLE, G. W. MILLER;
Envrn. Hlth., Emory Univ., Atlanta, GA

Abstract: The synaptic vesicle plays two important roles in dopamine neurons by packaging transmitter to prepare for neurotransmission, and by sequestering cytosolic toxicants from the rest of the cell. Impaired storage of dopamine is a characteristic of Parkinson’s disease (PD) and genetic mutations in the vesicular monoamine transporter 2 (VMAT2) lead to parkinsonism. Enhancement of vesicular function through increased expression of VMAT2 in either mice or humans confers resistance to dopamine neuron degeneration. Furthermore, autosomal dominant mutations in other vesicle-associated proteins, such as α-synuclein and LRRK2, cause PD. These data suggest that characterizing additional modulators of dopamine vesicle function may be important in further studying and identifying potential therapeutic targets in PD. Polymorphisms upstream of the synaptic vesicle glycoprotein 2C (SV2C), a vesicular protein enriched in the basal ganglia, were recently shown to mediate the protective effect of smoking against PD,

suggesting an important role for SV2C in dopaminergic neurons. While the exact molecular function of SV2C is unknown, it likely positively modulates vesicular function and may represent a novel mediator of basal ganglia neurotransmission. However, the role of SV2C protein in PD has not been previously investigated. Here, we present immunohistochemical data detailing SV2C's expression in human striata in PD, other neurodegenerative diseases, and in age-matched control cases. SV2C localizes to dopaminergic terminal regions and GABAergic cells in the striatum in humans and mice. SV2C expression is specifically and dramatically disrupted in PD but preserved in other neurodegenerative diseases. In PD, SV2C expression is punctate in an apparent aggregate-like pattern throughout the striatum. A similar disruption in SV2C staining is observed in the striata of animals overexpressing PD-associated A53T α-synuclein under a Pitx3 (dopamine-neuron specific) promoter. Immunoprecipitation studies demonstrated a physical interaction between SV2C and α-synuclein, strengthening the association of α-synuclein with SV2C. SV2C also has potentially significant therapeutic relevance, as its close family member SV2A is the specific target for the antiepileptic compound levetiracetam. The results from our experiments indicate that SV2C may represent a novel pathology in PD, and that an interaction with SV2C may underlie this pathology.

Title: A computational model of protein handling pathways in Parkinson's disease using SEED

Authors: *B. BEHROUZ, J. J. MORRISON, J. W. RYAN, A. M. GREEN, L. SCHAPPELL, K. S. INMAN, A. D. LEE;
Neuroinitiative, Jacksonville, FL

Abstract: While the cause of the neurodegeneration in Parkinson's Disease remains unknown, breakthrough discoveries of multiple genetic mutations provide clues into PD pathogenesis. These discoveries implicate biological pathways that are complex and heavily interconnected, making it insurmountable to decipher a clear picture of the downstream pathological impacts of each molecular change or interaction such as a genetic mutation. We utilized Simulation Environment for Experimental Design (SEED), a computing platform for virtual

experimentation, to create a preliminary in silico model of molecules and interactions implicated in PD. We focused on cellular protein handling mechanisms and genetic mutations such as VPS35. Within this system we have created multiple models based on gene knock-down and over-expression. These in silico models are a great complement to other *in vivo* and *in vitro* models with the advantage of spatio-temporal acuity. By visualizing these reaction chains in a unified system we are able to shed light on converging pathways that may be targeted for therapies with a higher likelihood of efficacy.

Title: Antagonistic signaling mediated by the nuclear factor-kappa B and p38 regulates dopaminergic apoptotic cell death induced by gene (alpha [α]-synuclein)-environment (paraquat and manganese) interactions

Authors: A. ANANDHAN, P. HERNANDEZ-FRANCO, R. M. FOGUTH, *R. FRANCO; Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract: The multifactorial etiology of Parkinson’s disease (PD) involves genetic, environmental, and aging risk factors. The pathological hallmarks of PD are the loss of dopaminergic neurons in the substantia nigra, and the accumulation of inclusion bodies (Lewy bodies) of aggregated alpha(α)-synuclein. Gene multiplications or point mutations in α-synuclein are associated with sporadic and familial PD. In addition, several reports have demonstrated that the toxicity of α-synuclein is modulated by pesticides, metals, mitochondrial toxins and pro-oxidant conditions. However, there is little consensus regarding the molecular mechanisms involved. We found that overexpression of wild type (WT) and mutant A53T α-synuclein exerts a toxic synergism in N27 dopaminergic cells exposed to the structurally unrelated environmental

toxicants paraquat and manganese (Mn). This toxic synergism was dependent on the activation of the mitogen/stress-activated protein kinase (MAPK/SAPK) p38, as evidenced by its inhibition with SB203580, and was not replicated in lung-derived A549 cells or neuroblastoma cells with low levels of tyrosine hydroxylase (TH). WT or A53T α-synuclein overexpression increased the phosphorylation (pSer536) of the nuclear factor kappa light-chain-enhancer of activated B cells (NF-κB) in mouse substantia nigra (AAV-mediated delivery), and in N27 dopaminergic cells, where it was also potentiated by paraquat and Mn exposure. However, the transcriptional activity of NF-κB was inhibited under the same experimental conditions. Ascorbic acid and inhibition of inducible nitric oxide synthase (L-NAME and 1400W) activity reduced the toxicity of α-synuclein and paraquat. Neither inhibition of the apoptosis signal-regulating kinase 1 (ASK1) or c-Jun N-terminal kinases (JNK) with NQDI-1 or SP600125, respectively, modulated the toxicity of α-synuclein and environmental agent exposure. These results suggest that while p38 exerts a pro-apoptotic, NF-κB acts as an anti-apoptotic signaling against of dopaminergic cell death induced by gene (alpha (α)-synuclein)-environment (paraquat and manganese) interactions.

Title: Testosterone increases oxidative stress-induced neuroinflammation in dopamine neurons

Authors: *S. HOLMES, R. L. CUNNINGHAM;
Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX

Abstract: Neuroinflammation and oxidative stress are hallmarks of neurodegeneration in dopamine neurons in Parkinson’s disease (PD). Interestingly, men have a two-fold risk for PD than women. While the mechanisms underlying this sex difference remains elusive, one possibility may be that testosterone, the primary male sex hormone, is involved in dopamine

neurodegeneration. Our previous studies show that testosterone increases oxidative stress and dopamine neuronal death. A possible mechanism involved in the negative effects of androgens, may include the pro-inflammatory mediators NFkB and COX2. These mediators are responsive to oxidative stress and can increase alpha synuclein protein expression. Alpha synuclein is associated with Lewy bodies and apoptosis. Therefore, we hypothesize that under oxidative stress conditions, testosterone will increase inflammatory mediators NFkB and COX2, exacerbating apoptotic cell death in dopamine neurons. To test our hypothesis, we exposed a dopaminergic cell line (N27 cells) to a sublethal concentration of the pro-oxidant, tert-butyl hydrogen peroxide (H2O2) and assessed the role of testosterone on oxidative stress, cell viability and pro-inflammatory markers. Under oxidative stress conditions, there is a decrease in dopamine cell viability and an increase in NFkB, COX2, alpha synuclein and apoptosis. Interestingly, these factors are exacerbated by testosterone exposure. Further, inhibition of either NFkB or COX2 signaling can block testosterone's negative effects on cell viability. Thus, our data shows that testosterone may mediate the sex differences observed in PD by increasing oxidative stress induced neuroinflammation and apoptosis in dopamine neurons.

[3]Boehringer Ingelheim, Biberach an der Riss, Germany

Abstract: Parkinson's disease (PD) is a multisystem neurodegenerative disorder. Emerging evidence points to a contribution of inflammatory processes to the pathogenesis of PD but implications of the peripheral immune system are still poorly understood. To investigate whether the composition of myeloid cells is altered in PD, we applied a FACS based approach to characterize different monocyte sub-populations from PD patients and age-matched healthy controls. Strikingly, we found a strong increase in the ratio of classical CD14+ to non-classical

CD16+ monocytes. Comparing total numbers of monocytes from PD patients and healthy controls revealed no significant differences. The changes in the monocyte ratio in the peripheral blood of PD patients compared to healthy donors are attributed to a strong enrichment of classical CD14+ monocytes, and concurrently, a reduction of the non-classical CD16+ monocytes in PD. Interestingly, similar results could be found in two different transgenic mouse models for PD. Equivalent to human peripheral blood monocytes classical and non-classical monocytes in mice can be distinguished based on their expression of Ly6C. In detail, human classical CD14+ and non-classical CD16+ monocytes correspond to Ly6Chi and Ly6Clo in mice. Notably, we found an increased ratio of classical to non-classical monocytes in LRRK2(R1441G)-overexpressing mice as well as in a Thy-1 αsyn-wt model. These results suggest that different PD mouse models have a deregulation of monocyte sub-populations as a common feature. Moreover, we saw the strongest effect in monocyte deregulation in the LRRK2(R1441G) mouse model. Therefore, we asked whether LRRK2 might be differentially expressed in immune cells in PD patients. Using FACS analysis and quantitative RT-PCR we found so far increased levels of LRRK2 in B-cells of PD patients and increased LRRK2 levels in PD lymphoblasts compared to healthy controls, respectively. Taken together, our data suggest that deregulation of monocyte sub-populations plays an important role in PD and that LRRK2 potentially contributes to immune dysfunction. Identifying the role of the peripheral immune system in PD and additionally the role of LRRK2 in different immune cells during PD may pave the way for new therapeutic strategies in PD.

Title: Inflammatory response to alpha-synuclein by monocytic cells from healthy controls and patients with Parkinson's disease

Authors: *V. GROZDANOV, C. BLIEDERHAEUSER, W. P. RUF, R. LANGOHR, L. ZONDLER, A. C. LUDOLPH, J. H. WEISHAUPT, K. M. DANZER;
Univ. of Ulm, Ulm, Germany

Abstract: Accumulating evidence suggests a role for the innate immunity in the pathogenesis of Parkinson's disease (PD). We have previously characterized peripheral blood monocytes from PD patients and compared them to healthy controls. We found an inflammatory dysregulation on transcriptome and functional level, including increased cytokine release upon inflammatory stimulation with lipopolysaccharide (LPS) and impaired phagocytic capacity. It has also been previously found that pathological alpha-synuclein (asyn) species can be found in the extracellular space, where they can possibly interact with immune cells. To investigate the immune response of myeloid innate immune cells to extracellular asyn, we studied the inflammatory response of monocytes and monocyte-derived macrophages to different forms of extracellular asyn. We found that pathological alpha-synuclein oligomers induce a robust cytokine response by monocytes. This inflammatory response is even potentiated by familial mutations of alpha synuclein. Furthermore, we found that the pathological hyperactivity of PD monocytes in response to LPS is also found in response to extracellular asyn. Taken together, our data indicates that pathological asyn species trigger an inflammatory response by myeloid innate immune cells and suggest that monocytes infiltrating the CNS in the course of PD can contribute to tissue damage by immune response to extracellular asyn.

Abstract: Accumulating evidence points to an abnormal immune response and blood-brain barrier dysfunctions as contributing factors to the pathogenesis of Parkinson's disease (PD). In the blood, α-synuclein (αSyn) is expressed in platelets, leukocytes and erythrocytes, with levels reported to correlate with disease duration (Pienimaeki-Roemer A and al. 2015; Barbour R and al. 2008; Colasanti T and al. 2014). In normal physiological condition, the production of extracellular vesicles (EV) such as microvesicles (MV) and exosomes is a property of most eukaryotic cells which may, however, be precipitated in a pathological context. The aim of our study was to quantify EV in the plasma of PD patients and assess their relevance as a potential biomarker of the disease. Using a FACS Canto II with a forward scatter coupled to a photomultiplier tube, we quantified cell-derived MV from platelets, erythrocytes, monocytes and endothelial cells in platelet-free plasma (PFP) from 59 PD patients and 37 age and sex-matched Controls. The concentrations of these cell-derived MV were similar between PD patients and Controls, with high concentrations of erythrocyte-derived CD235+ MV (EMV) (7.01 ± 1.7 x 108 and 9.83 ± 2.1 EMV/ml of PFP in PD patients and Controls, respectively, P=0.32). Positive correlations were identified between EMV concentrations and disease progression based on both the unified Parkinson's disease rating scale and Hoehn & Yahr scores (R2= 0.30 and 0.17 respectively, P<0.05). Exosomes and EMV were further isolated from erythrocytes following a treatment with calcium ionophore A23187 and sequential centrifugations, and the concentration of αSyn was quantified using ELISA assays. The mean concentration of αSyn was 1004 ± 128ng and 1028 ± 273ng in 100 µl of packed erythrocytes and 4.24 ± 0.54ng and 4.44 ± 1.01ng in EMV, in PD patients and Controls respectively (P=0.88). The concentration of αSyn in exosomes was similar with values of 0.21 ± 0.01 and 0.43 ± 0.23ng (PD vs. Control, P=0.96). Two-Way ANOVA analyses revealed higher concentration of αSyn in EMV as compared to exosomes (P<0.0001). This correlation unveils EMV as a potential non-invasive biomarker of disease progression as well as for monitoring drug efficacy. The presence of αSyn in EMV and exosomes may further point to the potential role of erythrocyte-derived EV in α-synucleinopathies. Further studies to investigate the mechanisms responsible for the erythrocyte-related EV release in PD and the specificity of EMV counts as a biomarker are currently underway.

Title: Park2-/- rats have a decreased ratio of tetrameric to monomeric alpha-synuclein in the striatum

Authors: *A. MOSZCZYNSKA[1], B. A. KILLINGER[2], L. XU[2], A. DUTTA[2];
[1]Pharmaceut. Sci., [2]Wayne State Univ., Detroit, MI

Abstract: Parkinson's disease (PD) is a neurodegenerative disease characterized by the progressive loss of dopamine neurons in the midbrain and the formation of alpha-synuclein positive inclusions termed "Lewy bodies." The molecular details of alpha synuclein aggregation *in vivo* are unclear. It is well known that excess monomeric alpha-synuclein readily aggregates; however alpha-synuclein *in vivo* forms a stable tetramer which is not known to aggregate. Loss of parkin function due to mutation of Park2 gene is a characteristic feature of familial PD. Here we tested the hypothesis that the stoichiometry of alpha-synuclein species would be altered in Park2-/- rats. Using a combination of blue native electrophoresis and chemical cross-linking we developed a straight forward method to measure alpha-synuclein stoichiometry in Triton x-100 soluble tissue samples that circumvent some of the issues associated with tissue cross-linking. We then used this method to measure the ratio of stable alpha-synuclein species in our PD model. In striatal lysates from Park2-/- rats native alpha-synuclein occurred as three detectable species; ~16 kDa (monomer), ~28 kDa (dimer), and ~56 kDa (tetramer). The apparent monomer was the most abundant species with the dimer and tetramer being less abundant. Recombinant alpha-synuclein also formed stable dimer and teramer when incubated for several days at 4°C. The recombinant alpha-synuclein also appeared to form disordered aggregate like species, which were not present *in vivo*. The ratio of stable alpha-synucelin tetramer to monomer decreases in the striatum of Park2-/- rats as compared to wild-type rats. This finding suggests that decreasing the ratio of tetramer to monomer may promote dysfunction in striatal neurotransmission and dopamine neuron neurodegeneration. Future studies should determine the biological function of native monomeric and tetrameric alpha-synuclein.

Abstract: Parkinson's disease (PD) is characterized by loss of dopaminergic neurons in the substantia nigra pars compacta (SNc), causing the decrease of dopamine levels in the innervating nuclei and producing impaired of motor activity. Various treatments have been proposed to counteract the symptoms, L-dopa is the most common drug for the treatment of PD because of its clinical efficacy; however, long-term L-dopa treatment induces involuntary abnormal movements, several evidences suggest that L-dopa can increase the oxidative stress pre-existing condition. However; some studies reported no damage, and shows protective action against free radicals. Therefore the aim of this study was to evaluate if the levodopa can cause some damage in healthy rats using the analysis of lipid peroxidation in several brain structures (SNc, striatum, motor cortex, hippocampus and globus pallidus). The Levodopa/carbidopa (10mg/1mg/kg) were administered orally daily for a 3 months (n=12) in rats, lipid peroxidation was determined in each cerebral structure by the technique of TBARS. Significant differences from controls were found in the globus pallidus, however, it was also evident the tendency to increase in the striatum and SNc. This data demonstrate that L-dopa induce lipid peroxidation.

Title: Exploring the potential of phospho-ubiquitin antibodies as a biomarker tool for aging and disease

Authors: *F. C. FIESEL, M. CASTANEDES-CASEY, D. DICKSON, Z. WSZOLEK, P. MCLEAN, H. MELROSE, W. SPRINGER;
Mayo Clin., Jacksonville, FL

Abstract: PINK1, a kinase involved in recessive familial forms of Parkinson's disease (PD), senses mitochondrial stress and is required to induce the degradation of damaged mitochondria (mitophagy). PINK1-dependent phosphorylation of Parkin at Ser65 in its N-terminal ubiquitin-like domain has been shown to be important to recruit and activate the E3 ubiquitin ligase to mitochondria. Parkin ubiquitinates a variety of different mitochondrial substrates. Subsequently, mitochondrial proteins are degraded by the ubiquitin proteasome pathway or lysosomal autophagic degradation. Recently, it has been discovered that PINK1 also phosphorylates ubiquitin itself at the conserved Ser65 position. This event is thought to enhance Parkin activation and mitochondrial degradation. We have generated two antibodies that are specific for the phosphorylated variant of ubiquitin. We have validated the antibodies using fibroblasts from controls and PINK1 mutation carriers. Since mitochondrial dysfunction plays a role for the pathogenesis of PD as well as other age-related diseases and the aging process itself, we will test our antibodies as a tool to characterize mitochondrial stress *in vivo*. Using brain sections from young, old and diseased individuals, we will analyze the burden of phospho-ubiquitin in different brain regions. We use classical IHC methods combined with state-of-the-art digital image analysis to analyze the abundance of phospho-ubiquitin. Our data shows a granular pattern of phospho-ubiquitin that partially colocalizes with mitochondria and lysosomes. In addition, we will analyze brains from mice that overexpress alpha-synuclein or express mutant LRRK2 and are used to model autosomal dominant forms of PD. Altogether, this study will address a potential functional overlap between different forms of familial and sporadic PD and will determine the suitability of phospho-specific ubiquitin antibodies as tools to detect mitochondrial stress in aging and disease.

Title: miRNAs and their involvement in the pathology of dopamine neurons in Parkinson's disease

Authors: *K. C. SONNTAG[1], C. E. BRIGGS[2], T.-U. W. WOO[1], L. K. IYER[3]; [1]Psychiatry, McLean Hospital/Harvard Med. Sch., Belmont, MA; [2]The Ctr. of Cancer Systems Biol., [3]Dept. of Neurosci., Tufts Univ. Sch. of Med., Boston, MA

Abstract: The degeneration of substantia nigra (SN) dopamine (DA) neurons in sporadic Parkinson's disease (PD) is characterized by disturbed gene expression networks. Micro(mi)RNAs are post-transcriptional regulators of gene expression and there is increasing evidence that they are involved in the molecular pathogenesis of neurodegenerative disorders, including PD. Here, we document a comprehensive analysis of miRNAs in SN DA neurons from postmortem brains of PD patients and healthy controls. Our data show that miRNAs are dysregulated in disease-affected neurons and are differentially expressed between male and female samples with a trend of more up-regulated miRNAs in males and more down-regulated miRNAs in females. Unbiased Ingenuity Pathway Analysis (IPA) revealed a network of miRNA/target-gene associations that is consistent with dysfunctional gene and signaling pathways in PD pathology. Based on our findings from the miRNA profiles and computational data analysis, we started to functionally analyze miRNAs of interest. To this end, we studied miR-126, which was upregulated in PD and has been implicated in regulating Insulin/IGF-1/PI3K signaling, a pathway that was also dysregulated in the PD DA neurons. Our data show that miR-126 may play a profound role in neuronal cell survival to toxic insult by regulating growth factor (GF)/PI3K/AKT and MAPK/ERK signaling cascades. Altogether, our data provide evidence for an association of miRNAs with the cellular function and identity of neurons in general and SN DA neurons in particular, and with deregulated gene expression networks and signaling pathways related to neurodegenerative diseases, including PD, that may be sex-specific. Further functional characterization of miRNA/target gene relationships in neurons may lead to the identification of novel therapeutic targets for the treatment of neurological and age-related disorders.

Abstract: In Parkinson´s diseases the best therapy is Levodopa, unfortunately after chronic treatment almost all patients developed dyskinesia, which are very disability motor disorder. The over expression of transcription factor FosB and ΔFosB after chronic levodopa treatment is considered the molecular mechanisms that are involved in the dyskinetogenic process. The aim in this study was evaluated the responses of striatal FosB and ΔFosB mRNA expression after acute, sub-chronic or chronic levodopa treatment in a rat model of Parkinson´s disease. The Sprague Dawley rats received unilateral 6-OHDA-injection in the medial forebrain bundle by stereotactic surgery. At eight day post-surgery the rats were evaluated in the cylinder test to determinate the degree of dopaminergic damage, two days after, rats received acute (single dose), sub-chronic (three dose /three days) or chronic (sixteen dose/sixteen days) levodopa (10 mg/kg i.p) treatment. Rats were decapitated to obtain the brain and was dissected the striatum 1 h, 3 h and 24 h after the last levodopa injection by each challenged levodopa. We determinate both isoforms FosB and ΔFosB mRNA by real time-PCR in the striatum. The results showed that single dose levodopa induces high fold ΔFosB and FosB mRNA at 1 h post-injection of the drug, while that 24 h after the fold induction of FosB and ΔFosB mRNA are very similar like control group. However, after sub-chronic levodopa treatment the fold induction of FosB and ΔFosB mRNA decreases with respect to acute treatment although is possible observed a little induction,

it is not significant. However after chronic levodopa the fold induction of striatal FosB and ΔFosB mRNA are again recuperate at three hours post-injection, although it is no the same magnitude as in acute treatment. In summary, this pattern of FosB and ΔFosB mRNA expression result reflecting neuronal response since the first levodopa dose although dyskinesia are expressed during the chronic levodopa treatment. Title: Kv1.3 mediates cholinergic hyperexcitability in a mouse model of Parkinson's disease

Authors: ***C. TUBERT**[1], I. R. E. TARAVINI[2], G. SANCHEZ[3], A. PROST[1], L. RELA[1], M. G. MURER[1];

Abstract: Balanced actions of dopamine (DA) and Acetylcholine (ACh) shape striatal function. In Parkinson´s disease (PD) this balance is lost, leading to an hypercholinergic state. ACh is released in the striaum by tonically active interneurons (ChIs). Recent work shows that ChIs are hyperexcitable in a rat model of PD as a result of a lack of “accommodation”, an intrinsic

property that markedly slows firing during sustained current injection. Here our aim is to identify currents that regulate ChIs accommodation in mouse brain slices. ChIs represent less than 5% of the striatal neurons, so we used mice expressing *tdTomato* fluorescent protein in ChIs (ChAT-Cre;rt) to find them easily. By means of immunohistochemistry we demonstrate that all *tdTomato* cells express ChAT in ChAT-Cre;rt mice, but not the markers of other striatal interneurons including PV, NPY and NOS. Moreover, *tdTomato*-ChIs have electrophysiological properties similar to those of ChIs recorded from wild type mice. Extending previous studies showing more excitable ChIs in juvenile mice, we found that ChIs almost always show accommodation in adult mice but many ChIs do not in juvenile animals. Thus, accommodation is developmentally regulated. Margatoxin (MgTx), a blocker of Kv1.3 channels, markedly attenuated accommodation in ChIs, shown by an increase in the number of spikes fired (from 7.2±1.3 to 13.3±1.1 spikes; p=0.003) and a prolongation of firing (from 332.2±127.2 to 828.8±55.6 s; p=0.008) during a 1s depolarizing current step. Dendrotoxin, a less selective Kv1 blocker, also reduced accommodation, while blockers of Kv7 channels like XE991 and UCL2077, were ineffective. MgTx also increased spontaneous firing (p=0.0455) measured in cell-attached recordings. We have isolated and characterized the MgTx-sensitive current in accommodating ChIs (V_{act}=-38$\pm$7mV, V_{50}=-3$\pm$8mV, I_{max}=1500pA). Immunohistochemistry in brain sections and PCR of laser dissected ChIs revealed the expression of Kv1.3 channels. Thus, ChIs express a functionally relevant Kv1 conductance. We have then evaluated the influence of endogenous DA on accommodation. Bath application of D_1 (SCH23390) and D_2 (sulpiride) type receptor antagonists does not block accommodation. However, as it is the case in rats, fewer ChIs show accommodation in a mouse model of PD induced with 6-OHDA. Moreover, MgTx-sensitive currents are smaller in ChIs of 6-OHDA-lesioned mice compared to sham-mice ($p<0.0001$). Our data indicate that chronic nigrostriatal lesions reduce the MgTx-sensitive current in ChIs, causing their lack of accommodation and hyperexcitability, and nominate Kv1.3 channels as potential new targets of antiparkinsonian therapy.

Title: Vagus nerve stimulation activates pparγ as a mechanism to treat Parkinson's disease

Authors: *H. A. BOGER[1], R. GREGORY[1], K. HELKE[1], S. HAYS[2], V. HINSON[1], A. FARRAND[1];
[1]Neurosciences, Med. Univ. of South Carolina, Charleston, SC; [2]Univ. of Texas at Dallas, Dallas, TX

Abstract: Vagus nerve stimulation (VNS) is approved by the FDA for the treatment of drug-resistant epilepsy and depression. Although the exact mechanism is unknown, previous studies have shown increased firing rates of noradrenergic (NE) neurons in the locus coeruleus (LC), leading to increased brain derived neurotrophic factor (BDNF) levels in the LC and its target regions. Based on these previous findings, VNS makes for an intriguing treatment strategy for Parkinson's disease (PD) since LC-NE degeneration typically occurs prior to the dopaminergic (DA) loss of the substantia nigra (SN). Preliminary studies from our lab show that chronic VNS can attenuate the loss of tyrosine hydroxylase (TH)-positive neurons in the LC and SN observed in a double lesion model of PD, and restored the locomotor activity deficit caused by the lesion. A potential mechanism for this alleviation could be activation of the anti-inflammatory transcription factor, PPARγ, which can result in increased BDNF levels. Therefore, our hypothesis is that chronic VNS activates PPARγ to increase BDNF levels and attenuate the deficits observed in a double-lesion model of PD. We examined this hypothesis by utilizing a double-lesion rat model to mimic the deficits of PD. Adults male rats were administered the NE neurotoxin DSP-4 (50 mg/kg, ip) and after seven days underwent surgery to administer the DA neurotoxin 6-OHDA (6 μL, intrastriatal). Animals in the VNS group also got vagus cuff implants and head caps during the 6-OHDA surgery that could later be attached to a stimulator. Starting ten days post-lesion, the VNS animals were stimulated twice a day for two weeks using precise bursts of stimulation at a set amplitude and rate. Following the last stimulation, the rats were euthanized, the right frontal cortex, hippocampus, and dorsal striatum tissue samples were taken for ELISA detection of BDNF, and the left hemisphere was sectioned for immunohistochemical detection of TH, PPARγ, the BDNF receptor TrkB, and the pro-inflammatory marker COX-2. Rats in the VNS group have increased levels of BDNF in LC target regions (frontal cortex and hippocampus) and in the SN target region, dorsal striatum, compared to the double-lesion rats, as well as increased PPARγ expression in these areas. These data taken together imply that PPARγ activation leads to BDNF upregulation, and subsequently attenuates DA and NE lesion-induced deficits. Studies are ongoing in the laboratory to determine the relationship between PPARγ activation, BDNF levels, and TrkB expression following chronic VNS stimulation. Collectivley, these data point to an exciting potential treatment strategy for individuals with PD.

Title: p53-dependent regulation of autophagy by c-Abl in Parkinson's disease

Authors: *R. KARIM, E. LIAO, M. K. LEE;
Univ. of Minnesota, Minneapolis, MN

Abstract: Abnormal α-synuclein (αS) accumulation in neurons is a likely contributor to neurodegeneration in Parkinson's disease (PD). Recent studies show that PD is associated with the induction of c-Abl, a non-receptor tyrosine kinase that is activated by oxidative stress. Our studies show that activation of c-Abl in mouse model of α-synucleinopathy (*A53TαS*) is associated with activation of p53, indicating that c-Abl could promote cell death via p53. In addition, previous studies show that c-Abl activity could regulate autophagy and αS toxicity. Thus, we hypothesized that increase in c-Abl and/or p53 activation was responsible for the impaired autophagy-lysosomal process (ALP) seen in *A53TαS* Tg mice. To determine pathological significance of c-Abl in progressive α-synucleinoapthy, we treated the *A53TαS* mice with Nilotinib (Nilo), a FDA-approved c-Abl kinase inhibitor. Chronic administration of Nilo showed an attenuation of pathology and facilitates autophagic clearance of pathological αS. To determine how c-Abl inhibition alleviates ALP defect in *A53TαS* mice, we investigated whether p53 was sufficient to modulate ALP. Our results show that Nilo and p53 inhibitor, pifithrin-α (PFT), both increased autophagic flux in N2a and M17 cell lines. Moreover, Nilo and PFT activated ER-stress marker eIF2α, PDI and upregulated the phosphorylation of AMP-activated kinase (AMPK) which was accompanied by pS555-ULK1 activation and conversely down-regulated mTORC1 signal molecule ribosomal S6 and translation repressor protein 4EBP1. These results suggest that c-Abl regulates ALP via regulation of p53 and subsequent activation of ULK1 and inhibition of mTORC1 signal. Together our data reveal that Nilo-mediated autophagic clearance of toxic αS is possibly dependent on p53 and that treatment with Nilo may provide a therapeutic strategy for PD.

Title: Acute administration of pramipexole alters Akt/GSK-3β signaling in the ventral pallidum

Authors: S. A. GRASSO[1], *A. L. PERSONS[1], S. E. TEDFORD[1], A. H. NEWMAN[2], T. C. NAPIER[1];
[1]Pharmacol., Rush Univ. Med. Ctr., Chicago, IL; [2]NIDA IRP, Baltimore, MD

Abstract: Pramipexole (PPX), a direct-acting dopamine agonist used in the treatment of Parkinson's disease and restless leg syndrome, is associated with the development of addiction-like behaviors such as problem gambling. PPX demonstrates high affinity for the D3 receptor (D3R) subtype, which may be involved in these behaviors, but the D3R-associated signaling mechanisms of PPX are largely unknown. D3Rs are pleotropic and can signal in a G protein-independent manner *via* a Akt/GSK-3β pathway. Stimulation of D3R activates protein phosphatase 2A (PP2A), which dephosphorylates Akt. Dephosphorylation of Akt reduces phosphorylation of constitutively active GSK-3β, a known mediator of addiction-related changes in the brain. The ventral pallidum (VP) is a limbic brain structure that regulates key aspects of addiction-associated behaviors, and it contains a high density of D3Rs; yet the nature of D3R signaling within the VP is largely unknown. We tested the hypothesis that acute PPX administration will decrease phosphorylation of Akt and GSK-3β in the VP. Rats were treated with saline or (±)PPX (4mg/kg), and 1hr post-injection, the VP was harvested. A Western blot protocol was used to determine levels of Akt and GSK-3β). Acute PPX reduced the ratio of pAkt/Akt (i.e., active/total) in the VP. Additionally, downstream of Akt, the ratio of pGSK-3β (inactive)/GSK-3β (total) VP was reduced. A 30 min pretreatment with PG01037, a D3R-selective antagonist, attenuated the PPX effects on both Akt and GSK-3β. These studies indicate that PPX-mediated activation of D3R alters signaling through Akt and GSK-3β in the VP. Neuroadaptive processes such as these may link PPX with the development of addiction-like behaviors.

Title: Huntington’s disease biomarker progression profile identified by transcriptome sequencing in peripheral blood

Authors: *W. M. VAN ROON-MOM, E. VAN DUIN, R. A. C. ROOS, R. C. VAN DER MAST, G. B. VAN OMMEN, J. T. DEN DUNNEN, P.-B. A. C. 'T HOEN, A. MASTROKOLIAS;

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder that manifests itself through cognitive, psychiatric and motor symptoms. The pathology is caused by an expanded CAG repeat in the HTT gene, resulting in a mutant huntingtin protein. With several therapeutic approaches in development for Huntington’s disease, there is a need for easily accessible biomarkers to monitor disease progression and therapy response. We performed next generation sequencing-based transcriptome analysis, of total RNA from peripheral blood of 91 mutation carriers, (27 presymptomatic and, 64 symptomatic) and 33 controls. Transcriptome analysis by DeepSAGE identified 167 genes significantly associated with clinical total motor score in Huntington’s disease patients. Relative to previous studies this yielded both novel genes, and confirmed previously identified genes , such as H2AFY, an overlap in results which has proven difficult in the past. Pathway analysis showed enrichment of genes of the immune system and of target genes of miRNAs which are downregulated in Huntington’s disease models. Using a highly parallelized microfluidics array chip (Fluidigm) we validated 12 of the top 20 significant genes in our discovery cohort and 7 in a second independent cohort. The five genes (PROK2, ZNF238, AQP9, CYSTM1, and ANXA3) which were validated independently in both cohorts present a candidate biomarker panel for stage determination and therapeutic readout in Huntington’s disease. Our data support the view that peripheral blood is a useful source to

identify biomarkers for Huntington's disease and monitor disease progression in future clinical trials.

Title: BN82451B in Huntington's disease: on the way to translational biomarkers

Authors: *P. E. CHABRIER[1], E. APARICIO[1], A.-L. BAUCHET[1], S. ROLLAND[1], A. MANON[1], P. PLAS[1], M.-N. ROCHER[1], L. NAUDIN[1], Z. ZHANG[2], V. PIERRON[1], C. BENSTAALI[3], L. VIGNAUX[1], M.-O. GALCERA[1], P. ROUBERT[1], F. SCHMIDLIN[1]; [1]IPSEN INNOVATION, Les Ulis, France; [2]IPSEN Biosci., Cambridge, MA; [3]INSERM U836, Grenoble Inst. des Neurosciences, Grenoble, France

Abstract: BN82451B is a small multitargeted orally active molecule which interferes with excitotoxicity (sodium channel blocker), oxidative stress (antioxidant) and inflammation (cyclooxygenase [COX] inhibitor) that is currently in Phase 2a in Huntington patients. In order to further support clinical development and to monitor pharmacological activity of this compound, we investigated potential target efficacy biomarkers in non-clinical samples, e.g. serum and whole blood in cynomolgus monkeys and serum, whole blood, urine and brain tissues in rats. In rats, oral treatment at 25 mg/kg/day during 4 days resulted in marked lower prostaglandin E2 (PGE2) levels in serum and urine. In brain tissues, measured PGE2 levels were reduced by 65% compared to controls in accordance with the BN82451B biodistribution (brain to plasma ratio of 3), demonstrating pharmacological activity of the compound in the central nervous system. In monkeys treated at 30mg/kg/day during 11 days, we confirmed PGE2 as a biomarker of BN82451B activity in the serum. Whole blood transcriptomic analysis in this species showed that treatment had an impact on gene expression highlighting 329 differentially expressed genes common to male and female monkeys ($p=0.05$, multiple test correction applied, 2 fold change cutoff). Regulated genes were either related to the pharmacological activity of the compound as COX inhibition, antioxidant activity and ion channel function or relevant to Huntington's disease (HD). Further evaluation of these genes is ongoing on cortical neurons

from a HD mutant mouse after *in vitro* treatment with BN82451B or vehicle. In this setting, BN82451B treatment was associated with an increase of neuronal viability. Altogether, these data demonstrate the pharmacological activity of BN82451B in the central nervous system and provide valuable information for biomarker exploration to improve the care of patients treated with BN82451B.

Title: Altered striatal resting state functional connectivity in children at risk for Huntington's disease

Authors: *J. LEE[1], E. AXELSON[1], J. BRUSS[1,2], V. MAGNOTTA[3], P. NOPOULOS[1,2,4]; [1]Psychiatry, [2]Neurol., [3]Radiology, Univ. of Iowa, Iowa City, IA; [4]Pediatrics, Univ. of Iowa, Iowa city, IA

Abstract: Background: Huntington's disease (HD) is an autosomal dominant disease caused by an expansion of the CAG repeats on the gene encoding for the huntingtin protein (*HTT*). The dysfunction of the striatum which shows selective vulnerability to mutant huntingtin (*mHTT*), is

known to underlie the characteristic HD symptom manifestation. Although the primary neuropathology is that of neurodegeneration of the striatum, the presence of *mHTT* throughout the life span may also affect normal maturational processes and circuit formation of the striatum that take place during development. Objective: In the current study, the effect of *mHTT* on striatal functional integrity was examined by evaluating resting-state functional magnetic resonance imaging (rs-fMRI) data in children (6-18 years of age) who are at risk for HD (no juvenile HD included). Method: Using seed-based analyses of the rs-fMRI data, the functional connectivity of the striatum in children tested as gene-expanded (n=26, CAG repeats ≥ 40) as a result of presymptomatic gene assessment (for research purposes only) were compared to that of 36 healthy children. Results: Compared to healthy peers, the gene-expanded children showed significantly weaker correlational strength between 1) the putamen and the motor cortex and 2) the ventral striatum and the anterior cingulate cortex. However, the gene-expanded children also exhibited significantly stronger functional coupling between 1) the caudate and the anterior prefrontal cortex, 2) the putamen and the superior frontal gyrus and 3) the ventral striatum and orbitofrontal cortex, when compared to healthy controls. Conclusions: The decreased functional synchronization between the striatum and associated frontal lobe areas in the gene-expanded children, indicate aberrant striatal functionality directly linked to *mHTT.* Interestingly, these decrements coincided with increased functional connectivity along the fronto-striatal circuitry which may reflect a potential compensatory mechanism. The results suggest that lifelong possession of *mHTT* could alter the striatum's intrinsic functional architecture, decades ahead of HD diagnosis. Importantly, understanding how the brain dynamically copes with such persistent effect of *mHTT* may help determine the most effective timing and target area to intervene prior to any irreversible structural degeneration.

Abstract: Introduction: Huntington's disease (HD) is a neurodegenerative disorder that induces striatal and cortical neuronal dysfunction and loss which main symptom is motor impairment. Goals: to study whether this motor impairment is accompanied by changes in brain activity and functional connectivity. Methods: Eighteen early stage HD patients with a UHDRS motor score > 5 (10 men, mean age = 50.5 ± 10.08, mean TFC = 11.83 ± 1.17) and 19 controls (11 men, mean age = 49.21 ± 8.05) matched in age, gender and educational background underwent 3T structural and functional MRI scanning while they performed a sequential tapping task with their right or left hand in alternated blocks. Regional brain activation and functional connectivity were analyzed using mean number of tappings per block as a covariate of no interest to correct for performance differences between patients and controls. Results: Compared to rest blocks, active tapping activated the contralateral primary motor, premotor and supplementary motor areas, thalamus and cerebellum in both patients and controls. However, in the right hand condition, patients deactivated the right putamen, caudate, insula and premotor cortex to a greater extent than controls, which suggests that patients need a greater inhibition of the ipsilateral motor network in order to suppress the movement of the opposite hand. Bilateral primary motor cortex (M1), putamen and supplementary motor area (SMA) were selected as seeds region for a whole brain functional connectivity analysis. Both controls and patients showed negative connectivity between each of the seed regions and the motor network of the contralateral hemisphere. However, in the right hand condition, patients showed more negative connectivity of bilateral M1, primary somatosensory cortex (S1) and left secondary somatosensory cortex (S2) with the left putamen. Furthermore, the negative connectivity between the right M1 and the left putamen correlated with disease burden. In the left hand condition, right insula, M1 and premotor cortex were more connected (negatively) with the right putamen in patients compared to controls. Moreover, left S1 was more connected (negatively) with the right M1 in patients when compared to controls. Conclusions: These results indicate that HD patients need to inhibit the contralateral motor circuit of the moving hand to compensate for the hyperactivation of the dopaminergic system that underlies their motor symptoms.

Title: Equilibrative nucleoside transporter 1 (ENT1) as a biomarker of Huntington's disease

Authors: X. GUITART[1], W. REA[1], I. DETTORI[2], A. MELANI[2], F. PEDATA[2], M. NARAYANAN[3], Y. CHERN[4], *S. FERRE[1];
[1]NIDA, IRP, NIH, DHHS, Baltimore, MD; [2]Univ. of Florence, Florence, Italy; [3]NIAID, IRP, NIH, DHHS, Bethesda, MD; [4]Inst. of Biomed. Sciences, Academia Sinica, Taipei, Taiwan

Abstract: Preclinical, and epidemiological studies point to a role of adenosine in the pathogenesis of Huntington Disease (HD). We previously found that an adenosine A2A receptor (A2AR) antagonist did not produce locomotor activation in a transgenic HD rat model. The results were interpreted as due to a selective downregulation of striatal A2A receptors. But in the same animal model we also found a lack of locomotor activating effect of an A1R antagonist, while both A1R and A2AR agonists produced locomotor depression. The results therefore indicated a reduced adenosine tone. In fact, the striatal extracellular concentration of adenosine was significantly reduced in transgenic HD rats compared to controls. A decrease in striatal adenosine was also demonstrated in the present study in Q175 knock-in mouse. As a mechanistic explanation, we found that the striatal expression of the equilibrative nucleoside transporter 1 (ENT1) was significantly increased in Q175 mice. We then tested if a similar association could also be observed in humans. The gene expression profiles of 14 adenosine system genes, including ENT1, were analyzed in a large human cohort of 157 HD vs 155 control individuals (C). We first tested if any of these genes were up/down-regulated in HD relative to C using a differential expression (DE) analysis, and found that HD patients had a slightly higher but not significant transcript level of ENT1 in the frontal cortex than C. Nevertheless, the transcript level

of ENT1 was statistically higher in female, but not in male, HD patients compared with C of the same sex. We next inspected if the co-ordinate regulation of our genes of interest with other genes in the genome were disrupted (gained/lost) in the HD group relative to C using a differential coexpression (DC) analysis, a complementary approach to DE analysis utilized by several recent studies to identify disease-dysregulated genes. Based on a network of previously published DC relations identified at FDR 1% in this cohort, we found that some adenosine system genes were disrupted in hub-like DC patterns, similar to that observed for several other HD dysregulated genes. Specifically, ENT1 and also the ecto-nucleotidase CD73 were each differentially correlated with more than about 60 gene reporters at a statistically significant level, with mostly gain of correlations for ENT1 in HD patients relative to C.

Abstract: Introduction: Huntington’s disease (HD) results in significant problems in judgement and decision making. However it is still unknown how early these capacities start to decline in these patients. **Objective:** Evaluate risky decision making in HD gene carriers with null or early clinical manifestations. **Participants:** 19 HD gene carriers with early evolution according to the scale of Total Functional Capacity UHDRS (TFD=11.7 ± 1.8); and 19 control volunteers

matched for sex, age and education. **Methods:** Subjects were evaluated using the Cambridge Gambling Task (CGT) of the CANTAB®. Participants saw ten boxes at the top of a screen, each of which is red or blue in some ratio. Under one of these boxes was a token, and participants had to guess whether the token was under the red or blue box. On a gambling trial, participants could select some proportion of their allotted points to bet on their judgment. Two bet conditions were applied, one ascending (possible bets start low and increase over time) and the other descending (bets start high and decrease over time). **Results:** The patient group bet a significant higher percentage of points in the descending condition (see Figure). Conclusion: HD gene carriers show a significant change in their decision making behavior even before revealing clinical changes. These changes from early stages of the disease suggest a judgment deterioration that could potentially put these patients in situations of risk; we suggest the development of strategies for individual care and judgment capacity adjusted for each patient.

Title: Regional stability of mutant htt mrna in post-rnai-induced degradation

Authors: *W. LIU, E. L. PFISTER, L. A. KENNINGTON, N. ARONIN;
Med., UMass Med. Sch., Worcester, MA

Abstract: Huntington’s disease (HD) is an autosomal dominant neurodegenerative disorder caused by expanded CAG repeats in first exon of HTT gene. The expanded CAG repeats encode a polyglutamine stretch near the N-terminus of the HTT protein. The CAG expansion is negatively correlated to the age of onset; particularly large expansions are linked to juvenile forms of the disease. There is no effective treatment available. Promising therapeutic strategies for HD include allele-selective and non-allele-selective RNAi techniques that target against the HTT mRNA. In either methods, RNAi induces a specific endo-nucleolytic cleavage of the target

HTT mRNA in the area complementary to the guide small RNA, and the resulting fragments are degraded by exo-nucleolytic process. We investigated the areal stability of HTT mRNA following the RNAi induced cleavage, especially the first exon that harbors the CAG repeats. YAC HD transgenic mice with 128 CAG repeats were injected with scAAV-mir-RNA-HTT-GFP designed against HTT targeting the middle part of transgenic HTT (exon 48). Transgenic HTT mRNA levels were estimated after two weeks, using primer-probe combinations covering different parts along the HTT mRNA. Our results show that at six sites examined, transgenic mutant HTT reduced to 63.9% to 71.2% in striatum injected with scAAV9-U6-mir-HTT-GFP. However, there was no significant difference between sites. Our results demonstrate that expanded CAG repeats in mutant HTT did not stop or slowdown the mRNA degradation following the RNAi-induced cleavage.

Title: Utility of genetic testings for clinically suspected Huntington’s disease and Spinocerebellar Ataxias from Movement Disorder clinic in India

Authors: *S. D. VENKATESH;
Psychiatry, Nimhans, Bangalore, India

Abstract: Objective: To study the utility of genetic testing for Huntington’s disease(HD) and spinocerebellar ataxia (SCA1, SCA2, SCA3 and SCA12) in referred from a Movement Disorder clinic in a tertiary care hospital in India. Background: HD and SCA are neurodegenerative conditions that haveworldwide distribution.The prevalence of HD varies from 0.6-10 per million in Asian to European populations.SCA3 is the most frequent mutation detected worldwide followed by SCA2 and SCA1. SCA12 is found prominently in specific Indian ethnic group. Only limited data is available on occurrence of HD and SCA in Indian population. Methodology: Subjects clinically suspected for HD (N=175) and SCA (N=844) were recruited from outpatient and inpatient referrals to Genetic Counselling and Testing Centre (GCAT) at the National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore, India after obtaining

informed consent with detailed explanation and genetic counselling. The genomic DNA was extracted from whole blood by salting out method. Polymerase chain reaction (PCR) was setup using appropriate primers to identify the HD, SCA1, SCA2, SCA3 and SCA12 mutation. The expanded CAG repeats were identified by high resolution agarose gel electrophoresis of the amplified products, followed by fragment analysis forrepeat sizing using ABI 3500xL and Gene Mapper v3.5 respectively. Result: Of the 175 subjects clinically suspected for HD, pathological expansion was confirmed in 120 (68.5%) samples (symptomatic, n=106, and pre-symptomatic, n=14. Among the 844 subjects clinically suspected for SCA, 246(28%) subjects had identifiable SCA mutations.SCA1 was most common [n=100 (12%)] followed by SCA2 [n=98 (11%)],SCA3 [n=40 (5%)] and SCA12 [n=8 (1%)]. Most of the confirmed HD cases were of southern Indian origin. Genetically confirmed SCA1, SCA2 and SCA3 cases were predominantly from southern India, whereas SCA12 was predominantly from northern India. Conclusion: Our study provides a large sample data on the occurrence of HD and SCA (SCA1, SCA2, SCA3 and SCA12) mutations from the patients recruited in GCAT clinic, NIMHANS, India. Pre-test and post-test counseling, as well as long term follow-up and care needs for this cohort and their families needs to be developed. This study is informative guide for prioritizing health care policies towards movement disorders in India.

Abstract: In the last couple of decades, non-human primates (NHP) played major roles in the development of treatments for Parkinson's and Huntington's diseases. Because of their high genetic similarity with humans, they bridge the gap between rodents and humans for therapy development and evaluation. However, translational research success from NHP to patients requires accurate phenotyping of the models. Magnetic resonance imaging (MRI) combined with automated segmentation methods offers the unique opportunity to assess brain morphological changes caused by neuronal degeneration in patients (volume, cortical thickness, sulci morphology). While a longitudinal follow-up of such parameters is essential in NHP models, few robust algorithms (Ballanger et al. 2013) are available because NHP brains are small and high magnetic fields used in preclinical imaging produce different contrasts. To overcome these obstacles, we propose an automated method (www.brainvisa.info) that merges structural information from a macaque brain probabilistic digital atlas (Rohlfing et al. 2012) and local information from MR signal We studied a common NHP model of striatum-related pathologies. Male macaca fascicularis injected with quinolinic acid (QA) in the striatum (n = 8) were compared to healthy ones (n = 13). All subjects were submitted to T2-weighted MRI at 7 Tesla (Varian). We developed an algorithm enabling accurate delineation of various neuroanatomical regions of interest (ROIs) from individual MR images. The atlas was warped on each MRI and used as prior to estimate ROI intensity profiles used to correct the atlas probabilities and match at best each individual brain anatomy. Images were finally segmented into 23 ROIs, for which volumes were computed. As a control, caudate nuclei from 7 animals were manually segmented on MR images. Our method was successfully applied to all healthy subjects and 75% of QA subjects. Delineated caudate volumes showed good correlation with control segmentations (our method: r^2=0.89; atlas registration: r^2=0.08). As expected, healthy and lesioned subjects were easily identified based on caudate volumes normalized for intracranial volume (T-test; left: p < 10-7; right: p < 10-4; Bonferroni correction). This method could be of major interest to characterize the shape and size of neuroanatomical ROIs longitudinally. This approach looks like a good complement to voxel-based analyses in highly variable NHP models and provides a valuable brain parcellation to analyze functional images. Some applications could be stereotaxy quality control and biomarker quantitation for *in vivo* evaluation of models and therapies.

Title: Acute chlorpyrifos exposure induces oxidative stress and mitochondrial dysfunction in a striatal cell model of Huntington's disease

Authors: *G. A. DOMINAH[1], G. F. KWAKYE[2];
[2]Neurosci., [1]Oberlin Col., Oberlin, OH

Abstract: In spite of the genetic cause of Huntington's disease (HD), emerging evidence suggests that potential exposure to environmental factors may contribute to the variability in the age of onset, progression, and severity of the disorder. However, the identity of the environmental risk factor is currently unknown. Recognizing some of the shared similarities in the pathophysiological mechanisms in HD and pesticide neurotoxicity such as oxidative stress and mitochondrial dysfunction, we hypothesized that the commonly used agrochemical, chlorpyrifos (CPF) would exhibit a disease-toxicant interaction and reveal the influence of CPF in HD neuropathology. Following a 48-hour exposure to the metabolites CPO and TCP, we report no significant dose and genotypic differences in cell survival. However, mutant $STHdh^{Q111/Q111}$ cells show increased susceptibility to CPF neurotoxicity compared to wild-type $STHdh^{Q7/Q7}$ cells. In addition, mutant $STHdh^{Q11/Q111}$ cells exhibit increased production of reactive oxygen species and diminished glutathione levels in a dose-dependent manner compared to wild-type $STHdh^{Q7/Q7}$. We examined the possibility of the antioxidant N-acetylcysteine (NAC) treatments to ameliorate the genotypic difference in cell survival. Pre- and simultaneous, but not post treatments to striatal cells with NAC was sufficient to decrease CPF induced toxicity and abolish the genotypic difference in the striatal HD cells. Moreover, we report decreased net energy production as well as decreased mitochondrial membrane potential in mutant $STHdh^{Q111/Q111}$ cells compared to wild-type $STHdh^{Q7/Q7}$ cells following CPF exposure. In addition, heme-oxygenase 1 (HO-1) protein expression levels, a biomarker for oxidative stress, increase in both $STHdh^{Q7/Q7}$ and $STHdh^{Q111/Q111}$ cells suggesting that CPF causes neurotoxicity via oxidative stress pathways to induce striatal neuron loss even without the influence of mutant Htt protein.

Title: Pridopidine selectively occupies sigma-1 rather than dopamine D2 receptors at low, behaviorally active doses

Authors: *K. SAHLHOLM[1], J. W. A. SIJBESMAA[2], B. MAAS[2], C. KWIZERA[2], D. MARCELLINO[3], N. K. RAMAKRISHNAN[2], R. A. J. O. DIERCKX[2], P. H. ELSINGA[2], A. VAN WAARDE[2];

Abstract: Dopamine stabilizers have stimulatory actions under low dopamine tone and inhibitory actions under high dopamine tone without eliciting catalepsy. These compounds are dopamine D2 receptor (D2R) antagonists or weak partial agonists, and may have pro-mnemonic and neuroprotective effects. The mechanism underlying their stimulatory and neuroprotective actions is unknown but could involve sigma-1R binding. The present study examined sigma-1R and D2R occupancy by the dopamine stabilizer pridopidine (ACR16) at behaviorally relevant doses in living rats. Rats were administered 3 or 15 mg/kg pridopidine, or saline, before injection of the radiotracer 11C-SA4503 (sigma-1R) or 11C-raclopride (D2R). Some animals received 60 mg/kg pridopidine and were only scanned with 11C-raclopride. Cerebral 11C-SA4503 binding was quantified using metabolite-corrected plasma input data and distribution volume (VT) calculated by Logan graphical analysis. 11C-raclopride binding was quantified using striatum-to-cerebellum ratios and binding potentials calculated with a simplified reference tissue model (SRTM). Cunningham-Lassen plots indicated sigma-1R occupancies of 57 ± 2% and 85 ± 2%

after pretreatment of animals with 3 and 15 mg/kg pridopidine. A significant (44-66%, as determined using SRTM and striatum-to-cerebellum ratio, respectively) reduction of 11C-raclopride binding was only observed at 60 mg/kg pridopidine. At doses shown to elicit neurochemical and behavioral effects, pridopidine occupied a large fraction of sigma-1Rs and a negligible fraction of D2Rs. Significant D2R occupancy was only observed at a dose 20-fold higher than was required for sigma-1R occupancy. The characteristics of dopamine stabilizers may result from the combination of high sigma-1R and low D2R affinity.

Title: Cerebrospinal fluid from HD subjects seeds aggregation of mutant huntingtin

Authors: *Z. TAN[1], W. DAI[2], J. PAULSEN[3], L. THOMPSON[4], C. GLABE[4], W. CHIU[2], S. POTKIN[5];
[1]Inst. for Memory Impairments and Neurolog. Disorders, Univ. California Irvine, Irvine, CA; [2]Baylor Col. of Med., Houston, TX; [3]Univ. of Iowa, Iowa City, IA; [4]Univ. of California Irvine, Irvine, CA; [5]Dept. of Neurol., Univ. California Irvine Sch. Med., Irvine, CA

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disease that results in progressive motor, cognitive and psychiatric impairment and ultimately death. The disease is caused by an abnormal CAG trinucleotide repeat expansion within exon 1 of the HD gene that produces a mutant Huntingtin protein (mHTT) containing an expanded polyglutamine (poly(Q)n, n≥ 36) tract. The length of the expansion has an inverse relationship to age-of-onset

of clinical motor symptoms, but onset of symptoms in mutant Huntingtin gene-carrying individuals remains unpredictable. We report that cerebrospinal fluid from BACHD transgenic rats and from human Huntington's subjects effectively seeds mutant Huntingtin aggregation in a cell model and its cell lysate. Our studies demonstrate that seeding is mutant Huntingtin template-specific and may reflect an underlying prion-like protein propagation mechanism. Light and cryo-electron microscopy show that synthetic seeds nucleate and enhance mutant Huntingtin aggregation. This seeding assay distinguishes blinded living Huntington's subjects from healthy and non-Huntington dementia controls without overlap. Seeding measures from expansion-gene-positive subjects without clinical symptoms range from HD to control values. Ultimately this seeding property in Huntington's patient cerebrospinal fluid may form the basis of a molecular biomarker assay to monitor HD and evaluate therapies that target mutant Huntingtin protein.

Title: Differential profiles of molecular pathology following repeat concussion in an animal model of projectile concussive impact (PCI) injury

Authors: *C. M. CARTAGENA, A. M. BOUTTE, H. HWANG, D. JOHNSON, F. C. TORTELLA, D. A. SHEAR;
Brain Trauma Neuroprotection and Neurorestoration, Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Closed-head concussive injury is one of the most common causes of traumatic brain injury (TBI) and represents a significant public health concern. While neurologic dysfunction from a single concussion may be limited, multiple concussions can result in cumulative damage and increased risk for long-term morbidity. However, there is very limited understanding of the clinical intervals between diagnosed injuries and emergence of latent pathologies. In the current study, we evaluated changes in key TBI markers after both single and repeated concussions using the WRAIR projectile concussion impact (PCI) model in rodents. Importantly, PCI caused

a delay in righting reflex indicative of mTBI in our model. Following PCI injury, cortex (CX) and hippocampus (HC) tissue lysates were evaluated as select regions of interest and compared to sham controls. Single PCI was evaluated at 4h, 24h, 72h and 7 days post injury; but no significant changes in APP, GFAP or tau were detected in the CX or HC. Repeat PCI injuries (4 injuries) were conducted at 1h, 24 hour or 7 day inter-injury intervals. Experimental endpoints included 3 days after the last injury (all injury cohorts) as well as 24h and 7 days post-PCI (1h inter-injury intervals only). Following 4 PCI injuries spaced 1h apart, significant increases in tau (33%) and phosphorylated tau (28%) were detected in the HC at 3 days post-injury that were normalized by 7 days post-injury. No changes were found in the CX. No changes were found in APP or APP beta cleavage at 3 or 7 days. Increased GFAP (138%) was seen in CX but not HC. Following 4 PCI injuries spaced 24h apart, no changes were seen in tau phosphorylation, APP or APP beta cleavage at 3 days post injury. However increased GFAP was detected in both CX (207%) and HC (44%) at 3 days post injury. No significant changes were detected in any of these markers following 4 PCI injuries spaced 7 days apart. Notably, the 24h interval between concussions produced substantially greater GFAP upregulation vs. the 1h interval, an affect that was observed in both CX and HC regions. Overall, these results indicate that tau and tau phosphorylation are more affected following rapid repeat injuries; whereas GFAP changes are more prevalent with longer inter-injury intervals and thus may prove more valuable for evaluating therapeutic interventions.

Title: Effects of diffuse axonal injury (DAI) in the retinal-thalamic pathway upon the synaptic input and intrinsic properties of relay cells in the dorsal lateral geniculate nucleus (dLGN)

Authors: *C. W. JURGENS, V. C. PATEL, T. E. KRAHE, J. T. POVLISHOCK;
Dept. of Anat. and Neurobio., Virginia Commonwealth Univ. Med. Ctr., Richmond, VA

Abstract: Visual deficits are a common occurrence in many types of traumatic brain injury (TBI), with some deficits resolving while others persist. Our lab has previously shown scattered axonal disconnection and dieback of axons in the mouse optic nerve following the central fluid percussion injury (cFPI) model of DAI. Here we utilized the mouse visual system to assess the functional consequences of DAI on visual circuits and their recovery. It is widely accepted that axonal deafferentation can induce synaptic plasticity and rearrangement in the cortex leading to at least some recovery of function. However, little is known about the contribution of the thalamus in recovery following DAI. To examine this at the synaptic level, we utilized whole cell patch clamp recordings from the dorsal lateral geniculate nucleus (dLGN) to assess the functional implications in the primary visual thalamus at 10 and 20 days post cFPI and its associated DAI. Slices containing an intact optic tract were used to determine differences in connectivity, EPSC characteristics and cell membrane properties between injured and sham mice. Our findings demonstrated a decrease in the number of inputs to each cell with little change of the remaining EPSC dynamics. Importantly, this decreased input persisted over the 20 day post injury period evaluated in this study. While the overall functional implications of these findings remain to be assessed, these persistent alterations in dLGN synaptic input would not suggest an adaptive response at the thalamic level. Although more work is required, these studies support the premise that the visual system may serve as an excellent model for further understanding the underlying interaction and compensation of circuitry pathways in some of the recovery associated with DAI.

Title: Structural studies of plasticity in dorsal lateral geniculate nucleus following TBI

Authors: *V. C. PATEL, T. E. KRAHE, J. T. POVLISHOCK;
Neuroanatomy and Neurosci., Virginia Commonwealth Univ., Richmond, VA

Abstract: Diffuse axonal injury (DAI) or traumatic axonal injury (TAI) is a consistent feature of most forms of traumatic brain injury (TBI) and is associated with most of its morbidity. Little is known however regarding its downstream consequences. Previous publications from our lab demonstrate that even mild TBI injury can induce TAI within the optic nerve. The result is diffuse and scattered pattern of axonal loss despite retention of a large fraction of optic nerve axons. In the current study we seek to evaluate if the remaining intact axons demonstrate adaptive or maladaptive plastic response. To do so, we utilized epifluorescent, and electron microscopy to study intact retinal ganglion axonal terminals and their potential rearrangement within dorsal lateral geniculate nucleus (dLGN) over a 20 day post injury period. Using 9 to 12 week old C57B6J mice, we performed central fluid percussion injury (~1.4 ATM), with the use of appropriate shams. On post-injury days 1, 7, and 17, CTB conjugated Alexa dyes are injected into the vitreous cavity of both eyes using separate colors for each eye. Seventy-two hours following eye injections, animals are perfused and coronal slices prepared. Projections from either eye were mapped using epifluorescent images with thresholded analysis to compare area of dLGN covered by ipsilateral and contralateral projections. Fluorescent signal intensity was compared between experimental groups within the monocular zone of dLGN using ImageJ on raw images. To confirm these fluorescent findings at the EM level electron dense conversion of CTB Alexa 488 was performed in additional animals at corresponding time points. Through this approach we found within dorsal LGN, scattered loss of axonal terminal input contiguous with retinal ganglion cells. We observed ~40% loss of ipsilateral retinal projections with ~20% loss of contralateral projections following injury. This distribution of terminal loss remains unchanged over the 20 day post-injury period. No evidence for synaptic rearrangement of overlap between ipsilateral and contralateral projections in dLGN was found. We believe there is limited to no anatomic adaptive plasticity of retinal ganglion axon terminals within adult mouse dLGN following a mild fluid percussion injury associated with diffuse axonal injury.

Abstract: A proteomic study after *in vitro* trauma yielded a list of fast trauma-released proteins, the mouse traumatome (Levine J et al., submitted). Cerebrospinal fluid (CSF) from traumatic brain injury (TBI) patients carried a strong astroglial signature determined by mass spectrometry. A new neurotrauma marker panel was identified from the overlap between traumatome and TBI CSF proteome by selecting astrocyte enriched proteins not found in healthy blood. Aldolase C (ALDOC), brain lipid binding protein (BLBP) and, for study rigor, glial fibrillary acidic protein (GFAP) were chosen from this panel. Their levels were significantly elevated in a cohort of TBI patients' CSF and blood samples versus controls and all displayed proteolytic breakdown products (BDPs). ALDOC and BLBP were faster released and had a longer detection window than GFAP. To further characterize their pathobiology, we stretch-injured *in vitro* matured human fetal astrocytes (Wanner I, 2012). ALDOC and BLBP were significantly released within 30 mins post-injury and were associated with trauma-inflicted membrane permeability, mechanoporation. GFAP 25-19 kDa lower BDPs were significantly released by 48 hours after stretching and were associated with cell death. Pharmacological inhibition of calpains and caspases suggest that both contributed to trauma induced proteolytic marker cleavage. Human traumatized astrocytes had process fragmentation and beading as well as GFAP filament disassembly and altered antigenicity. Fast released markers were depleted from mechanoporated cells acutely after injury. These changes were also found *in vivo*, in preliminary acute spinal cord injury (SCI) studies in the yucatan swine. Swine CSF levels for the three astroglial markers were elevated 20 mins to 3 days after mild-to-moderate contusion SCI and were associated with astroglial histopathology. Porcine astrocytes share complexity of human astrocytes including interlaminar processes. Astrocyte beading and process fragmentation were seen in white and gray matter near the lesion acutely post-injury. ALDOC and BLBP levels were reduced in lesion-near, injured astrocytes compared to least affected astrocytes in lesion-far areas. Process fragmentation was measured using new semi-automated image analysis to quantitate diffuse astrocyte injury. Astrocyte soma swelling is now quantifiable using ALDOC as feasible

cytoplasmic astrocyte marker. In conclusion, we provide new trauma-released astroglial injury markers that are released by mechanoporation and cell death, are cleaved by trauma-activated calpains and caspases and can be valuable as future diagnostic and predictive neurotrauma biomarkers.

Title: Neurotrauma in young mice induces changes in neuroprotectin D1 (NPD1) and other lipid mediators in brain and serum

Authors: *J. L. ROSSI[1], E. J. KNOTT[1], C. L. DAVIDSON[1], T. TODD[1], B. JUN[1], L. H. HOLLIER[2], N. G. BAZAN[1];

Abstract: Introduction: Traumatic injury to the skull and dura affects multiple brain cells perturbing neurotransmission, ion channels and early neural circuit establishment. Lipid signaling has been explored in TBI; however, the significance of the newly discovered neuroprotective docosanoids is not understood under these conditions. Here we examined early responses in young mice following closed head TBI aiming to understand the significance of the expression of protective lipids as a function of early age, time and severity of injury. **Methods:** PND21, PND24 and PND35 mice were anesthetized with avertin, mechanically ventilated, physiologically regulated, and subjected to a lateral closed-skull injury model with impact depth of 2mm- moderate, or 2.25 mm- severe injury (bregma level - 0.10mm). Mice sacrificed timepoints were T<2m (minutes), 30m, 1h (hour) and 4h and 24h. Lipids were extracted by solid phase and run by LC-MS/MS. **Results:** NPD1 shows significant elevation in the serum of PND35 mice at 24h after severe closed head traumatic brain injury (SCHT) [sham (s)-8.838 vs. severe-20.50] and when deuterium labeled DHA was injected 7d prior to impact an increased

level of D5-NPD1 in the serum was observed over sham operated animals [s-69.77 vs. severe-295.8]. This also matched with the endogenous LC-MS profile of enhanced NPD1. NPD1 also displayed a trend of enhancement at 1h in PND21 brains between moderate and severe impact depths [moderate-6.5 vs. severe-14.17]. Within two minutes of SCHT we found a selective, rapid and transient accumulation of 15- HETE in both PND24- [sham (s) 4.833 vs severe 15.5)] and PND21-[s 5.16 vs. severe 13.17]. PND24 mice also showed a rapid increase in PDG2 and PGE2 in both, with significance between sham and severe injuries at T< 2m for both [s-3.88 vs. severe 14.33] as well as in PND21 mice both PDG2 and PGE2 show significance at T< 2m in both depths of injury, sham vs. moderate (4.33 vs. 11.83) and sham vs. severe (4.33 vs. 12.33). HETE 12 shows significance in PND21 mice between shams vs. moderate injury at 1h (5.667 vs. 14). 12-HETE also trends slowly to elevation in the SCHT through 4h in PND24. **Conclusion:** This is an initial study to explore lipid mediators engaged in the neuroinflammatory response in TBI of young mice. The evidence of NPD1 in the serum is novel and provides potential usefulness as a marker. The rapid and transient upregulation of 15-HETE, PDG2 and PGE2 requires further investigation.

Title: Newly identified role for Arylsulfatase B in the upregulation of chondroitin-4-sulfate glycosaminoglycans after brain injury

Authors: *M. GUIZZETTI[1,2], S. BHATTACHARYYA[2], X. ZHANG[2], L. FEFERMAN[2], W. D. JOHNSON[3], F. C. TORTELLA[3], J. K. TOBACMAN[2];

Illinois at Chicago and Jesse Brown VA Med. Ctr., Chicago, IL; [3]Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Chondroitin-4-sulfate glycosaminoglycans (C4S-GAGs) are upregulated after brain injury and inhibit effective axonal regeneration, therefore contributing to permanent brain damage and impaired cognitive functions. Chondroitin 4-sulfotransferase 1 (C4ST1, also called CHST11), the last enzyme in the biosynthesis of C4S, has been reported to be upregulated in animal models of traumatic brain injury, indicating that injury triggers C4S biosynthesis. In this study we explored another mechanism by which C4S is upregulated after injury, i.e. through the inhibition of the activity of arylsulfatase B (ARSB), the enzyme that removes sulfate groups from C4S triggering the degradation of C4S-GAGs. Following penetrating ballistic-like brain injury, C4S-GAG levels increased in association with ARSB activity inhibition and C4ST1 mRNA expression and sulfotransferase activity upregulation at the ipsilateral site of injury, but were unaffected at the contralateral site or in sham controls indicating contributions from both increased production and reduced degradation to the accumulation of C4S following trauma. Reactive astrocytes are responsible for the dramatic increase in the levels of extracellular CS-GAGs at the lesion site. It has been reported that the phenotype of reactive astrocytes is not homogeneous and depends on the type of insult astrocytes are responding to. In the model of PBBI used in this study, the brain undergoes mechanical damage, which rapidly triggers an inflammatory response. In order to dissect the relative contribution to C4S-GAGs upregulation of mechanically-injured and inflammatory factors-exposed reactive astrocytes, we used two well-established *in vitro* models of reactive astrocytes: the scratch-would model and the transforming growth factor β1 (TGFβ1)-induced *in vitro* astrogliosis model respectively. The total levels of C4S-GAGs was increased in both models of reactive astrocyte; however, while scratch injury inhibited ARSB activity without affecting C4ST1 expression or sulfotransferase activity, TGF-β1 exposure increased C4ST1 expression and sulfotransferase activity with no effect on ARSB. Hence, inhibition of ARSB activity represents a newly identified mechanism by which glial scar C4S-GAGs are upregulated as a result of the activation of astrocytes selectively by mechanic injury. Based on these results, recombinant ARSB therapy, already in use to treat mucopolysaccharidosis VI (a genetic defect in the ARSB gene leading to deficiency in the ARSB enzyme) should be considered to reinstate plasticity after brain injury.

Title: Ephrin signaling in axon regeneration as a target for the treatment of traumatic brain injury

Authors: A. GIARRATANA[1], A. PALMIERI[1], S. TENG[1], J. PARK[1], R. ZHOU[2], J. ALDER[1], *S. THAKKER-VARIA[1];

Abstract: Molecules of the Eph/Eprhin family are repulsive to process outgrowth and recent studies suggest that blocking Eph function or expression promotes recovery following spinal cord injury. However, the effect of inhibition of Eph receptors in traumatic brain injury (TBI) has yet to be investigated. We have shown that the EphA6 receptor is expressed in the adult brain and is upregulated in the hippocampus following the lateral fluid percussion (LFP) model of TBI. In EphA6 mutant mice, neurons grow abnormally exuberant processes, supporting the notion that the EphA6 receptor functions to restrict growth of axons and dendrites. There is high expression of the ligand for this receptor, Ephrin-A5, in the hippocampus as well as in motor and sensory cortex of adult mice and we have shown that Ephrin-A5 is also inhibitory to process outgrowth *in vitro*. In the current study, we have used soluble Eph and Ephrin-Fc fusion proteins infused into the adult cortex and hippocampus to examine regeneration and behavioral recovery following LFP injury in adult male mice. The antagonist EphA6-Fc, the agonist EphrinA5-Fc or control IgG were administered to cortex of the wildtype mice via mini-osmotic pumps for one week following LFP. Sham mice were used as control. EphA6-Fc treated mice showed significantly less cell death as indicated by activated caspase-3 positive cells and fewer degenerating neurons as evidenced by Fluorojade-C labeled cells following LFP compared to IgG treated animals. There are also fewer GFAP positive cells in the EphA6-Fc treated mice suggesting a reduction in glial scar formation. The mice treated with EphA6-Fc also had a longer latency to fall on the rotarod 21 days after injury indicating improved motor function compared to control mice. Conversely, in mice treated with the EphrinA5-Fc, which acts as an agonist to the EphA6 receptor there was increased apoptosis and a trend to exacerbated motor function relative to control. The effect of EphrinA5-Fc on cell death, degeneration and glial scar formation are currently under investigation. We are also using EphA6 mutant mice crossed to transgenic Thy1-YFP mice to visualize axons and determine if the absence of EphA6 signaling enhances regeneration. Together these studies will yield insights into the role of Eph/Ephrin signaling in injury and demonstrate the therapeutic potential of Fc fusion proteins for the treatment of TBI.

Title: Diffusion MR imaging reveals abnormalities in the corpus callosum after single TBI versus overlying cortex after repetitive TBI

Authors: ***F. YU**[1,2], D. SHUKLA[2], R. ARMSTRONG[2,1], B. DARDZINSKI[2], R. SELWYN[3,2]; [1]Dept. of APG, [2]Ctr. for Neurosci. and Regenerative Med., Uniformed Service Univ., Bethesda, MD; [3]Radiology, Univ. of New Mexico, Albuquerque, NM

Abstract: Non-invasive detection of brain abnormalities from single and repetitive mild traumatic brain injury (TBI) is important for evaluation of the acute through chronic effects of impact-acceleration head injuries. Magnetic resonance imaging (MRI) is beginning to reveal findings in mild TBI patients that are not detected with conventional imaging. This MRI study used diffusion tensor imaging (DTI) to evaluate longitudinal changes in both the corpus callosum and the overlying cortical gray matter after single and repetitive impact injuries in adult male C57BL/6 mice. For single TBI (sTBI), mice had a scalp incision to expose the skull and received a stereotaxically controlled impact at bregma (3 mm tip; 1.5 mm depth; 4.0 m/sec; 100 msec dwell time). For repetitive TBI (rTBI), mice received a milder impact (1.0 mm depth; 4.0 m/sec; 200 msec dwell time) onto the scalp over bregma once each day for 5 days. Sham mice were run in parallel but without impact. T2-weighted MRI and DTI scans were performed at baseline and at 3 dys, 6 dys, and 6 wks post-TBI/sham. Fractional anisotropy (FA) values were significantly decreased in the corpus callosum after sTBI, but not rTBI. The FA decrease corresponded with a decrease of axial diffusivitiy (AD) and increase in radial diffusivity (RD), although neither AD or RD changes reached significance. Histological analysis of the corpus callosum showed significant axon damage, astrogliosis and microglial activation after sTBI; after rTBI, axon damage, astrogliosis and microglial activation was significantly increased compared to sham mice but was milder than after sTBI. Significant demyelination was found in the corpus callosum after sTBI but not following rTBI. In contrast to the corpus callosum, in cortical regions DTI showed reduced AD in the rTBI mice, but not in sTBI mice. FA and RD were not significantly

changed in the cortex after rTBI. These differential DTI findings indicate that rTBI can result in milder damage in the corpus callosum while having more significant changes in the overlying cortex following repetitive impacts that are each milder than the impact used in the sTBI model. The DTI evidence of cortical abnormalities in the rTBI mice is supported by behavioral deficits in social interaction at 3 wks after rTBI, but not sTBI. Respective DTI changes, in the corpus callosum after sTBI and in the cortex after rTBI, persisted through 6 wks post-TBI. These findings demonstrate that evaluation of mild rTBI should include region-of-interest analysis in the cerebral cortex and could be missed with widely used approaches for DTI analysis that are confined to white matter tracts.

Title: The role of par1 in regulating neuroinflammation following traumatic brain injury

Authors: *V. L. DIBONA[1], K. KRAUSE[2], L. BERNARD[1], Q. WU[1], D. CROCKETT[1], H. ZHANG[1];
[1]Rutgers Univ. / RWJMS, Piscataway, NJ; [2]Rutgers Univ., New Brunswick, NJ

Abstract: Millions of Americans are living with disabilities caused by traumatic brain injuries (TBI), making it a serious public health concern. Despite the overwhelming incidence of TBI, there is a lack of treatment options for those injured. A major obstacle of TBI recovery is the secondary neuronal damage caused by a prolonged neuroinflammatory response. The chief cells mounting the neuroinflammatory response are microglia, the brain's resident immune cell. However, mechanisms underlying microglial activation are still unclear. Following TBI, microglia transform from a highly ramified state to an activated state, where they lose most of their spatial asymmetry and become rounded. This raises the exciting possibility that proteins

regulating cellular polarity/asymmetry are involved in the microglia activation process. The partitioning-defective (Par) proteins are central regulators of polarity establishment in many different cellular contexts including embryogenesis, directional motility, epithelial morphogenesis, axon specification and dendritic spine formation. Here, we show that one of the polarity regulators, the Ser/Thr kinase Par1, play an important role in microglia activation following TBI. We show that Par1b knockout (KO) mice exhibit heightened basal levels of microglia activation, indicated by their altered morphology. Following controlled cortical impact (CCI) injuries, Par1b KO mice show excessive microglia activation that spreads more distally from the injury site than wild-type (WT) controls. Interestingly, even sham-operated KO mice show significant microglia activation, suggesting that the microglia in the Par1b KO mice are hypersensitized to insults. Further, knockdown of Par1 in primary microglia cultures resulted in morphological changes from a ramified to an amoeboid shape, which is reminiscent of activated microglia. By contrast, overexpression of Par1 blocked ATP-induced morphological changes in microglia. Moreover, we found that microglia depleted of Par1 phagocytize significantly more damaged neuronal particles than controls. Taken together, we propose that decreased Par1 activity and expression leads to increased neuroinflammation and worsens TBI outcomes.

Title: Magnetic resonance spectroscopy (MRS) of post-traumatic epileptogenesis

Authors: *A. YASMIN, O. GRÖHN, A. PITKÄNEN, R. IMMONEN;
Dept. of Neurobio. A.I. Virtanen Inst. for Mol. Sci., Univ. of Eastern Finland, Kuopio, Finland

Abstract: Traumatic brain injury (TBI) leads to post-traumatic epilepsy (PTE) in up to 53% of patients. In many cases, epileptogenic focus develops to the perilesional cortex. Here we hypothesized that TBI induces a metabolic fingerprint to the perilesional cortex that predicts

epileptogenesis. To address the hypothesis we used magnetic resonance spectroscopy (1H-MRS) to reveal metabolic alterations in the perilesional cortex *in vivo*. Methods: Fifteen *in vivo* detectable neurochemicals were analyzed in the perilesional cortex in lateral fluid-percussion injury (LFPI) rat model of TBI. Adult, male Spraque-Dawley rats (n=20 TBI, 10 sham) were imaged at 1, 3, and 6 months post-TBI. 1H-MRS was carried out at 9.4 Tesla high field magnet. Spectra were obtained from single perilesional voxel (1*3*5mm) by PRESS (TE 11ms, TR 2500ms, 320/640 averages for sham/TBI). Spectra were analyzed by LC model and only metabolites with SD%≤ 20 were included. Metabolite concentrations were normalized to creatine and phosphocreatine (Cr+PCr) peak to account for the tissue atrophy. In the end, rats were monitored for 4 wk with 24/7 video-EEG to detect epileptiform activity. Results: 6 out of 15 parameters showed changes at some follow-up point. Myo-inositol was increased up to 77% ($p<0.01$) at 1 month, 35 %($p<0.01$) at 3 months, and 21% ($p<0.01$) at 6 months post-TBI as compared to corresponding controls. There was partial recovery of elevated Myo-inositol levels among the injured animals ($p<0.01$, between 1 month and 6 months post injury). At 6 months post-TBI, NAA was increased by 14% ($p<0.05$) as compared to controls, and by 16 % ($p<0.01$) as compared to 1 month post injury animals. Also perilesional NAA+NAAG levels in trauma animals elevated 14% over time ($p<0.01$, 1 month vs 6 months) despite the progressive atrophy of the primary lesion. Glutathione (GSH) was increased by 17% ($p<0.05$) in 1 month post-TBI. Glycerophosphocholine (GPC) alone and with phosphocholine (GPC+PCh) both showed an increase over time in the TBI group (GPC 12%, GPC+PCh 11%, $p<0.05$ from 1 to 3 months). In further analysis the MRS findings will be correlated with the seizure susceptibility in EEG. Conclusions: We found markedly increased myo-inositol levels in the perilesional cortex, indicating gliosis. The elevated glutathione may reflect potential on-going oxidative stress. Phosphocholines are linked to membrane turnover. Whether any of these metabolic anomalies could identify the epileptogenic animals is yet to be examined.

Title: Intracerebroventricular transplantation of adult neural stem cells after traumatic brain injury: a proof-of-concept for activation of host neural stem cells in the subventricular zone

Authors: *G. SULLIVAN, R. C. ARMSTRONG;
APG, USUHS, Bethesda, MD

Abstract: Transplantation of neural stem cells (NSCs) may promote brain repair by replacing lost cells and by interacting with the host tissue to modulate the immune response and stimulate endogenous regenerative capacity. Determining an effective NSC delivery route in the CNS is particularly challenging for traumatic brain injury (TBI) that involves diffuse rather than focal lesions. In clinical management of TBI, ventriculostomy is often performed in patients with acute TBI after failure to control intracranial pressure by other means. Ventriculostomy may provide a route of access to the lateral ventricle for therapeutic delivery of stem cells. The current studies provide a proof-of-concept test of intracerebroventricular (ICV) delivery of adult NSCs into the lateral ventricle in an impact-acceleration TBI model with traumatic axonal injury in the corpus callosum. We also test the effect of NSC transplantation in stimulating a regenerative response in endogenous NSCs in the host subventricular zone (SVZ) based on activation of Sonic hedgehog (Shh) signaling. Shh maintains the NSC niche in the adult CNS and Gli1 transcription indicates active Shh signaling. TBI from impact to the skull at bregma was produced in adult Gli1CreERT2 mice crossed to RosaTdTomato reporter mice. To distinguish between endogenous and transplanted cells, NSCs were isolated from the SVZ of adult UBI-GFP mice, which ubiquitously express green fluorescent protein (GFP). GFP-NSCs, 2 µl of 2.5 X 104 cells/µl suspended in F12/DMEM medium, were microinjected unilaterally into the lateral ventricle of the Gli1CreERT2;RosaTdTomato mice 2 weeks after the TBI or sham procedure. Gli1CreERT2;RosaTdTomato host mice were then administered tamoxifen to label endogenous cells responding to Shh signaling after ICV transplantation. Mice were sacrificed for tissue analysis at 4 weeks post-TBI. Analysis of serial tissue sections taken from each mouse showed transplanted GFP-NSCs survived, maintained an immature phenotype, and were localized along the ependymal lining of the ventricle and adhering to the choroid plexus. Endogenous NSCs in the adjacent SVZ were Gli1 fate-labeled with the TdTomato reporter, indicating active Shh signaling. However, Gli1 fate-labeled cells were not changed significantly due to ICV transplantation of GFP-NSCs versus vehicle injection in TBI or sham mice. An inflammatory response to transplanted GFP-NSCs was not observed in sham or TBI mice. Ongoing studies are examining potential effects of the NSC transplant to attenuate neuroinflammation in the corpus callosum after TBI.

Title: A translational approach to the innate immune responses following TBI: exploring the nexus of the post injury proinflammatory cytokine mediated responses with the intracellular p38 MAPK signal transduction pathway

Authors: *L. J. VAN ELDIK[1], S. J. WEBSTER[1], D. S. GOULDING[1], D. M. WATTERSON[2], A. D. BACHSTETTER[1];
[1]Univ. of Kentucky, Lexington, KY; [2]Northwestern Univ., Chicago, IL

Abstract: Closed head traumatic brain injury (TBI) triggers a broad innate immune and acute inflammation response that involves resident glia and other immune cells. Neurologic outcome is dependent on the essential balance between restoration of tissue homeostasis after the initial injury and resolution of the injury-induced innate immune responses, especially those involving the proinflammatory cytokines that are implicated in both aspects of the neurologic outcome balance. Natural resolution of the injury-induced proinflammatory cytokine response such that neurologic sequelae are attenuated is generally not successful. Therefore, therapeutic interventions during critical dosing time windows are needed in order to reduce the dysregulated inflammation that is causally linked to the neuropathologic sequelae. Previous work has generated a causal link between the p38α mitogen-activated protein kinase (MAPK) mediated intracellular signaling pathway and the injurious proinflammatory cytokine response in neurodegenerative animal models of disease. The recent availability of highly specific *in vivo* molecular probes for p38α MAPK inhibition allow a more refined *in vivo* analysis of this intracellular signaling pathway and its link to dysregulated glia function and neuroinflammation in TBI with its more rapid pathology progression kinetics. We have recently explored these processes in TBI through the combined use of these *in vivo* p38α MAPK dynamic molecular probes and genetics based *in vivo* tools, such as targeted knockdown of p38α MAPK in specific inflammatory cell types. We found that genetic suppression of p38α MAPK in myeloid cells resulted in less TBI induced deficits in a running wheel behavioral task and cognitive deficits as measured by the radial arm water maze. Suppression of p38α MAPK activity through selective

pharmacological action or through reduction of p38α MAPK protein levels generated reduction of injury injury induced cytokine levels in the brain. The congruence of outcomes from genetic and pharmacological approaches provides a unique battery of outcomes consistent with p38aMAPK as a potential therapeutic target in TBI.

Title: Alterations in glutamate regulation after chronic lateral fluid percussion injury

Authors: *J. L. MCGUIRE, E. A. K. DEPASQUALE, A. E. GARDNER, R. E. MCCULLUMSMITH;
Psychiatry, Univ. of Cincinnati, Cincinnati, OH

Abstract: A significant number of patients experience persistent symptoms after brain injury (TBI), which may include deficits in cognition and memory, and changes in personality and behavior. Furthermore it is becoming clear that TBI is a significant risk factor for later emergence of psychological and behavioral disorders and early cognitive decline. In addition to significant contributions to energy homeostasis, glutamate is the major excitatory neurotransmitter in the brain and is utilized by both neurons and glia. Currently, there is a poor understanding of how injury impacts glutamate homeostasis over time. However, TBI increases the risk for developing a number of disorders and behaviors associated with dysregulation of the glutamate system including depression, substance abuse, epilepsy, impulsivity, aggression, and suicidality, suggesting injury-induced changes in glutamate regulation may contribute to chronic TBI symptoms. Glutamate neurotransmitter released into the synapse is taken up primarily by the astrocytic glutamate transporters EAAT1 and EAAT2 (GLT-1 and GLAST, respectively, in rodent). We propose that a persistent deficiency in astrocytic glutamate reuptake accompanies chronic cognitive and behavioral symptoms after TBI. Using the lateral fluid percussion (LFP) model of mild-moderate brain injury in rats, we will measure GLT-1 and GLAST protein levels and glutamate reuptake in membrane vesicle fractions from hippocampus (HPC) and frontal

cortex (FC) 60 days after injury. We will also assess the effects of the glutamate transporter modulator ceftriaxone on post-injury GLT-1 expression, glutamate uptake capacity, and long term memory. The data will provide evidence of the long-term effect of injury on glutamate homeostasis and the role of glutamate dysregulation in chronic cognitive symptoms after TBI. These data will also indicate whether injury-initiated changes in the glutamate system are reversible and suggest new avenues for treatment for injuries already in the chronic stage.

Title: Serine-threonine kinase signaling in traumatic brain injury

Authors: *E. DEPASQUALE[1], J. L. MCGUIRE[1], C. DORSETT[2], C. L. FLOYD[2], R. E. MCCULLUMSMITH[1];

Abstract: Traumatic brain injury (TBI) is one of the leading causes of death and disability worldwide. Understanding the biochemical processes that occur during and after TBI would better direct efforts in finding treatments. Previous research suggests that alterations in kinase expression and activity contribute to the injury mechanism of TBI. We used a kinome array to examine the changes in serine-threonine kinase activity in a rat lateral fluid percussion (LFPI) model of TBI in both the prefrontal cortex (PFC) and hippocampus (HPC). We found that 25 substrates in PFC and 15 substrates in HPC showed a 1.15 fold change in phosphorylation compared to sham. Using publically available databases, we mapped protein kinases predicted to target the substrates used in the kinome array. We then utilized random sampling permutation analysis to identify kinases targeting the substrates at a greater frequency than would be expected by chance. Signaling network models linking the kinases identified in the random sampling analysis were constructed using known interactions in the Ingenuity database. In PFC, protein kinase B (AKT), creatine kinase (CK), and p21-activated kinase (PAK) were three of the kinases that were both identified in the random sampling analysis and were major hubs in connecting all of the affected kinases in the signaling network models. In HPC, protein kinase C (PKC), protein

kinase A (PKA), and mechanistic target of rapamycin (mTOR) were similarly identified. We then performed inhibitor studies in the prefrontal cortex using pooled samples for TBI and sham groups with AKT, JNK (c-Jun kinase), and PKC-MEK (mitogen-activated protein kinase kinase) inhibitors. We found that in the presence of AKT inhibitor, the sham group had inhibition of phosphorylation of most substrates in the kinome array compared to the untreated control, where the TBI group showed activation in the presence of the same inhibitor compared to their untreated control. JNK and PKC MEK showed much less divergence in their profiles. These data suggest that there is differential regulation of key kinases that could both account for the biochemical changes observed after TBI, as well as acting as a target for potential treatments of traumatic brain injury in the future.

Title: Deletion of androgen receptor affects the expression of p53 and p62 in mice with traumatic brain injury

Authors: Y.-H. CHEN[1], C.-C. TSENG[2], *L.-Y. YANG[3];
[1]Grad. Inst. of Med. Sci., [2]Dept. of Physiol., [3]Taipei Med. Univ., Taipei, Taiwan

Abstract: Traumatic brain injury (TBI) is estimated to affect 10 million people each year and has become one leading global health issue. The common causes of TBI include traffic injuries, sports accidents, falls, violent fights and war. Severe TBI often leads to death or loss of the ability to work and dependence on long-term healthcare, which places an enormous financial burden not only on the National Healthcare System, but also on the patients themselves and the caring relatives. The pathophysiology of TBI is complicated and remains poorly understood. Therefore, it is critical for us to unveil the detailed mechanisms underlying TBI before we can invent optimal therapeutic treatments for TBI. Evidence has shown that androgens exert a beneficial effect on TBI patients and protect neurons against neurotoxicity. Androgen receptors are widely accepted to mediate the effects of androgens. Nonetheless, the role of androgen

receptor in pathophysiology of TBI remains poorly explored. Published results indicate that TBI increases the expression of p53, but decreases the expression of p62. In this study, we aimed to assess the effect of androgen receptor knockout on the expression of p53 and p62 following TBI using the androgen receptor knockout mice. We employed the cortical impactor to induce TBI and evaluated the expression of p53 and p62 in wild-type mice and androgen receptor knockout mice. Our preliminary results showed that TBI increased the expression of p53 and androgen receptor knockout further enhanced the expression of p53 four hours after injury. In contrast, our preliminary data showed that TBI decreased the expression of p62 and knockout of androgen receptor further reduced the expression of p62 four hours following injury. Our results strongly support the idea that androgen receptor plays an important role in the pathophysiology of TBI.

Title: Hippocampal neuron loss, white matter damage and behavioral alterations following a fluid percussion injury in mice: a role for CD74?

Authors: *L. A. SHAPIRO[1], A. OBENAUS[2], S. MUKHERJEE[3], R. TOBIN[3], K. NEWELL-ROGERS[3];
[1]Dept Surgery & Neurosurg., Texas A&M Univ. COM, Temple, TX; [2]Loma Linda, Loma Linda, CA; [3]Surgery, Texas A&M Univ. HSC, Temple, TX

Abstract: Traumatic brain injury (TBI) is a growing health concern and increasing evidence suggests that even mild TBIs can lead to profound and long-lasting neurobehavioral and neuropathological deficits. Treatment options are lacking, as is an overall understanding of disease pathogenesis. We have previously demonstrated the pattern of neurodegeneration in the ipsilateral cortex between 1-30 days after a fluid percussion injury (FPI) in mice. We also showed the pattern of ipsi and contralateral astrocyte and microglial activation within these time points. More recently, we demonstrated that antagonism of CLIP, the proteolytic cleavage product of the MHCII-associated, immune response gene-associated molecule, CD74, or deletion of CD74, is neuroprotective after TBI. However, these studies were limited to examination of ipsilateral and contralateral peri-lesion-cortices and lacked examination of neurological deficits. Thus, we expanded on these findings and examined white matter damage at 30 day after FPI, as

well as hippocampal cell loss and behavioral performance on a neurological testing battery. Moreover, we assessed performance on the behavioral battery in mice treated with a CLIP antagonist at 30 min after FPI. The results demonstrate hippocampal cell loss, white matter damage and behavioral deficits following fluid percussion injury. The results also showed that CLIP antagonism improved neurological outcome measures. It is possible that the improvements in contralateral hindlimb gate might simply be due to the reduced lesion size in the peri-lesion motor cortex, it is also possible that antagonizing CLIP and/or CD74 has other beneficial effects on TBI outcomes. Current and future studies will focus on investigating numerous acute and chronic outcomes after FPI and CD74 manipulations.

Title: Proteolytic cleavage of L1CAM is a redundant feature after traumatic brain injury in mice

Authors: *L. S. DANGEL, W. BOBKIEWICZ, A. SEBASTIANI, S. THAL, K. ENDRESS, M. SCHAEFER;
Universitätsmedizin Mainz, Mainz, Germany

Abstract: L1CAM (L1) is a cell adhesion molecule of the immunoglobulin superfamily. It is an important regulator in the developing brain and promotes neural repair and regeneration after injury. It has been shown that L1 is cleaved by various proteases such as ADAM10 and Plasmin *in vitro*. More recently, proteolytic cleavage of L1 has been linked to the pathophysiology of acute and chronic neurodegenerative processes. The overall aim of this study is to characterize the expression and cleavage pattern of L1 after traumatic brain injury (TBI) *in vivo*. In addition, L1 cleavage was investigated in transgenic mouse lines with genetically modified expression or function of ADAM-10 (transgenic overexpressing and dominant-negative) and plasmin activator-inhibitors (PAI-1 and PAI-2 gene-deficient mice). Controlled cortical impact (CCI) was used as an experimental model of TBI. Mice were sacrificed at different posttraumatic time points ranging from one day to seven days after TBI. Gene and protein expression levels were

analysed by qRT-PCR, western blot and immunohistochemistry. Cleavage of L1 was detected as early as one day after trauma, sustained until seven days after trauma and involved consecutive cleavage of membrane-associated L1 including nuclear translocation of a C-terminal fragment. This process was unchanged in mice deficient for the plasmin regulators PAI-1 or PAI-2 as well as in mice with transgenic expression of wild-type or dominant-negative ADAM10. These results demonstrate that TBI-induced L1 cleavage is a redundant feature independent of Plasmin and ADAM10.

Title: Pediatric traumatic brain injury induces selective loss of cortical inhibitory function

Authors: *J. NICHOLS[1,2], J. NEWBERN[1], T. ANDERSON[2];
[1]Arizona State Univ., Tempe, AZ; [2]Basic Med. Sci., Univ. of Arizona - Col. of Med. Phoenix, Phoenix, AZ

Abstract: Pediatric traumatic brain injury (TBI) is a leading cause of death and disability in children. When TBI occurs in children it often results in more severe cognitive and behavioral deficits. Post-injury, the pediatric brain may be particularly sensitive to the effects of TBI while it is undergoing a number of age-dependent physiological and neurobiological changes. The maintenance of proper cortical function is reliant on the activity of inhibitory interneurons that may be more sensitive to neural insult. Therefore, we hypothesize that traumatic brain injury to the cortex will induce selective loss of cortical interneurons and alter inhibitory cortical function. To model TBI we performed controlled cortical impact (CCI) in juvenile (post-natal day 22) mice with fluorescently tagged inhibitory interneurons (VGAT:Cre Ai9). Following a 14 day recovery period no distinct change in overall inhibitory number were observed in either the ipsilateral peri-injury zone or the corresponding contralateral cortex. However, immunohistochemical analysis revealed a greater than 80% loss of parvalbumin (PV) positive interneurons in the peri-injury zone. PV positive interneurons are reported to have a fast-spiking (FS) electrophysiological phenotype and are implicated in a variety of neurological diseases. Patch clamp recordings from FS interneurons revealed a significant decrease to the inhibitory

synaptic network within the peri-injury zone. Specifically, layer V FS interneurons in the peri-injury zone displayed an increase in the inter-event interval, rise, and decay time of spontaneous inhibitory post-synaptic currents (sIPSCs) as compared to recordings from sham animals. In contrast, excitatory activity was enhanced in the peri-injury zone as determined by an increase in the amplitude of excitatory PSCs onto FS interneurons. Taken together, the data suggests that CCI in pediatric animals induces selective loss of PV interneurons that results in a substantial decrease in network synaptic inhibition. Anatomical and synaptic changes to the cortical inhibitory network, particularly parvalbumin neurons, following TBI may lead to abnormal network activity and synchronization. If present in children, TBI induced disruption of the inhibitory network may have a profound impact on their neurodevelopment and the long-term consequences of brain injury.

Title: Pathological deficits in the chronic stage of traumatic brain injury: characterization of the secondary cell death in adult rats exposed to controlled cortical impact injury

Authors: *H. V. NGUYEN[1], S. A. ACOSTA[2], N. TAJIRI[2], J. HOOVER[2], M. ELIAS[2], S. REYES[2], Y. KANEKO[2], C. V. BORLONGAN[2];

Abstract: Long lasting histological consequences have been suggested as accompanying the chronic stage of traumatic brain injury (TBI) and present as a risk factor for the development of dementia and neurodegenerative diseases, such as Alzheimer's disease (AD). The region-specific secondary damage after TBI, specifically at the cellular level of cortical and subcortical regions, is not well characterized. In the present *in vivo* study, the neuronal and axonal damage were

evaluated in proximal and distal areas in late stage TBI model. Recognizing the contribution of AD-like pathology to TBI, we focused on AD pathological markers in brain regions implicated in the disease process, including neuronal cell loss, inflammation, cell proliferation, neurogenesis, and aberrant intra-neuronal and axonal beta-amyloid precursor protein (β-APP) expression, to link TBI and AD pathologies. Adult Sprague-Dawley male rats were subjected to moderate controlled cortical impact (CCI) injury model of TBI, and 6 months later euthanized and brain tissues harvested. Results from H&E staining revealed significant 33% and 10% reduction in the ipsilateral and contralateral side, respectively of hippocampal CA3 interneurons of TBI animals compared to sham animals (p's<0.001). Meanwhile, unbiased stereology showed significant increments in MHCII-activated inflammatory cells in gray matter (8-20 fold) and white matter (6-30 fold) of both the ipsilateral and contralateral hemispheres of TBI animals compared to sham animals (p's<0.001). Cell cycle regulating protein marker revealed significant 1.6 and 1 fold reductions in the SVZ and a 2.3 and 1.5 fold reductions in the dentate gyrus of the ipsilateral and contralateral side, respectively of TBI animals compared to sham animals (p's<0.001). Moreover, immature neuronal marker demonstrated a significant 2 and 1 fold decrements in both the SVZ and in the dentate gyrus ipsilateral and contralateral side, respectively of TBI animals compared to sham animals (p's<0.001). Additionally, we found increased β-APP distribution volume in white matter including corpus callosum, fornix, and internal capsule (4-38 fold), as well as in the gray matter including motor cortex, striatum hilus and dentate gyrus (6-40 fold) in TBI animals compared to sham animals (p's<0.001). These findings indicate AD-like pathological features in brain regions proximal to the core impact of injury in late stage TBI. The observed inflammation, impaired neurogenesis, and β-APP reminiscent of AD may prove to be valuable markers of TBI pathology.

Title: Repeated binge alcohol and traumatic brain injury results in decreased neural stem cell response

Authors: *S. T. TON[1], I. VAAGENES[3], S.-Y. TSAI[3], C. PAPADOPOULOS[3], G. KARTJE[3,2]; [1]Loyola Univ. Chicago, Chicago, IL; [2]Neurosci., Loyola Univ. Chicago, Maywood, IL; [3]Hines VA Hosp., Hines, IL

Abstract: We have previously found that a repeated dose of binge alcohol prior to TBI leads to worse recovery on a sensitive test of skilled forelimb function (Vaagenes et al. 2015). One means by which the brain is able to compensate for injury is in the mobilization of neural precursor cells. We therefore sought to determine the effect of binge alcohol at the time of TBI on subventricular zone (SVZ) and perilesional neural precursor cells. Adult, male rats were given three injections of alcohol (2gm/kg/i.p/per day). One hour after the final injection, animals were given a TBI directed to the forelimb sensorimotor cortical area and sacrificed three weeks after TBI. Brains were immunostained for proliferating cell nuclear antigen and doublecortin. In animals receiving binge alcohol there was a significant reduction in PCNA-positive cells in the SVZ. Alcohol also reduced the number of double labeled PCNA-positive/DCX-positive cells on the side of the TBI, but not contralateral to the cortical lesion. Furthermore, binge alcohol significantly reduced the number of PCNA-positive cells as well as double labeled PCNA-positive/DCX-positive cells in the cortical perilesional area. Thus, a relatively short repeated dose of binge alcohol prior to TBI reduced the proliferation of neural precursor cells in the SVZ and perilesional area as well as decreased the differentiation of these cells into neurons. We are currently using alcohol administration by gastric gavage (3gm/kg/per day for three days prior to TBI) to determine the neural precursor cell response in this more clinically relevant model of binge alcohol. Our preliminary results show that at 24 hours post TBI, there is decreased cell proliferation within the SVZ in binge alcohol animals, consistent with the observation made at 3 weeks post TBI in the i.p model. We are currently examining later time points to determine if the decrease in neural stem cells is the underlying mechanism for impaired functional recovery.

Title: Oxidative stress and inflammation associated with impairments in social familiarity-induced anxiolysis after mild blast-induced traumatic brain injury

Authors: *S. M. VEGA ALVAREZ[1,2], N. RACE[3], E. LUNGWITZ[4,5,6], T. R. WARNER[4], G. ACOSTA[1], W. TRUITT[4,5,6], R. SHI[1,3,2];

Biol., [5]Stark Neurosciences Res. Inst., [6]Grad. Program in Med. Neurosci., Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: Blast-induced traumatic brain injuries (bTBI) are most commonly suffered by military service members. These injuries can occur without noticeable physical signs of injury but can nonetheless be potentially crippling. While extreme cases of bTBI result in early diagnosis, immediate treatment, and monitoring of injury progression, mild bTBI (mbTBI), however, can go unnoticed due to the absence of acute clinical symptoms which result in delayed therapeutic intervention. The development of sensory, communication, cognitive, and behavioral problems is particularly alarming in mbTBI. Despite increased interest in TBI, and bTBI in particular, we are still lacking general pathophysiological information correlating the blast wave pressure component to specific behavioral and cognitive abnormalities. Among various post-bTBI neurological sequela, impairments in social behavior are probably the most difficult to detect and significantly affect social reintegration. We have previously established an animal model of mbTBI, which recapitulates social familiarity-induced anxiolysis (SoFiA), a similar phenomenon. During SoFiA the presence of a conspecific serves as a safety cue that gradually alleviates anxiety-like behavior in response to a threat. However, when rats were subjected to a mbTBI, such anxiolytic ability is impaired. In the presence of an anxiolytic stimulus and a familiar partner, injured animals present an anxiety-like response in the form of low social interaction time. These findings represent the first replication of post-mbTBI social processing impairment in an animal model. We have correlated these behavioral deficits to an early rise in acrolein, an oxidative stress and pro-inflammatory neurotoxin. This suggests that both the primary physical deformation as well as the secondary biochemical cascades work synergistically to damage the brain neurocircuits critical for the integrity of psychosocial capability. The medial prefrontal cortex (mPFC) has been shown to play a pivotal role in SoFiA. Consequently, we have focused our biochemical screening on the mPFC. In the absence of significant neuronal cell death, microglia activation and increased expression of pro-inflammatory cytokines in the mPFC after mbTBI were detected. Interestingly, similar biochemical abnormalities were obtained from animals injected with acrolein at a pathological

relevant concentration. Taken together, these data suggest that acrolein may be an early biomarker for predicting post-mbTBI psychosocial impairment, but could also serve as an effective target for therapeutic intervention.

Title: The acute effects of a blast overpressure on astrocytes in rat organotypic hippocampal slice cultures

Authors: ***A. P. MILLER**[1,2,3], A. S. SHAH[1,3], B. V. APERI[1,3], B. D. STEMPER[1,3], A. GLAVASKI-JOKSIMOVIC[1,2,3];
[1]Dept. of Neurosurg., [2]Dept. of Cell Biology, Neurobiology, & Anat., Med. Col. of Wisconsin, Milwaukee, WI; [3]Clement J. Zablocki Veterans Affairs Med. Ctr., Milwaukee, WI

Abstract: Blast traumatic brain injury (bTBI) is a significant injury afflicting soldiers and civilians around the world. Symptoms of a bTBI are multifaceted and involve several neuropathological impairments, including learning and memory deficits. The development of novel therapeutic strategies relies on the characterization of the cellular response to a blast injury. Specifically, susceptibility of astrocytes to a blast overpressure and their role in neurodegeneration following a blast injury has yet to be characterized. The aim of this investigation was to characterize the effects of a blast overpressure on astrocytes acutely following a blast injury. Rat organotypic hippocampal slice cultures (OHCs) were used to generate an *in vitro* bTBI model. The hippocampi obtained from neonatal Sprague Dawley (SD) rats (p7-p10) were cut into 400 μm thick sections and grown using the membrane interface method. At 8 days in culture, a blast injury was produced using an open-ended gas-driven shock tube. Sections were exposed to a single blast overpressure of either 147 ± 18 kPa (low) or 278 ± 22 kPa (high). Sham injured sections were treated identical to blast injured sections, except

the shock tube was not detonated. Sections were fixed 2 h following injury and the astrocyte morphology was characterized using immunostaining against glial fibrillary acidic protein (GFAP). Additionally, dead astrocytes were visualized by co-labeling of GFAP and the cell death marker propidium iodide (PI). At 2 h following injury, in both blast groups we detected shearing of astrocytes as well as clasmatodendrosis, which is characterized by cytoplasmic swelling, beading and dissolution of distal astrocytic processes. These morphological changes in astrocytes were infrequent in the sham-injured OHCs. Our preliminary quantification of GFAP and PI co-labeled cells in the CA1 hippocampal region revealed a significant increase in the number of dead astrocytes in the low- ($P<.01$) and high-blast ($P<.001$) group compared to the sham-injured group. Collectively, our data imply astrocytes are affected acutely following overpressure exposure both in the low- and high-blast group. Future studies will elucidate whether there is a correlation between the effects of a blast overpressure on astrocytes and delayed blast-evoked neuronal death.

Title: Susceptibility to Parkinson's disease following a mild-blast traumatic brain injury

Authors: *G. G. ACOSTA[1], N. RACE[2,5], G. KUZIEL[2], L. ZHENG[2], A. AMBAW[1], E. WALLS[3], C. ROCHET[4], R. SHI[2,1];
[1]Basic Med. Sci., [2]Weldon Sch. of Biomed. Engin., [3]Biol. Sci., [4]Dept. of Medicinal Chem. and Mol. Pharmacol., Purdue Univ., West Lafayette, IN; [5]Indiana Univ. Sch. of Med., Indianapolis, IN

Abstract: The prevalence of blast-induced traumatic brain injury (bTBI) is steadily increasing due to escalated terror activities, and constitutes the signature injury associated with the current military conflicts. Specifically, a mild-bTBI is the most common injury encountered by our military personnel. This type of injury presents a problem because the individual is initially asymptomatic and functional. However, growing evidence suggests that this type of injury may

produce long-term neurological consequences that affect the resilience and the performance of soldiers both on and off the battlefield. One such example is an increased susceptibility to Parkinson's disease (PD) by as many as three folds post-blast when compared to the general population. A critical strategy aiming at curtailing this alarming trend is to further our knowledge of pathogenic mechanisms responsible for the escalation of post trauma neurodegenerative diseases. The specific aim of this investigation was to identify the molecular mechanisms underlying the susceptibility to PD in post-blast rats. To this end, we have identified acrolein, a highly reactive aldehyde that persists days to weeks following CNS injury and perpetuates oxidative insult, as a point of convergence between bTBI and PD. Specifically, we have found that the elevation of acrolein post-blast is capable of triggering pathological changes in the vicinity of the basal ganglion, a known location of brain damage in PD. In particular, we have found signs of neuroinflammation and protein aggregation in blast animals that resembles the pathology in PD, although to a lesser extent. In addition, although a mild blast injury alone cannot elicit typical motor deficits seen in a PD model, additional application of a subthreshold PD-inducing toxin could lead to such deficits. Taken together, we hypothesize that bTBI triggers neurochemical events, such as neuroinflammation and oxidative stress, galvanized by acrolein, could increase the susceptibility of the blast-injured rats to PD when other PD-triggering factors are present. As such, we hypothesize that acrolein is a key pathological factor linking bTBI and the development of PD in our rat model. The results from this project are expected to advance our understanding of the long-term consequences of blast-related injuries leading to the development of PD. These efforts could eventually lead to the establishment of biomarkers for an earlier diagnosis as well as strategies for prevention and treatment to curtail the elevating incidence of post-bTBI PD, and significantly improve the quality of life for our men and women who suffer a great deal to ensure our freedom.

Title: In-vivo 2-photon imaging of neuronal activity and neuro-vascular unit disruption in somatosensory cortex in mouse model of traumatic brain injury

Authors: *M. K. JAISWAL[1,2], F. W. LISCHKA[1,2], X. XU[2], Z. GALDZICKI[1,2];
[1]Ctr. For Neurosci. and Regenerative Med., Bethesda, MD; [2]Dept. of Anatomy, Physiol. and Genetics,, USUHS, Sch. of Med., Bethesda, MD

Abstract: The adult brain must undergo plasticity driven events to respond to injury or insult. In response to TBI the functional somatosensory topography of the neocortex is altered such that cortical areas or 'maps' of severed inputs shrink, while maps of the spared inputs expand. However, it is not known how sensory-driven activity in individual L2/3 neurons changes over time after brain injury, and how these changes impact local excitatory/inhibitory (E/I) neuronal populations in response to injury. Moreover, the relationships between alterations in plasticity and vasculature disruption after injury have not been fully understood. We attempted to address these questions using our mild TBI open head model with injury inflicted by CCI device over somatosensory region. Activity of E/I neurons was monitored by *in vivo* two-photon calcium imaging in GAD67-GFP knock-in mice. In our approach we assessed the loss/gain of spontaneously evoked neuronal activity in the core of the microinfarct at 2 weeks and 6 months after injury. We examined changes in vasculature and integrity of the blood-brain barrier with combination of dyes: Rhodamine B dextran, Cascade blue or Texas red concavalin. We also performed simultaneous recordings of Ca2+ transients in E/I neurons, which revealed a decrease of spontaneous activity within L2/3 neuronal population in proximity of injury epicenter. In order to determine functional impact at 6 months post injury we measured evoked L2/3 neuronal activity by imaging the hindlimb region of the primary somatosensory cortex, where peripheral electrical stimulation reliably activated a large number of neurons. The number of excitatory neurons responsive to hindlimb stimulation appears to decrease in the injured area. These changes might be caused directly by injury impact or indirectly though time-dependent remodeling processes over 6 month period after injury. Overall, our preliminary results suggest reorganization of cortical population activity with vascular defects likely exacerbating neuronal deficits.

Title: Tryptophan metabolism after blast-induced traumatic brain injury

Authors: *P. ARUN, D. M. WILDER, W. B. RITTASE, M. A. MCCUISTION, S. A. OGUNTAYO, Y. WANG, I. D. GIST, J. B. LONG;
Ctr. for Military Psychiatry and Neurosci., Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Blast-induced traumatic brain injury (bTBI) is one of the major disabilities in service members returning from recent military operations. The neurobiological underpinnings of bTBI, which are associated with acute and chronic neuropathological and neurobehavioral deficits, are uncertain. The role of the essential amino acid tryptophan in the pathogenesis of bTBI has not been explored. We have reported earlier that blast exposure causes significant decrease in the levels of the neurotransmitter and tryptophan metabolite serotonin, which has been implicated in affective disorders such as depression and anxiety. In this study, rats and mice were subjected to single or repeated blast overpressure waves using a compressed air-driven shock tube. At different intervals after blast exposures, the animals were euthanized and brain, spleen and blood plasma were collected. The expression or levels of indoleamine 2,3-dioxygenase (IDO1) in different brain regions, spleen and plasma were determined by Western Blotting using rabbit monoclonal antibodies. Brain serotonin and plasma tryptophan levels were determined by ELISA. Our preliminary results revealed up-regulation of IDO1 in different regions of the brain after blast exposure which increased with repeated blasts. Blast exposure acutely increased expression of IDO1 in the spleen and the expression was further elevated with repeated blast exposures. Analysis of plasma samples indicated increased levels of IDO1 and decreased levels of tryptophan. The up-regulation of IDO1 in the brain after blast exposure, which may be an endogenous immunosuppressive protective mechanism mediated through the kynurenine pathway, could account for decreased levels of brain serotonin. The increased levels of IDO1 in the spleen and plasma may be responsible for the depletion of plasma tryptophan, which may also responsible for the decreased synthesis of serotonin in the brain. These results reveal that systemic and central tryptophan metabolism are disrupted following blast exposure which might play a significant role in the pathogenesis of neurobehavioral deficits associated with bTBI.

Title: Repetitive mild traumatic brain injury induces ventriculomegaly and cortical thinning in juvenile rats

Authors: C. GODDEYNE[1,2], J. NICHOLS[1,2], C. WU[1], K. MAGNUSON[1], Z. KILLEEN[1], *T. R. ANDERSON[3];
[1]Univ. of Arizona - Col. of Med. Phoenix, Phoenix, AZ; [2]Arizona State Univ., Tempe, AZ; [3]Univ. of Arizona-Com PHX, Phoenix, AZ

Abstract: Traumatic brain injury (TBI) most frequently occurs in pediatric patients and remains a leading cause of childhood death and disability. Mild TBI (mTBI) accounts for nearly 75% of all TBI cases, yet the underlying neuropathophysiology remains poorly understood. While even a single mTBI injury can lead to persistent deficits, repeat injuries increase the severity and duration of both acute symptoms and long term deficits. To model pediatric repetitive mTBI (rmTBI) we subjected unrestrained juvenile animals (post-natal day 20) to repeat weight-drop impacts. Animals were anesthetized and subjected to sham or rmTBI once per day for 5 days. Biomechanics of injury were measured using accelerometers, force meters and high-speed video. Magnetic resonance imaging (MRI) performed 14 days after injury revealed marked cortical atrophy and ventriculomegaly in rmTBI animals. Specifically, beneath the impact zone the thickness of the cortex was reduced by 46% and the area of the ventricles increased 970%. Immunostaining with the neuron-specific marker NeuN revealed an overall loss of neurons within the motor cortex but no change in neuronal density. Examination of intrinsic and synaptic properties of layer II/III pyramidal neurons revealed no significant difference between sham and rmTBI animals at rest or under convulsant challenge with the potassium channel blocker, 4-Aminophyridine. Overall, our findings indicate that the neuropathological changes reported after pediatric rmTBI can be effectively modeled by repeat weight-drop in juvenile animals. Developing a better understanding of how rmTBI alters the pediatric brain may help improve patient care and direct "return to game" decision making in adolescents.

Title: Septal and periventricular changes in a mouse model of repetitive concussive traumatic brain injury

Authors: *R. ACABCHUK[1], R. WOLFERZ, Jr.[1], L. TALBOT[1], M. STERM[1], M. SOLOWAY[1], M. ANGOA-PEREZ[2], D. BRIGGS[2], D. KUHN[2], J. CONOVER[1];
[1]Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT; [2]John D. Dingell VA Med. Ctr. and Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: Contact sports, such as football and boxing, significantly increase the risk of exposure to repetitive concussive traumatic brain injury (rcTBI), a public health concern reaching epidemic proportions, and repeated concussive impacts have been linked to long-term neurodegenerative pathology including chronic traumatic encephalopathy (CTE). Recently, a wide array of rodent models have been used to examine the cellular, molecular and behavioral sequelea resulting from rcTBI, with the majority of these studies focusing primarily on the hippocampus, amygdala and cortex. However, the septal and periventricular regions can also incur long-term damage from repeated exposure to concussions as revealed in post-mortem tissue analysis of patients diagnosed with CTE. Cavum septum pellucidum and expansion of the lateral ventricles are hallmark features of CTE. To investigate pathological changes in the lateral septum and periventricular regions following rcTBI, we utilize an unrestrained closed-skull impact mouse model that allows for 180^{o} free rotation following impact to mimic concussive forces found in humans. Regional and temporal alterations in astrogliosis, microglial activation, water channel protein expression, axonal damage, and phospho-tau levels are investigated to provide a detailed analysis of histological changes incurred following rcTBI. For our studies, two strains of mice (CD1 and C57/Bl6) were examined using multiple inter-injury intervals ranging from 5 hits in 3 days to 5 hits in 2 weeks. Our results demonstrate that immediate and persistent cellular alterations occur in the septum and periventricular region in both CD1 and C57/Bl6 mice. Together, these studies highlight the septum and periventricular regions as areas of interest in rcTBI research.

Title: Blast injury increases amyloid-beta deposition in cortical areas but not in subcortical visual pathways in young adult APP/PS1 mice

Authors: E. E. ABRAHAMSON[1,2], Z. MI[1,2], L. SHAO[1], D. S. RUDD[3], M. M. HARPER[3], *M. D. IKONOMOVIC[1,2];
[1]Neurol., Univ. of Pittsburgh, Pittsburgh, PA; [2]Geriatric Res. Educ. and Clin. Center, VA Pittsburgh Healthcare Syst., Pittsburgh, PA; [3]Ctr. for the Prevention and Treatment of Visual Loss, Iowa City Dept. of Veterans Affairs, Iowa City, IA

Abstract: Blast overpressure results in impaired retinal and higher-order visual functions. Because brain trauma is a risk factor for Alzheimer's disease (AD), we hypothesized that blast injury-induced visual dysfunction is associated with accumulation of β-amyloid (Aβ) peptide in the retina and visual pathways. We examined Aβ-immunoreactive aggregates in the retina, optic tract, lateral geniculate nucleus, primary visual cortex, and posterior parietal association/somatosensory/auditory cortices of adult APPswe/PS1ΔE9 (APP/PS1) transgenic mice (aged 83-106 days at injury; 150-175 days at sacrifice, when Aβ plaques develop in this model), after blast injury (unrestrained, head-only single blast wave to left side; ~150 kPa, 10-15 ms) compared to sham animals. In retina, small, diffuse extracellular plaques were infrequently observed in a subset of sham and blast exposed APP/PS1 mice, with no clear differences between groups. However, in blast, but not sham-surgery-exposed mice, we detected intense Aβ (4G8) immunoreactivity in blood vessels in the ganglion cell layer and inner and outer plexiform layers. No Aβ immunoreactivity was observed in the optic tract or lateral geniculate nucleus in either group. Cortical Aβ plaque load in primary visual cortex was comparable to posterior parietal association/somatosensory/auditory cortices in sham mice (<0.2% area coverage). In blast-exposed mice, plaque load values in all cortical regions were higher than in sham mice, with a two-fold increase in the posterior parietal association-somatosensory-auditory cortices compared to primary visual cortex. These results suggest that blast injury accelerates Aβ plaque development differentially across cortical regions in APP/PS1 mice. The less prominent increase in Aβ plaque pathology in the primary visual cortex might be due to de-afferentation or reduced synaptic activity/Aβ release in injured central visual pathways. Retina, optic tract, and lateral geniculate nucleus appear to be spared of intra- and extra- cellular accumulation of APP/Aβ in blast-injured APP/PS1 mice at the examined age and injury-to-death interval, despite substantial anterior afferent functional deficits compared to sham animals.

Title: A novel, quantitative, multi-analyte immunoassay to detect neuroinflammation following traumatic brain injury

Authors: M. ANDERSON, *G. HICKEY, I. O'BRIEN, P. YOUNGE, L. LEONG;
Bio-Techne Inc, Minneapolis, MN

Abstract: There is an increasing public awareness of Traumatic Brain Injury (TBI) that can be attributed to its appearance in widely diverse age groups that range from children, to military personnel, to retirement age individuals. This has created a need for the early detection of circulating biomarkers that reflect a traumatized state. Neuronal injury typically stimulates the release of pro-inflammatory mediators that induce a neuro-inflammatory response. Presumably this response is beneficial in the end, as it lays the groundwork for subsequent tissue repair and restoration. By contrast, a prolonged, unregulated release of pro-inflammatory cytokines and chemokines has the potential to damage uninvolved neurons and compromise brain function. The ability to distinguish between short-term and prolonged, or long term, inflammation is thus desirable, particularly when using a marginally-invasive method that utilizes serum or plasma. The study presented here evaluated several neuro-inflammatory markers including; CHI3L1/YKL40, ICAM-1, IL-1β, IL-6, IL-8, IL-10, IP-10 and TNF-α. The Simple Plex™ assay employed is a novel, quantitative, multi-analyte immunoassay platform that delivers high precision and accuracy all from ≤ 25 uL of sample. This platform measures up to four analytes simultaneously from a single, small sample with very high sensitivity. The microfluidic-based system allows parallel single analyte detection, and reduces non-specific antibody interactions that are often observed in other traditional multiplex platforms. The assay is a closed system, removing potential user variability. This is accomplished by automating the entire assay process within a single cartridge that provides results in just over one hour. Our studies suggest this platform may represent a highly efficient method for the detection of pro- and anti-inflammatory cytokines following TBI, and may also have relevance to chronic neurodegenerative diseases

such as Alzheimer's disease, Parkinson's disease, amyotrophic lateral sclerosis, and multiple sclerosis.

Title: Neurological consequences of mechanistically distinct toll-like receptor 4 signaling in the normal and injured brain

Authors: *A. A. KORGAONKAR[1], K. C. H. PANG[1,2], V. SANTHAKUMAR[1];
[1]Dept. of Pharmacology, Physiol. and Neurosciences, Rutgers New Jersey Med. Sch., Newark, NJ; [2]Dept. of Veteran Affairs Med. Center–New Jersey Hlth. Care Syst., Neurobehavioral Res. Lab., East Orange, NJ

Abstract: Traumatic brain injury (TBI) is a leading cause of acquired epilepsy and memory deficits. TBI causes both early activation of immune responses and increase in network excitability in the hippocampal dentate gyrus. Recently, we showed that enhanced neuronal expression of the innate immune receptor, Toll-like Receptor 4 (TLR4) contributes to increase in dentate excitability after TBI (Li et al., 2015). Unexpectedly, TLR4 agonists reduced excitability in uninjured rats. Here, we examine the cellular mechanisms underlying differential TLR4 effects on the excitability of normal and injured dentate and investigate the effect of TLR4 antagonism on seizure thresholds and working memory of uninjured and injured rats. Wistar rats (25-27 day old) were subject to moderate (2 atm) lateral fluid percussion injury (FPI) or sham procedures. Field recordings in hippocampal slices, video-EEG monitoring and memory studies were conducted at various time points after FPI. Afferent-evoked dentate population spike

amplitude *in vitro* was decreased following incubation in TLR4 antagonist (CLI095) 1 week after FPI, yet, was paradoxically increased in controls. Treatment with glial metabolic inhibitors (fluoroacetate and minocycline) failed to block CLI095-mediated suppression of excitability after FPI but selectively eliminated enhancement of dentate excitability by CLI095 in controls. A single dose of a TLR4 antagonist (LPS-RS or CLI095), administered 24 hours after FPI, prolonged the latency for seizures following kainic acid (5mg/kg, i.p.) injection one (vehicle: 16.2±2.09, LPS-RS: 180±0 min. in 8 rats each) and three months after FPI. However, similar to effects *in vitro*, TLR4 antagonists reduced the latency and promoted kainic acid-induced seizures in uninjured rats (vehicle 55.2±5.48, LPS-RS 15.6±1.38 min., in 8 rats each). Working memory performance (path efficiency) in a delayed match to sample task in the Morris Water Maze showed deficits up to one month after FPI. LPS-RS improved memory performance in rats 1 week and 1 month after FPI without adversely effects in controls. Our data show that glial signaling is necessary for TLR4 modulation of neuronal excitability in controls but not after FPI suggesting that the divergent neurophysiological effects of TLR4 in the normal and injured brain are mechanistically separable. While early post-injury TLR4 antagonism alleviates long-term behavioral deficits, the adverse outcome of the treatment in controls suggests that selectively targeting the processes underlying pathological TLR4 signaling may be efficacious in reducing epilepsy and memory impairments after TBI.

Title: Callosal function in pediatric traumatic brain injury linked to disrupted white matter integrity

Authors: *E. L. DENNIS[1], M. ELLIS[2,4], S. MARION[4], Y. JIN[1], C. KERNAN[2], T. BABIKIAN[2], R. MINK[5], C. BABBITT[6], J. JOHNSON[7], C. GIZA[8], R. ASARNOW[2,3], P. THOMPSON[1];

Center, Dept of Neurosurg. and Div. of Pediatric Neurol., Mattel Children's Hosp., Los Angeles, CA

Abstract: The corpus callosum (CC) is the most widely reported area of disruption in traumatic brain injury (TBI). Here we present data linking disrupted CC integrity to slowed callosal function in pediatric moderate/severe TBI in the post-acute phase (1-6 months post injury). We examined 63 participants: 32 TBI (mean age = 14.2, 9 female), and 31 controls (mean age = 14.9, 14 female). We used visual ERPs (event related potentials) to measure IHTT (interhemispheric transfer time, msec). EEG was recorded during a visual pattern matching task. To assess white matter integrity, we used a method developed in our lab, autoMATE (automated multi-atlas tract extraction), to generate along-tract measures of fiber integrity from HARDI data (high angular resolution diffusion imaging). The distribution of IHTTs was bimodal within the TBI group: some had IHTTs within 1.5 SD from the control mean, but others differed significantly (group cut-off = 18 msec min). We ran an element-wise linear regression testing for differences in FA and MD between the IHTT-slow TBI group and controls, and the IHTT-normal TBI group and controls. IHTT-slow and control groups differed significantly: the IHTT-slow group had lower FA and higher MD across large areas of the CC and beyond. There were minimal differences in FA between the IHTT-normal and control groups, and none in MD. This divergence was also displayed in neurocognitive function - the IHTT-slow TBI group performed more poorly than IHTT-normal TBI, who performed slightly poorer than healthy controls. This study reveals that there is a subset of pediatric msTBI patients during the post-acute phase of injury who have markedly impaired CC functioning and structural integrity that is associated with poor neurocognitive functioning.

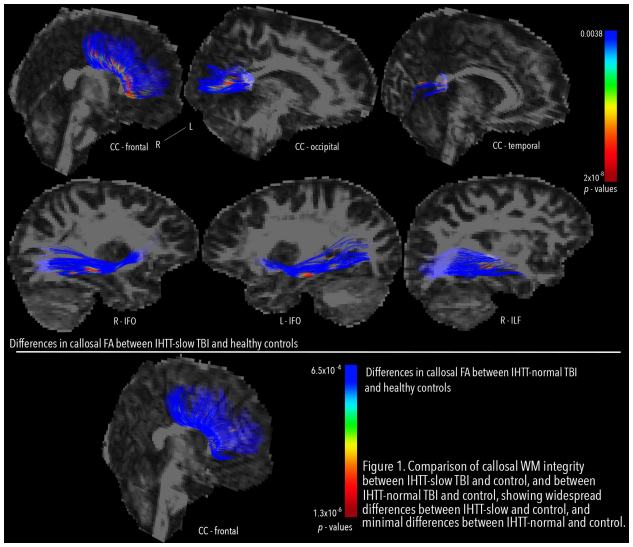

Figure 1. Comparison of callosal WM integrity between IHTT-slow TBI and control, and between IHTT-normal TBI and control, showing widespread differences between IHTT-slow and control, and minimal differences between IHTT-normal and control.

Clin., London, ON, Canada; [6]Children's Hlth. Res. Inst., London, ON, Canada; [7]Microbiology and Immunol., Univ. of Western Ontario`, London, ON, Canada

Abstract: Sports-related mild traumatic brain injuries, also known as concussions, are generating increasing concern due to potential long-term neurological consequences. However, there is currently no universally recognized diagnostic approach for concussion, and many of the current methods used for diagnosis are sub-optimal. This leaves patients with insufficient treatment and at enhanced risk of more severe damage from subsequent head trauma. We hypothesize that a signature temporal response of biomarkers of inflammation in systemic circulation will provide an objective concussion diagnostic. We predict that this panel of biomarkers could also be used to track patient recovery. The Western University Women's Rugby Team was the selected cohort as they are an understudied, concussion prone group, and they have been followed over 3 playing seasons. Participants underwent a set schedule of pre-season and post-season baseline evaluations including currently used concussion assessment tools (SCAT III and ImPACT), blood analysis, and a physical examination. Concussed players underwent serial evaluations at 24-72 hours, 1 week, 1 month, and 3 months post-concussion. Importantly, the inclusion of baseline assessments allowed each player to act as their own control in the study. A portion of the blood samples collected was used to determine the hematologic profiles. The remaining blood was separated into leukocytes, plasma, and serum. Plasma samples were analyzed for cytokine levels, as well as the neurotrauma marker glial fibrillary acidic protein (GFAP), and inflammatory marker C-reactive protein (CRP) using ELISA or Luminex methodology. Preliminary analysis showed that currently used concussion assessment tools failed to make an objective diagnosis. Pairwise analysis of players' hematology profiles from baseline to post-concussion show acute (1-5 days), and sub-acute (8-15 days) significant increases in systemic total leukocyte counts. These leukocyte increases positively correlated with symptom scores reported by concussed individuals. No signature changes were detected for the cytokine, GFAP, or CRP concentrations analyzed in the plasma of the concussion participants compared to their uninjured baseline level. A detailed flow cytometry analysis of leukocyte subsets and quantification of systemic inflammatory markers and their temporal response to concussion will be presented. The results of this multifactorial blood analysis would ideally reveal a constellation of biomarkers that could objectively indicate a concussion and determine an individual's progression towards recovery.

Title: Traumatic Brain Injury and its implication for Anaesthesia

Authors: *Y. O. OKUNOREN-OYEKENU, A. OYEKENU, P. EKWERE, M. O. DAWODU, O. OKUNOREN, A. OLAWUYI, A. AGBOOLA;
Anaesthesia, Ondo State Trauma and Surgical Ctr., Nigeria, Nigeria

Abstract: Traumatic brain injury (TBI) has become of public health concern as it has been observed to be a leading cause of death and disability globally. Every year reported figures of TBI are in the range of 1.7million for America and greater than 1million in European Union for hospital admission. World Health Organisation (WHO) records of daily figures of about 300 TBI cases in Africa leading to death has led to the establishment of Ondo State Trauma and Surgical Center, a new center in a remote part of Nigeria where motorcycles are the major means of transportation. Since inception around 2013 September, It has recorded 13 cases of TBI within a year which accounts for about 40% of the total number of brain and spinal cord injury cases requiring general anaesthesia. TBI cases are mainly classified as primary or secondary brain injury. The primary brain injury is due to direct impact to the brain leading to fracture, axonal injury, and disruption to the blood brain barrier while the secondary brain injury sequential to the primary brain injury occur via pathophysiologic processes like brain ischemia, inflammatory and cytotoxic processes with hypoxaemia, hypotension and hypoglycaemia leading to an increased risk of secondary brain injury. Anaesthetic management controls intracranial pressure, hypotension and hypoxaemia to avoid secondary brain injury, studies have however shown that anaesthesia negatively contributes to secondary injury in TBI cases. Anaesthesia is employed so that patients can be unconscious during surgery, as TBI patients are already unconscious before surgery arguments arise to the necessity of anaesthesia in TBI cases. The free radical gas Nitric Oxide (NO) is a molecule that has been implicated in brain injury cases for pathophysiolologic and therapeutic actions. Studies by Straub *et al* 2013, have shown that NO signalling affects synaptic remodelling and neuronal regeneration after axonal injury in *Lymnaea stagnalis* (The great pond snail) neurons while Terpolilli *et al* 2013 have proved that Inhaled NO reduces secondary brain damage after traumatic brain injury in mice. This study will therefore investigate if the secondary negative results of TBI cases after neurosurgery are caused by the original trauma or side effects of anaesthesia. We also intend to determine the role and level of expression of NO after Traumatic brain injury and whether therapeutic intervention with inhaled NO can be employed in TBI cases. **Grant Funding; Self-Funded Researchers Full Article will be published in the British Journal of Anaesthesia**

Title: Prevalence of memory loss following traumatic brain injury from blast versus non-blast exposure in a veteran population

Authors: *J. RAMOS[1], K. L. PANIZZON[2], A. PAPAZYAN[3], W. STEFANOS[3], J. WATSON[3], E. A. LICHT[4], R. A. WALLIS[3,5];
[2]Neurol., [1]VA West Los Angeles Med. Ctr., Los Angeles, CA; [3]Neurol., [4]VA Greater Los Angeles Healthcare Syst., Los Angeles, CA; [5]Neurolgy, David Geffen Sch. of Med. at UCLA, Los Angeles, CA

Abstract: OBJECTIVE: To evaluate the prevalence of memory loss in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) veterans with blast versus non-blast traumatic brain injury (TBI). BACKGROUND: TBI is a signature injury for OEF/OIF veterans. Memory loss is a frequent residual deficit after TBI. METHODS: We conducted a retrospective chart review of TBI patients in the Poly-Trauma Clinic of the VA Greater Los Angeles Healthcare System. We collected data about blast versus non-blast exposure in OEF/OIF veterans with memory loss and confirmed TBI. RESULTS: Of 563 charts reviewed, 377 were OEF/OIF veterans with a confirmed TBI diagnosis. The racial/ethnic distribution of subjects was 44 % Caucasian, 12% African-American, 25% Hispanic, 12% Asian and 7% other. The mean age of subjects was found to be 33 ± 1 and 32 ± 1 yr. for blast and non-blast TBI. Of 377 subjects with TBI, a mean 63 ± 3% (n = 237) were noted to have memory loss. In subjects with post-TBI memory loss, 51 ± 3% (n = 121) had blast-TBI, and 49 ± 5% (n = 116) had non-blast TBI. CONCLUSION: These data suggest that post-TBI memory loss is a frequent occurrence in OEF/OIF veterans, with both blast and non-blast-TBI exposure.

Abstract: Management of post-traumatic stress disorder (PTSD) is complicated by the overlapping symptoms of its comorbidities and the diagnostic reliance on self-report and time consuming psychological evaluation. A more comprehensive understanding of molecular pathophysiology of PTSD could facilitate an unbiased biomarker-driven next-generation intervention strategy. Herein, we cast light on the epigenomic consequences of combat elicited PTSD. In this study, hypermethylated genes were investigated as to the implications for behavior, immune response, nervous system development, and relevant PTSD co-morbidities such as cardiac disease and diabetes. 52 PTSD-positive male veterans of US Operation Iraqi Freedom (OIF) and Operation Enduring Freedom (OEF) were matched to 52 controls by age and ethnicity. PTSD diagnosis was determined by a clinician-administered PTSD scale (CAPS), score >40, while the control group demonstrated a CAPS <10. Methylation status of DNA extracted from whole blood was assayed using high density arrays (Agilent, Inc.). 5,000 probes were statistically differentially methylated (FDR < 0.1), representing approximately 3,600 unique genes. Chromosome 4 and 18 imprints a significantly large portion of the methylated probes, including those which control emotional and cognitive processes, and glucocorticoid deficiency. Interestingly, a significant number of genes facilitating telomere maintenance and insulin reception were hypermethylated at both promoter and gene body sites; therefore the DNA methylation status in these genes could be a significant factor. Nearly 85% of the differentially methylated probes were hypermethylated in PTSD patients. The majority of these probes encode the candidate proteins responsible for transcription regulation and enzymatic actions. Genes involved in memory consolidation, emotion/aggressive behavior, and perturbed circadian rhythm were preferentially hypermethylated. PTSD epigenetically perturbed both the cellular and humoral immune systems. In addition, the morphologies of two brain regions known to control PTSD symptoms, namely cerebral cortex and hippocampus were perturbed. Genes associated

with several PTSD comorbidities, such as cardiomyopathy and poor insulin regulation, were also hypermethylated. Integration of the epigenomic observations with other omics outcomes is currently underway, as well as validation of these findings in an independent cohort.

Title: Gray matter density and volume neuroimaging characterization of U.S. Military Veterans and retired National Football League players vulnerable to mild traumatic brain injury

Authors: *A. A. HERROLD[1,2], B. C. HARTON[5], X. WANG[3], T. PARRISH[3], Y. CHEN[3], J. L. REILLY[2], H. C. BREITER[2,6], T. L. B. PAPE[1,4];

Abstract: United States Military Veterans and National Football League (NFL) players represent two populations at elevated risk for mild traumatic brain injuries (mTBI) and mental health disorders (MHD). Impaired cognitive domains associated with mTBI and MHD include working memory, attention and executive function. The dorsolateral prefrontal cortex (DLPFC) supports these cognitive functions and existing evidence indicates that functional activation of the DLPFC is compromised with mTBI. However, less is known regarding the structural morphometry of the brain among those with mTBI and/or MHD. The purpose of this study was to characterize structural morphometry among a sample of Veterans and retired NFL players relative to healthy participants. Our samples of 9 Veterans, 9 retired NFL players and 9 healthy participants all completed a 3D T1-weighted volume MRI scan (MPRAGE). Veterans and retired NFL players completed neuropsychological testing procedures and mental health symptom

inventories prior to the scan. Veterans endorsed significantly higher Beck Anxiety Inventory scores ($p<0.05$) and Wisconsin Card Sorting Test total and perseverative errors T-scores ($p<0.05$) relative to retired NFL players. Gray matter density analyses, using voxel-based morphometry with age as a covariate, revealed significantly greater gray matter density in the right DLPFC of healthy participants relative to both Veterans ($p=0.05$, FWE corrected) and retired NFL players ($p=0.05$, FWE corrected). Findings also indicated significantly greater gray matter density in the left insula of healthy participants relative to Veterans ($p=0.05$, FWE corrected). Volume analyses, using age and total intracranial volume as covariates, revealed a trend level ($p=0.059$) difference in subcortical gray matter volume between the healthy participants and Veterans as well as the retired NFL players. Future volume analyses will focus on subcortical regions of interest. These findings suggest that Veterans and retired NFL players incurring mTBI and/or MHD may incur morphometric alterations in the DLPFC and insula: regions implicated in working memory, executive function and anxiety.

Title: Disambiguating structural and non-structural coma using network reachability analysis

Authors: M. KAFASHAN[1], S. RYU[2], D. ROBERTS[4], L. EISENMAN[4], T. T. KUMMER[4], *S. CHING[1,3];
[1]Electrical and Systems Engin., Washington Univ. In St. Louis, Saint Louis, MO; [3]Div. of Biol. and Biomed. Sci., [2]Washington Univ. in St. Louis, St. Louis, MO; [4]Neurol., Washington Univ. Sch. of Med., St. Louis, MO

Abstract: Coma is a state of severe cognitive impairment following brain injury. Although strictly pathological, a better understanding of coma could shed light on numerous aspects of

normal brain function. In particular, an analysis of how the lability of neural circuits - their overall dynamic range with respect to afferent excitation - is altered by brain injury could help define the underpinnings of normal cognitive functions in the brain. We report an analysis of the neural dynamics of coma using a new approach called 'Network Reachability Analysis (NetRA).' In this analysis scheme, a generative, dynamical, systems-based model for neural activity is used to fit observed EEG activity. A systems-theoretic reachability analysis is then performed on the model in order to quantify the effective dynamic range of the model. In essence, this analysis quantifies the extent to which the neural dynamics are labile with respect to ongoing recurrent activity. We proceeded to use NetRA to study EEG recordings from a cohort of 26 coma patients separated into two well-delineated coma variants: (i) coma arising due to focal injuries (structural coma) and (ii) diffuse, widespread injuries (non-structural coma). In conjunction with NetRA, we performed rigorous spectral and time-series analysis of these EEG data. We found that classical spectral analysis (e.g., band-limited EEG power) was not sufficient to disambiguate the two variants. Time-series analysis based on signal entropy did carry more discriminative power, with structural comas exhibiting more entropic variability overall (a surrogate for complexity). While useful as a discriminator, the highly statistical nature of these analyses did not allow for straightforward neurophysiological interpretations. In contrast, metrics derived from NetRA reliably (86% accuracy) disambiguated the two coma types and indicated that structural comas exhibited significantly more labile dynamics overall. Our results indicate that the dynamic range of neural activity in structural coma is generally larger than in non-structural coma, suggesting agreement with the intuitive interpretation that more circuits remain unaltered in the former condition. Importantly, this conclusion could not be made with conventional spectral analysis alone. Further, our findings show that mechanistic inferences regarding brain activity can be obtained from dynamical-systems based analyses. These inferences correlate with clinically-defined coma variants, and could be useful for clinical decision making and prognostication following brain injury.

Title: The computer assisted rehabilitation environment as a tool for differentiating traumatic brain injury from post-traumatic stress disorder: a retrospective analysis of three virtual environments

Authors: *M. M. ONAKOMAIYA[1,2], S. E. KRUGER[1], K. B. HIGHLAND[3,4,5], M. J. ROY[3,4]; [1]Natl. Intrepid Ctr. of Excellence (NICoE), Walter Reed Natl. Military Med. Ctr., Bethesda, MD; [2]Cherokee Nation Technol. Solutions, Catoosa, OK; [3]Dept. of Med., [4]Ctr. for Neurosci. and Regenerative Med., Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD; [5]Henry M. Jackson Fndn., Bethesda, MD

Abstract: Mild traumatic brain injury (mTBI) and post-traumatic stress disorder (PTSD) are common, and frequently associated with functional impairment in service members (SMs) returning from the conflicts in Afghanistan and Iraq. TBI and PTSD are frequently comorbid; one study found that 44% of returning SMs with mTBI met criteria for PTSD. Presenting symptoms markedly overlap and standard neuropsychological assessments and neuroimaging techniques have been ineffective in discriminating between the two conditions. This has prompted efforts to improve clinical assessments to ensure that SMs receive accurate diagnoses, and appropriate and effective treatment. The Computer Assisted Rehabilitation Environment (CAREN) is a dynamic system that incorporates multi-planar motion within interactive virtual environments (VEs). The immersive and flexible VEs allow clinicians to integrate advanced technology in the assessment and rehabilitation of injured SMs. Thus, the objective of this study was to assess whether physical performance in CAREN tasks varies according to diagnosis. Data was obtained by independent, retrospective review of clinical notes and objective outcomes from 191 patients with TBI (186 Male) assessed in the CAREN from 2010-2015. Patients were sorted into two categories based on diagnoses in their medical history: TBI alone or comorbid TBI-PTSD. Three preliminary VE tasks were used to acclimatize patients: 1) Balance Balls (BB): weight-shifting on a static platform (time); 2) Balance Cubes (BC): step-shifting with and without platform motion (time); and 3) Continuous Road (CR): ambulation (self-selected speed). T-tests were used to determine mean differences between diagnostic categories in VE task performance. A binary logistic regression was used to examine whether VE task performance could predict diagnostic category. T-tests revealed that patients with comorbid TBI-PTSD had significantly slower self-selected speeds on the CR task ($p = 0.036$) and spent marginally more time on the BC task ($p = 0.05$) than patients with TBI alone. In addition, a logistic regression showed that the CR task significantly predicted diagnostic category ($\beta = -0.607$; $p = 0.031$; OR 0.55, 95% CI [0.31, 0.95]), such that a 1 mph decrease in speed was associated with a 55% greater likelihood of having comorbid PTSD. In a population of SMs with TBI, self-selected speed on the CAREN effectively distinguished those with comorbid PTSD, as they were significantly more likely to choose a slower speed than patients with TBI alone. These results

portray the potential of the CAREN as a novel assessment tool for differentiating patients with a dual diagnosis from patients with TBI alone.

Title: EEG correlates of enduring pscho-affective alterations in athletes with a history of concussion

Authors: *R. MOORE, W. SAUVE, D. ELLEMBERG;
Univ. of Montreal, Montreal, QC, Canada

Abstract: Understanding the neuropathological underpinnings of sports-related concussion is critical for aiding the diagnosis, prognosis, and remediation of concussive injuries. Although electro-encephalographic (EEG) methods have proved invaluable for detailing the neuro-motor and neuro-cognitive outcomes of concussion, none have ventured to implement these methods in order to delineate the psycho-affective outcomes of sports-related concussion. Accordingly, the primary aim of this study was to evaluate the relation of electroencephalographic activity in collegiate athletes to measures of psycho-affective function. Resting electro-encephalograms (EEG) and measures of mood and affect, including the Beck Depression Inventory-II (BDI-II) and Profile of Mood States (POMS) were collected in 81 male athletes (45 concussion history; 36 controls). Although athletes with a history of concussion were 9+ months from injury and "free of concussion symptoms", they exhibited alterations in frontal-alpha power and asymmetry, as well as frontal-beta asymmetry (p's< .05). Athletes with a history of concussion also exhibited alterations in frontal-delta power (p's<. 05). Correlational analyses revealed that frontal alterations in alpha and beta asymmetry were related to self-reported depression, anxiety, and anger, respectively ($r2's \geq .26$, $p's \leq .04$). The current study demonstrates that "asymptomatic" athletes who are presumed to be healed may still exhibit neural activity associated with increased levels of depression, anxiety and anger, and that EEG may serve as a sensitive for clinicians to identify and track concussion-related alterations in psycho-affective

states. Thus, the current study adds scientifically novel and clinically relevant information regarding an important, but poorly understood aspect of concussion.

Title: The effect of claustrum lesions on human consciousness and recovery of function

Authors: ***A. CHAU**[1], A. M. SALAZAR[2], F. KRUEGER[3], I. CRISTOFORI[4,1], J. GRAFMAN[4,1];
[1]Rehabil. Inst. of Chicago, Chicago, IL; [2]Oncovir Inc., Washington D.C., DC; [3]George Mason Univ., Fairfax, VA; [4]Northwestern Univ., Chicago, IL

Abstract: The claustrum is a thin sheet of grey matter located between the putamen and insula and has extensive reciprocal projections, connecting the claustrum to numerous anterior and posterior cortical and subcortical regions, such as the prefrontal cortex, primary sensory cortices, thalamus, and reticular formation. Damage to the claustrum could impact multiple neural networks. Given its structure and connectivity, the claustrum is postulated to play a role in coordinating a set of diverse brain functions. For example, Crick and Koch proposed that the claustrum plays a crucial role in consciousness. Given there are few human studies investigating this claim, we examined the effects of claustrum lesions on consciousness in 171 combat veterans with focal penetrating traumatic brain injuries. Additionally, we studied the effects of claustrum lesions and loss of consciousness on long-term cognitive abilities 30 years post-injury. Claustrum damage was predominantly associated with the duration, but not frequency, of loss of consciousness. Thus, the claustrum may have an important role in regaining, but not maintaining, consciousness. Total brain volume loss, but not claustrum lesions nor loss of consciousness, was associated with long-term recovery of neurobehavioral functions. Disruption to a greater number of functional networks, characterized by increasing total brain volume loss, may lead to a greater probability of loss of consciousness and poorer long-term cognitive outcomes. Our study is the largest study to date to investigate the effects of claustrum lesions on consciousness in humans. Our findings constrain the current understanding of the neurobehavioral functions of the claustrum and its' role in maintaining and regaining consciousness.

Title: Mapping white matter changes in the corpus callosum following pediatric mild traumatic brain injury

Authors: ***S. WILCOX**[1], P. SERRANO[1], M. O'BRIEN[2], L. BECERRA[1], D. BORSOOK[1]; [1]Dept. of Anesthesiol., P.A.I.N Group, Waltham, MA; [2]Boston Children's Hosp., Division of Sport Medicine, MA

Abstract: Pediatric mild traumatic brain injury (mTBI) is the most prevalent neurological insult in children and is associated with both acute and chronic neurobehavioral sequelae, including headaches. White matter tracts are highly vulnerable to damage from impact-acceleration forces of TBI, with mTBI being characterized by evidence of traumatic axonal injury as assessed by diffusion tensor imaging. In particular, axons traversing the corpus callosum are particularly vulnerable to TBI. In this study we examined white matter integrity of the corpus callosum (CC) and specific inter-hemispheric tracts in adolescents at 3-12 months post-mTBI, compared to age-matched healthy controls. Group differences in diffusion parameters in the corpus callosum, as markers of altered white matter microstructure, were analyzed using tract based spatial statistics (TBSS). In addition, individual inter-hemispheric tracts were identified using probabilistic tractography. TBSS revealed that mTBI subjects displayed increased fractional anisotropy in the splenium and body, increased mean diffusivity in the splenium, decreased radial diffusivity in the body and increased radial diffusivity in the splenium, and increased axonal diffusivity throughout the entire CC (splenium, body and genu), compared to controls. These alterations in the corpus callosum's microstructural integrity may be part of the underlying pathomechanisms in post-concussive symptoms, such as headache. As such, diffusion parameters may serve a future clinical use as neuroanatomical indicators for early identification of children at risk of persistent post-concussive symptoms.

Title: Microglia activation phenotypes and their modulation following experimental TBI

Authors: *A. KUMAR[1], J. BARRETT[1], D.-M. ALVAREZ-CRODA[1,2], B. STOICA[1], F. TCHANTCHOU[1], A. FADEN[1], D. LOANE[1];
[1]Univ. of Maryland, Baltimore, MD; [2]Posgrado en Neuroetologia, Univ. Veracruzana,, Xalapa, Ver., Mexico

Abstract: Microglia can be polarized towards either an M1-like/classical or M2-like/alternative activation status in response to injury. These phenotypes can mediate neuroinflammation or promote tissue repair, respectively. Activation of NADPH oxidase (NOX2/gp91phox) is an important mechanism involved in pro-inflammatory signaling in microglia. We reported that NOX2 is chronically expressed in M1-like microglia in the peri-lesional area 1 year following controlled cortical impact (CCI) in mice. Here we compared wild-type (WT; gp91phox+/+) and NOX2-deficient (NOX2-KO; gp91phox-/-) mice to investigate the role of NOX2 in posttraumatic microglial polarization. Three-month old WT or NOX2-KO male mice were subjected to CCI (6m/sec, 2mm depth), and cohorts were followed for 1- 28d post-injury. M1-/M2-like polarization was analyzed by qPCR, flow cytometry, Western blot, and immunohistochemistry. Neurogenesis was assessed using doublecortin (DCX) immunohistochemistry; motor recovery and histology were assessed using a beam walk test and stereological methods. In WT TBI mice, NOX2 was expressed in reactive microglia (CD68+/Clic1+) in peri-lesional cortex through 28d; NOX2-KO significantly reduced CD68/Clic1 expression at 3 and 7d post-injury. Flow cytometry analysis of isolated microglia/macrophages revealed that IL-4Rα and its downstream signaling pathway (STAT6, JAK3) were significantly increased in CD45high microglia/macrophages of NOX2-KO TBI mice compared to WT controls. M2-like polarization (Arg1, Ym1, TGFβ) was increased at 3d post-injury in NOX2-KO, with effects sustained through 21d. There was significant reduction M1-like polarized microglia/macrophages (IL-1β, TNFα, IL-12, iNOS, CD16/32) in NOX2-KO TBI mice. M1/M2-like changes were associated with increased numbers of DCX-positive cells

in the SVZ, striatum and peri-lesional cortex, indicating increased neurogenesis. NOX2-KO TBI mice also showed significantly improved motor function and reduced cortical neurodegeneration at 21d. Thus, after TBI NOX2-KO mice exhibit enhanced IL-4Rα-mediated signaling, greater M2-like repolarization, and reduced neurodegeneration. Moreover, altering the M1-/M2-like balance appears to support increased neurogenesis. These data indicate that NOX2 drives the M1-like polarization of microglia/macrophages after TBI, and that inhibiting this pathway limits tissue damage and may promote tissue repair.

Title: New developments in calcium-channel targeted therapeutics in AD: Preventing pathology from cellular to network levels

Authors: ***G. E. STUTZMANN**[1], M. GARSTKA[2], N. KAPECKI[2], E. HILL[3], S. CHAKROBORTY[2], C. A. BRIGGS[2], A. GILMAN-SACHS[4], K. BEAMAN[4], W. FROST[3]; [2]Neurosci., [3]Cell Biol. and Anat., [4]Microbiology and Immunol., [1]Rosalind Franklin Univ. /Chicago Med. Sch., North Chicago, IL

Abstract: AD displays multiple seemingly unrelated phenotypes whose underlying causes are poorly understood, rendering the disease very difficult to treat. One strategy to improve upon the disappointing therapeutic outcomes is to target more upstream disease mechanisms, such as abnormalities in ryanodine receptor (RyR) calcium signaling. Here we describe more detailed and broader evidence of the contribution of aberrant RyR-calcium signaling to the complex range of AD-associated pathology, and further validate this channel as a drug target. Particularly notable were alterations in properties of key acidic and protein-regulating organelles. Normally, maladaptive proteins are recycled through authophagosome-lysosome mediated complexes; lysosomes require proper vacuolar ATPase proton pump (vATPase) function to maintain the

acidic pH necessary to break down cargo transported from autophagosomes. Without proper vATPase composition, autophagosomes, damaged organelles, and mis-aggregated proteins such as amyloid and tau can accumulate. Using immunoassays and confocal microscopy, we demonstrate a marked reduction in V1B2 vATPase subunit levels in cortex and hippocampus of young 3xTg-AD mice, suggesting an impairment in proton pump capacity and pH maintenance. In parallel, there were significant increases in mature autophagosomes in the AD mice, indicative of accumulated mis-aggregated proteins. Notably, sub-chronic treatment with RyR-stabilizing compounds such as dantrolene restored normal V1B2 and autophagosome levels in AD mice; amyloid and phospho-tau levels were also reduced with this treatment. This indicates that increased RyR-calcium signaling is impinging upon critical organelles and affecting protein handling early in AD. At more global levels, we also reveal blunted hippocampal network propagation in presymptomatic AD mice which occurs in parallel with exaggerated synaptically-evoked calcium signals within CA1 dendritic spines with network activation. Using 2-photon calcium imaging to study localized cellular deficits, and voltage-sensitive dyes with CMOS-based imaging of hippocampal slices, we have identified novel local, circuit and network level deficits which may ultimately drive the later cognitive deficits in AD.

Title: Intranasally delivered Wnt-3a enhances therapeutic effects of transplanted iPS cell-derived neural progenitor cells and increased endogenous regenerative activities after traumatic brain injury

Authors: *Z. WEI, X. GU, T. C. DEVEAU, J. LEE, M. M. WINTER, S. YU, L. WEI; Anesthesiology/Neurology, Emory Univ., Atlanta, GA

Abstract: Neonatal brain injury is a significant cause of mortality and long-term neurological deficits in infants and children. Studies to date using stem cell-derived neural progenitors have

shown great promise as a regenerative treatment against brain injury such as traumatic brain injury (TBI). The survival, migration and neuronal differentiation of these cells after transplantation, however, are poorly understood and need further improvements. Moreover, therapeutic outcomes from preclinical and clinical trials have been inconsistent and sometimes controversial. Although transplanted cells such as embryonic/induced pluripotent stem cell-derived neural progenitors (ES/iPS-NPCs), bone marrow stem cells (BMSCs) and neural stem cells (NSCs) have shown therapeutic benefits, the ability of these cells for sufficient morphological and functional recovery after brain injury has been unsatisfactory. In the current investigation, we tested the hypothesis that a strategy of combining transplanted cells with enhanced endogenous regenerative mechanism after TBI in the post-natal brain. We show in iPS-NPC cultures that recombinant Wnt-3a protein significantly increased cell survival, migration and neuronal differentiation of these cells. In P14 rats subjected to a closed impact insult, activating Wnt canonical pathway was enforced by intranasally-delivered Wnt-3a at 1 to 7 days after TBI. The iPS-NPCs were intranasally delivered at 3 and 7 days after TBI. At 14 days after TBI, the Wnt-3a plus iPS-NPC group showed the greatest increase of BDNF level in peri-contusion regions compared to both Wnt-3a alone group and iPS-NPC alone group. The Wnt-3a plus iPS-NPC treatment increased BrdU+NeuN+ cells and the level of myelin basic proteins (MBP). Behavioral tests and home cage monitoring showed significantly better improvements in sensory and motor function recovery in the Wnt-3a plus iPS-NPC group compared to both Wnt-3a group and iPS-NPC group. Our data highlight this novel combination method to enhance the cell-based neurorestorative therapy after neonatal TBI and other brain injuries.

Title: Boosting the power of exercise for brain trauma recovery using the capacity of a flavonoid derivative to activate BDNF-TrkB signaling

Authors: *F. GOMEZ-PINILLA[1,2], R. AGRAWAL[1], Y. ZHUANG[2], Z. YING[1], F. HONG[1]; [1]Integrative Biol. and Physiol., [2]Dept. Neurosurg., UCLA, Los Angeles, CA

Abstract: Traumatic brain injury (TBI) imposes a state of brain vulnerability in which neurons perform at a suboptimal level such that exposure to tasks involving activity can further compromise neuronal function. This period of neuronal vulnerability is particularly critical for patients engaging in physical rehabilitation programs or TBI encountered in sport practice. Although exercise has the intrinsic aptitude to counteract the effects of TBI, its application during the acute period of TBI may not be optimal. We studied the power of 7,8-dihydroxyflavone (7,8-DHF) to boost the effects of exercise on functional recovery after TBI. 7,8-DHF is a derivative of the flavonoid family abundant in fruits and vegetables, and a BDNF agonist that crosses the blood brain barrier. BDNF is one of the most influential molecules for brain function, which in addition to protecting neurons against a variety of insults, it has the unique capacity to counteract psychiatric like disorders within the spectrum of TBI pathology. The 7,8-DHF (5 mg/kg, ip) and/or exercise was administered daily in animals subjected to the fluid percussion injury (FPI). TBI reduced the BDNF-TrkB signaling and elements associated with regulation of energy homeostasis such as AMPK phosphorylation, cytochrome c oxidase II (COII) and regulators of mitochondrial biogenesis such as PGC-1α. These changes were concurrent with reductions in memory function observed in Barnes maze. Treatment with 7,8-DHF or exercise ameliorated reductions in the molecular systems under study, and more importantly, 7,8-DHF boosted the action of exercise after TBI. *In vitro* studies showed that 7,8-DHF (200 and 400 nM) upregulates the levels of biogenesis activator PGC-1α, and CREB phosphorylation, suggesting that activation of BDNF-TrkB signaling is pivotal for synaptic plasticity and energy metabolism. The treatment with 7,8-DHF (200 nM) also elevated the mitochondrial respiratory capacity, measured by Extracellular Flux analyzer, which emphasizes the role of BDNF-TrkB signaling as mitochondrial bioenergetics stimulator. This study highlights the power of 7,8-DHF to speed functional recovery, and to reduce the period of convalescence following TBI. This study emphasizes BDNF-TrkB signaling for supporting functional recovery following TBI engaging the interplay between mitochondrial function and synaptic plasticity.

Title: Tau oligomers and traumatic brain injury: toxicity and potential drug targets

Authors: *B. E. HAWKINS[1], J. GERSON[2], U. SENGUPTA[3], D. CASTILLO-CARRANZA[3], D. PROUGH[4], D. DEWITT[4], R. KAYED[3];

Abstract: Traumatic brain injury (TBI) is a chronic condition and may predispose individuals to develop an Alzheimer's disease-like dementia at an early age. Although the aggregation and accumulation of tau-based neurofibrillary tangles have traditionally been recognized as indicators of Alzheimer's, soluble tau oligomers are now thought to play a role in spreading the pathology. Tau oligomers exert their effects by causing toxicity in cells where they are present, but their soluble nature also allows them to spread from affected to unaffected brain regions. To demonstrate the ability of tau oligomers to spread and cause negative effects, we isolated tau oligomers from rodent brain homogenates that had received either an impact or blast-induced TBI and then injected those tau oligomers into htau mice that consequently developed spatial learning and memory deficits. Targeting extracellular tau oligomers may effectively halt the disease process. Passive immunotherapy is a promising mode of treatment against neurodegenerative disease because antibody doses can be controlled and specifically targeted to toxic species without impacting functional proteins. Anti-tau oligomer specific monoclonal antibodies (TOMA) is unique in that only recognizes oligomeric tau, a toxic form of the microtubule protein tau, while leaving normal, functional tau protein intact. We have demonstrated an increase in tau oligomers after fluid percussion injury in nontransgenic animals and attempted to block this increase by administering a single treatment with TOMA 24hrs after injury. We examined neuronal injury (using FluoroJade), vascular reactivity and tau pathology and found a reduction in FJ+ neurons in the TOMA-treated animals, suggesting a possible therapeutic effect. We conclude from these data that tau oligomers are toxic following TBI and that TOMA appears to have a beneficial effect following injury, most likely by binding to the toxic tau oligomers that accumulate after fluid percussion TBI. These studies were completed as part of an interdisciplinary research team funded by The Moody Project for Translational Traumatic Brain Injury Research.

Title: Ephrin-B3 restricts endogenous neural stem cell migration in the peri-lesional region following traumatic brain injury

Authors: ***K. J. DIXON**[1], E. J. PEREZ[2], J. MIER[2], A. TURBIC[4], A. M. TURNLEY[4], D. J. LIEBL[3];
[1]Virginia Commonwealth Univ., Richmond, VA; [2]Univ. of Miami, Miami, VA; [3]Univ. of Miami, Miami, FL; [4]Univ. of Melbourne, Melbourne, Australia

Abstract: Traumatic brain injury induces a robust induction of SVZ-derived neural stem/progenitor cell (NSPC) proliferation and differentiation. These NSPCs then migrate into the peri-lesional region where they initially provide neuroprotection from the mechanical insult and eventually differentiate into mature neurons. However, the factors regulating this migratory process have not been assessed. Eph receptors and their ephrin ligands negatively regulate SVZ-derived NSPC proliferation and survival, and are known regulators of cell and axonal migration. Ephrin-B3 regulates neural crest cell migration and was recently implicated in NSPC migration along the naïve RMS, therefore we sought to investigate the role of ephrin-B3 in NSPC migration, before and after TBI. We stereologically counted the number of NSPC migrating under naïve and TBI conditions using a model of cannula cortical injury infusing soluble ephrin-B3/Fc, in both wildtype and ephrin-B3-/- mice. Data from ephrin-B3-/- mice and infusion studies suggest ephrin-B3 restricts ectopic NSPC migration before and after TBI, and their mode of migration differs along a rostro-caudal gradient. In the rostral in the corpus callosum overlying

the RMS NSPCs appear to use chain migration in close proximity to the vasculature, while in the caudal corpus callosum and peri-lesional region the NSPCs migrate as single, dissociated cells seemingly independent of the vasculature. Additionally, acutely after injury some of the existing NSPCs were re-routed from the RMS to migrate to the peri-lesional region. To identify a direct or indirect effect of ephrin-B3 on the NSPCs we cultured SVZ explants and quantitated NSPC migration in the presence and absence of soluble ephrin-B3/Fc. The data shows unclustered (antagonist) ephrin-B3/Fc promotes chain migration, while clustered (agonist) ephrin-B3/Fc enhances dissociated single cell migration. Therefore, following cortical injury NSPCs in the SVZ migrate either along the RMS or re-routed towards the peri-lesional region, with extracellular ephrin-B3 restricting their migration. This data sheds light on the factors regulating NSPC migration before and after TBI and opens the window for future therapeutic interventions.

Title: Metabolite of gelatinase inhibitor prodrug attenuates brain damage and improves sensorimotor functions in a mouse model of severe traumatic brain injury

Authors: *R. NIZAM[1,2], Z. CHEN[1,2], B. TOMLINSON[1,2,3], O. HADASS[1,2,3], W. SONG[6], M. IKEJIRI[6], M. JUÁREZ[1,2], S. CHEN[1,2,4,5], J. CUI[1,2,4,7], S. MOBASHERY[6], M. CHANG[6], Z. GU[1,2,4,7];

Abstract: Traumatic brain injury (TBI) is a prevalent condition affecting 1.7 million individuals in the United States. After the initial injury, biochemical processes often lead to a second stage of brain injury that is considered the cause of many neurological dysfunctions. Biochemical, metabolic and cellular changes observed during this secondary injury are often associated with disruption of the blood-brain barrier (BBB), inflammatory responses and infiltration of blood-derived macrophages, edema, and cell death. Studies in our laboratory and others suggest that irregular signaling events seen after a TBI can lead to activation of endopeptidase enzymes called matrix metalloproteinases (MMPs) which can digest the extracellular matrix and tight junction molecules and cause axonal degeneration, resulting in edema, hemorrhage and brain damage. Among the 23 known human MMPs, MMP-9 (gelatinase B) in particular has been correlated with neuroinflammation and white matter damage in the brain. ND-478 is a water-soluble gelatinase inhibitor prodrug which is hydrolyzed into the active MMP-9 inhibitor ND-322. ND-322 is then *N*-acetylated to ND-364 in the brain and liver. Both ND-322 and ND-364 are capable of crossing the BBB, but only ND-364 achieves therapeutic concentrations in the brain. Thus, we chose to administrate ND-364 at a dose of 28 mg/kg. In this study, we performed a controlled cortical impact TBI model in mice, and subsequently treated them with ND-364 or vehicle injected at 2 and 4 hours after the surgery followed by daily treatment for the next 6 days. Three treatment groups were tested with different routes of administration: (**1**) subcutaneous injections only; (**2**) intraperitoneal injection for the first dose, followed by subcutaneous ones; and (**3**) intraperitoneal injections only. We observed neurological behaviors using beam-walking and a Simple Neuroassessment of Asymmetric imPairment (SNAP) test to evaluate motor, sensory and reflex abilities before surgery, and at 3 and 7 days post-surgery. We then dissected the brains at 7 days post-surgery for coronal sectioning, and stained brain sections with cresyl violet. Microscopic whole-slide image (WSI) analysis revealed that ND-364 was efficacious and significantly reduced cortical lesion percentage in all groups compared to vehicle. ND-364 significantly improved mouse behavior outcomes in groups **1** and **2**, but not in group **3**. In summary, these findings indicate that selective inhibition of MMP-9 by a second-generation thiirane gelatinase inhibitor is a promising therapy.

Title: Veliparib suppresses microglial activation after brain trauma in rats and pigs

Authors: *K. A. IRVINE, J. XU, R. K. BISHOP, P. SINGH, A. SONDAG, K. HAMEL, V. COPPES, D. J. KAPFHAMER, S. WON, S. PANTER, R. A. SWANSON;
Neurol., UCSF/VA/NCIRE, San Francisco, CA

Abstract: Brain trauma induces an innate immune response involving the activation of resident microglial and the infiltration of circulating immune cells. These cells release cytotoxic cytokines, proteases, and reactive oxygen species which may exacerbate injury and impair recovery. Inhibitors of poly(ADP-ribose) polymerase-1 (PARP-1) are also known to effectively suppress the innate immune response. The mechanism of this effect is not well understood, but likely involves blocking the transcriptional activities of the pro-inflammatory transcription factors NF-κB and/or AP1. Veliparib is an extremely potent, orally active inhibitor of (PARP-1) that is currently in clinical trials for certain types of cancers. In this study we are evaluating the effects of veliparib on outcomes after cortical controlled impact (CCI) in rats and pigs. Veliparib was given intraperitoneally to rats or orally to pigs beginning 2 hours after CCI at doses ranging from 0 to 9 mg/kg. Doses of above 1 mg/kg were found to markedly suppress microglial activation in both rats and pigs, as assessed by Iba-1 expression and microglial morphology. RT-PCR measures of gene expression in microglia isolated from rat brains, at times ranging from 6 hours to 14 days after CCI, showed that veliparib also attenuated the increase in matrix metalloproteinase-9 and NADPH oxidase-2 that otherwise occurred in peri-lesional microglia after CCI. Ongoing studies are evaluating the histological and behavioral correlates of this treatment approach, and the efficacy of veliparib treatment initiated at longer intervals after brain trauma.

Title: Neuroprotection against traumatic brain injury through disrupting the interaction of nNOS with PSD95

Authors: ***W. QU**[1,2], N. LIU[1], X. WU[1], Y. WANG[1], Y. SUN[1], Y. LAI[3], A. SHEKHAR[1], X.-M. XU[1];

Abstract: Traumatic brain injury (TBI) is the leading cause of death and disability in the most active population (<45 years of age) in the United States. Unfortunately, there have been no pharmaceutical interventions with proven efficacy to date. Here we propose that the glutamate-NMDAR-PSD95-nNOS cascade induces neural toxicity and mediates functional deficits following TBI. We hypothesize that ZL006, a small-molecule inhibitor of the nNOS-PSD95 interaction, may disrupt such detrimental cascade, resulting in neuroprotection and functional recoveries following TBI. In an *in vitro* model of primary cortical neuron culture, we examined whether ZL006 has an effect on glutamate-triggered excitotoxicity and neuronal death using LDH releasing and propidium iodide (PI) inclusion assays. *In vivo*, a moderate controlled cortical impact (CCI) injury to the right cerebral cortex was induced in the C57Bl/6 mouse followed by administration of ZL006 at two doses (5mg/Kg and 10mg/Kg) or saline at 30 min post-injury and daily thereafter up to 7 days. Behavioral outcomes were measured weekly from 2 to 28 days post-injury using composite neuroscore, adhesive removal test, rotarod, Morris water maze (WMM), direct contact social test, and social activity and novelty. Post-injury lesion volumes were quantified on tissue sections after Cresyl violet staining. Our result showed that exposure to glutamate *in vitro* induced neuronal loss and neurite disintegration. ZL006 treatments at both doses promoted a significantly reduction of neuronal cell death. ZL006 treatment also significantly decreased LDH release. *In vivo*, mice treated with ZL006 showed improved motor function (neuroscore and rotarod tests) as early as the first week post-injury. In the adhesive removal test, both contact and removal time in the ZL006-treated groups were significantly shorter than the vehicle group. Furthermore, ZL006-treated mice showed significant improvements in learning and memory (MWM test) in the strategy to find the hidden platform at 16 and 18 days as compared to the vehicle-treated group. Finally, ZL006 treatment attenuated cognitive impairment in direct contact social test and social activity and novelty. The observed functional improvements were closely associated with histological reduction of the lesion volume in the ZL006-treated groups. In conclusion, ZL006 protected primary cortical neurons from glutamate-induced excitotoxicity and cell death *in vitro*, reduced lesion volume, and improved sensorimotor, learning and memory, and cognitive recoveries in a mouse model of TBI. By targeting nNOS-PSD95, ZL006 may offer a new opportunity to treat patients with TBI.

Title: Suppression of Ca^{2+}-independent PLA2γ increased mitochondrial damage after *in vitro* traumatic brain injury

Authors: ***J. JI**[1,2], H. CHAO[3], H. CHEN[4], N. LIU[3];
[1]Dept. of Envrn. and Occup. Hlth., Univ. of Pittsburgh, Pittsburgh, PA; [2]Neurosurg., [3]Nanjing Med. Univ., Nanjing, China; [4]Nanjing Univ., Nanjing, China

Abstract: Ca2+-independent PLA2γ (iPLA2γ) hydrolyze phospholipids at the sn-2 position , thereby releasing free fatty acids and a lysophospholipids. iPLA2γ also participate in membrane phospholipid metabolism and remodeling especially under oxidative stress. The location of iPLA2γ is on endoplasmic reticulum and mitochondria. This implies that iPLA2γ may participate the membrane phospholipid injury and repair when mitochondria under oxidative stress. And This mitochondrial damage is common in neurodegeneration and trauma brain injury. So we use (R)-BEL, a specific inhibitor of iPLA2γ , to clarify the role of iPLA2γ when under mitochondrial oxidative stress damage after stretch in primary cortical neurons. In the current report, we found that iPLA2γ inhibitor increase the damage of mechanical stretch. Cytochrome c is released into the cytoplasm and caspase3 apoptosis pathway is activated. Mechanical stretch damage the mitochondrial membrane potential, and iPLA2γ inhibitor aggravated the damage. The inhibition of iPLA2γ may increase the mitochondrial apoptosis and injury. Further more, MDA,4-HNE, products of lipid peroxidation, increase after stretch, and iPLA2γ inhibitor exacerbated the lipid peroxidation. And iPLA2γ inhibitor also increased stretch-induced ROS production by DCFH-DA staining. Interestingly after stretch iPLA2γ expression level did not change significantly, but iPLA2γ activity significant increased. Our result suggested that iPLA2γ is neuroprotective and iPLA2γ can be up-regulated to relieve the mitochondrial injuries. Further mechanism about the iPLA2γ after stretch needs to be clarified .

Title: Implantable fibrin cylinders that recruit new cells into the striatum and cortex

Authors: ***A. CLARK**[1], L. E. HAGER[2], E. M. PRICE[2];
[2]Biol., [1]Marshall Univ., Huntington, WV

Abstract: Adult neural progenitor cells (NPCs) are constantly produced in the mammalian subventricular zone (SVZ), where they migrate along the rostral migratory stream (RMS) to the olfactory bulb. Our laboratory is interested in engineering fibrin cylinders containing a variety of factors that will, upon surgical implantation into rat brain, redirect SVZ-NPCs from their usual route into a new, typically non-neurogenic region. This has therapeutic possibilities for a number of diseases and disorders such as Parkinson's disease and traumatic brain injury. Such applications will require restoring functional neurons to both the striatum and the cortex. These are distinct regions of the brain, arising through different developmental mechanisms and containing different cell types. Due to these differences, it is reasonable to assume that restoring cells to these regions will require different factors for the striatum versus the cortex. We have recently used 3 mm long fibrin cylinders containing NGF and VEGF to recruit new neurons into the striatum of rats when implanted through the RMS and into the striatum. In order to minimize reactive astrocyte infiltration into the implant region, we administered dexamethasone for four days following the surgery. This significantly reduced the number of GFAP+ cells along the implant track. However, this procedure led to significant iatrogenic damage to the cortex since the implant apparatus had to pass through the cortex as it was being placed in the striatum. In order to prevent this damage to the cortex, we prepared 6 mm long VEGF/NGF cylinders which, upon implantation, spanned the entire distance from the surface of the brain to the striatum. This maneuver resulted in nearly complete restoration of the cortical material after 6 weeks. Although a significant number of new neurons were seen in the striatum, few new neurons were seen in the cortex despite the apparent healing of the region. We conclude that the factors (NGF and VEGF)

which were responsible for recruiting cells into the striatum were not capable of accomplishing the same result in the cortex. This suggests that the recruitment of new neurons into the cortical region requires different neurotrophic microenvironments than those required by the striatum. We then engineered cylinders with different factors in each half; the portion implanted in the striatum contained NGF and VEGF and the other half which passed through the cortex contained GDNF and bFGF. We anticipate that the ability to custom engineer these cylinders will enable investigators to create implantable microenvironments containing the appropriate factors for the region of interest.

Title: Amelioration of traumatic brain injury-induced cerebrovascular hyper-permeability by adipose tissue derived stromal vascular fraction cells

Authors: *N. MURADASHVILI[1], R. TYAGI[1], J. DALE[2], R. L. BENTON[3], S. C. TYAGI[1], J. B. HOYING[2], D. LOMINADZE[1];
[1]Physiol. & Biophysics, [2]Cardiovasc. Innovation Inst., [3]Anatom. Sci. and Neurobio. & Kentucky Spinal Cord Injury Res. Ctr., Univ. of Louisville, Louisville, KY

Abstract: Traumatic brain injury (TBI) is accompanied with development of inflammation and cognitive dysfunction. It contributes to vasculo-neuronal disorders leading to blood brain barrier disruption linked to increased cerebrovascular permeability to blood proteins. The loss of memory may be associated with the enhanced formation of un-degradable protein complexes such as fibrinogen (Fg) and cellular prion protein (PrP^C) complex after TBI. It is suggested that impairment in endothelial cell properties can be a main cause of enhanced protein extravasation/, and the resultant vasculo-neuronal degeneration. We tested the hypothesis that the treatment of vascular endothelium by anti-inflammatory and reparative stromal vascular fraction (SVF) cells derived from adipose tissue can mitigate TBI-induced hyper-permeability and reduce memory

loss by decreasing Fg-PrP^C complex formation. Permeability of pial venules in pericontusional area was studied in C57BL/6J mice brain after mild TBI. The day after induction of TBI, mice were injected with SVF cells suspended in 100 l of phosphate buffered saline (PBS) or with PBS alone (control group) through the jugular vein. After 10 days, cerebrovascular permeability in these mice was assessed by measuring the extravascular accumulation of Alexa-Fluor 647-labeled bovine serum albumin using an intravital fluorescence microscope. The protein leakage to interstitium was analyzed by changes in the ratio of fluorescence intensity in the interstitium to that inside the respective vascular segment. Cerebrovascular protein leakage was lesser in mice infused with SVF cells (131 ± 3 %) compared to that in mice infused with PBS alone (186 ± 6 %). Depositions of Fg and PrP^C in pericontusional area were mitigated in mice treated with SVF cells. Novel object recognition test showed a tendency of reduction in memory loss in mice injected with SVF cells. These results suggest that TBI-induced increased cerebrovascular permeability can be reversed by SVF cells, which can restore impaired property of vascular endothelium or cerebral microvascular network in pericontusional area. Thus, our data indicate a novel therapeutic role of SVF cells in treatment of vasculo-neuronal dysfunction after TBI.

Title: Effects of laquinimod on microglia and monocytes following traumatic brain injury

Authors: *A. KATSUMOTO[1], A. S. MIRANDA[2], O. BUTOVSKY[3], Z. FANEK[3], R. M. RANSOHOFF[1], B. T. LAMB[1];
[1]Neurosciences, Cleveland Clin., Cleveland, OH; [2]Sch. of Med., Federal Univ. of Minas Gerais, Belo Horizonte, Brazil; [3]Ctr. for Neurologic Dis., Brigham and Women's Hosp. Harvard Med. Sch., Boston, MA

Abstract: Background: Laquinimod is an orally administered neuroimmunomdulator in development for the treatment of multiple sclerosis (MS) and Huntington's disease (HD). The current studies utilized a model of traumatic brain injury (TBI) to assess the effect laquinimod

has on TBI induced neuroinflammation including microglial activation and monocyte infiltration along with persistent inflammation and neurodegeneration. **Methods:** To test the hypothesis that laquinimod differentially effects microglia and monocytes to alter inflammation following TBI, $CX3CR1^{GFP/+}$ $CCR2^{RFP/+}$ mice were utilized to isolate microglia and infiltrating monocytes following TBI and examined via nanostring analysis for the levels of immune gene mRNAs. Mice were administered laquinimod or vehicle by oral gavage before and after the TBI and sacrificed 3 days after the injury for gene expression analyses. **Results:** In monocytes, laquinimod up-regulated genes related to phagocytosis and down-regulated toll-like receptor (TLR) signaling and adhesion molecules. Notably, we also found a significant elevation of $CD45^{+}CCR2^{+}Ly6C^{high}$ inflammatory monocytes in the brain 3 days following TBI by flow cytometry, which was reduced by laquinimod treatment ($p<0.05$). Furthermore, gene expression analyses demonstrated microglia up-regulate TLR-4 cascade and NFκB signaling and at the same time down-regulate inflammatory (IL-6 and IL-8) at 3 days following TBI. Laquinimod treatment promoted an anti-inflammatory gene expression profile within microglia and hierarchical clustering showed that laquinimod treatment attenuated TBI-induced microglial gene expression closer to the sham group. In addition, immunohistochemistry showed that axonal damage was lessened following laquinimod treatment. Finally, laquinimod restored inhibited neurogenesis and enlarged ventricles induced by TBI. **Conclusions:** The current results suggest that laquinimod acts on both monocytes and microglia following TBI to attenuate inflammation by both reducing the recruitment of inflammatory monocytes as well as promoting a more sham-like microglial phenotype that leads to an amelioration of neuronal-based alterations induced by TBI.

Title: Rewiring of spinal respiratory neural network via cervical glutamatergic interneurons preserves respiratory function following chronic cervical spinal cord injury (cSCI)

Authors: *K. SATKUNENDRARAJAH, S. K. KARADIMAS, M. KHAZAEI, P. MERCADO, G. YAO, K. JACQUES-SMITH, M. G. FEHLINGS;
Genet. and Develop., Toronto Western Res. Inst., Toronto, ON, Canada

Abstract: Chronic and progressive compression of the cervical spinal cord disrupts the respiratory neural network leading to ventilatory dysfunction. In contrast to the severe respiratory insufficiency that follows acute traumatic cSCI, progressive cSCI results in milder dysfunction. Here, using a unique mouse model of progressive cSCI at C4-C6 vertebral level we attempt to elucidate this phenomenon. First, to neurophysiologicaly assess the modifications of spinal respiratory network induced by the progressive cSCI, we monitored diaphragmatic respiratory motor output after a left C2 hemisection injury (C2Hx) in cSCI and non-cSCI mice. C2Hx immediately silenced the ipsilateral respiratory function in non-cSCI mice, while cSCI mice had preserved ipsilateral respiratory motor output. Interestingly, a progressive loss of phrenic motoneurons (PMNs) with concurrent increase in Vglut2 positive boutons onto the preserved PMNs was found. This data led us to postulate that spinal glutamatergic interneurons (INs) relay and mediate rewiring between the brain stem respiratory CPG and the spinal respiratory network that curtails respiratory deficits in cSCI. To confirm this, dual injection of Rabies-Glycoprotein (RG) and Rb-ΔG-blue and HSV-Syn-GFP into the rVRG of the brainstem of cSCI and non-cSCI Vglut2::cre;tdtomato mice revealed that the connectivity between brainstem nuclei providing respiratory drive and PMNs is increasingly relayed through spinal glutamatergic INs under the progressive and chronic cSCI. Finally, to specifically silence the cervical glutamatergic relay interneurons (INs), we injected VSVG-pLV-TRE::IVMb-RFP and VSVG-pLv-vGlut2::aMVI-mPlum into the rVRG nuclei and RABV-Flippase-Cerulean and RG into the diaphragm muscle of Hoxb8-cre :: rTA GFP mice at 8 weeks post-cSCI. Subsequent ivermectin administration after C2Hx in these cSCI mice silenced this specific population and prevented the manifestation of preserved ipsilateral diaphragmatic EMG activity. Together, our data show that prephrenic spinal glutamatergic INs play a vital role in maintaining descending excitatory glutamateric drive to PMNs and maintain respiratory function in chronic and progressive cSCI. Moreover, these novel insights into the neural control of breathing can direct translational research for respiratory recovery in cSCI.

Title: Altered co-activation across the frequency spectrum of lower extremity muscles in individuals with incomplete spinal cord injury

Authors: ***S. S. LEE**[1], T. LAM[2], K. PAUHL[2], E. HARDER[3], J. M. WAKELING[3]; [1]Physical Therapy and Human Movement Sci., Northwestern Univ., Chicago, IL; [2]Sch. of Kinesiology, The Univ. of British Columbia, Vancouver, BC, Canada; [3]Biomed. Physiol. and Kinesiology, Simon Fraser Univ., Burnaby, BC, Canada

Abstract: Co-activation of antagonistic muscles is prevalent in individuals with incomplete spinal cord injury (SCI) and contributes to mobility limitations. In addition to kinematics and kinetic measurements to evaluate gait function, electromyography (EMG) is often used to measure muscle activity. In this study, we use wavelet analysis to resolve EMG signals into frequency components that provide information beyond the standard timing and amplitude measures. There is evidence that muscle fiber composition is altered in individuals with SCI and also influences the spectral properties of the EMG signal. The purpose of this study was to investigate co-activation in the lower extremity muscles: rectus femoris (RF), biceps femoris (BF), medial gastrocnemius (MG), and tibialis anterior (TA) in individuals with SCI and healthy age-matched unimpaired individuals using wavelet techniques and establishing an EMG normalcy score using principal component analysis as an indication of muscle function. A second aim was to determine if this type of frequency analysis of EMG signals would be effective and sensitive in evaluating the influence of body weight supported treadmill training that used robot-applied resistance at the hip and knee joints. Our main findings demonstrate that the co-activations of the knee extensor-flexors, RF-BF, and ankle plantar- and dorsiflexors, MG-TA, were significantly different between the individuals with incomplete SCI and age-matched control subjects. There were significant differences in the correlation coefficient of the total

EMG intensity between the SCI group and unimpaired control group for stride and stance phase. The correlation spectra, which indicate co-activation across the frequency spectrum, were also significantly different between the SCI and control group, in particular for the ankle muscles. The EMG-normalcy score, that considered the recruitment of different motor unit types by analyzing the frequency component of the EMG signal, supported the correlation coefficient results and also detected a difference between the pre-and post training for the MG-TA pair for stride and stance. In addition, both differences in pre-and post training EMG normalcy score and correlation coefficient of total intensity were correlated with pre- and post-training clinical tests such as the 6 Minute Walk Test and 10 Meter Walk Test. Application of this EMG analysis to quantify and evaluate muscle dysfunction and coordination in SCI offers new insights into the fundamental mechanisms behind SCI impaired gait and into the effectiveness of rehabilitation treatments.

Title: Optical dissection of cortical plasticity during recovery from spinal cord injury

Authors: *E. R. HOLLIS, N. ISHIKO, C.-C. LU, A. HAIMOVICH, Y. ZOU;
Biol., Univ. Calif San Diego, La Jolla, CA

Abstract: The learning of skilled tasks in rodents and primates is dependent upon circuit plasticity of motor representations within the motor cortex. Changes in these topographic motor maps are known to occur after spinal cord injury in animal models as well as in patients, however it is unknown whether motor maps are affected by increasing the plasticity of corticospinal motor axon collaterals after injury. Here we utilize optogenetic stimulation to examine motor map changes over time after the conditional deletion of the repulsive Wnt morphogen receptor related to receptor tyrosine kinase (Ryk), which limits corticospinal plasticity after spinal cord injury. We found that increased corticospinal axon collateralization after injury corresponded with a stabilization of the expanded cortical motor representations from

above the level of the injury. Recovery of skilled forelimb function was enhanced by increased axon collateralization and subsequently returned to control levels following the elimination of enhanced collateralization through a secondary injury. Our findings that 1) motor map changes in rodents mirror those that occur after spinal cord injury in patients and 2) that the corticospinal motor circuit can incorporate induced axonal changes, indicate that the axon repulsive Wnt-Ryk signaling axis is an attractive therapeutic target following spinal cord injury.

Title: Pten deletion promotes regeneration of corticospinal tract axons one year after spinal cord injury

Authors: *K. LIU, S. ZHENG;
HKUST, Kowloon, Hong Kong

Abstract: Chronic spinal cord injury (SCI) is a formidable hurdle that prevents a large number of injured axons from crossing the lesion, particularly the corticospinal tract (CST). This study shows that Pten deletion in the adult mouse cortex enhances compensatory sprouting of uninjured CST axons. Furthermore, forced upregulation of mTOR initiated either one month or one year after injury promoted regeneration of CST axons. Our results indicate that both developmental and injury-induced mTOR down-regulation in corticospinal motor neurons can be reversed in adults. Modulating neuronal mTOR activity is a potential strategy for axon regeneration after chronic SCI.

Title: The role of RhoA in retrograde neuronal death and axon regeneration after spinal cord injury

Authors: *J. HU, G. ZHANG, W. RODEMER, M. SELZER;
Shiners Hosp. Pediatric Res. Ctr. (SHPRC), Temple Univ. Sch. of Med., Philadelphia, PA

Abstract: Paralysis following spinal cord injury (SCI) is due to failure of axonal regeneration. It is believed that axon growth is inhibited by the presence of several types of inhibitory molecules in central nervous system (CNS), including the chondroitin sulfate proteoglycans (CSPGs). This also is true in the lamprey, whose brainstem contains 18 pairs of individually identified reticulospinal neurons with heterogeneous axon regenerative abilities. The “bad-regenerating” neurons often experience a delayed form of retrograde cell death. These same bad-regenerators selectively express the CSPG receptors PTPsigma and LAR, suggesting that CSPGs may affect intracellular signaling via their receptors. There is evidence that after SCI, the small GTPase RhoA is an intracellular convergence point for signaling by several extracellular inhibitory molecules, including CSPGs. RhoA also has been implicated in local neuronal apoptosis after SCI. Thus we hypothesize that RhoA may be involved in the delayed retrograde neuronal death in lamprey brain after SCI. To test this, we cloned lamprey RhoA and found its mRNA was expressed in both neurons and glia. Levels of active RhoA (RhoA-GTP) increased after spinal cord transection (tx). Next we designed morpholinos to knockdown RhoA *in vivo*, which reduced expression of total RhoA in the spinal cord by ~20%. The knockdown effect was even more robust in individual axons (~40%). RhoA knockdown significantly reduced retrograde apoptosis signaling in identified neurons in lamprey brains post-tx, as indicated by Fluorescent Labeled Inhibitor of Caspases (FLICA) in brain wholemounts. The reduction of caspase activity in the brain by knockdown of RhoA began at 2 weeks and was still seen at 10 weeks. Moreover, by measuring the distance between individual axon tips and the tx site, we found that RhoA knockdown slowed axon retraction and/or increased early axon regeneration. Moreover, RhoA

knockdown increased the number of axons whose regeneration extended more than 5 mm beyond the injury site at 7 weeks post-tx. Thus, *in vivo* RhoA knockdown may be useful not only to protect spinal-projecting neurons in the brain from retrograde neuronal death, but also to enhance axon regeneration after SCI.

Title: Targeting protease activated receptor 2 to improve recovery after spinal cord injury

Authors: *M. RADULOVIC[1], H. YOON[2,3], J. WU[2], K. MUSTAFA[1], M. G. FEHLINGS[4], I. SCARISBRICK[1,2,3];

Abstract: Astrogliosis and inflammation are key integrators of the complex continuum of injury and repair occurring after spinal cord injury (SCI) with molecular drivers representing new therapeutic opportunities. Protease Activated Receptor 2 (PAR2) is a G-protein coupled receptor playing fundamental roles in neural injury, including activities in inflammation and astrogliosis, although its contributions to SCI are essentially unknown. PARs are activated by proteolysis within their extracellular domain revealing a new amino-terminus that binds intramolecularly to elicit intracellular signaling. Thus, PARs enable cells to respond, or to over respond, to rapid changes in the proteolytic microenvironment such as those occurring in traumatic SCI. In this study, we critically evaluated the role and mechanism of action of PAR2 in SCI by determining the impact of PAR2 gene deletion on functional recovery and cellular and molecular signs of pathogenesis in an experimental murine contusion-compression SCI model. Specifically, compression-SCI in PAR2 knockout mice was associated with greater improvements in motor

coordination and strength compared to wild type littermates. Molecular profiling of the injury epicenter, and spinal segments above and below, demonstrated mice lacking PAR2 had significantly attenuated elevations in pro-inflammatory cytokine expression (IL-6, TNF and IL-1β) and in key hallmarks of astrogliosis (GFAP, vimentin, neurocan), but enhanced early elevations in the anti-inflammatory cytokine TGF-β. SCI in PAR2-/- mice was also accompanied by improved preservation of PKC-ϒ-positive corticospinal axons and reductions in GFAP-immunoreactivity, in BIM expression, and in STAT3 signaling. The mechanistic link between PAR2, STAT3 and astrogliosis was investigated in primary astrocytes revealing that the SCI-related serine protease, neurosin (kallikrein 6), promoted IL-6 secretion in a PAR2, MEK1/2- and STAT3-dependent manner. A model is proposed where PAR2-elicited IL-6 secretion drives expression of GFAP, vimentin, and additional IL-6, through canonical STAT3 signaling. Since IL-6 also promoted robust increases in astrocyte PAR2 and neurosin, these data collectively point to an IL-6-driven PAR2 feedback circuit that works hand-in-hand with STAT3 to drive inflammatory-astrogliosis. Given the superior neuromotor recovery observed in PAR2 knockout mice, we suggest that targeting PAR2 to limit inflammation and astrogliosis represents a promising drug target to improve motor outcomes after SCI. Title: A clinically relevant injectable matrix for Schwann cell transplantation following spinal cord injury

Authors: ***S. R. CERQUEIRA**[1], Y.-S. LEE[1], R. CORNELISON[2], C. SCHMIDT[2], M. BUNGE[1];

Abstract: Schwann cell (SC) transplantation is an extensively studied cell therapy for spinal cord injury (SCI), promoting axon regeneration and myelination. In an attempt to further enhance SC efficacy and maximize tissue repair, ultimately improving functional outcomes, biomaterial-based approaches are being tested in combination with cell therapy. Matrices to support transplanted cell survival, such as Matrigel, create more permissive interfaces that allow enhanced axon extension, but clinically relevant alternatives are needed for translational studies in humans. We chose an injectable biomaterial from acellular peripheral nerve (aPN) to fill the cyst formed after contusion to combine with transplanted SCs. Rat aPNs were obtained using an FDA-approved decellularization method (Hudson *et al., 2004, Tissue Eng 10:1346-58)* and further processed to be injectable and thermally gelling. Injectable aPN yields a solid matrix in physiological conditions with properties similar to native neural tissue. 28 female Fischer rats were subjected to a moderate T8 IH contusion injury (200 kDyn). One week after SCI, $2x10^6$ GFP-labeled SCs were injected into the lesion cavity in either Matrigel or aPN matrix. BBB scoring was performed weekly and grid walk, at 4 and 8 weeks post-transplantation. Longitudinal sections of the spinal cords were immunostained to evaluate SC survival, axon extension, macrophage/microglia activation and the glial scar, and toluidine-blue-stained plastic sections were used for graft integration and axon and myelination assessment. Although no significant differences were observed in BBB scores, BBB subscores revealed a noticeably faster recovery with SC/aPN grafts at 4 weeks, and significantly fewer footslip errors in the grid walk test at 4 weeks. The plastic sections revealed a plethora of SC-myelinated axons within the dense implants in both conditions. Moreover, the SC implants showed no distinct borders with the host tissue. Preliminary immunostaining results indicated no differences in the glial scar at the lesion site, and confirmed the integration of dense implants with the cord. Our results suggest that this clinically relevant injectable aPN matrix is promising to support SC transplantation to promote tissue repair and improve function after SCI in future translational studies. Title: Engineered hydrogels supporting fast neurite extension

Authors: *N. BROGUIERE, G. PALAZZOLO, M. ZENOBI-WONG;
ETH Zürich, Zürich, Switzerland

Abstract: Animal derived matrices like fibrin, collagen and matrigel enable encapsulation of neurons with high viability and fast neurite extension. As a result, they have found widespread use as vehicles for the delivery of cells into severed tissues, for gap filling after trauma, and as 3D *in vitro* culture models. Their usefulness is nevertheless limited by their fast degradation, low tunability, poor definition, and/or by the costs and contamination/immunogenicity risks inherent to isolation of proteins from animal tissue. Matrices engineered from polysaccharides or synthetic polymers would be interesting alternatives. We systematically optimized 3 defined gels respectively based on polyethylene glycol (PEG), alginate, and hyaluronan to support similar fast neurite extension in defined, non-immunogenic matrices. Chick dorsal root ganglia (DRGs), rat primary cortical neurons and human induced pluripotent stem cell derived neurons were used as models, covering a wide range of species and neuron types. With all the gel systems and cell types, physical properties were found to be essential to recapitulate high viability and fast neurite extension, whereas specific biological cues such as growth factors and adhesion peptides were unexpectedly found to be unnecessary. In optimized conditions, 2 day viability reached more than 95%, and 3D neurite extension from encapsulated cells occurred at average rates of the order of 100 um/neuron/day. All gels could sustain cultures of cortical neurons for more than a month, yielding synaptically connected and electrically active 3D neural networks. Such neurite permissive hydrogels could find use in the treatment of spinal cord injury, as they are excellent supporting scaffolds for axonal regeneration. They would ideally be used in combination with current strategies to overcome growth inhibition, such as electrochemical stimulation, drug treatment, and stem cell delivery.

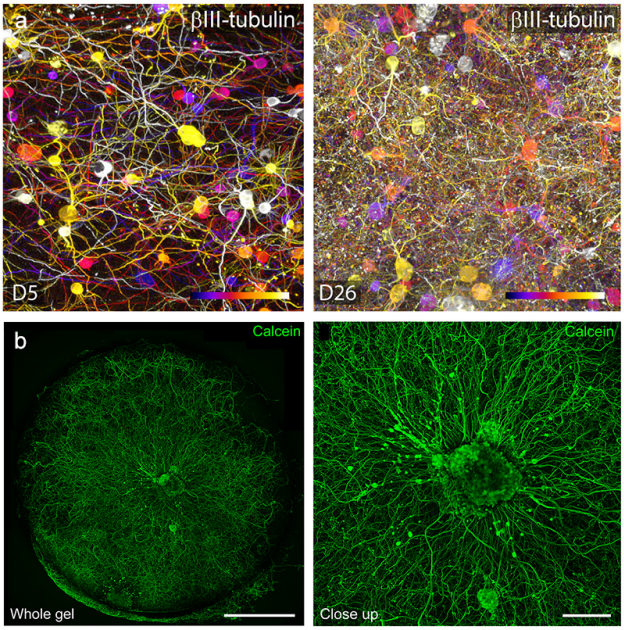

Figure 1. 3D growth in PEG gels (a) Cortical neurons (color scale showing the depth from 0 to 200 um) (b) DRG one month after encapsulation. Scale bars: 50 um (a) 1 mm and 250 um (b)

Title: Exercise-dependent modulation of neuro-urological health following spinal cord injury

Authors: ***L. R. MONTGOMERY**[1,2], A. N. HERRITY[2,3], S. J. HARKEMA[2,3,4], C. H. HUBSCHER[1,2];
[1]Dept. of Anatom. Sci. and Neurobio., [2]Kentucky Spinal Cord Injury Res. Ctr., [3]Frazier Rehabil. Inst., [4]Dept. of Neurolog. Surgery, Univ. of Louisville, Louisville, KY

Abstract: Spinal cord injury (SCI) affects thousands of people every year leading to dramatic changes in their quality of life. People with SCI must cope with urinary tract dysfunction requiring repeated daily and nightly catheterizations which can lead to further complications such as bladder and kidney infections. Despite bladder dysfunction being a high priority for SCI individuals, the focus of health care professionals is on rehabilitation aimed at optimizing mobility and the remaining musculoskeletal function in these patients. Our lab however, has recently demonstrated that repetitive sensory information generated through task-specific stepping and/or loading can improve non-locomotor functions, including bladder function, following a T9 contusion in male Wistar rats (Ward PJ et al., 2014. J Neurotrauma, 31: 819-833). In order to begin addressing potential underlying mechanisms, the current study was designed to ascertain whether the improvements could be attributed to a global exercise effect on the urogenital system. Male Wistar rats received a T9 contusion injury using the Infinite Horizon (IH) device. Following 2 weeks recovery, animals were randomly assigned into one of 3 groups - quadrupedal locomotion, forelimb exercise, or a non-trained group. All groups of rats were placed in metabolic cages (CLAMS) once a week for 24 hours to monitor water intake and urine output including at baseline (twice pre-injury), post-injury (two weeks), and throughout the 10 week period of daily one hour treadmill training. Following completion of the training period, cystometry data was collected and bladder tissue harvested for qRT-PCR to identify neurotrophin levels (NGF, BDNF, and NT-3). Metabolic cage data indicate that following SCI, mean urine volume increased in all groups of animals, a finding consistent with our previous study on SCI-induced polyuria (Ward P.J. and Hubscher CH, 2012. J Neurotrauma, 29: 2490-2498). However, mid-way through training, the average volume per void for both the quadrupedal and forelimb trained groups significantly decreased, returning towards pre-injury levels. Terminal cystometry data revealed no significant changes between the two exercise groups and sham surgical control animals, although animals in the non-trained group had significantly higher maximum contraction amplitude relative to the sham animals. Neurotrophin levels in the bladder were also altered, with higher levels in the bladders of non-trained animals compared to sham controls. Thus, the positive benefits of exercise on bladder function post-SCI are likely indirect. Currently studies are ongoing in our lab to elucidate the underlying mechanisms.

Abstract: It is a kind of dream for the paraplegic patients to walk again with their legs. The artificial neural connection (ANC) via a closed-loop computer interface is one candidate for accomplishing it because it connects mostly intact spinal cord regions above and below the responsible injury lesion for paraplegia. We have shown that an upper-limb muscle controlled non-invasive magnetic stimulation over the lumbar vertebra was able to induce volitionally-controlled walking behavior in healthy subjects (Sasada et al. 2014). The purpose of present study is to investigate whether or not the ANC is able to restore walking ability and compensate in individuals with severe spinal cord injury (SCI). Five individuals: with severe incomplete (a woman, 19 yo) and complete paraplegia (four men, 21-52 yo), participated in the experiment. The SCI at T3-L1 levels at least half a year before the experiment. All participants were unable to stand and walk independently even after the standard-of-care rehabilitation longer than 3 month. The ANC was accomplished by a computer interface designed to encode the outline of full-wave rectified and moving averaged surface EMG activity from a muscle, and convert it into stimulus pulses. In the present study, the hand-muscle activity was utilized to trigger pulses for TMS pulses which was then delivered over the lumbar vertebra while participants laid in a semi-prone position with their legs suspended. The stimulus intensity was kept constant in each trial, and its range was set at 40-60% of the maximum output of the magnetic stimulator, whereas stimulus frequency was modulated according to the hand-muscle activity between 1 and 20 Hz. All participants could voluntarily initiate and terminate walking-like behavior via the ANC. The induced leg movement enhanced by additional voluntary effort of walking with the ANC. This result implied that even in the individuals who had been clinically diagnosed as complete SCI, the residual corticofugal connection remained. The walking performance was improved by the repeated ANC trials within a day, and ANC trials for several weeks made the performance much better. The ANC successfully compensated for the interrupted descending pathways and can induce walking-like behavior in paralyzed legs in patients with severe SCI. The repeated ANC trials may have driven neural plasticity around the lumbar locomotor circuit that eventually improved walking performance.

Title: The spinal cord lesion: relationship to muscle changes and motor deficits

Authors: *A. C. SMITH[1], T. PARRISH[1], M. HOGGARTH[1], M. WASIELEWSKI[1], H. KIM[2], T. G. HORNBY[2], J. ELLIOTT[1];
[1]Northwestern Univ., Chicago, IL; [2]Rehabil. Inst. of Chicago, Chicago, IL

Abstract: Background:Prediction for recovery following incomplete spinal cord injury (iSCI) is a challenging yet important issue for all stakeholders. Magnetic resonance imaging (MRI) is a valuable tool in the prediction of volitional motor return after SCI. Currently, sagittal T2 weighted imaging is commonly used for relating cord lesion characteristics to clinical prognosis. Past literature employed the use of a midsagittal 2-D T2 image, and calculated the length of edema to predict volitional motor function, walking ability, and level of independence following spinal cord injury. Measuring spinal cord lesion volume has recently been explored and related to motor function in an animal model of SCI. However, no study has examined lesion volume in humans. Therefore, the purpose of this work is to quantify and establish relationships between lesion volume, muscle architectural alterations, and volitional motor control following human spinal cord injury. Methods: 5 subjects with chronic cervical iSCI were enrolled in a pilot study (average age = 31 ± 7 years old). Lesion volume was calculated by quantifying the area of edema seen on consecutive sagittal T2 images throughout the cord; then multiplying by slice thickness. Fat infiltration in the lower extremity shank muscles was assessed using a 3 T MRI (Siemens, Erlangen, Germany) with a 2-point Dixon fat/water separation application. Volitional motor

control was quantified using a central activation ratio (CAR), obtained by comparing maximum voluntary isometric plantarflexion torque production with a superimposed peak electrically elicited torque. The data was linearized and Pearson correlation coefficients were calculated to establish relationships between the measures. Results: Linearized lesion volume data was positively correlated with shank muscle fat infiltration (Pearson R = 0.88, P = 0.04) and negatively correlated with plantarflexion CAR values (Pearson R = -0.87, P = 0.05). When correlating edema length versus fat infiltration and CAR values, the relationships were weaker and not statistically significant (Pearson R = 0.57 and -0.56, P = 0.30 and 0.31, respectively). Furthermore, the ability to centrally activate the plantarflexors (CAR) was negatively correlated with amount of fat infiltration in the plantarflexor muscles (Pearson R = -0.93, P = 0.02). Conclusions: Quantifying spinal cord lesion edema volume offers a novel way of investigating spinal cord injury and preliminary results suggest this approach may be superior to measuring edema length, in regards to correlating with peripheral muscle changes and volitional motor deficits. Lesion volume may offer enhanced clinical prognostic value.

Title: Nociceptive stimulation activates caspase 1 following spinal cord injury by inducing pathologic purinergic signaling

Authors: *J. TURTLE[1], J. A. REYNOLDS[1], M. M. STRAIN[1], Y. J. HUANG[1], S. M. GARRAWAY[2], J. W. GRAU[1];
[1]Texas A&M Univ., Bryan, TX; [2]Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Processes that unfold within the first 48 hours of spinal cord injury (SCI) modulate cell death and determine long-term prognosis. We have shown that nociceptive signals influence these processes and exacerbate secondary damage. Based on studies from a transection model,

we hypothesize that nociceptive input after injury undermines cell survival, impairs recovery of locomotor function, and promotes neuropathic pain. However, the mechanism of impaired recovery following nociceptive input is relatively unknown. Here, we used two different models (uncontrollable electrical stimulation to the tail and peripheral treatment with capsaicin) of nociceptive stimulation (given 24 hours after a moderate spinal contusion at T12) to explore the mechanism of impaired recovery following spinal cord injury. We examined locomotor recovery following injury as well as the underlying cellular mechanisms using immunoblotting of the lesion site. Either peripheral capsaicin injection or uncontrollable tail shock significantly impaired locomotor recovery for at least 28 days when given 24 hours after injury. In addition, nociceptive input increased protein expression of active caspase 1 and increased processing of the pro-inflammatory cytokines IL-1beta and IL-18. These data suggest that after spinal cord injury, nociceptive stimulation promotes the activation of an inflammasome and leads to caspase 1 activation, inflammatory cytokine processing, and potentially pyroptotic cell death. We are exploring the role of purinergic signaling using pharmacologic inhibition of P2X7R with Brilliant Blue G (BBG). If successful, these data would indicate that noxious input soon after spinal cord injury engage a P2X7-dependent purinergic signaling pathway that is capable of activating caspase 1 and promoting cytokine processing. Future work is examining the cell types responsible for inflammasome activation, other mechanisms of cell death, and the effect of drug treatment on functional recovery.

Title: Impact of sustained sublesional nociception on locomotor recovery following a complete spinal lesion in mice

Authors: *R. JEFFREY-GAUTHIER, K. BERTHELET, M. PICHÉ, H. LEBLOND; Univ. Du Québec À Trois-Rivières, Trois-Rivières, QC, Canada

Abstract: Despite the loss of surpraspinal input following complete spinal cord section, central pattern generators (CPG) located in the lumbosacral spinal cord can generate treadmill locomotion, in various animal models. By enhancing cutaneous and proprioceptive inputs to CPG, treadmill training promotes locomotor recovery. Yet, it is not known if nociceptive inputs may alter this locomotor recovery. In spinal rats, nociceptive stimuli disrupt spinal regulation of the flexion reflex during conditioning. However, the impact of nociception on more complex tasks, including locomotion, is not known. The aim of this study was to investigate the impact of sustained sublesional nociception on locomotor recovery following a complete spinal section at T8 in mice. Sustained sublesional nociception in the form of chronic inflammation was induced immediately following complete spinal section by injecting complete Freund adjuvant (CFA) in paraspinal muscles bilaterally, in an experimental group of mice (CFA, n=7), while animals in the control group (CTL, n=8) received no injection. Animals of both groups were then trained daily on a treadmill until locomotor recovery was achieved. Interlimb coordination and detailed kinematic analysis of left hindlimb were assessed by monitoring the step cycle pattern and articular excursions using high speed camera recordings of treadmill locomotion at day 2, 8, 15, 21 and 28 post-lesion. The kinematic analysis showed that CFA mice exhibited a lack of articular excursion throughout the step cycle, which resolved by day 28. This deficit was associated with a large step length decrease observed until day 15. This altered kinematics was observed minimally in CTL mice, but was still sufficient to induce a hindpaw drag during the swing phase. However, paw drag vanished in the late swing phase by day 15 for CTL mice while it was observable until day 28 for CFA mice. Moreover, interlimb coordination measured with the left-right step cycle coupling was more affected in CFA mice. Normally patterned locomotion was not observable before day 28 in this group, while CTL mice exhibited normal left-right coupling by day 15. Altogether, these findings suggest that sustained sublesional nociceptive activity significantly alters locomotor recovery following complete spinal lesion in mice. Since sustained nociception presumably occurs in human patients with spinal cord injury, these results bring new insights for human research aiming at optimizing locomotor recovery.

Title: HIV-1 transgenic rat: alterations in naturally rewarding voluntary wheel running and medium spiny neurons of the nucleus accumbens

Authors: *M. N. CRANSTON, R. M. BOOZE, S. B. HARROD, R. F. ROSCOE, Jr., C. F. MACTUTUS;
Psychology, Univ. of South Carolina, Columbia, SC

Abstract: Motivational alterations in HIV-1+ individuals are associated with decreased performance on tasks involving frontal-subcortical circuitry and the nucleus accumbens. In the present study, the HIV-1 transgenic (Tg) rat was used to assess long-term HIV-1 viral protein exposure on motivated behavior using voluntary wheel running and on medium spiny neurons (MSNs) in the nucleus accumbens. Adult ovariectomized female HIV-1 Tg animals (n=21) to F344 controls (n=26) were pair-housed under a 12:12 light/dark cycle. Voluntary running was measured with 34cm-diameter running wheels for 60 minutes per day for 3 months. There were no significant differences between HIV-1 Tg and F344 control rats in voluntary wheel running during the light phase. Animals were then run in the nocturnal phase of their light/dark cycle. We found that the HIV-1 Tg animals initially ran more than F344 controls and reached an earlier asymptotic plateau; however, F344 controls continued to escalate their overall running and surpassed the stabilized HIV-1Tg group after ~4 weeks of nocturnal running, until reaching their asymptotic plateau at week 11. Maximal running speed was not different between the HIV-1 Tg and F344 controls. MSNs in the nucleus accumbens were ballistically-labeled with the indocarbocyanine dye DiI, followed by 3-dimensional dendritic spine analysis. Decreased length and volume of MSN dendritic spines in HIV-1 Tg rats, relative to F344 controls, suggests a reduction of longer spines and an increase in shorter, less projected spines. Collectively, selective alterations in the rewarding efficacy of voluntary wheel running and altered dendritic spines of the MSNs, indicates a dysfunction of the motivational circuitry within the HIV-1 Tg rat brain. These findings may help elucidate mechanisms of motivational alterations in HIV-1+ individuals.

Title: nNOS positive interneuron subpopulations in CA1 subregions are selectively vulnerable to HIV-1 Tat

Authors: W. D. MARKS[1], C. J. SCHIER[1], *K. F. HAUSER[1], S. FITTING[2];
[1]Pharmacol. & Toxicology, Virginia Commonwealth Univ., Richmond, VA; [2]Psychology Dept., Univ. of North Carolina at Chapel Hill, Chapel Hill, NC

Abstract: The hippocampus is known to be significantly disrupted in neuro-acquired immunodeficiency syndrome (neuroAIDS). This region is comprised of a large variety of interneuron subtypes with varying structures and functions that give rise to a complex processing network. Moreover, hippocampal pathology has been suggested to underlie certain HIV-associated neurocognitive deficits and HIV-1 Tat is thought to contribute markedly to the pathological processes observed in neuroAIDS. We hypothesize the diverse interneuron subtypes are selectively vulnerable to HIV-1 Tat and that this selective susceptibility will underlie deficits in network function. To test this hypothesis, neuronal vulnerability was assessed in GFAP-driven, doxycycline-inducible Tat transgenic mice, with control mice lacking only the tat transgene. Subregions of the hippocampus CA1 were probed in brain slices using antibodies for neuronal markers, including parvalbumin (PV), neuronal nitric oxide synthase (nNOS), neuropeptide Y (NPY), and neuronal nuclear marker (NeuN), combined with fluorescent tagged secondary antibodies. No significant effect was found for Parvalbumin positive cells in the CA1. There were regional and subtype difference observed in nNOS positive neurons. The percentage of nNOS-immunoreactive interneurons without NPY immunoreactivity was significantly decreased in the pyramidal layer of the CA1 region of the hippocampus, as was the percentage of nNOS-immunoreactive interneurons in the stratum radiatum of CA1 in Tat expressing animals compared to controls. The results indicate that at least one subset of CA1 nNOS-expressing interneurons is selectively vulnerable to HIV-1. This finding reveals novel structural deficits in hippocampal circuitry that are likely to underlie behavioral deficits in neuroAIDS.

Title: Exposure to HIV-1 Tat protein modulates forebrain glutamate levels and increases depression-like behavior

Authors: *J. P. MCLAUGHLIN[1,2], M. L. GANNO[2], S. O. EANS[1,2], J. M. MEDINA[1,2], H. M. STACY[2], T. E. GILLIS[3], A. N. ROCK[3], D. MINTZOPOULOS[3], J. J. PARIS[4,2], M. J. KAUFMAN[3];

Abstract: Aims: While exposure to the HIV-1-accessory protein Tat increases striatal dopamine levels and anxiety-like behaviors, the functional consequences of Tat protein on forebrain neurotransmitter levels and behavioral depression are little known. Accordingly, we hypothesized that HIV-1 Tat expression in brain would modulate glutamate levels and promote behavioral depression. Methods: In the GT-tg bigenic mouse model, which enables controlled brain-selective Tat expression by activation of a doxycycline (Dox) promotor, we used magnetic resonance spectroscopy (MRS) to determine whether Tat protein alters medial frontal cortex (MFC) glutamate and N-acetylaspartate (NAA) levels. Furthermore, we tested the effects of Tat protein on depression-like behavior in the tail-suspension test (TST) and saccharin consumption. Additional mice treated daily with the NMDA-receptor antagonist ifenprodil during the induction of Tat protein were also examined for depression-like behavior. Results: Western blot analysis confirmed that the expression of Tat protein in GT-tg bigenic mice correlated with dose and duration of Dox treatment, lasting between 7 and 14 days. MRS scans detected trending and significant MFC decreases in glutamate and NAA, respectively, in GT-tg mice treated 7d with Dox versus the baseline measures in these mice. In initial behavioral testing, GT-tg bigenic mice expressing Tat protein for 7 d demonstrated significant increases in time spent immobile during the TST as well as a significant decrease in saccharin consumption as compared to saline-treated littermates lacking Tat, both characteristic of depression-like behavior. Time spent immobile in the TST was dependent on the magnitude of exposure to Tat protein, as demonstrated by the dose and duration of Dox treatment to induce Tat-protein, as was the persistence of the effect. Of

interest, daily treatment with ifenprodil (10 mg/kg/d, i.p.) reduced the time Tat-induced GT-tg mice spent immobile in the TST for the first 7 days after Tat induction. Conclusions: Overall, these data suggest that expression of HIV-1 Tat protein in the mouse brain is sufficient to increase behavioral depression. Moreover, the Tat-induced decrease in MRS metabolites suggests biological mechanisms by which HIV infection may increase the vulnerability to depression, which could be exploited via specific therapeutic interventions such as glutamate-receptor antagonists.

Title: A unique subset of CD8 T cells (CD4DIMCD8Bright T Cells) is associated with HIV control in the CNS and better neuropsychological function

Authors: ***M. H. RICHARDS**[1], V. LUTGEN[2], S. NARASIPURA[2], L. AL-HARTHI[2]; [1]Immunol. and Microbiology, Rush Univ. Med. Ctr., Hanover Park, IL; [2]Immunol. and Microbiology, Rush Univ. Med. Ctr., Chicago, IL

Abstract: HIV invades the brain within two weeks of infection and can lead to a spectrum of neurocognitive dysfunction termed HIV-Associated Neurocognitive Disorders (HAND). We previously determined that a subset of CD8+ T cells, $CD4^{dim}CD8^{bright}$ T cells (referred to as Double Positive (DP) T cells), is enriched in anti-HIV responses. We evaluated the role of DP vs. single positive (SP) CD8+ T cells in CNS HIV control using HIV+ NOD/SCID/IL-2rcγ-/- (NSG) mice reconstituted with human PBMCs (NSG-huPBMCs) and a cohort of HIV- infected patients on and off antiretroviral therapy. Both DP and SP CD8+ T cells are found in the brain of NSG-huPBMCs within three weeks of infection. Given that DP T cells constitute 3-5% of CD8+ T cells in healthy individuals, these cells could have migrated to the brain as DP T cells or the brain environment may facilitate CD4 induction on CD8+ T cells. To assess whether the brain environment could induce the DP T cell phenotype, CD8+ SP T cells were intracranially injected

into the brain of NSG mice. We report that CD4 expression was induced by 10-fold, indicating that the brain microenvironment can induce the DP T cell phenotype. Further, percentage of DP T cells was inversely correlated with HIV-gag mRNA (r_s=-0.61, p≤0.001) in the mouse brain while no correlation was established between CD8SP and HIV-gag mRNA (R=-0.23,p≤0.3). We extended these studies to the human condition by evaluating the relationship between CSF DP and CD8SP T cells and CSF viral load (VL) among 40 HIV- infected patients who were either on therapy and controlling HIV (HIV RNA < 500 copies/mL; n=11), on therapy but failing to control HIV (>500 copies/mL; n= 12), or not on therapy (n=17). CSF DP T cells inversely correlated with CSF VL (r_s = -0.53565, p≤0.0019) across all groups of HIV-infected patients. Conversely, CSF CD8SP T cells positively correlated with CSF VL (r_s = +0.55913, p≤0.0011) across all groups of HIV infected patients. Further, we evaluated the relationship between DP and CD8SP T cells and Neurospychological Z -4 score (NPZ-4). NPZ is a composite Z score for a short battery of tests (grooved pegboard, timed gait, finger tapper, and WAIS-R digit symbol) which evaluate memory, psychomotor speed, and executive function. We show that percentage of CSF DP T cells is positively correlated with neuropsychological function (r_s=+0.45341, p≤ 0.008) and no such association exists for CD8SP T cells (r_s=-0.18642, p≤ 0.2911). Collectively, these data indicate that a higher frequency of DP T cells and not CD8SP T cells is associated with HIV control in the CNS and better neurocognitive function.

Title: Effect of antiretroviral therapy on HIV-1 tat protein-induced neurotoxicity

Authors: *W. M. DANIELS, S. ZULU, V. RUSSELL, M. MABANDLA;
Univ. of Kwazulu-Natal, Durban, South Africa

Abstract: Previous studies have demonstrated that the viral protein Tat is neurotoxic. Its damaging effects are mediated through increasing reactive oxygen species (ROS) and the excessive production of pro-inflammatory cytokines. The objective of this study was to

investigate whether a combination of antiretroviral drugs is effective in reducing the toxic effects of Tat. Male Sprague-Dawley rats were divided into four groups (n=10). Each rat received bilateral intrahippocampal injections of either Tat (5µg/10µl) or vehicle, followed 7 days later by a combination of antiretroviral drugs (Zidovudine 12mg/kg, Lamivudine 6mg/kg and Efavirenz 24mg/kg) or saline injected intraperitoneally, twice a day, for 7 days. After treatment, animals were sacrificed and hippocampal tissue was collected for analysis of active caspase-3,4-hydroxynonenal (NHE), tumor necrosis factor alpha (TNF-α), phosphorylated extracellular signal-regulated kinase (pERK) and synaptophysin. Tat increased caspase-3 levels in the hippocampus that was decreased by antiretroviral treatment. Tat increased HNE, a marker of lipid peroxidation and reduced hippocampal synaptophysin. The latter Tat-induced effects were not reversed by antiretroviral treatment. The antiretroviral treatment activated the pERK pathway and increased TNF-α levels in hippocampal tissue, independent of Tat infusion. Our findings showed that antiretroviral drugs reversed Tat-induced activation of caspase-3, reducing apoptosis but did not reverse Tat-induced increase in lipid peroxidation and the synaptic marker, synaptophysin. The evidence suggests that the combination of antiretroviral drugs may be toxic, elevating hippocampal pERK and TNF-α levels. However, these effects could also be beneficial to the individual, since TNF-α has been shown to inhibit viral replication. The present results provide novel insight into the mechanism of antiretroviral action.

Title: Involvement of potassium channel KV1.3 in HIV Tat-induced oligodendrocyte/myelin injury

Authors: ***H. LIU**, J. LIU, G. TU, H. XIONG;
Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Brain white matter (WM) is composed of bundles of neuronal axons myelinated with oligodendrocytes (Ols), the myelin-forming cells. Without infection of neuronal cell body and axons, HIV-1 does cause myelin/WM injury and myelin pallor is one of well-established

pathological features in HIV-1-infected brain. Myelin/WM damage has indeed been found not only in patients with HIV-associated cognitive disorders (HAND), but also in HIV-1 positive asymptomatic individuals. How HIV-1 induces myelin/WM damage and consequent cognitive impairment remain incomplete understood. It has been shown that Ols are sensitive to viral proteins such as HIV Tat (a key viral transactivator of transcription) and that a decrease in number of Ols is one of the manifestations of myelin damage. It has also been shown activation of voltage-gated K^+ (K_V) channels mediates apoptosis in various types of cells. We hypothesize that HIV Tat induces Ol injury via activation of $K_V1.3$ channel because $K_V1.3$ is the most predominant K_V channel expressed in Ols and potentially involved in regulation of Ol development. To test this hypothesis, we studied the effects of Tat on whole-cell outward K^+ current conducted by $K_V1.3$ in Ol lineage cells and examined association of Tat alteration of $K_V1.3$ current and Tat-mediated Ol injury. Our results showed incubation of Ols with Tat enhanced outward $K_V1.3$ current and the levels of $K_V1.3$ expression, but decreased the expression of myelin basic protein. Tunel staining revealed that Tat caused Ol apoptosis *in vitro* and decreased axonal myelination *ex vivo.* The Tat-associated alterations were blocked either by specific $K_V1.3$ blockers 5-(4-phenoxybutoxy) psoralen, Margatoxin or by siRNA knockdown of $K_V1.3$ gene. Taken together, our results suggest that Tat-induced Ol/myelin damage via $K_V1.3$ and blockade of $K_V1.3$ may have a therapeutic potential.

Title: Methamphetamine potentiates HIV-1gp120-induced microglia neurotoxicity via potassium channel $K_V1.3$

Authors: *J. LIU, H. LIU, E. XU, G. TU, H. XIONG;
Dept. of Pharmacol. and Exptl. Neurosci., Univ. NE Med. Ctr., Omaha, NE

Abstract: Human immunodeficiency virus (HIV) brain infection causes microglia (MG) activation and release of pro-inflammatory molecules leading to the development of HIV-associated neurocognitive disorders (HAND) and methamphetamine (Meth) abuse exacerbates

HAND. However, the mechanisms underlying Meth exacerbation of HAND are not fully understood. Voltage-dependent potassium (K_V) channels have recently gained attention in the regulation of MG functionality and MG express several types of K_V channels such as outward delayed rectifiers $K_V1.5$ and $K_V1.3$. We hypothesize that Meth potentiates HIV-1-induced MG neurotoxic activity via activation of MG $K_V1.3$. To test this hypotheses, we studied co-morbid effects of Meth and HIV-1 glycoprotein 120 (gp120) on MG $K_V1.3$ expression, $K_V1.3$ current and involvement of $K_V1.3$ in MG production of neurotoxins. Our results revealed that Meth potentiated gp120 enhancement of $K_V1.3$ protein expression, $K_V1.3$ current and MG production of neurotoxins leading to neuronal apoptosis in a does dependent matter, which were blocked by pretreatment of MG with specific $K_V1.3$ channel blocker 5-(4-Phenoxybutoxy)psoralen (PAP), or by broad spectrum K_V channel blocker, 4-AP, indicating an involvement of $K_V1.3$ in Meth/gp120-induced MG neurotoxic activity. Further studies were carried out to identify intracellular signaling for Meth/gp120/$K_V1.3$-associated MG neurotoxic activity. Our data showed that Meth and gp120 activated caspase-8 and caspase-3/7 sequentially and increased their activity. Blockage of caspase-8 and caspase-3/7 by their specific inhibitors significantly decreased MG secretion of pro-inflammatory cytokines and resultant neurotoxic activity. Interestingly, blockage of $K_V1.3$ by specific blockers largely mitigated Meth/gp120 enhancement of caspase-8 and caspase-3 activity, resulting in an attenuation of Meth/gp120-induced MG neurotoxicity. Taken together, our results demonstrated an involvement of MG $K_V1.3$ in the mediation of a co-morbid effect of Meth/gp120 on MG neurotoxic activity. Our results also suggest that blockade of MG $K_V1.3$ could be a potential therapeutic strategy in the suppression of Meth/HIV-associated MG neurotoxicity.

Title: Lrrk2 kinase inhibition attenuates inflammasome priming in microglia

Authors: *P. MILLER-RHODES, C. KIM, S.-M. LU, H. GELBARD;
Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: Human immunodeficiency virus (HIV) associated neurocognitive disorder (HAND) encompasses a wide variety of neurologic disease observed in up to half of HIV-positive patients. HAND varies in its severity and persists despite combination antiretroviral therapy, regardless of its ability to penetrate the central nervous system. Despite its prevalence, the neuropathophysiology of HAND is not well understood, and adjunctive therapies remain an unmet medical need. A literature based on neuropathologic studies and experimental laboratory models identifies microglial activation and pro-inflammatory cytokine secretion as hallmarks of HAND; and further suggests a role for inflammasomes in this disorder. Inflammasomes are multiprotein complexes that mediate the processing and release of the proinflammatory cytokines IL-1β and IL-18, which are secreted signaling molecules involved in the inflammatory response, via the activation of caspase-1. Recent research indicates that HIV-1 infection of monocytes initiates inflammasome "priming" by upregulating the expression of pro-IL-1β and pro-IL-18. Current work in our lab has focused on characterizing the therapeutic effects of inhibition of leucine-rich repeat kinase type 2 (LRRK2) in our *in vitro* and *in vivo* HAND models. Recently, we identified a role for LRRK2 in modulating inflammasome priming in a murine microglial cell line (BV-2), in which we used qRT-PCR to measure the time course of pro-IL-1β expression following lipopolysaccharide (LPS) treatment of BV-2 cells. After identifying peak pro-IL-1β expression six hours after LPS exposure, we then tested whether pharmacological inhibition of LRRK2 could attenuate this process. We found that LRRK2 kinase inhibition results in a robust inhibition of pro-IL-1β expression following treatment with inflammatory stimuli relevant to HIV-1 infection. These results suggest a novel pathway through which inhibition of LRRK2 exerts therapeutic effects in the context of HAND.

Title: Cocaine- and methamphetamine-induced disruption of striatal dopamine and medium spiny neurons in HIV-1 transgenic rats

Authors: *M. JAVADI PAYDAR, R. F. ROSCOE, Jr, C. F. MACTUTUS, R. M. BOOZE; Univ. of South Carolina, Columbia, SC

Abstract: HIV-associated neurocognitive disorders (HAND) are associated with serious complications, and addictive drugs such as cocaine (COC) and methamphetamine (METH) exacerbate these clinical manifestations. In the present experiments, we investigated the consequences of COC- and METH-induced DA release and transport in striatal brain slices from HIV-1 transgenic (Tg) and F344 control female rats during diestrous using fast-scan cyclic voltammetry. We examined DA reuptake and release in control, HIV-1, COC-treated (5μM), HIV-1 + COC-treated, METH-treated (8 μM) and HIV-1 + METH-treated striatal slices. In striatal slices from F344 control animals, COC and METH treatment produced a significant increase in DA reuptake time (T80), relative to untreated control slices. In HIV-1 Tg striatal slices, DA reuptake was significantly prolonged following METH; however, DA reuptake time remained unchanged after treatment with COC. DA levels were altered in HIV-1 Tg striatal slices, as DA in HIV-1 Tg slices was significantly increased relative to the F344 control striatum. Although DA was not affected in METH-treated controls, DA significantly increased in COC-treated controls. In HIV-1 Tg, DA decreased two-fold following exposure to both COC and METH compared to untreated HIV-1 Tg slices. Analysis of DiOlistically-labeled medium spiny neuron (MSN) dendritic spines from HIV-1 Tg brain slices treated with cocaine had the longest dendritic spines with the widest head diameters, relative to F344 controls. Taken together, the current study provides evidence for the dysfunctional role of DAT in mediating DA reuptake within the striatum of HIV-1 Tg rats following exposure to COC and METH. Collectively, dysfunction of the DAT protein and altered dendritic spine morphology of the MSNs, suggests a dynamic, functional disruption of the cocaine reward circuitry within the HIV-1 Tg rat brain.

Title: Dickkopf-related protein 1 is associated with hiv-associated neurocognitive impairment

Authors: *C. YU[1], M. SEATON[1], S. LETENDRE[2], R. HEATON[2], L. AL-HARTHI[1];
[1]Dept. of Immunol. and Microbiology, Rush Univ., Chicago, IL; [2]UCSD, San Diego, CA

Abstract: Dickkopf-related protein 1 (DKK1) is a soluble antagonist of the Wnt/b-catenin pathway. We demonstrated that b-catenin is a critical regulator of the glutamate/glutamine cycle in astrocytes, diminished Wnt/b-catenin signaling perturbs their neuroprotective properties, and methamphetamine (Meth, a frequent co-morbid of HIV infection) inhibits b-catenin signaling. We hypothesized that increased DKK1 would diminish b-catenin signaling and increase the risk for neurocognitive impairment (NCI) in HIV+ subjects. To assess the relationship between plasma DKK1 and NCI, plasma samples from 41 HIV+ and 43 HIV- adults were obtained from the UCSD TMARC cohort. DKK1 and MCP-1 plasma levels were measured by immunoassay. A neuroinflammatory chemokine, MCP-1 was included as a comparison marker. Meth usages were self-reported. All subjects were assessed using a standardized comprehensive NC battery that adhered to Frascati guidelines. NC performance was summarized using the global deficit score method. Levels of MCP-1 ($p = 0.02$) but not DKK1 ($p = 0.65$) were higher in HIV+ subjects than in HIV- subjects. Higher DKK1 levels ($p = 0.02$) were associated with meth density/use frequency in all subjects. Among HIV+ subjects, higher levels of DKK1 ($d=0.63$, $p = 0.05$) but not MCP-1 ($p = 0.59$) were associated with NCI, those who had plasma DKK1 levels of at least 1,129 pg/ml had a 6.0-fold increased odds of having NCI (75% vs 33%, 2-tail FET $p=0.04$). The effect size was large and the association between DKK1 and NCI was highly specific (92%). In comparison, recursive partitioning failed to identify a statistically significant threshold value for MCP-1. Multivariable analysis among HIV+ subjects identified that the association between higher DKK1 levels and NCI remained statistically significant after accounting for the effects of nadir CD4+ T-cell counts, drugs of abuse, and ART use. These findings underscore the potential specificity of DKK1 as a biomarker for NCI in HIV+ adults.

Title: HIV induces a unique neurotoxic phenotype in human monocyte-derived macrophages that is suppressed by nerve growth factor and the neurotrophin ligand, LM11A-31

Authors: *K. S. WILLIAMS[1], J. A. SEAWELL[2], V. ZHURAVLEVA[3], R. B. MEEKER[3]; [1]Neurol., Univ. of North Carolina Sch. of Med., Chapel Hill, NC; [2]Neurol., [3]UNC Chapel Hill, Chapel Hill, NC

Abstract: When macrophages or microglia encounter HIV they secrete neurotoxic substances which cause neural damage. The damage includes a destabilization of intracellular calcium, appearance of varicosities in the dendrites, actin aggregation and dendritic pruning and mimics the pathology seen in other neurodegenerative diseases such as Alzheimer disease. One approach to prevent neurotoxicity is to reduce the activation of the macrophages by HIV. However, the processes that lead to toxin secretion and the nature of the toxins are not well understood. Neurotrophin receptors on macrophages may play a role in the control of toxic activity by altering the signaling machinery essential for HIV-induced activation. In particular, differential signaling by pro-neurotrophins versus mature neurotrophins in macrophages may contribute to neuronal damage in a fashion that parallels the proposed actions of these neurotrophins in neurons. NGF and a potential therapeutic small non-peptide molecule that resembles loop 1 of NGF, LM11A-31, suppressed neurotoxin secretion during HIV stimulation of human monocyte derived macrophages (hMDM) whereas proNGF facilitated neurotoxin production as assessed by calcium destabilization in primary rat cortical neurons. Specific actin rich structures in hMDM correlated with neurotoxin production. Cultures of hMDM possessing podosomes were more neurotoxic than cultures containing ruffled hMDM. Podosome formation in macrophages was induced by HIV and suppressed by treatment with NGF or LM11A-31. The latter stimuli typically resulted in macrophages with membrane ruffling. Blocking the p75NTR but not TrkA, during HIV stimulation prevented HIV induced podosome formation. These morphological features correlated closely with high (ruffles) or low (podosomes) levels of intrinsic calcium spiking in hMDM. HIV suppressed calcium spiking which was restored in the presence of NGF or LM11A-31. Calcium spiking was reduced by proNGF. A parallel assessment of the conditioned medium showed a subset of secreted proteins that were increased by HIV and that

correlated with calcium destabilization in neurons. NGF and LM11A-31 co-stimulation with HIV reversed the secretion of these proteins while proNGF often increased their secretion and induced a distinctive phenotype. These data suggest that NGF and LM11A-31 have the ability to control the neurotoxic activity induced by HIV while proNGF may enhance neuorinflammation. Targeting neurotrophin receptors on macrophages with LM11A-31 may be a novel therapeutic avenue to suppress neuroinflammation during HIV associated cognitive disorders and other neuroinflammatory diseases.

Title: Independent and combined effects of methamphetamine and HIV gp120 protein on neural microstructure in mice using diffusion tensor imaging

Authors: B. S. MCKENNA[1], *G. G. BROWN[4,2], S. ARCHIBALD[2], M. SCADENG[3], R. BUSSELL[3], J. KESBY[2], A. MARKOU[2], S. SEMENOVA[2];

Abstract: Methamphetamine (METH) abuse is common among individuals infected by human immunodeficiency virus (HIV). METH and HIV cause injury to both cortical and subcortical brain regions. However, it is unclear what the independent versus combined effects of HIV and METH are on brain microstructure. The expression of HIV gp120 protein induces neuropathology in mice similar to HIV-induced pathology in humans. We examined the independent and combined effects of HIV gp120 protein and METH on the brain using *in vivo*

diffusion tensor imaging (DTI) with 27 gp120-transgenic and 27 non-transgenic mice, of which 14 in each group underwent an escalating METH binge or saline control regimen. Mean diffusivity (MD) served as a measure of microstructural integrity of neural tissue. DTI was conducted 3-4 months post-regimen when mice were 9-10 months old. MD maps were calculated and data were aligned to atlas space for analyses. Multiple linear regression with an orthogonal set of contrast codes designed to examine independent and combined effects were used with the following comparisons: 1) control mice vs. the three experimental groups; 2) dual gp120/METH vs. gp120 only and METH only mice; and 3) gp120 only vs. METH only mice. A corrected p-value for multiple comparisons of 0.05 was used for all analyses. Compared to the control group, the combined METH, gp120, and dual gp120/METH groups demonstrated increased MD within bilateral hippocampi, genu of the corpus callosum, and posterior isocortex. Within hippocampi similar increases in MD were found in each experimental group. Compared to METH only and gp120 only groups, dual gp120/METH mice had increased diffusivity in bilateral midbrain, right hypothalamus, entorhinal cortex, globus pallidus, and caudate. Increased MD was observed in METH only relative to gp120 only within bilateral caudate, right internal capsule, left globus pallidus and hippocampus; whereas increased diffusivity in gp120 only relative to METH only was observed in right midbrain, left thalamus, and genu of the corpus callosum. The results highlight both spatially distinct independent and combined effects of METH and HIV protein gp120 on DTI-measured MD. Prior METH exposure had a larger impact on the striatum relative to gp120, whereas gp120 had larger relative impact on midbrain and diencephalic nuclei. Combined METH and gp120 led to further increases in MD in some, but not all these regions. Hippocampi were affected by both METH and gp120, but not additively. Increased mean diffusion in these regions may reflect damage to cell bodies and/or their processes suggesting METH and gp120 may impact the brain through overlapping and distinct mechanisms.

Title: The critical role of the inflammatory cytokine interleukin-1 beta and the iron storage protein ferritin heavy chain in synaptodendritic injury during HIV infection

Authors: *L. FESTA[1], C. GUTOSKEY[2], A. GRAZIANO[1], B. WATERHOUSE[2], O. MEUCCI[1];
[1]Pharmacol. & Physiol., [2]Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Despite the introduction of combination antiretroviral therapy (cART), HIV-associated neurocognitive disorders (HAND) continue to persist. While the molecular mechanisms of HAND are not fully understood, both viral (e.g. HIV gp120) and host (e.g. inflammatory cytokines) factors can contribute to neuronal dysfunction, including synaptodendritic injury. Here, we propose that HIV proteins and inflammatory cytokines induce synaptic damage by upregulating neuronal expression of the iron storage protein ferritin heavy chain (FHC), a novel negative regulator of the homeostatic chemokine/receptor pair CXCL12/CXCR4. We previously found that the HIV envelope protein, gp120, can regulate neuronal levels of FHC, which is mediated by gp120-evoked release of the inflammatory cytokine, IL-1 beta, from glial cells. In order to further investigate the consequences of FHC alterations, we utilized two noninfectious rodent models of HAND (HIV-Tg and gp120-treated rats). We observed significant reductions in both dendritic spine density and basal dendrite branching in layer II/III pyramidal neurons of the medial prefrontal cortex (mPFC), suggesting decreases in neuronal complexity and connectivity. In line with this, gp120-treated rats exhibited deficits in reversal learning, a measure of cognitive flexibility, and this was negatively correlated with dendritic spine density (Pearson r= -0.8036). Interestingly, elevated levels of FHC were observed in frontal cortex lysates in the same HIV-Tg rats used for spine analysis. Furthermore, in neuronal/glial bilaminar co-cultures, the relative FHC staining intensity in neurons was negatively associated with dendritic spine density (Pearson r= -0.7441), regardless of treatment group (vehicle or gp120). Importantly, gp120 was unable to decrease dendritic spine density in FHC-deficient neurons, thus establishing FHC's critical role in the spine changes mediated by the envelope protein. Taken together, with our previous findings in HIV patients and SIV-infected primates, these data validate FHC's critical role in synaptodendritic injury and point to IL-1 beta as a valid therapeutic target.

Title: Neurotrophin/CXCR4 receptor interactions regulate calcium activity and HIV-induced neurotoxin secretion in human monocyte-derived macrophages

Authors: V. ZHURAVLEVA, K. WILLIAMS, J. SEAWELL, *R. B. MEEKER;
Neurol., Univ. of North Carolina, Chapel Hill, NC

Abstract: Therapeutic approaches designed to restore cognitive function by suppressing macrophage and microglial activation by HIV in the central nervous system (CNS) have not yet been successful, in part, due to limited knowledge of the cellular mechanisms that control toxin secretion. Human monocytes, macrophages and microglia express the neurotrophin receptors p75 (p75NTR) and TrkA and respond differentially to nerve growth factor (NGF) and its precursor proNGF, by downregulating or exacerbating HIV-induced toxic activity, respectively. To determine how neurotrophins might influence HIV-associated activation, we evaluated the interaction between the neurotrophin receptors and the HIV co-receptor CXCR4. Blockade of CXCR4 but not CCR5 reduced HIV-induced neurotoxin secretion as assessed by calcium destabilization in primary rat cortical neurons. A similar suppression of HIV-induced neurotoxin secretion was seen when the p75NTR was blocked whereas blockade of TrkA signaling enhanced macrophage neurotoxin secretion. HIV stimulation suppressed calcium spiking in macrophages which was reversed by NGF but not proNGF. The reversal by NGF was dependent on CXCR4 since it was blocked by the specific antagonist AMD3100 and a CXCR4 neutralizing antibody. These results indicated that the neurotrophin receptors p75NTR and TrkA have opposing roles in macrophage neurotoxin production and may interact closely with HIV stimulation of CXCR4. Co-immunoprecipitation confirmed that CXCR4 formed complexes with

p75NTR and TrkA. NGF stimulation of macrophages in the presence or absence of HIV increased CXCR4 phosphorylation whereas HIV stimulation alone or proNGF had small or negligible effects. NGF induced phosphorylation was blocked by inhibition of TrkA signaling. Immunostaining showed that neurotrophin receptors and phosphorylated CXCR4 (pCXCR4) were expressed in similar cellular domains of the macrophages. HIV reduced the co-localization of pCXCR4 with both p75NTR and TrkA. NGF but not proNGF restored overlap between pCXCR4 and the p75NTR and partially restored pCXCR4/TrkA overlap. G-protein receptor kinase 2 (GRK2) was also associated with CXCR4, with a pattern that matched CXCR4 phosphorylation. This interaction between neurotrophin receptors and CXCR4 identifies a novel mechanism by which neurotrophins orchestrate phenotypic modifications of the macrophage and regulate inflammation in the central nervous system.

Title: NeuroAIDS in NSG mice with humanized brain and hematolymphoid tissue

Authors: *W. LI, L. WU, J. KNIBBE, S. GORANTLA, H. E. GENDELMAN, L. Y. POLUEKTOVA;
Univ. of Nebraska Med. Ctr., Omaha, NE

Abstract: Rodent models of human immunodeficiency virus (HIV) brain infections are limited as none reflect human glial-immunocyte-virus interactions as they occur in an infected human host. To achieve such a goal would require simultaneous humanization of both the immune system and brain. This was now achieved by combined reconstitution of the peripheral hematolymphoid and brain tissue. Herein, human glial precursors (GP) were generated from human fetal tissue. GP derived from neural stem cells were injected into lateral ventricle of neonatal NSG mice. The same mice were simultaneously inoculated intrahepatically with CD34+ hematopoietic stem cells (HSC) from human fetal liver from the same donor. At two months of age blood was tested for human immune cells by flow cytometry. Animals were infected with

HIV-1 peripherally by intraperitoneal inoculation then observed for 7 weeks and sacrificed. Brain tissues demonstrated anatomically symmetric humanization of both hemispheres by human glial cells. Immunohistochemistry for Glial fibrillary acidic protein and microtubule-associated protein 2 antigens showed the presence of large number of human astrocytes. In corpus callosum and periventricular areas, 70-90% of the identified astrocytes were of human origin. These cells were also distributed through the meninges and ventricular walls. Their presence did not induce mouse microglial activation. HIV-1 infection in these dual humanized mice showed blood viral load ranging from 1.55x105 to 6.14x105 copies/mL and HIV p24+ cells readily identified in mouse spleen. Virus infected mice brains showed reduced human glial cell density but increased Ki67+ nuclear staining. In contrast to HIV-1 infected animals without glial repopulation the dual reconstituted HIV infected mice showed increased peripheral lymphocytes and monocytes infiltration in the brains. Successful reconstitution of NSG mouse with both human glial cells and peripheral hematopoiesis offers a novel animal system to systematically explore the pathological mechanism underlying human-specific virus infections as they occur in an infected human host.

Inst. on Drug Abuse, Baltimore, MD; [5]Natl. Inst. on Alcohol Abuse and Alcoholism, Rockville, MD; [6]Dept. of Neurosci., Univ. of California at San Diego, La Jolla, CA; [7]Dept. of Systems Biol., Columbia Univ., New York, NY; [8]Mol. and Cell. Neurosci. Dept., The Scripps Res. Inst., La Jolla, CA

Abstract: We profiled gene expression in the hippocampus of HIV-1 Tg rats, a rodent model of HIV infection in which multiple HIV-1 proteins are expressed under the control of the viral LTR promoter in disease-relevant cells including microglia and astrocytes. The Gene Set Enrichment Analysis (GSEA) algorithm was used for pathway analysis. Gene expression changes observed are consistent with astrogliosis and microgliosis and include evidence of inflammation and cell proliferation. Among the genes with increased expression in HIV-1 Tg rats was the interferon stimulated gene 15 (ISG-15), which was previously shown to be increased in the cerebrospinal fluid (CSF) of HIV patients and to correlate with neuropsychological impairment and neuropathology, and prostaglandin D2 (PGD2) synthase (Ptgds), which has been associated with immune activation and the induction of astrogliosis and microgliosis. GSEA-based pathway analysis highlighted a broad dysregulation of genes involved in neuronal trophism and neurodegenerative disorders. Among the latter are genesets associated with Huntington's disease, Parkinson's disease, mitochondrial, peroxisome function, and synaptic trophism and plasticity, such as IGF, ErbB and netrin signaling and the PI3K signal transduction pathway, a mediator of neural plasticity and of a vast array of trophic signals. Additionally, gene expression analyses also show altered lipid metabolism and peroxisomes dysfunction. Supporting the functional significance of these gene expression alterations, HIV-1 Tg rats showed working memory impairments in spontaneous alternation behavior in the T-Maze, a paradigm sensitive to prefrontal cortex and hippocampal function. Comparison of gene expression of the hippocampus of HIV-1 Tg rats with the National NeuroAIDS Tissue Consortium (NNTC) human HIV gene expression dataset showed largely consistent results including changes in in genes related to neuronal trophism and degeneration. Altogether, differentially regulated genes and pathway analysis identify specific pathways that can be targeted therapeutically to increase trophic support, e.g. IGF, ErbB and netrin signaling, and reduce neuroinflammation, e.g. PGD2 synthesis, which may be beneficial in the treatment of chronic forms of HIV-associated neurocognitive disorders in the setting of viral suppression.g

Title: Protective effects of the lignan secoisolariciresinol diglucoside (SDG) against oxidant stress, neuroinflammation, and HIV neurotoxicity

Authors: *M. A. ERICKSON[1], J. KING[4,1], A. ODELEYE[5,1], K. SETO[1,2], R. PIETROFESA[3], C. AKAY ESPINOZA[1], B. WINKELSTEIN[2], M. CHRISTOFIDOU-SOLOMIDOU[3], K. JORDAN-SCIUTTO[1];
[1]Pathology, Sch. of Dent. Med., [2]Bioengineering, [3]Med., Univ. of Pennsylvania, Philadelphia, PA; [4]Biol., Ursinus Col., Philadelphia, PA; [5]Biol., Univ. of Virginia, Charlottesville, VA

Abstract: HIV-associated neurocognitive disorder (HAND) is a neurologic syndrome consisting of cognitive, motor, and behavioral deficits. Up to 50% of HIV-infected individuals are afflicted with HAND despite effective viral suppression with antiretroviral therapies (ART). Therefore, the identification of novel therapies to mitigate CNS complications of HAND would greatly improve the quality of life in HIV-infected patients. Such therapeutics would likely need to be brain-penetrant, and target multiple HAND-associated pathologies and be safe for prolonged use. Secoisolariciresinol diglucoside (SDG), a flaxseed-derived lignan, has anti-inflammatory and antioxidant properties and protects against damage to peripheral organ systems in diverse disease contexts. Therefore, we hypothesized that SDG could also protect against inflammation and oxidative stress in multiple CNS cell types, and protect neurons in an *in vitro* model of HIV neurotoxicity. Our data in mice demonstrate that SDG is CNS-penetrant and when administered systemically, acts as an indirect antioxidant in the CNS by activating the endogenous antioxidant response. *In vitro*, SDG protects against astrocyte loss following treatment of rat neuroglial cultures with hydrogen peroxide, and inhibits inflammatory responses in primary rat microglia induced by TNF-α. Finally, we show that SDG has protective effects against oxidative stress and neuronal loss in rat neuroglia treated with supernatants from HIV-infected human macrophages. Together, these data demonstrate that SDG has protective effects in multiple CNS cell types *in vitro*, and suggest that activities of SDG could synergize to mitigate inflammation and oxidative stress in HAND.

Title: Cathepsin B released from HIV-infected macrophages is internalized by neurons and induces apoptosis in rat primary cortical neurons

Authors: ***Y. M. CANTRES-ROSARIO**[1], M. PLAUD[1], Y. GERENA[2], R. J. NOEL, Jr.[3], L. M. MELENDEZ[1];
[1]Microbiology and Med. Zoology, [2]Dept. of Pharmacol. and Toxicology, Univ. of Puerto Rico, Med. Sci. Campus, San Juan, Puerto Rico; [3]Basic Sci. Dept., Ponce Res. Inst., Ponce, Puerto Rico

Abstract: Human immunodeficiency virus (HIV-1) targets CD4-positive lymphocytes, macrophages and microglia. HIV-infected macrophages infiltrate trough the blood brain barrier into the brain, triggering a strong inflammation that results in synaptodendritic injury, neuronal dysfunction and apoptosis. Clinical manifestations range from asymptomatic, mild cognitive disorders to encephalitis and dementia. HIV-infected macrophages secrete cathepsin B, a lysosomal protease, inducing apoptosis of SK-N-SH neuroblastoma cells. The apoptosis is decreased by 10% when macrophage-conditioned medium is pre-treated with cathepsin B inhibitor or antibody. Cathepsin B is also increased in the deep frontal white matter of patients with HIV-associated dementia. The molecular action of cathepsin B remains unknown. We therefore hypothesize that HIV infection of macrophages fails to prevent cathepsin B internalization into neurons, promoting apoptosis. To determine the mechanism of cathepsin B-induced neuronal death, we exposed SK-N-SH to active recombinant His-tagged cathepsin B for

24 hours, and tracked its entry with a PE-conjugated His-tag antibody by intracellular flow cytometry. A high percentage of neurons internalized His-tagged cathepsin B diluted in plain medium (93.8%) or medium derived from HIV-infected macrophages (86.9%) when compared to neurons exposed to His-tagged cathepsin B in medium derived from uninfected macrophages (35.6%). Neuronal internalization of His-tagged cathepsin B was confirmed by western blot. We next determined the contribution of macrophage secreted cathepsin B to apoptosis in primary neurons. We exposed primary rat cortical neurons to uninfected and HIV-infected macrophage conditioned media pre-treated cathepsin B antibody for 24 hours and tested caspase-3 by western blot. Cleavage of caspase-3 is higher in neurons exposed to HIV-infected macrophage-conditioned medium compared to neurons exposed to uninfected macrophage medium. Moreover, pre-treatment of HIV-infected macrophage-conditioned medium with anti-cathepsin B antibody decreases the levels of cleaved caspase-3 in neurons, therefore decreasing apoptosis. In conclusion, we report for the first time that HIV-1 infection of macrophages fails to prevent internalization of cathepsin B by neurons and that macrophage-secreted cathepsin B induces apoptosis in primary neurons. Our results support the role of cathepsin B interference in reducing HIV-induced neuronal damage, representing a new approach for restoring the protective activity of macrophages against HIV-associated neurocognitive disorders.

Title: Changes of mitochondrial homeostasis in hippocampus of hiv transgenic(tg26) mice

Authors: *P. R. GUDA[1], T. MAKAR[2,3], S. RAY[2], A. SAGI[2], J. BRYANT[4];
[1]10-2-884/1, Karimnagar, India; [2]Univ. of maryland, Baltimore, MD; [3]Multiple sclerosis center of excellence, VA Maryland Hlth. care system, Baltimore, MD; [4]Inst. of Human Virology, Baltimore, MD

Abstract: Mitochondrial physiology is fundamental to the maintenance of cellular function. This is particularly relevant in the nervous system, in which pathology is mostly associated with mitochondrial deficiencies. Defects in mitochondria are indeed key players in most neurodegenerative diseases, including HIV- associated dementia. There is no clear information

regarding mitochondrial roles in HIV associated dementia. The objectives of this study were to evaluate mitochondrial biogenesis, fusion/fission, mitochondrial function and apoptotic neuronal cell death in HIV-transgenic (Tg26) mice in relation to HIV progression. This was a hippocampal comparison study between five age and gender-matched groups (n=5×3) of healthy wild type (WT) mice and HIV-transgenic (Tg26) mice. We analyzed mitochondrial biogenesis, mitochondrial fusion and fission, mitochondrial apoptosis, and mitochondrial function by RT-PCR and Western blot analysis. Mitochondrial biogenesis (as measured by PGC-1α, Nrf1, Nrf2, and TFAM mRNA and protein levels) was decreased significantly in Tg26 mice compared to WT mice. Mitochondrial Fusion (as determined by Mfn-2 and OPA-1) was decreased in Tg26 mice with respect to WT mice. On the other hand, mitochondrial fission (as determined by Drp-1, Fish-1) was increased. All apoptotic parameters (Caspase-3, Caspase-9, and Bax) significantly increased. However, the mitochondrial functional parameter (COX-6) was inhibited in Tg26 mice compared to WT mice. Findings from this study identify a novel mitochondrial role in neuronal apoptosis associated with HIV induced neurocognitive disorder. Furthermore, we propose that this animal model is effective for mitochondrial and apoptotic assessment and could be useful for clinical research purposes.

Title: HIV-1 Tat-mediated neurotoxicity and anxiety-like behavior of mice may be protected by the pregnane neurosteroid, allopregnanolone

Authors: ***J. J. PARIS**[1], D. CHEN[2], S. KIM[3], P. E. KNAPP[3], K. F. HAUSER[2];
[2]Pharmacol. & Toxicology, [3]Anat. & Neurobio., [1]Virginia Commonwealth Univ., Richmond, VA

Abstract: Human immunodeficiency virus (HIV) infection is associated with neurodegeneration and mood disorders. Gender/sex differences in the prevalence of such disorders are reported.

Actions of the HIV-1 regulatory protein, trans-activator of transcription (Tat), are involved in HIV-associated toxicity and may be partly ameliorated by sex steroid hormones. Using mice that conditionally-express HIV-1 Tat1-86 in the CNS, we have observed less behavioral impairment, neurotoxicity, astrogliosis, and neuroinflammation among Tat-exposed females compared to their male counterparts. Moreover, progesterone administration reduced anxiety-like impairments in ovariectomized transgenic female mice centrally-expressing Tat. We hypothesized that the Tat-protective effects of progesterone involved metabolism to its neuroprotective metabolite, allopregnanolone, given that allopregnanolone's protective actions overlap with targets of Tat-excitotoxicity. Complimentary *in vitro* and *in vivo* experiments were conducted. Neuronal co-cultures were incubated with media that did, or did not, contain allopregnanolone (100 nM) in the absence or presence of HIV-1 Tat1-86 (50 nM). Transgenic, female mice that did, or did not, express the transcription factor necessary for CNS-mediated Tat expression were ovariectomized and received a hormone-replacement regimen that consisted of intermittent progesterone (4 mg/kg), with or without pretreatment of a progesterone-metabolism inhibitor (finasteride 50 mg/kg). Mice were assessed in a battery of anxiety-like tasks (open field, elevated plus maze, marble burying). Consistent with prior reports, HIV-1 Tat caused significant neurotoxicity in culture and increased anxiety-like behavior of ovariectomized mice. Allopregnanolone significantly attenuated Tat's neurotoxic effects *in vitro* and progesterone ameliorated anxiety-like behavior associated with central Tat expression *in vivo*. The latter protection could be blocked via pretreatment with finasteride. Thus, pregnane steroids confer neuroprotection *in vitro* and ameliorate anxiety-like impairments *in vivo* that are associated with HIV-1 Tat. These effects may be dependent on formation of the neurosteroid, allopregnanolone. Hormone therapies may confer prophylactic advantages in the treatment of neuroAIDS.

Title: Enhanced expression of immunoreactive L-type calcium channels in the mesocorticolimbic pathway of HIV-1 transgenic rats

Authors: *W. N. WAYMAN, A. L. PERSONS, T. C. NAPIER;
Pharmacol. Department,, Rush Univ., Chicago, IL

Abstract: The mesocorticolimbic pathway is affected in HIV^+ humans by toxic HIV-1 proteins. Two key structures of the mesocorticolimbic system are the medial prefrontal cortex (mPFC) and nucleus accumbens (NAc). Recently, we revealed that the pathophysiology occurs in mPFC pyramidal neurons and NAc medium spiny neurons from HIV-1 transgenic (Tg) F344 rats as compared to non-transgenic F344 controls (non-Tg) (Wayman et al. JNIP 10:S108, 2015; Chen et al. JNIP 10:S64, 2015). There were striking differences in the electrophysiological profiles of mPFC pyramidal neurons and NAc medium spiny neurons between Tg and non-Tg rats. Both pyramidal and medium spiny neurons from Tg rats demonstrated hyper-excitability, including increased evoked and spontaneous firing, and a greater tendency for depolarization-induced inactivation. In the mPFC, this altered electrophysiological profile was mitigated by diltiazem, indicating a contribution of high-voltage-activated L-type Ca^{2+} channels. Here, we extend this work by determining if expression of $Ca_{v1.2}$-α1c (the pore forming subunit of L-type Ca^{2+} channels) is altered in male, young adult Tg rats. Brain tissue from non-Tg and Tg rats was harvested and prepared for immunohistochemical assessments of $Ca_{v1.2}$-α1c. We found that $Ca_{v1.2}$-immunoreactivity (ir) was readily detected in the mPFC and NAc of both non-Tg and Tg rats. For these pilot studies, observers who were blinded to genotype, qualitatively determined the staining patterns of $Ca_{v1.2}$-ir of neurons in mPFC layers 5/6 and the NAc core. Staining scores ranged from 1, which described a low number of $Ca_{v1.2}$-ir neurons with low staining intensity, up 4, which described a high number of $Ca_{v1.2}$-ir neurons with high staining intensity. In layers 5/6 of the prelimbic mPFC revealed differences in staining for $Ca_{v1.2}$-ir between non-Tg and Tg rats. The average score for $Ca_{v1.2}$-ir in the mPFC of Tg rats was 3 compared to score of 2 for the $Ca_{v1.2}$-ir in non-Tg rats Likewise, the average score for $Ca_{v1.2}$-ir in the NAc core of Tg rats was 4, compared to a score of 2 for the $Ca_{v1.2}$-ir in non-Tg rats. Taken together, these findings indicate increased expression of L-type Ca^{2+} channels may contribute to the increased neuronal excitability observed in Tg rats.

Title: IFNβ protects cerebrocortical neurons in a CCL4-dependent fashion against HIV-1 gp120-induced injury

Authors: *V. E. THANEY[1], M. M. HOEFER[1], M. KAUL[1,2];
[1]Infectious and Inflammatory Dis. Ctr., Sanford Burnham Med. Res. Inst., La Jolla, CA; [2]Dept. of Psychiatry, Univ. of California San Diego, San Diego, CA

Abstract: HIV-1 appears to invade the CNS soon after peripheral infection. However, severe neurological symptoms may be delayed until a later stage of disease progression. Type I interferons are critical mediators of anti-viral immune response and IFNβ has been implicated in the control of HIV and SIV infection of the brain. However, the potential role of IFNβ as a neuroprotective factor in the context of HIV/gp120-induced neuronal injury remains to be characterized. Therefore, we investigated the neuroprotective potential of IFNβ against toxicity of HIV/gp120 in the brain using *in vivo* and *in vitro* models. Using mixed rodent cerebrocortical cultures (RCC), containing neurons, astrocytes, and microglia, we found that treatment with IFNβ can provide concentration-dependent neuroprotection against HIV/gp120. Additionally, treatment with IFNβ of RCC increased levels of natural ligands of the HIV co-receptor CCR5 and up-regulated expression of anti-viral IFN-stimulated genes (ISGs). These ligands, MIP-1β/CCL4 and RANTES/CCL5, are known to suppress HIV-1 infection; disease progression and all can provide significant *in vitro* protection against gp120-induced neuronal injury. In fact, we found that MIP-1β/CCL4 is required for IFNβ mediated neuroprotection. Recently, we used a microarray-based genome-wide gene expression analysis to identify genes that are differentially expressed in connection with the neuropathological phenotype of HIV/gp120-transgenic (tg) mice at different ages. HIVgp120tg mice express the viral envelope protein in the brain and manifest several neuropathological features observed in AIDS brains, such as decreased synaptic and dendritic density, increased numbers of activated microglia, and pronounced astrocytosis. We found that gp120tg brains can mount an anti-viral immune response, specifically inducing the expression of ISGs. In addition, qRT-PCR analysis confirmed a transient IFNβ expression in gp120tg brains and up-regulation of numerous ISGs, prior to the development of neuropathology and behavioral impairment. Moreover, a four-week intranasal IFNβ treatment completely abrogated neuronal damage in gp120tg mice while triggering a biological response of IFN-induced gene expression. Similarly to the *in vitro* studies, we found that IFNβ treatment significantly increased MIP-1β/CCL4 expression levels in the HIV/gp120tg brains and therefore propose a critical role for this chemokine in the mechanism of IFNβ mediated neuroprotection.

Title: M1/M2 polarization and type 1 interferon response in morphine-potentiated LP-BM5 murine AIDS

Authors: *V. D. MCLANE[1,2], C. L. WILLIS[1], L. CAO[1];
[1]Col. of Osteo. Med., Univ. of New England, Biddeford, ME; [2]Grad. Sch. of Biomed. Sci. and Engin., Univ. of Maine, Orono, ME

Abstract: Of the 1.1 million people infected with human immunodeficiency virus (HIV-1) in the United States, it is estimated that between 15 and 50% will develop cognitive deficits. Over 30% of HIV-1 patients abuse opiates such as heroin, which increase the risk and severity of HIV-associated neurocognitive disorders. Morphine mediates this effect through its influence on glia, the initiators of innate immune defense against viral infection in the central nervous system (CNS). Through the LP-BM5 murine acquired immunodeficiency syndrome (MAIDS) model, we have shown that morphine induces region-specific changes in viral load and cytokine expression in the CNS. We hypothesized that the change in viral RNA is the result of the synergistic effects of morphine and LP-BM5 viral infection on the antiviral type 1 interferon response and the proinflammatory cytokine response of the CNS. To investigate this, we infected male C57BL/6 mice with LP-BM5 (5e4 plaque-forming units, intraperitoneal injection). At 7 weeks post-infection, animals received 1 week of treatment with a subcutaneous morphine (25 mg) or placebo pellet. We measured expression of type 1 interferons (IFN-α and IFN-β) and pro- (M1) and anti-inflammatory (M2) markers in key regions of interest - hippocampus, striatum, and frontal cortex - through quantitative real-time PCR and immunohistochemistry. Following morphine treatment, we observed reduced viral load and significantly higher type 1 IFN relative expression in striatum compared to the hippocampus, which exhibits increased viral load and a weak type 1 IFN response. We hypothesize that the reduced type 1 IFN response, in conjunction with the global reduction in proinflammatory cytokines such as CCL5, leaves the hippocampus vulnerable to viral infection. Through our work with the LP-BM5/MAIDS model, we are

identifying novel pathways for the treatment and prevention of opiate-potentiated HIV-associated neurocognitive disorders.

Title: Pharmacologic targeting of host innate immune responses decreases viral replication in a brain slice culture model of HSV encephalitis

Authors: ***D. R. WILCOX**[1,2], W. J. MULLER[1], R. LONGNECKER[2];
[1]Pediatrics, [2]Microbiology-Immunology, Northwestern Univ. Sch. of Med., Chicago, IL

Abstract: The increased susceptibility and severity of herpes simplex virus (HSV) infection in the newborn compared to the adult is thought to be due to differences in the host response to infection between the developing and the mature brain, but the precise reasons remain unknown. In order to successfully replicate in the host cell, HSV counters several pathways in the innate immune response to infection. Our group and others have demonstrated that the multifunctional HSV protein γ34.5 counters several pathways in the host response to infection, and contributes to disease in both the newborn and adult CNS. Although HSV inhibition of autophagy contributes to disease in the adult CNS, we previously demonstrated that it is dispensable for pathogenesis in the neonatal brain. We hypothesized that additional virus-host interactions mediated by HSV γ34.5 contributed to disease in the newborn. To investigate additional host interactions with HSV γ34.5 that contribute to CNS disease, we used a virus carrying a mutation that specifically disrupts γ34.5 binding to the host phosphatase PP1α (ΔPP1α). Intracranial inoculation of mice was used as a model of HSV encephalitis. In both newborn and adult mice, infection with ΔPP1α resulted in significant attenuation of the virus in the CNS, with a longer time to mortality and slower replication compared to the rescue virus. Furthermore, after inoculation of interferon-receptor knock out (IFNAR KO) mice, we show that attenuation of the ΔPP1α virus is IFN dependent in both age groups. To gain a detailed understanding of viral replication dynamics and specific host targets of PP1α modulation by HSV, we established an *ex vivo* organotypic brain slice culture (BSC) model of HSV encephalitis. In BSCs from either newborn or adult mice, the

ΔPP1α virus replicated more slowly than the rescue virus control. HSV γ34.5 binding of PP1α resulted in retargeting of the host phosphatase to dephosphorylate eIF2α, effectively reversing translational arrest in the host cell during infection. Furthermore, treating BSCs with salubrinal, a drug that causes the phosphorylation of eIF2α, significantly reduces viral replication in both the adult and newborn brain. We conclude from our data that reversal of host translational arrest by HSV binding of PP1α contributes to CNS pathogenesis in both age groups, and salubrinal, a drug that increases eIF2α phosphorylation, significantly decreases viral replication in a BSC model of HSV encephalitis.

Title: Modeling HIV-1-induced platelet-mediated dysfunction of the blood-brain barrier in mice

Authors: *L. JONES[1], V. SINGH[1], D. DAVIDSON[2], S. MAGGIRWAR[1];
[1]MBI, Univ. of Rochester Med. Ctr., Rochester, NY; [2]Pathology and Physiol. Res. Br., Natl. Inst. for Occup. Safety and Hlth., Morgantwon, NY

Abstract: In spite of combined antiretroviral therapy (cART), the number of HIV-1 positive individuals developing some form of HIV-associated neurocognitive disorder (HAND) is increasing. Normally, the blood-brain barrier (BBB) serves to regulate transport into and out of the CNS, thus serving as a protective barrier; however, in HIV-1infected individuals, the integrity of the BBB is compromised due to an increase in the expression of proinflammatory mediators as well as viral proteins. Our lab, and others, has shown that sCD40L is released upon platelet activation and important mediator of the pathogenesis of HAND. However, the molecular mechanisms underlying this phenomenon are not fully understood. In order to recapitulate the factors observed in HIV-1 positive individuals, and thus identify the key mechanisms that drive the pathogenesis of HAND, an animal model is needed. Consistently, in our study we have utilized a novel animal model in which wild-type (WT) mice are infected with EcoHIV; a virus with the HIV-1 genomic gp120 attachment protein replaced with MuLV's gp80. We hypothesized that EcoHIV would replicate efficiently *in vivo* and would be able to induce

pathology similar to that observed in HIV-1-infected humans. Here we now demonstrate that upon infection with EcoHIV, platelets are activated, and as early as two-weeks post infection, BBB permeability is increased. In addition, tight junction proteins of the CNS are adversely affected. Here in, the results are evidence that platelet activation and sCD40L are still mediators of BBB disruption in a model of chronic inflammation. Therefore, this animal model will serve as a stepping-stone toward expanding research into the molecular mechanisms underlying HAND, and underscores the utility of this model to study further therapeutic treatments.

Title: Denoising of diffusion MRI boosts power to detect Hepatitis C effects on the brain in HIV+ adults

Authors: *D. SCHONFELD[1], T. M. NIR[1], N. JAHANSHAD[1], C. R. K. CHING[1], X. HUA[1], A. GONGVATANA[2], B. NAVIA[3,4], R. A. COHEN[5,6], P. M. THOMPSON[1];
[1]Imaging Genet. Center/Keck Sch. of Med. of, Los Angeles, CA; [2]UCSD, San Diego, CA; [3]Tufts Univ. Sch. of Med., Boston, MA; [4]Dept. of Publ. Heath and Community Med., Tufts Sch. of Med., Boston, MA; [5]Dept. of Aging-Geriatric Res., Univ. of Florida Col. of Med., Gainesville, FL; [6]Brown Univ. Sch. of Med., Providence, RI

Abstract: Hepatitis C may affect white matter integrity, especially in the context of co-morbid HIV infection. Here we used diffusion tensor imaging (DTI) to detect effects of Hepatitis C virus (HCV) on white matter (WM) integrity in an adult HIV+ population. We also tested whether effects were more sensitively detected after we incorporate a local PCA denoising approach (Manjon et al., 2013) into our image analysis workflow. 62 HIV+ patients (age: 45.25 +/- 10.38 yrs ; 41 M/21 F) were scanned with 3D volumetric T1-weighted anatomical and diffusion MRI (10 b0 and 64 DWI). 23 patients had co-morbid HCV infection. Both raw and denoised sets of the data were preprocessed in parallel. Fractional anisotropy (FA), mean diffusivity (MD), radial diffusivity (RD) and axial diffusivity (AD) maps were calculated from the diffusion tensor after correcting for eddy current and EPI distortions. Each subject's FA map was then elastically

registered to a study-specific minimal deformation template (MDT), based on FA, and the warps were then applied to all diffusivity maps. Voxel-wise linear regressions, adjusted for sex and age, tested for the effects of HCV co-infection on DTI measures of WM integrity. We corrected for multiple comparisons using the false discovery rate (FDR) procedure. Subjects co-infected with Hepatitis C had significantly higher MD than the HIV mono-infected group (FDR critical raw $p < 0.00075$; LPCA $p < 0.0014$) and RD (FDR critical raw $p < 0.00086$; LPCA $p < 0.0013$) - a sign of poorer WM integrity. The image denoising method detected twice as many significant voxels after FDR correction, as shown in the cumulative distribution function (CDF) plots of the voxelwise *p*-value maps and the higher critical FDR p values (see Figure). Denoising DWI images may boost power to detect subtle brain differences associated with co-infection of HCV and HIV.

Title: Effect of autophagy on L-type calcium channel current induced by gp120V3 loop in hippocampus neurons

Authors: *J. DONG[1], Y. XING[2], Q. YU[4], J. WANG[2], G. CHEN[2], M.-L. JIANG[2], L. LIN[2], S. LIU[2], Y. XU[3];
[1]Jinan Univ., Guangdong, China; [2]Dept. of Pathophysiology, [3]GHM Inst. of CNS Regeneration, Jinan Univ., Guangzhou, China; [4]Dept. of Microbiology and Immunol., Indiana Univ., Bloomington, IN

Abstract: This research aims to observe the influence of autophagy on L-type calcium channel current induced by gp120V3 loop in hippocampal neurons. Hippocampal neurons were exteriorized from rats born within one day and then cultured for seven days before they were used for experiments. Experiments were divided into two parallel groups, namely control group, gp120V3 loop group, autophagy inhibotor 3-MA group, gp120V3 loop plus 3-MA group; control group, gp120V3 loop group, autophagy activator Rapamycin group, gp120V3 loop plus Rapamycin group. Whole-cell patch clamp was used to record L-type calcium channel current. Compared with control group, L-type calcium channel current density significantly increased in gp120V3 loop group and 3-MA group ($P < 0.05$). Compared with gp120V3 loop group, L-type calcium channel current density significantly increased in gp120V3 loop + 3-MA group ($P <0.05$). Compared with control group, L-type calcium channel current density significantly decreased in Rapamycin group ($P <0.05$). Compared with gp120V3 group, L - type calcium channel current density significantly increased in gp120V3 + Rapamycin group ($P< 0.05$). Thus our electrophysiological data indicates that autophagy may be involved in the gp120V3 loop-mediated L-type calcium channels in hippocampus neurons.

Title: Cognitive impairment in HIV: Assessment using manual, saccadic, and traditional neuropsychological measures

Authors: *T. SHIRAZI[1], A. SUMMERS[1], S. STEINBACH[2], B. SMITH[2], S. KAPETANOVIC[1], A. NATH[2], M. ETTENHOFER[3], J. SNOW[1];
[1]NIMH, Bethesda, MD; [2]NINDS, Bethesda, MD; [3]Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD

Abstract: Whereas some studies estimate the rate of cognitive impairment in HIV to be as high as 60%, other studies suggest no differences in cognitive function between HIV+ and HIV- individuals. Conflicting results have emerged in studies using traditional neuropsychological (NP) measures, considered to be the 'gold standard' in the evaluation of cognition, as well as in studies using measures of manual reaction time (RT), which allow for detection of more subtle cognitive deficits. However, saccadic measures, which have been evaluated in the context of cognition in various neurodegenerative disorders, have not been recently studied in HIV. Unlike NP and manual RT measures, saccadic measures may be more resistant to confounds of testing such as poor effort, depression, or intelligence. We compared cognitive function in HIV+ participants (n=15) and demographically matched HIV- controls (n=11) using manual and saccadic measures of RT and inhibition, as well as traditional NP tests. All HIV+ participants were on antiretroviral therapy (ART) and had well-controlled viremia. Participants were on average 50.25 years old (SD=9.75) and had 14.00 years of education (SD=2.57). Participants were administered a NP battery assessing 7 cognitive domains purported to be impaired in HIV, as well as a computerized task measuring manual and saccadic RT and inhibition. In the task, a white or red cue appeared at the center of the screen, and was followed by a white circle appearing either below, above, to the left, or to the right of the cue. Participants were instructed to make a saccade to the circle as well as manually press a button if a white cue preceded presentation of the circle, and to inhibit saccadic and manual responses if a red cue preceded presentation of the circle (go no-go task) while eye movements were recorded using remote optics. Data were analyzed using Applied Science Laboratories software, a customized data parser, and SPSS. There were no significant differences between HIV+ and HIV- participants in any of the 15 NP variables or on composite NP measures. Similarly, there were no significant between-group differences in manual RT, manual response inhibition, saccadic RT, and saccadic response inhibition (all $p>0.05$). Effect sizes were small (Cohen's d <0.4), with the exception of that for manual inhibition (d=0.46) and verbal delayed recall (d= 0.56). Taken together, the preliminary results suggest the absence of large differences in cognition between HIV+ and HIV-

participants in our small sample. Ability to detect subtle deficits could be increased by examining more specific saccadic and manual metrics, or more sophisticated diagnostic classification algorithms.

Title: Wnt7a skews monocyte differentiation: relevance to neuroAIDS

Authors: *J. WALLACE[1], L. AL-HARTHI[2];
[2]Immunology/Microbiology, [1]Rush Univ. Med. Ctr., Chicago, IL

Abstract: Monocytes infiltrate the central nervous system for pathological and/or homeostatic purposes and differentiate into proinflammatory M-1, alternative M-2-like macrophages or a variation of intermediate phenotypes. The non-classical CD14+CD16+ monocytes have been observed to more readily traverse the blood brain barrier, and in HIV infection, an expansion of this phenotype correlates with worsened disease prognosis. Increased CD163 expression on brain macrophages/microglia is also associated with HIV encephalitic lesions. Published data from our lab illustrates that β-catenin; a protein primarily regulated by a family of morphogenetic glycoproteins known as Wnts, is a restrictive factor for productive HIV infection of monocytes. Canonical Wnt signaling stabilizes β-catenin, enabling its translocation to the nucleus, where it is a transcriptional co-activator. Non-canonical Wnts activate the Ca2+ and planar cell polarity (PCP) signaling pathways. Our objective is to evaluate the impact of Wnts on monocyte differentiation, phenotype and function as it relates to HIV neuropathogenesis. We show that human monocytes express all 19 Wnt mRNAs, and after 24 hours in culture, all but Wnts 2b, 9a, 10a, 10b and 16 are differentially expressed. This differential expression occurs in untreated monocytes as well as monocytes cultured in the presence of M-CSF or GM-CSF. Immunohistochemical staining for Wnts 1, 3 and 7a in C57BL/6 mouse brain slices revealed robust expression of Wnt 7a in the striatum and hippocampus. Additionally, culturing monocytes for 24 hrs with Wnts 1, 5a, or 7a recombinant proteins revealed that only Wnt 7a inhibited CD14+CD16- phenotype by 3-, 5- and 7- folds relative to untreated, M-CSF and GM-CSF treated groups respectively. After 7 days of Wnt 7a treatment, further inhibition of CD14+CD16-

(by 10- folds for both untreated and M-CSF treated and 25- folds relative to GM-CSF treated), CD14+CD16+ (3-, 5- and 12- folds for untreated, M-CSF treated and GM-CSF treated respectively), as well as CD163 expression (3-, 4-, and 7- folds for untreated, M-CSF and GM-CSF treated respectively) were measured. These Wnt 7A-mediated effects did not correlate with changes in active β- catenin expression. These data suggest that Wnt 7A induces monocyte differentiation, as indicated by down regulation of CD14. Ongoing studies are assessing the involvement of non-canonical Wnt pathways, as well as the phenotype and functionality of the MDMs from each experimental group. Ultimately, our studies will provide a better understanding of how Wnts within the CNS skew differentiation and function of infiltrating monocytes.

Center, Inst. for Neuroimaging & Informatics, Univ. of Southern California, Los Angeles, CA; [3]Dept. of Psychiatry, Univ. of California, San Diego, San Diego, CA; [4]Dept. of Publ. Health, Infection Unit, Tufts Univ. Sch. of Med., Boston, MA; [5]Dept. of Aging and Geriatric Research, Univ. of Florida, Gainesville, Gainesville, FL

Abstract: Up to 50% of HIV+ individuals experience neurocognitive impairment. Here we applied a novel subcortical shape analysis technique to better understand how impairment relates to brain structure in a large cohort of HIV+ adults. We hypothesized that shape analysis would detect subcortical morphometric differences associated with neurocognitive performance. T1-weighted brain MRI scans from 82 HIV+ patients were collected through the HIV-associated brain dysfunction study at Brown University (mean age: 45.6 +/- 9.9 yrs.; 54M/28F). Two shape metrics of local thickness and surface area were derived from structural MRI, radial distance

(thickness) and the Jacobian determinant (Jacobian) or surface dilation ratio to a template, across thousands of homologous points for the left and right nucleus accumbens, amygdala, caudate, hippocampus, putamen, pallidum, and thalamus shape models. A multiple linear regression was fit to predict thickness and Jacobian values at each surface point to evaluate associations with neurocognitive domain-specific T-scores where lower scores indicated greater impairment. Domains of interest included processing speed (PS), learning (LT), and motor function (MT). Analyses were adjusted for age, sex, ethnicity, intracranial volume, HIV duration, HIV RNA presence, history of Hepatitis C, antiretroviral treatment, history of drug use (alcohol, cocaine and opiates), and CD4+ T-lymphocyte count. All results were corrected for multiple comparisons using a standard FDR correction (q=0.05). Lower PS was significantly associated with lower Jacobian and thickness values in the left hippocampus/accumbens and right hippocampus/thalamus (Figure 1). Lower MT was associated with lower thickness values in the right pallidum. Lower LT was associated with lower Jacobian values in the left thalamus. High-resolution shape analysis revealed significant associations between reductions in subcortical volume/surface area and reduced processing speed, learning and motor function and may be a powerful new technique to track HIV+ related brain change.

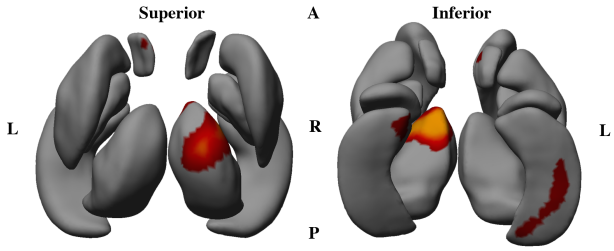

Figure 1: Associations between subcortical Jacobian values and processing speed (PS) showing β values for regions passing FDR correction (q=0.05). Red/Yellow regions indicate positive β values or regions where lower Jacobian values (reduced surface area and volume) are associated with lower PS scores (greater impairment). *Left Image: superior view; Right Image: inferior view; A: anterior; P: posterior; L: left; R: right*

Title: Adolescent cannabinoid exposure increases the susceptibility for a schizophrenia-like phenotype in a novel rodent model

Authors: *D. D. AGUILAR, S. M. PEREZ, A. GIUFFRIDA, D. J. LODGE;
Pharmacol., UTHSCSA, San Antonio, TX

Abstract: Schizophrenia is a debilitating disorder that affects over one percent of the population. Adolescent cannabis abuse is associated with an increased risk of developing schizophrenia. However, this is not a causal relationship. As many adolescents use cannabis in a recreational setting and do not develop psychiatric illnesses, it is likely that cannabinoids increase the risk of developing schizophrenia only in individuals with an underlying predisposition. To explore this phenomenon, we have developed a model of "susceptibility" to schizophrenia-like symptoms. Specifically, the second filial (F2) generation of a developmental rodent model of schizophrenia [i.e. gestational methylazoxymethanol acetate (MAM) administration in rats] show increased susceptibility to a schizophrenia-like phenotype. We believe that this "F2 MAM" model is unique in that it provides a model of susceptibility by which we can examine potential gene x environment interactions as they pertain to schizophrenia. Based on the relationship between cannabinoids and schizophrenia, we hypothesized that cannabinoid exposure during adolescence would increase the proportion of 'susceptible' F2 generation MAM rats displaying a schizophrenia-like phenotype while having no observable effects in control animals. Our preliminary data shows that exposure to a high dose of the synthetic cannabinoid WIN55,212-2 (1.2mg/kg) during adolescence increases a schizophrenia-like phenotype in F2 MAM and control rats. However, a lower dose of WIN55,212-2 (0.2mg/kg) during adolescence seems to affect the more 'susceptible' F2 MAM but not control rats. Although exogenous cannabinoids can transiently evoke psychotic symptoms in adult patients with schizophrenia, endogenous cannabinoid upregulation can alleviate positive and negative symptoms in these patients. Rodent models of schizophrenia also experience therapeutic effects following endogenous cannabinoid upregulation in adulthood. Therefore, we were interested in the differences between adolescent exposure to endogenous and exogenous cannabinoids in our susceptible model. Augmenting endogenous cannabinoids during adolescence increased the proportion of F2 MAM rats displaying a schizophrenia-like phenotype without producing noticeable effects in control rats. This supported our theory that the F2 MAM population may be more susceptible to certain environmental factors during adolescence than controls.

Abstract: Telomeres are tandem repeats located at the end of chromosomes, and they play a role in maintaining chromosomal integrity during cell division. It has been reported recently that leukocyte telomeres in patients with schizophrenia were shorter than those in healthy subjects. In addition, numerous studies have shown that telomere shortening can be induced by stress exposure in early life, which is a prominent risk factor for developing schizophrenia. However, the molecular link between telomere shortening and schizophrenic pathophysiology is still unclear. We detected the interesting connection among telomere shortening in the hippocampus, stress exposure and schizophrenia. We found that the therapeutic effects of second-generation antipsychotics might be mediated by hippocampal telomerase activation via the antagonism of serotonin 5-HT2A receptors, and telomere shortening in hippocampus might be related to the negative symptom-like behavior, cognitive impairment, and prepulse inhibition deficit, but not to

the positive symptom-like behavior in schizophrenia. They are novel findings of telomere alteration that connects a specific brain region, a molecular pathway, and the associated behavioral phenotypes using human samples and a mouse model. Our report suggests that drugs modulating telomeres might serve as novel medications for the treatment of schizophrenia.

Title: Determination of mitochondrial activity in a mice juvenile two-hit model of schizophrenia

Authors: *C. MONPAYS[1], J. DESLAURIERS[2], P. SARRET[2], S. GRIGNON[2,3];
[1]Physiol. and Biophysics, [2]Univ. De Sherbrooke, Sherbrooke, QC, Canada; [3]Psychiatry, Univ. de Sherbrooke, Sherbrooke, QC, Canada

Abstract: Schizophrenia is a chronic mental illness characterized by different clinical symptoms with three core features (positive (eg hallucinations), negative (eg lack of motivation) and cognitive (eg executive dysfunction). Among a large array of neurochemical disturbances, imbalance between production of reactive oxygen species and activity of antioxidant enzymes, convincingly points toward mitochondrial dysfunction. Our laboratory has recently developed a juvenile murine two-hit model (THM) of schizophrenia based on the combination of two environmental risk factors (gestational inflammation induced by poly IC, followed by juvenile restraint stress at postnatal days 33-35) to gain a better understanding of the early disease onset. We previously reported relevant behavioral and neurochemical disturbances, including oxidative stress (as assessed by an increase in protein carbonylation), thus providing preliminary validation of this THM of schizophrenia. Moreover, the antioxidant lipoic acid (LA) reversed these deficits, thereby pointing to a key role of oxidative stress in schizophrenia. Here, we investigated mitochondrial function in this juvenile murine THM of schizophrenia. The mitochondrial activity was determined using the Mitoxpress commercial kit within two relevant regions (prefrontal cortex (PFC) and striatum) associated with schizophrenia. Our measures were performed in state 3, with substrates for complex I (glutamate-malate + ADP) and complex II (succinate + ADP) induced mitochondrial respiratory activity. We observed an increase in complex I induced

respiratory activity in the PFC and striatum in both sexes but an increase in complex II activity only in males. LA treatment prevented this increase only in complex II induced respiration in males but had no effect on complex I induced activity. Expression levels of the different respiratory chain complexes were not modified under our conditions. In conclusion, our juvenile two-hit model of schizophrenia shows an increase in mitochondrial activity reversed by lipoic acid treatment, specifically in complex II induced respiratory activity in males, without changes in respiratory chain protein expression. Further work is required to investigate the origin and consequences of these modifications.

Title: Adolescent cannabinoid administration negatively impacts the dopaminergic system and cognition in normal rats, but provides a protective effect in MAM schizophrenia model

Authors: *F. V. GOMES[1], F. S. GUIMARAES[2], A. A. GRACE[1];
[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Med. Sch. of Ribeirao Preto - Univ. of Sao Paulo, Ribeirao Preto, Brazil

Abstract: Adolescent exposure to cannabinoids is proposed to be a risk factor for psychiatric conditions, particularly schizophrenia. Animal studies have indicated that a combination of repeated cannabinoid administration during adolescence with either neonatal prefrontocortical lesion, isolation rearing, or chronic NMDA receptor antagonism administration induces enhanced schizophrenia-like signs. The effects of adolescent exposure to CB1 receptor agonists, however, have not been tested in a developmental disruption model of schizophrenia. This was tested in the methylazoxymethanol (MAM) model, in which repeated treatment with the synthetic cannabinoid agonist WIN 55,212-2 (WIN; 1.2mg/kg) was extended over 25 days throughout puberty (postnatal days 40-65) in control and MAM rats. The rats received 20 injections, which were delivered irregularly to mimic the human condition. Adult rats were

tested for attentional set-shifting task and locomotor response to amphetamine, which was compared with *in vivo* recording from ventral tegmental area (VTA) dopamine (DA) neurons. As expected, MAM-treated rats showed impairment in the attentional set-shifting task, augmented locomotor response to amphetamine, and an increased number of spontaneously active DA neurons in the VTA. Adolescent WIN treatment in normal animals induced similar changes at adulthood as those observed in MAM-treated rats, supporting the notion that adolescence exposure to cannabinoids may represent a risk factor for developing schizophrenia-like signs at adulthood. However, contrary to our expectations, pubertal WIN administration did not exacerbate the changes in MAM-treated rats beyond that observed in WIN-treated normal rats. Indeed, WIN treatment actually attenuated the locomotor response to amphetamine in MAM rats without impacting DA neuron activity states. Altogether, our results indicate that the impact of cannabinoids during adolescence on schizophrenia models is more complex than may be predicted.

Title: Developmental antioxidant treatment in the neonatal ventral hippocampal lesion model of schizophrenia: effects on executive function and control

Authors: D. ACS, B. BENANZEA-FONTEM, D. LAFFERTY, *A. H. BRADY;
Psychology and Neurosci., St. Mary's Col. of Maryland, St Marys City, MD

Abstract: Animals with a neonatal ventral hippocampal lesion (NVHL), a developmental model of schizophrenia, exhibit impairments in executive function and control, including deficits in set-shifting and enhanced drug-seeking behavior. Attempts to reverse or prevent cognitive impairments in animal models have been largely unsuccessful, paralleling the low efficacy of antipsychotic treatments in alleviating cognitive symptoms in the clinic. Recent evidence supporting a role of oxidative stress in both schizophrenia and in the NVHL model led us to investigate the effects of developmental administration of the anti-oxidant N-acetylcysteine (NAC) on the adult emergence of behavioral impairments in the NVHL model. We examined two aspects of executive function and behavioral flexibility: set-shifting, previously demonstrated to be impaired in NVHL animals, and habit learning, not previously characterized

in the NVHL model. Regarding the latter, we hypothesized that NVHL rats would show a bias toward habit-based over goal-directed behavior, which may contribute to their enhanced motivation to self-administer drugs of abuse. Male Sprague-Dawley rats received bilateral hippocampal infusions of ibotenic acid (NVHL group) or artificial CSF (sham group) on postnatal day 7 (P7). Two groups of rats were given NAC treatment in the drinking water (900 mg/l) from P5 through P50 (juvenile administration). Another two groups were given the same NAC treatment from P35 to P50 (adolescent administration). At adulthood, all animals were trained to lever press, and then given an outcome devaluation procedure to assess sensitivity to changes in reinforcer value. A failure to decrease responding to the devalued reinforcer was characterized as a bias toward habit-based responding. Preliminary results suggest the presence of a modest bias toward habit-based responding in NVHL animals that was lessened by NAC administration. Animals were then trained on an operant set-shifting task where they were required to learn a position-based rule on the first day of testing (Set), and then shift to a visual cue-based rule on the second day of testing (Shift). As previously observed in this task, NVHL rats were unimpaired on learning the first rule (Set), but required more trials to reach criterion and made more errors than shams on the second rule (Shift). This set-shifting deficit was prevented by juvenile, but not adolescent, NAC administration. Together, these results replicate and extend the characterization of executive function impairments in the NVHL model, and suggest that antioxidant treatment is a promising direction in the treatment of cognitive symptoms of schizophrenia.

Title: Inhibition of luteinizing hormone rescues recognition memory and raises hippocampal GAD67 in an animal model of schizophrenia

Authors: *C. E. LYONS, A. W. SCHALER, A. J. RIORDAN, J. FRIED, T. A. PAINE, J. E. THORNTON;
Dept. of Neurosci., Oberlin Col., Oberlin, OH

Abstract: Schizophrenia is a psychiatric disorder characterized by debilitating and presently untreatable cognitive deficits. Some studies suggest that lowered levels of GAD67, the rate-limiting enzyme for GABA production, and reduced numbers of parvalbumin-expressing (PV+) GABA neurons in the cortex and hippocampus may underlie this cognitive loss. Concurrent research suggests that estradiol may help to alleviate cognitive symptoms in people with schizophrenia. Our lab recently showed that estradiol treatment reverses memory deficits in an animal model of schizophrenia. As one of estradiol's effects is reduction of luteinizing hormone (LH), we sought to determine whether inhibition of LH would also rescue cognition in this schizophrenia model. Furthermore we tested the hypothesis that estradiol and inhibition of LH act to restore memory by increasing PV+ neurons and/or GAD67 levels in the prelimbic cortex and/or hippocampus. Adult female rats were ovariectomized and implanted with either a blank or estradiol-filled silastic capsule. To induce schizophrenia-like symptoms, animals were injected with either PCP (phencyclidine, 2 mg/ml/kg) or vehicle bidaily for 7 days. Following a 7-day washout period, the LH-inhibiting drug Antide (a gonadotropin releasing hormone antagonist) or vehicle was administered 6 hours prior to cognitive testing on the Novel Object Recognition Task. For both the prelimbic cortex and the hippocampus, the numbers of parvalbumin immunopositive (PV+) cells were determined using immunohistochemistry and GAD 67 levels were measured via Western blots. As previously seen, estradiol reversed object recognition deficits induced by PCP. Furthermore, Antide also rescued memory deficits and increased GAD67 levels in the dorsal hippocampus of PCP-treated animals. PCP did not significantly alter the number of PV+ cells in either the prelimbic cortex or hippocampus (CA1, CA3, or dentate gyrus). These results suggest that inhibition of luteinizing hormone rescues cognition by restoring GAD67 in a PCP-model of schizophrenia. Hence, lowered levels of hippocampal GAD67 may be responsible for memory deficits in schizophrenia, and hormonal manipulations may offer promising treatments for the devastating cognitive symptoms of this disorder.

Title: GABAergic promoter remodeling in an immune-mediated neurodevelopmental mouse model with relevance to schizophrenia

Authors: *M. A. LABOUESSE[1], E. DONG[2], W. LANGHANS[1], D. GRAYSON[2], A. GUIDOTTI[2], U. MEYER[1,3];
[1]ETH Zurich, Schwerzenbach, Switzerland; [2]The Psychiatric Inst., Univ. of Illinois at Chicago, Chicago, IL; [3]Univ. of Zurich-Vetsuisse, Zurich, Switzerland

Abstract: Accumulating evidence has identified epigenetic abnormalities in post-mortem brains of schizophrenic patients, including aberrant levels of methylating/demethylating enzymes and enhanced promoter methylation of disease-relevant genes such as glutamic acid decarboxylase 1 (GAD1), the rate-limiting enzyme for gamma-aminobutyrate (GABA) biosynthesis. These findings have led to the hypothesis that schizophrenia pathology may (at least partly) emerge from a dysregulation of epigenetic networks. However, the precise environmental and genetic factors triggering such epigenetic modifications remain largely elusive. Maternal infection is a recognized environmental risk factor for neurodevelopmental psychiatric diseases such as schizophrenia. Experimental rodent models support this idea by demonstrating disease-relevant long-term behavioral abnormalities following maternal immune activation that associate with reductions in cortical GAD1 and GAD2 levels. In the present study, we thus aimed at identifying the presence of aberrant epigenetic marks at GAD1 and GAD2 promoter regions and their potential association with cognitive deficits in offspring born to immune-challenged mothers. We used a well-established mouse model of maternal exposure to the viral mimic polyriboinosinic-polyribocytidilic acid (PolyI:C). Methylated-and hydroxymethylated DNA immunoprecipitation techniques revealed enhanced methylation and hydroxymethylation levels at GAD1 and GAD2 promoters in offspring born to PolyI:C-treated mothers. These effects were specific to the promoter region and associated with a concomitant reduction in GAD1 and GAD2 mRNA levels. Hypermethylation of GAD1 and GAD2 promoters was accompanied by enhanced chromatin binding of methyl CpG binding protein 2 (Mecp2). Further behavioral analyses revealed marked deficits in social interaction and spatial working memory in PolyI:C offspring. Interestingly GAD1 (but not GAD2) promoter methylation and hydroxymethylation levels negatively correlated with spatial working memory performance and social interaction scores, supporting a functional role for these epigenetic modifications in the emergence of behavioral deficits induced by maternal immune activation. Though the origins of GABAergic abnormalities in schizophrenia are likely multifactorial, the present findings delineate one putative mechanism by which maternal infection, a risk factor for the disease, may affect the integrity of GABAergic systems in affected patients. These chromatin-remodeling events may in turn possibly contribute to the emergence of behavioral symptoms that characterize schizophrenia.

Title: Interactions between testosterone and brain-derived neurotrophic factor on brain development - with relevance to schizophrenia

Authors: *X. DU[1], M. VAN DEN BUUSE[2], R. A. HILL[1];
[1]The Florey Inst. of Neurosci. and Mental He, Melbourne University, Australia; [2]Sch. of Psychological Sci., La Trobe Univ., Melbourne, Australia

Abstract: Reduced expression of the key neurotrophin brain-derived neurotrophic factor (BDNF) is a common biological feature in schizophrenia patients. Restoration of its levels is a target of therapeutics. Our group has previously shown in mice that forebrain BDNF levels correlate with pubertal elevations in testosterone (TT), suggesting TT is able to drive BDNF expression during adolescence. Men are more likely to develop schizophrenia than women and male patients suffer worse outcomes. Hence, the relationship between TT and BDNF during adolescence, the period of dynamic brain system alterations and the phase leading up to the window of peak onset for schizophrenia, becomes immensely important with regards to explaining sex differences and disease mechanisms of schizophrenia. Utilising both wild-type (WT) and BDNF heterozygous (het) mice, we found that reduced BDNF alters the way forebrain GABAergic interneurons develop throughout adolescence, suggesting interplay between TT and BDNF. We further examined the effect of pre-pubertal hormone manipulation on drug-models of schizophrenia. Prepubescent mice were gonadectomised and implanted with placebo, TT or dihydrotestosterone (DHT). Upon adulthood, amphetamine and MK801 induced hyperactivity and pre-pulse inhibition (PPI) were tested to examine the regulation on the dopamine and NMDA systems respectively. Our data show an intricate interaction between TT and BDNF, with TT but not DHT able to mediate MK801 and amphetamine-induced hyperactivity in WT mice, signifying the importance of the conversion of TT to estrogen in mediating this effect. In het mice however, while TT was able to suppress amphetamine-induced hyperactivity, only DHT was able to suppress MK801-induced hyperactivity. This indicates altered reliance in the het mice towards androgen receptor signalling in mediating NMDA pathways. In the WT mice, TT but not DHT was able to increase PPI after amphetamine, again signifying conversion to estrogen to be involved. Het mice show an overall enhanced startle response but no changes in

PPI in response to hormone manipulations. Further work is being carried out using cell targeted viral gene knockdown to deactivate BDNF and sex hormone signalling in specific areas of the brain during prepubescence to allow more targeted and higher resolution analyses of the effects of the interaction between sex hormone and BDNF. The multifaceted relationships between sex hormone signalling and BDNF may provide novel and effective targets for pharmacological treatments. Our results highlight the possibility of using various agents to increase BDNF and/or sex hormone signalling to mitigate symptoms of schizophrenia.

Title: Accelerated GSK3β activity promotes spine elimination by facilitating LTD in developing prefrontal cortex in a schizophrenia model

Authors: *B. XING, W.-J. GAO;
Neurobio. & Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Schizophrenia is a neurodevelopmental disorder with its peak onset during adolescence. Although the pathophysiology of schizophrenia remains largely unknown, synaptic dysfunction, especially dendritic spine loss in the prefrontal cortex (PFC), appears to be a consistent hallmark trait associated with this disorder. A fundamental question that haunts the field is when and how this spine loss happens during early development in schizophrenia. Here we address this question using a neurodevelopmental model of gestational exposure to a neurotoxin methylazoxymethanol (MAM). We found that MAM exposure induced a significant decrease in inhibitory serine 9 phosphorylation of GSK3β during the juvenile period of development, indicating an age-dependent increase in GSK3β activity. This transient, accelerated GSK3β activity dramatically facilitated long-term depression (LTD) by decreasing its threshold of induction in juvenile PFC neurons, which can be efficiently blocked by GSK3β inhibitors. The facilitated induction of LTD in MAM-exposed rat PFC only exists within a brief window of juvenile development, but it obviously prolongs the critical period for synaptic elimination. Indeed, MAM exposure resulted in a significant decrease in spine number in apical, but not

basal, dendrites of both layer II/III and layer V pyramidal neurons; and more importantly, treatment with a GSK3β inhibitor in juvenile development effectively rescued dendritic spine deficits in adult rats. These results highlight the importance of the developmental trajectory of GSK3β for synaptic plasticity and spine maturation during a critical period of PFC development, suggesting that alterations in synaptic plasticity related to GSK3β dysregulation in juveniles may contribute to the spine loss this is a classical feature of the pathological processes of schizophrenia. *Supported by NIH R01MH085666 to W.J. Title: A methionine induced prenatal animal model of schizophrenia

Authors: *L. WANG, A. ALACHKAR, S. LEE, Z. WANG, G. ABBOTT, O. CIVELLI; Pharmacol., Univ. of California, Irvine, Irvine, CA

Abstract: Methionine directs methylation which is central to epigenesis and is recognized as an important factor in the etiology of schizophrenia. Methionine administration to patients with schizophrenia has been reported to exacerbate the psychotic symptoms. Further, our previous study showed that repeatedly administration of L-methionine to adult mice led to behavioral changes that reflect the three types of schizophrenia-like symptoms. Here we established a developmental mouse model of schizophrenia. Pregnant mice were repeatedly administered L-methionine during the third trimester. We report that the male offspring of the female treated with L-methionine exhibited behavioral changes that reflect the three types of schizophrenia-like symptoms since adolescent hood until adulthood (positive, negative or cognitive deficits). We also show that the schizophrenia-like responses induced by the methionine treatment are reversed differentially by haloperidol and clozapine. Moreover, we show that these male offspring exhibited changes in brain size, neuronal development and genes associated with schizophrenia.

Our model relies on an essential natural amino acid and on an environmental and developmental intervention and may offer an additional tool for assessing novel antipsychotics.

Title: Role of Prenatal methionine load in Schizophrenia

Authors: ***A. ALACHKAR**, L. WANG, S. LEE, Z. WANG, G. ABBOTT, O. CIVELLI; Pharmacol., Univ. of California Irvine, Irvine, CA

Abstract: Exposure to environmental factors during gestation results in changes in the fetal epigenome. DNA methylation is a critical epigenetic factor that modifies expression of genes involved in vital neural functions such as neurogenesis and differentiation. Maternal methyl-donor diet at the conception influences the DNA methylation and leads to permanent changes in the offspring gene. Abnormal DNA methylation has been implicated in schizophrenia. Here we test the effect of methionine overload during the third trimester of gestation on the neurodevelopment and behavioral responses of the male offspring in mice. Pregnant mice were repeatedly administered L-methionine for the last 7 days of pregnancy. Adults offspring were tested in a battery of behavioral assays. Microarray of mRNA was performed to determine changes in gene expression. Our data show that prenatal methionine administration in the period E14-E20 of the gestation produced permanent changes in the adult pups genes that are involved in neurodevelopment including Npas4, ARC, Fos, and FGF1. These changes were accompanied with the changes in the behavioral phenotype that mimic schizophrenia symptoms including positive, negative symptoms and cognitive deficits.

Title: Altered context processing in the MAM rat model of schizophrenia: relationship to dopamine dysfunction

Authors: *K. M. GILL, A. GRACE;
Dept. of Neurosci., Univ. Pittsburgh, Pittsburgh, PA

Abstract: The appropriate acquisition of context information is vital for the disambiguation of neutral and aversive contexts, a process known to be impaired in schizophrenia (SZ) patients. In normal rats, repeated pre-exposure to the same context results in a transition from facilitation to a suppression of context-induced fear responses. This pattern of progressive alterations in the response to context information relies on intact amygdala and hippocampal activity. There is evidence for altered activity within amygdala and ventral hippocampus in SZ, which could underlie impaired context processing. In the present study, we examined contextual fear learning in the methylazoxymethanol acetate (MAM) developmental model of SZ in the rodent. Specifically, we tested the time course of context pre-exposure effects on fear learning in MAM animals in the immediate shock fear learning paradigm. Given the known dopamine (DA) system pathology in MAM animals, amphetamine-induced locomotion was used as a means of assessing DA system activation and its relationship to prior contextual fear learning. Saline and MAM-treated offspring were trained in a modified context pre-exposure fear conditioning paradigm involving varying amounts of context pre-exposure (0,1,3,5,7, and 10 days). The last day of context pre-exposure took place 24 hours prior to conditioning. For conditioning, all rats received a 0.4-mA, 2-sec shock 120-sec after being placed in the conditioning context. 24-hr after conditioning, animals were placed in the same context, and freezing scored for 5-min. At least one week following fear conditioning, locomotor activity was assessed following an acute injection of amphetamine (0.5 mg/kg, i.p.). Saline rats demonstrated the expected increase in freezing behavior following a single pre-exposure session. In contrast, MAM animals exhibited reduced fear responses compared to normal rats. In addition, MAM animals failed to show the

expected context-induced facilitation of fear responses. Surprisingly, MAM rats demonstrated a blunted amphetamine-induced locomotor response compared to saline animals following fear exposure. In addition, the enhanced locomotor response in saline animals was context-dependent and greatest at fewer pre-exposure sessions. MAM rats were unable to engage consolidated contextual information even with extensive context pre-exposure occurring prior to fear conditioning. In addition, fear learning produced a persistent reduction in DA system activation in MAM rats. These data provides insight into the behavioral pathology regarding how disruption of hippocampal-dopamine interactions in SZ may impact context processing.

Title: Heightened amygdala theta response oscillation in rats with MAM model of schizophrenia

Authors: *Y. DU[1], A. A. GRACE[2];
[1]Dept. of Neurosci., [2]Neuroscience, Psychiatry and Psychology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Previous studies from our group have shown that rats exposed during gestational day 17 to the mitotoxin methyl azoxymethanol acetate (MAM) exhibit behavioral, pharmacological, and anatomical characteristics consistent with an animal model of schizophrenia. Recently, we have observed abnormal stress response, and also a higher level of anxiety in both adolescent and adult MAM-treat rats, which is consistent with altered responses to stress and emotional stimuli in schizophrenia patients. Moreover, heightened stress sensitivity and level of anxiety are observed in children and adolescents at a risk of developing schizophrenia later in their life. Studies have observed abnormal activity of the amygdala in schizophrenia patients, particularly during tasks with emotional stimuli. The amygdala sends extensive projections to the PFC and hippocampus; regions commonly reported to be altered in postmortem and structural imaging studies of schizophrenia. In addition, pharmacological activation of the amygdala can mimic the alterations observed in the schizophrenia brain, such as loss of parvalbumin interneurons in the hippocampus. The amygdala is a central brain region in stress response and emotional regulation.

Thus abnormal activity of the amygdala could contribute to stress hypersensitivity in MAM-treated rats. In this study, stainless steel wire electrodes were implanted into the basolateral amygdala (BLA)/ lateral amygdala (LA). After one week recovery, rats were trained on a standard fear conditioning paradigm in which a 2-s tone presentation was paired with a mild footshock (0.45mA) for 10 times, with a pseudorandom inter-trial interval (45-100 s). Rats were returned to a different chamber 24 hr later, and local field potentials (LFPs) were recorded. Tone-evoked change in LFP power was calculated by normalizing LFP power in the 10-s period after tone presentation to that in the 10-s period before tone presentation. Preliminary results showed an increase after tone presentation in theta band (4-8 Hz) in both Sal and MAM rats. The overall increase in the theta band response was not significantly different when comparing Sal and MAM rats (MAM rats showed a trend of larger increase, $p=0.1$). However, the MAM rats showed a marked peak of increase in oscillatory activity around 5.5 Hz that was significantly larger ($p<0.01$, t-test) (160%+/-30%, n=3) than that in Sal rats (80%+/-20%, n=5). This highly synchronized activity in the amygdala of MAM rats may be related to the hypersensitivity to stress in these rats.

Title: Adolescent cannabinoid exposure leads to molecular and neuronal alterations in the mesocorticolimbic system and behavioural impairments resembling schizophrenia symptomology

Authors: *J. RENARD, M. LOUREIRO, L. G. ROSEN, W. J. RUSHLOW, S. R. LAVIOLETTE;
Anat. and Cell Biol., Western Ontario Univ., London, ON, Canada

Abstract: Marijuana (MJ) is the most widely used illicit drug among adolescents. Considerable clinical evidence now supports the hypothesis that adolescent exposure to high levels of delta-9-

tetrahydrocanabinol (THC), the principal psychoactive component in MJ, increases the risk of developing neuropsychiatric symptoms in early adulthood, characterized by emotional dysregulation and affective disturbances. This MJ-associated risk is believed to be related to increasing relative levels of THC found within commonly used cannabis strains. Importantly, cannabinoids strongly interact with the mesocorticolimbic dopamine (DA) pathway, a neural system that is believed to underlie the neuropsychopathological effects of schizophrenia. Given the exponential rise in cannabis use for both recreational and therapeutic purposes, an important question concerns the differential risk profile between adolescent, vs. adulthood THC exposure. In the present study, we used an integrative combination of molecular analyses, behavioural studies and *in vivo* neuronal electrophysiology to compare the effects of adolescent vs. adulthood exposure to THC in rats. Our results reveal important distinctions between the effects of adolescent vs. adulthood THC exposure on various schizophrenia-related behavioural, molecular and neuronal phenotypes: 1) Adolescent, but not adult exposure, causes profound psychotomimetic symptoms including social cognition, motivational, sensorimotor gating and depressive-like behavioural disturbances, 2) Adolescent, but not adult exposure to THC profoundly decreases prefrontal cortical (PFC) phosphorylated protein levels of GSK-3 alpha and beta isoforms, mTOR and p70S6 kinase, similar to findings observed in post-mortem PFC analyses from schizophrenia and mood disordered patients, 3) Adolescent, but not adult exposure, leads to a profound state of hyper-dopaminergia, evidenced by increased levels of spontaneous firing frequency and bursting rates in DA neurons of the ventral tegmental area (VTA), an effect that is mechanistically consistent with our observed molecular alterations showing decreased PFC expression of phosphorylated GSK-3. Our findings represent the first demonstration that adolescent THC exposure may simultaneously lead to neuronal, behavioural and molecular phenotypes closely resembling those observed in schizophrenia. In addition, our findings have profoundly important implications for public health policy development related to regulating adolescent vs. adulthood exposure to high-THC strains of cannabis.

Title: Downregulation of parvalbumin in the prefrontal cortex during adolescence causes enduring disruptions of prefrontal processing of ventral hippocampal inputs

Authors: *A. CABALLERO, D. R. THOMASES, E. FLORES-BARRERA, K. Y. TSENG; Cell. and Mol. Pharmacol., Rosalind Franklin Univ., North Chicago, IL

Abstract: One consistent observation during the development of cortical structures is the activity-dependent upregulation of the calcium binding protein parvalbumin (PV) in local GABAergic interneurons. In the prefrontal cortex (PFC) of mammals, this finding is recapitulated during postnatal development with a significant increase in PV expression during adolescence which reaches relatively stable levels once in adulthood. Given the role of PV in the regulation of neurotransmitter release, we asked whether the increase in PV during adolescence was necessary to sustain PFC GABAergic function. For this purpose, we utilized an RNAi strategy to directly downregulate prefrontal PV levels during adolescence and tested GABAergic function during adulthood. Our results indicate that a decrease in PV expression (~30%) in the PFC was sufficient to decrease the frequency of IPSC onto pyramidal neurons to levels seen in juvenile/early adolescent animals. Moreover, these animals failed to properly process afferent information in the PFC, as measured by a suppression of the normal inhibitory LFP resulting from ventral hippocampal stimulation at 20 and 40 Hz. These electrophysiological findings were mirrored by an impaired extinction response in a trace fear conditioning assay, a behavioral paradigm that requires intact PFC-ventral hippocampus connectivity. We therefore conclude that the developmental upregulation of PV in the PFC is required for proper GABAergic transmission and local inhibitory control of afferent drive, and any insults that prevent it will lead to a disinhibited PFC. Importantly, these results suggest there is a critical window of plasticity during which PV upregulation supports the acquisition of mature GABAergic phenotype necessary to sustain adult PFC functions.

Title: Aspirin treatment prevents behavioral deficits in a maternal immune activation model in mice

Authors: *A. KHAN[1], J. LUCERO[2], M. BEHRENS[2], M. A. GEYER[1,3], S. B. POWELL[1,3]; [1]Dept. of Psychiatry, Univ. of California San Diego, LA Jolla, CA; [2]Salk Inst. for Biol. Studies, La Jolla, CA; [3]Res. Service, VA San Diego Healthcare Syst., San Diego, CA

Abstract: Activated inflammatory responses in brain and periphery have been implicated in a variety of neuropsychiatric and neurodevelopmental disorders, including schizophrenia and autism. These inflammatory responses are likely triggered by various genetic and environmental factors. For example, epidemiological studies indicate that the risk of developing schizophrenia and autism is increased by prenatal exposure to bacterial or viral infection during pregnancy. There is also evidence for an ongoing neuroinflammation in schizophrenia patients, including elevations in pro-inflammatory cytokines (e.g. IL-6, IL-12, IL-1β, TNF-α, interferon-γ) and activated microglia. Thus, because there is evidence that neuroinflammation occurs in acutely ill first-episode patients, anti-inflammatory drugs may be an effective treatment. Microglia are the first line of defense in brain and have recently become the focus of possible therapeutic targets in schizophrenia. Here we investigated the effects of the non-steroidal anti-inflammatory drug (NSAID), acetylsalicylic acid (aspirin), in the maternal immune activation (MIA) model in mice. We hypothesize that administration of aspirin will prevent the behavioral deficits by possibly blocking the microglial activation in brain. To produce MIA polyriboinosinic-polyribocytidilic acid (Poly I:C) was injected to pregnant C57BL/6J dams at two gestational time points (3 mg/kg on day 12.5 and 1.5 mg/kg on 17.5) according to our previously published methods. Pups born to poly I:C- or vehicle-exposed dams (control group) were assigned to either water or aspirin treatment groups. Aspirin was administered in water (480μg/mouse/day) from postnatal day 30-72. Mice were subsequently tested for schizophrenia-like behavioral phenotypes and brains were taken for assessment of microglia. MIA mice showed deficits in spatial working memory as measured in the t-maze spontaneous alternation task. Aspirin administration prevented the spatial working memory deficit in MIA mice [Prenatal exposure x postnatal treatment interaction, $[F(1,31)=5.96, p<0.05]$. We are currently examining the number and shape of microglia in frontal cortex and hippocampus. Our findings will help determine whether anti-inflammatory drugs may target microglia activation and show promise as a treatment for disorders that involve ongoing inflammation such as schizophrenia and autism.

Title: Prenatal dynamics of kynurenine pathway metabolism in rodents

Authors: *N. GOEDEN[1], A. POCIVAVSEK[2], F. M. NOTARANGELO[2], S. BEGGIATO[2], A. BONNIN[3], R. SCHWARCZ[2];
[1]USC, Los Angeles, CA; [2]Univ. of Maryland Sch. of Med., Baltimore, MD; [3]Cell and Neurobio., Keck Sch. of Med. of the Univ. of Southern California, Los Angeles, CA

Abstract: Malfunction of the kynurenine pathway (KP) of tryptophan degradation has been linked to the pathophysiology of schizophrenia (SZ). Specifically, elevated levels of the KP metabolite kynurenic acid (KYNA), which are found in postmortem brain and cerebrospinal fluid of individuals with SZ, may be causally related to cognitive deficits seen in the disorder. Moreover, in line with the neurodevelopmental hypothesis of SZ etiology, experimental increases of KYNA in the fetal brain cause delayed up-regulation of brain KYNA and cognitive impairments in adulthood (Pocivavsek et al. 2014). To provide insights into the prenatal dynamics of KP metabolism in this context, we now used L-kynurenine ("kynurenine"), the immediate bioprecursor of KYNA, as an experimental tool. Using *ex vivo* technology (Goeden et al. 2012), we perfused increasing concentrations of kynurenine (0.5 to 100 μM) for a total of 100 min through intact placentas harvested from pregnant mice on embryonic day (ED) 18, and determined kynurenine and KYNA levels in 20-min perfusate fractions obtained from the umbilical vein. This experiment revealed a significant transplacental transfer of kynurenine, and suggests that, if any, only a small fraction of maternal kynurenine is converted to KYNA in the placenta under physiological conditions. Interestingly, transplacental transfer rates decreased when 100 μM kynurenine was used, indicating that maternal-fetal transport of kynurenine is limited and saturable, and therefore likely involves a specific transporter. To further study the impact of elevated maternal kynurenine on fetal KP metabolites, we then used an *in vivo* approach and injected pregnant rats with kynurenine (100 mg/kg, i.p.) on ED18. Animals were sacrificed, and tissues were collected 90 min later. Analysis of KP metabolites revealed significant increases in kynurenine, KYNA and 3-hydroxykynurenine (3-HK) levels in both the maternal and the fetal brain. Taken together, these *ex vivo* and *in vivo* approaches begin to define maternal and placental roles in determining the characteristics of the KP in the fetal brain.

Title: A test of the aversive versus the rewarding effects of nicotine in rats neonatally treated with quinpirole: Analysis of brain plasticity mechanisms

Authors: S. L. KIRBY[1], E. D. CUMMINS[1], D. J. PETERSON[1], A. R. DENTON[1], *J. M. DOSE[2], R. W. BROWN[1];
[1]Psychology, East TN State Univ., Johnson City, TN; [2]Psychology, St. Norbert Col., De Pere, WI

Abstract: Neonatal quinpirole (a dopamine D2-like receptor agonist) treatment to rats has been shown to increase dopamine D2 receptor sensitivity throughout the animal's lifetime, and increased dopamine D2 sensitivity is a hallmark of schizophrenia. Schizophrenics are three to four times more likely to smoke than the normal population, but there is no delineating mechanism. The objective of this study was to behaviorally test a rewarding versus aversive dose of nicotine in adolescent rats neonatally treated with quinpirole tested in a conditioned place preference (CPP) paradigm. Brain tissue was analyzed for several proteins known to be important in brain plasticity. Rats were neonatally treated with quinpirole from postnatal days (P)1-21 and raised to P40 without any further drug treatment. After two drug free preference tests were administered in a three-chambered place preference shuttle box at P41-42, animals were conditioned with saline, a 0.6 or a 1.8 mg/kg free base dose of nicotine for eight consecutive days from P43-50. A drug free post-conditioning test was given 24 h after conditioning on P51. Time spent in the paired and unpaired context were measured on the post-conditioning test which was subtracted from time spent in the same contexts on the pre-conditioning test and used as the behavioral dependent measure. Results revealed that neonatal quinpirole enhanced the rewarding associative effects of the lower dose of nicotine (0.6 mg/kg free base) compared to animals neonatally treated with saline and conditioned with the same dose of nicotine, which showed a slight place preference compared to saline controls. Interestingly, although neonatal saline animals conditioned with the higher dose of nicotine

demonstrated conditioned place aversion, neonatal quinpirole treated animals demonstrated no aversion to this same dose. Therefore, rats neonatally treated with quinpirole demonstrate an enhancement to the rewarding properties of nicotine, but do not demonstrate an aversion to higher doses of nicotine. Brain tissue was removed on P52 and is currently being analyzed for the phosphorylated protein mammalian target of rapamycin (mTOR), ribosomal protein S6, and cyclic AMP response element binding protein (pCREB). All of these proteins have been implicated in the regulation of synaptic growth and synaptic strength. The behavioral data are congruent with recent self-administration data in our lab, and suggest that increases of dopamine D2 sensitivity may blunt aversive aspects of nicotine.

Title: Maternal, placental and fetal KYNA production in mouse tissue slices

Authors: *S. BEGGIATO, F. M. NOTARANGELO, R. SCHWARCZ;
Psychiatry, Maryland Psychiatric Research, Univ. of Maryl, Baltimore, MD

Abstract: Studies in animals and humans suggest a pathophysiologically significant association between elevated brain kynurenic acid (KYNA) levels on one hand and major brain diseases such as schizophrenia on the other (Nat. Rev. Neurosci., 13: 465-477, 2012). Prenatal exposure to kynurenine, the direct bioprecursor of KYNA, induces cognitive impairments reminiscent of SZ in adult rats (Neuropharmacology, 90: 33-41, 2015), suggesting a developmental dimension of the link between KYNA and SZ. Pharmacological agents that mitigate the elevations in brain KYNA levels, for example inhibitors of KYNA's biosynthetic enzyme kynurenine aminotransferase II (KAT II; Schiz. Bull., 40: S152-S158, 2014), might be useful to attenuate or reverse the detrimental effects and possibly guide the development of fundamentally new clinical interventions. In this context, the present *in vitro* study was designed to evaluate the ability of various tissues, obtained from pregnant FVB/N mice on embryonic day 18, to synthesize KYNA from its immediate bioprecursor L-kynurenine (L-KYN). Specifically, we used freshly prepared

tissue slices from maternal brain, placenta and fetal brain, to investigate de novo KYNA synthesis under physiological conditions (incubation in Ringer buffer) or using L-KYN (10 μM) to drive KYNA formation. Tissues were incubated for 1 hour at 37º C, and KYNA levels were determined in the incubation medium. Basal KYNA levels measured after incubation of fetal brain and placenta slices were 4-5 times higher than after incubation of maternal brain slices. Incubation with L-KYN significantly increased KYNA levels in all tissues. Incubation in the presence of aminooxyacetic acid (1 mM), a non-specific KAT inhibitor, completely prevented L-KYN-induced KYNA formation in all tissues. More selective KAT inhibitors (1 mM glutamine to block KAT I, 1 mM BFF-122 to inhibit KAT II, and 500 μM aspartate to inhibit KAT IV; J. Neurochem., 102: 103-111, 2007) were used to further characterize the roles of the various KYNA-synthesizing enzymes in the three tissues examined. This approach increases the understanding of the dynamics of kynurenine pathway metabolism during pregnancy in basal conditions as well as after exposure to L-KYN. Exploring the source and the regulation of KYNA production in the fetus could be particularly important for developing therapeutic interventions in disorders that have etiological links to events in early life.

Title: Neonatal quinpirole treatment enhances nicotine self-administration in adult rats

Authors: *R. W. BROWN, L. A. BEUTTEL, E. M. ODINEAL, E. D. CUMMINS, G. KASSEM, C. A. BRADLEY, M. I. PALMATIER;
East TN State Univ., Johnson City, TN

Abstract: This study analyzed nicotine self-administration in adult male rats neonatally treated with the dopamine D2/D3 agonist quinpirole. Our laboratory has shown that neonatal quinpirole treatment produces increases in sensitivity of dopamine D2-like receptors throughout the animal's lifetime without a change in receptor number, consistent with schizophrenia. Schizophrenics are 3 to 4-fold more likely to smoke cigarettes than the general population, but no mechanism for this comorbidity has been delineated. Male Sprague-Dawley rats were given

single intraperitoneal (i.p.) injections of either quinpirole (1mg/kg) or saline from postnatal days (P)1-21. Animals were then socially housed and raised to adulthood (P60). Rats were reduced to 85% of their free-feeding body weight and shaped to press a nose poke for a sucrose reward. The schedule of reinforcement during 15-min sessions was increased from an FR1 to FR5 schedule of reinforcement as animals acquired nose poke for a reward. After acquisition, rats were surgically implanted with an indwelling jugular catheter before nicotine self-administration commenced. Responding on an active nose poke was reinforced with nicotine delivered in a volume of 0.1 ml/kg, whereas responding on an inactive lever had no consequence. Once animals demonstrated stable responding on the FR schedule, animals were given the opportunity to respond on a progressive ratio (PR) schedule. Results showed that animals neonatally treated with quinpirole demonstrated an increase in the motivation to self-administer nicotine compared to controls administered neonatal saline at the highest dose tested (0.9 mg/kg). Neonatal quinpriole animals demonstrated a 4-fold increase in the number of active lever presses and the number of reinforcers obtained at this dose as compared to neonatal saline controls. These results show that increases in dopamine D2 sensitivity increases the motivation to self-administer nicotine, and provides further validation of the neonatal quinpirole treatment as a model of schizophrenia. Future work will analyze higher doses, such as 1.2 mg/kg to investigate whether neonatal quinpirole results in an increased motivation to self-administer doses found to be aversive in controls.

Title: Evaluation of chronic administration of nicotine in the NVHL model of schizophrenia

Authors: *A. OSTOS VALVERDE[1,2], D. B. PAZ-TREJO[1,3], A. MARTÍNEZ-TORRES[2], H. SANCHEZ-CASTILLO[1,3];
[1]Univ. Nacional Autonoma De Mexico, Mexico City, Mexico; [2]Neurobiologia Mol. y Celular,

Inst. de Neurobiologia, UNAM, Juriquilla, Queretaro, Mexico; [3]Sociedad Iberoamericana de Neurociencia Aplicada, Mexico City, Mexico

Abstract: Schizophrenia is a neuropsychiatric disorder characterized by three groups of symptoms: positive, negative and cognitive. Antipsychotic has been the primary treatment. It has been widely report that schizophrenic patients consume tobacco in a high rate. This gives place to the self-medication hypothesis, which postulates that patients consume nicotine in an attempt to ameliorate the cognitive deficits untreated by the classic medication. The goal of the work was to evaluate the effects of chronic administration of nicotine in the Neonatal Ventral Hippocampal Lesion (NVHL) model of schizophrenia. Subjects were 68 male Sprague-Dawley rats, which were trained in a radial labyrinth. After 8 sessions of training, delays in the execution were introduced (10, 30, 90 or 180 seconds). In this phase, rats were able to see the context of each arm. The last evaluation was made with an opaque confinement of 180 seconds. Chronic administration of nicotine was given with a subcutaneous injection of 0.5 mg/kg twice a day. The morphology of granular neurons of the hippocampus and pyramidal neurons of the cortex were evaluated using rapid Golgi. The obtained results indicate that the NVHL rats commit more errors and spend more time re-entering arms that no longer content the reinforcer. The deficits in execution were more marked in the performance with delays, where the 10 and 30 seconds interruption significantly impair the execution of the NVHL rats. The chronic administration of nicotine improved the execution of the NVHL animals diminishing the number of errors and time spent in committing errors. The results of the present work support the proposal of the self-medication hypothesis in schizophrenia, since the chronic administration of nicotine was effective in ameliorating the cognitive deficits in working memory shown by the NVHL animals. It can be conclude that the nicotine display a pro-cognitive effect because it was administered in a chronic fashion, versus acute administration shown in other reports. It has been previously reported that NVHL rats display deficits in the excitatory-inhibitory regulation of the cortex, that relies in the pyramidal neurons of this area, and that this deficit is closely related to the cognitive impairments of the rats. Because of this, it can be discussed that the pro-cognitive effect of the nicotine is mediated by the effect of this drug in the pyramidal neurons of the cortex, normalizing its morphology and function.

Title: Prolonged impact of perinatal exposure to phencyclidine on brain arginine metabolism in rats

Authors: *Y. R. JING, L. T. KNOX, H. ZHANG, P. LIU;
Anat., Univ. of Otago, Dunedin, New Zealand

Abstract: Schizophrenia is a debilitating psychiatric disorder associated with prominent prefrontal and hippocampal dysfunction. Neurodevelopmental disruption and N-methyl-D-aspartate (NMDA) glutamate receptor hypofunction have been linked to the aetiology and/or pathophysiology of the disease. Phencyclidine (PCP), a non-competitive NMDA receptor antagonist, induces schizophrenia-like symptoms and cognitive decline in health individuals. Recent genetic linkage and post mortem studies suggest that altered metabolism of L-arginine, a semi-essential amino acid with a number of bioactive metabolites, may also contribute to the pathogenesis of schizophrenia. The present study aimed to investigate how perinatal treatment with PCP affected brain arginine metabolism in rats during the perinatal period and adulthood. Male Sprague-Dawley pups received PCP (10 mg/kg) or saline (5 ml/kg) subcutaneously on postnatal days (PN) 7, 9 and 11. Animals were sacrificed on PN 13 (n = 6 per group) or PN 100 (n = 8 per group), and the prefrontal cortex (PFC) and hippocampus (the CA1, CA2/3 and dentate gyrus sub-regions for PN 100 rats) were freshly dissected out for quantification of L-arginine and nine downstream metabolites (L-citrulline, L-ornithine, agmatine, putrescine, spermidine, spermine, glutamate, glutamine and γ-aminobutyric acid (GABA)) using liquid chromatography/mass spectrometry and high performance liquid chromatography. For PN 13 rats, the levels of L-arginine and its metabolites were largely unchanged in the whole hippocampus and PFC, except for a significantly increased spermidine level in the PFC in the PCP group. For PN 100 rats, by contrast, the PCP group displayed significantly reduced glutamate and GABA levels in the PFC and hippocampal CA2/3 sub-region, as well as reduced spermidine level in the CA1 sub-region of the hippocampus when compared with the saline group. This study, for the first time, demonstrated that perinatal exposure to PCP during PN 7-11 in rats (equivalent to the third trimester in humans) had prolonged impact on brain arginine metabolism in a region-specific manner. These alterations may contribute to the neurobiological basis for the neurodevelopmental interruption induced schizophrenia-like behavior during the adulthood.

Title: The role of the α7 and α4β2 nicotinic receptors in nicotine sensitization and neural plasticity of adolescent rats neonatally treated with quinpirole: Effects on mTOR

Authors: *D. J. PETERSON[1,2], E. D. CUMMINS[1], S. L. KIRBY[1], M. E. HOWELL[2], C. A. STUART[2], R. W. BROWN[1];
[2]Intrnl. Med. Quillen Coll of Med., [1]East TN State Univ., Johnson City, TN

Abstract: We have established that neonatal treatment with quinpirole, a dopamine D2/D3 agonist, results in increases of dopamine D2 receptor sensitivity throughout the animal's lifetime and has a number of consistencies with schizophrenia. The focus of the current study was to analyze the roles of α7 and α4β2 nicotinic receptors in nicotine sensitization in adolescent male and female rats neonatally treated with quinpirole as well as the roles of the α7 and α4β2 nicotinic receptors were analyzed in their effects on Brain-Derived Neurotrophic Factor (BDNF) and mammalian target of rapamycin (mTOR) in rats neonatally treated with quinpirole and sensitized to nicotine. Animals were neonatally treated with quinpirole or saline from postnatal days (P)1-21. Beginning on P33, animals were ip injected with nicotine (0.5 mg/kg free base) or saline and tested every second day from P33-49. Approximately 15-30 min before the nicotine or saline injection, animals were ip injected with either the α7 nicotinic receptor (nAChR) antagonist methllycacontine (MLA; 2 or 4 mgkg) or the α4β2 nAChR antagonist dihyro-β (DhβE; 1 or 2.5 mg/kg) erythrodine. Brain tissue was taken 1 or 24 h after the last day of testing. Results revealed that neonatal quinpirole enhanced nicotine sensitization and DhβE blocked nicotine sensitization regardless of neonatal treatment and was more effective in blocking sensitization in males versus females. MLA failed to block nicotine sensitization. However, MLA blocked the acute hypoactive response to nicotine in males, and the higher dose of MLA reduced sensitization in males. Neonatal quinpirole sensitized the accumbal BDNF response to nicotine, but neonatal quinpirole resulted in a decrease of mTOR in the nucleus accumbens when brain tissue was taken 24 h after the last nicotine administration. When brain tissue was taken 1 h post-nicotine administration, nicotine resulted in a significant increase of accumbal mTOR which was sensitized by neonatal quinpnirole. These changes in BDNF and mTOR have strong implications towards changes in synaptic growth and strength, and suggest that neonatal quinpirole may result in a significant decrease of mTOR leading to a decrease in synaptic strength, which may be alleviated by nicotine. In conclusion, the α4β2 receptor plays a critical role in adolescent nicotine sensitization. Interstingly, the α7 nAChR appears to be important in

the acute response to nicotine and is more important in nicotine sensitization in males. Both nAChRs appear to be important in accumbal BDNF and their roles will be analyzed in the mTOR response.

Title: Neonatal functional inactivation of the prefrontal cortex results in increased dopaminergic responses in the core part of the nucleus accumbens to MK801 administration in adult rats

Authors: E. TAGLIABUE, S. EYBRARD, *A. E. LOUILOT;
INSERM U1114- Fac. of Medicine- U.d.S., Strasbourg, France

Abstract: Schizophrenia would result from a defective connectivity between several integrative regions, stemming from neurodevelopmental disturbances (Weinberger and Lipska, 1995; Bullmore et al., 1997; Lewis and Levitt, 2002). Various anomalies reminiscent of early brain development failures have been observed in the patients' left prefrontal cortex (PFC) (Akbarian et al., 1993; Kalus et al., 2000). The existence of a striatal dopaminergic (DA) dysregulation in schizophrenia is generally accepted (e.g. Harrison, 1999; Carlsson et al., 2001). Psychomimetic drugs such as non-competitive NMDA/glutamate receptor antagonists can induce psychotic symptoms in healthy humans and exacerbate these symptoms in patients with schizophrenia (Malhotra et al., 1997; Lahti et al., 1995; 2001). The striatal DAergic dysregulation in schizophrenia may be dependent of prefronto-striatal disconnection involving glutamatergic NMDA receptors (Jentsch et Roth, 1999 ; Carlsson et al., 2000 ; Laruelle et al., 2005). The present study was designed to investigate the effects of MK801 (a non-competitive NMDA receptor antagonist) in adult rats on DA responses in the nucleus accumbens (ventral striatum), following an early postnatal inactivation of the left PFC (infralimbic/prelimbic region). During the neurodevelopmental period, impulse electrical activity appears to be crucial for shaping connections once developing axons reach the target structure (Katz and Shatz, 1996 ; Frostscher et al., 2000). Tetrodotoxin (TTX), is a potent and specific Na+ channel blocker (Mosher, 1986).

Therefore, reversible functional inactivation of the left PFC was carried out by local TTX microinjection in 8-day-old rats, i.e a critical time of the neurodevelopmental period (Clancy et al., 2001). DA variations were recorded in the core part of the nucleus accumbens using *in vivo* voltammetry in freely moving adult rats (11 weeks). DA variations and locomotor responses were measured in parallel. Control animals received a s.c. injection of NaCl (0.9%); MK801 was injected s.c. at 0.1 mg/kg or 0.2 mg/kg. The obtained results were the following : 1) A clear dose effect was observed for the two conditions (PBS and TTX microinjected at PND8); 2) DA increase in the core part of the nucleus accumbens in adult animals after the administration of the highest MK801 dose (0.2 mg/kg) was more elevated in TTX microinjected animals than in PBS microinjected animals. These data suggest that animals microinjected with TTX in the left PFC at PND8 present a more important reactivity to MK801 than PBS microinjected (control) animals. In conclusion, these findings may provide new insights in the pathophysiology of schizophrenia.

Title: The neurotrophic factor-like (Cerebrolysin) reduces alterations in myelin and the neurogenesis in dorsal hippocampus induced by the neonatal ventral hippocampal lesion

Authors: *R. A. VAZQUEZ, SR[1], A. ADAME[2], E. MASLIAH[2], G. FLORES[3];
[1]Inst. De Fisiología Benemérita Univ. Autónoma De Puebla, Puebla, Mexico; [2]Dept. of Neurosciences and Pathology, Sch. of Med., Univ. de California San Diego, San Diego, CA; [3]Inst. de Fisiología, Benemerita Univ. Autónoma de Puebla, PUEBLA, Mexico

Abstract: The Neonatal ventral hippocampal lesion model (nVHL) in rats has been widely used as a neurodevelopmental model to mimic schizophrenia-like behaviors. Recently, we reported that the neurotrofic factor-like (cerebrolysin) may have beneficial effects in the management of

the schizophrenia-like behaviors exhibited by nVH-lesions rats. In other hand, Cerebrolysin (CBL) has been shown to increase neurogenesis in models of stroke and AD. CBL is composed of small peptides with activity similar to neurotrophic factors, which may mediate its neurogenic effects. Several reports have been established that newborn neurons migrate a short distance to be integrated into a pre-existing neuronal circuit in the hippocampus. Interestingly, deficits in the expression of doublecortin and proliferating cell nuclear antigen (PCNA) have been described in brain regions in schizophrenia (SZ) in association with abnormalities of cell cycle markers. This study aimed to determine first whether nVH-lesioned rats also exhibited changes in the expression of these cell markers for neurogenesis and the myelin levels (using luxol fast blue stain) in the Hippocampus and second whether Cbl was capable of reducing these alterations in nVHL rats. Our results suggest that nVH-lesion rats shown a reduction in the expression of neuroblast in the DG and a decrease of levels myelin in the Dorsal Hippocampus (DH). Interestingly, Cbl treatment ameliorated these changes and increased the expression of neuroblast (using doublecortin marker) in DG and the levels of myelin in DH of the nVH-lesion rats. In conclusion, this study demonstrates that Cbl promotes neurogenesis in the DG and reduces the alteration in myelin levels induced by the lesion. These findings support the possibility that Cbl may have beneficial effects in the management of schizophrenia symptoms. Title: Postnatal NMDA receptor antagonism models positive and cognitive, but not negative, symptoms of schizophrenia in adult rats

Authors: *D. C. LOWES, T. A. PAINE;
Oberlin Col., Oberlin, OH

Abstract: Background: Schizophrenia is characterized by positive, negative, and cognitive symptoms. Increasingly, these symptoms are hypothesized to arise from perturbations that occur

during neurodevelopment, although the biological basis of the symptoms is not yet clear. That said, the cognitive symptoms have been linked to dysregulation in GABA neurotransmission in the prefrontal cortex and hippocampus. Furthermore, neonatal exposure to the NMDA receptor antagonist MK-801 has been found to recapitulate positive and cognitive symptoms of schizophrenia and has been found to cause some of the observed changes in GABA transmission. The goal of the current experiment was to determine whether neonatal exposure to a low dose of MK-801 could cause behaviors consistent with the negative symptoms of schizophrenia and could cause changes in GABA system function consistent with that found in schizophrenia. Methods: Male and female rats injected with MK-801 (0.025 mg/kg, s.c.) or saline twice daily from postnatal days (PND) 7-12 were tested for amphetamine-induced hyperlocomotion, sucrose preference, sociality, social preference, and Morris water maze performance in either adolescence (PND 30) or adulthood (PND 90). At the end of testing brains were extracted for Western blot analysis of GABA-related proteins. Results: Postnatal MK-801 administration enhanced amphetamine-induced hyperlocomotion in female adult rats and impaired learning of the Morris water maze in both male and female adult rats. There was no effect on sucrose preference, sociality, or social preference. Preliminary Western blot analysis has found decreased expression of GAD67 in the dorsal hippocampus of male adolescent rats. Discussion: Postnatal exposure to a low dose of MK-801 resulted in mild schizophrenia-like behavioral changes in male and female adult rats. However, there was no change in behaviors that reflect negative symptoms in adult rats. Furthermore, no behavioral changes were observed in rats tested during adolescence. Interestingly, a schizophrenia-like decrease in GAD67 was observed in male adolescent rats suggesting that alterations in GABA function may occur prior to the onset of schizophrenia-like behavioral changes.

Title: Lack of preventive effect of acute DHA and subacute EPA/DHA combination on PPI disruption in a murine juvenile two-hit model of schizophrenia

Authors: R. GIRARD[1], C. MAURICE-GELINAS[1], C. FAYE[2], G. PARE[1], C. MONPAYS[1], J. DESLAURIERS[3], P. SARRET[1], *S. GRIGNON[1];

Abstract: Schizophrenia is a multifactorial, chronic disease in which multiple and intricate pathophysiological factors have been suspected. Among these, oxidative status (OS) disturbances are gaining interest, based on genomic, transcriptomic, biochemical and interventional data. We have recently described and characterized a two hit model (THM) (gestational inflammation followed by adolescent restraint stress (RS)) mimicking some aspects of schizophrenia in juvenile mice, in which behavioural and neurochemical disturbances could be efficiently prevented by the antioxidant lipoic acid1. In clinical studies, ω3 polyunsaturated fatty acids have been shown to efficiently prevent transition to psychosis in an ultra high-risk group, which prompted us to assess their preventive effect in our juvenile THM. **Methods:**. THM: Pregnant C57BL/6 mice were injected with poly-inosinic/cytidylic acide (PolyI:C) 20 mg/kg at gestational day 12 ; their offspring was submitted to RS from PN33 to PN35 (2 hours per day). Prepulse inhibition (PPI) was performed 24h after the last session of RS and the mice were sacrificed for biochemical analyses. Drug administration: Control mice received mineral oil (IP) from PN26 to PN35. The ω3 group received a commercial preparation of PUFA (302.67 mg/kg IP; 20% docosahexaenoic acid (DHA), 30% eicosapentaenoic acid (EPA); content verified by LC-MS), from PN26 to PN35. The DHA group received purified DHA 4 mg/kg (IP) from PN33 to PN35. PN33-35 injections were performed 3h before the RS session. PPI and protein carbonylation were assessed as previously described1. **Results:** As previously described, the THM induced significant PPI deficits, as well as an increase in protein carbonylation, in males. The PPI deficits were not prevented in the ω3 group, and were actually increased in the DHA group in males ($p<0.001$) and females ($p<0.05$). Protein carbonylation was unchanged by DHA or ω3 in the THM x DHA or THM x ω3 groups relative to THM only. **Conclusion:** Under our conditions purified DHA or mixed ω3 did not prevent PPI deficits induced by the THM. Pending further investigation of glutamatergic or dopaminergic markers, timing or duration of administration could account for the discrepancy with existing literature. 1 Deslauriers et al. Title: Cannabinoid transmission in the ventral hippocampus modulates excitatory neuronal activity in the nucleus accumbens and induces schizophrenia-like disturbances in emotional processing and social cognition behaviors

Authors: *M. LOUREIRO[1], J. RENARD[2], L. G. ROSEN[2], S. R. LAVIOLETTE[2];
[1]Anat. and Cell Biol., [2]Univ. of Western Ontario, London, ON, Canada

Abstract: Cannabis use is a primary risk factor for schizophrenia. Given the exponential increase in marijuana consumption due to legalization, there is an urgent need to better understand the neurobiological mechanisms underlying the effects of cannabinoids on schizophrenia-related emotional processing and social cognition deficits. Cannabinoid type 1 receptors (CB1r) are highly expressed in the mammalian ventral hippocampus (vHipp), a brain region known for its involvement in emotional memory formation and which is profoundly disturbed in schizophrenia. Importantly, the vHipp sends dense excitatory projections to neurons in the nucleus accumbens (NAc), an integrative brain region that is a point of convergence for information arising from cortico-limbic regions, including the amygdala (signalling emotional valence), prefrontal cortex (providing action-outcome information) and vHipp-dependent contextual relevance. The CB1r regulates vHipp output pathways via modulation of inhibitory inputs to excitatory hippocampal output neurons. In addition, previous evidence demonstrates that CB1r activation increases the activity of hippocampal principal neurons. Accordingly, we hypothesized that direct pharmacological activation of intra-vHipp CB1r would increase excitatory vHipp projections to the NAc, thereby activating NAc neuronal activity and potentially modulating mesolimbic-dependent emotional associative memory formation. Using a combination of *in vivo* electrophysiological recordings and behavioural pharmacology in rats, we report that micro-infusion of a direct CB1r agonist (WIN-55,212) into the vHipp, dose-dependently increases spontaneous NAc neuronal firing frequency rates. In addition, we report that intra-vHipp CB1r activation (1) potentiates the emotional salience of normally non-salient context-dependent fear memory, (2) potentiates the reward salience of normally sub-threshold conditioning doses of morphine, measured in an unbiased place conditioning procedure; and (3) induces profound disturbances in social interaction and cognition. Interestingly, these behavioral

effects were completely blocked with direct blockade of AMPA/NMDA receptor transmission, within the NAc, demonstrating a GLUTergic-dependent mechanism underlying these effects. Taken together, these data add new insights into the functional role of hippocampal cannabinoid transmission in the modulation of mesolimbic NAc activity and behavioural dysregulation linked to neuropsychiatric disorders.

Title: Developmental vitamin D deficiency leads to multiple changes in basal neurotransmitter levels in the neonate rat brain

Authors: ***T. H. BURNE**[1], K. M. TURNER[1], S. ALEXANDER[1], D. EYLES[1], J. J. MCGRATH[1], J. P. KESBY[1,2];
[1]Queensland Brain Inst., Brisbane, Australia; [2]UCSD, San Diego, CA

Abstract: Epidemiological evidence suggests that developmental vitamin D (DVD) deficiency is a risk factor for schizophrenia. We have shown that this is biologically plausible in a rodent model, in which DVD deficiency is associated with changes in brain structure and adult behaviour, and may be associated with altered dopamine and glutamate signalling. Here, we tested the hypothesis that DVD deficiency impacts on multiple neurotransmitter levels in the neonate brain. Sprague-Dawley rats were fed a vitamin D deficient diet (DVD-deficient) or control diet six weeks prior to mating until birth and housed under UVB-free lighting conditions . Basal neurotransmitter levels were then assessed by high-performance liquid chromatography on post-mortem neonate brain tissue. There were significant ($p<0.05$), region-specific increases in the levels of dopamine in the basal ganglia and noradrenaline in the hippocampus of newborn DVD-deficient rats. Whereas, glutamine levels were consistently reduced ($p<0.05$) by 12-24% in most brain regions examined. Our results confirm that DVD deficiency leads to changes in multiple neurotransmitter systems in a regionally-specific manner in the neonate brain. These data suggest that the glutamate-glutamine cycle is altered and may underlie the alterations in

dopamine and glutamate signalling previously described in DVD-deficient rats. Taken together, these data suggest that DVD deficiency alters neurotransmitter systems relevant to schizophrenia in the developing rat brain.

Title: Effects of the antioxidant n-acetyl cysteine on behavioral and neurophysiological deficits induced by developmental NMDA-R antagonism

Authors: *A. J. PHENSY[1], C. DRISKILL[2], V. JEEVAKUMAR[2], S. BREWER[2], C. DE LA HOZ[2], S. KROENER[2];
[1]Univ. of Texas At Dallas - BBS, Dallas, TX; [2]Sch. of Behavioral and Brain Sci., Univ. of Texas At Dallas, Dallas, TX

Abstract: The NMDA-hypofunction theory of schizophrenia suggests that schizophrenia is associated with a loss of NMDA receptors, specifically on corticolimbic parvalbumin (PV)-expressing GABAergic interneurons, leading to disinhibition of pyramidal cells and cortical desynchronization. We recently characterized the behavioral and physiological effects of developmental NMDAR antagonism model in which mice receive ketamine (KET) injections on postnatal days (PND) 7, 9 and 11 (Jeevakumar and Kroener, Cereb. Cortex, 2014; Jeevakumar et al., Behav. Brain Res. 2015). We found that sub-chronic developmental KET treatment results in a loss of PV expression in the medial prefrontal cortex; reduced cognitive flexibility in an attentional set-shifting task; an unexpected upregulation of NMDAR responses in PV expressing interneurons in layer 5, and changes in the excitation-inhibition balance as measured by recordings of spontaneous and miniature EPSCs and IPSCs, respectively. The loss of PV expression following subchronic NMDA antagonism appears to be the result of oxidative stress, involving the activation of nicotinamide adenine dinucleotide phosphate (NADPH) oxidase. Here we investigated whether the antioxidant N-acetyl cysteine (NAC) can prevent the KET-induced loss of PV expression as well as the resultant behavioral and physiological changes. Groups of ketamine- and saline-treated animals were given subcutaneous injections of either NAC or saline between PND 5-21. After weaning, animals in the NAC treatment groups

continued drinking NAC in their drinking water through adulthood. In adult NAC-treated animals levels of PV expression in the mPFC remain elevated close to control levels, whereas the numbers of PV+ cells in animals that received saline injections after KET treatment sharply declined. NAC also improved performance on the attentional set-shifting task in KET-treated animals. In agreement with our previous findings, developmental KET treatment decreased the frequency of miniature IPSCs at layer 2/3 pyramidal cells, suggesting reduced GABAergic inhibition. The reduction in mIPSCs onto pyramidal cells in KET-treated mice was mirrored by an increase in spontaneous excitatory postsynaptic currents onto PV+ interneurons in the same layer, further suggesting persistent cortical disinhibition. Both of these KET-induced changes in synaptic transmission were prevented by the NAC treatment. Ongoing experiments investigate whether KET treatment also alters the NMDA:AMPA ratio in layer 2/3 interneurons, and whether these changes can be prevented by NAC, thus preserving normal prefrontal cortical synchronization and cognitive abilities.

Title: Scopolamine produces greater attenuation of forced swim immobility in mice housed in a short-active photoperiod

Authors: *Z. A. COPE[1], D. DULCIS[1], J. W. YOUNG[1,2];
[1]Dept. of Psychiatry, Univ. of California San Diego, La Jolla, CA; [2]Res. Service, VA San Diego Hlth. Care Service, San Diego, CA

Abstract: Seasonal variation in day-length is believed to increase risk for relapse to depression or mania in individuals with bipolar disorder (Wang et al. J. Psych. Practice 2013). This risk can be partially attenuated with treatments such as social rhythm therapy or timed light exposure (Dallaspezia et al. Informa Expert Reviews 2011). Housing normal rats in altered photoperiods is sufficient to produce behaviors consistent with mania- or depression-relevant behaviors. That is, rats housed in a long-active (LA) photoperiod (19 hours dark, 5 hours light) exhibited increased

elevated plus maze open arm entries, while those housed in a short-active (SA) photoperiod (5 hours dark, 19 hours light) exhibited increased immobility in the forced swim task (FST). These behaviors were associated with respective switches in expression of tyrosine hydroxylase (TH) or somatostatin (SST) in neurons of the periventricular nucleus (PVN) that are coincident with decreases (LA) or increases (SA) in corticosterone and corticotrophin releasing factor (CRF, Dulcis et al. Science 2013). Preliminary experiments from our lab have behaviorally replicated these findings in mice. Given that the immobility resulting from a SA photoperiod was associated with increased SST in PVN neurons and subsequent increases in CRF, we hypothesized that the resulting depressed phenotype is likely to result from elevated CRF stimulated acetylcholine (ACh). To test this hypothesis, male C57BL/6J mice were housed in either a normal (12 hours light, 12 hours dark) or SA photoperiod for two weeks before testing in the FST. Mice were injected (s.c.) with one of three doses of the muscarinic acetylcholine receptor antagonist scopolamine 10 min before testing. All doses of scopolamine significantly reduced immobility in the FST compared to saline. Interestingly, SA mice appeared more sensitive to the effects of scopolamine at the lowest dose administered as indicative of a larger effect size. These preliminary findings indicate that extended exposure to a SA photoperiod modified cholinergic signaling in these animals, supporting our hypothesis. Hence, SA photoperiod may induce a depressive-like state by altering the balance of SST expression in PVN neurons, thereby increasing CRF release, and ultimately impinging on normal ACh function.

Title: SGE-516, a novel allosteric modulator of synaptic and extra-synaptic GABAA receptors, has an anxiolytic-like effect *in vivo*

Authors: *R. S. HAMMOND, M. A. ACKLEY, C. MACIAG, G. M. BELFORT, G. MARTINEZ-BOTELLA, F. G. SALITURO, J. J. DOHERTY, A. J. ROBICHAUD;
Sage Therapeut., Cambridge, MA

Abstract: Neurosteroids such as allopregnanolone, a reduced metabolite of progesterone, have been associated with affective disorders including anxiety and depression. Decreased serum or CSF allopregnanolone levels have been observed in depressed patients, supporting the

hypothesis that the down regulation of neurosteroids may be a risk factor for the development of affective disorders. Consistently, allopregnanolone administration produces antidepressant-like and anxiolytic-like effects in rodents. Unlike the vast majority of benzodiazepines, neurosteroids are positive allosteric modulators of both synaptic and extrasynaptic GABAA receptors and may provide a differentiated therapeutic profile in affective disorders. However, these endogenous neurosteroids have limited oral bioavailability and rapid clearance, limiting their utility as oral therapeutics. We have therefore designed novel neurosteroid modulators of synaptic and extrasynaptic subunit-containing GABAA receptors with improved pharmacokinetic properties. SGE-516 is an exemplar with pre-clinical anxiolytic-like properties at exposures that do not cause sedation. SGE-516 potently potentiates GABA currents at synaptic and extra-synaptic receptors, respectively composed of either $\alpha1\beta2\gamma2$ or $\alpha4\beta3\delta$ subunits, and was designed to have pharmacokinetic properties that are appropriate for oral administration. The anxiolytic potential of SGE-516 was assessed following acute dosing in two rodent models, the mouse elevated plus maze and the rat Vogel conflict test. In the elevated plus maze, SGE-516 increased the number of entries and time spent in open arms, an effect consistent with anxiolytic-like efficacy and similar to diazepam (2 mg/kg, IP). At the minimal effective dose (MED) of 3 mg/kg (IP), the total exposure was 1,182 nM in plasma and 1,479 nM in brain. SGE-516 also had an effect consistent with anxiolytic efficacy in the rat Vogel conflict test. SGE-516 increased the number of shock episodes and punished licks in 10 minutes. At the MED of 3 mg/kg (IP), the total exposure was 760 nM and 1082 nM in plasma and brain respectively. At similar plasma and brain exposures SGE-516 (3 mg/kg, IP) did not reduce locomotor activity in the open field or impair motor coordination on the rotarod in mice. These data suggest that SGE-516, a novel positive allosteric modulator of GABAA receptors, has anxiolytic-like effects in two different models. Compounds such as SGE-516 may therefore represent a novel class of molecules with potential therapeutic use as non-sedating anxiolytics.

Abstract: The observation that cholinergic deafferentation of circuits projecting from forebrain basal nuclei to frontal and hippocampal circuits occurs in Alzheimer's disease has led to drug-targeting of muscarinic M1 receptors to alleviate cognitive symptoms. The high homology within the acetylcholine binding domain of this family however has made receptor-selective ligand development challenging. This work presents the structure-activity-relationship study findings for M1-selective ligand and its functional characterization as an orthosteric ligand. Additionally, homology modeling work will illustrate that the binding site of this compound spans from the acetylcholine pocket to the extracellular loops of the receptor, a common allosteric vestibule for the muscarinic protein family. Altogether data presented will support that this M1-selective ligand represents a growing class of multi-topic ligands which interact with the receptors in both the ortho- and allosteric binding sites, but which exert their activation mechanism as an orthosteric ligand.

Title: Enhanced endocannabinoid signaling amplifies neural activity flow through the hippocampal trisynaptic circuit and promotes safety learning

Authors: J. STEPAN[1], V. MICALE[2], *J. DINE[1], C. WOTJAK[1], M. EDER[1];
[1]Max Planck Inst. of Psychiatry, Munich, Germany; [2]Research group Exptl. and Applied Neuropsychopharm., Central European Inst. of Technol., Brno, Czech Republic

Abstract: Anxiety disorders like post-traumatic stress disorder, panic disorder, and phobias are frequently diagnosed and represent a relevant global health problem. Exposure-based therapies in combination with drug administration are widely used as treatment for most of these brain based diseases. Classical drugs like benzodiazepines hamper therapeutic effects by severely disturbing amnestic functions. Recently, substances targeting the endocannabinoid system were found to be effective anxiolytics without detrimental side effects on memory function. However, the alterations in millisecond-scale brain circuit dynamics that might underlie their therapeutic actions remain elusive. Here, enabled by a recently developed voltage-sensitive dye imaging assay in mouse brain slices, we compared the impact of diazepam and the cannabinoid neurotransmission enhancer AM404 on neuronal activity propagations through the entire trisynaptic circuitry of the hippocampus ("HTC": perforant path-dentate gyrus-area CA3-CA1 output subfield). Bath applied diazepam (1 μM) led to markedly weakened activity propagations ("HTC-Waves"), which coincided with impaired safety learning. In contrast, bath applied AM404 (10 μM) caused an amplification of HTC-Waves in CA regions, and promoted safety learning. These effects were absent in D1CB1-KO mice. Collectively, we demonstrate bidirectional effects of two anxiolytic drugs on the hippocampal network that might underlie their opposing effects on memory function during exposition-based therapies.

Title: Cannabinoid Receptor 1 interaction with Epigenetic mechanisms

Authors: J. S. DESAI[1,2], H. KUSUMO[1,2], S. C. PANDEY[1,2], *D. P. GAVIN[1,2];
[1]Jesse Brown VA Med. Ctr., Chicago, IL; [2]Dept. of Psychiatry, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Background: Cannabis use in adolescence is a recognized environmental risk factor that decreases the age of schizophrenia onset and increases the severity of psychosis. On the other hand, schizophrenia patients abuse cannabinoids at a higher rate than nonpsychiatric controls. It is unclear whether cannabinoid use by schizophrenia patients is a precipitating factor for enduring psychotic symptoms potentially maintained through epigenetic mechanisms or is a means of self-medication. Increases in restrictive chromatin inducing-enzymes leading to decreases in Glutamate decarboxylase 1 (GAD1) and Brain-derived neurotrophic factor (BDNF) expression have been reported in schizophrenia. In the current study we hypothesized that cannabinoid 1 receptor (Cb1) modulation would alter epigenetic parameters in neurons, thereby affecting the expression of these genes. Methods: We treated mouse E18 primary cortical neuron cultures with the Cb1 agonist, arachidonyl-2-chloroethylamide (ACEA). We measured changes in epigenetic gene expression via qRT-PCR, as well as potential downstream schizophrenia candidate genes in neuron culture. Western blot was used to quantify Cb1 agonist induced changes in the 'open' chromatin mark histone H3 lysine 79 dimethylation (H3K79me2). Results: In primary neuron cultures, ACEA increases the mRNA expression of the enzyme that catalyzes the addition of methyl groups to H3K79, Dot1l, in a dose and time dependent manner with maximal increase at 0.1 μM at 6 hours. This increase in Dot1l corresponds to increases in H3K79me2 protein levels, as well as Gad1 and BdnfIXa mRNA. At ACEA doses exceeding 1 μM, enzymes that catalyze the transcription silencing mark dimethylation of lysine 9 of histone 3 (H3K9me2), Glp, G9a, and Setdb1, as well as DNA methylating enzymes, Dnmt1 and Dnmt3a are induced. Discussion: This is the first study to our knowledge to examine the effects of cannabinoids on epigenetic parameters in neurons. We find that low doses of a Cb1 agonist induce factors that 'open' chromatin, while high doses induce expression of chromatin restricting factors. Dysregulation of epigenetic mediators affecting Gad1 and Bdnf gene expression have been repeatedly implicated in schizophrenia. Based on these results we speculate that altered cannabinoid system functioning, whether due to substance abuse or endogenous differences in the endocannabinoid system, may contribute to the epigenetic and gene expression differences

observed in schizophrenia. [Supported by NIAAA, Department of Veterans Affairs Merit and Senior Career Scientist Awards to SCP and VA career development award (IK2BX001650) to DPG].

Title: The T-type calcium channel antagonist Z944 disrupts prepulse inhibition in three strains of rats

Authors: *J. G. HOWLAND[1], W. N. MARKS[2], Q. GREBA[2], S. M. CAIN[3], T. P. SNUTCH[3]; [1]Physiol., Univ. Saskatchewan, Saskatoon, SK, Canada; [2]Physiol., Univ. of Saskatchewan, Saskatoon, SK, Canada; [3]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Low voltage-activated T-type calcium channels are widely expressed in the brain. The electrophysiological characteristics of T-type calcium channels and their role in brain diseases such as absence epilepsy and neuropathic pain have been studied extensively. However, less is known regarding the involvement of T-type channels in cognition and behavior. Sensorimotor gating is a basic process whereby the brain filters incoming stimuli to enable appropriate responding in sensory rich environments. Prepulse inhibition (PPI) is a common measure of sensorimotor gating used in studies employing both humans and animals because of its cross species validity, face and predictive validity, ease of implementation, and reliability. The regulation of PPI involves a network of limbic, cortical, striatal, pallidal, and pontine brain areas, many of which show high levels of T-type calcium channel expression. Therefore, we tested the effects of blocking T-type calcium channels on PPI with the potent and selective T-type antagonist Z944 (0.3, 1, 3, 10 mg/kg; i.p.) in adult Wistar rats and two related strains, the Genetic Absence Epilepsy Rats from Strasbourg (GAERS) and Non-Epileptic Control (NEC). All rats were carefully handled during the week prior to the PPI test. PPI was tested using a protocol that varied prepulse intensity (3, 6, and 12 dB above background) and prepulse-pulse interval (30, 50, 80, 140 ms). Wistars showed significantly higher startle responses to the pulse alone during the test session than the other two strains; Z944 did not significantly affect startle at the doses tested.

All three strains had similar levels of PPI when injected with vehicle. Z944 dose-dependently disrupted PPI in all strains for both long (50, 80, 140 ms) and short intervals (30 ms) with the most potent effect observed following treatment with the higher doses. These findings suggest that T-type calcium channels contribute normal patterns of brain activity that regulate PPI. Given that PPI is disrupted in psychiatric disorders including schizophrenia, Huntington's disease, and obsessive compulsive disorder, future experiments that test the specific brain regions involved in the regulation of PPI by T-type calcium channels may help inform therapeutic development for those suffering from sensorimotor gating impairments.

Title: Tardive dyskinesia induced by prolonged antipsychotic treatments in a non-human primate model is associated with Akt/GSK-3ß kinase activities

Authors: *G. A. HERNANDEZ[1], S. MAHMOUDI[2], M. CYR[4], P. J. BLANCHET[3], D. LÉVESQUE[2];
[1]Physiologie, Univ. de Montreal, Montreal, QC, Canada; [2]Faculté de Pharmacie, [3]Stomatologie, Univ. de Montréal, Montreal, QC, Canada; [4]Biologie Médicale, Univ. du Québec à Trois-Rivières, Trois-Rivières, QC, Canada

Abstract: Tardive dyskinesia (TD) is a delayed and potentially irreversible motor complication arising in patients chronically exposed to dopamine receptor antagonists. Typical antipsychotic drugs, metoclopramide and several atypical drugs are associated with generation of TD. But, the pathophysiology of TD remains elusive and difficult to treat. Antipsychotic drugs modulate multiple kinase pathways, but their involvement in TD is unknown. To investigate the neurochemical basis of TD, we exposed capuchin (Cebus apella) monkeys to prolonged haloperidol (N=11) or clozapine (N=6) treatments. Six untreated animals were used as controls.

Five haloperidol-treated animals developed mild TD movements similar to those found in humans. No TD was observed in the clozapine group. We measured ERK1/2, GSK-3β and Akt activities with phospho[Thr202/Tyr204]-p44/42 (pERK1/2), phospho[Ser9]-GSK-3β (pGSK-3β) and phospho[Ser473]-Akt (pAkt) specific antibodies by Western blots. Relative pERK1/2, pGSK-3β and pAkt levels were calculated from respective total kinase levels. Haloperidol, but not clozapine, strongly enhanced pERK1/2 immunoreactivity in the putamen. Nonetheless, both dyskinetic and non dyskinetic animals showed similar pERK1/2 levels. On the other hand, haloperidol reduced putamen pAkt and pGSK-3β immunoreactive signals. Interestingly, only haloperidol-treated monkeys that did not develop dyskinesia have reduced pAkt and pGSK-3β levels, as compared to dyskinetic animals, and pAkt levels nicely correlated with dyskinetic scores ($r2 = 0.916$; p value = 0.011). These results suggest that a reduced Akt/GSK-3β activity minimizes the risk of haloperidol-induced TD.

Title: Preclinical development of a novel class of competitive inhibitors of the Glycine Transporter-1 (GlyT-1) for the treatment of cognitive deficits

Authors: *N. MOORE[1], A. RASSOULPOUR[1], C. CIOFFI[2], S. LIU[3], P. GUZZO[3], M. LUCHE[2], A. MHYRE[4];
[1]Brains On-Line LLC, South San Francisco, CA; [2]AMRI, Albany, NY; [3]Concerted Therapeut. Inc., Albany, NY; [4]Fred Hutchinson Cancer Res. Ctr., Seattle, WA

Abstract: Treatments for cognitive deficits associated with Alzheimer's disease, schizophrenia and aging remain a major unmet need. Recent evidence suggests that the glycine transporter-1 (GlyT-1) may be a promising target. Behavioral data from both rodent and primate studies demonstrate positive effects of non-competitive GlyT-1 inhibitors in a range of cognitive models; however, clinical evidence is less compelling. Some studies have suggested that an optimum level of occupancy is necessary to see positive effects. We have speculated that this narrow therapeutic window may in part be due to the non-competitive nature of the binding to the GlyT-1 site. We have developed a novel series of competitive GlyT-1 inhibitor compounds.

AMR-GLY-6 and AMR-GLY-10 represent examples of the series that have been shown to be competitive and selective. Here we present data demonstrating that *in vivo* these compounds possess GlyT-1 inhibitor-like properties in both rats and non-human primates leading to indications of cognitive enhancement with no adverse side effects. AMR-GLY-6 and AMR-GLY-10 were shown to block the reuptake of [14C]-glycine by hGlyT-1a expressed in JAR cells (IC50 0.67nM and 1.06nM respectively) with negligible activity at GlyT-2 or other off-target sites. The binding to the GlyT-1 site was competitive in nature. *In vivo*, the compounds were evaluated using both microdialysis (prefrontal cortex [Pfc] glycine levels) and measurements of cerebrospinal fluid (CSF) glycine coupled with compound exposure in brain and plasma following acute oral administration in rats. Both compounds produced significant dose-related elevations in Pfc glycine which translated into dose-dependent increases in CSF glycine levels. Upon repeat dosing AMR-GLY-6 maintained elevated CSF glycine levels throughout a five day dosing period without producing adverse effects seen with earlier non-competitive GlyT-1 inhibitors. The effect was reversible with glycine levels rapidly returning to normal once dosing was stopped. In cynomolgus monkeys, AMR-GLY-10 produced dose-related increases in CSF glycine levels and improvements in cognitive functioning in an objective retrieval task in normal primates without producing adverse effects. This data demonstrates that competitive inhibition of the GlyT-1 site may offer a novel approach to improve cognitive functioning. Furthermore the use of CSF glycine measurement coupled with brain and plasma compound analysis could be an inexpensive biomarker for dose selection in clinical studies.

Title: *In vivo* evaluation of target occupancy by positron emission tomography (PET) and pharmacodynamic assessment of ABT-419, a glycine transporter-1 (GlyT1) inhibitor in non-human primates (NHP)

Authors: *A. M. BASSO[1], R. RAJAGOVINDAN[1], J.-Q. WANG[1], A. E. TOVCIMAK[1], Y. LAO[2], C. KALVASS[2], M. J. VOORBACH[1], A. GIAMIS[1], D. REUTER[1], S. CASSAR[1], P. JACOBSON[1], R. CARR[3], E. VAN DER KAM[4], B. BEHL[4], G. B. FOX[1], J. D. BEAVER[1]; [1]Translational Sciences-Imaging, [2]Preclinical Pharmacokinetics, [3]Translational Modeling, AbbVie, North Chicago, IL; [4]Neurosci. Discovery, AbbVie, Ludwigshafen, Germany

Abstract: GlyT1 regulates synaptic glycine concentration in the forebrain. Since glycine is a co-agonist of the NMDA receptor, GlyT1 inhibition has been proposed as a potential treatment to reverse the NMDA receptor hypofunction suggested to be affected in schizophrenia. ABT-419 is a novel, potent (Ki = 1 nM), selective and competitive GlyT1 inhibitor. The goal of this study was to determine the relationship between ABT-419 plasma concentrations and brain GlyT1 occupancy and changes in CSF glycine in NHP following administration of ABT-419. Occupancy of GlyT1 was measured by dynamic PET scans with arterial sampling using [^{18}F]CFPyPB, a previously reported radiotracer. Scanning was conducted at baseline and following different doses of ABT-419 infused i.v. over a 3-h period or given as i.v. bolus. [^{18}F]CFPyPB was administered as i.v. bolus 1-h after the start of ABT-419 infusion and was followed by 2-h dynamic scans. Time course studies evaluated the relationship between GlyT1 occupancy and ABT-419 plasma concentrations as well as changes in CSF glycine, ABT-419 plasma and CSF concentrations following ABT-419 administration. Glycine and ABT-419 concentrations were determined by LC-MS/MS. The highest uptake of [^{18}F]CFPyPB and GlyT1 occupancy with ABT-419 was observed in brainstem, pons, midbrain, cerebellum and thalamus. Dose-dependent target occupancy was achieved, reaching full occupancy (>90%) at 5 mg/kg of ABT-419. A counter-clockwise hysteresis was observed for ABT-419 plasma pharmacokinetic profile and the brain GlyT1 target occupancy, with time dependent EC_{50} values and lower EC_{50} at the later scan time points. ABT-419 displayed a longer half-life in CSF (13 h) as compared to plasma (3 h). Administration of ABT-419 resulted in a significant increase of glycine in CSF which demonstrated a direct relationship with GlyT1 target occupancy and ABT-419 CSF concentration. PET and pharmacodynamic data suggest prolonged GlyT1 brain occupancy and indirect kinetics with respect to ABT-419 plasma concentrations but a direct relationship with respect to ABT-419 CSF concentration. Therefore, occupancy analysis using a direct ABT-419 plasma levels/ target occupancy relationship is not appropriate and further indirect kinetic modeling is needed. NHP *in vivo* PET studies with ABT-419 supported the prediction of pharmacologically active doses in humans and initial planning for a first-in-human study (Brain PET 2015, poster presentation). Current data strongly support the use of PET target occupancy

and pharmacodynamic biomarker studies for translational purpose in clinical development. All authors are AbbVie employees. Financial support was provided by AbbVie.

Title: Known CNS medications produce distinct behavioral profiles in a larval zebrafish high content phenotypic screen

Authors: *G. CAREY[1], T. EVRON[1], A. VELENICH[1], D. LENSEN[1], D. KOKEL[2], R. T. PETERSON[3];
[1]Teleos Therapeut., Medford, MA; [2]Inst. for Neurodegenerative Dis., UCSF Sch. of Med., San Francisco, CA; [3]Cardiovasc. Res. Ctr., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Behavioral phenotypes are powerful tools for drug discovery and the analysis of neuronal signaling. Given the heterogeneous nature of many CNS diseases, phenotypic approaches are once again gaining acceptance as an effective method for identifying new CNS medicines. The goal of the present study was to assess and characterize the behavioral effects of a range of approved CNS drugs from multiple therapeutic classes in the Teleos zebrafish phenotypic profiling platform. Fertilized eggs (up to 20,000 embryos per day) were collected from group mating's of wild-type zebrafish. Larvae were raised until 7 days post fertilization and then distributed into the wells of clear 96-well plates. Test drugs, including DMSO control, were

added to each well at various concentrations and their effects on zebrafish behaviors were recorded using a digital video of the entire 96-well plate. We found that compounds in the same pharmacological class generate similar phenotypic effects, whereas compounds in different classes generate dissimilar effects. These behavioral data can be represented geometrically as points in a high dimensional space, and therefore time series corresponding to compounds in the same pharmacological class cluster together. Such clustering allowed us to visualize the relations among all known compounds in the screen. In this way it is possible to distinguish between active drugs from different therapeutic classes and, in many cases, distinguish between drugs from the same therapeutic class that have distinct mechanisms of action. Together, these data suggest that behavioral profiling in zebrafish is an effective way to identify and classify CNS compounds for research and therapy.

Title: Involvement of long noncoding RNA- NEAT1 and paraspeckles proteins in oligodendrogenesis - relevance to schizophrenia

Authors: *V. HAROUTUNIAN[1], P. FAM[2], W. TAN[3], M. PLETNIKOV[4], S. NAKAGAWA[5], P. KATSEL[3];

[1]Director, Neurobio. Labs., Bronx, NY; [2]JJ Peters VA Med. Ctr., Bronx, NY; [3]Icahn Sch. of Med. at Mount Sinai, New York, NY; [4]Johns Hopkins Univ. Sch. of Med., Baltimore, MD; [5]RNA biology Lab., RIKEN, Wako, Japan

Abstract: Long noncoding RNA - NEAT1 is a structural component of paraspeckles, subnuclear bodies in interchromatin region that control sequestration of paraspeckle proteins. Paraspeckle function in neural cell types has not been studies extensively. Microarray studies of multiple cortical regions from individuals with schizophrenia (SZ) showed strong downregulation of NEAT1 levels across 15 different brain regions compare to controls. Gene clustering placed NEAT1 in proximity to myelin-specific genes. Myelin-related gene/protein expression decline is among the most corroborated observations in the pathophysiology of SZ. We hypothesize that NEAT1 dysregulation is associated with oligodendrocyte (OLG) function. We tested this hypothesis in three different mouse models: 1) demyelination model, quaking mouse (Qke5); 2) increased OLG proliferation model, forebrain restricted expression of mutant hDISC1 mouse and 3) NEAT1 knock out model. We examined gene expression of lncRNA - NEAT1, paraspeckle protein - PSPC1, and the molecular determinants of different glial cell types. We found: i) Myelin specific genes (MAG, CNP, Sox10, PLP and MBP) and astrocyte marker, ALDH1L1 were dramatically downregulated in white matter of Qke5 mice. Similarly, the levels of NEAT1 and PSPC1 were significantly decreased (near 6 fold and 1.4 fold, respectively) in white matter of Qke5 mice. ii) Forebrain-restricted overexpression of mutant hDISC1 mice had the profound effect on NEAT1 and PSPC1 expression throughout development and in adult mice, similarly to the effect on myelin-related genes. iii) Myelin specific genes (MAG, CNP, Sox10 and CLDN11), OLG progenitors (PDGFRA and CSPG2) and astrocyte marker, ALDH1L1, were significantly downregulated in frontal cortex of adult NEAT1 KO mice. Neuronal ENO2, or a microglia-specific marker, CD86 were unchanged. These findings suggest strong involvement of NEAT1 and paraspeckle protein PSPC1 in oligodendrogenesis including early development and throughout the lifespan and bring into prominence the role of paraspeckles and NEAT1 in the pathophysiology of SZ.

Title: Using IntelliCage to study alcohol drinking behavior in mice

Authors: *M. VEREMIEVA[1], T. PIEPPONEN[2], J.-O. ANDRESSOO[1], V. VOIKAR[3], M. AIRAVAARA[1];
[1]Inst. of Biotech., [2]Fac. of Pharm., [3]Neurosci. centre, Univ. of Helsinki, Helsinki, Finland

Abstract: Background: Ethanol is the most widely misused abused substance leading to alcohol-related disorders. A big challenge in a treatment of alcohol addiction is relapse that can occur even after long period of abstinence. Unlike in rats, mouse models of alcohol craving are not well established and the number of gene manipulated mouse strains offers the possibility for investigating biology of alcohol craving. We aimed at developing a novel model of alcohol craving in mice in the group housed environment with minimal handling by human during experiment. Methods: C57BL/6 mice were used and individually recognized in the IntelliCage by subcutaneously implanted transponders. The mice were placed into IntelliCages in groups of 8-10 and had access to either 12% ethanol in 0.5% of saccharin, 12% ethanol, or 0.5% saccharin and water. In the training phase, the mice had access to bottles in two corners of the cage. One side of the corner contained CS+ treatment and the other side water. Nosepoke to CS+ side was signaled by green light (conditioned stimulus). Training lasted for 10 days and then the mice were transferred to regular cages. After withdrawal period (1-10 days) the experimental procedures were the same, but there was no liquid available. Results: During alcohol drinking training the number of visits was increased in alcohol+saccharin group and decreased in alcohol group as compared to control (water only) group. The number of nosepokes was increased in alcohol+saccharin group during the 10-day training compared to any other group. The number of licks was higher in saccharin group in comparison to alcohol, alcohol+saccharin and water groups. After withdrawal the number of nosepokes in correct corner and number of conditioned licks were higher only in alcohol+saccharin group on both withdrawal days 1 and 10. Conclusion: The mice did not develop high voluntary preference for alcohol in home-cage and social environment. However, increased activity in the corners with light signal and especially distinct changes after withdrawal period suggest development of alcohol craving. Moreover, only sweetened alcohol produced significant craving after withdrawal. In conclusion, new methodology will give us an opportunity to study alcohol drinking behavior and alcohol craving after withdrawal in mice in automated and time saving manner.

Title: Ethanol self-administration and decision making in a free reward choice task in the rat

Authors: J. J. MCGRAW[1], L. C. ZONA[2], *H. C. CROMWELL[1];
[1]Bowling Green State Univ., Bowling Green, OH; [2]Bowling Green State Unviersity, Bowling Green, OH

Abstract: Drinking alcohol can affect many aspects of decision making. Discriminating and choosing between reward outcomes, developing preferences, and updating reward information that is susceptible to change (i.e., incentive contrast; Flaherty, 1996) are important processes of choice behavior that have been studied using animal models of decision making. For example, alcohol exposure has been known to alleviate negative contrast caused by downshifts in sucrose reward (Becker & Flaherty, 1982). However, the long-term effects of alcohol on incentive contrast in accordance with other measures of motivation have not been investigated. Previous studies have used reward discrimination tasks such as mazes and runways and operant tasks such as lever pressing to study reward-based decision making. Despite success, these traditional methods rely heavily on learning, offer limited space, and force behavior which restricts the ability to make choices based solely on reward outcomes. Our paradigm examines the effect of a history of voluntary alcohol consumption on free reward choice in a novel apparatus and how reward processing may be altered by chronic self-administration of alcohol by rats. A novel 3-box design was used to assess how these components of decision making may interact to motivate unrestricted choice behavior in rats. The present study investigated acute and chronic effects of alcohol on normal outbred Sprague-Dawley rats trained to drink moderate amounts of alcohol voluntarily for a chronic period concurrent with 6 weeks of behavior testing. We offered two different reward outcomes each week to examine how behavior toward changing reward scenarios is impacted by a history of alcohol consumption. A modified sucrose-fade procedure was used to establish significant and consistent voluntary consumption of 10% alcohol over a period of 8 weeks. During the first 3 weeks of testing, alcohol rats consumed less sugar pellets and spent less time in reward boxes than controls. During the second 3 weeks, alcohol rats preferred constant over variable rewards and extinguished faster than controls. However, both groups displayed similar contrast effects for average pellets consumed during testing, indicating that voluntary alcohol consumption did not impact the ability to shift to optimal rewards. Our results suggest that alcohol consumption devalues reward outcomes, promotes preference for reliable rewards, and does not affect optimal reward-based decision making over time. Future work should further investigate how voluntary alcohol consumption may alter reward seeking, intake, and memory.

Title: Insular cortex and alcohol consumption: neurons encode reward expectancy during a operant conditioning task

Authors: ***S. VICENCIO**[1], M. AGUILAR[2], P. MALDONADO[1];
[1]ICBM, Fac. of Medicine, Univ. De Chile., Santiago, Chile; [2]Bioengineering, Univ. of California, San Diego, CA

Abstract: Drug dependent individuals present altered internal body states which leads to the increase of the drug's motivational effects, such as drug craving, thereby incrementing the risk of drug use. Because the insular cortex (IC), the highest structure in the interoceptive system, has been proposed as a region that integrates internal bodily states into decision-making processes involving rewards1, we examined the neuronal activity of IC in rats during an alcohol-craving paradigm.We designed an operant conditioning task that allowed us to perform single unit recordings at the IC while the rats were anticipating and also consuming a reward. Operant responding for ethanol was initiated by means of a sucrose solution substitution procedure. Afterwards, the animals were trained daily to respond for ethanol (10% w/v) or water under a two-lever free-choice paradigm. Then, animals learned to respond for a series of three light cues: the first indicated the trial start, the second showed which lever would be available (water or ethanol) and the third signaled the moment to start pressing the lever to obtain the reward. Over time, the rats developed a preference for ethanol over water and consumed enough ethanol to produce pharmacologically relevant blood alcohol concentrations. We recorded 120 single units from IC of three rats. We found that IC neurons display an increment in their firing rate when rats were expecting to receive ethanol and a decrease in the firing rate during the consumatory phase. These changes were no observed in omitted trials. These results suggests that the IC are directly involve in the neural representation of the emotional content of reward expectancy and also suggest that such changes in firing could reflect drug craving and its relief. Title: Inactivation of CeA neuronal ensembles prevents alcohol drinking in dependent and non dependent rats

Authors: *G. DE GUGLIELMO[1], B. HOPE[2], O. GEORGE[1];
[1]Committee on the Neurobio. of Addictive Disorder, The Scripps Res. Inst., La Jolla, CA;
[2]Neurobio. of Relapse Section, Natl. Inst. on Drug Abuse, Natl. Inst. of Hlth., Baltimore, MD

Abstract: Withdrawal from alcohol is associated with the recruitment of neurons in the central nucleus of amygdala (CeA) in rats binge-drinking on alcohol (non-dependent) as well as in dependent rats. However, whether the recruitment of this withdrawal neuronal ensemble in the CeA is causally related to excessive drinking or represents a consequence of the excessive drinking remains to be demonstrated. Here we tested the hypothesis that inactivation of the withdrawal neuronal ensemble in the CeA is responsible for the excessive alcohol drinking observed in non-dependent binge drinking rats and in dependent rats. In order to test our hypothesis we investigated the effect of the inactivation of neuronal ensembles in the CeA using a pharmacogenetic approach (Daun02 inactivation method in Fos-Lac Z transgenic rats). One group of rats was made dependent using chronic, intermittent exposure to alcohol vapor and tested for alcohol drinking in 30 minutes session 6-8 hours into withdrawal. In a second group of animals (non-dependent binge-drinker) we tested the effect of Daun02 on ethanol intake using chronic intermittent access to two-bottle choice. We found that inactivation of neuronal ensembles by injection of Daun02 in the CeA significantly decreased alcohol drinking in both groups with the only difference that in non-dependent animals the decreased ethanol intake was transient the day of the injection and returned to normal the day after the injection, while in the

dependent animals inactivation of the withdrawal neuronal ensemble produced a long-term decrease in alcohol drinking that lasted at least 2 weeks. We also found a significant reduction of the somatic withdrawal signs in the dependent animals injected with Daun02 in the CeA. These results demonstrate that the recruitment of a neuronal ensemble in the CeA during alcohol withdrawal is causally related to the excessive alcohol drinking observed in alcohol dependent rats but that this withdrawal neuronal ensemble only partially contributes to alcohol drinking in non-dependent rats.

Title: The role of the ventral hippocampus in ethanol drinking and glutamate release in the nucleus accumbens

Authors: *W. C. GRIFFIN, III[1], H. L. HAUN[2], L. N. LUDERMAN[2], K. E. KOCH[2], M. KATES[2], H. A. BOGER[3], H. C. BECKER[2];
[2]Charleston Alcohol Res. Ctr, Psychiatry and Behavioral Sci., [3]Neurosciences, [1]Med. Univ. South Carolina, Charleston, SC

Abstract: Glutamatergic transmission within the nucleus accumbens (NAc) is important for regulating ethanol drinking and an important source of glutamate in the NAc is the ventral hippocampus (vHipp). The current study tested the hypothesis that the ventral hippocampus (vHipp) regulates ethanol drinking and contributes to glutamate release in the NAc. AAV containing inhibitory DREADDs under control of a synapsin promoter were infused into the vHipp. After 2 weeks of recovery, mice were habituated to injections and trained to drink ethanol in the binge-like drinking-in-the-dark paradigm. Systemic challenge (IP) with clozapine-N-oxide (CNO; 3 mg/kg) or vehicle (VEH; 0.9% saline) 30 min before ethanol access produced a 54% reduction in ethanol drinking versus the vehicle challenge (5.3 ± 0.7 g/kg vs. 2.9 ± 0.3 g/kg; $p < 0.05$). In a separate group of mice, following infusion of the inhibitory DREADDs into the

vHipp, *in vivo* electrochemistry procedures were performed to measure glutamate release in the NAc before and after CNO challenge. Mice where anesthetized using urethane (1.5 g/kg), placed in a stereotaxic apparatus and an enzyme-coated probe was lowered into the NAc. Once the probe stabilized (~1 hr), glutamate release was evoked by focal application of 70 mM KCl every 10 min, 4 times. Next, CNO (3 mg/kg) was injected and 30 min later glutamate release was measured again. Inactivating the vHipp to NAc projection neurons significantly reduced stimulated glutamate release ~40% (1.2 μM vs. 0.75 μM; $p < 0.05$). These data indicate that the vHipp to NAc projections play an important role in glutamate release in the NAc and, further, the vHipp contribute to the regulation ethanol drinking. Ongoing work is evaluating the influence of activating this pathway on ethanol drinking and glutamate release in the NAc.

Title: Evaluating the reward- enhancing effects of nicotine on ethanol self-administration in male and female rats

Authors: *S. BARRETT, S. LYON, S. PITTENGER, N. DUSZENKO, O. LOH, R. A. BEVINS;
Univ. of Nebraska - Lincoln, Lincoln, NE

Abstract: Nicotine and alcohol dependence disorders are highly correlated: up to 80% of alcohol-dependent persons in the US smoke regularly, and risk of alcohol-dependence is four times higher among people who are nicotine-dependent. Additionally, there are significant differences in the prevalence and nature of nicotine- and alcohol-dependence between the sexes. Women, on average, are less likely to attempt to quit smoking and more likely to relapse after quitting. Additionally, women show greater sensitivity to the intoxicating effects of alcohol, slower metabolism of alcohol, and greater risk for adverse health consequences alcohol use. However, binge drinking and alcohol-dependence is more common among men than women. Understanding the behavioral mechanisms that underlie alcohol- and nicotine-dependence and

their high comorbidity will require a consideration of the multifaceted causes that include an individual's sex. There is mounting evidence that the reward-enhancing properties of nicotine synergistically enhances behavior directed at obtaining other rewards, and this reward-enhancement effect holds promise in deciphering the mechanisms that drive nicotine dependence. That is, nicotine administration that occurs in the same context as the reception of other rewarding stimuli may enhance their rewarding properties, and this enhancement may drive motivation to abuse nicotine. However, no published work to date as investigated the role that reward-enhancement may play in the comorbidity between nicotine- and alcohol-abuse. The present work investigated the role that reward-enhancement by nicotine plays in the comorbidity of nicotine- and alcohol-abuse using an operant ethanol self-administration procedure in male and female rats. Rats were trained to self-administer 15% ethanol using a sucrose fading procedure. Nicotine or saline was injected 10 min preceding 45 min ethanol self-administration sessions. Over blocks of sessions, the unit cost per gram ethanol was systematically examined across two separate reinforcer demand assessment phases: fixed-ratio schedule escalation and ethanol concentration reduction. A behavioral economic, reinforcer demand model was applied to the data from both unit cost manipulation phases and the effects of nicotine on ethanol reinforcement value were compared between the sexes and between unit cost manipulation procedures.

Title: The effect of environmental enrichment on behavioral economic demand for ethanol and sucrose in Long-Evans rats

Authors: M. R. FARRELL, L. LANSBERRY, R. CAUGHRON, *M. P. MARTINETTI; Dept Psychol, The Col. of New Jersey, Ewing, NJ

Abstract: The literature on environmental enrichment (EE) and ethanol (EtOH) oral self-administration has revealed inconsistent results in animal models, with studies reporting that EE increases, decreases, or has no effect on EtOH consumption. Although these studies have addressed the effects of EE on EtOH preference, it is unclear whether EE affects the reinforcing

efficacy of EtOH. In a behavioral economic analysis, reinforcing efficacy can be defined as demand, or the extent to which EtOH consumption is "defended" when its price is increased. Demand analyses have been widely applied to the study of alcohol and drug self-administration in both human and animal models. Two key demand metrics include intensity of demand (i.e., consumption as price approaches zero) and sensitivity to price, or the degree to which consumption decreases when prices are increased. The current study assessed the effect of EE on behavioral economic demand for EtOH and sucrose in randomly bred rats. Sixteen male Long-Evans rats were randomly assigned to an EE group (housed with crinkle paper) or a control (Ctrl) group (no crinkle paper). All animals were trained to lever press for 10% EtOH (v/v) using a modified sucrose-substitution procedure. Thereafter, delivery of EtOH and concurrent 1% (w/v) sucrose solutions was contingent upon responding on concurrent fixed-ratio (FR) 4 schedules of reinforcement. After stable responding for EtOH and sucrose solutions was established, the FR value, or "price," of each of the solutions was independently increased (FR4, 8, 16, 32) every six sessions while the price of the alternative remained at FR4. In two control conditions, the price of each reinforcer was increased with water concurrently available on an FR4 schedule. The exponential demand equation (Hursh & Silberberg, 2008) was fitted to the behavioral economic demand data (mean reinforcer deliveries at each price) for each set of price manipulations and each group (EE and Ctrl). We found that rats in the EE condition demonstrated greater sensitivity to increases in EtOH and sucrose prices, across all conditions, compared with the Ctrl rats. In addition, EE rats demonstrated lower intensity of demand for sucrose compared with the Ctrl rats, but only when sucrose was concurrently available with water. These results suggest that EE reduces the reinforcing efficacy of both EtOH and sucrose as assessed in a behavioral economic paradigm.

Title: Efficacy of delta opioid receptor agonist induced β-Arrestin 2 recruitment positively correlates with alcohol intake in mice

Authors: *T. CHIANG[1], K. SANSUK[2], R. M. VAN RIJN[2];
[2]Medicinal chemistry and molecular pharmacology, [1]Purdue Univ., West Lafayette, IN

Abstract: The delta opioid receptor (DOR) is a member of the opioid receptor family that is known to be involved in many different physiological responses such as pain transmission, ischemic protection, depression and drug abuse. As suchTherefore DOR agonists are being developed as for therapeutic use, and some are already in clinical trials. However, no DOR selective agonist has currently received approval by the Federal Drug Administration nor has one even entered phase III clinical trials, which suggests perhaps the pharmacology is not fully understood. While most DOR agonists that have been studied are able to reduce depression-like behavior, we have previously shown that DOR agonists vary widely in their ability to modulate alcohol intake. More precisely some agonists decrease alcohol intake but other agonists can actually increase alcohol consumption. This would be a serious potential adverse effect for DOR agonist under development. This Sseemingly paradoxical behavior may be explained by the differences in receptor signaling bias. Here, we propose that DOR agonists that increase alcohol intake have different binding preference for β-arrestin 2 than those DOR agonists that decrease alcohol intake. To test our hypothesis we used two previously studied DOR agonists TAN-67 and SNC80, as well as four novel DOR agonists: two SNC80-like agonists (SNC162, AR-M390) and two agonists that do not structurally resemble SNC80 (KNT127, and NIH11082). We measured the ability of these agonists to inhibit cAMP and recruit β-arrestin 2 *in vitro* and we also determined how these agonist modulate alcohol intake in C57BL/6 mice using a voluntary, limited access 2-bottle choice paradigm. We found that there is a positive correlation between the efficacy of β-arrestin 2 recruitment by DOR agonists and alcohol intake in mice. More specifically, we found that 'super β-arrestin2 recruiters' increased alcohol intake and that super recruiters are dependent on β-arrestin 2 to function both with regard to alcohol behaviors and for their anti-depressant-like behaviors. These findings hold importance in future DOR agonist development for treatment for alcohol use disorders and depressive disorders.

Title: Intravenous caffeine increases oral ethanol self-administration in rats

Authors: E. WILLIAMS, C. N. SWYMER, M. R. KELLICUT-JONES, A. M. BROWN, C. A. BRADLEY, *M. I. PALMATIER;
East Tennessee State Univ., Johnson City, TN

Abstract: In recent years, caffeinated alcoholic beverages have risen in popularity. These combination beverages increase binge drinking, an effect that has been attributed to a reduction in the hypnotic (sleep-inducing) effects of alcohol. However, in our laboratory, we have shown that caffeine enhances the motivation to obtain non-drug rewards such as sucrose and saccharin (sweet tastes). Others have shown that caffeine can increase the reinforcing effects of cocaine. Since no previously published study has demonstrated that caffeine self-administered alone serves as a primary reinforcer (increases operant responding) we investigated whether caffeine infusions delivered in conjunction with oral alcohol could increase alcohol self-administration. Twenty male Sprague-Dawley rats were randomly assigned to one of three groups that received different combinations of oral and IV reinforcers (EtOH+SAL, EtOH+CAFF, or H2O+CAFF). EtOH denotes 20% (v/v) ethanol available orally, via a liquid dipper delivery system (0.1 mL); H2O denotes oral water; CAFF denotes IV infusions of caffeine, and SAL denotes isotonic saline infusions. Rats were initially shaped to respond for the oral reinforcer under a fixed ratio 2 (FR2) reinforcement schedule; after stable responding was observed they were instrumented for IV infusions. In subsequent tests, the assigned infusion (CAFF or SAL) was delivered each time a rat earned an oral reinforcer (EtOH or H2O). Caffeine infusions (0.05-0.4 mg/kg/ing) increased operant responding for alcohol in the EtOH+CAFF group, relative to the EtOH+SAL group in a dose dependent manner. Caffeine dose was inversely related to operant responding, with the lowest dose tested (0.05 mg/kg/inf) producing the most robust increases in responding. Rats were subsequently shifted to a progressive ratio (PR) reinforcement schedule which measures motivation by increasing the amount of effort required to earn each reinforcer. The EtOH+CAFF group reached a significantly higher breaking point than the other two groups at the 0.1 mg/kg/inf dose. These findings implicate the reward-enhancing effects of caffeine in the binge-intoxication associated with caffeinated alcoholic beverages.

Title: Oxytocin reduces binge-like alcohol drinking

Authors: C. E. KING[1], L. N. LUDERMAN[1], W. C. GRIFFIN[1], J. F. MCGINTY[2], *H. C. BECKER[3];
[1]Charleston Alcohol Res. Ctr, Psychiatry and Behavioral Sci., [2]Neurosciences, [3]Charleston Alcohol Resch Ctr., Med. Univ. South Carolina, Charleston, SC

Abstract: Accumulating evidence demonstrates a role for the neuropeptide oxytocin (OXT) in modulating drug-taking behavior. Specifically, studies have shown that administration of OXT decreases alcohol (ethanol), opiate, and methamphetamine self-administration, and prevents the development of tolerance and withdrawal symptoms to these drugs. The present study was designed to extend these findings by examining the effects of OXT on binge-like ethanol consumption using the drinking-in-the-dark (DID) model.. Adult male C57BL/6J mice were presented in the home cage with a single bottle of 20% (v/v) ethanol in place of water starting 3 hours into the dark cycle. In this 4-day paradigm, the ethanol access period was for 2 hr/day for three consecutive days and extended to 4 hr/day on the final (fourth) day. Vehicle injections (IP) were given 30 min prior to each of the first three drinking sessions in order to acclimate mice to the injection. On Day-4, mice were administered OXT (0, 0.3, 1, 3, or 10 mg/kg) 30 min prior to the test session. Results indicate that OXT reduced ethanol intake in a dose-related manner, with maximal reduction (~50% reduction) produced by 3 and 10 mg/kg OXT doses ($p < 0.001$). Separate studies using lickometer circuitry to track temporal patterns of drinking indicated that OXT produced a significant delay in onset of drinking and assessment of open-field locomotor activity indicated that the reduction in drinking is not simply due to impaired locomotion. Next, we examined whether blockade of the oxytocin receptor antagonized oxytocin's effects on ethanol consumption. Prior to drinking, mice were administered a selective oxytocin receptor antagonist L368,899 (0,1,3, 10 mg/kg) followed by injection of OXT (1 mg/kg) or saline. Results indicated that the oxytocin-induced reduction in drinking was blocked by the 10 mg/kg dose of the oxytocin receptor antagonist L368,889. Taken together, these data suggest a role for oxytocin, mediated through the oxytocin receptor, in binge-like ethanol consumption. Studies are underway to investigate the potential role of vasopressin (V1b) receptor blockade in mediating oxytocin's effect on binge-like ethanol consumption.

Title: Effects of ghrelin antagonist D-Lys3-GHRP-6 on alcohol consumption may be mediated by the Urocortin 1 peptide

Authors: *J. L. GOMEZ, A. E. RYABININ;
Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Heavy alcohol consumption has many deleterious effects on behavior and physiology and animal models such as mice are useful to test mechanisms regulating alcohol intake and dependence. These studies have led to novel theories on mechanisms that attribute to alcohol dependence and possible treatments using behavioral and pharmacological strategies. A number of recent studies have pegged the ghrelin system as a contributor of alcohol drinking in both human and rodent models, and ghrelin antagonists are a promising treatment to decrease alcohol abuse. Similarly, Urocortin 1 (UCN1), a peptide of the corticotropin releasing family, has been implicated in regulation of alcohol drinking in mouse studies. UCN1 is preferentially expressed in the centrally-projecting Edinger-Westphal nucleus of the brain. This nucleus also expresses high levels of ghrelin receptors. It is possible, therefore, that UCN1 and ghrelin regulate alcohol consumption through overlapping mechanisms. In the current experiment we used female wild-type (WT) and knockout (KO) UCN1 mice to examine the effects of a ghrelin receptor antagonist D-Lys3-GHRP-6 (DLys) on alcohol drinking over 7 days. Following baseline acquisition of alcohol intake mice were injected daily with DLys (15 mg/kg) beginning at lights off and presented with 10% v/v ethanol in a 24-hour two-bottle choice procedure. Alcohol, preference, water, and food intake was measured 4- and 24-hours post-injection. At the onset of drug administration, DLys reduced alcohol intake in wild-type, but not KO mice. This decrease diminished following 2-3 days of administration. The reduction in alcohol intake was accompanied by a reduced preference for alcohol in the DLys group, but again this was only present in WT mice, not KO. Generally, DLys increased water intake, but only 4-hours post-injection, and had no effect on food intake. The effects seen in the female WT mice are similar to those previously found in our lab in male C57BL/6J mice. However, in the current study DLys-

induced reduction of alcohol intake was still present at 24-hours, a result not seen in males. Given the effects of DLys were present in WT, but not KO mice, we hypothesize that ghrelin (in part) works through the UCN1 system to mediate alcohol intake in female mice. Future studies need to further investigate interactions of between the UCN1 and ghrelin systems.

Title: Ketamine reduces alcohol intake in olfactory bulbectomized rats

Authors: J. KUCEROVA[1,2], Z. BABINSKA[1,2], *Y. TIZABI[3];
[1]Pharmacol., Fac. of Medicine, Masaryk Univ., Brno, Czech Republic; [2]Central European Inst. of Technol., Brno, Czech Republic; [3]Pharmacol., Howard Univ. Col. Med., Washington, DC

Abstract: The co-morbid condition of depression and alcoholism is a well-established epidemiological finding. Although the exact cause-effect of this phenomenon is not at hand, it is known that high consumption of alcohol can lead to numerous neurochemical alterations that can precipitate depressive-like behavior. On the other hand, initial low or moderate alcohol intake may result in euphoric or dissociative feelings and hence may be used to counteract the low mood. However, regardless of this initial effect, such self-medication by alcohol may lead to rapid tolerance and eventual exacerbation of the depressive characteristics. Indeed, mood dysregulation following abrupt alcohol withdrawal may be a common cause for relapse to alcoholism. Ketamine, an NMDA receptor antagonist with potent dissociative anesthetic properties has been shown to have rapid and lasting antidepressant effects. The two major goals of this study were: 1. To determine whether olfactory bulbectomized rats, a putative animal model of depression, will consume more alcohol, and 2. If so, whether an acute administration of ketamine to such animals would reduce their alcohol intake. The results indicate that bulbectomized (OBX) adult male Wistar rats consumed significantly more alcohol during the entire 3-week period compared to the sham-operated controls. Moreover, intraperitoneal administration of a low ketamine dose of 5 mg/kg 20 min prior to the alcohol session dramatically reduced the amount of alcohol consumed by these OBX animals in terms of actual

amount and % of baseline intake. Interestingly, the same ketamine dose also reduced the % of baseline alcohol intake in sham-operated animals. These results indicate that depressive mood can lead to higher alcohol consumption and that a novel antidepressant such as ketamine could mitigate alcohol intake in such depressive-like conditions. However, since ketamine also had an effect on alcohol intake in sham-operated animals, it remains to be determined whether the effect of ketamine on alcohol consumption is solely due to its antidepressant properties, or may also arise from some other pharmacodynamic interactions with alcohol. Title: Moxidectin alters dopamine levels and reduces ethanol intake in female mice: implications for developing novel therapeutic agents for alcohol use disorder

Authors: N. HUYNH[1], N. ARABIAN[1], J. THUY[1], H. PEI[1], L. ASATRYAN[1], S. LOUIE[1], M. JAKOWEC[2], *D. L. DAVIES[1];
[1]Titus Family Dept of Clin. Pharm., [2]Dept. of Neurol., USC, Los Angeles, CA

Abstract: Considerable efforts have been put forth on drug development for alcohol use disorder (AUD) which has yielded limited success. Currently, there are only three FDA-approved medications for the treatment of AUD. Unfortunately, high rates of uncontrolled heavy drinking continue to persist highlighting the needs for the development of new and effective medications for AUD. Our approach has focused on repurposing ivermectin (IVM), an FDA-approved drug for the treatment of onchocerciasis, as a novel pharmacotherapy for AUD. Preclinically, IVM significantly reduces acute and longer term ethanol intake in mice. Despite promise, IVM's weak blood brain (BBB) penetration may limit its utility as a long-term treatment for AUD. As such, we have started testing another avermectin, moxidectin (MOX) for use against AUD. MOX has superior BBB penetration compared to IVM and may represent another pharmacotherapy for

AUD. The present study tested the effects of MOX administered for 5 days using a 24-h-two-bottle choice paradigm, where mice had continuous access to both 10% ethanol v/v solution and water, and also using a Drinking-in-the-Dark paradigm, where mice had 2 hours access to 20% ethanol v/v solution during the dark phase resulting in consumption of high levels of ethanol similar to what is reached in humans while binge drinking. In both paradigms, we found that 2.5 mg/kg MOX significantly reduced ethanol intake in female C75BL/6 mice across the five days. Importantly, the mice exhibited no signs of overt toxicities. In addition, changes in dopamine levels were identified using HPLC method at the end of day one and day five in the prefrontal cortex and nucleus accumbens for MOX treated mice vs. saline controls suggesting the ability of MOX to modulate mesolimbic dopamine activity. These findings, coupled with our previous work on IVM, suggest that avermectins may represent a new class of compounds that can be developed as novel therapeutics for AUD. Title: Mechanical stimulation of the HT7 acupuncture point reduces ethanol self-administration in rats

Authors: *S.-Y. KANG, Y. RYU, O. KWON, S. YEON, S. CHO, K.-H. CHOI, J. KIM, M. KIM, Y. SHIN, J.-W. CHOI;
Korea Inst. of Oriental Med., Daejeon, Korea, Republic of

Abstract: Background: Alcoholism, a disabling addiction disorder, is a major public health problem in the U.S. and worldwide. Acupuncture has been shown to alleviate various drugs of abuse, including alcohol. The present study was designed to determine whether the application of acupuncture at Shenmen (HT7) points suppress voluntary alcohol consumption in the rats and whether this suppressive effect is potentiated by administration of naltrexone, the clinically approved medication for alcoholism in combination with acupuncture. Methods: Rats were initially trained to self-administer a sucrose solution (20% w⁄v) to facilitate operating lever. After stable baseline responding was established, the sucrose concentrations were gradually

decreased to 0% and ethanol concentrations were increased to 10%. After rats showed stable responding for 10% ethanol and met an established criterion for ethanol baseline responding, behavioral testing was initiated. A mechanical acupuncture instrument (MAI) for objective mechanical stimulation was given to rats whose baseline responding had been determined prior to the test session. Additionally, the effects of naltrexone (0.1, 0.3, 1, 3mg／kg) on ethanol self-administration were investigated in different groups of rats. Results: We found that the ethanol intake in rats under the application of MAI at HT7, but not Joksamli (ST36) and tail point were significantly reduced. Whereas the treatment of naltrexone at high dose (1, 3mg/kg) significantly reduced ethanol intake, low dose of naltrexone (0.1, 0.3mg/kg) did not produce any reducing effect. Especially, low-dose injection of naltrexone in conjunction with MAI synergistically suppressed ethanol intake. Conclusions: The results of current study indicate that MAI at HT7 effectively reduces ethanol consumption in rats. Furthermore, co-administration of MAI and low-dose naltrexone can produce more potent reducing effect of ethanol intake than one treatment, indicating a potential novel strategy for the management of alcoholism.

Title: The effects of brief conditioning trial duration on ethanol-induced conditioned place preference in mice

Authors: E. M. JOHNSON, *S. D. DICKINSON;
Psychology and Neurosci. Program, St. Olaf Col., Northfield, MN

Abstract: Previous studies have demonstrated that the timing of ethanol administration relative to cue exposure (CS) can affect the outcome of place conditioning in mice. If ethanol is administered before exposure to a floor CS, a preference is developed, whereas if ethanol is administered after or during exposure to the floor CS, an aversion is developed (Cunningham et al., 1997, 2000, 2003). To explain these findings, Cunningham has proposed a biphasic motivational response whereby ethanol administration results in a short-lived aversive effect followed by an enduring rewarding effect. In an attempt to measure this brief aversive phase, we examined the effects of a brief conditioning trial duration on conditioned place preference. A

place conditioning procedure was used in which adult male DBA/2J mice were exposed to 4 pairings of 2 g/kg ethanol with a distinctive floor stimulus. Saline was administered on alternate days and paired with a different floor. Conditioning trials lasted 1 or 5 minutes and the experiment concluded with four 60-minute floor preference tests 1, 3, 8, and 10 days after the final conditioning day. Contrary to what would be predicted if ethanol injection has an initial, aversive motivational effect, mice in the 1 min trial group demonstrated conditioned place preference after 4 trials, as did mice receiving our standard 5 min trials. Additionally, we found no difference in the strength of learning between groups; there was no difference in magnitude of preference and preference was extinguished at approximately the same rate in 1-min and 5-min trial groups over multiple drug-free preference tests. Thus, these findings suggest that the rewarding effects of ethanol develop within the first minute after injection and do not support the biphasic motivational response theory. Strikingly, four 1-minute pairings of 2 g/kg ethanol with a floor cue produced a preference that persisted through more than two hours of drug-free preference tests. Further research is needed to explain why ethanol administration after cue exposure results in a conditioned place aversion.

Title: Potential roles of the nucleus accumbens and amygdala mGluR5 in the acquisition and expression of ethanol-induced place preference

Authors: J.-Y. LEE[1], *S. YOON[2], J.-W. SEO[1];
[1]Res. Ctr. for Safety Pharmacol., [2]Korea Inst. of Toxicology, Daejeon, Korea, Republic of

Abstract: We have previously demonstrated that the type 5 metabotropic receptor (mGluR5) attenuated the rewarding effects of ethanol. Here we investigated functional roles of mGluR5 in the nucleus accumbens and the amygdala on the acquisition or expression of ethanol conditioned place preference in mice. In the first set of experiment, mice were intraperitoneally conditioned

with saline or ethanol (20% v/v, 1.5 g/kg) on alternating days for 8 consecutive days and received local injection of the mGluR5 antagonist MPEP into the nucleus accumbens or the amygdala immediately before ethanol conditioning. Result showed that 1.5 g/kg ethanol alone did not induced ethanol place preference, whereas inactivation of mGluR5 receptors produced by MPEP enhanced conditioned rewarding effects of ethanol. These results indicate that activation of mGluR5 plays a significant role in inducing conditioning rewarding effects of ethanol. In the second set of experiment, mice were conditioned with saline or ethanol (20% v/v, 2.0 g/kg). After ethanol conditioning, MPEP was administered into the nucleus accumbens or the amygdala prior to the post-conditioning. Results showed that pretreatment with MPEP reduced the expression of ethanol-induced conditioned place preference. Taken together, these data suggest that pharmacologically blockade of the mGluR5 in the nucleus accumbens and the amygdala differentially affect the acquisition and expression in the condition place preference of ethanol. *Supported by a grant (14182MFDS979) from Ministry of Food and Drug Safety in 2015 and Korea Institute of Toxicology (KK1512-02).*

Title: Role of projections from dorsal medial prefrontal cortex to nucleus accumbens core in context-induced reinstatement of ethanol seeking

Authors: *P. C. BIANCHI[1], R. M. LEÃO[1], P. E. CARNEIRO-DE-OLIVEIRA[1], F. C. CRUZ[2], C. PLANETA[1];
[1]PANT, UNESP - State Univ. of São Paulo, Araraquara, Brazil; [2]Physics Inst. of São Carlos (IFSC), USP - Univ. of São Paulo, São Carlos, Brazil

Abstract: In human addicts, relapse is often precipitated by re-exposure to environmental contexts that were previously associated with drug use. Specific patterns of sparsely distributed neurons, called neuronal ensembles, have been hypothesized to encode learned associations

between drug-associated contexts and drug effects. Male and Female Long Evans rats were trained to self-administer ethanol 10% (1h/day for 14 days). Drug infusions were paired with a discrete tone-light cue. Subsequently, lever responding was extinguished over 10 days in the presence of the discrete cue in a non-ethanol context with different sensory features than the drug self-administration context. Rats were then re-exposed to the ethanol-associated context (or the non-drug extinction context as the control condition) and lever pressing was assessed under the same extinction conditions for 60 min as a measure of ethanol seeking. Neuronal ensembles in dorsal medial prefrontal cortex that were activated during context-induced reinstatement were identified using Fos immunohistochemistry. We also determined the proportion of dorsal medium prefrontal cortex (dmPFC) neurons expressing Fos during the reinstatement test by double-labeling Fos and the neuron-specific protein marker (NeuN). Reexposure to the ethanol-associated context reinstated alcohol seeking (active lever presses: 16.61 ± 2.59, extinction context and 34.78 ± 6.32, training context; n=14 per group) and increased expression of the neural activity marker Fos in the dorsal medial prefrontal cortex (fos/mm2 - extinction context: 38,9 ± 6,6 n=6 and training context: 60,6 ± 9,3; n=5). Double-labeling for Fos and NeuN indicated that in the dmPFC, only a small proportion of neurons were activated during context-induced ethanol seeking (5,6 ± 0.86% in the extinction context and 6,4 ± 0.4% in the training context). Conclusions: Our results showed context-induced alcohol seeking correlated with activation of dmPFC. Future experiments: We will analyze by double-labeling for Fos and NeuN immunohistochemical detection the neural activation in the accumbens (Acc) core. Furthermore, we will determined neuronal activation in Acc core brain area projecting to dmCPF during etanol context-induced tests by measuring double labeling of the retrograde tracer cholera toxin subunit B (CTb; injected in Acc core) with Fos.

Title: Decreased neurogranin in the nucleus accumbens promotes the reward motivation and reinforcement for ethanol seeking

Authors: *H. NAM[1], J. M. SULLIVAN[1], O. ALFREDO[2], D. J. HINTON[2], D.-S. CHOI[2]; [1]Pharmacology, Toxicology, and Neurosci., LSU Hlth. Sci. Center-Shreveport, Shreveport, LA; [2]Mol. Pharmacol. and Exptl. Therapeut., Mayo Clin. Col. of Med., Rochester, MN

Abstract: Striatal glutamate signaling has been implicated in the pathophysiology of neurological disorders and alcoholism. NMDA glutamate receptors play an essential role in both reward motivation and seeking behaviors, but its intracellular target is not well studied. Neurogranin (Ng) is predominantly expressed on the postsynaptic dendrite and is an intracellular target of NMDAR signaling, however, evidence for the role of Ng signaling in alcohol related behaviors have not yet been established. In the present study, we identified that the dampening of NMDAR-Ng signaling enhances the reward motivation during Pavlovian conditioning and promotes excessive ethanol seeking during operant conditioning, while also increasing sensitivity to ethanol intoxication. We found that the lack of Ng in the nucleus accumbens (NAc) increases intrinsic motivation and insensitivity to aversive effects of reinforcement during ethanol seeking behaviors. Ng -/- mice also show enhanced motivation measured by a progressive ratio schedule (PR) schedule, while Ng +/+ mice showed significant increased response by NAc specific optogenetic stimulation. Finally, we demonstrated that chronic ethanol administration could reduce both the length of axons and mGluR5 expression in the NAc, which promotes excessive ethanol drinking in Ng -/- mice. Our results indicated that Ng is a key determinant in the postsynaptic intracellular mechanism resulting from NMDAR and is associated with a higher susceptibility of enhanced reward motivation for excessive ethanol drinking.

Abstract: Alcohol is one of the most widely abused drugs in the United States and relapse presents a considerable challenge for recovering alcoholics. Relapse is often driven by alcohol-associated cues that trigger craving even after extended abstinence. Reducing the probability of relapse in alcoholics will require a better understanding of the neurobiology that mediates these behaviors. Previous research has focused on the regulation of alcohol seeking by limbic-striatal circuitries - especially basolateral amygdala (BLA) and nucleus accumbens shell (NAcS). However, the functional regulation of these circuits by the medial prefrontal cortex (PFC) has received little investigation. We previously used a contralateral lesion strategy to functionally disconnect infralimbic PFC (ilPFC) from NAcS and BLA to assess the necessity of these pathways for alcohol-related behaviors. We found that disconnection of ilPFC and NAcS increased alcohol self-administration and cue-induced reinstatement, whereas disconnection of ilPFC and BLA decreased these behaviors. However, a limitation of these experiments is that lesions disrupt the circuit in both directions. A remaining question is whether "top-down" neurons projecting from ilPFC to each structure serve a different role than "bottom-up" neurons projecting in the opposite direction. Here we demonstrate the utility of a novel technique for more specific disruption of neural circuits based on their projection targets. Specifically, we inject a Cre-dependent virus expressing diphtheria toxin receptor (DTR) into ilPFC and a retrogradely transported AAV6-Cre virus into NAcS or BLA. This leads to expression of DTR only in ilPFC neurons projecting to the selected subcortical target, and enables specific ablation of these neurons by systemic injection of diphtheria toxin (DT) at any subsequent time point. In the current experiments, we inject DT after animals learned to self-administer alcohol, then test the necessity of ilPFC → NAcS projection neurons for extinction and cue-induced reinstatement of alcohol seeking. Preliminary results suggest that ablation of ilPFC → NAcS neurons reduces cue-induced reinstatement of alcohol seeking but does not affect extinction. Given that ilPFC also connects reciprocally with BLA, current experiments are testing the separate effects of either top-down ilPFC → BLA or bottom-up BLA → ilPFC ablation on these same relapse-associated behaviors.

Title: Interactive effects of ethanol and HIV-1 viral proteins on novelty-seeking behaviors

Authors: T. WINGO[1], T. NESIL[1], S. CHANG[2,3], *M. D. LI[1];
[1]Psychiatry and Neurobehav Sci., Univ. of Virginia, Charlottesville, VA; [2]Inst. of NeuroImmunology Pharmacol., South Orange, NJ; [3]Dept. of Biol. Sci., Seton Hall Univ., South Orange, NJ

Abstract: Novelty-seeking behavior is related to the reward system in the brain and could predict the potential for addiction. Alcohol use is prevalent in HIV-1 infected patients and adversely affects anti-retroviral medication. The difference in vulnerability to alcohol addiction between HIV-1 infected and non-infected populations has not been fully investigated. This study was designed to determine whether HIV-1 viral proteins alter the effects of ethanol on novelty-seeking behaviors in the HIV-1 transgenic (HIV-1Tg) rat. The hole board and open field tests were used to first compare the baseline (pre-session ethanol) novelty-seeking behaviors in HIV-1Tg and F344 control rats. Rats then received a single daily intra-peritoneal injection of ethanol (1 g/kg) or saline for 13 d. The rats were then re-exposed to the hole board and open field test on the Days 10 and 11 (post-session ethanol trials) to determine the combined effects of HIV-1 viral proteins and chronic ethanol exposure on novelty-seeking behaviors. There was a significant strain difference in baseline novelty-seeking behaviors; HIV-1Tg rats exhibited both higher head dip scores in the hole board test ($p = 0.001$) and center entry scores ($p = 0.01$) in the open field test compared to the F344 control rats. In the post-session ethanol trials, novelty-seeking behaviors were increased in the ethanol-treated groups, but decreased in the saline control groups in both the hole board ($p = 0.001$) and open field ($p = 0.004$) tests. Ethanol-treated HIV-1Tg rats had higher head dip ($p < 0.01$) and center entry ($p < 0.05$) scores compared to the ethanol-treated F344 rats. There was a significant difference in head dip ($p = 0.03$) and center entry ($p = 0.02$) scores in pre- and post-ethanol treatment sessions, respectively, in the HIV-1Tg rats. Our results indicate that HIV-1 viral proteins alter novelty-seeking behaviors, induce neuronal adaptations in the mesolimbic reward pathway, and enhance the effects of ethanol on novelty-seeking behaviors. Using the novelty-seeking trait as a correlative behavioral marker of alcohol dependence could have important implications for the development of new psychopharmacological treatments for alcohol-dependent HIV-1 infected patients.

Title: Brain activation to cannabis- and alcohol-related words in alcoholism

Authors: ***T. SCHULTE**[1,2], A.-P. LE BERRE[3], M. SERVENTI[3], J. METZLER[2], E. V. SULLIVAN[3], A. PFEFFERBAUM[1], E. M. MÜLLER-OEHRING[3];

Abstract: Cannabis abuse commonly occurs with alcohol use disorder. With increased acceptance and accessibility to cannabis in the US, it is imperative to understand the potential consequences on cognition and behavior. Taking a lead from alcohol research, alcohol-related stimuli can become conditioned cues with repeated alcohol consumption by associating the stimulus with the rewarding effects of alcohol. In alcoholism, an implicit attentional bias toward alcohol-related stimuli has been associated with craving and relapse and at the neural level with activation of midbrain-based cortico-striatal and limbic brain systems such that processing of these stimuli takes precedence over cortical control systems. We hypothesized that cue-sensitive reward systems may be also responsive to other drug-related stimuli. Here we used fMRI to examine the neural correlates of alcohol- and cannabis-related stimuli in 11 abstinent alcoholics (ALC) (abstinent from alcohol median=25 weeks; n=6 with past cannabis abuse, abstinent median=26 years) and 10 age-matched healthy controls. The task was to match the color of a patch to the font color of a word by pressing a Yes-key for color matches and a No-key for non-

matches. Words were congruent color words (e.g., the word RED in red font), alcohol-related (WINE, BEER), or cannabis-related words (WEED, DOPE) written in green, red, or blue font. As expected, participants showed faster response times for color matches than non-matches. Groups did not differ in overall task performance (response time (RT), errors, misses). An interaction between group and task conditions revealed that relative to controls, ALC had faster RT to cannabis than alcohol words and were slowest to color words. Shorter alcohol abstinence in ALC correlated with faster RT to alcohol (vs. color) words (Rho=.67). ALC deactivated premotor and cingulate cortices to alcohol (vs. color) words, and the extent of the deactivation was related to shorter alcohol abstinence (Rho=.66), whereas controls activated midline frontoparietal cortical areas. For cannabis (vs. color) words, ALC engaged midbrain, hippocampal, and cerebellar regions more than controls, whereas controls activated medial frontal, premotor, and cingulate regions more than ALC. Greater cerebellar activity in ALC correlated with greater response facilitation to cannabis words (Rho=-.73). These results suggest that both cannabis and alcohol stimuli in alcohol dependence can activate midbrain-limbic and cerebellar systems associated with stimulus-driven attention and response facilitation. Title: Cocaine-induced alterations in structural plasticity in the dmPFC of rats during early withdrawal

Authors: ***B. M. SIEMSEN**, P. MULHOLLAND, J. KOERBER, S. LANDER, P. KALIVAS, J. MCGINTY;
Med. Univ. of South Carolina, Charleston, SC

Abstract: Relapse to drug-seeking is a major clinical obstacle in treating addiction. Numerous studies have shown that dysregulation of the dorsomedial prefrontal cortex (dmPFC) to nucleus accumbens core (NAc core) glutamatergic projection precipitates relapse in rodent models. Altered synaptic plasticity and dendritic spine morphology and density (structural plasticity) within corticolimbic circuitry are associated with different phases of withdrawal and relapse. Previously, our lab has shown that cocaine self-administration (SA) in rats results in a depression of ERK, CREB, and NMDA receptor subunits, GluN2A and GluN2B, phosphorylation. These signaling alterations are associated with a parallel increase in striatal-enriched tyrosine phosphatase (STEP) activity in the dmPFC two hours after the final of 14 short access SA sessions (early withdrawal), suggesting decreased synaptic activity. A similar decrease in ERK and CREB phosphorylation, as well as GluN2A/B expression, is associated with decreased apical dendritic complexity in stress and depression models. In light of these observations, the current study investigated whether cocaine SA decreases apical spine head diameter (dH) and density in the dmPFC during early withdrawal. Fifteen male Sprague Dawley rats self-administered cocaine or were exposed to non-contingent yoked saline infusions for 14 days, and were transcardially perfused two hours after the final session. Coronal sections containing the dmPFC were labeled with the lipophilic dye DiI, and apical dendrites were acquired with confocal microscopy, and analyzed with Imaris 3D image analysis software. Results indicate that cocaine SA decreases layer II/III apical spine density as well as layer V apical spine dH ($p < 0.05$). The decreased layer II/III apical spine density is specific to a loss of thin and mushroom type spines. Ongoing experiments are delineating whether these alterations are occurring in dmPFC neurons that project to the NAc core using retrogradely transported fluorescent microspheres injected into the NAc core. We predict this alteration in structural plasticity plays a role in decreased synaptic activity during early withdrawal. This alteration may be facilitating relapse following abstinence because a single BDNF microinfusion immediately after SA suppresses relapse by reversing a cocaine-induced depression of phosphoproteins in the dmPFC during early withdrawal. Thus, investigation as to whether a BDNF microinfusion, or STEP inhibition, will reverse these cocaine-induced alterations in structural plasticity is a future direction.

Title: Alterations in dmPFC neuronal activity during and immediately after cocaine self-administration

Authors: *T. S. DENNIS, J. A. KOERBER, T. C. JHOU, J. F. MCGINTY;
Med. Univ. of South Carolina, Charleston, SC

Abstract: Previous work from our laboratory has identified a down-regulation of activity-related phospho-proteins (p-GluN2A/B, pERK and pCREB) in the dorsomedial PFC (dmPFC) during early withdrawal from cocaine self-administration (SA) that appears to be crucial for relapse. Reversing these changes with a single infusion of brain-derived neurotrophic factor (BDNF) into the dmPFC immediately after the last cocaine SA session suppresses subsequent cue- and cocaine-induced drug-seeking in a TrkB- and ERK-dependent manner, and normalizes cocaine-induced dysregulation of glutamate levels in the nucleus accumbens (NAc) that are associated with relapse. Given the profound therapeutic potential of this understudied time point, the current study aims to explore direct measurements of neuronal activity in the dmPFC during SA and early withdrawal through the use of *in vivo* single-unit electrophysiological recordings in awake, behaving rats. Male Sprague Dawley rats were implanted with an intra-jugular catheter and a drivable 16-wire electrode bundle into the dmPFC and allowed to recover for 5 days. Rats were habituated to the SA chamber for 1 day before taking a 4 hr and 50 min baseline recording to assess the activity of dmPFC neurons in the absence of any stimulation. Rats were then trained to self-administer cocaine on an FR1 schedule, with electrophysiological recordings taken on Days 1-2 (Early SA) and Days 11-12 (Late SA). Neural activity was continually recorded during a 20 min baseline, during the 2 hr cocaine SA period, and during the 2.5 hr post-cocaine SA period. Preliminary data suggest that cocaine SA in cocaine-experienced (but not naïve) animals suppresses neuronal firing in the dmPFC when compared to the 20 min baseline. Interestingly, after the levers are withdrawn and cocaine access is taken away (indicating the beginning of early withdrawal), neuronal activity increases dramatically and is sustained at a higher rate of firing through the end of the session. This increase in neuronal firing during early withdrawal may paradoxically explain the decreases in NMDA receptor-related phospho-proteins that are observed 2 hr after the final SA session. It is likely that increases in neuronal activity following cocaine-induced suppression are robust enough to induce calcineurin-dependent phosphatases that dephosphorylate GluN2A/B receptor subtypes and ERK. These data show promise in expanding our understanding of the mechanisms involved during cocaine SA and in early withdrawal. Supported by DA033479

Title: Inhibition of Src family kinases prevents the suppressive effect of BDNF on cocaine-seeking

Authors: *S. M. BARRY, E. L. HERZIG, J. F. MCGINTY;
Neurosci. Inst., Med. Univ. of South Carolina, Charleston, SC

Abstract: Relapse to drug seeking remains a major obstacle in the treatment of cocaine addiction in human addicts. Animal models of relapse have demonstrated that neuroadaptations in reward circuits following cocaine self-administration underlie reinstatement to drug seeking. Specifically, dysregulation of the pathway from the prefrontal cortex (PFC) to the nucleus accumbens (NAc) is implicated in reinstatement. Brain-derived neurotrophic factor (BDNF) is synthesized in PFC pyramidal neurons and anterogradely transported to the NAc where it is the primary source of BDNF. Our lab has shown that a single BDNF infusion into the prelimbic cortex following a final cocaine self-administration session results in attenuation of reinstatement to cocaine-seeking. Inhibiting BDNF's receptor, TrkB, ERK/MAP kinase activation, or AMPA/NMDA receptors can block this attenuating effect. These results imply that the interaction between glutamate-mediated synaptic activity and TrkB signaling is imperative to BDNF's suppressive effect on drug-seeking. Src family kinases (SFKs) are involved in both NMDA/AMPA-mediated activation of TrkB and TrkB-mediated phosphorylation of NMDA receptors. Thus SFKs serve as a likely link between these two signaling systems. We hypothesized that infusion of the SFK inhibitor, PP2, into the prelimbic cortex prior to a BDNF infusion immediately after the end of the last cocaine self-administration session will block BDNF's attenuation of both context- and cue-induced reinstatement in rats. PP2 blocked BDNF's suppressive effect on context-induced relapse after one week of abstinence and cue-induced reinstatement after extinction. Because cocaine induces a dephosphorylation of GluN2A and GluN2B receptors and BDNF reverses this action, PP2 is likely blocking this reversal. Analysis of phospho-GluN2A/B, phospho-ERK, and activated SFK levels performed on the automated immunoassay system WES^{TM} (Protein Simple, BioTechne) will be presented to determine if PP2's blocking action occurs from dysregulation of TrkB-mediated NMDA receptor activation.

Title: Involvement of CaMKII within the prefrontal cortex and the nucleus accumbens in the effects of Taar1 agonist on reinstatement of cocaine seeking in rats

Authors: ***J. LIU**, J.-X. LI;
Pharmacol. and Toxicology, Univ. at Buffalo, SUNY, Buffalo, NY

Abstract: The trace amine-associated receptor 1 (TAAR1), a novel G protein coupled receptor, has proven to play a crucial role in modulating the dopaminergic system in brain. Our recent study demonstrated that systemic administration of TAAR1 agonist decreased cue- or drug-induced reinstatement of cocaine seeking in rats. However, the neuronal mechanism underlying the role of TAAR1 in cocaine addiction remains unknown. Here, we examined the effect of selective TAAR1 agonist RO5166017 on cocaine seeking behavior in rats, and investigated the underlying mechanism. Rats were tested drug-induced reinstatement one day after extinction of cocaine self-administration. Immediately after cocaine reinstatement test, rats were decapitated and tissues of two critical brain regions in drug addiction, the prefrontal cortex (PFC) and the nucleus accumbens (NAc), were harvested for examining the alterations of related molecules. The results showed that pretreatment of RO5166017 (10 mg/ kg, i.p.) reduced cocaine priming-induced reinstatement of cocaine seeking. After reinstatement, the levels of phosphorylated Ca2+/calmodulin-dependent protein kinase II (pCaMKII) and phosphorylated extracellular signal-regulated kinases 1/2 (pERK1/2) in both brain regions were elevated. RO5166017 prevented cocaine priming-induced increase in pCaMKII in both the PFC and the NAc, but it did not affect the level of pERK1/2. Furthermore, bilateral microinjection of RO5166017 (5 ug/ 0.5ul/ side) into the prelimbic cortex of PFC and NAc shell both inhibited cue- and drug-induced reinstatement of cocaine seeking. These results suggested that CaMKII-dependent signaling pathway within the PFC and the NAc may mediate the role of TAAR1 in reinstatement of cocaine seeking.

Title: nNOS-expressing interneurons: A master switch for nucleus accumbens plasticity underlying cocaine relapse

Authors: *A. W. SMITH[1], J. L. HEINSBROEK[1], M. D. SCOFIELD[1], M. R. LORANG[2], P. W. KALIVAS[1];
[1]Neurosciences, Med. Univ. of South Carolina, Charleston, SC; [2]Biol., Col. of Charleston, Charleston, SC

Abstract: Chronic cocaine exposure produces neuroplasticity within the nucleus accumbens core (NAcore) that leads to increased vulnerability to relapse, even after protracted abstinence. Relapse is associated with a transient synaptic potentiation of corticostriatal synapses in the nucleus accumbens core, and the magnitude of this potentiation is correlated with the intensity of relapse behavior. Matrix metalloproteinases (MMPs) are Zn^{2+}-dependent endopeptidases that degrade the extracellular matrix to promote synaptic plasticity, and recent work from our lab has shown that upregulated MMP activity is required for synaptic plasticity accompanying cocaine addiction. One mechanism of MMP activation is through S-nitrosylation via nitric oxide (NO). NO is synthesized in a small subset of GABAergic interneurons within the accumbens (~1%), and these neurons are characterized by the expression of neuronal nitric oxide synthase (nNOS). We hypothesized that nNOS activity and MMP S-nitrosylation is both necessary and sufficient to drive cue-induced reinstatement of cocaine seeking. In order to test this, we used NOS1-Cre transgenic mice for selective targeting of nNOS-expressing interneurons. By stimulating Ca^{2+} signaling via Cre-dependent Gq-DREADD expression selectively in nNOS-expressing interneurons, we were able to stimulate MMP activity, potentiate cue-induced reinstatement, and drive reinstatement in the absence of cues. Furthermore, Gq stimulation in nNOS-expressing interneurons induced MMP activity throughout the accumbens, and this activity was completely abolished by an nNOS inhibitor. Future experiments will determine the effects of this activity on synaptic strength, measured by AMPA:NMDA ratio. Together, these data indicate that nNOS-

expressing interneurons are a novel portal for cortical regulation of cocaine-seeking, and furthermore that they may constitute a 'master switch' for plasticity on medium spiny neurons that underlies relapse to drug seeking.

Title: Electrochemical detection of glutamate- and Gq-dreadd-evoked nitric oxide release in the nucleus accumbens

Authors: *M. D. SCOFIELD[1,2], A. W. SMITH[2], C. D. GIPSON[2], H. A. BOGER[2], P. W. KALIVAS[2];
[1]Neurosci., [2]Med. Univ. of South Carolina, Charleston, SC

Abstract: The gaseous transmitter nitric oxide (NO) is produced in the nucleus accumbens core (NAcore) by a subpopulation of interneurons that express neuronal nitric oxide synthase (nNOS). Among other things, NO plays a critical role in the nitrosylation and activation of matrix metalloproteinases (MMPs) required for dendritic spine head (dh) expansion on medium spiny neurons (MSNs), linked to cue-induced cocaine seeking. We have shown that cocaine exposure enhances activity of the nNOS enzyme in the NAcore leading to the nitrosylation of MMPs, while inhibition of nNOS inhibits cue-induced activation of MMPs and cocaine seeking. Further, we show here that infusion of the mGluR5 agonist CHPG into the NAcore produced reinstated drug seeking, which was blocked by the co-infusion of nNOS inhibitor N-Propyl-L-Arginine (NPLA). In order to validate that activation of NAcore nitrergic interneurons translates to NO release in real time, evoked NO levels were measured in anesthetized animals using Nafion + o-PD coated S2 multi electrode arrays and the Quanteon FAST16mkII system. Puff application of glutamate or CHPG produced a reproducible dose-dependent increase in NO release in the

NAcore, which was inhibited by the mGluR5 antagonist MTEP or NPLA, respectively. Moreover, NO efflux was dose-dependently evoked by stimulation of Gq-coupled designer receptors exclusively activated by designer drugs (DREADDs), selectively expressed in NAcore nitrergic interneurons. Taken together, our results demonstrate that activation of glutamate receptors (including mGluR5) in the NAcore produced NO release. Further, we show that activation of Gq-signaling specifically in NAcore nitrergic interneurons also induced NO release. Combined, these data indicate that activation of nitrergic interneurons, and the subsequent NO release, is a crucial step in the signal transduction cascade between cue-induced glutamate release in the NAcore and the activation of MMPs and increased dh associated with cued cocaine seeking.

Title: Integrins and integrin linked kinase as a signaling pathway for mmp-9 induction of transient synaptic plasticity in cocaine relapse

Authors: *C. GARCIA-KELLER, S. SPENCER, M. D. SCOEFIELD, A. N. PHOENIX, P. W. KALIVAS;
Neurosci., Med. Univ. of South Caroline, Charleston, SC

Abstract: Chronic cocaine exposure produces neuroplasticity within the nucleus accumbens core (NAcore) that leads to increased vulnerability to relapse, even after protracted abstinence. Matrix metalloproteinases (MMPs) are inducible endopeptidases that degrade extracellular matrix (ECM) proteins (such as fibronectin, laminin and thrombospondin), as well as non-ECM signaling molecules, and reveal an RGD domain that binds and signals through integrins. Integrins are heterodimeric transmembrane cell adhesion receptors composed of subunits αβ, and their primary signaling kinase is the integrin linked kinase (ILK). A variety of data support integrin in the accumbens as a possible signaling mechanism for addictive behaviors. Previous results from our lab show that β3 integrin is upregulated by cocaine self-administration and its stimulation promotes changes in spine morphology and AMPA receptor trafficking. Moreover, administering an RGD-containing peptide into the NAcore inhibits cocaine-induced

reinstatement. It has also been shown by others that MMP-9 activation produces changes in spine morphology and NMDA receptor surface diffusion by signaling through β1 integrins in the hippocampus. We know that chronic cocaine exposure increases activity of MMP-9 and this promotes transient synaptic plasticity (t-SP: increases in spine head diameter and AMPA/NMDA) and reinstatement of drug seeking. We hypothesized that β1 and β3 integrin signaling through ILK are important in order to promote synaptic growth and regulate actin polymerization and AMPA receptor trafficking during t-SP. In order to support this hypothesis, we reduced integrin and ILK protein using an antisense morpholino and evaluated the capacity of both to mediate cue-reinstated behavior. Our preliminary studies with knock-down of NAcore levels of B1 integrin and ILK is contrary to our hypothesis, and a reduction in cue-induced reinstatement of cocaine seeking was observed in morpholino treated versus control rats. However, this may occur because the knockdown of B1 integrin caused a compensatory upregulation of ILK. We are conducting further studies us small molecule antagonists of ILK to evaluate the role of integrin signaling on reinstated cocaine seeking.

Title: Overexpression of acid-sensing ion channel 1A in the nucleus accumbens core potentiates cocaine-seeking, but not food-seeking, behavior in rats

Authors: *V. A. MULLER EWALD[1], C. V. COSME[2], A. L. GUTMAN[2], W. R. WORTH[2], M. NOTERMAN[3], Y. LU[4], J. A. WEMMIE[4], R. T. LALUMIERE[2];

Abstract: Recent evidence indicates that acid-sensing ion channels (ASICs) in the nucleus accumbens influence conditioned place preference for cocaine and cocaine self-administration. However, whether ASICs are involved in regulating cocaine-seeking behavior is unknown. To address this issue, male Sprague-Dawley rats underwent surgery for intravenous catheter implantation and implantation of bilateral cannulas aimed at the nucleus accumbens core. The rats then underwent cocaine self-administration for a minimum of 12 d, in which active lever presses produced an intravenous infusion of cocaine and a light-tone combination of cues. Upon completion of self-administration, rats received microinjections of adeno-associated virus (AAV) into the nucleus accumbens core to produce overexpression of the ASIC1A subunit or GFP alone (control group). Groups were matched based on self-administration behavior (cocaine infusions and active lever pressing). The rats then remained in their homecages for 3 weeks in order to ensure robust ASIC1A overexpression as well as mimic procedures necessary for the incubation of craving. Rats were then returned to the operant chambers to begin drug-seeking testing. In the first session, rats underwent a cue-induced drug-seeking session, in which active lever presses produced the cocaine-associated cues. ASIC1A overexpression induced significantly more active lever pressing than their control GFP-alone counterparts. Rats then underwent a minimum of 7 d of extinction, during which active lever presses had no consequences, in order to extinguish their lever pressing. Rats overexpressing ASIC1A had more active lever presses on day 1 of extinction and required more extinction sessions in order to reach criterion. Subsequent reinstatement testing using either cues, a cocaine-prime, or a combination of cues with a cocaine-prime revealed similar effects, as rats overexpressing ASIC1A had higher levels of cocaine-seeking behavior. A subsequent experiment replicated the behavioral procedures but with food self-administration and food-seeking behavior. In this case, ASIC1A overexpression in the nucleus accumbens core had no effect on any measure of food-seeking behavior. Together, these findings indicate that overexpression of ASIC1A in the nucleus accumbens core potentiates cocaine-seeking behavior and that this effect does not appear to generalize to non-drug reward-seeking behavior. The present results suggest that targeting ASICs, and particularly the ASIC1A subunit, may be an effective and selective method for altering cocaine seeking.

Title: Systemic administration of a kainate receptor antagonist attenuates cocaine seeking and alcohol preference in rats

Authors: ***D. VAN NEST**, N. HERNANDEZ, J. MAURER, M. DE BIASI, H. R. KRANZLER, H. D. SCHIMDT, R. C. PIERCE;
Psychiatry, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cocaine addiction in the United States continues to be a large public health concern for which there are no FDA-approved pharmacological treatments. Ionotropic glutamate receptors play an important role in cocaine-seeking behavior. To date, the vast majority of studies of the role of ionotropic glutamate receptors in cocaine addiction have been limited to AMPA receptor function primarily because of a lack of available drugs that selectively target kainate receptors. Thus, the role of kainate receptors in cocaine-seeking behavior remains unclear. Here, we examined the role of kainate receptors in cocaine seeking using novel pharmacological antagonists of kainate receptors. Rats were allowed to self-administer cocaine (0.25 mg/infusion i.v.) for 21 days. Cocaine self-administration was extinguished by replacing cocaine with saline. Rats were then given an acute systemic injection of cocaine (10 mg/kg, i.p.) to assess their drug-seeking behavior. In subsequent reinstatement tests, rats were pretreated with the selective kainate receptor antagonist UBP302 (0.5, 1, 5, 10 mg/kg, i.p.) or LY466195 (4, 10 mg/kg, i.p.) followed by a priming injection of cocaine. Systemic administration of LY466195 attenuated the ability of an acute priming injection of cocaine to reinstate drug-seeking behavior. In a separate set of experiments, the effect of LY466195 on alcohol consumption was assessed using the intermittent two-bottle choice paradigm. Preliminary results indicate that LY466195 (4, 10 mg/kg, i.p.) administration showed a strong trend towards reducing alcohol preference.

Together, these results suggest that kainate receptor antagonists may be useful in the treatment of cocaine craving and may influence alcohol intake as well.

Title: The role of projections from the nucleus accumbens shell to the ventral pallidum in mood and motivation for cocaine

Authors: ***A. L. LORIAUX**, D. W. SELF;
Dept. of Psychiatry, UT Southwestern Med. Ctr., Dallas, TX

Abstract: Cocaine users often cite negative affect as a key factor behind relapse. However, the relevant neurocircuitry behind mood and motivational changes in cocaine addiction, and their relationship to one another, is not fully understood. We have recently shown that selective stimulation of nucleus accumbens shell (NAcSh) neural projections to the lateral hypothalamus (LH) increases motivation for cocaine, while producing depression-like despair in rats trained to self-administer cocaine. Global stimulation of NAcSh cell bodies also produces despair, but decreases motivation for cocaine, suggesting that other NAcSh outputs may override the motivational effects of NAcSh-LH terminal stimulation. Activity in NAc projections to ventral pallidum (VP) has been associated with depressed mood in drug naïve animals, but with conflicting effects on the motivation for cocaine. In the present study, we used a target-specific optogenetic approach to selectively activate NAcSh projections to the VP in male rats. We tested the hypothesis that increased activity in the NAcSh-VP depresses both mood and motivation for cocaine, and, thus, is behaviorally differentiated from the effects of NAcSh-LH projections. Rats were bilaterally injected with either AAV2-hSyn-hChR2(H134)-EYFP or AAV2-hSyn-EYFP

control virus into the NAcSh, and implanted with optic fibers in the terminal fields of the NAcSh in the VP. Rats were trained to self-administer intravenous cocaine (0.5 mg/kg/infusion, i.v.) 4 h/day for 3 weeks. We measured the effect of laser stimulation of the NAcSh-VP pathway (30 min pretreatment, 10 sec/min, 20 Hz, 50 mW) on motivation for cocaine as assessed by 1) performance on a progressive ratio (PR) schedule of reinforcement for cocaine, 2) drug-paired lever presses under extinction conditions and 3) cocaine-primed reinstatement. We measured behavioral despair and anhedonia with the forced swim and sucrose preference tests, respectively. Optogenetic stimulation of NAcSh-VP terminals significantly decreased the effort to self-administer cocaine in ChR2 animals compared to eYFP controls, as indicated by 43.6% lower breakpoints. ChR2 animals also had a 43.6% reduction in lever presses during early extinction and a 32.9% decrease during reinstatement compared to eYFP controls. However, in contrast to global stimulation of the NAcSh, we found no differences in measures of immobility in the forced swim test, or a difference in preference for a 1% sucrose solution. These findings suggest that activity in the NAcSh-VP circuit may decrease motivation for cocaine independent of changes in mood, and thus may serve as a possible neural substrate for addiction treatment.

Title: Loss of BDNF-TrkB-PLCγ signaling in accumbens shell neurons attenuates cocaine-induced dendritic spine formation

Authors: *E. M. ANDERSON[1], A. WISSMAN[1], D. GUZMAN[1], C. COWAN[2], D. SELF[1]; [1]UT Southwestern, Dallas, TX; [2]McLean Hosp., Belmont, MA

Abstract: Chronic cocaine induces dendritic spine growth in accumbens shell (NACsh) neurons, but this effect has not been shown to directly enhance addictive behavior. Spine formation has been functionally linked to BDNF-TrkB signaling in other brain regions, but whether this mechanism underlies cocaine-induced spine formation is unknown. We previously found that

cocaine induces BDNF activation of TrkB signaling through PLC. In this study, we tested the necessity of BDNF-TrkB-PLC signaling on dendritic spine formation in NACsh neurons, and compared effects with modulation of cocaine self-administration behavior. We constructed a novel HSV bicistronic vector expressing both GFP and a mutated TrkB that selectively blocks endogenous TrkB-PLC signaling (HSV-TrkB^{Y816F}), while preserving other TrkB signaling pathways. Rats implanted with bilateral NACsh cannulae were trained to self-administer (SA) cocaine on a fixed ratio (FR) schedule for 3-4 weeks, and dose-response for cocaine SA was assessed before, during, and after transient HSV expression TrkB^{Y816F} or GFP-only controls. A second HSV infusion was followed by assessment of motivation for cocaine on a progressive ratio reinforcement schedule (PR). For morphological analysis, separate cohorts engaged in cocaine or saline SA for 3 weeks, and HSVs were infused into the NACsh followed by 2 more days of SA and 24 h withdrawal prior to brain perfusion. Dendritic spine densities were quantified from confocal images of GFP-labeled neurons using Volocity 3D analysis. TrkB^{Y816F} expression caused a transient leftward shift in the dose threshold necessary to maintain cocaine SA compared with GFP controls, indicating increased sensitivity to cocaine reinforcement with loss of endogenous TrkB-PLC signaling. TrkB^{Y816F} expression also increased motivation for cocaine as assessed by breakpoints on the PR reinforcement schedule. Chronic cocaine SA increased dendritic spine densities in NACsh neurons compared to tissue from saline SA animals, similar to previous reports. In contrast, TrkB^{Y816F} expression during SA reversed cocaine-induced increases in spine density without affecting basal spine density in saline SA animals. These results are the first to implicate BDNF-TrkB activity in cocaine-induced morphological changes in the NACsh, and suggest that the TrkB-PLC signaling pathway is important for this effect. Since inhibiting this TrkB-PLC pathway also enhances the motivation for cocaine, cocaine-induced dendritic spine formation may not functionally contribute to cocaine addiction, and could represent a counter-adaptation process that reduces addictive behavior.

Title: Vagus nerve stimulation modulates plasticity in the prefrontal cortex-amygdala pathway and enhances extinction of drug-seeking behavior

Authors: *J. PRUETT, E. NICKEL, J. DELEON, S. KROENER;
Univ. of Texas At Dallas, Sch. of Behavioral and Brain Sci., Richardson, TX

Abstract: Cocaine addiction can cause maladaptive neuroplasticity that persists long after cessation of drug taking. The relative permanence of cue associations formed during drug taking contributes to the difficulties in treating addiction. Exposure to these cues can trigger relapse to drug use. Breaking the cue/drug association via extinction learning is one approach to prevent relapse. Vagus nerve stimulation (VNS) has previously been shown to enhance extinction of conditioned fear and to alter neural plasticity in fronto-limbic circuits. Here we trained animals to self-administer cocaine and extinguished them in the presence or absence of VNS. Two stimulation parameters were tested: Non-contingent VNS (30 seconds every 5 minutes, 500 μs pulse width, 30 Hz, 0.4 mA) or contingent VNS (500 ms every active lever press, 500 μs pulse width, 30 Hz, 0.8 mA). VNS-treatment under both conditions increased rates of extinction and reduced cue-induced reinstatement. In control experiments we delivered VNS during extinction from food self-administration and found that VNS similarly facilitated extinction from food-seeking. Lastly, VNS administered concurrently with either food or drug self-administration did not impact rates of response, suggesting that VNS does not affect appetitive behaviors. After reinstatement, we recorded local field potential recordings in the basolateral amygdala (BLA) of anesthetized animals to study VNS-induced changes in plasticity in the pathway between the medial prefrontal cortex (PFC) and the BLA. Stimulation of the infralimbic PFC (900 pulses at 1Hz) induced LTD in naïve and sham-stimulated animals, but caused no change in VNS animals, suggesting that VNS can reduce reinstatement by modulating the projection from the infralimbic PFC to the BLA. We further studied VNS modulation of the circuitry associated with drug-seeking and extinction learning by quantifying expression of activated cAMP response element-binding protein (pCREB) immediately after reinstatement in the mPFC, BLA, and nucleus accumbens. We found differential expression patterns in naïve, Sham-VNS, VNS, and Drug Only (animals that went through self-administration but not extinction) conditions. Because both contingent and non-contingent VNS facilitated extinction learning we are currently testing the effects of VNS on extinction of conditioned place preference to differentiate between effects on operant responding and contextual cues.

Title: Riluzole impairs reinstatement to cocaine seeking

Authors: *M. T. SEPULVEDA-ORENGO, A. C. AURIEMMA, K. L. HEALEY, J. A. ROJAS, K. J. REISSNER;
Dept. Psychology, Univ. of North Carolina@Chapel Hill, Chapel Hill, NC

Abstract: Cocaine abuse alters cellular dynamics within several regions of the brain's reward circuitry, including the ventral tegmental area, nucleus accumbens and prefrontal cortex (PFC), among others. Elucidation of these cellular adaptations can help identify pharmacotherapeutic candidates for cocaine addiction. One example of such a candidate is the glutamate transporter GLT-1/EAAT2, which is decreased in the nucleus accumbens following cocaine experience. GLT-1 is responsible for approximately 90% of glutamate uptake in the brain, and is critical for neuroprotection and fidelity of synaptic processing. Previous studies have reported that compounds which restore expression of GLT-1 can also reduce behavioral measures of drug seeking. Thus, we wished to test the hypothesis that another known regulator of GLT-1, riluzole, might also reduce cocaine seeking. Riluzole is an FDA approved drug for Amyotrophic Lateral Sclerosis (ALS), which decreases neuronal activity by blocking voltage-gated sodium channels. In addition, riluzole upregulates expression of GLT-1 *in vitro* and *in vivo*, leading to increased glutamate uptake by astrocytes. To determine whether riluzole has an effect on cocaine seeking, we employed the rat self-administration/extinction/reinstatement model of cocaine abuse. During the extinction phase, rats received chronic intraperitoneal injections of vehicle or riluzole (1 or 4 mg/kg), thirty min before each session. We observed a dose-dependent reduction in cue- and cocaine-primed reinstatement to cocaine. However, riluzole had no effect on cue-primed reinstatement of sucrose seeking. In addition, we recorded intrinsic excitability in prefrontal cortical neurons using whole-cell patch clamp electrophysiology in slices of rats trained to self-administer cocaine or saline, receiving chronic riluzole or vehicle injections during extinction. Preliminary data indicate a cocaine-dependent increase in prelimbic neuron excitability, which is reversed by administration of riluzole. Surprisingly, preliminary results also indicate that riluzole administration results in an increase in excitability in infralimbic neurons. These results suggest that riluzole restores levels of intrinsic excitability in the prefrontal cortex, which may contribute to its effect on cocaine seeking. These results further support an existing body of literature which implicates GLT-1 regulators as therapeutic candidates for psychostimulant addiction.

Title: Regulation of glutamate transporter-1 gene expression by cocaine self-administration and withdrawal

Authors: *R. KIM, M. T. SEPULVEDA-ORENGO, K. J. REISSNER;
Dept. of Psychology and Neurosci., UNC Chapel Hill, Chapel Hill, NC

Abstract: Relapse to cocaine abuse is characterized by alterations in glutamatergic signaling in the nucleus accumbens (NAc). For example, glutamate levels are increased in the NAc during reinstatement to cocaine seeking in the rat. Glutamate uptake is maintained primarily by the astroglial glutamate transporter GLT-1, which accounts for up to 90% of glutamate clearance from the synapse. GLT-1 protein expression and function is decreased in the NAc following cocaine self-administration and withdrawal, and this decrease is correlated with both cocaine exposure and length of withdrawal. Moreover, restored expression of GLT-1 is a necessary component of compounds which block reinstatement to cocaine, including N-acetylcysteine and propentofylline. However, the mechanism responsible for regulation of GLT-1 protein by cocaine remains unclear. To examine this question, rats were trained to self-administer IV cocaine or saline in a short access (SA, 2 hours) or long access (LA, 6 hours) paradigm. Following 2 weeks of SA to cocaine (n=8) or saline (n=8), rats underwent extinction training in the operant chambers for 3 weeks. In contrast, following 10 days of LA to cocaine (n=8) or saline (n=7), rats remained abstinent in the home cage for 45 days. Twenty four hours following the last extinction session (SA rats) or last day of abstinence (LA rats), tissue was harvested from the NAc and prelimbic cortex (PL), a region known to have important projections to the NAc. Gene expression was then examined in these two regions using qRT-PCR and primers specific for two GLT-1 splice variants (GLT-1A and GLT-1B). In SA rats, no differences in GLT-1A or GLT-1B mRNA levels were found between cocaine and saline rats in NAc or PL samples. In the NAc of LA rats, a significant decrease was found in GLT-1A gene expression in cocaine vs. saline rats ($t(13) = 2.735$, $p < .05$), but no difference was found in GLT-1B gene expression. In the PL of LA rats, we observed a trend toward a decrease in GLT-1A and a statistically

significant decrease in GLT-1B gene expression ($t(13) = 2.527$, $p < .05$). These results show that the decrease in GLT-1 protein after SA to cocaine and extinction may not be due to a decrease in gene expression, and may reflect protein degradation and/or trafficking. Furthermore, prolonged abstinence after LA cocaine self-administration induces specific changes in GLT-1 gene expression that differs amongst the GLT-1 splice variants, and differs between PL and NAc. Future studies will be designed to investigate the mechanism of the identified genetic suppression of GLT-1 following LA to cocaine.

Title: Subpopulations of adenosine a2a receptors in the nucleus accumbens play different roles in cocaine seeking

Authors: *N. HAYNES, C. E. O'NEILL, S. LEVIS, D. SCHREINER, J. STAFFORD, R. K. BACHTELL;
Psychology and Neurosci., Univ. of Colorado, Boulder, CO

Abstract: Repeated cocaine administration produces perturbations in dopamine and glutamate neurotransmission that contribute to the reinstatement of extinguished cocaine seeking. The synaptic localization of adenosine A2A Receptors (A2AR) can influence both dopamine and glutamate neurotransmission to have a differential roles on behavior. Thus, A2AR's are localized on presynaptic glutamate terminals that oppose direct pathway medium spiny neurons, while postsynaptic A2AR's are localized on indirect pathway neurons. These studies sought to elucidate differential effects of these subpopulations of A2AR's on cocaine seeking. Male Sprague-Dawley rats self-administered cocaine in 10 daily self-administration sessions on a fixed-ratio 1 schedule. Lever pressing was then extinguished in six daily extinction sessions. We first tested whether presynaptic and postsynaptic A2AR antagonism (SCH 442416 and KW 6002, respectively) was sufficient to reinstate cocaine seeking. We next tested the effects of SCH 442416 and KW 6002 on reinstatement to cocaine seeking induced by systemic cocaine or prefrontal cortex (PFC) stimulation. We found that KW 6002 induced reinstatement of cocaine seeking and facilitated cocaine-induced seeking. Conversely, SCH 442416 had no effect on cocaine seeking alone and blunted cocaine-induced seeking. We saw similar bidirectional effects

when cocaine seeking was induced by pharmacological stimulation (cocaine or AMPA) of the PFC. Analysis of the phosphorylation state of the presynaptic marker, synapsin, suggests that presynaptic A2AR antagonism inhibits PFC-NAC neurotransmission. Together, the data suggest that postsynaptic A2AR antagonisms facilitates reinstatement via disinhibiting dopamine D2 receptor activity on indirect pathway neurons while presynaptic A2AR antagonism inhibits reinstatement by reducing glutamate neurotransmission onto direct pathway neurons. This research helps clarify differential roles of A2AR subpopulations in the NAC in cocaine addiction.

Title: Deep brain stimulation (DBS) of nucleus accumbens afferent structures attenuates the reinstatement of cocaine seeking

Authors: *L. A. GUERCIO, H. SCHMIDT, R. PIERCE;
Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Cocaine abuse is a major public health concern, with more than 2 million current users in the United States alone. One of the major obstacles in treating cocaine addiction is the discouragingly high rate of relapse after detoxification. Drug craving and relapse to cocaine seeking are modeled in rodents using the reinstatement paradigm. Deep brain stimulation (DBS) is an FDA-approved treatment for movement disorders. The success of DBS in treating movement disorders has paved the way for its examination as a therapeutic modality in many psychiatric disorders, including drug addiction. Previous work has shown that DBS of the

nucleus accumbens shell attenuates priming- and cue-induced reinstatement of cocaine seeking, likely due to modulation of efferent glutamatergic projections from the mesocorticolimbic system. The medial prefrontal cortex (mPFC), ventral hippocampus (vHipp), and basolateral amygdala (BLA) send strong glutamatergic projections to the nucleus accumbens and have been shown to be critically involved in cocaine seeking. Here, we investigated the effects of DBS in these nuclei on the reinstatement of cocaine seeking. Initially, rats were allowed to press a lever for cocaine (0.254 mg/59 μL, i.v.) using a fixed-ratio 5 (FR5) schedule of reinforcement. After 21 days of cocaine self-administration, responding was extinguished by substituting saline for cocaine. Following extinction, we assessed cocaine priming-induced reinstatement of drug seeking. During reinstatement test sessions, DBS was administered bilaterally to each nucleus through bipolar stainless steel electrodes. Our findings show that DBS of the mPFC, vHipp, and BLA attenuates the reinstatement of cocaine seeking in rats. These results suggest a role for DBS as a possible therapeutic modality for cocaine addiction and relapse.

Title: Cav1.2 channel-mediated regulation of GluA1 phosphorylation and trafficking in the hippocampus is essential for extinction of cocaine conditioned place preference

Authors: *C. BURGDORF[1], K. C. SCHIERBERL[1], A. S. LEE[1], F. HOFMANN[2], R. L. HUGANIR[3], A. M. RAJADHYAKSHA[1];
[1]Feil Family Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY; [2]Tech. Univ. Munich, Munich, Germany; [3]Solomon H. Snyder Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Cocaine addiction is a chronic, life-long relapsing disorder. To date, no treatments have been effective in extinction of cocaine seeking behavior. Cav1.2 L-type Ca2+ channels

(LTCCs) are necessary for cocaine-induced behaviors, LTP and long-term memory. Cocaine exposure also modifies glutamatergic synapses in regions innervated by dopaminergic inputs through the regulated trafficking of AMPA receptor (AMPAR) localization. Trafficking of the GluA1 AMPAR subunit to the neuronal postsynaptic density (PSD) is regulated by changes in phosphorylation at its serine 831 (S831) residue, a CaM kinase II (CaMKII)-dependent site and its serine 845 (S845) residue, a protein kinase A (PKA) site. Previous findings from our lab has shown that Cav1.2 LTCCs increase cell surface GluA1 levels via CaMKII phosphorylation of S831 in the nucleus accumbens of cocaine sensitized mice. However, the role of Cav1.2 and Cav1.2-mediated GluA1 trafficking in extinction of cocaine seeking behavior remains unknown. Thus, in this study, we employed the cocaine conditioned preference (CPP) model in combination with genetic and molecular techniques to address this question. Using mice lacking Cav1.2 in dopamine D1-containing neurons we found Cav1.2 in the hippocampus to be required for extinction of cocaine CPP. Site-specific knockout of Cav1.2 using AAV-Cre identified a role of Cav1.2 specifically in the hippocampus in cocaine extinction. In cocaine extinguished C57BL/6 mice, there was an increase in S831 P-GluA1 and total GluA1 levels at the PSD in the hippocampus with no change in S845. To directly test the requirement of GluA1 phosphorylation in cocaine extinction, phosphomutant mice with a serine to alanine substitution (S831A or S845A) were utilized. While both genotypes acquired cocaine CPP, both S831A and S845A phosphomutant mice were unable to extinguish cocaine place preference, demonstrating a critical role for S831 and S845 in cocaine extinction. Subcellular fractionation of hippocampus tissue and western blot analyses found no difference in total GluA1 levels in the cytoplasmic fractions of S831A and S845A mutant mice compared to their respective wild-type littermates. However, lower levels of GluA1 were found in the synaptosomal fractions of both phosphomutant mice compared to wild-type littermates. Experiments examining GluA1 levels in PSD fractions and intracellular mechanisms of Cav1.2 regulation of GluA1 trafficking are currently ongoing. In summary, we have identified a role of Cav1.2 channels in dopamine D1 receptor-containing neurons of the hippocampus in extinction of cocaine CPP via regulation of GluA1 phosphorylation-dependent trafficking.

Title: Cav1.3 L-type Ca^{2+} channels: Role in VTA dopamine neurons on cocaine's behavioral effects and genetic variants in cocaine dependent humans

Authors: *A. MARTINEZ[1,2], J. HAO[2], R. RICE[2], J. STRIESSNIG[3,4], S. HAN[5], A. M. RAJADHYAKSHA[1,2];
[1]Pediatric Neurol., Weill Cornell Med. Col., New York, NY; [2]Dept. of Pediatrics, Div. of Pediatric Neurol., New York Presbyterian Hosp., New York, NY; [3]Pharmacol. and Toxicology, [4]Ctr. for Mol. Biosci., Univ. of Innsbruck, Innsbruck, Austria; [5]Psychiatry, Univ. of Iowa, Iowa, IA

Abstract: It is well established that Ca2+ neurotransmission through glutamate receptors within the reward pathway regulates cocaine addiction-related behaviors. Most recently, another route of calcium neurotransmission through L-type calcium channels (LTCCs), has been gaining prominence in the field of addiction. Two subtypes of LTCCs are expressed in the brain, Cav1.2 and Cav1.3, important mediators of CREB activation and CREB-mediated gene expression. We previously reported that Cav1.2 channels mediate the expression of cocaine psychomotor sensitization while Cav1.3 channels, the development (Giordano et al. 2010). In addition, we showed that nifedipine (LTCC blocker) attenuates acute cocaine-induced phosphorylation of CREB (P-CREB) in the nucleus accumbens. However, the specific contribution of the two LTCC subtypes in other cocaine behavioral protocols with greater clinical relevance, like cocaine conditioned place preference (CPP) and cocaine self-administration still remains unknown. Since it has been found that Cav1.3 is more abundant in the VTA (Rajadhyaksha et al. 2004), we investigated the role of VTA Cav1.3 in cocaine CPP. In the present study, using mutant mice expressing 1,4-dihydropyridines (DHP)- insensitive Cav1.2 (Cav1.2DHP-/-) treated with nifedipine or Cav1.3shRNA in the VTA, we found that Cav1.3 is necessary for the acquisition of cocaine CPP and not consolidation or expression. Molecular studies have revealed that Cav1.3 mediates acute cocaine-induced P-CREB in the VTA via activation of CaMKinase II. Treatment with KN93 (CaM kinase II inhibitor) in the VTA of wild type C57BL/6J mice blocked the acquisition of cocaine CPP. Additional studies are currently underway to identify the pathway that signals from Cav1.3/CamKII to CREB in response to cocaine. Recently, it has been shown in neuronal cultures that Ca2+ influx via Cav1.3 translocates γCaMKII into the nucleus to shuttle Ca2+/CaM for the induction of P-CREB (Huan Ma et al. 2014). Our preliminary results find that acute cocaine increases nuclear levels of γCaMKII and P-CREB in the VTA. Ongoing studies are examining the role of Cav1.3 channels in cocaine-induced nuclear translocation of γCaMKII. Our preclinical Cav1.3 findings in cocaine behaviors is further supported by human GWAS study. Examination of 947 single nucleotide polymorphisms (SNPs) within the gene for Cav1.3 (CACNA1D) has identified three significant SNPs associated with cocaine dependence. Taken together, these findings suggest that VTA Cav1.3 channel-activated pathway plays an

important role for the acquisition of cocaine CPP, a measure of cocaine reward that may contribute to cocaine addiction seen in humans.

Title: L-type calcium channels in the ventral tegmental area mediate cue-induced cocaine-seeking

Authors: ***E. J. NUNES**[1], S. M. HUGHLEY[1], W. SOLECKI[1], A. M. RAJADHYAKSHA[4], N. A. ADDY[1,2,3];

Abstract: Exposure to drug associated cues promotes drug-seeking behavior and is a challenge for the treatment of drug addiction. The presentation of cues induces burst firing in ventral tegmental area (VTA) DA neurons and subsequent phasic DA release in the nucleus accumbens (NAc) that promotes drug-seeking behavior. Nicotinic and muscarinic receptors in the VTA are critical regulators of burst firing in the VTA and phasic DA release in NAc. Recent data from our laboratory has demonstrated that pharmacological blockade of VTA cholinergic receptors decreases phasic DA release in NAc and reduces cue-induced drug seeking in cocaine withdrawn rats. Importantly, L-type calcium channels (LTCCs) are also expressed on VTA DA neurons and interact with cholinergic receptors to regulate burst firing of VTA DA neurons. However, the role of VTA LTCCs in cue-induced drug seeking are unknown. Here, we sought to determine if pharmacological blockade of LTCCs in the VTA would alter cue-induced drug-seeking following cocaine withdrawal. Male Sprague-Dawley rats underwent 10 days of IV cocaine (0.5 mg/kg/inf) self-administration training, where active lever response resulted in intravenous cocaine delivery in the presence of a compound cue (tone + light), and inactive lever response had no programmed consequence. Following a withdrawal period of 10 days, with no exposure to cocaine or the cues, rats were tested for cue-induced cocaine-seeking, where active lever

response resulted in the presentation of the compound cue alone, in absence of cocaine delivery. VTA infusion of the LTCC antagonist, nifedipine (10 μg/side) reduced cue-induced cocaine seeking on withdrawal day 10 (WD 10). In parallel experiments, where male Sprague-Dawley rats were trained to self-administer sucrose pellets, VTA infusion of nifedipine (10 μg/side) on WD10, had no effect on cue-induced sucrose seeking. In subsequent experiments, our data revealed that VTA administration of the LTCC antagonist, isradipine (288 pg/side), also reduced cue-induced cocaine-seeking on WD10. Our results thus far suggest that blockade of L-type calcium channels in VTA specifically reduces cue-induced seeking for the drug reinforcer, cocaine, but not the natural reinforcer, sucrose. Ongoing experiments are seeking to identify the role of specific LTCC subtypes and to determine whether these effects are mediated through regulation of phasic DA release.

Title: Role of intra-accumbens brain-derived neurotrophic factor on cue-induced reinstatement after cocaine self-administration

Authors: *A.-C. BOBADILLA, C. GARCIA-KELLER, S. MCWHIRTER, P. W. KALIVAS; Dept. of Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Brain-derived Neurotrophic Factor (BDNF) has been shown to have a critical role not only on neurite growth during early stages of development, but also on physiological functions in the adult brain, as well as on maladaptive behaviors like addiction. Several studies found in the literature explored the role of BDNF in addiction-related brain regions, like the pre-frontal cortex (PFC), the ventral tegmental area (VTA) or the nucleus accumbens, both shell and core (NAcore). In adulthood, the expression of BDNF in the NAcore is low, and the two main sources

of BDNF are glutamatergic projections from the PFC and dopaminergic input from the VTA. Both D1- and D2-receptors expressing medium spiny neurons (MSNs) of the NAcore express the primary receptor for BDNF, TrkB. BDNF binding to TrkB induces activation of several intracellular signaling cascades like MAPK, PI3K, phospholipase C-γ. It has been proposed that BDNF affects on cocaine reward are mainly due to activation of TrkB on D2-expressing MSNs, since specific TrkB gene deletion induces a decrease in cocaine-induced place preference and profound neuronal firing modifications (Lobo et al., 2010). Here we seek to understand the rapid, acute effects of BDNF in the NAcore on drug seeking, using the behavioral model of cocaine self-administration in rats. To study the non-transcriptional effects of BDNF in the NAcore, we microinjected BDNF 15 min before cue-induced reinstatement. BDNF induced a clear decrease of reinstatement that seemed endure for days after administration. Conversely, we used TrkB/Fc, a soluble fusion protein that blocks BDNF binding to TrkB, to test whether blocking endogenous BDNF-induced activation of TrkB could prevent this effect. Preliminary data shows that blocking TrkB activation 15min before reinstatement potentiates reinstatement and prevents co-administration of BDNF from antagonizing reinstated cocaine seeking. These results suggest that, in addition to the long lasting transcriptional effects of BDNF shown in literature, acute activation of the TrkB intracellular pathway just before reinstatement can prevent cocaine seeking.

Title: Fluoxetine potentiates methylphenidate-induced behavioral stereotypies and subsequent cocaine self-administration in rats

Authors: M. MARINELLI, J. A. BEVERLEY, L. LAMOUREUX, *H. STEINER;
Chicago Med. School/RFUMS, North Chicago, IL

Abstract: The psychostimulant methylphenidate (Ritalin) is used in the treatment of attention-deficit hyperactivity disorder (ADHD) and as a cognitive enhancer in the healthy. Methylphenidate, like cocaine, acts by blocking the reuptake of dopamine. However, unlike cocaine, methylphenidate does not affect serotonin. Serotonin contributes to addiction-related gene regulation and behavior induced by cocaine. Thus, the lack of a serotonin effect may explain methylphenidate's more moderate gene regulation and addiction liability. Indeed, our previous studies showed that enhancing serotonin, by adding a selective serotonin reuptake inhibitor (SSRI), fluoxetine, to methylphenidate, potentiates methylphenidate-induced gene regulation in the striatum and nucleus accumbens, mimicking cocaine effects. Here, we investigated behavioral correlates of these neuronal changes in adult rats. Behavior was assessed during a repeated drug pretreatment phase (6-8 days) and in response to cocaine, two weeks later. Our results show that adding fluoxetine (5 mg/kg) to methylphenidate (5 mg/kg) potentiates the increase in stereotypies over the course of the repeated pretreatment phase. This effect was particularly pronounced in a subset of rats (about 40%), which showed emerging stereotypies early-on during pretreatment. Two weeks after the pretreatment phase, rats were either given a cocaine challenge (15 mg/kg) and tested in an openfield test or started cocaine self-administration training (150 μg/kg per infusion, 2 h per day for 10 days). In the openfield test, cocaine-induced stereotypies correlated with stereotypies during pretreatment. Moreover, pretreatment with methylphenidate plus fluoxetine facilitated the acquisition of cocaine self-administration. This effect was limited to animals that showed early development of stereotypies during pretreatment. These results show enhanced behavioral responsiveness to cocaine (stereotypies, and cocaine self-administration) in a subpopulation of rats after exposure to methylphenidate plus fluoxetine. Our findings suggest that SSRIs may enhance the addiction liability of methylphenidate in a subpopulation of individuals.

Title: Food restriction stress enhances cocaine seeking and VTA dopamine neuron activity

Authors: *A. GORDON, M. MARINELLI, V. S. RAMACHANDRA;
UT Austin, Austin, TX

Abstract: Stress augments drug consumption, sensitizes animals to locomotor activation of psychomotor stimulants, and induces reinstatement of drug seeking. The interaction of stress and drug use is well documented in humans and animals; however, the effects of repeated mild stressors on drug seeking and activity of dopamine (DA) neurons within the ventral tegmental area (VTA) remain under-studied. We carried out a series of experiments to determine if the repeated mild stressor, food restriction (FR), alters basal activity of VTA DA neurons, and to determine if FR during protracted abstinence from cocaine consumption influences drug seeking behavior by a DA dependent mechanism. In the VTA DA recording experiment, rats were either fed ad libitum (control) or were food-restricted to maintain 90% of baseline body weight (FR) for an extended period of time. We then measured the basal firing rates of VTA DA neurons using *in vivo* single unit recordings under anesthesia to determine if food restriction alters VTA DA activity. In a separate group of animals, male rats were trained to self-administer cocaine (600ug/kg) i.v. for one week, and were then maintained on either control or FR diets for 9 days. Following this schedule, animals underwent a within session extinction/reinstatement (cocaine precipitated) procedure during which we measured drug seeking behavior and locomotion. Prior to this procedure, rats were injected i.p. with either a low dose of quinpirole (decrease DA neuron firing rate) or saline (control) to determine if observed effects were dependent on DA neuron activity. We discovered that FR leads to increased basal VTA DA activity. We also demonstrated that FR during protracted withdrawal increases drug seeking during extinction and reinstatement, and this increase is blocked by reducing DA neuron activity. This data adds to the literature on the interaction between stressful environmental cues and drug seeking behaviors.

Title: The LPO: role on dopaminergic transmission, drug taking, and seeking

Authors: *R. G. WILL[1], R. C. TWINING[2], V. S. RAMACHANDRA[3], M. MARINELLI[3]; [1]Psychology, Univ. of Texas Austin, Austin, TX; [2]Biomed. Sci., Marquette Univ., Milwaukee, WI; [3]Pharmacol. & Toxicology, Univ. of Texas, Austin, TX

Abstract: The lateral preoptic area of the hypothalamus (LPO) projects to the ventral tegmental area (VTA). Activity of neurons in the VTA is important for addiction-related behaviors such as cocaine taking and seeking. The goal of this study was to determine how LPO activation modulates neural response in the VTA, and dopamine responsive behaviors such as cocaine taking and seeking. Optogenetic activation of LPO projections to the VTA decreased the firing rate of GABAergic neurons and increased the firing rate of dopaminergic neurons in the VTA. Disinihibition of the LPO neurons via administration of bicuculline into the LPO facilitated cocaine seeking behavior but had no effect on cocaine taking during self-administration. Our results suggest that the LPO sends inhibitory projections to GABAergic neurons of the VTA, thereby increasing dopaminergic activity. Furthermore, disinhibition of the LPO increases cocaine seeking suggesting projections from the LPO to VTA modulates behavioral responsiveness to cocaine. This data supports the role of LPO as a novel structure involved in cocaine-seeking behavior.

Title: Pharmacological antagonism of the toll-like receptor 4 attenuates cocaine induced reinstatement

Authors: *K. T. BROWN, C. ONEIL, S. LEVIS, T. FABISIAK, A. NORTHCUTT, L. WATKINS, R. BACHTELL;
Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Cocaine addiction is a chronic relapsing disorder characterized by persistent perturbations to an organism's homeostatic processes resulting in continued relapse vulnerability. Although considerable attention has been paid to the neuroadaptive consequences of chronic cocaine taking, few studies have examined the role of microglia, the brain's resident immune cells, in cocaine relapse. The Toll-Like Receptor 4 (TLR4) is largely expressed on microglia and is a molecular pattern receptor that recognizes xenobiotics as foreign and induces proinflammatory signaling in the central nervous system. Cocaine binds to the TLR4 complex resulting in the release of the proinflammatory cytokines interleukin-1 beta (IL-1β), interleukin-6 (IL-6), and nuclear factor of kappa B1A (NFKB1A) in the mesocorticolimbic dopamine system. Here, we used a rodent model of cocaine addiction where male Sprague-Dawley rats self-administered cocaine in 15 daily 2-hour sessions. Following self-administration, animals underwent extinction training and were challenged with cocaine. In one experiment, tissue punches from the ventral tegmental area (VTA) and nucleus accumbens (NAc) were collected and analyzed for expression of proinflammatory cytokine mRNA. Results indicate that cocaine self-administration enhanced the expression of the proinflammatory cytokine, IL-1β. In another experiment, rats were tested in a drug-induced reinstatement paradigm where pharmacological antagonism of the TLR4 receptor with lipopolysaccharide from the bacterium Rhodobacter sphaeiroides (LPS-RS) was administered locally in the NAc and VTA. The results demonstrate that TLR4 antagonism in either the VTA or the NAc significantly reduced cocaine-primed reinstatement of drug seeking. These results are consistent with the hypothesis that cocaine-induced microglia-dependent proinflammatory signaling is involved in cocaine relapse that is characteristic of drug addiction.

Title: The role of HCRTr1 in the VTA on Dopamine signaling; implications for addiction

Authors: *D. L. BERNSTEIN[1], C. BASS[2], K. LEVY[1], R. A. ESPAÑA[1];
[1]Neurobio. and Anat., Drexel Univ., Philadelphia, PA; [2]Immunol. and Pharmacol., Univ. of Buffalo, Bufflalo, NY

Abstract: The hypocretin / orexin (HCRT) system has been recognized to modulate motivated behavior via actions on the mesolimbic dopamine (DA) system. This generally neuroexcitatory peptide system sends extensive projections to numerous reward-related regions including the ventral tegmental area (VTA) where both the HCRT receptor 1 (HCRTr1) and HCRT receptor 2 subtypes are found. HCRT peptides have been shown to drive VTA DA cell activity, increase DA responses to cocaine in the nucleus accumbens (NAc), and promote cocaine self-administration, while blockade of HCRTr1 produces the opposite effects. Although the existing literature points to the HCRTr1 as an important regulator of reward and reinforcement processing, the majority of studies have employed acute, pharmacological manipulations of HCRT signaling. Moreover, these studies have traditionally relied on peripheral delivery of the HCRTr1 antagonist, SB-334867. Therefore, currently little is known about the long-term, modulatory role of HCRTr1 in the brain, or the specificity of actions at this receptor within the VTA. To address these issues, we knocked down HCRTr1 in the VTA and used fast scan cyclic voltammetry to measure baseline and cocaine-induced changes to DA signaling in the NAc. Further, we evaluated the effects of VTA-HCRTr1 knockdown on the acquisition and maintenance of cocaine self-administration behavior. Preliminary results suggest that long-term knockdown of VTA-HCRTr1 disrupts DA neurotransmission in the NAc under baseline and cocaine conditions, and also reduces cocaine self-administration behavior. When considered in the context of the existing literature, our experimental findings provide further support for the involvement of HCRTr1 in the VTA in regulating reward and reinforcement processes, and further suggest that HCRTr1 may be an effective target for future pharmacotherapies to treat substance abuse, particularly the abuse of cocaine.

Title: Increased expression of 5-HT6 Receptors in the indirect pathway reduces cocaine self-administration

Authors: *M. BRODSKY[1], A. W. GIBSON[1], D. SMIRNOV[1], S. NAIR[1], J. F. NEUMAIER[2]; [2]Psychiatry and Behavioral Sci., [1]Univ. of Washington, Seattle, WA

Abstract: "Increased expression of 5-HT_6 Receptors in the indirect pathway reduces cocaine self-administration" Drug addiction affects millions of people throughout the world and contributes heavily to healthcare costs and death. The nucleus accumbens (NAc) in the mammalian ventral striatum plays a large role in addiction, particularly in motivation for drug and reward-seeking behavior. Serotonin (5-HT) neurotransmission has also been implicated in addiction, and 5-HT_6 receptors are strongly expressed in the direct and indirect pathway medium spiny neurons (MSNs), the main outputs from the NAc. While there is evidence linking these receptors to drug reward, the exact mechanism by which they influence drug-associated behavior is unknown. In the present study we used viral vectors using dynorphin- or enkephalin promoter to drive expression of 5-HT_6 receptors or enhanced green fluorescent protein (eGFP) selectively in the direct or indirect pathway MSNs of the NAc shell (NAcSh), respectively. Rats were then trained to self-administer cocaine and their responding was investigated using fixed ratio, progressive ratio, and dose-response operant reinforcement conditions. Increased 5-HT_6 receptor expression in indirect but not direct pathway MSNs changed the overall pattern of cocaine taking, reduced the amount of cocaine self-administered under fixed ratio schedules, especially at low doses, increased the time to the first response and length of the inter-infusion interval, but did not alter motivation as measured by progressive ratio "break point" analysis. We conclude that 5-HT_6 receptors in indirect pathway neurons of NAcSh increased the sensitivity to the reinforcing properties of cocaine, particularly at low doses, suggesting that these receptors may be a target for pharmacological manipulation in the treatment of cocaine addiction.

Title: Phasic dopamine release in the nucleus accumbens during cocaine self-administration under different operant requirements

Authors: *I. OLIVA, M. WANAT;
Neuroscience Institute, University of Texas at San Antonio, San Antonio, TX

Abstract: The mesocorticolimbic dopamine system plays a crucial role in the development of drug addiction. Dopamine levels are elevated in response to drug-paired cues in rats self-administering cocaine, though this has been primarily examined only under low effort conditions with a fixed ratio 1 (FR1) reinforcement schedule. A hallmark of drug addiction is the willingness to exert considerable time and effort to obtain the drugs. However, it is not known whether cue-evoked dopamine release is related to the effort exerted in rats self-administering cocaine under high effort reinforcement schedules. We utilized fast-scan cyclic voltammetry to monitor phasic dopamine release using chronically-implanted electrodes in the nucleus accumbens in rats self-administering cocaine under FR3 and progressive ratio (PR) reinforcement schedules. Upon completion of the required number of nosepokes, rats received an intravenous 300 μg/kg cocaine infusion. Cocaine administration was paired with a 5 second duration audio cue (tone) and a 20 second time out period. Our preliminary results illustrate higher dopamine release to cocaine-paired cues during the PR reinforcement schedule sessions relative to the FR3 reinforcement schedule sessions. We also employed a model to estimate the cocaine concentration in the brain during these behavioral sessions to associate the dopamine response to cocaine levels. Preliminary analysis suggests the dopamine-release towards cocaine-paired cues is not related to the cocaine concentration in the brain. These findings suggest that dopamine release toward cocaine-paired cues is sensitive to the amount of effort required to earn a drug infusion, and is not driven by the pharmacological actions of cocaine.

Title: Region-specific role of DNA methylation in the reconsolidation of appetitive and aversive memories associated with morphine in rats

Authors: *J.-J. ZHANG[1], P. LIU[2], N. SUI[2];
[1]Inst. of Psychology, Chinese Acad. of Scienc, Beijing, China; [2]Inst. of Psychology, Chinese Acad. of Sci., Beijing, China

Abstract: Drug-related positive and aversive memories are the main factors contributing to the persistence of relapse risk. Upon retrieval, established memories enter a transiently reconsolidation state, which is important for the persistent maintain of addiction memories. Our previous work demonstrated that DNA methylation are essential regulators in memory consolidation, but little is known about the role of DNA methylation in the memory reconsolidation. Here, we used conditioned place preference (CPP) and conditioned place aversion (CPA) paradigms to investigate the role of DNA methylation in the reconsolidation of morphine-related emotional memory. The results showed that the microinjections of DNA transmethylase inhibitors 5-aza-2-deoxycytidine into basolateral amygdala (BLA) but not central nucleus of amygdala (CeA), nucleus accumbens (NAc) shell or core immediately after memory reactivation disrupted the reconsolidation of morphine-induced CPP. Similarly, the inhibition of DNA methylation in agranular insula but not in BLA or CeA persistently disrupt morphine-naloxone induced CPA. These results indicate that the reconsolidation of drug-related positive and aversive memory is region-spcific regulated by DNA methylation.

Title: Blocking infralimbic basic fibroblast growth factor (bFGF or FGF2) facilitates extinction of drug seeking

Authors: *M. HAFENBREIDEL, C. RAFA TODD, C. W. SMIES, R. C. TWINING, D. MUELLER;
Psychology, Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Stimulant drug use results in structural and functional changes in reward-related brain regions (Flores & Stewart, 2000). These changes may underlie the persistence of compulsive drug seeking and relapse that characterizes drug addiction. Neurotrophic factors, such as basic fibroblast growth factor (bFGF or FGF2), are necessary for neuronal survival, growth, and differentiation, and may mediate drug-induced morphological changes that underlie the perseveration of addiction. Following cocaine exposure, bFGF is increased in reward-related brain regions (Fumagalli et al., 2006), including the infralimbic medial prefrontal cortex (IL-mPFC). The IL-mPFC is necessary for extinction (Otis et al., 2014; LaLumiere et al., 2010), but whether drug-induced over-expression of bFGF in this region affects extinction is unknown. Thus, we aimed to determine if blocking bFGF in IL-mPFC would facilitate extinction following cocaine self-administration. Rats were trained to lever press for i.v. infusions of cocaine (0.25mg/inf, 90 min/day) prior to extinction. Extinction consisted of four 30 min extinction sessions, in which rats were infused into the IL-mPFC with a neutralizing antibody against bFGF that blocks the biological function of bFGF, prior to each session. Extinction retention was tested during a subsequent 90 min extinction session. Blocking bFGF in the IL-mPFC decreased lever pressing during the 90 min extinction session, indicating facilitated extinction. In contrast, blocking bFGF alone was not sufficient to facilitate extinction, as blocking bFGF and returning rats to their home cage had no effect on subsequent extinction of drug seeking. Next, we examined if bFGF or its high affinity receptor fibroblast growth factor receptor 1 (FGFR1) protein expression was altered following extinction. Rats were trained to self-administer cocaine as before with half undergoing extinction or not. Additionally, rats that were reinforced with sucrose and underwent extinction or not, rats that received yoked-saline infusions that were paired with cocaine self-administering rats (extinction or not), and a naïve home cage control were included. bFGF protein expression in the IL-mPFC was only increased following cocaine self-administration, an effect reversed by extinction. FGFR1 protein expression was not significantly altered in any group. These results suggest that cocaine-induced over-expression of bFGF in the IL-mPFC inhibits extinction, as reducing bFGF expression during extinction permits rapid extinction. Therefore, targeted reductions in bFGF during therapeutic interventions could enhance treatment outcomes for addiction.

Title: PKA mediates prelimbic neuronal excitability underlying cocaine-associated memory retrieval

Authors: *H. YOUSUF[1], J. M. OTIS[1,2], M. K. FITZGERALD[1], D. MUELLER[1];
[1]Univ. of Wisconsin-Milwaukee, Milwaukee, WI; [2]Univ. of North Carolina-Chapel Hill, Chapel Hill, NC

Abstract: Persistent drug seeking is maintained by drug-associated memories, through which cues can elicit craving and relapse. Thus, impairing retrieval of drug-associated memories could dampen the motivation to seek drugs. Recently, retrieval of drug-associated memories was shown to be disrupted by inhibition of β-adrenergic receptors (β-ARs) in the prelimbic medial prefrontal cortex (PL-mPFC; Otis et al., 2013). β-ARs stimulate cAMP dependent protein kinase A (PKA; Mueller et al., 2008) which enhances neuronal excitability by inhibiting the slow afterhyperpolarization (sAHP; Zhang et al., 2013). However, whether this intracellular signaling cascade underlies retrieval is unknown. Using patch-clamp electrophysiology and the conditioned place preference (CPP) paradigm, we determined whether intrinsic excitability of PL-mPFC neurons maintains memory during retrieval. Rats were conditioned to associate one chamber, but not another, with cocaine. During post-conditioning CPP retention trials, rats had access to both chambers and spent more time in the previously cocaine-paired chamber than in the saline-paired chamber. Microinfusions of the PKA antagonist (RP-2'-O-MB-cAMPs) in the PL-mPFC before the first retrieval test disrupted expression of the CPP on that trial and all subsequent trials. This retrieval deficit was rescued by co-administration of a sAHP antagonist (UCL-2077). *In vitro* patch-clamp recordings were used to examine the physiological consequences of noradrenergic signaling in the PL-mPFC. Pyramidal cells in the PL-mPFC were dialyzed with Rp-cAMPs or not prior to bath application of norepinephrine (NE). In the absence of Rp-cAMPs, NE increased the number of evoked action potentials by reversing the sAHP to a slow afterdepolarization (sADP). However, Rp-cAMPs blocked the NE-induced reversal of the sAHP, and prevented the increase in evoked action potentials. Finally, we examined whether

intrinsic excitability maintains cocaine-associated memory retrieval. Cocaine-conditioned rats were split into low retrieval (LR) and high retrieval (HR) groups based on CPP scores. Patch-clamp recordings from PL-mPFC pyramidal neurons revealed that the number of evoked action potentials was correlated with CPP scores, and was increased in neurons from HR rats compared to LR rats. These data demonstrate that intrinsic neuronal excitability in the PL-mPFC maintains drug-associated memory retrieval through a PKA-dependent signaling cascade. Thus, modulation of the intrinsic excitability of PL-mPFC neurons could have therapeutic potential in the treatment of drug addiction.

Title: The role of medial prefrontal cortex gap junction communication in retrieval and extinction of cocaine seeking

Authors: ***M. FITZGERALD**, J. L. BURKARD, A. GASPARINI, A. ANDERSON, D. MUELLER;
Univ. of Wisconsin - Milwaukee, Milwaukee, WI

Abstract: Drug-associated cues can trigger craving and relapse for drug addicts. Preventing retrieval of cue-associated memories or reducing cue reactivity through extinction could reduce relapse rates. Retrieval of a cocaine-associated memory is dependent on activation of the prelimbic medial prefrontal cortex (PL-mPFC; Otis et al., 2013) whereas extinction of cocaine seeking is consolidated in the infralimbic medial prefrontal cortex (IL-mPFC; Otis et al., 2014). Although the neurochemical and synaptic mechanisms underlying drug-related behavior have been investigated extensively, little is known regarding the contribution of gap junction communication between neurons and astrocytes. Both neurons and astrocytes express gap junctions. Gap junctions are specialized membrane structures built of connexin channels that allow cytoplasmic continuity between connected cells. Previous work has demonstrated that

activity of either neuronal or astrocytic gap junctions can alter neuronal activity and plasticity (Palacios-Prado et al., 2014; Pannasch et al., 2011). Thus, we investigated the role of neuronal gap junctions, astrocytic gap junctions, or the combination of both during retrieval and extinction of cocaine seeking using the conditioned place preference (CPP) model. Following conditioning and prior to the first retrieval (15 min) or extinction (30 min) test, rats received a bilateral microinfusion of either a non-selective gap junction blocker (carbenoxolone), a neuron-specific gap junction blocker (quinine), an astrocyte-specific gap junction blocker (IRL-1620), or vehicle into the PL-mPFC or IL-mPFC and were tested daily. General and astrocytic gap junction blockade in the PL-mPFC initially disrupted retrieval of a CPP, but failed to maintain prolonged disruption as demonstrated by a return of CPP in later test trials compared to extinguished controls. Neuronal gap junction blockade in the PL-mPFC enhanced maintenance of the cocaine-associated memory relative to other groups. General, neuronal, or astrocytic gap junction blockade in the IL-mPFC resulted in disrupted extinction learning. These results suggest that individually or collectively disrupting neuronal and astrocytic gap junction networks in the PL-mPFC or IL-mPFC prolong drug-seeking behavior, further suggesting that gap junction communication in the mPFC may play a critical role in drug-seeking behavior.

Title: Identification of distinct neuronal ensembles selectively activated by discrete cues associated with cocaine or heroin seeking in rats

Authors: *F. RUBIO, D. CAPRIOLI, F. SOTO DEL VALLE, M. VENNIRO, V. WALLACE, Y. SHAHAM, B. HOPE;
Behavioral Neurosci. Res. Branch, NIDA IRP, NIH, Baltimore, MD

Abstract: Background: Learned associations between discrete cues (or contexts) and drug effects are thought to be encoded by sparsely distributed patterns of neurons called “neuronal ensembles”. Here, we determined whether cocaine- and heroin-related cues are encoded by

distinct neuronal ensembles within the medial prefrontal cortex (mPFC) in a rat model of drug relapse. Methods: We trained rats to self-administer cocaine (0.75 mg/kg) and heroin (0.0375 mg/kg) on alternate days (3-h/day; 18-days). Cocaine and heroin infusions were paired with two distinct levers and the presentations of discrete cue-lights (20-sec). After 5 days of forced abstinence, rats were assigned to four groups based on the order of two 5 min extinction tests (spaced by 20-min) with the drug-related cues: Cocaine-Cocaine, Heroin-Heroin, Cocaine-Heroin and Heroin-Cocaine. A Non-test control group was trained but kept in the operant chamber on test day. We detected Homer 1a, Arc and Fos mRNA using RNAscope assay. We selected target-probes to detect nuclear signal for Homer 1a- and Arc-activated neurons from the ensembles activated during the first test and second test, respectively. Results: Preliminary analysis showed higher overlap (co-expressing Homer 1a and Arc) in the Cocaine-Cocaine group than in the Heroin-Cocaine, Cocaine-Heroin, and Heroin-Heroin groups for both dorsal and ventral mPFC. Furthermore, 92-98% of these Homer 1a- and Arc-positive cells co-expressed Fos mRNA, a common marker of neural activity. Conclusions: Our results suggest that distinct mPFC neuronal ensembles encode two different drug-cue memories. Further experiments are needed to characterize these ensembles and assess mutually exclusive causal roles in drug-seeking behavior.

Title: Interleukin-1 in the dorsal hippocampus is a novel mediator of acquisition of heroin-conditioned immunosuppression

Authors: ***C. LEBONVILLE**[1], M. E. JONES[1], L. W. HUTSON[1], R. A. FUCHS[2], D. T. LYSLE[1];
[1]Psychology and Neurosci., Univ. of North Carolina At Chapel Hill, Chapel Hill, NC;
[2]Integrative Physiol. and Neurosci., Washington State Univ., Pullman, WA

Abstract: Like many other opiates, heroin suppresses the immune system. Similarly, exposure to environments associated with heroin use can produce immunosuppression through Pavlovian conditioning. The dorsal hippocampus (DH) is necessary for this conditioned effect. Interleukin-1β (IL-1β), a pro-inflammatory cytokine expressed in the DH, has been linked to learning and memory. Our laboratory has demonstrated that siRNA-mediated IL-1β gene silencing in the DH prevents the *expression* of heroin-conditioned immunosuppression. Here we investigated the role of DH IL-1 in the *acquisition* of heroin conditioned immunosuppression. To this end, rats were conditioned to associate heroin (1 mg/kg, SC) with a distinct context. During Pavlovian conditioning, rats received bilateral microinfusions of the endogenous IL-1 antagonist (IL-1RA; 1.25 μg/0.5 μL/side) or saline into the DH either 30 min before or 24 h after each of 5 context-heroin pairings. To control for the timing of the injections, each group received saline when the other group received IL-1RA. Six days later, rats were either re-exposed to the heroin-paired context for 60 min or remained in their home cages. Immediately after this manipulation, their immune system was challenged using lipopolysaccharide (LPS, 1 μg/kg, SC), a component of gram negative bacteria. The rats were sacrificed 6 h later. Splenic iNOS, IL-6, IL-1β, and plasma nitrate/nitrite levels were assessed. IL-1RA microinjection 30 min before, but not 24 h after, context-heroin pairing blocked the acquisition of heroin-conditioned immunosuppression, as indicated by no significant suppression of splenic proinflammatory responses to LPS after heroin context re-exposure. Future studies will evaluate whether this time-dependent, IL-1RA-induced acquisition deficit is due to a disruption of associative learning or of the primary immune suppressing effects of heroin during training. Regardless of the mechanism, these findings suggest that elements of the IL-1 signaling pathway may be therapeutic targets for restoring immune function in opiate-exposed populations.

Title: Dopamine D3 receptor activity and downstream calcium/calmodulin signaling targets are altered within the basolateral amygdala as a function of opiate exposure state

Authors: *L. G. ROSEN, W. J. RUSHLOW, S. R. LAVIOLETTE;
Anat. and Cell Biol., The Univ. of Western Ontario, London, ON, Canada

Abstract: The potent rewarding effects of opiate drugs facilitate the formation of associative memories linked to the drug-taking experience and play a key role in triggering relapse. These memories are encoded in the basolateral amygdala (BLA). Intra-BLA processing of opiate-related reward memories is mediated by dopamine D1 receptors (D1R) and D2 receptor (D2R) signaling as a function of opiate exposure state. D1Rs are required for acute opiate memory formation in the previously drug-naïve state, but D2R signaling is necessary for memory formation during opiate dependence and withdrawal. The D3 receptor (D3R) is highly expressed in the mesocorticolimbic system, and is also critical for the learning and memory of emotional memory. There is evidence of changes to D3R availability in chronic opiate users, thus raising the question of the molecular mechanisms underlying alterations to D3R expression and function following chronic opiate use. D3R activation is linked to calcium/calmodulin kinase pathways, particularly to cascades involving calcium/calmodulin protein kinase IV (CaMKIV) and calcineurin. These signaling pathways play important roles in synaptic plasticity, and are crucial for the formation of conditioned reward memory in limbic regions. Here, we identify opiate exposure-induced changes to intra-BLA dopamine receptors and their downstream molecular targets. Protein analysis revealed that opiate dependence and withdrawal results in a downregulation of intra-BLA D2R and D3R, but not D1R expression. Additionally, the expression of CaMKIV and calcineurin are profoundly downregulated and upregulated, respectively. We further use a place conditioning procedure paired with targeted microinfusions to probe the behavioural significance of these molecular alterations. We found that intra-BLA D3R activity is not necessary for the formation of opiate reward memories in a previously opiate-naïve state, but that opiate dependence and withdrawal renders these memories sensitive to manipulations of D3R signaling. Ongoing studies are continuing to examine how further manipulations of these molecular pathways may relate to opiate addiction-related memory formation. Overall, this work demonstrates that opiate dependence and withdrawal affects the expression and function of intra-BLA D3Rs and their downstream molecular targets.

Title: Remembering to abstain: the impact of working memory on length of first quit attempt in drug users

Authors: *T. E. MOSES[1], E. DUNNE[2], J. J. ROSE[1], W. W. LATIMER[1];
[1]Lehman Col., Bronx, NY; [2]Univ. of Florida, Gainesville, FL

Abstract: Background: Drug addiction continues to be a major public health problem: more than 20 million Americans aged 12 or older use illicit drugs (NCADD). While much attention is given to treatment and prevention, limited attention is given to the work drug users themselves conduct in order to quit. Most drug users have tried to quit using drugs at some point, and most often find themselves unsuccessful. One factor associated with this difficulty may be related to working memory. Recent research has examined working memory in drug users and found poorer working memory than in non-users. To explore this further, the present study aimed to examine the link between working memory and the length of time an individual was able to abstain from substance use during their first quit attempt. Methods: A secondary data analysis of participants enrolled in the NIDA-funded NEURO II-HIV Prevention RCT study in Baltimore, Maryland. The sample included 167 drug-using adults aged 18 to 59 (M age=42.2, SD=9.8). Participants were community-recruited. They completed an HIV-risk behavior interview that included questions about substance use and whether they had previously attempted to quit using drugs. Participants completed a battery of neuropsychological tests which included the WAIS-III digit span test, which measures forward and backward digit span memory. Linear regression was conducted using the raw scores in order to determine the association between digit span and the length of the time of first quit attempt. Results: Linear regression was conducted to compare digit span total score (M=13.78, SD=4.36) and the length of first quit attempt in years (M=2.28, SD=3.24). Digit span total score was significantly associated with length of first quit attempt, $b = -.22$, $t(165) = -2.88$, $p = .005$, such that those with stronger working memory ability maintained a longer period of nonuse. The results for the Shipley Institute of Living total score (M=33.7, SD=97.20) were included in these analyses to control for general intellectual functioning. Conclusions: Working memory appears to play a role in how long a person is able to maintain abstinence from drugs and alcohol. Individuals who were able to remember more numbers during the digit span test seemed to be able to abstain longer from drugs and alcohol during their first quit attempt than those who remembered fewer. These findings suggest a way in which we can enhance treatment techniques aimed at drug addicts by including memory exercises to improve working memory. Perhaps individuals who are struggling to maintain abstinence may show improved lengths of sobriety--ideally long-term--as working memory is improved.

Title: PP1/GSK3 signaling pathway is involved in the reconsolidation of cocaine reward memory

Authors: *X. SHI, J. PALMA, E. M. UNTERWALD;
Dept. of Pharmacol. & Ctr. for Substance Abuse Res., Temple Univ. Sch. of Med., Philadelphia, PA

Abstract: Our previous study demonstrated that glycogen synthase kinase-3 (GSK3) activity is highly induced in nucleus accumbens (NAc), hippocampus, and prefrontal cortex during memory retrieval, and that reconsolidation of cocaine reward memory can be attenuated by inhibition of GSK3. Since protein phosphatase 1 (PP1) is an activator of GSK3β and GSK3β is part of a multi-protein NMDA receptor complex, the roles of PP1 and NMDA receptors in the reconsolidation of cocaine contextual reward memory were investigated in this study. Adult male CD-1 mice underwent cocaine place conditioning for 8 days and were tested for place preference on day 9. Twenty-four hours after the test for place preference, mice were confined to the compartment previous paired with cocaine in a drug-free state for 10 minutes to reactivate cocaine-associated memories. Western blotting indicated that levels of phosphorylated GSK3αSer21 and GSK3βSer9 were down-regulated in the mouse nucleus accumbens and hippocampus after the reactivation of cocaine cue memories, consistent with our previous findings. Interestingly, PP1 inhibition with okadaic acid (OA, 150 ng/3ul, i.c.v) 30 minutes before re-exposure to the compartment previously paired with cocaine prevented the decrease in phosphorylated GSK3α/β in both nucleus accumbens and hippocampus. Furthermore, administration of OA 30 minutes prior to the reactivation of cocaine cue memories abrogated a previously established place preference when tested 24 hours later. Similarly, administration of the NMDA receptor antagonist MK-801 (0.3 mg/kg, i.p.) immediately after re-exposure to cocaine-paired compartment disrupted the previously established place preference, suggesting interference with reconsolidation of cocaine-associated reward memories. The role of nucleus accumbens in the reconsolidation of cocaine associated memories was also investigated in this study. Immediately after the reactivation session, microinjection of SB216763, a selective inhibitor of GSK-3, into nucleus accumbens blocked the reconsolidation of cocaine-associated

reward memories. These findings suggest that the dephosphorylation of GSK3 that occurred upon activation of cocaine-associated reward memory may be initiated by the activation of PP1 during the induction of NMDA receptor-dependent reconsolidation of cocaine-related memory. Moreover, the role of PP1 and NMDA receptor in cocaine memory reconsolidation makes them potential therapeutic targets in treatment of cocaine addiction and prevention of relapse.

Title: Transcriptional and epigenetic factors underlying the extinction of nicotine-seeking behaviour in the rat

Authors: *M. R. CASTINO[1], N. A. YOUNGSON[2], D. BAKER-ANDRESEN[3], V. S. RATNU[3], T. W. BREDY[3,4], K. J. CLEMENS[1];

Sci., Univ. of California, Irvine, CA

Abstract: Relapse to cigarette smoking is a principle characteristic of tobacco addiction. This may be due to the persistence of drug-associated memories that prompt drug use across abstinence. This clinical finding can be modelled in rodents, as rats previously trained to self-administer nicotine are susceptible to reinstatement of drug-seeking following exposure to priming doses of nicotine, or cues previously associated with its delivery. Like other forms of memory, drug-associated memories appear to depend on changes in gene expression that are coordinated, in part, by epigenetic mechanisms. Research in this field suggests that the formation and extinction of contextual drug memories are regulated by dynamic modifications to chromatin. Previous work in our laboratory has demonstrated that administration of the histone deacetylase (HDAC) inhibitor, sodium butyrate (NaB), facilitates the extinction of nicotine-

seeking in a manner that provides resistance to reinstatement. The present study aimed to investigate the molecular mechanisms involved in this potentiated extinction learning, examining the effect of both nicotine exposure and NaB treatment on mRNA expression and histone acetylation in the rat medial prefrontal cortex. Sodium butyrate induced a significant increase in gene expression of the neuronal protein kinase, Cdk5, in both saline and nicotine treated rats. In contrast, NaB increased BDNF mRNA only in saline control rats. Furthermore, nicotine, but not saline, exposure induced a decrease in histone H3K14 acetylation at the BDNF Exon IV promoter that was normalised by NaB treatment. These findings indicate that NaB and nicotine may act individually and in concert to regulate the genetic profile of the brain, though the behavioural consequences of their interactions are yet to be fully elucidated.

Title: Timing of SCH 23390 administration influences extinction of conditioned hyperactivity in mice

Authors: *A. S. RAUHUT[1,2], K. A. RATNER[2], S. BUCK[2], E.-R. SUNG[2];
[1]Psychology, [2]Neurosci. Program, Dickinson Col., Carlisle, PA

Abstract: Previous research has suggested that the dopamine subtype-1 (D1) receptor system has a role in extinction of context-drug memories. However, the precise role of the D1 receptor system in different memory processes (i.e., retrieval vs. reconsolidation) involved with extinction of conditioned hyperactivity is unknown. Thus, the present experiments determined the effect of a selective D1 receptor antagonist, SCH 23390, on extinction of conditioned hyperactivity produced by methamphetamine when SCH 23390 was administered immediately after (memory reconsolidation; Experiment 1), or administered before (memory retrieval; Experiment 2), daily extinction sessions. The experiments consisted of 2 phases: acquisition and extinction. During the acquisition phase, male, Swiss-Webster mice received injections (s.c.) of either vehicle

(physiological saline; unpaired) or methamphetamine (1.0 mg/kg; paired) immediately prior to 30-minute sessions in the locomotor activity chambers on Chamber Days 1, 3, 5 and 7. On the intervening days (Chamber Days 2, 4, 6 and 8), paired and unpaired mice received injections of either vehicle or methamphetamine in their home cages, respectively. Following the acquisition phase, paired and unpaired mice received daily injections of vehicle immediately prior to 30-minute sessions in the locomotor activity chambers for 5 (Experiment 1) or 7 (Experiment 2) consecutive sessions (extinction). Paired and unpaired mice also received daily injections (i.p.) of either vehicle (physiological saline) or SCH 23390 (0.0125, 0.025, 0.05 mg/kg) immediately after (Experiment 1), or received daily injections of vehicle or SCH 23390 (0.05 mg/kg) 30 minutes before (Experiment 2), the extinction sessions. In both experiments, methamphetamine produced robust conditioned hyperactivity followed by extinction. Furthermore, we found that SCH 23390 (0.05 mg/kg) facilitated the rate of extinction when administered prior to the session, but did not alter the rate of extinction when administered immediately following the sessions. Taken together, these results suggest that the D1 receptor is involved with memory retrieval (or expression), but not memory reconsolidation, processes during extinction of conditioned hyperactivity.

Title: Modeling Pavlovian alcohol seeking in rats using a retractable sipper to study both appetitive and consummatory behavior

Authors: *R. U. COFRESI[1], S. M. LEWIS[1], N. CHAUDHRI[2], H. J. LEE[1], M. H. MONFILS[1], R. A. GONZALES[1];
[1]The Univ. of Texas At Austin, Austin, TX; [2]Concordia Univ., Montréal, QC, Canada

Abstract: Appetitive conditioned responses elicited by cues that predict access to alcohol may promote problematic alcohol use in individuals at varying risk for alcohol abuse and alcoholism. We developed an appetitive Pavlovian paradigm in which time-limited access to unsweetened alcohol (10% or 15% v/v ethanol in tap water: 10E or 15E) via a retractable sipper tube and

bottle assembly served as the reinforcer. In our paradigm, 10s after the houselight turned on, the sipper inserted into the chamber, and after 10s elapsed, the sipper retracted, and the houselight turned off. Several such trials were given per conditioning session, with 4 min elapsing between trials on average. All sessions were recorded and all trials were scored for behaviors of interest (rearing/orienting, sipper site approach, sipper contact) using a sampling method. Lickometers provided an additional, direct measurement of sipper contact. We first induced drinking in 12 singly housed, adult, male Long-Evans rats by providing 24 hr access to unsweetened alcohol in the homecage on MWF for 5 weeks (standard chow and water were available ad libitum; mean ± s.e.m. ethanol intake over last 3 sessions drinking 10E or 15E = 3.2±0.4 g/kg). Rats were then conditioned over 12 consecutive daily sessions, each providing 8 light-sipper pairings. Despite only 8 access periods per session, each only 10s long, rats ingested psychopharmacologically relevant quantities of ethanol (mean ± s.e.m. ethanol intake over last 3 sessions drinking 10E or 15E = 0.58 ±0 .07 g/kg; mean ± s.e.m. blood ethanol content = 22±7 mg/dL 5-10 min post-session). Two cue-conditioned responses developed in all rats: approach to the sipper site during the 5s prior to sipper insertion and sipper contact upon presentation. Conditioned approach and contact were then extinguished over 12-14 consecutive daily sessions, each providing 12 light-sipper pairings with an empty bottle. A long-term memory test (4 light-sipper pairings, empty bottle) conducted 48 hr after the last extinction session revealed low spontaneous recovery of conditioned responses. Providing the scent of alcohol during a second memory test conducted 48 hr later resulted in reinstatement of conditioned sipper approach ($F_{1,11}$=7.118, p=0.0219) and contact ($F_{1,11}$=13.77, p=0.003) relative to the first memory test. In conclusion, we established a model of Pavlovian alcohol seeking in adult, male rats. In traditional preparations, fluid and food ports allow measurement of only appetitive behavior. Importantly, the use of a retractable sipper in our preparation allows us to measure both appetitive and consummatory behavior.

Title: Nicotine attenuates the effects of HIV-1 proteins on the neural circuitry of working and contextual memory

Authors: *T. NESIL[1], J. CAO[1], Z. YANG[2], S. L. CHANG[2,3], M. D. LI[1];
[1]Psychiatry and NB Sci., Univ. of Virginia, Charlottesville, VA; [2]Inst. of NeuroImmune Pharmacol., [3]Dept. of Biol. Sci., Seton Hall Univ., South Orange, NJ

Abstract: Human immunodeficiency virus (HIV)-1-associated neurocognitive disorders (HAND) are characterized by synaptic damage and neuronal loss in the brain. Excessive glutamatergic transmission and loss of cholinergic neurons are the major indicators of HAND. By acting as a cholinergic channel modulator, the cognitive-enhancing effect of nicotine in neurodegenerative and cognitive disorders has been documented. However, it remains to be determined whether nicotine has any beneficial effects on memory and synaptic plasticity formation in HAND. In this study, we investigated the effects of nicotine on synaptic plasticity and hippocampus/prefrontal cortex (PFC)/amygdala-dependent memory formation in HIV-1Tg and F344 control rats. Chronic nicotine treatment (0.4 mg/kg/day, s.c.) significantly attenuated the cognitive deficits in both spatial and contextual fear memory in the HIV-1Tg rats, but impaired the contextual learning memory in the F344 rats. To further determine the role of nicotine in the synaptic dysfunction caused by HIV-1 proteins, we analyzed the expression of key representative genes related to synaptic plasticity in the hippocampus, PFC, and amygdala of HIV-1Tg and F344 rats using a custom-designed qRT-PCR array. The HIV-1 proteins significantly altered the glutamate receptor-mediated intracellular calcium cascade and its downstream signaling cascade in a brain region-specific manner. Further, chronic nicotine treatment reversed the effects of the HIV-1 proteins on the expression of genes involved in synaptic plasticity in the three brain regions. The effects of nicotine differed significantly in the HIV-1Tg and F344 rats. Our findings indicate that nicotine can attenuate the effects of viral proteins on cognitive function and produce brain region- and strain-specific effects on the intracellular signaling cascades involved in synaptic plasticity and memory formation.

Title: Common brain mechanism underlying pathological gambling and problematic pornography consumption

Authors: *M. K. GOLA[1,2], M. WORDECHA[3], G. SESCOUSSE[4], B. KOSSOWSKI[3], M. WYPYCH[3], M. LEW-STAROWICZ[5], A. MARCHEWKA[3];

Abstract: In recent years clinicians have observed an increase in the number of people suffering from out-of-control sexual behaviors (OCSB) such as excessive pornography consumption, masturbation or use of paid sexual services. There is ongoing discussion on how to conceptualize these behaviors and perform efficient psychotherapeutic or pharmacological intervention. To address this issue we have used an incentive delay task that was previously employed to study pathological gambling (PG) - a well-characterized behavioral addiction. This previous study (Sescousse et al., 2013) showed that pathological gamblers are characterized by a blunted VStr response to non-monetary reward cues. The magnitude of this effect was correlated with gambling severity and accompanied by lower motivation for erotic cues. If the brain mechanisms underlying OCSB are similar to PG, we should expect the opposite pattern, i.e. a blunted VStr response to non-erotic cues, correlated with OCSB severity and diminished motivation. We examined this hypothesis in 28 Caucasian heterosexual males. Half of them were in treatment because of excessive pornography consumption and masturbation. This 'OCSB group' met the criteria of hypersexual disorder5 (HD; Kafka, 2010) and had no other psychiatric conditions (according to ICD 10). The other 14 participants were pornography users who did not qualify for HD and were matched on age and income. We used fMRI and the exact same protocol as the in previous study on PG (Sescousse, et al., 2013) In line with our prediction there was a significant interaction between group and monetary/erotic cues on VStr reactivity, primarily driven by a diminished VStr response to non-erotic (i.e. monetary) cues in OCSB individuals. The differential VStr reactivity to erotic and monetary cues was correlated with the relative motivation for these two rewards (as measured by RTs) as well as with OCSB symptoms (as measured by the Sexual Addiction Screening Test) and frequency of masturbation. Given the role of the VStr in reward learning and expectation (Berridge et al., 2009), these results suggest that in individuals with OCSB, erotic cues may act as powerful incentives overriding the motivational value of alternative sources of reward (such as money) and more likely drive them to out-of-control behaviors. Our findings points also to a possible overlap between OCSB and the concept of behavioral addiction.

Title: Acute methamphetamine produces long-term deficits in hippocampal-dependent spatial learning and memory retention, decreases PKMzeta, GluA2 and dopamine 1 receptors (D1), and increases microglial expression

Authors: *S. BRAREN[1], D. DRAPALA[1], J. AVILA[1,2], P. A. SERRANO[1,2];
[1]Hunter Col., New York, NY; [2]The Grad. Ctr. of CUNY, New York, NY

Abstract: The purpose of our study was to evaluate the effects of two bolus doses of methamphetamine (MA; 30 mg/kg) on spatial learning and memory. MA is known to have significant effects on dopaminergic terminals within the striatum and also known to decrease Dopamine 1 receptor (D1) expression in the hippocampus (Braren, 2014 Front. Behav. Neuro. 4, 438). We evaluated spatial learning and memory using the hippocampal dependent task, the radial 8-arm maze (RAM). The hippocampi from this study were evaluated for the expression of several synaptic markers important for memory and synaptic plasticity. These include the D1 receptor, the atypical protein kinase M zeta (PKMζ), and the AMPA receptor subunit GluA2. PKMζ is important for trafficking the GluA2 subunit to the membrane and maintaining GluA2 on the membrane improves memory retention (Migues, 2010 Nat. Neurosci. 13, 630-4; Sebastian, 2013 PLoS One. 8, e81121). We hypothesize that neuroinflammation plays a role in exacerbating the negative effects of MA-induced memory deficits. One inflammatory marker in particular, COX2, is one of two isoenzymes, which catalyze the conversion of arachidonic acid into prostaglandins. Several prostaglandins are catalyzed by COX2, but one in particular is very toxic, the prostaglandin J2 (PGJ2). We have found that PGJ2 can induce memory deficits when

injected into the hippocampus. Thus, we are interested in determining how MA toxicity may activate this inflammatory pathway involving PGJ2, perpetuating the toxicity leading to sustained cognitive deficits. Our results show that two bolus doses of MA delivered 1 week apart produces deficits in learning the RAM 7 weeks later and decreases PKMζ, GluA2 and D1 expression. These results identify the long lasting effects of MA on hippocampal function. Additionally, delivering these two bolus doses of MA after acquiring the RAM memory results in retrieval deficits at 2 weeks after the end of training and results in increased in microglia expression in the CA1 region of the hippocampus. These results elucidate the long lasting learning and memory impairments from acute MA treatment. We hypothesize that these long-term effects of MA are mediated through an inflammatory pathway, as microglia expression is upregulated after MA. Future studies will examine the role of COX2 expression in these samples.

Title: Activation and transition of the ventral and dorsal striatum during cue reactivity in Internet gaming disorder

Authors: ***L. LIU**[1], J.-T. ZHANG[2], L.-J. WANG[2], B. LIU[2], S.-S. MA[2], Y.-W. YAO[2], X.-Y. FANG[1];
[1]Beijing Normal Univ., Inst. of Developmental Psychology, Beijing, China; [2]Beijing Normal University, State Key Lab. of Cognitive Neurosci. and Learning and IDG/McGovern Inst. for Brain Res., Beijing, China

Abstract: According to dual-systems accounts, instrumental behavior consists of two dissociable learning processes mainly mediated by corticostriatal pathways: goal-directed system is performed according to the relationship between actions and their consequences mediated by VMPFC, ventral striatum (VS); habitual system controlled by dorsal striatum (DS) is directly

triggered by related cues even when the outcomes have lost their goal values. As a potent forms of reinforcement learning, many studies have focused on substance dependence and supported the hypothesis that drug addiction can be viewed as the endpoint of a series of transitions from initial voluntarily drug use to habitual drug use. And the addiction is the result of dynamic shifts in the neural control over behavior, from ventral to dorsal striatal control. But this transition hasn't previously been studied in Internet Gaming Disorder (IGD), which has been identified in Section III of the DSM-V as a non-substance addiction requiring further study. **Methods** We used a cue-reactivity functional magnetic resonance imaging (fMRI) design during which pictures of Internet games and general Internet surfing stimuli were presented. Thirty-nine IGDs (18.92±9.85 gaming hours/ week, score of Chinese Internet Addiction Scale (CIAS) > 67) and 23 matched healthy controls (HC) (0.92±0.20 gaming hours/ week, score of CIAS < 60) were examined. **Results** IGDs showed significant higher activations in the VS and DS compared to HC [contrast 'game > general Internet cues'; region of interest analyses: $P < 0.05$ false discovery rate-corrected]. In IGDs, the left VS and right caudate activation correlated negatively with self-reported cue-induced craving (Pearson's $r = -0.34$, $P = 0.03$; $r = -0.31$, $P = 0.05$). Positive associations were found between cue-induced activation in the DS (right pallidum and putamen) and duration of current online gaming state in IGDs ($r = 0.43$, $P = 0.007$; $r = 0.29$, $P = 0.07$). Furthermore, cue-induced activation in the putamen was negatively associated with VS volume ($r = - 0.33$, $P = 0.04$). **Conclusions** In line with the hypothesis we found higher cue-induced activation of the VS and DS in IGDs, and the decreasing relevance of cue processing in the ventral and dorsomedial part of striatum involved goal-directed actions, whereas the increasing involvement of gamer's DS in cue processing. Furthermore the aberrant of VS morphometry may underlie the dominant of DS, which may implicate the deficit of goal-directed processing and the over-reliance on habitual system. Our results excluded the impact of substance on dopamine functioning, suggesting that the transition may also be a general feature of behavioral addiction.

Title: High fat dieting delays the extinction of conditioned preference for places paired to palatable food and upregulates addiction biomarkers in the nucleus accumbens

Authors: ***J. M. PÉREZ-ORTIZ**, A. GALIANA, E. SALAS, C. GONZÁLEZ-MARTÍN, M. GARCÍA-ROJO, L. F. ALGUACIL;
Translational Res. Unit, Univ. Gen. Hosp. of Ciudad Real, Ciudad Real, Spain

Abstract: We have developed a mouse model of food addiction to quantify the effect of dietary fat on palatable food seeking and to validate three proteins as potential biomarkers of addiction vulnerability in the nucleus accumbens: fumarate hydratase (FH), ATP synthase subunit alpha (ATP5a1) and transketolase (TKT). Forty C57BL/6J male mice, four-weeks old, were fed either with a high fat diet (HF) or a standard diet (controls). After two weeks animals started a daily training of double conditioning sessions; in one of them animals were placed in a compartment with palatable food (chocolate cereals), while in the other mice were placed in a different compartment with no food at all. After one week this training was reduced to one daily session preceded by 12 h of food deprivation. A final session was conducted one week later that consisted in placing half of the animals in food unpaired compartments and the other half in compartments previously paired with cereals, but now devoid of the expected palatable food. Animal activity was recorded by videotracking. When mice were placed in compartments devoid of palatable food they initially spent most of their time in the small area around the feeder (% time 0-10 min: controls = 53 ± 4, n = 10; HF = 54 ± 5, n =10). Control mice gradually extinguished this behavior, which was more persistent in HF mice (% time 20-30 min: controls = 39 ± 4, $p < 0.05$ vs 0-10 min; HF = 49 ± 7). Total activity and serum corticosterone levels were similar in all groups regardless the diet or compartment considered. Immunohistochemistry of FH, ATP5a1 and TKT showed an increase in the expression level of the three markers in the group of HF mice. Moreover, a positive correlation was found between those expression levels and the persistence of preference for the palatable-food feeder in HF and standard fed mice, as quantified by the time spent in the food area 20-30 min after the start of the behavioral test. The procedure seemed useful to quantify food addiction as delayed extinction of preference for places paired with palatable foods, and confirmed FH, ATP5a1 and TKT expression in the nucleus accumbens as correlates for drug and food addiction.

Title: Chronic fluoxetine ameliorates long-term trace conditioning deficits in mice exposed to chronic nicotine during adolescence

Authors: *D. A. CONNOR[1], T. J. GOULD[2];
[1]Temple Psychology, Philadelphia, PA; [2]Temple Univ., Philadelphia, PA

Abstract: Adolescence represents a critical period in which brain areas important for cognition, including the hippocampus and medial prefrontal cortex (mPFC), rapidly develop. As a result, adolescence marks a time when the CNS is sensitive to exogenous insults. Exposure to chronic nicotine during adolescence causes long-term changes in synaptic function, which disrupts cognition. In addition, adolescent nicotine exposure results in cognitive deficits later in life, i.e., in adulthood. In 2014, the CDC reported that 24% of high school students used tobacco products. Given that cognitive deficits are associated with smoking relapse and addiction, long-term cognitive deficits that result from adolescent nicotine exposure may lead to increased risk of nicotine dependence in adulthood. Indeed, adolescent exposure to tobacco increases risk for adult smoking by a factor of 16. Thus, it is important to investigate treatments that ameliorate the long-term cognitive impacts of adolescent nicotine exposure. Here we investigated whether or not chronic fluoxetine (FLX) could ameliorate adolescent chronic nicotine-associated disruption of trace fear conditioning. Trace fear conditioning is a hippocampus-depended form of associative learning well suited to investigate adolescent nicotine-associated cognitive deficits as it also recruits the mPFC via working memory processes. Chronic FLX was selected as a treatment due to its ability to increase BDNF within the mPFC and hippocampus, as well work showing it can reduce hippocampus-dependent cognitive impairments. Adolescent (PND 38) C57BL/6J mice were administered chronic nicotine or saline via osmotic minipumps for 12 days. Upon pump removal mice were immediately put on FLX treatment via their drinking water (160g/L). After 30 days of FLX treatment, these same mice, now adult aged, were trained in trace fear conditioning and tested 24 hr later with FLX treatment maintained throughout. Mice that received chronic nicotine treatment during adolescence demonstrate deficits in trace fear conditioning during adulthood, while mice that received saline did not. In addition, chronic FLX ameliorated the nicotine-associated deficit in trace fear conditioning. Our data support previous findings that nicotine administration during adolescence leads to deficits in hippocampus-dependent learning. Furthermore, our data suggest that chronic fluoxetine treatment may be protective against development of long-term cognitive deficits associated with adolescent nicotine exposure. In sum, FLX may be an effective therapy for long-term cognitive deficits associated with adolescent nicotine exposure.

Title: Individual differences in voluntary alcohol consumption predict reversal learning performance in rats

Authors: M. GALLO, N. BRIGHT, H. FISHER, M. GREER, A. PAJSER, M. RAY, M. WANG, *C. L. PICKENS;
Kansas State Univ., Manhattan, KS

Abstract: Alcohol abuse is associated with impaired decision-making. However, it is unclear whether alcohol consumption causes impaired decision-making, or if alcohol consumption and poor decision-making result from pre-existing tendencies that are present before alcohol abuse. The control provided by animal models can address this question in ways that human research cannot. Our study investigated whether the motivation to consume alcohol correlates with reversal-learning performance (a model of decision-making) in rats. The rats received 6 weeks of chronic intermittent access to alcohol beginning in adolescence and continuing on until early adulthood (PND 26-66). Half of the rats received 24-h alcohol access periods 3 times per week where 20% alcohol was available (Alcohol group). The control group received only water during the 6 weeks (Water group). Seventeen days after the final access period, rats began go/no-go discrimination training in which rats earned a food pellet for pressing one lever and earned a pellet for withholding responding from another lever. Once the rats met the discrimination criterion, reversal training began. In the first reversal, the rats were required to press the lever that previously required withholding responding and to withhold lever pressing to the lever they were previously required to press. Once the rats attained the reversal criterion, the contingencies were reversed back to the original contingencies. We found no difference between the Alcohol vs. Water group during any phase. However, there was a significant negative correlation between the quantity of alcohol consumed during the final two weeks of alcohol access and the number of commission errors within the Alcohol group in both reversals. There was no correlation found between the quantity of alcohol consumed and the number of commission errors in the original discrimination, or the number of omission errors during any phase. Our results suggest that rats that consume higher levels of alcohol in early adulthood exhibit better response inhibition in a reversal learning task. We found no evidence that the consumption of alcohol impaired reversal

learning or response inhibition. This suggests that individual differences in motivation to consume alcohol are correlated with performance in a decision-making task, apart from any direct effects of alcohol consumption on the decision-making brain circuits. Our future studies in the lab will investigate potential genetic differences or neural mechanisms in the brain, as well as potential sex differences in the pattern of reversal learning performance.

Title: The neural responses of cognitive performance deficits in Internet gaming disorder during prospective memory task

Authors: *J. CHUN, J. KIM, A. PYEON, H. CHO, J. CHOI, D. KIM;
Dept. of Psychiatry, The Catholic Univ. of Korea Col. of Medici, Seoul, Korea, Republic of

Abstract: As Internet Gaming Disorder (IGD) was added to Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5), the seriousness of IGD was magnified recently. The aim of this study was to investigate cognitive performance deficits in Internet gaming disorder during prospective memory task by assessing behavior task results between IGD group and healthy control (HC) group playing Internet game. Seventeen with IGD and fifteen HC were recruited for the fMRI study and underwent the structured interview by a clinician. All participants had normal or corrected-to-normal vision and were right-handed (assessed by the Edinburgh handedness inventory). The participants had to decide congruency (duration 2,000 ms) of shape or color in two figures (figure matching task) as a foreground task. While the task was ongoing, the participants performed prospective memory task and they had to remember a prospective memory trial number presented in the upper right corner of the screen. Functional and structural MRI data were acquired using a 3T MRI system equipped with an 8-channel head coil. Participants' heads were cushioned with attached earmuffs. The functional images were

obtained using a T2*-weighted gradient echo-planar imaging sequence (38 slices, 4 mm thickness and no gaps, repetition time [TR] = 2,000 ms, echo time [TE] = 30 ms, flip angle [FA] = 90°, image matrix = 64 x 64, field of view [FOV] = 220 mm, with voxel resolution of 3.75 x 3.75 x 3.85 mm. Structural MRI data were also acquired using a magnetization-prepared rapid gradient echo sequence: TR = 1.780 ms, TE = 2.19 ms, voxel size = 0.50 mm × 0.50 mm × 1.00 mm, matrix size = 512 × 512, and slice number = 176. In the behavioral results, IGD group compared with HC group showed lower accuracy and slower reaction time on long-term prospective memory condition. In the fMRI results, IGD group compared with HC showed deactivation on the dorsal lateral prefrontal cortex and visual cortex during short-term prospective memory condition. Also, IGD group compared with HC revealed deactivation on the medial prefrontal cortex including anterior cingulate cortex and orbito-prefrontal cortex. In this study, we investigated cognitive performance when remembering to perform a planned action in IGD using prospective memory task. Participants with IGD revealed deficit of performance when they had to perform a planned action during prospective memory and they showed neural deactivation the regions related to cognitive control. It suggested that a planned action induced cognitive conflict in IGD and they showed cognitive deficit.

Title: Age and dose are important factors in the acquisition phase of the tobacco dependence animal model

Authors: *C. GELLNER;
Pharmacol., Univ. of California, Irvine, Irvine, CA

Abstract: To understand how factors such as age, dose, and type of drug tested affect the acquisition phase of the tobacco dependence animal model, we have established a model of intravenous self-administration (IVSA) comparing cigarette smoke extract (CSE) to nicotine (Nic) alone at five different doses in adolescent and adult male rats. Previous research in our lab

has shown that adult male rats will not only self-administer CSE but that they find it more reinforcing than nicotine alone at the 7.5µg/kg per infusion dose. We now test the hypothesis that CSE will be even more reinforcing in adolescence, the age at which most humans initiate tobacco use. Adolescent (aged postnatal day 25, P25) and adult (P85) rats were trained to work for food pellets on an FR1TO20 schedule (one food pellet per lever press with a time out period of 20 seconds). After rats reached the reinforced lever press threshold (R=35 and 50 for adolescents and adults, respectively), they underwent surgery in which a catheter was implanted into the right jugular vein. After three days recovery, rats (P37 and P97, adolescents and adults, respectively) underwent three progressively harder schedules of lever pressing: FR1TO20, FR2TO20, and FR5TO20 for one of 5 doses of CSE or Nic (0, 3.75, 7.5, 15, or 30µg/kg/infusion nicotine content). We have found that both adolescent and adult rats acquire self-administration behavior of CSE or Nic at all doses. Although there are no differences between CSE and Nic reinforcement at either age, adolescents take more drug than their adult counterparts at all doses on an FR1 schedule and at the 30µg/kg/infusion dose of nicotine on an FR5 schedule. These findings suggest that age and dose are important factors in acquisition phase of the tobacco dependence animal model.

Title: The effects of chronic Cigarette Smoke Extract exposure on somatic withdrawal in adolescent rats

Authors: *D. REYNAGA, A. REZK, C. PON, D. GHOBRIAL, F. LESLIE;
Univ. of California Irvine, Irvine, CA

Abstract: Adolescence is a sensitive period of development where the initiation of smoking typically occurs. Human adolescents are especially sensitive to withdrawal, exhibiting symptoms of dependence soon after smoking initiation and before the formation of daily smoking habits. In adult rodents, discontinuation of chronic nicotine administration results in the development of many of the same characteristic withdrawal symptoms as humans. However, whereas human adolescents have an increased sensitivity to the effects of smoking cessation, rodent adolescents experience little to no somatic withdrawal symptoms after chronic nicotine exposure (O'Dell,

2009; Torres et al., 2013). This discrepancy may be due to the lack of other non-nicotine smoke constituents in current preclinical models. We have previously shown that cessation to chronic exposure of cigarette smoke extract (CSE), a saline solution containing nicotine and other aqueous smoke constituents collected from whole stream cigarette smoke, resulted in enhanced spontaneous somatic withdrawal in adult rats. The goal of this study is to determine whether adolescent rats show spontaneous somatic withdrawal symptoms after chronic exposure to CSE, and to investigate the involvement of nicotinic acetylcholine receptors (nAChRs) in CSE cessation-induced withdrawal using mecamylamine, a nonselective and noncompetitive nAChR antagonist, to precipitate withdrawal. Adolescent rats were treated by intravenous administration of saline, nicotine (1.5 mg/kg/day), or CSE (1.5 mg/kg/day nicotine content) 3 times a day for 10 consecutive days. Following the last day of drug treatment, spontaneous or precipitated somatic signs of withdrawal (gasps, writhes, ptosis, body shakes, teeth chattering, chewing, yawns, and shortness of breath) were scored. Adolescent rats showed spontaneous somatic withdrawal after CSE exposure, but not after chronic nicotine. Mecamylamine (1 mg/kg; s.c.) administration precipitated withdrawal after chronic CSE exposure. This provides evidence that non-nicotine constituents in CSE mediate withdrawal processes, possibly via nAChRs .

Title: A high-throughput phenotypic screen to identify compounds that protect human astrocytes from oxidative stress: a proof-of-concept study using stem cell-derived astrocytes for neurodegenerative disease drug discovery

Authors: ***N. THORNE**[1], N. MALIK[2], S. SHAH[2], J. ZHAO[1], B. CLASS[1], F. AGUISANDA[1], N. SOUTHALL[1], M. XIA[1], M. RAO[3], W. ZHENG[1];
[1]NCATS/NIH, Rockville, MD; [2]NIAMS/NIH, Bethesda, MD; [3]NIH Ctr. for Regenerative Med., Bethesda, MD

Abstract: It is becoming increasingly clear that astrocytes play key roles in proper neuronal function in the central nervous system. Astrocytes serve to maintain an extracellular environment conducive to neuronal signaling, in addition to supplying neurons with nutrients necessary for cell health and metabolic precursors that can be used for neurotransmitter synthesis. Recently, astrocytes have been implicated in the pathogenesis of a variety of neurodegenerative diseases including Alzheimer's disease, Parkinson's disease, Huntington's disease and amyotrophic lateral sclerosis (ALS), and have thus become a new target for drug discovery. In order to identify potential therapeutics for these diseases, we have developed astrocyte-based assays that can be used for high-throughput screening (HTS), and that can be used to screen astrocytes differentiated from induced pluripotent stem cells (iPSC) from neurodegenerative disease patients. Towards this effort, our group has developed methods for successfully growing and maintaining astrocytes differentiated from human embryonic stem cells (hESCs) in 1536-well microtiter plate format. Additionally, we have developed a high-content screening assay in 1536-well format to identify compounds that are cytoprotective to astrocytes challenged with oxidative conditions – conditions characteristic of neurodegenerative disease. Using this screening assay, we identified 32 compounds that prevented apoptosis in astrocytes faced with oxidative stress. Some of these compounds were found to activate the antioxidant response element (ARE) and Nrf2 (nuclear factor erythroid 2 [NF-E2]-related factor 2) pathway, while others have previously been shown to be neuroprotective. This miniaturized oxidative stress assay can thus be successfully used to screen chemical libraries using patient-derived astrocytes to identify lead compounds for drug development.

Title: Minocycline inhibits inflammatory responses but does not prevent neuronal loss in a mouse model of neurodegeneration

Authors: *G. CHEN, S. CHENG, J. HOU, C. ZHANG;
Nanjing Univ., JIANGSU, China

Abstract: Accumulating evidence has shown that minocycline, a broad-spectrum tetracycline antibiotic, exhibits neuroprotective effects in various animal models of neurological diseases. However, it remained unknown whether minocycline could be used effectively to prevent neurodegenerative diseases. To address this question, minocycline was used to treat Dicer conditional knockout (cKO) mice which display age-related neuron loss. The drug was given to mutant mice prior to the occurrence of neuroinflammation, and the treatment had lasted 2 months. Levels of inflammatory markers, including glial fibrillary acidic protein (GFAP), ionized calcium-binding adapter molecule1 (Iba1) and interleukin6 (IL6), were significantly reduced in minocycline-treated Dicer cKO mice. In contrast, levels of neuronal markers and the total number of apoptotic cells in Dicer cKO mice were not affected by the drug. Therefore, minocycline is effective to inhibit neuroinflammation but does not prevent neurodegeneration.

Title: cGMP/CREB signaling as therapeutic target for the chronic or acute treatment of Alzheimer’s disease, migraine and epilepsy

Authors: *M. BEN AISSA[1], R. P. GANDHI[1], S. H. LEE[1], A. PRADHAN[2], I. GAISINA[1], G. R. THATCHER[1];
[1]Dept. of Medicinal Chem. and Pharmacognos, Chicago, IL; [2]Dept. of Psychiatry, Col. of medecine, UIC, Chicago, IL

Abstract: cGMP/CREB signaling is involved in several stimulus-induced cellular signaling pathways leading to the transcriptional control of numerous genes implicated in many important physiological functions in the CNS. Depression of the CREB pathway is a feature of Alzheimer's disease (AD) associated with synaptic dysfunction and coupled with amyloidogenesis. Conversely, aberrant activation of NO/cGMP/CREB signaling has been related to migraine

induced hyperalgesia and persistent MAPK/CREB-mediated gene transcription associated with discrete brain insults has been proposed to underlie epileptogenesis. The overarching objective is to discover the therapeutic potential of brain bioavailable inhibitors and activators of cGMP formation, requiring validation of both *in vitro* and *in vivo* models. For AD therapeutic intervention, a new cGMP/CREB activator NMZ was validated in three FAD mouse models APP/PS1, 3xTg and EFAD and in a new AD sporadic model. NMZ treatment attenuated hallmark AD pathology and restored LTP and memory as well as biomarkers of synaptic and neuronal functions. A second activator VL-102 was also selected and validated as potent activator of cGMP/CREB. VL-102 induced hyperalgesia in mice, mimicking a validated animal model responsive to clinical migraine drugs. In this model, cGMP inhibition by acute treatment with RG2-12 reversed both acute and chronic hyperalgesia, and also reversed the actions of VL-102. To closely mimic the patterns seen in epileptic high-spiking human neocortex, we reproduced a rapid sustained MAPK/CREB-mediated gene transcription using repeated depolarization of SH-SY5Y cells to select potent cGMP/CREB inhibitors for intervention in epileptogenesis. Together, our data indicate that cGMP/CREB signaling is a promising therapeutic target for the chronic or acute treatment of multiple systems associated with neurological insults.

Title: Identification and characterization of a novel and highly potent agonist of the human Smoothened receptor

Authors: *J. A. VAN BERGEIJK[1], L. A. SMYTH[2], S. RENNER[1], A. HEUTLING[2], M. SCHMIDT[1], A. H. MEYER[1];
[1]Biol. Dept., [2]Medicinal Chem. Dept., Abbvie Deutschland GmbH & Co. KG, Ludwigshafen, Germany

Abstract: The Hedgehog pathway plays a fundamental role in embryogenesis and becomes silent during adulthood. In adolescence distinct activation can be observed mediating proliferation, migration and differentiation of stem as well as precursor cells. In CNS, pathway stimulation induces adult neurogenesis in the subgranular zone of the dentate gyrus, subventricular zones as well as in non-classical neurogenic regions like the cerebral cortex. Neuroregenerative effects have been reported for the endogenous ligand of Patched, Shh, and low molecular weight agonists of the Smoothened receptor (Smo) downstream of Patched. Disease modification has been demonstrated *in vivo*, most notably in neurodegenerative animal models of Parkinson's disease and trisomy. So far, all potent *and* efficacious Smo agonists are derivatives of chlorobenzothiophene, a core structure initially identified by Frank-Kamenetsky *et al.* in 2002 (SAG1.1 - SAG1.7, CUR201807). Here, we report identification of a novel highly potent and efficacious Smo agonist which we derived from Purmorphamine. Compound Y is chemically distinct from chlorobenzothiophenes and allows a non-biased approach for pathway analysis. In contrast to Purmorphamine, the new activator has a high affinity for hSmo ($K_i^{Cmpd\ Y}$: 60 nM vs. $K_i^{Purm.}$: 2690 nM). Regarding osteoblast differentiation of murine mesenchymal C3H10T1/2, it is more efficacious and about 20 fold more potent ($EC_{50}^{Cmpd\ Y}$: 19 nM). Compound Y induces Gli dependent pathway activation in murine NIH3T3 Gli-*bla* (EC_{50}: 12 nM) as well as in a human mesenchymal cell line (EC_{50}: 6 nM). It selectively activates the hedgehog pathway and does not cross-react with Frizzled receptors modulating canonical Wnt / β-catenin signaling. Stimulation of primary rat granule cerebellar precursor cell proliferation *in vitro* indicates that similar to SAG, compound Y may induce neurogenesis *in vivo*.

Title: 7,8-Dihydroxyflavone protects mitochondrial injury by regulating energy metabolism in an animal model of multiple sclerosis

Authors: *T. K. MAKAR[1,2], V. NIMMAGADDA[1,2], P. GUDA[1], S. JUDGE[1,2], D. TRISLER[1,2], C. BEVER[1,2];
[1]Neurol., Univ. of Maryland Baltimore, Baltimore, MD; [2]Multiple sclerosis center of excellence, VA Maryland Hlth. care system, Baltimore, MD

Abstract: Multiple sclerosis (MS) is an autoimmune neuroinflammatory, demyelinating and neurodegenerative disease influenced by genetics and environmental factors. Post-mortem MS studies have reported mitochondrial abnormalities within neurons. The pathophysiological involvement of mitochondrial injury and energy metabolism in MS and EAE (Experimental allergic encephalomyelitis), an animal model is still not clear.7,8-Dihydroxyflavone (DHF), a TrkB agonist, is a neuro protective agent used for different animal models of neurodegenerative diseases. In addition, the capacity of DHF to inhibit mitochondrial injury and regulate mitochondrial energy homeostasis in MS/EAE is unknown. We first explored the mechanism of mitochondrial injury and perturbation of energy homeostasis in C57 BL/6 EAE mice. Furthermore, we explored the effects of DHF on mitochondrial protection and balancing energy metabolism in EAE. Treatment with DHF (5mg/kg, I.P, daily for 30 days) in EAE mice inhibited clinical severity and inflammation. Treatment with DHF increased TrkB activation after EAE. Improvement in EAE, suggests a pivotal role of TrkB signaling in anti-inflammatory performance after EAE. A potential action of DHF on mitochondrial injury and neuronal energy homeostasis was balanced by the normalization in levels of PGC-1α, Nrf1, TFAM, Drp-1, Mfn2, PINK 1 and SIRT1 in EAE mice. These results suggest a potential mechanism by which DHF counteracts EAE pathology via activation of the TrkB receptor and engaging the interplay between cell energy balance and mitochondrial protection. Since metabolic dysfunction is an important factor for the development of neurodegeneration in MS/EAE, these results set a precedent for the therapeutic use of DHF in EAE and perhaps MS.

Title: Computer modeling for binding prediction and characterization of cdk5-p5 association

Authors: A. CARDONE[1,2], A. HASSAN[3], M. BRADY[1], R. SRIRAM[1], *H. C. PANT[4]; [1]Information technology Laboratory, Software and Systems Division, NIST, Gaithersburg, Maryland 20899, NIST, Gaithersburg, MD; [2]Inst. for Advanced Computer Studies, Univ. of Maryland, College Park, MD; [3]c Div. of Computat. Bioscience, Ctr. for Mol. Modeling, CIT, Natl. Inst. of H, [4]LNC NINDS, NIH, Bethesda, MD

Abstract: The cyclin-dependent kinase Cdk5 plays a fundamental role in mature nervous system development and function. Cdk5 physiological activity is regulated by its activator, p35. Under neuronal insults such as A-beta toxicity as well as Ca2+-induced oxidative stress, p35 is proteolyzed into the p25 and 10 kDa. P25 binds with Cdk5, deregulates and hyperactivates its activity and induces plaques and neurofibrillary tangles, hallmarks of AD pathology. Past research efforts have directly targeted the phosphorylation mechanism, for instance by preventing ATP-binding by the kinase inhibitors. However, this might cause toxic effects due to their ability to bind all the kinases. Our *in situ* experimental conditions showed that truncated fragments from p35 effectively inhibit the Cdk5-p25 activity. The smallest fragment derived from p25 is p5, a 24 amino acid peptide appears to be an ideal therapeutic candidate since it selectivity inhibited Cdk5-p25 (deregulated) compared to the physiological Cdk5-p35 activity. Thus does not induce toxicity. Furthermore, TFP5, a p5-modified peptide, can cross the blood brain barrier and reduced the Alzheimer disease phenotypes in model mice. Recent developments in computer modeling of complex formation are used here to study cdk5-p5 association. The method is designed to detect and characterize non-specific binding and sparsely populated modes, and accounts for both conformational selection and mutually induced fit. A high-affinity, high-population Cdk5-p5 binding mode could be identified as inhibitory as it competes with p25 for binding. Its main characteristics, including electrostatics, hydrophobic, and hydrogen bond patterns, are reproduced in several independent simulations, providing statistical confidence in the data. The pharmacophore was characterized, revealing a set of interactions that can be reproduced by small, drug-like compounds. A subset of amino acids at the cdk5/p5 interface was also identified, which provide valuable information for targeted mutagenesis studies in order to map the binding site experimentally.

James J. Peters Veteran's Affair

Title: Targeting inflammation and synaptic plasticity for the treatment of stress disorder and depression

Authors: *J. WANG[1,2], G. HORDES[3], S. GOLDEN[3], W. BI[3], W. ZHAO[3], L. HO[3], S. RUSSO[3], G. M. PASINETTI[3,2];
[1]Mt Sinai Sch. Med., New York, NY; [2]James J. Peters Veterans Affairs Med. Ctr., Bronx, NY; [3]Icahn Sch. of Med. of Mount Sinai, New York, NY

Abstract: Depression is a multifaceted mood disorder linked to various mechanisms that are poorly understood. There is a long-standing need for improved anti-depressant treatment. We found that dietary supplementation with a bioactive dietary polyphenol preparation (BDPP) significantly promotes resilience to depression/anxiety phenotypes in a repeated social defeat stress (RSDS) model of depression. Bioavailability studies identified a panel of phytochemicals in the brain and plasma following oral administration of BDPP, including polyphenol metabolites through xenobiotic metabolism and colonic microbiome-derived phenolic acids. Based on our previous observation of stress-mediated long-term disruptions in nucleus accumbens (NAc) medium spiny neuron (MSN) synaptic plasticity and induction of IL-6 in the periphery, which are key contributory factors to depression/anxiety phenotypes, we screened these phytochemicals for their impacts on modulating IL-6 expression in peripheral blood mononuclear cells and/or neuronal synaptic plasticity in MSN-enriched primary neuron cultures. We selected one phytochemical that is potent in attenuating IL-6 expression and one that is potent in promoting synaptic plasticity and conducted *in vitro* discovery stage toxicity and drug-like properties studies and *in vivo* toxicology and efficacy studies. We found that combination therapy with the two phytochemicals targeting periphery proinflammation and CNS synaptic plasticity mechanisms of depression significantly attenuates RSDS-induced depression phenotypes, including improving social interaction and reducing anhedonia, compared to vehicle treated control mice, and these improvements coincide with reduced peripheral IL-6 and increased synaptic plasticity in the NAc. Our studies provide the first experimental evidence that targeting multiple pathologic mechanisms underlying depression may be a viable novel treatment strategy. Based on the safety and drug-like properties of these two phytochemicals, our study can immediately translate into human clinical studies for the treatment of stress disorders and depression.

Sciences, Sun Yat-Sen Univ., guangzhou, China; [5]Dept. of Pharmacol., university of nevada, reno, NV; [6]Dept. of Anesthesiol., Stony Brook Univ., stony brook, NY

Abstract: Our previous studies reported that, a synthetic steroid 5α-androst-3β,5,6β-triol (codename YC-6) is neuroprotective against hypoxia/reoxygenation induced neuronal injury *in vitro*. In the current study, we examined the neuroprotective effect of YC-6 *in vivo*. The effect of YC-6 was tested in a transient middle cerebral artery occlusion (MCAO) model of ischemia in rats. We found that administration of Triol 15 minutes prior to 2h MCAO dose-dependently reduced the infarction volume quantified by 2,3,5-triphenyltetrazolium chloride (TTC) staining and improved the neurological score as well as behavior outcomes. Remarkably, the therapeutic time window for YC-6 could be extended to 5h. Furthermore, we examined the mechanisms underlying the neuroprotective effect of YC-6. Our results showed that 1) YC-6 protected against

glutamate-induced excitotoxicity in both primary cultured cortical neurons and cerebella granule neurons in SD rats through inhibition of glutamate-mediated cytoplasmic calcium overload and acidosis. 2) YC-6 attenuated the acid sensing ion channel (ASIC) currents in cortical neurons. 3) YC-6 suppressed the release of proinflammatory factors and suppressed the inflammatory pathways via inhibition of microglia activation in primary cultured microglia. In summary, these results suggest that YC-6 is a powerful and effective neuroprotectant that can simultaneously and synergistically target at multiple mechanisms of ischemic stroke-induced injuries, including glutamate-mediated [Ca2+]i overload and acidosis, ASICs, and inflammatory pathways. Therefore, YC-6 may be a novel neuroprotectant and a promising drug candidate for the treatment of ischemic stroke.

Abstract: As human life expectancy has improved rapidly in industrialized societies, counteracting age-related cognitive impairment presents an increasing challenge. Histopathological hallmarks correlating with age-related cognitive declines are, among others, neuroinflammation, low levels of neurogenesis, blood-brain barrier disintegrity, and altered neuronal activity. While targeting such age-related processes, for example by exposure to a young systemic environment, i.e. young blood through heterochronic parabiosis, indeed leads to structural and functional rejuvenation of the aged brain, clinical translation of the brain rejuvenation concept is still awaiting evidence. Here, we identified leukotriene receptor signalling as a safe and druggable pathway with a combined mode of action to reduce neuroinflammation and to enhance neurogenesis, specifically in the aged brain. Treatment with montelukast, an already marketed anti-asthmatic drug acting on leukotriene receptors, successfully rejuvenated the aged brain and restored cognitive function in aged animals. Moreoever, similar regenerative and cognition-stimulating effects were obtained by treatment of a genetic Parkinsons disease animal model with montelukast. This paves the way to future clinical translation for the treatment of neurodegenerative diseases and dementias.

Title: NDC-1308, a small molecule with remyelinating activity for treatment of secondary progressive multiple sclerosis patients

Authors: *S. H. NYE, J. G. YARGER;
Discovery, ENDECE Neural, LLC, Mequon, WI

Abstract: Background: Current therapeutics for MS patient's impact the immune mechanisms of the disease, rather than the elusive remyelination activity needed to repair the damaged myelin sheath. NDC-1308 is known to activate intracellular pathways for oligodendrocyte progenitor cell (OPC) differentiation. NDC-1308 induces mouse OPCs to differentiate into mature, myelinating oligodendrocytes *in vitro* and significantly increases remyelination of axons *in vivo*. These studies extend the *in vivo* remyelination results while addressing the safety and exposure of NDC-1308. Objectives: A main goal was to correlate the ability of NDC-1308 to repair the damaged myelin sheath, in the cuprizone mouse model of demyelination, with a functional improvement. Intended outcomes also included an initial safety assessment for NDC-1308 and determining the dosing parameters for non-clinical IND-enabling studies. Methods: Male mice were treated for 12-weeks with cuprizone and rapamycin to cause demyelination of white and gray matter regions of the brain. The demyelinated mice were administered NDC-1308 (68 mg/Kg, i.p., q.d.) for up to 6 weeks. Blood was collected at termination for clinical chemistry analysis, along with reproductive tracts for pathology, and brain regions for assessing the level of NDC-1308 remyelination. The OPC population in different brain regions was evaluated by immunohistochemistry using PDGFRα antibodies. The degree of mutagenicity and genotoxicity of NDC-1308 was measured by a bacterial reverse mutation assay and a mammalian cell micronucleus screening assay, respectively. Results: NDC-1308 rapidly crosses the blood brain barrier and is absorbed into CNS tissues at levels exceeding the EC50 required for OPC differentiation *in vitro*. NDC-1308 is eliminated from the CNS and periphery after 24 hours. Following chronic treatment of demyelinated mice with NDC-1308, remyelination was significantly increased 18% ($P<0.01$) in cortical regions and 44% ($P<0.0001$) in hippocampal regions. A significant increase in grip strength was measured in the animals treated with NDC-1308. Observed animal behavior and clinical chemistries were normal and the OPC population remained intact. NDC-1308 was found to be non-mutagenic and non-genotoxic. Conclusions: These results suggest NDC-1308 can be delivered to the CNS tissues in amounts sufficient for inducing OPCs to differentiate into mature, myelinating oligodendroctyes that can then repair the myelin sheath. NDC-1308 appears to be a potentially safe and effective therapeutic for treating SPMS patients. Non-clinical IND-enabling studies and a first-in-human Phase 1 study are planned.

Title: ISP - An *in vivo* based systems pharmacology platform for phenotypic characterization of CNS treatments, translational modelling and drug discovery

Authors: ***P. SVENSSON**, S. WATERS, C. SONESSON, E. LJUNG, B. SVANBERG, N. WATERS;
Integrative Res. Labs. (IRL), Gothenburg, Sweden

Abstract: The CNS is a complex biological system, and as such, inherently prone to degeneracy of functions. This promotes robustness and flexibility of any complex biological system. However, this property limits the efficiency of highly reductionist approaches to understand physiological and pharmacological mechanisms in healthy or in disease states. A manifestation of this problem is that phenotypic screening has proven more successful than target based screening in generating first-in-class drugs within the CNS area (1). In order to overcome this limitation we developed a standardized process, called Integrative Screening Process (ISP), for *in vivo* systems-response profiling, using a comprehensive array of biomarkers, as a way to obtain a sensitive fingerprint of the functional, network level effects of CNS-acting compounds. The response profiles provide a basis for comparison and classification of CNS compounds and for predicting potential clinical properties of new agents, beyond what can be achieved using single-endpoint *in vivo* or *in vitro* methodologies. ISP can be described as an established, efficient and

validated *in vivo* based systems pharmacology platform for phenotypic characterization of CNS treatments and translational modelling. It has been systematically implemented and integrated throughout our drug discovery process. ISP has been developed and utilized for more than a decade, resulting in a database covering *in vivo* systems response profiles of approximately 900 in-house compounds and more than 300 reference compounds with documented CNS effects in humans. During this decade ISP has generated 8 candidate drugs, of which three are in late stage preclinical development, two are in in phase I, and one is in late stage development for Huntington's Disease. Key features of ISP such as standardization/comparability, translational ability and predictivity, ability to capture direct and indirect effects as well as state dependent effect will be discussed. Experimental and computational methodology, QC aspects, utility in classification, QAAR and QSAR, and data analytical strategies for translational modelling will be described and discussed. Abstract: Anticipating safety issues early on in the drug discovery process would greatly improve its success rate. Similarly, identifying neurotoxic risks of environmental factors would help to better understand their impact on human and animal health. To specifically address these two aspects, we developed two new simulators validated by *in vitro* and *in vivo* experiments. A first simulator was created in the framework of a Defense program (*) aiming at studying neuronal hyperexcitability induced by irreversible organophosphate inhibitors of acetylcholinesterase (AChEIs), such as Paraoxon (POX). This new tool integrates morphological and electrochemical properties of hippocampal CA1 neurons, interneurons (OLM and Basket cells), glutamatergic afferents from entorhinal cortex and hippocampal CA3 neurons, as well as cholinergic afferents from the septum. Synapses comprise many models of receptors, channels, second messenger systems as well as acetylcholinesterase (AChE) and muscarinic M1R coupled to the potassium channel Kv7. This simulator reproduced the effects of POX on hyperexcitability and occurrence of epileptiform patterns. It allowed developing strategies to counteract POX neurotoxic effects, in particular by identifying drug combinations, which could reduce side effects or serve as antidotes to protect against chemical weapons. A second simulator developed in the framework of the EC program (**) integrates mitochondria and the p53 and NFkB pathways to address the biology and toxicity of metallic ZnO and SiO_2 nanoparticles (MNPs). These different models, interconnected with each other and with a pharmacokinetic model enable studying the dose-, size- and time-dependent effects of MNPs on diverse biological reactions, targets and pathways, such as dehydrogenase flux, electron transport system fluxes (Complex I, III and IV), substrate transport fluxes (ATP, ADP, AMP, and inorganic phosphate), adenine nucleotide translocase flux (ANT flux), superoxide production and transport (IMAC), superoxide

dismutase (SOD) and catalase (CAT) activity, glutathione (GSH), P53 activation, and NFκB activation, as regulated by three IκB isoforms (IκBα, IκBβ, and IκBε). These new simulators can be used alone or in combination with our existing physiological and pathological multilevel and translational simulators. They are available to perform specific studies for industrial, government, foundation and academic research partners.

Title: Combined Ca^{2+} channel/NMDAR antagonism reduces excessive voltage-gated Ca^{2+} influx in pyramidal neurons from the medial prefrontal cortex of HIV-1 transgenic rats

Authors: *C. KHODR[1], S. DAVE[1], L. CHEN[1], C. ZHANG[1], L. AL-HARTHI[2], X.-T. HU[1]; [1]Dept. of Pharmacol., [2]Dept. of Immunol. and Microbiology, Rush Univ. Med. Ctr., Chicago, IL

Abstract: HIV-1 infection is associated with impaired neurocognitive function that is regulated by the medial prefrontal cortex (mPFC) and other HIV-vulnerable brain regions. Ca^{2+} dysregulation, especially excessive Ca^{2+} influx which increases cytosolic Ca^{2+} levels, is a significant risk factor for neurotoxicity associated with chronic exposure to HIV. Neuronal Ca^{2+} influx is mainly regulated by the NMDA receptor (NMDAR) and voltage-gated Ca^{2+} channels (including the L-type Ca^{2+} channel, L-channel). Use of NMDAR antagonist or L-channel blocker alone to treat HIV dementia complex has either failed or shown limited improvement in clinical trials, suggesting that novel therapeutic strategies (including combined NMDAR/L-channel antagonism in earlier disease states) may be needed to reduce Ca^{2+} related toxicity in neuroAIDS. Our recent studies showed that *in vivo* exposure to HIV-1 proteins induces hyper-excitation of mPFC pyramidal neurons due in part to increased, NMDAR-independent Ca^{2+} influx, using

HIV-1 transgenic (Tg) rats that express 7 of the 9 HIV-1 genes. L-channels are involved in this hyper-excitation because enhanced Ca^{2+} influx was abolished by acute L-channel blockade *in vitro.* Here we evaluated whether combined chronic blockade of over-active L-channels and NMDARs *in vivo* would reduce excessive Ca^{2+} influx due to HIV exposure. Five to six week old male non-Tg and HIV-1 Tg rats received daily s.c. injections of saline (SAL) or diltiazem (15 mg/kg, a selective L-channel blocker) plus memantine (10 mg/kg, a selective NMDAR blocker) for 2 weeks. Whole-cell current-clamp recordings were performed on mPFC pyramidal neurons in brain slices to assess voltage-gated Ca^{2+} influx reflected by evoked Ca^{2+} plateau potentials. During experiments, all neurons were studied under blockade of glutamate and $GABA_A$ receptor mediated synaptic activities, as well as voltage-gated Na^+ and K^+ channels. We found that neurons from SAL-pre-treated HIV-1 Tg rats displayed significantly longer Ca^{2+} potentials (2752±341 ms) measured at the half spike amplitude compared to those from SAL-pretreated non-Tg rats (1619±243 ms, $p \leq 0.01$). Combined chronic blockade of L-channel/NMDAR significantly reduced this increased Ca^{2+} influx in neurons from HIV-1 Tg rats (1866±225 ms, $p \leq 0.05$). No significant difference was found in the half-peak duration of Ca^{2+} potentials between neurons from HIV-1 Tg rats pre-treated with combined blockers and those from non-Tg rats pre-treated with SAL (1866±225 *vs.* 2268±339 ms, $p > 0.05$). Collectively, these findings demonstrate promising effects of combined L-channel/NMDAR antagonism on reducing excessive neuronal Ca^{2+} influx induced by HIV.

Title: Human stem cell-based high-throughput screening platform for neurodegenerative diseases

Authors: *Z.-W. DU, S.-C. ZHANG;
Waisman Cntr, Univ. Wisconsin, Madison, WI

Abstract: Drug screening for neurodegenerative disease often employ fibroblasts or lymphocytes immortalized from patients and ectopic reporter transgene, leading to high failure rates in clinical trials. The selective vulnerability of subtype-specific neuron is a defining feature of neurodegenerative disease. Therefore, subtype-specific neurons are more relevant target cells for drug screening. In this study, we established disease iPSC reporter lines by CRISPR technology to target only one copy of a sensitive reporter (Nanoluc) into the endogenous disease related gene locus, such as SMN2 gene for spinal muscular atrophy and NEFL gene for amyotrophic lateral sclerosis. Combined with our recently developed method to produce large-scale and pure subtype-specific neurons from iPSCs, we have established a neuron based high-throughput screening (HTS) platform. The HTS platform is optimized in a 384-well format, validated with previously identified compounds and applied for primary screening with NIH clinical collection library. These results suggest that human stem cells can be readily engineered and formatted for phenotypic and mechanistic HTS screening for neurodegenerative diseases

Title: Extracellular zinc changes the kinetics of streptokinase in thrombolysis *in vitro*

Authors: *Z. WANG, Y. LI;
Biomed. Sci., Ohio Univ., Athens, OH

Abstract: Thrombotic ischemic stroke occurs when local blood clot obstructs an artery to brain, causing neurons lose function and die. It is one of the leading causes of mortality and a major cause of disability. The effect of thrombolysis by injecting intravenous thrombolytic agents is critical for reducing stroke damages. Streptokinase (SK) is a widely used thrombolytic agent in the treatment of thromboembolism in the blood vessels. High unit of SK was used in thrombolytic therapies of myocardial ischemia and could improve tissue reperfusion. It is a potent plasminogen activator. However, safety concerns of usage of high unit of SK are still noticed. In our present study, we performed on the effect of SK and how zinc affect SK-induced thrombolysis *in vitro* studies, and proposed a strategy to improve SK effectiveness in thrombolysis. The mice whole blood was used to produce blood clot *in vitro* by incubated with

calcium at 37C for 3h. SK was used for inducing thrombolysis. Zinc and its chelator, CaEDTA, were applied with SK respectively. Spectorphotometer was used to measure thrombolysis effect at 580 nm wavelength. Results showed that SK had dose dependence effect and exhibited thrombolysis effect after 60 minutes. Zinc inhibited thrombolysis effect of SK. Zinc chelator, CaEDTA, significantly increased the effect of SK-induced thrombolysis. We concluded that zinc inhibit SK effect in blood clot lysing *in vitro*. Chelation of zinc improves SK effectiveness in thrombolysis.

Title: Addressing innovation in CNS drug discovery: preclinical proof of concept for parallel campaigns that employ either functional or single molecular target approaches for delivery of novel candidates that attenuate synaptic and cognitive dysfunction

Authors: *D. WATTERSON[1], O. ARANCIO[2], S. M. ROY[1], L. VAN ELDIK[3];
[1]Dept. of Pharmacol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [2]Columbia Univ., New York, NY; [3]Univ. of Kentucky, Lexington, KY

Abstract: Diverse CNS disorders display common pathophysiology themes. Ongoing efforts to develop disease-modifying therapeutics reflect the increasing appreciation of these core mechanisms. Major challenges include identification of disease progression time windows amenable to intervention, the linkage of disease related phenotypes to druggable molecular targets, and the need for clinical landmarks. Retrospective analyses of new molecular entity drug

approvals reveal the differing impact of phenotypic vs single molecular target drug discovery approaches, dependent on the state of knowledge about druggable disease progression mechanisms. The less biased phenotypic approach allows probing for interventions in the absence of established mechanisms in areas of critical unmet medical need, whereas single molecular target approaches provide exceptional efficiencies in the context of established mechanisms. As part of a multi-site collaboratorium focused on innate immunity and synaptic dysfunction as a common pathophysiology progression theme, we explored the potential for novel small molecule drug candidate discovery using these two distinct approaches and a common molecular scaffold or fragment. Specifically, the functional approach focused on early stage overproduction of proinflammatory cytokines causally linked to synaptic dysfunction and the single molecular target was brain p38aMAPK, an established regulator of innate immunity in glia and an intracellular neuronal kinase up-regulated in stress responses. Our goal was to start with: 1) an *in vivo* screening approach based on disease-relevant pharmacodynamic end points (functional approach), or 2) a structure-assisted, pharmacoinformatics-driven design (p38aMAPK). An aminoarylpyridazine molecular fragment was the common core. Deliverables from each approach used a common secondary phase, pharmacology driven medicinal chemistry refinement. Novel small molecule deliverables from each approach showed efficacy in diverse preclinical animal models. Both showed *in vivo* attenuation of innate immunity related pathologies and behavioral deficits. Novel candidates are in preclinical or clinical drug development.

Title: Etiology-based drug discovery is a route for new amyotrophic lateral sclerosis (ALS) therapeutics

Authors: *T. J. LUKAS[1], H. ARRAT[2], T. SIDDIQUE[2];
[1]Pharmacol., [2]Neurol., Northwestern Univ., Chicago, IL

Abstract: The treatment of neurodegenerative diseases is difficult because of multiple etiologies and the interplay of genetics and environment as precipitating factors. In the case of amyotrophic lateral sclerosis (ALS), we have knowledge of of several genes that cause this fatal disease when mutated. However, drugs to counteract the effect of genetic mutations have not yet been found. One of the causative genes, Cu, Zn-superoxide dismutase (SOD1) is responsible for about 10-15% of the genetically linked autosomal dominant disease. Our rationale was that compounds that reduce expression of the toxic protein would be beneficial to slow onset and/or disease progression. We screened candidate compounds using a cell-based *in vitro* assay for those that reduce mutant SOD1 (G93A) protein levels. This led to the discovery of 2-[3-iodophenyl)methylsulfanyl]-5pyridin-4-yl-1,3,4-oxadiazole, a known protein kinase inhibitor that decreases G93A-SOD1 levels *in vitro* and in the brain and spinal cord of mice *in vivo*. However, this compound has a biphasic dose response curve and a potential toxophore which limits its therapeutic window for chronic disease such as ALS. Therefore, we designed and tested a focused library of analogues for their ability to decrease SOD1 expression *in vitro*. This exercise resulted in the identification of two new lead compounds with improved drug-like characteristics and activity. Currently, optimization of delivery vehicle and route are in progress for preclinical testing in the G93A-SOD1 mouse model of ALS. In the course of the preliminary testing of another agent for efficacy in the G93A-SOD1 mouse we unexpectedly found that ACTH (Acthar gel, Questcor) also decreased the expression of mutant SOD1 in the mouse spinal cord and brain. Acthar also delayed onset of disease and trended toward slowing of disease progression. Additional preclinical testing in a larger animal cohort is underway to determine whether Acthar can significantly improve survival. Thus, two different agents have been found with the potential for treating SOD1 mutant-linked ALS. Development of small molecules and other agents that reduce the expression of etiologically relevant toxic proteins is a strategy that may also be extended to other familial ALS genes for which a toxic gain of function leads to disease.

Title: A peptidylic inhibitor approach to suppress polyglutamine disease toxicity

Authors: *E. CHAN, T. ZHANG, H. TSOI, I. PENG, K.-F. LAU, J. NGO;
The Chinese Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Polyglutamine (polyQ) diseases are dominantly inherited neurological disorders caused by CAG trinucleotide insertion mutation in the human genome. These diseases are characterized by progressive neuronal cell dysfunction and cell death. Polyglutamine disease toxicity is attributed to the neuronal expression of both RNA and protein that respectively carry elongated runs of CAG and glutamine repeats. We report the identification of a peptide sequence which targets CAG RNA toxicity. Mechanistically, our inhibitor suppresses the nucleolar stress-induced caspase activation triggered by elongated CAG RNA. Our findings raise the possibility of targeting both RNA and protein toxicities of polyQ degeneration.

Title: Shared genetic etiology underlying Alzheimer's disease and type 2 diabetes

Authors: K. HAO[1], A. F. DINARZO[1], W. LUO[1], S. LI[1], R. CHEN[1], L. HO[2], *G. M. PASINETTI[3,4];
[1]Dept. of Genet. and Genomic Sci., [2]Neurol., Icahn Sch. of Med. at Mount Sinai, New York, NY; [3]Mount Sinai Sch. of Med., New York, NY; [4]Geriatric Res. Educ. and Clin. Ctr., James J. Peters Veterans Affairs Med. Ctr., Bronx, NY

Abstract: Epidemiological evidence supports the observation that subjects with type 2 diabetes (T2D) are at higher risk to develop Alzheimer's disease (AD). However, how/if these two conditions are causally linked is unknown. Possible mechanisms include shared genetic risk factors, which we investigated in this study based on recent genome wide association study (GWAS) findings. In order to achieve our goal, we retrieved single nucleotide polymorphisms (SNPs) associated with AD and T2D from large-scale GWAS meta-analysis consortia and tested for overlap among the AD- and T2D-associated SNPs at various p-value thresholds. We then explored the function of the AD-T2D shared GWAS SNPs by leveraging expressional quantitative trait loci, pathways, gene ontology data, and co-expression networks. We found 927 SNPs associated with both AD and T2D with pvalue≤0.01, an overlap significantly larger than random chance (p-value=6.93E-28). Among these, 395 of the shared GWAS SNPs have the same risk allele for AD and T2D, suggesting common pathogenic mechanisms underlying the development of AD and T2D. Most excitingly, we found that 532 of the AD-T2D shared GWAS SNPs had divergent risk alleles in the two diseases, suggesting they play opposite pathogenic roles underlying AD and T2D etiology in the brain and in the peripheral organs. Collectively, our GWAS studies tentatively support the epidemiological observation of the disease incidence correlation between T2D and AD. Moreover, the studies provide the much needed information for the design of future novel therapeutic approaches that might benefit T2D without promoting further deterioration of AD neuropathology and cognitive functions.

Title: Exploration of human cannabinoid 2 receptor binding site using AM1336, a novel covalent ligand

Authors: *S. MALLIPEDDI[1], N. ZVONOK[2], A. MAKRIYANNIS[3];
[2]Pharmaceut. Sci., [1]Northeastern Univ., Boston, MA; [3]Pharmaceut. Sci. and Chem. and Chem. Biol., Northeastern Univ., Northeastern University, MA

Abstract: Cannabinoid 2 receptor (CB2R) belongs to the Class A family of G-protein coupled receptors and is expressed predominantly in the periphery, but to a certain extent in the central nervous system. CB2 receptors, upon activation by endogenous or synthetic ligands, modulate a diverse set of downstream signaling pathways and therefore an attractive drug target for pain management and other neurological and inflammatory disorders. But the lack of a complete experimental characterization of the CB2 receptor structure and its ligand-binding site has hampered rational drug design and development. AM1336 is a novel biarylpyrazole derivative, functionalized with an isothiocyanate group for covalent attachment to cysteine residue(s) at or near the ligand binding site. It acts as a high-affinity, inverse agonist at both cannabinoid receptors, however binds irreversibly only to CB2R. We expressed a full-length human CB2R in insect cells and purified functional receptor using a single-step immunoaffinity chromatography with yields of ~200 ug/L of culture. A modified radioligand binding assay confirmed the efficient labeling of the purified CB2 receptor with AM1336 and a top-down high-resolution mass spectrometry (MS) based proteomics approach identified the modification of cysteines in transmembrane helix 7 (TMH7). This data directly confirms the previously published mutational study results and provides a new MS-based proteomics approach for ligand binding site characterization and guidance for structure-based GPCR ligand design.

Title: Targeting the kynurenine pathway of tryptophan metabolism: a structural biology approach

Authors: *L. PIDUGU[1], B. ROTH[1], C. BEATO[2], S. MALIK[1], R. BADDAM[1], T. L. WANG[1], D. N. PATTERSON[1], K. VARNEY[1], G. COSTANTINO[2], R. SCHWARCZ[3], D. J. WEBER[1], E. A. TOTH[1];
[1]Biochem. and Mol. Biol., CBT, Univ. of Maryland Sch. of Med., Rockville, MD; [2]Dept. di Farmacia, Università degli Studi di Parma, Parco Area delle Scienze 27/A, 43124 Parma, Italy; [3]Maryland Psychiatric Res. Center, Dept. of Psychiatry, Univ. of Maryland Sch. of Medicine,, Baltimore, MD

Abstract: The kynurenine pathway (KP) of tryptophan degradation maintains a delicate balance of neuroactive metabolites such as kynurenic acid (KYNA), 3-hydroxykynurenine (3-HK) and quinolinic acid (QUIN). 3-HK and QUIN are toxic to neurons, but are also intermediates in a metabolic cascade leading to the ubiquitous co-factor NAD^+. Notably, changes in QUIN levels can affect the levels of other neuroactive metabolites in the pathway, including KYNA (H.-Q. Wu et al., this meeting). KYNA, which is protective against the neurotoxic effects of QUIN, also plays a major role in cognition, and enhanced cerebral KYNA levels cause distinct cognitive impairments. Thus, if the ratio of these KP metabolites is altered beyond a physiological range, the balance of neuroprotection and cognition is shifted, possibly contributing to diseases ranging from Huntington's disease and Alzheimer's disease to schizophrenia and major depressive disorders. The need to maintain homeostasis consequently makes the KP an attractive therapeutic target. As part of our ongoing drug design program, we have so far focused on three KP enzymes: 3-hydroxyanthranilic acid oxygenase (3HAO); quinolinic acid phosphoribosyltransferase (QPRT); and kynurenine aminotransferase II (KAT II). We present here an overview of our recent efforts to characterize these enzymes and relevant ligand complexes thereof by X-ray crystallography and/or NMR. With regard to 3HAO, we report the first structural evidence, by NMR, that the inhibitor 2-amino-6-methylnicotinic acid 1-oxide (UPAR-12) interacts with the human enzyme. TROSY-HSQC of 3HAO indicated a substantial conformational change on binding to this compound. Further, our NMR titrations of 3HAO with Fe^{2+}, Zn^{2+} and EDTA revealed that the bound metal can be controlled, likely due to the presence of a large open cavity that facilitates metal exchange. Comparison of crystal structures of QPRT, i. e. native, in complex with its inhibitor phthalic acid and, most recently, with its product

nicotinic acid mononucleotide, helped us identify the key residues that are involved in structural transitions necessary for the activity of this enzyme. Finally, we describe the crystal structure of human KAT II at a higher resolution (1.69Å) than previously reported. The above observations will aid in structure-based optimization of inhibitor efficacy and thereby in the development of new potential therapeutics.

Title: Alpha-synuclein familial mutant analysis in yeast models

Authors: *C. ALVARADO[1], M. TEMBO[2], N. KUKULKA[2], M. MUNOZ[2], S. K. DEBBURMAN[2];
[2]Neurosci. Program, [1]Lake Forest Col., Lake Forest, IL

Abstract: Parkinson's disease (PD) is associated with the aggregation and misfolding of alpha-synuclein in midbrain dopaminergic neurons. The gene for alpha-synuclein has six known mutations that directly cause familial forms of PD. The pathological determinants of three mutants (A30P, E46K, and A53T) have been extensively studied and characterized in diverse model systems that indicate that each mutant affects cellular toxicity in distinctive ways. How these three amino acids influence each other's properties is unclear. Unlike these three mutants, the three more recently discovered familial mutants (H50Q, G51D, and A53E) are not extensively studied. First, we created combination mutants of A30P, E46K, and A53T and characterized them in budding and fission yeast models and found support for the dominance of

the A30P mutant over E46K and A53T mutants in both models, shedding new light on the dominance of A30P on alpha-synuclein's conformation. Secondly, we expressed H50Q, G51D, and A53E mutants in both yeasts models and hypothesized that each would generate toxicity by altering membrane-association, and aggregation properties of alpha-synuclein, but each would do so in distinctive ways. We found that the H50Q and A53E mutants were toxic to yeast, and bound membranes and aggregated within yeast, while G51D was cytoplasmically diffuse and non-toxic. Finally, we are currently characterizing combination mutants of the newer mutants in both yeasts. This work adds insight into the pathogenicity of different familial PD mutants of alpha-synuclein.

Title: Tetramer-abolishing alpha-synuclein variants cause neurotoxicity and inclusion formation: clearance mechanisms and relevance for Parkinson's disease

Authors: *V. VON SAUCKEN, A. J. NEWMAN, T. BARTELS, U. DETTMER, D. SELKOE; Ann Romney Ctr. for Neurologic Dis., Brigham and Women's Hosp. and Harvard Med. S, Boston, MA

Abstract: There is disagreement on what the major physiological structure of alpha-synuclein (aS) is in healthy, intact cells. Our work suggests that aS exists principally as a helically folded tetramer of ~60 kDa and related multimers. We hypothesize that if native multimers are triggered by various genetic or environmental factors to destabilize, unfolded monomers will accumulate in neurons, resulting in toxic aggregates characteristic of Parkinson's disease. To assess the determinants of stability of aS multimers in intact cells, we introduced strategic point mutations in the canonical aS repeat motifs (KTKEGV). We essentially abolished physiological aS multimers by certain (but not all) in-register repeat substitutions, as assessed by the intact-cell methods of chemical crosslinking and YFP complementation. We have evidence of greater neurotoxicity from those aS variants that shift equilibrium from multimers to monomers in cells.

Trypan blue staining and western blotting for the apoptotic marker, cleaved PARP, in M17D human neuroblastoma cells transfected with untagged aS showed multimer-abrogating variants (KLKEGV, KTKKGV, KTKEIV, KTKEGW) to be more neurotoxic than cells expressing wild-type aS or multimer-permissive variants (GTKEGV, KTEEGV, KTKEGR). Strikingly, multimer-abrogating variants yielded apparent aS-rich inclusions upon transfection in neuroblastoma cells and primary rat neurons as shown by immunocytochemistry. To characterize these aS inclusions, we tested the effects of candidate drugs that interfere with cellular vesicle trafficking, protein degradation and protein folding on inclusion formation by tetracycline-inducible aS expression in neuroblastoma cells. Unlike past studies, our analysis of aS inclusions are temporally sensitive due to controlling the multimer:monomer ratio via the induction of multimer-abrogating aS variants. In support of our overall model of PD pathogenesis, our data suggest strong neurotoxic effects from abolishing stable aS multimers in intact neural cells.

Title: A functional phenotypic screening *in vitro* assay for novel Parkinson's drugs - comparing effects of human iPSC-derived dopaminergic neuronal networks and primary mouse midbrain cultures

Authors: *B. M. BADER, A.-M. PIELKA, C. EHNERT, K. JUEGELT, A. GRAMOWSKI-VOSS, O. H.-U. SCHROEDER;
NeuroProof GmbH, Rostock, Germany

Abstract: Human iPSC-derived neurons are promising tools to increase predictability, sensitivity and specificity of cell-based *in vitro* assays for drug discovery. Cell-based disease models are suitable for phenotypic screening which has led to the majority (7/8) of successfully launched CNS drugs in the last decade. Thus, our aim was to close the gap of functional phenotypic *in vitro* screening using human iPSC-derived neuronal networks of mesencephalic identity cultured on multiwell micro electrode arrays (mwMEA) for a toxin induced Parkinson's

screening model. We cultured human iPSC-derived post-mitotic dopaminergic neurons and recorded spontaneously activity during functional development of network communication patterns. We used a short pulse of the dopaminergic neuron-specific and sensitive toxin MPP+ to induce a strong functional but small morphological impairment. We further tested known neuroprotective compounds such as GDNF to prevent the functional impairment by single pre-treatment. Using multi-parametric data analysis of functional activity patterns, we calculated a read-out able to capture both, impairment and prevention of the neuronal network activity. We demonstrated that the used neuronal cultures produce robust spontaneous activity showing a functional maturation into a communicating network within 3 weeks *in vitro*. We further show that MPP+ induces significant functional effects which can be prevented by single GDNF treatment. We compare the results with those of primary mouse midbrain neuron/glia co-cultures using the same experimental design. In summary, our functional phenotypic *in vitro* screening platform with human iPSC-derived dopaminergic neurons growing on mwMEAs allows the robust and reproducible screening of novel leads or advanced drugs (repurposing) robust and reproducible screening of novel leads or advanced drugs (repurposing) for future therapies for Parkinson's disease.

Title: Effects of binge ethanol exposure on transient receptor potential melastatin 7 expression in brain microvascular endothelial cells of the HIV-1 transgenic rats

Authors: M. L. MACK[1], Y. WEI[1], M. D. LI[2], *S. L. CHANG[1];
[1]Inst. of NeuroImmune Pharmacol., Seton Hall Univ., South Orange, NJ; [2]Dept. of Psychiatry & Neurobehavioral Sci., Univ. of Virginia, Charlottesville, VA

Abstract: The HIV-1 transgenic (HIV-1Tg) rat was created with a *gag*- and *pol*-deleted HIV-1 viral genome under the control of the LTR viral promoter, and it persistently expresses 7 of the 9 HIV-1 genes. This rodent model mimics HIV-infected patients on combination anti-retroviral therapy (cART), who have controlled viral replication, but persistent HIV infection. The HIV-1Tg rat has also been used to study the effects of HIV-1 viral proteins on the response to addictive substances, including ethanol (EtOH). We previously demonstrated that the effects of binge exposure to EtOH are concentration dependent. EtOH exerts its physiological effects through a variety of target proteins, including transient receptor potential melastatin 7 channels (TRPM7). TRPM7 plays an essential role in maintaining cellular homeostasis of divalent ions, including Mg^{2+} and Ca^{2+}. We have recently shown that TRPM7 is highly expressed in primary cultures of mouse brain microvascular endothelial cells (BMVECs), the major cellular component of the blood-brain barrier (BBB). We found that EtOH modulates both protein and mRNA TRPM7 expression in a concentration-dependent manner, and that TRPM7 antagonists disrupt the integrity of an *in vitro* BBB model. In this study, rBMVECs were first isolated from both HIV-1Tg and F344 control rats at different ages, and then analyzed by flow cytometry for expression of intracellular TRPM7 protein. Our data showed that TRPM7 expression was lower in HIV-1Tg rats at 3-4 wks of age (25.6% TRPM7+) compared to that in the F344 control rats (44.1 %), whereas both F344 and HIV-1Tg rats expressed similar TRPM7 levels (42.2% and 40.4%, respectively) at 9 wks or older, indicating that the persistent presence of HIV-1 viral proteins delays TRPM7 expression in adolescents. Next, both 9 wk old HIV-1Tg and F344 rats were randomly assigned to receive saline or EtOH (2 g/kg/d, 3d) in either an 8% or 52% EtOH solution for 4 wks. Twenty four hours after the last treatment, rBMVECs were isolated from brain tissue and stained for intracellular TRPM7 protein. Binge exposure to EtOH for 4 wks decreased TRPM7 expression in rBMVECs of the F344 rats in a concentration-dependent manner; however, HIV-1Tg rats exhibited complete TRPM7 down-regulation when given either 8% or 52% EtOH. These results suggest that binge EtOH exposure completely blocks TRPM7 expression in adults, and could be one of the mechanisms underlying the damage to the BBB caused by repeated binge alcohol in HIV-1 patients, even with cART treatment.

Title: Synthesis of high surface area gold nanoparticle for brain disease drug carrier

Authors: M. PARK, *S. CHUNG;
Dept. of Physiology, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: There are many types of brain diseases, such as an Alzheimer's Disease (AD) and Parkinson's Disease (PD). For the case of Alzheimer's Disease, it is caused mainly by beta-amyloid accumulation. To treat such disease, anthocyanin can be used to protect beta-amyloid accumulation. In case for Parkinson's Disease, it is caused by death of dopamine-generation cells in the midbrain region and many drugs are used for treatment. However, the possibility of the efficient drugs passing the BBB (Blood Brain Barrier) is low. Therefore, the use of drug carriers is an alternative method to treat brain disease. However, such treatment also requires several standards – ability to transport molecules across the BBB, biocompatibility, proper circulation time, and right particle size and shape. Based on such reasons, Gold nanoparticles satisfy as one of the best drug carriers for treating brain diseases. Here, we report method to synthesize gold nanoparticles, where size can be controlled with asymmetric shape, resulting in sufficient use as a drug carrier for treatment of brain diseases. To synthesize the gold nanoparticle, asymmetric gold nanoparticle's seed was used, also known as polyol process. Gold (III) chloride trihydrate ($HAuCl_4 \cdot 3H_2O$) was used for metal precursor and ethylene glycol was used as a reducing agent, which donates electrons to gold ions ($Au^{3+} + 3e^- \rightarrow Au^0$). Finally, for surfactant, also called the Capping agent, poly (diallyldimethyl ammonium chloride) (PDDA) was used which has the ability to attach {111} plane, explained by the Miller Index. By mixing N, N-dimethylformamide (DMF) and Gold (III) chloride trihydrate ($HAuCl_4 \cdot 3H_2O$), followed by 5 hour sonication, gold nanoparticles were synthesized. To check the nanoparticles, morphology, UV-Vis absorption, zeta potential and applications through Ussing chamber were checked. Through SEM (Scanning Electron Microscope) and TEM (Transmission Electron Microscopy), octahedral gold nanoparticles and asymmetric gold nanoparticles were successfully synthesized. Also, it was found that different experimental conditions, such as washing time, amount of gold ion's solution, concentration of DMF, and temperature, can affect the morphology of the gold nanoparticles. In addition through solution color observation, UV-Vis absorption, zeta potential and use of Ussing chamber, we confirmed the positive use of asymmetric gold nanoparticle's potential as use of nano drug carriers. Keywords: Asymmetric gold nanoparticle, Brain disease treatment, Drug carrier, Polyol process, Octahedral gold nanoparticle.

Title: Histamine H3 receptor inverse agonist, SUVN-G3031 produces procognitive effects without affecting sleep in preclinical animal models

Authors: *V. BENADE, S. DARIPELLI, J. THENTU, R. MEDAPATI, R. SUBRAMANIAN, V. MEKALA, A. SHINDE, L. KOTA, N. GANGADASARI, V. GOYAL, S. PANDEY, R. NIROGI;
Suven Life Sci. Ltd, Hyderabad, India

Abstract: SUVN-G3031, potent histamine 3 (H3) receptor inverse agonist is being developed for the treatment of cognitive deficits associated with Alzheimer's disease (AD). SUVN-G3031 is a lead molecule with hKi of 8.7 nM and has more than 100 fold selectivity against the related GPCRs. SUVN-G3031 exhibited desired pharmacokinetic properties and brain penetration. SUVN-G3031 blocked R-α-methylhistamine induced water intake and increased tele-methylhistamine levels in brain and cerebrospinal fluid. Treatment with SUVN-G3031 significantly reversed time induced memory deficit in novel object recognition test & T-maze task. It also reversed scopolamine induced memory deficit in Morris water maze task. Single dose oral administration resulted in H3 receptor occupancy up to 85% in rats and significantly raised acetylcholine and histamine levels in the cortex. At therapeutically effective doses, SUVN-G3031 produced no change in the sleep/ wake profile of rats. SUVN-G3031 was well tolerated in toxicity studies in animals with wide margin of safety, and was found to be non-genotoxic in bacterial reverse mutation assay and chromosomal aberration test in human lymphocytes. SUVN-G3031 produced procognitive effects in rats without affecting the sleep and it possess safety and desired pharmacokinetic profile for further development.

Abstract: Ligands at α7 subtype receptors (α7-nAChRs) have been described as endowed with procognitive activity in preclinical and in clinical studies, both in Alzheimer's Disease and schizophrenia. Besides procognitive effects, action at this receptor might be of interest in relieving some deleterious actions induced by β-amyloid peptide, as already described in preclinical studies (eg : A-582941 (Hu et al 2008), S 24795 (Wang et al 2010), ABT-107 (Bitner et al 2010)). The aim of the present study was to characterize pharmacological properties of S 76892, a new ligand at α7-nAChR. S 76892 is a very weak partial agonist at rat α7-nAChR subtype, since it induced a very small inward current on Xenopus laevis oocytes injected with rat α7 mRNA. The current was blocked by α-bungarotoxin. As described for typical partial agonists (Briggs and McKenna, 1998), S 76892 decreased the ACh-induced current in a concentration dependant manner with an IC_{50} of 18 µM, confirming S 76892-mediated desensitization of the receptors. No agonistic activity of S 76892 was detected on Xenopus laevis oocytes injected with rat mRNA α4β2-nAChR. Potential protective effect of S 76892 on $A\beta_{1-42}$ peptide-induced toxicity on rat cortical cells culture was evaluated, S 24795 being used as an internal pharmacological reference. S 76892 had a very high permeability of the Blood-Brain-Barrier both in mice and in rats (Kp > 100). *In vivo*, S 76892 improved episodic-like memory in a novel object recognition test in mice and rats (3 mg/kg, p.o.). Furthermore, S 76892 reversed age-induced deficits in spatial contextual and serial discrimination task (0.1-0.3-1 mg/kg 9 administrations p.o.) in middle-aged mice. S 76892 improved spatial working memory as assessed by spontaneous alternation behavior on a T-maze in adult mice (0.03-0.1-0.3 mg/kg, i.p.). Besides its procognitive action, S 76892 also displayed neuroprotective activity (30 mg/kg

i.p.) in a model of delayed hippocampal neuronal death induced by a global transient ischemia in rats. S 76892 (1-3-10 mg/kg i.p.) did not induce wake-promoting effect as assessed by cortical EEG recordings in freely moving Wistar rats. Taken together, these results indicate that S 76892, on top of a potential counteractive action *in vitro* against Aβ-induced toxicity, enhances cognitive activity and is neuroprotective in rodents. It may therefore be of interest for pharmacological treatment of Alzheimer's disease.

Abstract: (STriatal-Enriched protein tyrosine Phosphatase) is a protein tyrosine phosphatase implicated in several neuropsychiatric and neurodegenerative disorders. STEP is highly expressed in striatum, where it functions as a coincidence detector for converging dopamine and glutamate signals in medium spiny neurons. Here, we identify a novel of role STEP in dopaminergic neurons, where it acts as a link between neurotrophin and dopaminergic signaling. Our studies show STEP is expressed in midbrain dopaminergic neurons and its protein levels are regulated by the ubiquitin mediated proteasomal system through BDNF-TrkB signaling. Exposure of midbrain dopaminergic neurons to BDNF leads to degradation of STEP, sustained activation of ERK1/2 and increased phosphorylation of tyrosine hydroxylase (TH) at Ser^{31} (ERK1/2 site), which regulates TH activity and stability. In support of our findings, increased ERK1/2 activity in striatum from STEP KO mice is correlated with increased TH phosphorylation at Ser^{31} and increased TH protein levels, suggesting enhanced dopamine signaling. Our preliminary findings also suggest that STEP KO mice exhibit enhanced dopamine release compared to wild type mice. Our future studies are aimed at understanding the regulation of STEP by BDNF signaling and its role in TH activity, dopamine synthesis and release. These findings suggest a potential role of STEP in neuronal diseases where both BDNF and dopamine signaling are implicated. Title: Novel small molecule triazolopyrimidine derivatives exhibit microtubule-stabilizing activity and represent potential therapeutic candidates for Alzheimer’s disease and related tauopathies

Authors: J. KOVALEVICH[1], A.-S. CORNEC[2], Y. YAO[1], M. JAMES[1], A. CROWE[1], V. M. Y. LEE[1], J. Q. TROJANOWSKI[1], A. B. SMITH, III[2], C. BALLATORE[2], *K. R. BRUNDEN[1]; [1]Ctr. Neurodegen Res., Univ. Pennsylvania, Philadelphia, PA; [2]Chem., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Alzheimer’s disease (AD) and related tauopathies are characterized by hyperphosphorylation and aggregation of the microtubule (MT)-associated protein, tau. Through incompletely understood mechanisms, hyperphosphorylation of tau induces its dissociation from MTs, where it normally plays an integral role in MT stability and facilitation of axonal transport in neurons. Loss of tau function leads to MT hyperdynamicity and disrupted transport of critical cellular proteins, likely leading to neuronal dysfunction and cognitive decline. Therefore, compensation for tau loss-of-function through introduction of MT-stabilizing compounds might normalize the altered MT dynamics that accompany tauopathies and serves as a viable therapeutic approach in the treatment of AD and related tauopathies. In this context, we have generated a number of brain-penetrant small molecule triazolopyrimidine derivatives that exhibit MT-stabilizing activity in both proliferating cells and in rat primary cortical neurons, as assessed by post-translational modifications of tubulin (i.e.; acetylation and detyrosination) that are indicative of MT stabilization. Interestingly, although highly similar in structure, these small molecules can be subdivided into two classes based on their *in vitro* behavior. One set of compounds, deemed “Class 1” molecules, increase markers of stable MTs in dividing cells and

in primary neurons without affecting total alpha- or beta-tubulin levels or significantly altering MT morphology at effective doses. The structurally related "Class 2" molecules increase markers of stable MTs at moderate doses in QBI-293 cells (a HEK-293 cell derivative) but not in primary neurons, and appear to induce degradation of alpha- and beta-tubulin across multiple cell types. Furthermore, in QBI-293 cells, Class 2 compounds lose efficacy in inducing post-translational modifications of tubulin indicative of stabilization at high doses. Although Class 2 compounds appear to possess MT-stabilizing activity based on activity in the acetyl-tubulin assay at moderate doses, their substantial negative impact on total tubulin levels likely preclude them from providing any therapeutic benefit under pathological tau conditions. Therefore, studies to further characterize the molecular mechanisms underlying the effects of Class 1 compounds on MT stability and axonal transport, as well as the potential for therapeutic use through compensation for tau deficits in AD, are currently underway.

Title: Clinical pharmacology of the 5-HT6 antagonist, RVT-101: summary of phase 1 studies

Authors: I. LOMBARDO[1], *L. FRIEDHOFF[1], S. PISCITELLI[2], G. RAMASWAMY[3]; [1]Axovant Sciences, Inc, New York, NY; [2]Roivant Sciences, Inc, New York, NY; [3]Axovant Sciences, Inc., New York, NY

Abstract: Background: RVT-101 (formerly known as SB-742457) is an orally administered, 55-HT6) serotonin receptor antagonist that promotes the release of acetylcholine and other neurotransmitters. RVT-101 is being evaluated in Alzheimer's disease (AD) as an adjunctive therapy to the cholinesterase inhibitor, donepezil. Methods: Nine studies in 225 healthy subjects were completed. These include single-and repeat-dose studies, positron emission tomography (PET) studies (data not presented here), and drug interaction studies. Population PK analyses were also conducted using data from Phase 2 studies. Healthy adults have received single doses ranging from 2 to 175 mg. Multiple doses up to 35 mg daily for 28 days in healthy elderly subjects and up to 50 mg daily for 13 days in younger adult subjects have been administered.

Results: RVT-101 demonstrates linear pharmacokinetics (PK) over the dosage range studied. The average time to maximal concentration was 4 to 7 hours and the half-life was approximately 30 hours. On repeat dosing, steady state was reached within 7 days. The PK were not affected by administration with a high fat meal. No major age or gender differences in PK have been observed, and the PK in subjects with AD was similar to that in healthy volunteers. A CYP450 probe interaction study showed RVT-101 has no significant effects on 3A4, 2D6 and 1A2 metabolic pathways. RVT-101 exhibits modest inhibitory effects on CYP2C9; the international normalized ratio (INR) was 23% higher when warfarin was co-administered with RVT-101 compared with co-administration with placebo. Studies also demonstrated that RVT-101 did not significantly alter the exposure of donepezil or risperidone. Conclusion: Phase 1 studies demonstrate that RVT-101 possesses a number of favorable properties for use in the AD population including once daily dosing, lack of food effect, and low potential for drug interactions.

Title: Effects of inhibiting STriatal-Enriched protein tyrosine Phosphatase (STEP) on dendritic morphology in mice with Alzheimer's disease

Authors: *J. B. BENEDICT[1], M. CHATTERJEE[2], J. ELLMANN[3], A. NAIRN[4], P. LOMBROSO[2,4,5];
[2]Child Study Ctr., [3]Chem., [4]Psychiatry, [5]Neurobio., [1]Yale Univ., New Haven, CT

Abstract: STEP (STriatal-Enriched protein tyrosine Phosphatase) is a neuron-specific phosphatase that is overactive in several neuropsychiatric conditions including Alzheimer's disease (AD). Alzheimer's disease presents with reduced dendritic complexity, which is thought to cause cognitive deficits through alterations in synaptic connectivity. Genetic reduction of

STEP resulted in significant behavioral improvements in 3xTg AD mice, and validated STEP as a target for drug discovery. We now have a STEP inhibitor, TC-2153, which is a potent and specific inhibitor of STEP. STEP inhibition by TC-2153 is achieved through oxidative attack of the catalytic cysteine residue in the phosphatase domain of STEP. Administration of TC-2153 also improved the cognitive functions of 3xTg mice in various behavioral paradigms. Here we present the effects of pharmacological inhibition of STEP on the dendritic morphology in 3xTg AD mice. Using Golgi Cox staining, dendritic morphology was analyzed in 6-month old WT and AD mice treated with a vehicle, then compared to WT and AD mice treated with TC-2153 for two weeks. Due to improvements in the behavior and dendritic morphology of AD mice when treated with a STEP inhibitor, we consider STEP a novel target for the treatment of a range of psychiatric disorders including AD.

Title: Selective sphingosine-1-phosphate receptor 5 agonists can modulate lipid content in the brain and thereby potentially treat neurodegenerative disorders

Authors: *E. VAN DER KAM[1], S. C. TURNER[2], M. OCHSE[2], J. VAN BERGEIJK[2], R. MUELLER[2], M. MEZLER[3], K. HEMPEL[4], A. HOBSON[6], C. M. HARRIS[6], A. BESPALOV[2], A. HAHN[2], B. RENDENBACH-MUELLER[5];
[1]Discovery Project Mgmt., AbbVie Deutschland Gmbh & CO KG, Ludwigshafen, Germany; [2]Neurosci. Discovery, [3]Developmental Science, Drug Metabolism & Pharmacokinetics, [4]Neurosci. Preclinical Safety, [5]Neurosci. Develop., AbbVie Deutschland GmbH and Co KG, Ludwigshafen, Germany; [6]Immunol. Discovery, AbbVie Bioresearch Ctr., Worcester, MA

Abstract: Sphingosine-1-phosphate (S1P) plays an important role as a regulator of signal transduction, cellular plasticity, cell proliferation, membrane stability/BBB integrity, and is proposed to modulate the ceramide-S1P and cholesterol homeostasis. S1P exerts these actions through G protein-coupled receptors, such as the brain-preferred S1P5 receptor. Given these actions, S1P5 agonism could potentially be a beneficial treatment for neurodegenerative disorders. AbbVie has recently developed highly selective S1P5 receptor agonists, such as A-

971432. A-971432 has an EC50 of 10 nM on the hS1P5 receptor with a large selectivity window. The compound shows an excellent *in vivo* PK profile with good oral bio-availability (60% in mice, 100% in rat, 92% in dogs), half-life (7-9h), and brain penetration (B/P ~0.2). Moreover, the compound was well tolerated in a 14d Sprague-Dawley rat exploratory toxicity study up to 100 mg/kg bw/day and with favorable profile in cardiovascular examination. As such, this compound was used to test the hypothesis that selective S1P5 agonists will a) reduce CNS, but not peripheral lipid content, b) improve cognition, and c) change disease progression as assessed in a model mimicking key features of AD. A-971432 was examined in models of age-related cognitive decline, such as the spontaneous alternation T-maze assay, the Morris Water Maze (MWM), and the Object Recognition (ORT) task in aged (12+ months or 18+ months) mice and rats. Sub-acute treatment (≥7 days) in either T-maze (0.03 mg/kg - 3 mg/kg) or MWM/ORT (0.1 and 0.5 mg/kg) fully reversed age-related cognitive deficits with a minimal effective dose of 0.1 mg/kg (40 ng/mL). Concomitantly, A-971432 normalizes the age-related CNS sphingolipid imbalance without affecting plasma levels. Finally, a single dose was examined in the murine model of Niemann Pick C disease (NPC). NPC (endosomal-lysosomal storage disease) animals display AD-like pathology such as Aβ and Tau accumulation. A-971432 (1 mg/kg) was able to improve the behavioral phenotype (dystonia, motor impairment), promote survival, normalized CNS sphingolipid content, and normalized Aβ levels in the CSF. The data, together with the cognition and lipid modulation findings indicate that S1P5 agonism provides an innovative mechanism for the potential treatment of neurodegenerative disorders such as AD and lysosomal storage disorders such as Niemann Pick C. Title: SUVN-D4010: Novel 5-HT4 receptor partial agonist for the treatment of Alzheimer's disease

Authors: ***N. MUDDANA**, R. SUBRAMANIAN, R. MEDAPATI, R. ABRAHAM, V. BENADE, R. PALACHARLA, A. MANOHARAN, V. GOYAL, S. PANDEY, M. RASHEED, S. RAVELLA, R. NIROGI;
Suven Life Sci., Hyderabad, India

Abstract: SUVN-D4010 is a potent, selective and orally bioavailable 5-HT4 partial agonist being developed for the treatment of Alzheimer's disease. The procognitive properties of SUVN-D4010 were characterized in animal models of cognition like object recognition task, radial arm maze task and fear conditioning assay. The effect on the cholinergic neurotransmission was studied using brain microdialysis technique. *In vivo* receptor binding profile was measured using non-radiolabeled tracer in rats. The effect of SUVN-D4010 on the toxic β-amyloid and the

neuroprotective sAPPα were evaluated in the preclinical species using ELISA kits. Safety, general toxicity and mutagenic potential of SUVN-D4010 were evaluated in rodents/non rodents and *in vitro* models. SUVN-D4010 improved the episodic memory deficits in object recognition task. It also reversed the working and emotional memory deficits induced by scopolamine in radial arm maze task and fear conditioning assay. Oral administration of SUVN-D4010 significantly increased the brain acetylcholine levels. SUVN-D4010 also potentiated the pharmacological effects of donepezil. The effect on the cognition and cholinergic neurotransmission were blocked by GR 125478, a selective 5-HT4 antagonist. SUVN-D4010 showed significant 5-HT4 receptor occupancy at pharmacologically effective doses. A significant increase in cortical sAPPα and decrease in amyloid-β protein levels was also seen. SUVN-D4010 was well tolerated in animal toxicity studies and did not show any mutagenic potential. SUVN-D4010 is a novel, potent, selective, orally bioavailable, efficacious and a safe 5-HT4 receptor partial agonist. IND enabling GLP safety studies have been completed. US IND filing is in progress.

Title: Pharmacological inhibition of striatal-enriched protein tyrosine phosphatase (STEP) with TC-2153 attenuates seizure frequency and severity in the pilocarpine model of temporal lobe epilepsy

Authors: *D. B. LAWRENCE[1], R. M. SAMPLES[1], F. A. HARRSCH[1], E. S. WEISS[1], M. R. PELTON[1], M. VAN ZANDT[1], M. CHATTERJEE[2], T. BAGULEY[3], J. ELLMAN[3], A. C. NAIRN[3], P. J. LOMBROSO[2,4,5], J. R. NAEGELE[1];
[1]Dept. of Biol., Wesleyan Univ., Middletown, CT; [2]Child Study Ctr., [3]Dept. of Chem., [4]Psychiatry, [5]Neurobio., Yale Univ., New Haven, CT

Abstract: Striatal-Enriched Protein Tyrosine Phosphatase (STEP) levels are elevated in several neurological disorders, including Alzheimer's disease and schizophrenia. STEP deficiency caused by gene knockout or pharmacological inhibition of STEP with TC-2153, a STEP inhibitor, ameliorates cognitive deficits in these disorders. A role for STEP in epilepsy is implicated by prior studies showing that STEP knockout mice exhibit increased seizure thresholds in the pilocarpine model of temporal lobe epilepsy (TLE). The present study was conducted to determine whether STEP inactivation with TC-2153 prevents or attenuates seizures. Following pilocarpine induced status epilepticus (SE) in C57BL/6 mice (Harlan Laboratories,) TC-2153 was injected intraperitoneally every day for two weeks at doses of 0, 5, or 10 mg/kg. Seizure activity from 40 mice was monitored with continuous video-EEG (vEEG) for varying periods from 21 days to 85 days after SE. vEEG analyses were carried out on 27 mice from post SE days 40-60 to quantify seizure frequency, severity, and duration. Mice receiving TC-2153 injections showed significantly reduced seizure frequency and severity. Studies are underway to examine seizure-induced changes in STEP levels and the effects of TC-2153 on STEP substrate phosphorylation after SE. Our preliminary findings suggest a role for STEP in epileptogenesis and potential therapeutic benefits of STEP inhibition for the treatment of TLE.

Title: Development of a novel and robust pharmacological model of okadaic acid-induced Alzheimer's disease in zebrafish

Authors: S. NADA[1], F. E. WILLIAMS[2], *Z. A. SHAH[3];
[1]Univ. of Toledo, Toledo, OH; [2]Pharmacol., [3]Medicinal & Biol. Chem., Univ. of Toledo Col. of Pharm. and Pharmaceut. Sci., Toledo, OH

Abstract: Alzheimer's disease (AD) is the leading neurodegenerative disorder that incapacitates the elderly population all over the world. Most of the experimental models for AD are transgenic

or pharmacological in nature and do not simulate the pathophysiology in entirety. In the present study we intended to develop a pharmacologically induced AD using economically affordable species that will recapitulate most of the phenotypes of the disease. The pharmacological agent, okadaic acid (OKA) used in this study is the best pharmacological agent that has already been shown to work in other species. In this model the expression profile of phosphorylation of GSK-3α/β, Aβ, p-Tau and Tau protein and senile plaque formation in zebrafish brain were significantly increased with the exposure of increasing concentration of OKA and these represent the majority of the hallmarks of AD pathophysiology. The observed morphological changes were also accompanied by the learning and memory deficits which are important physiological components in AD pathophysiology. Zebrafish disease models are gaining popularity mostly due to their economic cost and relevance to human disease pathophysiology. Existing pharmacological methods of inducing AD are not adequately developed in this species and do not represent all the features of the disease as was observed in OKA-induced AD model. OKA-induced AD in zebrafish can become a robust model to study drug discovery for AD or unravel the molecular mechanisms underlying the complex pathophysiology that leads to AD using relatively economical species.

Title: Adenosine A2A receptor expression in human brain and beneficial effects of A2A receptor blockade in aging and models of neurodegenerative disease

Authors: *A. G. ORR[1,2], K. HO[1], A. LUNDQUIST[1], G. SHLAGER[1], S. LEE[1], D. H. KIM[1], X. WANG[1], W. GUO[1], G.-Q. YU[1], E. MASLIAH[3,4], W. W. SEELEY[2,5], L. MUCKE[1,2]; [1]Gladstone Inst. of Neurolog. Dis., San Francisco, CA; [2]Dept. of Neurol., Univ. of California, San Francisco, CA; [3]Dept. of Neurosci., [4]Dept. of Pathology, Univ. of California, San Diego, CA; [5]Dept. of Pathology, Univ. of California, San Francisco, CA

Abstract: Adenosine receptor signaling regulates neural function and may play a role in neurodegenerative disorders. We previously reported that hippocampal astrocytes in humans with sporadic Alzheimer's disease (AD) had increased levels of the adenosine receptor A2A and these increases correlated with astrogliosis and tau pathology (Orr et al., 2015, Nat Neurosci). In the same study, we demonstrated that conditional genetic ablation of astrocytic A2A receptors prevented memory loss in mice with or without amyloid plaque deposition, suggesting that these receptors regulate cognitive function. In the present study, we further investigated the expression of A2A receptors in postmortem human brain tissues from aging nondemented controls and cases with sporadic AD, dementia with Lewy bodies (DLB), or frontotemporal lobar degeneration (FTLD). Early data show that astrocytic A2A receptor levels are increased in the hippocampal formation, but not frontal cortex, of cases with AD, DLB or FTLD, suggesting a brain region-specific response of astrocytes that could contribute to memory loss in these diverse neurodegenerative conditions. Together, our findings also imply that blocking astrocytic A2A receptors could be a therapeutic strategy for memory enhancement. However, A2A receptors are also highly expressed by striatal medium spiny neurons and known to regulate motor function. Therefore, we tested the effects of global pharmacological blockade of A2A receptors on cognitive and motor functions in aging animals. After conducting preliminary pharmacokinetic analyses, we treated aging nontransgenic (NTG) and transgenic mice expressing human amyloid precursor protein (hAPP) with istradefylline, a potent and selective A2A receptor antagonist. We found that administration of high doses of istradefylline induced hyperactivity in the open field, but did not affect context habituation, in NTG and hAPP mice. In contrast, lower doses of istradefylline enhanced context habituation in NTG and hAPP mice without inducing prolonged hyperactivity or anxiety. Low doses of istradefylline also enhanced motor performance in the rotarod test, suggesting that, within an appropriate therapeutic window, A2A receptor blockade can enhance both cognitive and motor functions in aging animals. Our ongoing neuropathological and preclinical studies may guide the development of therapeutic strategies for AD and other neurodegenerative disorders that involve aberrant A2A receptor activity.

Title: Safety, tolerability and pharmacokinetics of a potent and selective H3 receptor inverse agonist, SUVN-G3031 following single and multiple ascending doses in healthy adult subjects

Authors: *G. BHYRAPUNENI, K. MUDIGONDA, K. PENTA, N. MUDDANNA, R. PALACHARLA, P. JAYARAJAN, R. ABRAHAM, R. SUBRAMANIAN, V. GOYAL, S. PANDEY, R. BOGGAVARAPU, D. AJJALA, A. SHINDE, R. NIROGI;
Suven Life Sci., Hyderabad, India

Abstract: SUVN-G3031, a potent and selective histamine 3 (H3) receptor inverse agonist is being developed for the treatment of cognitive deficits associated with Alzheimer's disease (AD). SUVN-G3031 demonstrated cognitive enhancement and relevant neurochemical changes without affecting the sleep in rodent models. SUVN-G3031 was studied in a single-center, multi-faceted, phase 1 clinical trial (US IND) to evaluate its safety, tolerability, and pharmacokinetics after single and multiple ascending doses in healthy young adult subjects. SUVN-G3031 was quantified in plasma using a validated LC-MS/MS method. SUVN-G3031 was tolerated up to 20 mg/day following single oral administration in healthy adult subjects. There were no clinically relevant or serious adverse events observed at any of the doses tested. During multiple ascending dose studies, SUVN-G3031 has shown a favorable pharmacokinetic profile. SUVN-G3031 achieved the projected efficacy concentrations and attained steady state from seven days in the tested population. SUVN-G3031 is well tolerated in humans with adequate plasma exposure for efficacy and favorable pharmacokinetics suitable for once a day oral administration.

Title: Inhibitors of STEP as a novel treatment of fragile-x-syndrome

Authors: *M. CHATTERJEE[1], J. KWON[1], J. BENEDICT[1], E. FOSCUE[1], T. BAGULEY[2], J. ELLMANN[2], A. NAIRN[3], P. LOMBROSO[1,3,4];
[1]Child Study Ctr., [2]Chem., [3]Psychiatry, [4]Neurobio., Yale, New Haven, CT

Abstract: STEP is a brain specific phosphatase has recently emerged as a promising target in various neuropsychiatric condition including Alzheimer's disease, Parkinson's disease, schizophrenia and fragile-X syndrome. Fragile X syndrome (FXS), an X-linked condition caused by an increase in the number of CGG repeats located in the first exon of the Fragile X mental retardation 1 (FMR1) gene, which encodes the RNA-binding protein FMRP. FMRP acts as a translational silencer of mRNAs that encode several synaptic proteins. In the absence of FMRP, translation of some of these mRNAs is upregulated and one such message that associates with FMRP is STEP (STriatal-Enriched protein tyrosine Phosphatase) mRNA. STEP is known to be downstream of the Fmr1 protein and Fmr1 suppresses the translation of STEP. Absence of Fmr1 gene in mice leads to overexpression of STEP, dephosphorylating its key substrates GluN2B, ERK and Pyk 2 mainly involved in synaptic strengthening. Genetic reduction of STEP in Fmr1 KO mice showed improvements in behavioral abnormalities commonly found in fragile-X mice. Our recent focus was on developing a STEP Inhibitor, which can rescue these abnormalities in KO mice. TC-2153, a potent STEP inhibitor has been found to inhibit STEP in WT mice and is able to rescue memory related abnormalities in AD mice model. Our goal was to test whether TC-2153 rescues the behavioral abnormalities in fragile X mouse model similar to genetic reduction of STEP. Further, we will also look at the effect of this inhibitor in rescuing abnormalities in dendritic spine density and morphology in cell based assays. Funding: FRAXA

Title: Exercise regulates STEP (STriatal-Enriched protein tyrosine Phosphatase) through BDNF signaling

Authors: *M. POWELL[1], D. GHOSH[1], E. P. FOSCUE[1], A. C. NAIRN[2], P. J. LOMBROSO[3]; [1]Yale Child Study Ctr., [2]Psychiatry, [3]Yale Child Study Center, Neurobiology, Psychiatry, Yale Univ., New Haven, CT

Abstract: Exercise has been widely accepted to increase general health, but over the last fifteen years, interest in the strengthening effects of exercise on specific brain functions has grown. Brain-derived neurotrophic factor (BDNF) is upregulated by exercise and correlated with synaptic plasticity and cell genesis, growth, and survival. It has been suggested that the majority of exercise-induced neuronal strengthening takes place through N-methyl-D-aspartate (NMDA) receptor glutamatergic transmission, as lack of the key NR2A subunit of the NMDA receptor prevents exercise from increasing neurogenesis or BDNF levels in the brain. The NMDA receptor is necessary for improving memory and learning, enabling neurons to modify themselves in accordance with past stimulations. A regulator of NMDA receptor trafficking is a tyrosine phosphatase called striatal-enriched protein tyrosine phosphatase, or STEP. STEP de-phosphorylates many substrates linked with brain maintenance and degradation, including the NR2B subunit of the NMDA receptor (GluN2B), which results in internalization of the receptor within the neuron. Through this mechanism, STEP opposes the development of synaptic strengthening and is linked to various neuropsychiatric disorders, including Alzheimer's disease, fragile X syndrome, and schizophrenia. Previous work has shown that STEP levels have an inverse relationship with BDNF. Our findings demonstrate that exercised animals have lower levels of STEP as compared to sedentary age-matched controls. In addition, experiments using the Y maze behavior task revealed that exercised animals improved their working memories over sedentary animals, and experiments using the novel object recognition behavior task added that exercised STEP knockout (KO) animals, though their cognition was improved over their wild-type counterparts, did not exceed sedentary STEP KO animals on the task. These findings, taken together with an understanding of STEP regulatory mechanisms, have led to the hypothesis that exercise leads to elevated BDNF resulting in STEP degradation through the ubiquitinate proteasome pathway. Lower levels of STEP leads to increased phospho-extracellular signal-related kinase (pERK1/2) and phospho-NR2B (pGluN2B), with improvements in cognition and synaptic strengthening. We seek to better understand this pathway in the hope that it may eventually become a target for therapeutics seeking to replicate the beneficial effects of exercise on the brain.

[2]Preclinical Res. & Develop., [3]Res., [4]Clin., [5]Regulatory, [6]Manufacturing, [1]NeuroPhage Pharmaceuticals, Inc., Cambridge, MA; [7]Neurosciences, Univ. of California San Diego, La Jolla, CA; [8]Neurobio., Barrow Neurologic Inst., Phoenix, AZ; [9]Biotech. of Neurodegenerative Dis., Tel Aviv Univ., Tel Aviv, Israel

Abstract: Alzheimer's disease (AD) and other neurodegenerative disorders are associated with the accumulation of aggregates of multiple species of misfolded proteins, such as amyloid-β (Aβ), tau, and α-synuclein. The need to target multiple types of protein aggregates in a single disease suggests the need for therapeutic strategies that target aggregates independent of primary protein sequence. We isolated a protein motif from bacteriophage M13 that binds and remodels multiple misfolded proteins that assume an amyloid conformation including Aβ, tau, and α-synuclein. We call this motif the General Amyloid Interaction Motif (GAIM). NPT088, our development candidate, is a human immunoglobulin (huIgG1Fc) fusion protein that displays two copies of GAIM. We have shown that NPT088 has uniquely broad activities, both *in vitro* and *in vivo*, against multiple neuropathological aggregates, making it a novel candidate for treating AD. NPT088 specifically and potently binds amyloid fibers of Aβ, tau and α-synuclein, but does not bind the corresponding monomers or native protein assemblies. NPT088 binds Aβ oligomers, prevents Aβ and tau aggregation, and protects differentiated N2a cells from Aβ oligomer-induced cytotoxicity. NPT088 recognizes Aβ aggregates from brains of aged Tg2576 mice. NPT088 is efficacious in transgenic AD and Parkinson's disease mouse models. In the Tg2576 hAPP model, NPT088 significantly improves cognition, reduces brain Aβ(1-42) and Aβ plaque load, and reduces Aβ in cerebral spinal fluid. In rTg4510 tau mice, NPT088 significantly improves cognition and reduces levels of phospho-tau associated with neuropathology. In

mThy1-Hα-synuclein mice, NPT088 significantly reduces proteinase K-resistant α-synuclein and increases tyrosine hydroxylase levels. NPT088 has successfully completed pilot rat and monkey safety studies. These results demonstrate that NPT088 is a first-in-class therapeutic candidate for AD and other neurodegenerative diseases that targets misfolded proteins, including aggregates of Aβ, tau and α-synuclein. Following IND filing in 4Q2015, NPT088 will be tested for safety in healthy volunteers and then for proof of activity in AD patients by measuring reduction of PET amyloid markers.

Title: PD-61-W3 (Synuclere™) reduces and detoxifies alpha-synuclein aggregates and improves motor dysfunction: Development of a potential novel Parkinson's disease-modifying therapeutic

Authors: *L. A. ESPOSITO, K. L. HANSON, J. CUMMINGS, M.-C. YADON, T. M. CHONG, T. LAKE, Q. HU, J. CAM, A. D. SNOW;
ProteoTech Inc, Kirkland, WA

Abstract: PD-61-W3 (*Synuclere*™) is an organic proprietary small molecule that inhibits the formation of toxic alpha-synuclein aggregates at substoichiometric proportions and rapidly reduces and detoxifies pre-formed alpha-synuclein aggregates, a central pathogenic component in Parkinson's Disease (PD). PD-61-W3 efficacy and mechanism of action was established in a comprehensive set of *in vitro,* cell-based and *in vivo* (animal model) studies. Most importantly, PD-61-W3 efficacy was demonstrated in independent studies using PD-relevant Thy-1 human wild-type alpha-synuclein transgenic mice (Line 61). These studies showed that PD-61-W3 is well-tolerated *in vivo* and that PD-61-W3 targets brain alpha-synuclein as evidenced by marked reductions in alpha-synuclein aggregates in the substantia nigra, cortex and hippocampus, following 3-month treatment of younger mice (45-90% reductions) and 6-month treatment of older mice (79-91% reductions). Western blot analysis of brain extracts showed PD-61-W3 treatment significantly reduced soluble alpha-synuclein oligomers (by 72%). Reduced alpha-synuclein aggregates in PD-61-W3-treated transgenic mice were accompanied by improved motor performance on the challenging beam traversal and pole tests. The primary backup molecule, PD-61-F2, (an analog of PD-61-W3) also significantly reduced brain -synuclein aggregates (by 62%-96%). Additionally, drugability studies demonstrate that PD-61-W3 exhibits good properties characteristic of a CNS drug, including micromolar exposure in brain, plasma and CSF following a single subcutaneous injection in mice at a therapeutic dose level, no significant off-target binding to a panel of brain receptors, transporters or ion channels, no significant CYP450 inhibition, and good chemical stability. Furthermore, PD-61-W3 is non-mutagenic in the Ames test at dose levels up to 5000 micrograms per plate. In conclusion, PD-61-W3 safely and effectively reduced alpha-synuclein aggregation, improved motor function, and is being developed as a disease modifying therapeutic for Parkinson's Disease and related synucleinopathies. Funded by ProteoTech and a LEAPS Award from the Michael J. Fox Foundation for Parkinson's Disease Research.

Title: Clinical development of a bioactive dietary polyphenol preparation for treating patients with mild cognitive impairment and prediabetes

Authors: *L. DUBNER[1], L. HO[1], J. WANG[1,2], P. B. ROSENBERG[3], G. M. PASINETTI[1,2]; [1]Dept. of Neurol., Icahn Sch. of Med. At Mount Sinai, New York, NY; [2]Geriatric Res. Educ. and Clin. Ctr., James J. Peters Veterans Affairs Med. Ctr., Bronx, NY; [3]Divisions of Geriatric Psychiatry and Neuropsychiatry, Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Mild cognitive impairment (MCI) is an important target population for prevention of Alzheimer's disease (AD). Diabetes is a major cause of vascular problems and is associated with cognitive decline in older people, either through vascular mechanisms or by directly affecting the AD development process. Prediabetes is defined as the state of having an elevated fasting blood sugar level, increasing the risk of developing diabetes in the near future. Moreover, there is evidence that people with MCI and prediabetes are at particularly high risk of progressing to AD. There are currently no FDA-approved treatments for comorbid MCI and prediabetes. In addition, there is evidence that drugs controlling blood sugar may be detrimental to cognition. Thus, there is a great need for new interventions to prevent people with MCI and prediabetes from progressing to AD. We have strong preclinical preliminary data on the potential efficacy of a combination of three nutraceuticals (a Bioactive Dietary Polyphenol Preparation [BDPP]) in targeting amyloid load, synaptic plasticity, and cognition in mouse models of AD and metabolic syndrome. Based on this and of the safety profile of orally administered BDPP, BDPP has great potential for secondary prevention of cognitive/functional decline in comorbid MCI with metabolic risk factors. We have evidence for excellent penetrance of orally administered BDPP in the central nervous system (CNS) of mice, but further evidence on BDPP CNS penetrance, safety, and tolerability in humans is needed in order to assess its potential as a therapeutic agent. Thus, we are currently conducting a 4-month, phase Ib, ascending-dose, randomized, placebo-

controlled, double-blind study of oral BDPP administration in 48 participants with MCI and prediabetes. Primary outcome measures are cerebrospinal fluid (CSF) penetrance and safety, with secondary outcome measures of change in cognition and in CSF amyloid and tau content. The results of our pilot studies may support a single-dose, proof-of-concept trial of BDPP in participants with MCI and prediabetes, conceivably leading to the development of BDPP as a secondary prevention in this important population. We will present evidence supporting the safety of BDPP, bioavailability of BDPP polyphenols in the brain, and the mechanism by which BDPP polyphenols may modulate multiple inter-relating AD pathogenic mechanisms. Lastly, we will present an update of our ongoing BDPP clinical trial.

Title: Active cytosolic Rac1 and nuclear RhoA: Effects on neurite morphology

Authors: *J. M. REDDY, N. G. R. RAUT, D. L. HYNDS;
Biol., Texas Woman's Univ., Denton, TX

Abstract: Rho family guanine nucleotide triphosphatases (GTPases) are molecular switches that play a fundamental role in axon growth and guidance by directing growth cone cytoskeletal changes through interaction with downstream effectors. Small GTPases are considered active when bound to guanosine triphosphate (GTP), a process promoted by plasma membrane-associated guanine exchange factors (GEFs), and inactive when bound to guanosine diphosphate (GDP). RhoA, a member of the Rho family GTPases, participates in the formation of focal adhesions, retraction of neuron processes in response to injury or insult and growth cone collapse. Rac1, thought to be a competitor of RhoA, is responsible for cell proliferation, cell cycle entry, and extension of neuronal processes. The interplay between Rac1 and RhoA dynamics is not well elucidated, though they are thought to be direct competitors with opposing functions. Both require prenylation for membrane localization, though active forms of both have been found in other cellular compartments (GTP bound Rac1 in the cytosol and GTP RhoA primarily in the cytosol and nucleus). We constructed non-prenylatable a Rac1 and RhoA to test how inhibiting prenylation affects morphology and the location of active RhoA and Rac1. Non-prenylatable Rac1 induced cell clustering in B35 neuroblastomas, hallmarks of degeneration, while non-prenylatable RhoA increased neurite outgrowth. Non-prenylatable Rac1 was found active in the cytosol in both B35 neuroblastomas and rat cortical neurons while non-prenylatable RhoA was localized to the membrane, cytosol and nucleus. In fact, RhoA retained the ability to be made active independent of membrane targeting by prenylation after treatment with lovastatin. We have found transfection of these constructs in rat cortical neurons increase neurite outgrowth (for non-prenylatable RhoA and wildtype Rac1), neurite branching (for RhoA) and neurite formation (for non-prenylatable Rac1). With emerging evidence of differential activation of these Rho GTPases based on their subcellular localization, elucidating the signaling cascades of the active GTPases may identify novel targets to facilitate axon regeneration in traumatic or degenerative neurological conditions.

Title: Regulation of rac1-gtp by statin therapy in a genetically modified mouse model of autism spectrum disorders

Authors: Q. LING, *M. V. TEJADA-SIMON;
Dept Pharmacol & Pharma Sci., Univ. Houston, Houston, TX

Abstract: Rac1, one of the small Rho GTPases, is a critical mediator of dendritic spine development and long-term plasticity in the brain. Significant up-regulation of Rac1 has been documented in fragile X mental retardation 1 (fmr1) knockout mice, an animal model for autism spectrum disorder (ASD), suggesting that loss of Fragile X Mental Retardation Protein (FMRP) affects Rac1 activity. Interestingly, abnormal phenotypes described for this rodent model (e.g., cognitive deficits, risk of audiogenic seizures, altered long-term plasticity) are rescued upon normalizing levels of Rac1 by using specific pharmacological inhibitors. Since those Rac1 inhibitors have not been clinically developed yet, it is imperative to find an alternative way to benefit ASD patients. To be functional, Rac1 needs to undergo a post-translational modification in which an isoprenoid group is added to the protein, facilitating its subcellular localization and association with specific membranes. These prenylated proteins are uniquely formed through the mevalonate/cholesterol pathway, an important metabolic pathway for numerous cell functions. Based on our previous research, we hypothesized that restricting the availability of prenylated proteins by inhibiting the central mevalonate pathway with statins (3-hydroxy-3-methylglutaryl coenzyme A [HMG-CoA] competitive inhibitors) might also control Rac1 activation and function in the fmr1- knockout mice, similar to our previous results with the specific Rac1 inhibitors. To test this hypothesis we first investigated whether statin therapy reduces Rac1-GTP in fmr1 knockout mice. We chose Rosuvastatin as a test drug because of its higher bioavailability and higher half-life time compared to other statins. We incubated hippocampal slices derived from fmr1- knockout mice (FVB129 background) with different concentrations of Rosuvastatin (0-20μM) for 2 hours. Levels of active Rac1 (Rac1-GTP bound) by G-LISA as well as total Rac1 by Western Blots were determined. Our preliminary results suggested that, while statin treatment showed a slight trend to enhance total Rac1 content, activated Rac1 (Rac1-GTP) was still significantly decreased, suggesting that statin treatment might indeed be effective in reducing the prenylation of this small GTPase, hindering its membrane translocation and full activation. These findings indicated that regulation of isoprenoids might be useful to regulate overactivation of Rac1, and suggested that specific inhibition of protein prenylation could be a potential therapeutic strategy to rescue cognitive and plasticity deficits associated with neurodevelopmental diseases.

Title: PTI-51-CH3 (TauPro™) and PTI-80 are novel small molecule tau aggregation inhibitors and pre-clinical candidates for the treatment of tauopathies

Authors: K. L. HANSON, J. CAM, J. CUMMINGS, L. A. ESPOSITO, T. LAKE, T. M. CHONG, A. D. SNOW, Q. HU;
ProteoTech, Inc., Kirkland, WA

Abstract: Accumulation of intracellular neurofibrillary tangles (NFTs) composed of aggregated tau protein is a key pathological hallmark of Alzheimer's disease and other tauopathies such as Progressive Supranuclear Palsy (PSP). Lead compounds PTI-51-CH3 (TauPro™) and PTI-80 were identified as highly potent tau aggregation inhibitors through a screen of ProteoTech's proprietary small molecule library. PTI-51-CH3 and PTI-80 both prevent tau aggregation at substoichiometric proportions in a dose-dependent manner as measured by Thioflavin S fluorometry, circular dichroism spectroscopy and electron microscopy. Drugability studies demonstrate a favorable profile, with no potent reversible inhibition of major cytochrome P450 enzymes and reasonable stability in plasma and brain homogenates. Compound formulation studies in support of pharmacokinetic studies demonstrate that both compounds are readily stable (>95%) in formulations for at least several weeks. Importantly, PK studies in mice reveal that PTI-51-CH3 and PTI-80 provide good plasma, brain and CSF exposure after subcutaneous injection. For example, brain levels of both compounds at the Cmax significantly exceed estimated free tau in brain cells, suggesting that PTI-51-CH3 and PTI-80 are present in the brain at levels sufficient to modulate tau aggregation. PTI-51-CH3 and PTI-80 are currently being tested for *in vivo* efficacy in a transgenic mouse model that expresses a human tau isoform with a FTDP-17 P301S mutation that is commonly used as a tauopathy animal model. Initial results from tau transgenic mice treated with PTI-51-CH3 and PTI-80 (versus vehicle) will be presented. Our studies establish PTI-51-CH3 (TauPro™) and PTI-80 as top pre-clinical candidates for development as tau aggregation inhibitors for the treatment of Alzheimer's disease, Progressive Supranuclear Palsy and other tauopathies.

Title: Intestinal microbiota-derived phenol acids are capable of accumulating in the brain and interfere with β-amyloid oligomerization

Authors: *L. HO[1], J. FAITH[2], G. M. PASINETTI[3,4];
[1]Dept Neurol., [2]Dept. of Genet. and Genomic Sci., [3]Dept. of Neurol., The Icahn Sch. of Med. at Mount Sinai, New York, NY; [4]Geriatric Res. and Clin. Ctr., James J. Peters Veterans Affairs Med. Ctr., Bronx, NY

Abstract: Grape seed polyphenol extract (GSE) is receiving increasing attention for its potential preventative and therapeutic roles in Alzheimer's disease (AD) and other age-related neurodegenerative disorders. The intestinal microbiota is known to actively convert many dietary polyphenols, including GSE, to phenolic acids. There is limited information on the bioavailability and bioactivity of GSE-derived phenolic acid in the brain. Thus, we orally administered GSE to rats and investigated the bioavailability, in both plasma and in the brain, of 12 phenolic acids that are known to be generated by microbiota metabolism of polyphenols. We found GSE treatment significantly increased the content of two phenolic acids in the brain: 3-hydroxybenzoic acid (3-HBA) and 3-(3´-hydroxyphenyl) propionic acid (3-HPP), resulting in the brain accumulations of the two phenolic acids at μM concentrations. In pilot studies, we explored the feasibility of using germ-free mice and conventionalized mice where germ-free mice were colonized with the intestinal contents of a conventional mouse to study conversion of GSE into brain-available phenolic acids. We found ~8-fold lower plasma contents of 3-HPP in

germ-free versus conventionalized mice. Ongoing studies are analyzing plasma contents of 3-HBA, as well as brain contents of 3-HBA and 3-HPP in germ-free versus conventionalized mice. Lastly, we investigated effects of 3-HBA and 3-HPP on interfering with oligomerization of β-amyloid (Aβ) peptides that plays key roles in AD pathogenesis. Using multiple *in vitro* complementary assays we demonstrated that both 3-HBA and 3-HPP potently interfere with the assembly of Aβ peptides into neurotoxic Aβ aggregates. Our observation suggests important contribution of the intestinal microbiota to the protective activities of GSE (as well as other polyphenol preparations) in AD. Outcomes from our studies support future preclinical and clinical investigations exploring the potential contributions of the intestinal microbiota in protecting against the onset/progression of AD and other neurodegenerative conditions. Moreover, our evidence validates the utility of germ-free and gnotobiotic animals as a platform to study the effects of microbiota on phenolic acid bioavailability.

Title: Implications of activated Rho GTPases in different subcellular locations

Authors: *D. L. HYNDS, N. G. R. RAUT, R. CHABAYTA, K. RHODEN, F. SAMUEL, J. REDDY;
Texas Woman's Univ., Denton, TX

Abstract: Precise regulation of activity in the Rho family of guanosine triphosphatases (GTPases) is necessary for proper development and functioning of the nervous system, and alterations in Rho GTPase signaling are implicated in a variety of neurodegenerative and neurotraumatic disorders. Rho GTPase activation is regulated by both membrane localization, through the addition of geranylgeranyl groups, and through interactions with activation guanosine exchange factors (GEFs) and inactivation guanosine dissociation inhibitors GDIs) and GTPase activating proteins (GAPs). It is commonly assumed that Rho GTPases must be translocated to the plasma membrane to interact with GEFs to become activated. However, investigations into the cellular spatial and temporal patterns of Rho GTPase activation have indicated that a portion of each of the prototypical GTPases (RhoA, Rac1 and Cdc42) are active in the cytosol of neurons or neuron-like cells. To further define the contribution of this pool of GTPases to mediating neurite outgrowth, we have generated and expressed non-prenylatable Rho GTPase mutants in neuron-like cell lines and primary cultures of cortical neurons. As expected, expression of non-prenylatable RhoA or wild-type Rac1 increased neurite outgrowth, with expression of non-prenylatable Rac1 and wild-type RhoA decreasing outgrowth. Interestingly, expressing non-prenylatable Rho GTPases also affected downstream signaling from well-known cell differentiation pathways (e.g. ERK 1/2 and JNK) and actin binding proteins (e.g. Arp2/3, WAVE and cofilin). Since prenylation, and subsequent membrane localization, of Rho GTPases is suggested to be altered in ageing and neurodegeneration, understanding the differential effects of subcellular Rho GTPase localization on signaling pathways is important for deciphering the pathology of and designing therapies for a host of neurodevelopmental, neurodegenerative and neurotraumatic disorders.

Title: Upregulation of protein farnesylation in Alzheimer's disease

Authors: A. JEONG[1], D. CAO[1], S. CHENG[1], M. DISTEFANO[2], D. BENNETT[3], *L. LI[1]; [1]Exptl. and Clin. Pharmacol., [2]Chem., Univ. of Minnesota, Minneapolis, MN; [3]Neurolog. Sci., Rush Univ., Chicago, IL

Abstract: The pathogenesis of Alzheimer's disease (AD), particularly the sporadic form of AD, is not fully understood. Emerging evidence indicates that isoprenoids and prenylated proteins may play an important role in the pathogenesis of AD. Prenylation reactions are catalyzed by prenyltransferases, including farnesyl transferase (FT) and geranylgeranyl transferase (GGT) type-1 and -2. FT and GGT attach isoprenoids to proteins, which facilitates anchoring of proteins in cell membranes and mediates protein-protein interactions. A variety of important intracellular proteins, including almost all small GTPases such as members of Ras, Rho, and Rab subfamilies, undergo prenylation for proper location and function. Small GTPases are involved in regulating a wide range of cellular processes and functions. The levels of isoprenoids have been shown to be elevated in brains of Alzheimer's patients. Recently, we have demonstrated that protein farnesylation and geranylgeranylation pathways play distinct neurophysiological roles and that reducing farnesylation, but not geranylgeranylation, rescues cognitive function as well as attenuates AD-like pathology in the APP/PS1 transgenic mouse model of AD. However, the prenylation state of proteins in AD has not been investigated. This study is undertaken to determine the level of prenylated proteins in brain tissues from both AD model mice and human subjects with a spectrum of cognition from normal, mild cognitive impairment (MCI), to AD dementia. The levels of representative FT and GGT substrate small GTPases, including RhoA, H-Ras, and Rab7, in total brain homogenate and subcellular (membrane-bound and cytosolic) fractions were measured. The levels of relevant downstream signaling molecules including ERK were also quantified. Our preliminary results showed that the level of membrane-bound (farnesylated) H-Ras was significantly increased in the brain of APP/PS1 mice, whereas there was no change in the level of geranylgeranylated RhoA and Rab7. Consistent with the results in AD mice, there was a significant increase in membrane-bound H-Ras levels in MCI and AD brains compared to those in normal cognition brains. Also, the level of membrane-bound H-Ras was significantly correlated with the tangle burden in the brain. In addition, there was an increase in the activated form of ERK (p-ERK) in MCI brains. Taken together, these findings suggest that farnesylated small GTPases and downstream signaling pathways are upregulated in the early stage of AD and that farnesyltransferase could be a potential target for therapeutic intervention.

Title: Deficiency of geranylgeranyltransferase-1 reduces spine density and synaptic plasticity

Authors: *D. A. HOTTMAN[1], S. CHENG[1], L. YUAN[2], M. BERGO[4], W. G. WOOD[3], L. LI[1]; [1]Exptl. and Clin. Pharmacol., [2]Neurosci., [3]Pharmacol., Univ. of Minnesota, Minneapolis, MN; [4]Inst. of Med., Univ. of Gothenburg, Gothenburg, Sweden

Abstract: Isoprenoids and prenylated proteins are involved in regulating a variety of cellular functions including neurite growth and synaptic plasticity and are implicated in the pathogenesis of a number of diseases including Alzheimer disease (AD). Recently, we have demonstrated that the two protein prenyltransferases, farnesyltransferase (FT) and geranylgeranyltransferase-1 (GGT), differentially affect AD-related neuropathology and cognitive function in a transgenic mouse model. Heterozygous deletion of FT reduced amyloid-β (Aβ) deposition and neuroinflammation and rescued spatial learning and memory function in AD mice. In contrast, heterozygous deletion of GGT reduced Aβ levels and neuroinflammation but failed to rescue learning or memory function in AD mice. The current study investigated mechanisms that may account for the lack of cognitive benefits despite attenuated neuropathology in GGT haplodeficient mice. Preliminary data showed that the magnitude of long-term potentiation (LTP) was markedly suppressed in hippocampal slices from GGT-haplodeficient mice compared with wild-type or FT-haplodeficient mice. Consistent with the synaptic dysfunction, there was a significant decrease of postsynaptic protein PSD95 in the synaptosomal preparation from GGT-haplodeficient mice. To further study the neuronal effects of GGT deficiency, we have generated conditional neuron-specific GGT knock-out (GGTnKO) mice. In these mice, the level of GGT was reduced in the forebrain in an age-dependent manner. Preliminary studies showed that the dendritic spine density was significantly decreased in cortical neurons of GGTnKO mice compared to wild-type mice. Immunoblot analyses showed that there was a 4-fold reduction of membrane associated (prenylated) RhoA in GGTnKO mice, suggesting that insufficient prenylation of Rho family of small GTPases may underlie the negative effects of GGT deficiency. This also implies the critical role of GGT in maintaining spine structure and synaptic

plasticity. Our data are in line with recent findings that GGT is downregulated in the brain of aged mice, leading to a decrease of prenylated RhoA family of proteins, which may cause age-related weakening of synaptic plasticity. Experiments are underway to study the downstream signaling pathways leading to spine loss and synaptic dysfunction associated with GGT deficiency.

Title: Statin-encapsulating nanoparticles as a potential therapeutic strategy for the management of inflammatory peripheral nerve disorders

Authors: *K. A. LANGERT[1], E. B. STUBBS, Jr[2];
[1]Res. Service, Hines VA Hosp., Hines, IL; [2]Res. Service, Edward Hines Jr. VA Hosp., Hines, IL

Abstract: Inflammatory peripheral neuropathies constitute one of the largest and least understood spectrums of neurologic disorders. Inclusive among these disorders is acute inflammatory demyelinating polyradiculopathy (AIDP), a debilitating autoimmune disease that affects the peripheral nervous system. Despite its overwhelming prevalence, treatment remains palliative and relies on the use of non-specific immune-modulating therapies. While the mechanisms that govern disease onset and progression are not completely understood, trafficking of autoreactive leukocytes across the blood-nerve barrier and into peripheral nerves is an early pathological hallmark. Our group has reported that therapeutic administration of statins safely attenuates the clinical severity of an animal model of AIDP (experimental autoimmune neuritis, EAN) by restricting leukocyte migration. Statins, in addition to inhibiting HMG-CoA reductase, inhibit the activation and signaling of monomeric GTPases. Using a novel cell line of the blood-nerve barrier, we demonstrated *in vitro* that leukocyte trafficking is dependent on active

monomeric GTPases. Our data suggest that Cdc42 and RalA, specific subfamilies of geranylgeranylated GTPases, promote release of chemotactic cytokines from peripheral nerve microvascular endothelial cells. Despite these advancements, the clinical application of systemically-administered statins for the management of inflammatory disorders remains controversial. Here, we examined the feasibility of a non-systemic drug-delivery system as an alternative means to locally administer statins for the management of EAN. Biodegradable lovastatin-encapsulating poly(lactic co-glycolic) acid (PLGA) nanoparticles were synthesized and characterized. The mean diameter of synthesized particles was 257.2 ± 7.0 nm as measured with dynamic light scattering and confirmed with scanning electron microscopy. Encapsulated lovastatin was quantified by HPLC. Drug loading ranged from 5.1 - 6.6% with an encapsulation efficiency of 81.6 - 91.5%. The use of biodegradable statin-encapsulating nanoparticles offers the advantage of a testable non-systemic, localized, delivery strategy by which to better manage difficult-to-treat inflammatory peripheral nerve disorders.

Title: Geranylgeranylation regulates Rho GTPase mRNA expression and protein stability

Authors: *C. L. PERVAN[1,2], E. B. STUBBS, Jr[1,2];
[1]DVA, Edward Hines, Jr. VA Hosp., Hines, IL; [2]Ophthalmology, Loyola Univ. Chicago, Maywood, IL

Abstract: Post-translational addition of 15-carbon farnesyl and 20-carbon geranylgeranyl isoprenoids to conserved -CaaX motifs on small monomeric Rho GTPases precedes their target

membrane localization and subsequent activation (GTP-binding). Using cells isolated from the trabecular meshwork (TM), a specialized tissue within the eye that regulates intraocular pressure (IOP), our laboratory has expanded this field to include a novel role for isoprenoids in regulation of Rho GTPase mRNA and protein expression. Here, we demonstrate that inhibition of geranylgeranylation with the HMG-CoA reductase inhibitor lovastatin (10 μM, 24h) or a geranylgeranyl transferase inhibitor (GGTI-298; 10 μM, 24h), significantly enhances mRNA and protein content of RhoA and RhoB GTPases in both primary and transformed human TM cells. Quantifiable increases in RhoA expression occur as a result of enhanced protein stability. By comparison, inhibition of geranylgeranylation induces *de novo* mRNA and protein synthesis of RhoB, and increases stability of RhoB proteins. Accumulated Rho GTPases remain compartmentalized within the cytosol in an inactive (GDP-bound) state. In marked contrast, facilitating geranylgeranylation of accumulated, inactive Rho GTPases markedly enhances their target membrane distribution, functional activation (GTP-binding), and rapid degradation by the 20*S* proteasome. Collectively, this study demonstrates that post-translational geranylgeranylation represents a novel mechanism by which newly-synthesized Rho GTPases are translocated to target membranes, activated, and subsequently degraded. We hypothesize that a geranylgeranylation-dependent mechanism governing Rho GTPase expression and turnover represents a novel means by which intracellular Rho GTPase signaling is regulated.

Title: Evaluation of olfactory ensheathing glia gene reprogramming by recombinant adeno-associated viral vector type 2 *in vitro* and *in vivo*

Authors: *L. A. CARVALHO[1], L. C. VITORINO[2], H. PETRS-SILVA[2], S. ALLODI[2];
[1]Univ. Federal do Rio de Janeiro, Rio De Janeiro, Brazil; [2]Inst. de Biofísica Carlos Chagas Filho, Univ. Federal do Rio de Janeiro, Rio de Janeiro, Brazil

Abstract: The olfactory ensheathing glia (OEG) is a special type of glial cells that ensheath the axons of olfactory receptors of the olfactory mucosa. Axonal bundles of receptor axons extend toward the cribiform plate and enter the brain via the olfactory bulb, providing a direct route for pathogens to access the brain from the periphery. OEG has been used in cell therapy studies after spinal cord lesions and/or neurodegenerative diseases, with little success regarding the functional recovery of the central nervous system (CNS). Therefore, we intend to use a new approach: gene reprogramming the OEG into a pump of neurotrophic factors *in situ* by recombinant adeno-associated viral vector type-2 (rAAV-2 WT) through intranasal delivery and evaluate if the self-complementary AAV-2 mutant Y444F (scAAV-2 MUT Y444F), which contains single-point mutations of surface exposed tyrosine residues in the VP3 capsids, could significantly increase gene transduction efficiency *in vitro* and *in vivo*. Our preliminary results *in vitro* indicate that both rAAV-2 WT and scAAV-2 MUT Y444F containing the reporter green fluorescent protein (GFP), supplied at 1x10E8vg/µl in culture medium (DMEM/ F12 supplemented with 10% fetal bovine serum and antibiotics) after 7 days from infection was the best condition compared with other times (10 and 14 days) and with other dilutions (1x10E6vg/µl and 1x10E7vg/µl). To assess this issue *in vivo*, we conducted the technique of dot blot using brain samples dissected into three regions: 1) a region encompassing the olfactory bulb and the most cephalic portion of the cortex; 2) a region encompassing the mesencephalon and the hippocampus; and 3) the cerebellum and the medulla. We observed that, after intranasal instillation of rAAV-2 WT-GFP (1x10E9vg/µl, diluted in 10µl sterile NaCl 0,9%), the three cerebral regions were strongly labeled by the GFP antibody, showing that the gene transduction was successful. Our results indicate that the OEG can be used as pump of neurotrophic factors to CNS *in situ* by gene reprogramming with rAAV-2, delivered directly through the olfactory pathway, providing a new therapeutical approach for neurodegenerative diseases and CNS injuries.

Title: Trans-splicing gene therapy for dominant diseases: evidence of *in vivo* efficiency in a mouse model of retinitis pigmentosa induced by mutation of the rhodopsin gene

Authors: *A. .-P. BEMELMANS[1], A. BERGER[2], S. MAIRE[1], C. JOSÉPHINE[1], M. DESROSIERS[2], M.-C. GAILLARD[1], P. HANTRAYE[1], J.-A. SAHEL[2];
[1]CEA, Fontenay Aux Roses, France; [2]Inst. de la Vision, Univ. Paris VI, Paris, France

Abstract: Point mutations in the rhodopsin gene (RHO) are the most frequent cause of retinitis pigmentosa (RP), a group of inherited retinal dystrophy leading to blindness. Most of these mutations result in a gain of function or a dominant negative effect deleterious to the photoreceptors, thus leading to a dominant mode of transmission. In addition, it has been shown that variations in RHO expression level are also deleterious to the retina. A gene therapy strategy for RHO mutations should lead to both the suppression of expression of the mutant protein and restoration of a physiological level of the normal protein. Spliceosome-mediated RNA trans-splicing technology (SMaRT) should in theory respect these constraints by repairing mutations in the enbdogenous RHO pre-mRNA. This technology consists in introducing, by gene transfer, an exogenous RNA - called PTM, for pre-trans-splicing RNA molecule, capable of binding to the endogenous pre-mRNA and promoting a trans-splicing reaction, thus leading to replacement of the mutant portion of RHO pre-mRNA. We designed fourteen RHO-PTM, able to repair any mutations in exons 2, 3, 4 and 5, which differ only by their binding sequence to intron 1 of RHO pre-mRNA. To determine the effectiveness of each PTM, we co-transiently transfected HEK293T cells with a plasmid encoding the PTM to be tested and a RHO-expressing plasmid. The best candidate led to a trans-splicing efficiency of about 25% at the mRNA level. We increased this efficiency to 40% by refining the PTM sequence, consisting in the reintroduction of an endogenous RHO intron in the cDNA portion of the PTM. We then tested the PTM at the protein level in a cellular model expressing RHO stably. We precisely quantified the phenotype of cells expressing the mutant gene by a flow imaging method (ImageStreamX), and showed that trans-splicing allows to partially restore this phenotype. We then built an AAV vector encoding our best PTM to assess its *in vivo* activity after subretinal injection in a mouse model expressing the mutant RHOP347S. By co-injection with an AAV-GFP and micro-dissection of the transduced part of the retina, we have shown that trans-splicing reached 30% at the RNA level, while it was not detectable in non-transduced part of the retinaor in animals that received a control PTM. This study shows that trans-splicing may provide a therapeutic benefit in the case of dominant mutations of the rhodopsin gene.

Title: Non-invasive intrathecal AAV-10 vector-mediated administration of Neurotrophin-3 (AAV10-NT3-gfp) at chronic stage of contusion spinal cord injury (SCI) in rats

Authors: *V. L. ARVANIAN[1,2], H. PETROSYAN[1], V. ALESSI[1], J. M. LEVINE[2];
[1]VA Med. Ctr., Northport, NY; [2]Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Insufficient neurotrophin (NT-3) support is one of the major factors restricting synaptic transmission and plasticity in the damaged spinal cord. From our previous studies: although administration of NT-3 alone immediately after SCI has not shown significant improvements, NT-3 is an essential component of combination treatment. In an attempt to design an approach for prolonged delivery of NT-3, we have successfully created the new AAV10-NT3-gfp construct. Our previous experiments revealed an excellent transduction of neurons and glial cells in damaged spinal cord, after two weeks following thoracic contusion and *intraspinal* injections of AAV10-NT3-gfp, immediately after contusion injury. In this study, we sought to examine a more clinically relevant approach for AAV vector administration, i.e. *intrathecal* administration of AAV vector at chronic stage of injury. Adult rats received moderate contusion (150 kdyn) injury at thoracic T10 level using an IH impactor device. Locomotor performance was evaluated pre-injury, 2 days after SCI and then weekly for 6 weeks (automated Catwalk gait; Irregular Grid and Narrowing Beam tests). After 6 weeks post-injury, when the scores of all behavioral tests and gait analyses plateaued, rats were re-anesthetized and AAV10-NT3-gfp was administered intrathecally, using a 32 Gage Teflon catheter that was inserted through a small hole in the dura (made by needle) one segment caudal to injury, with the tip of the catheter positioned just caudal to the injury. Consistent with the results of previous experiments that examined acute effects of NT-3 alone, we found that delayed administration of AAV10-NT3-gfp alone has not induced improvements of locomotor function following chronic contusion SCI.

After completion of behavioral testing, spinal horizontal sections were prepared and unamplified GFP signal is under examination. So far, we have observed the GFP signal in axons and glial cells close to injury epicenter; although this signal was lower as compared to intraspinal injections. Quantitative analyses of the transduction efficacy of neurons and glia are still on-going. Although these experiments were important to examine effects of AAV10-NT3-gfp alone and to ensure transduction efficacy following intrathecal administration of AAV10-based vector at the chronic stage of SCI, further experiments will be conducted to examine effects of intrathecal administration of AAV10-NT3 combined with other treatments, i.e. AAV10-NG2-antibody, following chronic SCI.

Title: Evaluation of three partial sequences of human TH promoter to specifically target dopaminergic neurons in a context of gene therapy for Parkinson's disease

Authors: *A.-S. ROLLAND, T. KAREVA, O. YARYGINA, N. KHOLODILOV, R. E. BURKE;
Columbia Univ., New York, NY

Abstract: We have observed that increased Akt/mTor signaling in dopamine neurons of the substantia nigra (SN), achieved by transduction with AAV myristoylated-Akt (Myr-Akt) or AAV hRheb (S16H), two constitutively active mutants, induces axon re-growth weeks after their destruction by neurotoxin (Kim et al, Ann Neurol 2011; Mol Ther, 2012). However, both of these genes are potent oncogenes, so strategies must be devised to avoid their potential to transform cells before they can be considered safe for clinical use. One strategy would be to restrict gene expression to the desired neuron target and avoid expression in glia which have neoplastic potential. It may be possible to limit expression specifically to dopamine (DA) neurons by use of the TH promoter. Previous work has shown that transgene expression in living animals and cell lines can be achieved with a number of partial sequences of varying sizes of human TH (hTH) promoter: 11kb (Kaneda et al, 1991), 5kb (Sasaoka et al, 1992), 3.3kb (Kim et

al, 2003), a combination of 5' and 3' flanking region (Gardaneh et al, 2000), 522bp (Coker et al, 1988; Steffers et al, 2004). We therefore undertook to find the optimal human TH promoter among those that can be accommodated by the capacity limits of an AAV vector (i.e. ≤4.7kb). In order to assess expression in DA neurons and evaluate efficiency and specificity we designed constructs in which each of three hTH promoter sequences drove expression of a photostable red fluorescent protein TagRFP-T: hTHp-522-TagRFP-T, hTHp-5,3-TagRFP-T and hTHp-3.3-TagRFP-T. 6 weeks after injection of AAV in SNpc, we observed expression of TagRFP-T in TH-positive neurons and in both subpopulations of dopaminergic neuron, the AHD2-positive neurons and calbindin-positive neurons for all three constructs. Moreover, no expression was observed following injection of striatum or cortex which contain few, if any, DA neurons. For all three constructs we never observed expression in glial cells identified by GFAP fluorescent staining. To assess the level of expression mediated by these promoters, the number of TagRFP-T-positive cells in the entire SN was determined: hTHp-5,3-TagRFP-T (517±81.8) > hTHp-3.3-TagRFP-T (328.8±50.2) > hTHp-522-TagRFP-T (251.5±30.7). The number of TagRFP-T-positive neurons in the SN that are Nissl-positive but also TH/Nissl-positive was determined to evaluate specificity and efficiency. We found that hTHp-522-TagRFP-T had the highest sensitivity (76%) and specificity (20%). We conclude that the human 522bp TH promoter in an AAV vector can be useful to mediate expression of genes with therapeutic potential such as Akt or hRheb (S16H).

Title: Adeno-associated viral vector serotype 5 (AAV5) mediates efficient neuronal and astrocytic therapeutic transgene expression in the substantia nigra pars compacta (SNpc)

Authors: *J. MUDANNAYAKE, D. FONG, A. MURAVLEV, D. YOUNG;
Univ. of Auckland, Auckland, New Zealand

Abstract: Given that reactive astrocytes contribute to pathological processes in neurodegeneration, astrocytes are an equally appealing and important target for CNS gene therapy as neurons. The aim of this study was to achieve dual targeting of therapeutic transgene expression to neurons and astrocytes in the SNpc, leading to neuroprotection in a rat model of Parkinson's disease (PD). We firstly compared AAV serotypes 5 and 9 cell transduction profiles in the SNpc. AAV vectors expressing destabilised yellow fluorescent protein (dYFP) regulated by an astrocytic glial fibrillary acidic protein (GFAP) promoter (AAV-GFAP-dYFP) were packaged, and injected unilaterally into the SNpc of adult male Sprague-Dawley rats (n=3 per vector). At 3 weeks, immunohistochemical (IHC) analysis of transgene expression confirmed a superior targeting of both nigral neurons and astrocytes by AAV5. We then generated an AAV5 vector expressing hemagglutinin-tagged nuclear receptor related 1 (AAV5-GFAP-HA-NURR1), a transcription factor that maintain dopaminergic neurons (DA) and regulate inflammatory mediators in astrocytes. To determine neuroprotective potential of astrocytic and neuronal HA-NURR1 expression, AAV5 vectors expressing dYFP, an empty control or HA-NURR1 were injected into the SNpc (n = 4 per control vector; 8 per therapeutic vector). Degeneration of DA neurons and motor deficits were induced by injecting 6-OHDA (20μg) into the ipsilateral striatum 3 weeks post vector. The cylinder test at 4 and 8 weeks post toxin infusion revealed that, while control groups retained a motor bias at 8 weeks (-27.29% and -26.48% contralateral forepaw use relative to baseline in empty and dYFP vector groups respectively), HA-NURR1 animals exhibited a recovery in motor deficits (0.08%). At 8 weeks, stereological quantification of tyrosine hydroxylase (TH)-positive DA neurons indicated that compared to empty (38.9% surviving neurons relative to contralateral SNpc) and dYFP (43.8%) vector groups, a greater neuronal survival was evident in the HA-NURR1 (53.7%) treated SNpc. Lower immunoreactivity to astrocyte and microglia markers, GFAP and Iba1 respectively, in HA-NURR1 brains indicated reduced neuroinflammation. These results suggest that AAV5 vectors could be used to genetically manipulate nigral cells for therapeutic purposes. Supported by the Royal Society of NZ Marsden Fund

Title: Translating an optogenetic gene therapy approach for treatment of neuropathic pain in humans

Authors: C. TOWNE, J. AGUADO, A. ARGUELLO, C. B. DISCENZA, S. KHAN, T. GALFIN, S. GEHRKE, *S. P. BRAITHWAITE, M. G. KAPLITT;
Circuit Therapeut., Menlo Park, CA

Abstract: Optogenetics has been established as a powerful tool to study the central and peripheral nervous systems with its potential for directly treating human disease tantalizingly on the horizon. Optogenetic inhibition of pain in mice has been shown to be effective and provides an attractive initial clinical application of this technology. We aim to translate this approach to treat neuropathic pain in humans. Firstly, we demonstrated that the inhibitory opsin, NpHR, delivered by intraneural injections of AAV6 could reduce pain (mechanical allodynia) in a clinically meaningful paradigm i.e. vector delivery after establishment of neuropathic pain in the chronic constriction injury (CCI) model. The inhibitory opsin, SwiChR (a chloride channel requiring less light than NpHR to pass currents) could also reduce pain in this system. We next tested a surgical approach more amenable to patients than nerve injection. Lumbar puncture is a routine clinical practice and AAV8 delivery by this method results in efficient gene delivery to sensory neurons in rodents, dogs and pigs. We found that intrathecal administration of AAV8 expressing SwiChR could decrease mechanical allodynia in the CCI mouse model. The magnitude of pain inhibition correlated with transduction levels and only 10% transduction of sensory neurons was required for pain relief. To further validate this approach we utilized a second rodent pain model with translational relevance. The mouse tibia fracture/cast immobilization model of Complex Regional Pain Syndrome (CRPS) presents extreme allodynia and recapitulates human disease effectively. We found that intrathecal delivery of AAV8 encoding SwiChR following development of the CRPS model resulted in light-mediated pain inhibition. Taken together, our results confirm optogenetic therapy for neuropathic pain as an attractive clinical application of this technology.

Title: Widespread gene delivery to the nonhuman primate brain for the treatment of Huntington's disease

Authors: *L. M. STANEK[1], P. HADACZEK[5], B. MASTIS[2], M. KELLY[3], C. O'RIORDAN[4], P. PIVIROTTO[5], J. BRINGAS[5], A. CIESIELSKA[5], W. SAN SEBASTIAN RAMIREZ[5], S. CHENG[1], K. BANKIEWICZ[5], L. SHIHABUDDIN[2];

[5]Neurolog. Surgery, Univ. of California San Francisco, San Francisco, CA

Abstract: Huntington disease (HD) is an autosomal dominant neurodegenerative disease caused by a CAG-trinucleotide repeat expansion in a coding exon of a single allele in the HTT locus. In HD, the resulting polyglutamine (polyQ) expansion confers a toxic gain-of-function to the mutant huntingtin protein (mHTT). Reduction of expression of mHTT using gene silencing by RNA interference (RNAi) may confer transformative disease modifying therapeutic approach for HD. Adeno associated vectors (AAV) provide an ideal delivery system for nucleic acid therapeutics and have the potential to allow for long lasting and continuous expression of these huntingtin lowering RNAi in the brain. Despite this promise, global delivery of AAV to the adult brain remains an elusive goal. Furthermore, the appropriate brain areas to target for achieving transformative therapeutic benefit in HD patients remain to be defined. Postmortem analyses of HD patient brains reveal extensive medium spiny neuronal loss in the striatum, in addition to loss of pyramidal neurons in the cerebral cortex and hippocampus. Recent studies in rodent models suggest that simultaneous targeting of striatum and cortex is more efficacious than targeting either individually. Thus, available evidence suggests that delivery of Htt-lowering therapeutics to both striatal and cortical regions may provide optimal therapeutic efficacy. The current study demonstrate for the first time the successful use of an AAV targeting strategy that leads to viral transduction in key brain areas considered to be important for HD pathology. The study compared the efficiency of transduction of AAV1 and AAV2 vectors in the rhesus monkey brain following intra-striatal injection. Both vectors encoded green fluorescent protein (GFP) under control of a hybrid CMV enhancer/chicken beta-actin promoter. One month following injection, brains were analyzed for distribution of GFP-positive cells. We found that the AAV1 vector provided extensive delivery to the majority of the primate striatum, and additionally transduced large numbers of cells within the cerebral cortex, thalamus, and hippocampus. In summary, the data suggest that intrastriatal delivery maybe sufficient to for the delivery of nucleic acid-based therapeutics to multiple areas of the human brain relevant in HD.

Title: Evaluation of compound gene therapy in combination with physical exercise in the treatment of chronic SCI neuropathic pain

Authors: *S. JERGOVA[1], C. E. GORDON[1], S. GAJAVELLI[1], E. DUGAN[1], J. ZADINA[2], J. SAGEN[1];

Abstract: The insufficient pain relief provided by current pharmacotherapy for chronic neuropathic pain is a serious medical problem and development of new treatment strategies are of a high clinical interest. Mechanisms underlying chronic neuropathic pain include decreased spinal tonic inhibition due to the dysfunction of GABA signaling and increased excitatory signaling via NMDA receptors. Previous studies in our lab showed beneficial effects of the intraspinal transplantation of GABAergic neuronal precursor cells (NPCs) enhanced with the addition of serine histogranin (SHG), an NMDA receptor antagonist. In addition, our studies showed that combined injection of viral vectors engineered to produce SHG with another analgesic peptide vector, endomorphin-1 (EM-1) lead to enhanced analgesia. Other ongoing studies in our lab have shown positive effects of intensive treadmill locomotor training on alleviation of neuropathic pain behaviors in animals with SCI. The current study evaluated the combination of either recombinant cells or recombinant AAV vectors to deliver SHG and EM1 with treadmill training on pain behavior in rats after a clip compression SCI. Recombinant plasmids encoding single- and multi-SHG and EM-1 were engineered. Animals showing clear

signs of pain-related behavior at four weeks post-SCI were used for intraspinal injection of either recombinant NPCs or recombinant AAVs. Two weeks post injection animals treated with rAAVs showed significant attenuation of tactile sensitivity compared to controls and the antinociceptive effects were sustained up to 6 weeks post injection. More robust analgesic effects were observed in the group with 6SHG-EM1 construct compared to 1SHG-EM1. Animals treated with rNPCs did not display significant pain relief compared to the nonrecombinant NPCs group. However, some of the rNPC animals were included in the intensive treadmill training starting one week post grafting and these animals showed enhanced analgesic effects of the rNPCs. This study demonstrates that combination strategies taking advantage of multiple pain processing targets and including rehabilitation may provide enhanced benefits in reducing SCI neuropathic pain.

Title: *In vivo* 5-HT6 receptor occupancy- an assessment with radiolabeled and non-radiolabeled Lu AE60157 as a tracer in rats

Authors: J. THENTU, *S. M. IRAPPANAVAR, G. BHYRAPUNENI, R. ALETI, N. MUDDANA, A. SHINDE, R. BADANGE, R. NIROGI;
SUVEN LIFE SCIENCES LTD, HYDERABAD, India

Abstract: Selective 5-HT6 ligand, Lu AE60157 has been used as a tracer in the determination of *in vivo* receptor occupancy using radiolabeled technique. Lu AE60157 binds preferentially to rat brain regions with expected high 5-HT6 receptor density and the displacement of tracer upon pre-treatment is widely employed in the calculation of receptor occupancy for test compounds. In the present investigation, receptor occupancies of selective 5-HT6 antagonists were tested using liquid scintillation counter and mass spectrometry based techniques employing [3H] Lu AE60157 and Lu AE60157 as tracers, respectively. For comparison of receptor occupancy, treatment time for 5-HT6 antagonists was kept identical in both techniques and dose response curves were generated upon pre-treatment. Non- radiolabeled Lu AE60157 was used a tracer in the mass- spectrometry based experiments and was administered at a dose of 0.3 μg/kg, i.v. and 30 min as a sacrifice time. Tritiated Lu AE60157 was used as a tracer in radiolabeled

experiments and was dosed at 10 μCi/ rat, i.v. using 15 min as a sacrifice time. Receptor occupancy in the striatum as a 5-HT6 receptor rich region was determined against the cerebellum as a receptor null region using specific binding method. Dose dependent receptor occupancy of test compounds was obtained with non- labeled and [3H] Lu AE60157 tracer. The ED50 values for tested 5-HT6 antagonists were comparable across both mass spectrometry and radiolabeled techniques. Results from the present investigation justify the use of mass spectrometry based method for rapid screening of new chemical entities during early stages of drug discovery.

Title: A novel aryl 2-cylcopropylamine improves motor impairment in a rat model of Parkinson's disease

Authors: *B. D. BRADARIC[1,2], D. MCCAFFERTY[4], F. NWOGBO[4], K. ALSER[4], L. OLIVERE[4], N. STEDER, III[3], A. L. PERSONS[1,2], T. C. NAPIER[1,2];
[1]Pharmacol., [2]Ctr. for Compulsive Behavior & Addiction, [3]Med. Lab. Sci., Rush Univ. Med. Ctr., Chicago, IL; [4]Chem., Duke Univ., Durham, NC

Abstract: Parkinson's disease (PD) is a common neurodegenerative disease. Clinical symptoms of PD include resting tremor, rigidity, slowness of voluntary movement, and postural instability, which are associated with loss of dopamine in the nigrostriatal pathway. A treatment for PD is dopamine replacement with L-3,4-dihydroxyphenylalanine (L-DOPA); however, chronic treatment can result in abnormal involuntary movements (AIMs) called dyskinesias. Thus, the development of novel compounds that exhibit motor efficacy without the unwanted side effects will be useful for the treatment of PD. Toward that end, the McCafferty laboratory synthesized and screened over 15 novel aryl 2-cylcopropylamine compounds in a dopamine transporter knockout/dopamine depleted mouse model of PD for improved locomotor activity. Two of the most promising novel compounds were then tested in the Napier laboratory for postural instability and dyskinesias in the unilateral 6-hydroxydopamine rat model of PD. Following

administration of the aryl 2-cyclopropylamine compounds (3-12 mg/kg, ip) or L-DOPA (3 mg/kg, ip; the positive control), lesioned rats were tested for postural instability using the forelimb adjusted step task and evaluated for dyskinesias using locomotor, axial dystonia, and limb dyskinesia parameters. The safety profile for the aryl 2-cyclopropylamine compounds was also determined. Lesions were confirmed by tyrosine hydroxylase immunoreactivity. Lesioned-induced stepping deficits improved following acute administration of the aryl 2-cyclopropylamine compounds. However, higher doses (9-12 mg/kg) resulted in adverse events, including tremors, catalepsy and in some rats, seizures. To determine if motor efficacy could be retained with diminished toxicity, a subthreshold dose (3-0.5mg/kg, ip) of the most promising aryl 2-cyclopropylamine compound was co-administered with a subthreshold dose of L-DOPA (3 mg/kg). Combination treatment showed stepping improvement compared to supra-threshold L-DOPA treatment; however, the combination also resulted in AIMs. Taken together, these data indicate therapeutic potential for modified aryl 2-cylcopropylamine small molecules in PD, but suggest that additional derivatives to the ones tested here will need to be developed for use as adjunct treatment with L-DOPA.

Title: Induction of phase II detoxification enzymes through Nrf2 pathway provides protective effects in cerebral ischemic stroke

Authors: ***P.-C. KUO**[1], B. A. SCOFIELD[1], D. A. BROWN[2], J.-H. YEN[1];
[1]Dept. of Microbiology and Immunol., Indiana Univ. Sch. of Med., Fort Wayne, IN; [2]Dept. of Pharmaceut. Sci., Manchester Univ. Col. of Pharm., Fort Wayne, IN

Abstract: Stroke is a leading cause of death in the world and cerebral ischemic stroke is composed of over 80% of all stroke cases. During cerebral ischemia reactive oxygen species (ROS) is produced in brain tissue, which can then initiate numerous signaling pathways and cause oxidative stress and inflammatory response. Studies suggest that both oxidative stress and

inflammatory damage are essential pathological mechanisms in cerebral ischemia. To date, recombinant tissue plasminogen activator (tPA) is the only available therapy for the treatment of ischemic stroke; however, the treatment does not prevent ischemia-induced oxidative stress and reperfusion-mediated inflammation in ischemic brains. Therefore, the development of new anti-oxidant and anti-inflammatory therapies for the treatment of ischemic stroke is necessary and urgent. Nuclear factor erythroid 2-related factor 2 (Nrf2), a major regulator of oxidative responses, is a key transcription factor which induces a wide set of anti-oxidant enzymes and phase II detoxification enzymes, including heme oxygenase 1 (HO-1) and NAD(P)H dehydrogenase, quinone 1 (NQO1). In addition, Nrf2 exerts an anti-inflammatory effect through downregulating NF-κB expression that would subsequently suppress inflammatory mediators in ischemic brains. Our lab has identified a small molecule (BY-23) with a property of inducing Nrf2 activation, and we evaluated its therapeutic potential for the treatment of ischemic stroke in the animal model of transient middle cerebral artery occlusion/reperfusion (MCAO/R). Our results show BY-23 treatment not only ameliorated neurological deficits in ischemic stroke mice but dramatically reduced infract size in ischemic brains. We also observed significant reduction of CNS infiltrating cells including neutrophils and monocytes in the ischemic brains of BY-23-treated MCAO mice when compared to those of vehicle-treated MCAO mice. At the molecular level, BY-23 treatment enhanced the expression of anti-oxidant enzymes HO-1 and NQO1 in the ischemic brains of MCAO mice. The effect of BY-23 on the induction of anti-oxidant associated genes was confirmed in primary microglia. In the presence of BY-23, the expression of Nrf2, HO-1, NQO1, and glutamate-cysteine ligase, catalytic subunit (GCLC) was significantly upregulated in LPS-activated microglia. Moreover, the expression of inflammatory cytokine IL-1β, IL-23, and IL-12 in activated microglia was inhibited by BY-23. Altogether, our results suggest that BY-23 confers a protective effect against ischemic stroke through its anti-oxidant and anti-inflammatory properties.

Sci. of Ribeirão Preto, UNIVERSITY OF SÃO PAULO, Ribeirao Preto - São Paulo, Brazil

Abstract: Excitotoxicity in Stroke is mainly triggered by exacerbated glutamate (Glu) release, which is worsened when it is followed by reperfusion. Excessive extracellular Glu leads to necrotic and apoptotic signaling pathways onset. Therefore, compounds that enhance Glu uptake represent promising tools for providing an efficient protection against stroke injury through increase of Glu clearance. Parawixin-10 (Pwx10), presents a potent activity in enhancing glutamate uptake in rat cerebrocortical synaptosomes. Besides that, it presents anticonvulsant effects on acute models of chemically induced seizures. Therefore, the present study aim to evaluate the neuroprotective effects of Pwx-10 on motor cortex and striatum, as well as evaluating neurological deficits after treatment in experimental model of Stroke. Wistar rats were stereotaxically implanted with a steel guide-cannula into the piriform cortex, to access Middle Cerebral Artery (MCA) and in right ventricule to drug delivery. Occlusion of the right MCA was induced in awake rats by endothelin-1 (ET-1; 400 ρmol in 4 μL) injection. SHAM animals were injected with saline (in 4 μL). Neurologic deficit (inclusion parameters) were evaluated 10 minutes after ischemia by Open field test (OFT) (counterclockwise circling, clenching, or failure to extend the contralateral forelimb) and Tail Suspension Test (TST). Treatment was conduct 30 min from behavioral analyzes, with Pwx10 (2 μg/μL; 1μL) or Saline 0.9% (1 μL) injections. Neurologic deficit were assessed by OFT, TS additionally with Adhesive Test (AT), after 3 days post stroke. Shortly afterwards, rats were decapitated or transcardially perfused. Neuronal death in cortical and striatal infarcted areas was evaluated by quantification of Fluoro-Jade C (FJC) positive cells and triphenyltetrazolium chloride (TTC) method, respectively. Treatment with Pwx10 improved neurological function in and in OFT ($n=6$, $p<0.0001$), TST tests ($n=6$, $p<0.001$) and AT test ($n=6$, $p<0.001$). Noteworthy, Pwx10 was efficient in reducing infarct volume area ($n=$, $p<0.0025$) in TTC method and decreasing FJC-positive cells in cortex ($n=7$, $p<0.0001$) and striatum ($n=7$, $p<0.0001$). Considering that Pwx10 is one of very few compounds that stimulate promptly the activity of glutamate clearance, our findings suggest that this neuroprotective potential might represent a promissory drug in stroke therapeutic

Title: Action of copaxone at the mitochondrial level in EAE

Authors: *V. K. NIMMAGADDA[1,2], P. GUDA[1], C. BEVER[1,2], T. MAKAR[1,2];
[1]Neurol., Univ. of Maryland Baltimore, Baltimore, MD; [2]Multiple sclerosis center of excellence, VA Maryland Hlth. care system, Baltimore, MD

Abstract: Multiple sclerosis (MS) is characterized by various pathophysiological molecular alterations, such as ionic homeostasis, overproduction of reactive oxygen and nitrogen species. Oxidative and nitrosative stress leads to the induction of apoptosis. All these events comprise several fundamental neuronal functions. These molecular changes seem to have as a common feature the malfunctioning of mitochondria which has led to the “mitochondrial hypothesis” of axonal degeneration in MS. Glatiramer acetate (Copaxone) is one of the drug used for MS. The therapeutic effects of this drug in the treatment of MS are thought to be via immunomodulation and neuroprotection. However, its role in mitochondrial protection and regulating energy metabolism is not well studied. In this study, we explored the effects of Copaxone on mitochondrial protection and balancing energy metabolism in EAE. Treatment with Copaxone (20 mg/kg, ip, daily for 30days) in EAE mice showed an inhibition of clinical severity and inflammation compared to EAE mice. Quantitative Western blot analysis and immunohistochemical staining revealed an increase in PGC-1α, an upstream regulator of transcription factors involved in mitobiogenesis, and several of its downstream targets (NRF2, TFAM) in Copaxone- treated EAE animals compared to EAE mice. This correlated with an increase in protein expression of citrate synthase, a mitochondrial marker and increase in protein reflecting mitochondrial fusion (as determined by detecting Mfn2 and OPa-1). We also found inhibition of mitochondrial fission (as determined by detecting Drp-1, Fis-1) in Copaxone treated EAE animals compare to EAE animals. SIRT1 and SIRT3 also significantly elevated after Copaxone treatment in EAE mice. These enzymes play a key role in mitochondrial protection. Collectively, these results revealed an increase in mitochondrial function, integrity and

biogenesis after Copaxone treatment in EAE mice. Furthermore, our findings suggest that Copaxone exerts a regulatory effect on mitochondria through SIRT1 and SIRT3 mechanisms involving mitochondria and cytosolic proteins.

Title: Lack of additive effect of D-cycloserine and cerebrolysin to inhibit formation of kynurenic acid in rat liver homogenate

Authors: *H. BARAN, B. KEPPLINGER;
Karl Landsteiner Res. Inst. Mauer, Mauer-Amstetten, Austria

Abstract: Background and aim of study: Effect of Cerebrolysin (CER) and D-cycloserine (D-CS) in the treatment of dementia and brain injury has been reported. Kynurenic acid (KYNA), a metabolite of tryptophan, is an antagonist of the glutamate ionotropic EAA and of the 7α-nicotine-cholinergic receptors and its involvement in the impairment of memory and cognition have been suggested. Recently, we demonstrated the ability of CER and D-CS to lower the activities of kynurenine aminotransferase I, II, III (KAT I, II, III), enzymes synthesising KYNA (Baran H and Kepplinger B, Eur. Neuropsychopharmacol 2008, 2014). Furthermore, we have shown that lowering of KATs activities by D-CS is primary due to lowering of pyridoxal-5-phosphate levels (Baran H and Kepplinger B Soc. Neurosci. Abstr 2014). Since an increased kynurenine metabolism has been documented in several brain pathologies, we investigated if the effect of CER or D-CS to lower KYNA synthesis is additive. In this study we investigated if CER also affects pyridoxal-5-phosphate levels. Methods The activities of the KAT II in rat liver homogenate were analysed in the presence of CER or D-CS or mixture of CER and D-CS and in the absence, as control. KAT II activities were measured in the presence of 1 mM pyruvate and 100 µM L-kynurenine and synthesized KYNA as well pyridoxal-5-phosphate levels were determined by HPLC method. The statistical analysis was carried out by one-way-ANOVA and Student's-T-Test. The study was performed according to the ethical regulations of the government of Austria. Results CER and D-CS reduce KAT II activity significantly of rat liver

homogenate, by 80 % of CO and 30 % of CO, N=8; P<0.01, respectively, but the mixture of CER and D-CS did not additively affect the inhibition of KYNA formation (30 % of CO, N=8), at least *in vitro* conditions. CER does not affect pyridoxal-5-phosphate levels under present experimental conditions. Discussion The mechanism of CER and D-CS to lower KYNA levels in rat liver homogenate seems to be different. Furthermore, revealed data indicate that the inhibitory effect on KAT II activity of both agents was non additive in the incubation medium. We observed that the effect of a CER and D-CS mixture was similar to the effect of D-CS alone. CER does not affect the levels of pyridoxal-5-phosphate levels under experimental conditions using rat liver homogenate. Since both drugs are used for the treatment of dementia and cognition further work needs to be done to exclude interaction between both pharmacological agents.

Title: Identification of hypothalamus biomarkers in orexin knockout and ataxin mouse models of narcolepsy: a proteomic quantitative approach

Authors: *S. AZZAM[1], P. J. SHIROMANI[3], P. FENG[2], K. P. STROHL[4];
[1]Ctr. for Proteomics and Bioinformatics, [2]Physiol. & Biophysics, Med., Case Western Reserve Univ., Cleveland, OH; [3]Dept. of Psychiatry and Behavioral Sci., Med. Univ. of South Carolina, Charleston, SC; [4]Pulmonary, Critical Care and Sleep Med., UH Case Med. Ctr., Cleveland, OH

Abstract: Human narcolepsy is a chronic brain disorder characterized by excessive daytime sleepiness with a dysregulation of the sleep-wake cycles. Narcolepsy is linked to the loss of orexin neurons producing orexin neuropeptides. Although the proximate cause of orexin neuron cell loss is unknown, a neurodegeneration process occurs. Two mouse models of narcolepsy have been used extensively to test drugs: orexin-Knockout (KO, orexin gene knockout), and orexin/ataxin-3 (Atx, genetic ablation of orexin neurons). The hypothesis was that models might have different functional consequences depending on how orexin loss is achieved, and to this end we employed label-free quantitative proteomics and pathway analysis. In this study, we

examined the hypothalamus proteome of KO, Atx and appropriate wild type (WT=C57BL/6J) mice. Each sample was subjected to in-solution digestion and analyzed by LC-MS/MS using an LTQ-Orbitrap Elites mass spectrometer. Differential quantification of peptides was performed using Rosetta Elucidator (FDR <2%). ANOVA was performed comparing peptide intensities across groups. Protein fold changes were determined by dividing the median protein intensity for each peptide in each study group. Differentially expressed proteins (p-value ≤ 0.05, fold-change ±1.5, and a minimum of 2 peptides per protein) were imported into Ingenuity Pathway Analysis (IPA). Analysis of 16 samples identified 2282 non-redundant proteins; only 39 proteins were statistically different across the groups. From these 39 proteins, 12 were specific to Atx/WT, 3 were specific to KO/WT, 10 were shared between KO/WT and Atx/WT, and 2 were shared between Atx/WT and Atx/KO. The majority of proteins, including MAO, DARPP-32, SIRT2, SNAP-25, COX5A, PKM, Hbb-b1, NFs, DPYSL3 and CKB, are associated with neurodegeneration, and mitochondrial respiratory and axonal dysfunction. IPA analysis revealed dysregulated pathways including glycolysis and mitochondrial dysfunction, as well as dopamine signaling, melatonin degradation, and glutamate degradation not expected by known orexin pathway action. Additionally, IPA analysis revealed a number of less specific but significant networks (p-value ≤0.05); including those “cellular assembly and organization”, “neurological disease”, and “behavior” networks. No protein differences were uniquely shared across all three groups. Taken together, peptide identification in this analysis found several dysregulated pathways, some like MAO which is targets for current narcolepsy therapy and other targets for circadian, excitatory circuit, and cell cycle deficits.

Title: Increased myeloperoxidase expression in brain areas affected by neurodegeneration in Alzheimer's and Parkinson's disease

Authors: S. GELLHAAR[1], D. SUNNEMARK[2], H. ERIKSSON[2], L. OLSON[1], *D. GALTER[1]; [1]Karolinska Institutet, Dept. of Neurosci., Stockholm, Sweden; [2]AstraZeneca R&D, Södertälje, Sweden

Abstract: Myeloperoxidase (MPO), a key enzyme in inflammatory processes, has been implicated in neurodegeneration by genetic and histological findings. We studied MPO expression in Parkinson's disease (PD) and Alzheimer's disease (AD) patients and neurologically unaffected control cases and in two rodent PD models, the 6-OHDA rat model and the MitoPark mouse. In human brain tissue MPO immunoreactivity (ir) was detected in monocytes in capillaries, perivascular macrophages and amoeboid microglia in the brain parenchyma, and no co-localization with GFAP ir was observed. In brain regions highly affected by PD such as midbrain, caudate and putamen we found a significant increase of MPO ir cells in parkinsonian brains as compared to control brains, whereas there was no such difference in cerebellum. MPO ir was not detected in neuronal cells or in occasional small beta-amyloid ir plaques in any region from PD or control cases. In frontal cortex of AD patients many MPO ir microglia / macrophages were detected together with plenty of MPO ir in extracellular plaques. In hippocampus of several AD cases MPO-like ir was observed in some pyramidal neurons, preferentially in the CA1 region, most likely unspecific binding to highly modified proteins. Neither the rapid dopamine (DA) depletion in the rat PD model, nor the slow degeneration of DA neurons in MitoPark mice induced expression of MPO in brain cells in any brain region. MPO mRNA was not detectable with radioactive in-situ hybridization in any human or rodent brain tissue and no enzymatic MPO activity was observed with antibodies recognizing hypochloric-acid modified proteins. Taken together we demonstrate a significant increase in numbers of MPO ir cells in brain regions affected by neurodegeneration in both PD and AD, indicating that higher MPO enzyme activity may be part of the pathological process.

Title: Deletion of Nogo Receptor 1 enhances fear extinction in adulthood

Authors: *S. M. BHAGAT[1], B. S. MCEWEN[3], J. R. TAYLOR[2], S. M. STRITTMATTER[2]; [1]Cell. Neuroscience, Neurodegeneration and Repair, [2]Yale Univ., New Haven, CT; [3]Rockefeller Univ., New York, NY

Abstract: In adult rodents, fear conditioning produces a lifelong fear memory that cannot be permanently repressed or erased, even following extinction training. This contrasts with what has been reported in juvenile rodents, which exhibit fear erasure following extinction training. The formation of myelin and perineuronal nets, which are extracellular matrices rich of chondroitin sulfate proteoglycans, coincide with the critical period for fear erasure. We have found that Nogo Receptor 1 (NgR1), a neuronal receptor for myelin-associated inhibitors that block neuronal sprouting and cortical plasticity in adulthood, significantly inhibits plasticity during fear and extinction learning. We have found that adult male NgR1 knockout (KO) mice, in contrast to wild-type (WT) controls, show a significant enhancement in fear extinction recall and no spontaneous recovery or fear renewal, which are behavioral assays to measure recall of the original fear memory. We have used genetic and viral-manipulations to explore the temporal, regional, and cell-specific role of NgR1. In conclusion, NgR1 plays a pivotal role in limiting extinction learning in adulthood, which could help enhance our current insight into neuropsychiatric diseases, such as anxiety disorders and post-traumatic stress disorder (PTSD).

Title: Elevation of peripheral BDNF promoter methylation predicts the risk of Alzheimer's disease

Authors: *L. CHANG[1], H. JI[2], G. LIU[2], S. DUAN[2], Q. WANG[2];
[1]Zhejiang Provincial Key Lab. of Pathophysiol, Zhejiang, China; [2]Ningbo Key Lab. of Behavioral Neuroscience, Sch. of Medicine, Ningbo Univ., Ningbo, China

Abstract: Brain derived neurotrophic factor (BDNF) can protect neurons from various attacks and thus play an important role in various mental diseases such as Alzheimer's disease (AD). Previous study has shown a significantly higher BDNF methylation in AD brain tissues. The aim of our study was to assess whether BDNF promoter methylation in peripheral blood was able to predict the risk of AD. DNA was extracted from the blood samples of 44 AD patients and 62 age- and gender-matched controls. Using the bisulphite pyrosequencing technology, we evaluated 4 CpG sites in BDNF promoter. Our results showed that BDNF methylation in the blood was significantly higher in AD cases than controls (CpG1: $p = 0.021$; CpG2: $p = 0.002$; CpG3: $p = 0.007$; CpG4: $p = 0.005$; average methylation: $p = 0.004$). BDNF methylation in the blood was shown as a good predictor of AD risk (CpG1: area under curve (AUC) = 0.617, $p = 0.041$; CpG2: AUC = 0.692, $p = 0.001$; CpG3: AUC = 0.663, $p = 0.004$; CpG4: AUC = 0.649, $p = 0.009$; average CpG: AUC = 0.657, $p = 0.006$). In addition, BDNF promoter methylation was shown to be significantly correlated with the levels of alkaline phosphatase (ALP), glucose, Lp(a), ApoE and ApoA in males (ALP: $r = -0.308$, $p = 0.042$; glucose: $r = -0.383$, $p = 0.010$; Lp(a): $r = 0.333$, $p = 0.027$; ApoE: $r = -0.345$, $p = 0.032$;), ApoA levels in females ($r = 0.362$, $p = 0.033$) and C Reactive Protein (CRP) levels in both genders (males: $r = -0.373$, $p = 0.016$; females: $r = -0.399$, $p = 0.021$). Our work was the first one to show that elevation of peripheral BDNF methylation was able to predict the risk of AD.

Title: Impact of environmental toxicants on mitochondrial dynamics and function in neurons

Authors: L. ZHANG, B. GATENO, *E. TRUSHINA;
Dept. of Neurol., Mayo Clin., Rochester, MN

Abstract: Mitochondrial dysfunction is implicated in the etiology of multiple neurodegenerative diseases including Alzheimer's Disease (AD). Since most of neurodegenerative disorders are sporadic, environmental exposure may play a major role in initiating the disease via affecting mitochondrial function. Indeed, many compounds commonly used in agriculture selectively target individual components of mitochondrial electron transport chain (ETC). We tested whether the exposure to multiple toxicants that target different ETC complexes leads to common downstream effects on cellular energetics, mitochondrial dynamics and function in primary cortical neurons from wild type mice. We examined the exposure to rotenone (ROT, pesticide), paraquat (PQ, herbicide), maneb (MB, fungicide), atpenin (A5, fungicide) and 3-nitropropionic acid (3NA) using two experimental paradigms, an acute (2 h) and prolonged (72 h) exposure at sub-lethal levels, which mimics occupational hazard and daily life exposure. We found that acute exposure to all toxicants rapidly depleted cellular ATP levels. These changes were especially significant when neurons were exposed to rotenone, a specific inhibitor of mitochondrial complex I. However, an acute exposure had little impact on mitochondrial respiration or function assessed in intact neurons using a Seahorse Extracellular Flux Analyzer. In contrast, prolonged exposure to toxicants along with a significant reduction in cellular ATP levels induced substantial energetic crisis. Specifically, toxicant-treated neurons displayed significant loss (>50%) of spare respiratory capacity, a measure of mitochondrial ability to produce energy under stress conditions. Both acute and prolonged exposure inhibited mitochondrial axonal trafficking and significantly increased the number of stationary mitochondria measured using time-lapse imaging in live neurons. Unexpectedly, increased production of reactive oxygen species was observed under both conditions only in neurons treated with ROT, NB and A5 but not in cells

exposed to PQ or 3NA. Our findings suggest that similar to what we observed in neurons from multiple animal models of AD, exposure to environmental toxicants, regardless of their origin, in the first place depletes cellular energy reserve and inhibits axonal trafficking where loss of bioenergetics occurs only after a prolonged exposure.

Title: Elevated OPRD1 promoter methylation in Alzheimer’s disease patients

Authors: ***Q. WANG**[1], H. JI[2], L. CHANG[2], G. LIU[2], S. DUAN[2];
[2]Ningbo Key Lab. of Behavioral Neuroscience, Zhejiang Provincial Key Lab. of Pathophysiol, [1]Ningbo University, Med. Sch., Zhejiang, China

Abstract: DNA methylation was reported to be involved in Alzheimer’s disease (AD), a most common neurodegenerative disorder in the elderly. In the current study, we tested the levels of OPRD1 promoter CpG sites (CpG1, CpG2, and CpG3) among 51 AD cases and 63 controls by bisulphite pyrosequencing technology. Our results showed that significantly higher CpG3 methylation was found in AD cases than controls (CpG3: p = 1.68E-7, adjusted p = 0.001). Significant associations were found between the CpG3 methylation and a series of phenotypes. Subsequent luciferase assay showed that DNA fragments of OPRD1 promoter tended to have higher expression of the reporter gene (CpG1-3 containing DNA fragment: fold = 1.923, p = 0.0883; CpG1-3 nearby DNA fragment: fold = 2.221, p = 0.0114). In summary, our results suggested that OPRD1 promoter hypermethylation increased the risk of AD through the regulation of gene expression.

Title: Modeling neurological disorders using human induced Pluripotent Stem cells-derived neurons

Authors: *B. B. DOROTHEE[1], E. GRAS LAVIGNE[1], L. THON[1], C. BADJA[2], M. OUAMER[1], R. STEINSCHNEIDER[1], F. MAGDINIER[2];
[1]Neuron Experts, Marseille, France; [2]INSERM UMR_U910 GMGF, Marseille, France

Abstract: Neurodegenerative diseases are a major health problem. About 20-30 million people worldwide suffer from Alzheimer disease and this number is predicted to quadruple by 2050. Unfortunately, very few treatments are available. New therapeutic strategies allowing to diminish symptoms but also to cure are needed. Tt is now essential to develop appropriate tools to better understand the underlying molecular mechanisms of these diseases and to create relevant models of these pathologies. Animal models and corresponding cellular models have given important insight in the understanding of disease mechanisms and have greatly facilitated the assessment of new therapeutic strategies. However, these models also display major limitations such as the inability to reproducibly mimic human pathology and the often unpredictable effect of test compounds on humans. The use of human induced Pluripotent Stem cells (iPS) derived neurons is an attractive approach to get closer to human physiological conditions and to propose relevant *in vitro* cellular models to be used for drug discovery through *in vitro* high content screening. For these reasons, we attempt to produce two kinds of neurons for two major neurodegenerative diseases. Firstly, we differentiated human iPS cells into cortical neurons in order to develop Alzheimer's disease cellular models. By employing phenotypic and molecular markers, we characterize the iPS-derived neurons before testing them in widely used cell models of exitotoxic stress and β-amyloid insult. Secondly, we produced dopaminergic neurons in order to develop Parkinson's disease cellular models. We confirmed their molecular identity by immunolabeling and submitted them to mimicking models of Parkinson's disease such as: impairment of mitochondria by MPP+ intoxication, oxidative stress (6-OHDA injury) or α-synuclein intoxication. Finally, we quantified the responsiveness of the generated human dopaminergic neurons to these toxins and compared them to our rodent cell models. These new *in vitro* cellular models, based on human neurons appeared to be more predictive and relevant models than rodent ones and could be used for the evaluation of therapeutic compounds.

Title: *In vivo* preclinical efficacy of Nav1.7 inhibitors in pain and olfactory models

Authors: *R. SANOJA, F. ZHAO, M. HOLAHAN, C. WINKELMANN, C. BURGEY, A. HOUGHTON;
Merck and Co., Inc., West Point, PA

Abstract: Pain is a frequent debilitating feature reported in peripheral neuropathies with involvement of small nerve (Aδ and C) fibers (Faber et.al., J. Peripher. Nerv. Syst.; 2014). Voltage-gated sodium channels are responsible for the generation and conduction of action potentials in the peripheral nociceptive neuronal pathway where voltage-gated sodium channel 1.7 ($Na_V1.7$) has a critical role. Human loss-of-function (LOF) mutations in the SCN9A gene, which encodes $Na_V1.7$, result in congenital indifference to pain and anosmia (Ruitenberg et. al., Channels; 2012). To test the ability of small molecule inhibitors of $Na_V1.7$ to recapitulate the human phenotype, we examined the efficacy of two Merck $Na_V1.7$ inhibitors (Compound A and B) *in vivo* assays that are preclinical surrogates for either neuropathic pain (ectopic firing in rats) or olfaction (functional MRI olfactory assay in non-human primates). *Sprague Dawley Rats' electrophysiology protocol:* A lumbar laminectomy 3-7 days after CCI (chronic constriction injury model) induction was performed to expose the left L5 dorsal root, cut at the spinal cord level, teased and immersed in a mineral oil pool. The ipsilateral sciatic nerve was exposed and freed from adherences to allow electrical stimulation and fiber characterization. Only single teased Aδ fibers with ongoing irregular spontaneous activity were chosen to study further. *NHP functional olfactory magnetic resonance imaging protocol:* Rhesus monkeys were exposed cyclically to an odor (Isoamyl acetate ~ 2800 ppm), for one minute followed by three minute recovery, for an hour while continuous fMRI images were taken. For both protocols, long baselines -no stimulation- were always done followed by iv compounds infusion (10 min for rats, 60 min for NHP) and vehicle was 30% captisol in all cases. Both protocols were also done under isoflurane anesthesia. *Results:* Compound A regularized and decreased Aδ ectopic firing activity in CCI induced animals and Compound B significantly impaired the NHP fMRI signal, both in a

dose dependent manner. These results demonstrate that small molecule inhibitors of $Na_V1.7$ can replicate the clinical phenotype of human LOF patients. Our findings corroborate the critical role of $Na_V1.7$ channels in neuropathic spontaneous pain and anosmia, and provide pre-clinical efficacy for our $Na_V1.7$ inhibitors.

Title: Effect of tumor necrosis factor inhibition on central nervous system structure and function in rheumatoid arthritis patients

Authors: ***M. BJORNSDOTTER**[1], S. TÖYRÄ SILVERSWÄRD[2], L. LEIFSDOTTIR[2], H. BACKLUND-WASLING[1], H. OLAUSSON[3], M. BOKAREWA[2];
[1]Clin. Neurophysiol., Univ. of Gothenburg, Goteborg, Sweden; [2]Dept. of Rheumatology and Inflammation Research, Sahlgrenska Univ. Hospital, Univ. of Göteborg, Göteborg, Sweden; [3]IKE, Linkoping Univ., Linkoping, Sweden

Abstract: Rheumatoid arthritis (RA) is an autoimmune disorder characterized by chronic joint inflammation. Inhibition of tumor necrosis factor (TNFi) has emerged as an effective treatment reducing systemic inflammation. In the short-term, TNFi reverses hyperactivity in pain circuits (Hess et al. PNAS, 2011:108; Rech et al. Arthritis Rheum, 2013:65). Any long-term effects of TNFi on the central nervous system are unclear, however. We therefore studied the effect of TNFi on brain structure and function by examining i) group differences between TNFi treated and untreated RA patients, and, ii) effects of duration in TNFi patients. We collected anatomical and functional MRI scans in 15 female patients (mean age 55 years, std 8.6 years) with established RA (mean duration 11.4 years, std 7.7 years). Eight patients had long-term TNFi medication (mean duration 56, range 11-100 months). The fMRI paradigm involved alternating blocks of painful compression of the left metacarpophalangeal II joint and rest. Data processing

was performed SPM8 and VBM8. We conducted general linear modeling analyses, including age and duration as covariates, within an anatomically defined mask comprising structures associated with pain and sensorimotor processing (Hess et al. PNAS, 2011:108; Smallwood et al. J Pain, 2013:14). Results were assessed at uncorrected $p < 0.01$, corrected for multiple comparisons using AlphSim with 1,000 iterations. Patients treated with TNFi had larger gray matter volume and higher pain responses in sensorimotor regions (post/pre-central gyrus) and the anterior cingulate cortex ($p < 0.01$, $\alpha < 0.05$). Duration of TNFi treatment correlated positively with gray matter volume of the postcentral gyrus, and negatively with gray matter volume in a range of areas including the anterior cingulate cortex ($p < 0.01$, $\alpha < 0.05$). Duration of TNFi treatment correlated negatively with the induced pain responses of the anterior cingulate cortex ($p < 0.01$, $\alpha < 0.05$). Our results suggest that TNFi treatment induces structural and functional central nervous system alterations also in the long term, corroborating previous findings from studies of short-term effects of medication (Hess et al. PNAS, 2011:108). Moreover, our findings support the notion that patients who are hyperresponsive to painful stimuli benefit from treatment with TNFi (Rech et al. Arthritis Rheum, 2013:65).

Title: Analgesic and anti-inflammatory activities of water extract of Euphorbia thymifolia (Euphorbiaceae)

Authors: *E. NGO BUM, K. NGO NGIMOUT, J. K. S. NJAPDOUNKE, G. N. C. NKANTCHOUA, G. N. C. NKANTCHOUA;
Univ. Ngaoundere, Cameroon, Ngaoundere, Cameroon

Abstract: Euphorbia thymifolia (Euphorbiaceae) is a plant used in traditional medicine in the Littoral Region in Cameroon to treat pain and inflammation. This study evaluated the analgesic and anti-inflammatory effects of the whole plant of E. thymifolia. Mice or rats were divided into 5 groups of 5 animals. One negative control group, one positive control group and three groups treated with the macerate of the plant. Intraperitoneal administration of acetic acid 1% was used to induce abdominal contractions in mice. Tail immersion in the water heated to 55 ± 0.5°C was

used to induce pain in mice. Inflammation was induced by injecting 0.1 ml of carrageenan 1% in the footpad of the right posterior leg of the rats. Chronic inflammation was induced by the implantation of cotton pellets (sterilized at 69°C) in the left axilla of rats. The macerate was administered orally. The analysis of variance (ANOVA) two-way, followed by Turkey as post hoc test was used for statistical analysis using XLSTAT 2007. E. thymifolia at the dose of 75 mg/kg and morphine at the dose of 10 mg/kg inhibited 65.7 and 88.3% of abdominal contractions induced by acetic acid, respectively. When pain was induced by the immersion of the rat tail in heated water, the administration of E. thymifolia (75 mg/kg) and morphine (10 mg/kg) resulted to a maximum inhibition of 82.6 and 98.66% respectively, from the first 30 min and for 3 hours. In the third experiment, the edema of the footpad induced by carrageenan was inhibited by 63.63 and 90.9% by E. thymifolia (75 mg/kg) and dexamethasone (5 mg/kg), respectively. While the inhibition induced by the positive control dexamethasone was decreasing with time (54.55% 6h later), the inhibition induced by E. thymifolia was increasing (77% 6h later). The granuloma induction by implantation of cotton pellets in the axilla was inhibited by 74.3 and 73.4% by E. thymifolia (75 mg/kg), and by dexamethasone (5 mg/kg), respectively. These results show that water extract of E. thymifolia administered orally has analgesic and anti-inflammatory activities. The effectiveness of E. thymifolia could be due to alkaloids, flavonoids, tannins or saponins contained in the plant. These results justify the use of E. thymifolia in traditional medicine in Cameroon.

Title: Oxaliplatin-induced neuropathic pain is prevented by A3 adenosine receptor agonists through spinally mediated mechanisms of action that engage IL-10 signaling

Authors: *C. WAHLMAN[1], K. JANES[1], K. JACOBSON[2], D. SALVEMINI[1];
[1]St. Louis Univ., Saint Louis, MO; [2]Natl. Inst. of Diabetes and Digestive and Kidney Dis., Bethesda, MD

Abstract: Chemotherapy-induced peripheral neuropathy (CIPN), accompanied by chronic neuropathic pain, is a major dose-limiting side effect and cause of dose reduction for many anti-cancer agents. Oxaliplatin is one such chemotherapeutic in which approximately 35% of patients suffer from enduring neuropathic pain that lasts for months to years following treatment cessation severely limiting their quality of life. Currently, there are no effective treatments. Adenosine, an endogenous nucleoside, acts on four different G-protein coupled receptors: A1AR, A2AAR, A2BAR, and A3AR, of which A1AR and A2AAR have been investigated for their beneficial activities in models of neuropathic pain, but negative side effects limit their therapeutic potential. However, A3AR agonists are in phase II/III clinical trials for inflammatory disorders and as novel anti-cancer agents with good safety profiles. Our lab has shown that systemic administration of A3AR agonists prevents the development of oxaliplatin-induced neuropathic pain by attenuating spinal neuroinflammatory processes; A3AR agonists do not interfere with oxaliplatin's anti-cancer effects *in vitro*. Here we demonstrate that the spinal cord is an important site of action for the beneficial effects of systemic MRS5698, since spinal injection of an A3AR antagonist blocked the effects of systemic MRS5698. Spinal injection of MRS5698 given during oxaliplatin treatment abrogated the development of neuropathic pain as well. Noteworthy, the prevention of neuropathic pain by spinal MRS5698 was blocked by an intrathecal injection of an anti-IL-10 antibody but not its IgG control given just prior to MRS5698. These results suggest that MRS5698's preventative actions are dependent upon continuous IL-10 signaling within the spinal cord. IL-10 can be regulated in numerous ways, one of which is through miRNAs; this is under investigation. These results support A3AR agonists as a novel class of non-narcotic analgesics that are urgently needed for individuals currently suffering from CIPN.

Title: Effects of palmitoylethanolamide upon cyclooxygenase enzyme activity

Authors: *L. E. GABRIELSSON, C. FOWLER;
Pharmacol. and clinical neuroscience, Umea Univ., Umea, Sweden

Abstract: Department of Pharmacology and Clinical Neuroscience, Umeå University, SE-901 87 Umeå *N*-palmitoylethanolamide (PEA), belonging to the class of *N*-acetylethanolamines (NEAs), has been shown to have anti-inflammatory and analgesic effects. The mechanism behind these effects is not yet fully understood although it seems like the most prominent explanation is trough peroxisome proliferator-activated receptor alpha (PPAR-α). It has been reported that treatment of rats with PEA reduces the observed activity of cyclooxygenase (COX)[1], but it is not known whether this is a direct or indirect effect of the compounds. Numerous fatty acids have been shown to bind allosterically to COX-1 and -2 and alter their activity[2,3], raising the possibility that this also occurs with PEA. With an Oxygraph System we investigated the effects of PEA upon the COX-catalysed oxygenation of arachidonic acid (AA, COX-1 and -2) and 2-arachidonoylglycerol (2-AG, COX-2). PEA was used in concentrations of 1, 3, 10μM and COX substrates were used in concentrations of 2 and 10μM. We found that PEA has no direct effect upon COX-2 enzyme activity. However, an interaction was observed between PEA and COX-1 at 2 μM AA (but not 10 μM AA) where the initial velocity of the enzyme activity was increased ($P<0.05$). It is concluded that PEA has modest direct effects upon the catalytic activity of COX isoforms *in vitro*. References [1]Costa *et al.*, (2002) Br J Pharmacol [2]Yuan *et al*. Title: AN363, a novel GABAA α2/3/5 receptor subtype selective positive allosteric modulator for treatment of chronic pain

Authors: D. AMRUTKAR, P. AHRING, T. DYHRING, *K. S. NIELSEN, T. JACOBSEN, J. LARSEN;
Saniona A/S, Ballerup, Denmark

Abstract: Chronic pain is still a largely unresolved medical condition. Effective pharmacological approaches need to target alterations in the nociceptive system that are

responsible for mediating the pain sensation and resulting disability. Reduction in inhibitory GABAergic control in dorsal horn neurons is believed to be a relevant aspect of the neuroplastic changes observed in inflammatory and neuropathic conditions. Based on this hypothesis, we here report on analgesic activity of a novel receptor subtype selective GABAA α2/3/5 positive allosteric modulator in preclinical models of pain. We have tested AN363 at doses of 1,3,10 and 30 mg/kg p.o., in Complete Freund's adjuvant (CFA,100 µg), formalin (5%) and capsaicin (10 µg) induced acute inflammatory pain models as well as chronic constriction injury (CCI) induced neuropathic pain model in male Sprague-Dawley rats. The minimum effective dose (MED) varied between 3 to 10 mg/kg across the models. In accordance with lack of activity at the GABAA α1 subtype, AN363 did not cause ataxia at the therapeutic doses, as measured in the rat rotarod test. By the use of an *in vivo* 3H-L-655,708 binding assay it was demonstrated that AN363 readily penetrates the brain in rats and occupies the benzodiazepine site with an ED50 of 4.5 mg/kg, p.o. in Sprague-Dawley rats, which is in good correspondence with the MED in pain models. AN363 has a half-life of more than 2h in rats and is highly stable in human hepatocytes. The robust therapeutic effect seen with AN363 in animal models of pain, together with its selective *in vitro* profile, suggest that it could have potential benefit in clinical treatment of chronic pain in humans with improved side effects profile compared to existing treatment. These findings indicate more selective targeting of pain pathways with subtype selective GABAergic drugs. The lead candidate, AN363, constitute a new and promising class of analgesics particularly suitable for treating chronic pain syndrome.

Title: FTY720, a functional antagonist of sphingosine-1-phosphate receptor subtype 1, prevents bortezomib-induced neuropathic pain through modulation of spinal neuro-inflammation

Authors: *K. STOCKSTILL, K. JANES, D. SALVEMINI;
Pharmacol. and Physiological Sci., St. Louis Univ. Sch. of Med., Saint Louis, MO

Abstract: Bortezomib, a chemotherapeutic agent that is used to treat multiple myeloma and mantle cell lymphoma, can cause peripheral neuropathy in about 40% of patients. Bortezomib-induced peripheral neuropathy (BIPN) is often accompanied by chronic neuropathic pain and is one of the major reasons why patients either limit or discontinue their chemotherapy treatment. Currently, there are no effective therapies. Our lab has demonstrated that activation of the S1P-S1PR1 axis in the spinal cord (SC) is critical to the induction and maintenance of BIPN through activation of neuro-inflammatory processes [increases in pro-inflammatory substances (TNF, IL-1β, CCL2, CXCL1) and decreases in anti-inflammatory substances (IL-10, IL-4)]. Inhibiting the S1P-S1PR1 signaling pathway with FTY720, a functional antagonist of S1PR1, either during bortezomib treatment or when given 48 hours after the last dose of bortezomib, blocked the progression of BIPN throughout the observation period of 25 days. Fortunately, FTY720 is already FDA approved for the treatment of multiple sclerosis and could therefore be rapidly evaluated as an adjunct to bortezomib to block neuropathic pain. Importantly, FTY720 has well documented anti-cancer effects and inhibition of the S1P-S1PR1 axis is under investigation for anti-cancer treatments. Activation of TLR4 has been shown to be a key regulator of the release of pro-inflammatory cytokines. In our preliminary studies rats treated with bortezomib have increased TLR4 expression, pro-inflammatory cytokines, and chemokine/receptor transcription, and decreased anti-inflammatory cytokines. Inhibiting the S1P-S1PR1 axis with FTY720 leads to decreased TLR4 expression, pro-inflammatory cytokines, and chemokine/receptor transcription as well as increased anti-inflammatory cytokines. Overall these results show that inhibition of S1P-S1PR1 with FTY720 prevents the development of BIPN at least in part through modulation of neuro-inflammation in SC and implicate potential contribution of TLR4 in these effects. Additional studies are ongoing in support. Our results with FTY720 were extended to other S1PR1 antagonists such as NIBR14 strengthening our global hypothesis that targeting S1PR1 is an effective strategy to block neuropathic pain states.

Title: Preclinical profiling of a novel mglur8 positive allosteric modulator

Authors: ***M. COSDEN**[1], S. STACHEL[2], Y. ZHOU[1], J. J. RENGER[1], R. E. DROLET[1];
[1]Merck and Co., Inc., West Point, PA; [2]Merck, West Point, PA

Abstract: The metabotropic glutamate receptor 8 (mGluR8), is a presynaptic g-protein coupled receptor that inhibits neurotransmitter release through multiple presynaptic effector molecules. mGluR8 is enriched at several presynaptic sites within the CNS including the dorsal striatum, periaqueductal grey, amygdala, and nucleus tractus of the solitarius and as such remains an attractive target for multiple CNS disorders. However, the orthosteric binding site of metabotropic glutamate receptors (mGluR's), venus-fly-trap domains, are highly conserved among the eight mGluR subtypes and this hinders orthosteric agonist or antagonist development. Allosteric modulation however, has led to the development of selective compounds for several of the mGluR's. The usefulness and validation of mGluR8 as a target in the Neurosciences is hindered by the lack of selective and potent molecules that modulate the receptor. The data described in this presentation describe the preclinical *in vitro* and *in vivo* profiling of a novel mGluR8 positive allosteric modulator (PAM). The compound described here has *in vitro* activity in cell-based assays at sub 100nM concentrations, and has greater than 10-fold selectivity over other group III mGluR's, and no activity at group I or II mGluR's. The compound also has good selectivity against a broad panel of neuroscience-related protein targets and receptors with moderate activity against three un-related targets with potency values in the micromolar range. With respect to physicochemical properties, the compound is moderately soluble at pH7 and has reasonable plasma protein binding that predicts sufficient free plasma levels necessary to activate the receptor after peripheral dosing. The compound has good oral bioavailability and permeability and is not a PGP substrate that enables good CNS drug exposure. Consistent with this, the compound showed dose-dependent efficacy in a mouse formalin paw assay. Efficacy correlated well with free plasma drug exposure and was consistent with predicted *in vitro* potency values, indicative of mGluR8-dependent activity. Together, these data suggest this novel mGluR8 PAM molecule is a useful tool to evaluate mGluR8 activation as a potential target for multiple CNS disorders.

Title: F17475, a glutamatergic/NMDA receptor antagonist with a safer profile than ketamine: activity in a rat model of post-operative pain

Authors: *R. Y. DEPOORTERE[1], B. VACHER[1], A. AUCLAIR[1], J. C. MARTEL[1], P. HEUSLER[1], P. MOSER[1], M. GEORGY[2], T. CLERC[2];
[1]Lab. Pierre Fabre, Castres, France; [2]PFI, Lab. Pierre Fabre, Toulouse, France

Abstract: Glutamatergic/NMDA receptor antagonists, like ketamine, have benefited from a renewed interest recently, in particular for their anti-hyperalgesic and potential antidepressant properties. However, their propensity to produce side-effects (in particular dizziness and psychotomimetic symptoms) at doses close to or overlaping with those with therapeutic effect, has sparked an interest for ketamine-like compounds with a better safety margin. Here, we report the *in vitro* and *in vivo* activities of F17475 (3-amino-N,N-diethyl-1-phenylcyclobutanecarboxamide, patent WO2014086825-A1), using ketamine as a positive comparator. F17475 had slightly higher affinity than ketamine at rat NMDA receptors (Ki : 0.74 and 1.05 µM, respectively) and more potently blocked NMDA currents using cloned human NMDA receptors (IC50 : 0.52 and 0.74 µM, respectively). In addition, F17475 was more selective than ketamine against 120 targets. In the Brennan rat model of post-operative pain, using flinches as a marker of spontaneous pain (scored 24 h post-surgery), F17475 was as efficacious but at least twice as potent as ketamine, whether injected 1 h before or after surgery, or 1 h before scoring (MED: 1.25-2.5 and 5 mg/kg iv, for F17475 and ketamine, respectively) In addition, F17475 further potentiated the analgesic efficacy of morphine (0.63 to 2.5 mg/kg sc, 30 min pre-scoring), with a MED : 1.25 mg/kg iv when given 1 h pre-operatively, and a strong tendency at 2.5 mg/kg when given 1 h post-surgery. Ketamine showed a tendency to potentiate morphine at +1 h, but was ineffective at -1 h. In models of abuse liability (ketamine drug discrimination and locomotor activity in rats), F17475 was active at doses (MED : 10 and 25 mg/kg iv, respectively) above those active in the Brennan model, giving a safety ratio of 4 to 10. By contrast, ketamine produced effects at doses (MED : 1.25 and 10 mg/kg iv, respectively) below or just above analgesic ones, giving a safety ratio of 0.25 to 2. This advantageous safety profile was confirmed by the finding that F17475 produced no impact in an Irwin test up to 10

mg/kg iv, whereas ketamine produced signs from 0.63 mg/kg iv. These results suggest that F17475, a potent and efficacious glutamatergic/NMDA receptor antagonist, following iv administration, is at least as efficacious as, but more potent than ketamine in a rat model of post-operative pain. It is additionally endowed with a superior safety profile. These observations, combined with its opiate sparing potential, point towards the utility of F17475 as a substitute for ketamine, alone or in combination with opiates, for peri-operative pain relief, and prevention of chronification of pain.

Title: Selective enhancement of slow inactivation of Nav1.7 WT and pain-linked gain-of-function mutations

Authors: A. LAMPERT[1,2], A. O. O'REILLY[2], M. POHLER[2], J. MAJERCAK[3], *R. KLEIN[3]; [1]Inst. of Physiol., RWTH Aachen Univ. Hosp., Aachen, Germany; [2]Inst. of Physiol. and Pathophysiology, Friedrich-Alexander Univ. Erlangen-Nürnberg, Erlangen, Germany; [3]Merck Sharp and Dohme, West Point, PA

Abstract: Gain-of-function mutations of voltage-gated sodium channels are linked to inherited pain disorders and these channels are of pharmacological interest as targets for analgesic compounds. We investigated the effect of two novel compounds (A and B) and compare these results with the known sodium channel modulators mexiletine and carbamazepine. These compounds were tested on wild-type Nav1.7 and three different gain-of-function mutations associated with pain channelopathies. 1) L823R, which is linked to erythromelalgia, an inherited pain syndrome that is characterized by triggered attacks of intense burning pain, with onset

occurring in young adulthood. 2) I1461T, a paroxysmal extreme pain disorder (PEPD)-linked mutation, that induces excruciating pain attacks in children close to birth. 3) M1532I, a small fiber neuropathy (SFN) linked mutation, that induces gloves and stocking like symptoms of neuropathic pain in older adults. The voltage-dependence of activation of the PEPD and SFN mutants was shifted to more depolarized potentials by all tested compounds, whereas that of WT and the IEM mutation was unaffected. Fast inactivation was shifted to more hyperpolarized potentials for almost all Nav1.7 constructs and drugs tested. The most notable effect that compounds A and B had on WT Nav1.7 and all tested mutations was a potently-enhanced slow inactivation. The observed strong enhancement of slow inactivation at physiological resting membrane potentials suggests that these new compounds may represent promising new therapeutics for pain patients.

Title: A meta-regression analysis of placebo response in clinical trials of neuropathic pain

Authors: *A. H. TUTTLE[1,5], S. TOHYAMA[1], J. KIMMELMAN[2], T. RAMSAY[6], G. J. BENNETT[3], P. SCHWEINHARDT[4], J. S. MOGIL[1,5];
[1]Dept. of Psychology, [2]Dept. of Biomed. Ethics, [3]Dept. of Anesthesia, [4]Dept. of Dent., McGill Univ., Montreal, QC, Canada; [5]Alan Edwards centre for research on pain, Montreal, QC, Canada; [6]Fac. of Med., Ottawa Hosp. Res. Inst., Ottawa, ON, Canada

Abstract: Increasingly, novel pharmacological targets for treating neuropathic pain are unable to pass randomized controlled drug trials, calling into question whether current drug study design may in part explain lack of demonstrable drug efficacy. In an effort to identify potential contributors to recent trial failures, we conducted a literature review of neuropathic pain placebo-controlled randomized clinical trials published between 1980 and 2014 using EMBASE, Medline, and Cochrane online databases. Specifically, a search for "neuropathic pain" and "drug," limited to randomized clinical trials, yielded a combined total of 1793 articles. We also included an additional 106 articles from a similar meta-analysis conducted by Finnerup et al. (2005), bringing our article total to 1899. First-pass inclusion criteria included: English language only, randomized controlled-trials, neuropathic pain conditions (except for migraine, trigeminal neuralgia, or orofacial pain), systemic drugs only, visual analogue scales or numeric rating scales, and parallel or cross-over trial design. After first-pass screening, 221 articles were included for additional analysis. After second-pass screening, a total of 80 articles were included in our final data set. Analysis of reported pain measures extracted from placebo and treatment groups yielded several striking correlations between study design and reported placebo-group pain scores. First, placebo ratings (reductions in pain measures) are becoming stronger over time. Furthermore, the increasing placebo response correlates with a significant decreasing trend in treatment advantage, indicating that increasing placebo response may negatively impact neuropathic pain trial outcome. However, our systematic review of the literature highlights several factors that might explain our correlations: Size of the study, number of treatment arms, and study duration/number of site visits appear to be significant correlative factors that predict an increase in placebo response. Finally, the magnitude of the placebo response appears to be limited to North American studies. Taken together, these findings are similar to those reported in both the depression and schizophrenia literature. While the magnitude of the placebo response appears to be increasing over time, causal mechanisms of these trends are still unknown.

Title: Kinetic analysis of membrane potential dye response to NaV1.7 channel activation identifies antagonists with pharmacological selectivity against Nav1.5

Authors: ***M. F. FINLEY**[1], A. CONVERSO[2], M. CLEMENTS[2], C. DALEY[2], R. KRAUS[2], W. LEMAIRE[2], M. LAYTON[2], K. SOLLY[1], D. STAAS[2], J. WANG[2], M.-T. LAI[2], J. CASSADAY[1], T. KREAMER[1], X. LI[1];
[1]Automated Biotech., Merck, North Wales, PA; [2]Merck, West Point, PA

Abstract: The NaV1.7 voltage-gated sodium channel is a highly valued target for the treatment of neuropathic pain due to its expression in pain-sensing neurons and human genetic mutations in the gene encoding NaV1.7 resulting in either loss- (congenital analgesia) or gain- (paroxysmal extreme pain disorder) of-function pain phenotypes. We exploited existing technologies in a novel manner to identify selective antagonists of NaV1.7. A full-deck high-throughput screen was developed for both NaV1.7 and cardiac NaV1.5 channels using a cell-based membrane potential dye FLIPR assay. In assay development, known local anesthetic site inhibitors produced a decrease in maximal response; however, a subset of compounds exhibited a concentration-dependent delay in the onset of the response with little change in the peak of the response at any concentration. Therefore, two methods of analysis were employed for the screen: one to measure peak response and another to measure area under the curve (AUC) which would capture the delay-to-onset phenotype. Although a number of compounds were identified by a selective reduction in peak response in NaV1.7 relative to 1.5, only the AUC measurement and a subsequent refinement of this measurement were able to extract compounds with novel Nav1.7 pharmacological selectivity over Nav1.5 as confirmed in electrophysiology.

Title: A novel functional assay for both μ-opioid receptor and nociception receptor

Authors: *J. WU, J. SCHOCH, M. WERGER, A. CIPPITELLI, L. TOLL;
Torrey Pines Inst. For Mol. Studies, Port Saint Lucie, FL

Abstract: Traditionally GTPgS binding and adenylyl cyclase (AC) activity inhibition are often used to measure μ-opioid receptor activation. We developed a novel assay in which intact live cells can be used to screen new ligands (agonist or antagonist) for both mu-opioid receptor and nociceptin receptor (NOP). Chinese hamster ovary cells were stably transfected with μ-opioid receptor and NOP receptors respectively. CHO cells expressing mu or NOP were seeded in 96-well plates, loaded with membrane potential-sensitive fluorescent dye for 60 minutes, and then treated with or without mu and NOP agonists. CHO-mu and CHO-NOP cells hyperpolarized upon the treatment of its own agonist, which is probably mediated by G protein-coupled inwardly-rectifying potassium channel or other certain potassium channel. Membrane potential change induced by CHO-MOR/NOP activation can only be detected only through membrane potential-sensitive fluorescent potassium dye but not through calcium dye. The resulting fluorescence changes could be detected in real time. The μ-opioid receptor agonist DAMGO has an EC50 of ~3.28nM in mu cells, and 100nM DAMGO-induced μ-opioid receptor activation can be inhibited by μ-opioid receptor antagonist naloxone in a dose-dependent manner, with an IC50 of is ~40nM. Similarly, NOP receptor agonist N/OFQ has an EC50 of ~14nM and activation of NOP receptors with 100nM N/OFQ can be inhibited by an NOP receptor antagonist in a dose-dependent manner with an IC50 of is ~30nM. This novel functional assay provides a simple, quick and safe method for real-time measurement of mu and NOP receptor activation or

inhibition through their action on native CHO cells. This method can greatly facilitate the drug discovery for opioid receptors.

Title: Antihyperalgesic effects of the α2 GABA-A and α3 GABA-A receptor positive allosteric modulator HZ-166 on pain-related stimulation and depression of behavior

Authors: *B. D. FISCHER[1], M. M. POE[2], J. M. COOK[2];
[1]Cooper Med. Sch. of Rowan Univ., Camden, NJ; [2]Univ. of Wisconsin, Milwaukee, WI

Abstract: GABAergic inhibition in the dorsal horn of the spinal cord is thought to contribute significantly to nociceptive processing. Drugs that enhance this inhibition produce antihyperalgesic effects in preclinical models, likely through GABA type A receptors that contain an α2 and/or α3 subunit (α2GABA-A receptors and α3GABA-A receptors, respectively). From a drug development perspective, it has been argued that the concurrent assessment of both pain-stimulated and pain-depressed behaviors may improve the translation of preclinical findings to the clinic. The purpose of the present study was to assess the antihyperalgesic effects of the α2GABA-A and α3GABA-A receptor positive allosteric modulator HZ-166 in a model of pain-stimulated behavior (withdrawal reflex from a mechanical stimulus) and a model of pain-depressed behavior (voluntary wheel running) in C57BL/6 mice. To assess pain-stimulated behavior, the yeast extract zymosan A (24 hr pretreatment; 0.06 mg/0.02 ml) was injected subcutaneously into the plantar surface of the footpad and mechanical sensitivity was assessed before and following HZ-166 administration (1.0 - 32 mg/kg, i.p.). Zymosan A increased sensitivity to the mechanical stimulus, resulting in a mean (± SEM) threshold of 3.8 ± 0.38 g. This increase in mechanical sensitivity was dose- and time-dependently reversed by HZ-166 and resulting in a peak threshold of 6.8 ± 0.26 g. In a separate group of mice, voluntary wheel

running was used as the dependent measure to assess pain-depressed behavior. Once stable wheel running was observed, complete Freund's adjuvant (CFA; 24 hr pretreatment; 0.01 ml) was injected bilaterally in to the plantar surface of both footpads. Injections of CFA reduced wheel running behavior to 1.0 ± 0.66 rotations/min during the onset of the dark cycle. Here, HZ-166 increased wheel running behavior to 8.1 ± 2.8 rotations/min during this same time period. These data suggest that systemic administration of a α2GABA-A and α3GABA-A receptor positive allosteric modulator produces an antihyperalgesic effect which may be observed in assays of both pain-stimulated and pain-depressed behavior. Together, these observations should provide a framework for studying GABA-A receptor pharmacology which in turn should help guide the development of improved therapeutic agents for the treatment of pain.

Title: Electrophysiology studies and homology modeling to increase the selectivity of NaV1.7 inhibitors

Authors: R. KLEIN, A. ROECKER, *M. CLEMENTS, C. DALEY, D. WANG, M. LAYTON, V. SANTARELLI, J. MAJERCAK, R. KRAUS, A. HOUGHTON;
Merck, West Point, PA

Abstract: NaV1.7 is a voltage-gated sodium channel genetically validated to play a critical role in nociception and pain. Local anesthetics (LAs) are effective at reducing pain but lack subtype selectivity, resulting in safety risks. Our team has identified small molecule NaV blockers with selectivity between NaV1.7 and NaV1.5 (cardiac isoform) and identified their binding site by manual patch clamp using an innovative chimeric channel approach. This approach, using a library of NaV1.7/1.5 chimeric constructs, led to the identification of a novel binding pocket in the less-conserved DIV,S2S3 voltage sensor region of the sodium channel alpha-subunit. This site is distinct from both the highly conserved LA binding site (DIV,S6 pore region) and other known toxin inhibition sites. From these efforts, a homology model was constructed to inspire design elements that led to the development of novel and potent aryl-sulfonamide compounds, offering the potential for highly selective NaV1.7 inhibitors. Furthermore, these mutagenesis and homology studies identified key point residues, Y1537 (DIV, S2), W1538 (D1V,S2), and A1585

(DIV,S3), responsible for aryl-sulfonamide binding and selectivity over NaV1.5. This approach continues to inspire target design and aids in rationalization of selectivity over NaV isoforms.

Title: Stimulation of soluble guanylate cyclase triggers migraine-associated pain

Authors: ***A. A. PRADHAN**[1], A. F. TIPTON[1], R. GHANDI[2], L. SEGURA[1], A. ACHARYA[1], G. THATCHER[2];

Abstract: Migraine is a complex brain disorder that affects hundreds of millions of individuals worldwide. Available treatments are only effective in a limited number of patients; and there is a desperate need for novel drug therapies. Nitroglycerin (NTG) is a known migraine trigger, and produces migraine-associated hyperalgesia in mice. How NTG induces migraine is unclear, as it activates the soluble guanylate cyclase pathway, but also produces radical oxygen species leading to oxidative stress. The aim of this study was to determine the specific contribution of the soluble guanylate cyclase (sGC) pathway to migraine-associated pain. C57Bl6/J mice were treated acutely and chronically with either vehicle or the sGC stimulator VL-102. Basal and post-treatment mechanical responses were determined using von Frey hair stimulation. VL-102

produced acute hyperalgesia in a dose-dependent manner. Chronic administration of VL-102 produced both acute and basal hypersensitivity. VL-102-induced hyperalgesia was blocked by the anti-migraine medications sumatriptan and topiramate. These results are similar to the migraine-related pain induced by NTG. Stimulation of guanylate cyclase mimics the effects of NTG-induced pain, and appears to be migraine-associated. These results show that the effects of NTG on migraine are due to direct activation of the nitric oxide pathway. Furthermore, this work indicates that soluble guanylate cyclase inhibitors may be a novel therapeutic target for the treatment of migraine.

Title: Inhibition of electrical-field stimulation-evoked signals in cultured mouse DRG neurons by sodium channel inhibitors is highly predictive of their ability to increase the threshold to action potential firing as measured by current clamp

Authors: ***C. DALEY II**[1], J. WANG[1], I. GREGAN[1], A. HOUGHTON[1], M. KARLSSON[2], S. LARDELL[2], C. LINDWALL-BLOM[2], P. KARILA[2];

Abstract: Manual patch clamp recordings performed in the current clamp configuration, using cultured dorsal root ganglion (DRG) neurons, afford unique insight into the excitability of native tissue. Patch clamp using this native tissue allows one to examine the pharmacological effects of modulators of cellular excitability in a physiologically relevant configuration. In this way, electrical current is applied to the patched neuron at various frequencies and current amplitudes in order to evoke a depolarization of the membrane which is initiated by the opening of voltage-gated sodium channels (VGSCs). In these native tissue, the opening of VGSCs initiates the start of membrane depolarization from the resting potential, subsequently resulting in the opening of voltage gated calcium channels (VGCCs) and action potential firing. While the current clamp technique provides unparalleled insight into the excitability of native tissue, it is extremely low-throughput, requiring high-quality native tissue sources, delicate tissue digestion and culture conditions, and highly experienced electrophysiologists trained in patch clamp recording.

Alternatively, by utilizing an electrical field stimulation (EFS) electrode head to induce membrane depolarization in DRG cultures, in combination with a calcium-sensitive fluorescent dye and rapid image acquisition, the action potential can be indirectly monitored in excitable cells. The EFS technique therefore provides a dramatically higher-throughput means of quantifying the excitability of native tissues. Here we describe the use of an EFS system custom-built by Cellectricon, in the development of an assay using mouse DRG neurons, which is sensitive to sodium channel inhibitors. We found an excellent correlation between sodium channel blockade measured by EFS and by conventional current clamp. Prototypical sodium channel blockers tetrodotoxin (TTX), and tetracaine inhibited the EFS signal, as did internally developed, subtype-selective small molecule inhibitors of NaV1.7. This correlation strongly suggests that this EFS platform can be used to screen for inhibitors of VGSC-driven action potential firing in a high-throughput manner, enabling triage of compounds likely to modulate the excitability of native tissue earlier on in the drug development cycle.

Title: Inhibition of soluble guanylate cyclase alleviates migraine-associated pain

Authors: ***A. F. TIPTON**[1], R. GANDHI[2], Y. WANG[2], G. THATCHER[2], A. A. PRADHAN[1]; [1]Psychiatry, Univ. of Illinois At Chicago, Chicago, IL; [2]Medicinal Chem. and Pharmacognosy,, Univ. of Illinois at Chicago, Chicago, IL

Abstract: Migraine is an extraordinarily common brain disorder for which therapeutic options continue to be limited. The nitric oxide pathway has been heavily implicated in migraine, and the nitric oxide donor nitroglycerin (NTG) has been shown to reliably trigger migraine in humans. NTG stimulates soluble guanylate cyclase (sGC), the main NO receptor in the body, which increases production of cGMP. The guanylate cyclase pathway is of particular relevance to migraine as upregulation of cGMP by NTG or sildenafil (a phosphodiesterase 5 inhibitor) produces headache but no other type of pain. Previously we have shown that stimulating sGC produces a migraine-associated pain in mice, which was reversed by prototypic anti-migraine medications. The aim of this study is to determine the effectiveness of sGC inhibitors as novel anti-migraine therapies. C57bl6/J mice were treated acutely and chronically with either vehicle or RG2-12 prior to administration of NTG, vehicle, or the sGC stimulator VL-102. Basal and post-treatment mechanical thresholds were determined using von Frey hair stimulation. RG2-12 reversed acute hyperalgesia and basal hypersensitivity induced by both VL-102 and NTG. Acute treatment with RG2-12 also alleviated established hyperalgesia produced by chronic administration of NTG or VL-102. These results indicate that inhibition of soluble guanylate cyclase alleviates migraine-associated hyperalgesia in a mouse model of acute and chronic migraine. These data indicate that soluble guanylate cyclase inhibitors could be a promising therapeutic target for the treatment of migraine. Title: Effect of SUVN-H1106036, a CB2 receptor agonist, on spinal wide dynamic range neuronal activity in neuropathic rats

Authors: V. GOURA, *A. K. SHINDE, A. VUYYURU, R. KALLEPALLI, P. JAYARAJAN, R. ABRAHAM, S. DARIPELLI, V. KAMUJU, G. BHYRAPUNENI, V. BHATTA, K. KANDUKURI;

Abstract: A selective canabinoid 2 receptor (CB2) agonist SUVN-H1106036 showed anti-nociceptive effects in rat models of pain. We investigated the effect of SUVN-H1106036 on wide dynamic range dorsal horn neuronal firing in an animal model of nerve injury. Chronic constricted sciatic nerve injury model of neuropathic rat was selected after 2-3 weeks of the nerve ligation. Selected rats were used for investigation of neuronal excitability in dorsal horn region of the spinal cord using *in vivo* electrophysiology techniques. Microdialysis was carried out in dorsal horn in order to evaluate the changes in monoamine levels. Peripheral nerve injury is associated with increased excitability of sensory neurons and decreased monoaminergic transmission. SUVN-H1106036 and Gabapentin attenuated spontaneous and mechanically-evoked neuronal firing of spinal wide dynamic range neurons. In spinal microdialysis SUVN-H1106036 elevated the levels of monoamines providing the neurochemical basis for the anti-nociceptive activity of the test compound.

Title: Dural sensory innervation expresses unique opioid and adrenergic receptor subtypes: Implications for migraine pathology and treatment

Authors: F. L. RICE[1], J. R. BOURGEOIS[2], J. Y. XIE[3], C. M. KOPRUZINSKI[3], N. EYDE[3], F. PORRECA[3], *P. J. ALBRECHT[2];

Abstract: Effective prevention and treatment of migraine headaches remains a major clinical challenge. A high priority therapeutic target has become the potent vasodilator Calcitonin Gene Related Peptide (CGRP), which is increased in jugular vein blood of people with migraines. A postulated source of the increased CGRP is hyperactivity of trigeminal sensory innervation to meningeal arteries of the dura mater, with resultant neurogenic inflammation (excessive vasodilatation, plasma extravasation, and mast cell infiltration) as the underlying etiology of pain. However, despite many studies, a comprehensive assessment of the multi-molecular characteristics of dural innervation remains lacking. Here, we discriminate among molecular varieties and distributions of sensory and autonomic innervation of the dura to provide new high-priority target identification and evidence for rational development of novel therapeutic strategies. We used the highly predictable patterns of meningeal arteries in adult male rats to collect identical sectors of 4% paraformaldehyde fixed dura. The repeatable whole-mount samples enabled compiling of double and triple immunolabel combinations designed to profile innervation based on functionally-implicated neurochemical characteristics. Our work emphasizes the extensive and diffuse innervation of the dura between the meningeal arterial arbors among a dense capillary meshwork. Utilizing the pan-neuronal marker PGP9.5 as the baseline for total innervation immunolabeling, we identified noradrenergic sympathetic innervation co-expressing neuropeptide Y (NPY), Tyrosine Hydroxylase (TH), and Dopamine beta-Hydroxylase (DβH), at least two type of likely Aδ fibers co-expressing 200kD neurofilament protein (NF) and myelin basic protein (MBP), and several varieties of C-fibers (NF- and MBP-negative) that mostly express CGRP. Importantly, intimate intertwining of individual sympathetic fibers and sensory C-fibers expressing CGRP and that also co-expresses an α-adrenergic receptor were observed, suggesting a sympathetic regulation of the sensory fiber activity. Furthermore, we observed that nearly all dural peptidergic (CGRP-positive) C-fibers bind the isolectin IB4, and coexpress the δ-opioid receptor (δOR), while largely lacking μOR expression. This contrasts with cutaneous peptidergic C-fibers of which most lack IB4 binding, and express μOR but not δOR. These important properties of dural sensory innervation provide the basis for novel migraine treatment strategies.

Title: *In vivo* imaging of mouse auditory cortex during associative fear learning

Authors: *S. N. GILLET[1], H. K. KATO[2], M. A. JUSTEN[2], J. S. ISAACSON[2];
[1]Ctr. for Neural Circuits and Behavior, [2]UC San Diego, La Jolla, CA

Abstract: Although previous work has suggested that auditory fear conditioning causes a rapid increase in cortical representations to conditioned tones, how sensory representations are modulated across cortical layers is unclear. To address this question we developed a strategy for studying auditory fear learning in head-fixed mice. This approach allows us to use chronic two-photon imaging and GCaMP6 to examine the activity of identified cell populations throughout all phases of auditory fear learning (conditioning, memory retrieval, and extinction). We first used an optogenetic approach to determine whether auditory cortex is required for discriminative memory retrieval. VGAT-ChR2 mice and LED illumination were used to rapidly silence firing activity across all layers of auditory cortex. Head-fixed mice were conditioned in a discriminative fear learning task in which the suppression of licking behavior indicated a fear response. Mice were conditioned with two FM tones differing by one octave: one paired with a mild tail shock (CS+), and the other unpaired (CS-). Fear memory retrieval was tested one day after conditioning. On control trials, mice showed a robust fear response to the CS+, but not the CS-. In contrast, optogenetic inactivation of the auditory cortex contralateral to the sound stimuli on interleaved trials abolished the animals' ability to discriminate between the CS+ and CS- tones. In control experiments, discriminative responses were intact when the ipsilateral cortex was inactivated during memory retrieval. These results indicate that auditory fear conditioning is effective in head-fixed mice and that the auditory cortex is required for the correct discrimination of CS tones. We next examined whether discriminative fear conditioning modulates cortical sensory representations. We performed chronic, *in vivo* two-photon imaging of layer 5 pyramidal cells and imaged responses of the same populations of neurons to the CS+ and CS- before and after tone/shock conditioning. Preliminary experiments suggest that layer 5 sensory representations of the two tones become more dissimilar after conditioning. These data suggest that auditory cortex contributes to discriminative learning via an increase in contrast between behaviorally relevant and irrelevant tones.

Title: Experience-dependent modulation of sound representations in mouse primary auditory cortex

Authors: *H. K. KATO, S. N. GILLET, J. S. ISAACSON;
UCSD Sch. of Med., La Jolla, CA

Abstract: Acoustic experience during early development modulates the maturation of sound representations in the auditory system. During brief critical periods in rodents, repeated passive exposure to a tone results in enlarged cortical representations of that tone. In contrast, the adult nervous system is largely refractory to this treatment. Here we use chronic, two-photon Ca2+ imaging to reinvestigate the effects of simple passive experience on the responses of the same populations of neurons in primary auditory cortex (A1). We find a marked reduction in excitatory responses of layer 2/3 pyramidal neurons to tones experienced repeatedly across five days. This “habituation” is accompanied by an increase in the fraction of neurons with inhibitory responses to the experienced tone. This increased inhibition was not observed in thalamocortical recipient layer 4, suggesting a cortical source of layer 2/3 plasticity. Furthermore, cell type-specific Ca2+ imaging revealed that habituation enhanced the activity of somatostatin-expressing, but not parvalbumin-expressing interneurons. Together, our results demonstrate the neuronal correlates of habituation in A1 and suggest a role for specific local inhibitory circuits in this modulation. Currently, we are studying how positive associative learning changes sound representations.

Title: Neural coding of self-generated sounds in mouse auditory cortex

Authors: *D. M. SCHNEIDER, R. MOONEY;
Dept. of Neurobio., Duke Univ., Durham, NC

Abstract: Sounds generated by our own movements (reafferent sounds) often co-occur with sounds emanating from the environment (exafferent sounds), and distinguishing between these two sound classes is critical to many forms of auditory-guided motor learning, such as speech and musicianship. To distinguish between environmental and self-generated sounds, the brain may take advantage of the fact that self-generated sounds can be anticipated, since they are time-locked to our movements and their acoustic features are often predictable. One strategy for exploiting this predictability is through copies of motor-related commands, termed corollary discharge, that are sent to the auditory system, where they may suppress or otherwise modulate predictable self-generated sounds. A corollary discharge circuit connecting the motor cortex to the auditory cortex in the mouse is active during movement and suppresses auditory cortical pyramidal neurons, providing a potential substrate for such a mechanism. However, it is not known whether copies of motor-related signals acting at the level of the auditory cortex specifically modulate self-generated sounds. To address this question, we developed a novel acoustic virtual reality paradigm in which we can precisely control and manipulate the timing, spectral features and predictability of the sounds produced by a mouse's movements. Mice ran on a quiet, non-motorized treadmill, the rotational velocity of which was monitored in real time, and brief tone pips of a fixed pitch were presented through a speaker at a rate proportional to the treadmill's velocity. Over several days of acclimation, mice ran the equivalent of many hundreds of meters and heard several thousand reafferent tone pips. After acclimation, we made extracellular recordings from multiple auditory cortical neurons while mice ran and rested on the treadmill and listened to expected reafferent sounds as well as unexpected "probe" sounds that deviated from the anticipated pitch. Preliminary experiments indicate that for the majority of auditory cortical neurons, sound-evoked responses are suppressed during movement, but that the sign and degree of movement-related modulation is heterogeneous and a subset of neurons have enhanced responses during movement. Ongoing experiments aim to determine the degree to which movement-related modulation is specific to predictable self-generated sounds and to identify circuits through which neural responses to self-generated sounds may be selectively modulated.

Title: The effects of pre and post-natal exposure to extremely low frequency electric fields on mismatch negativity component of the auditory event-related potentials

Authors: *P. A. YARGICOGLU[1], D. AKPINAR[2], D. KANTAR GOK[2], M. ASLAN[3], S. OZEN[4];
[1]Akdeniz University,Faculty of Medicine, Dept. of Biophysics, Antalya, Turkey; [2]Akdeniz University, Fac. of Medicine, Dept. of Biophysics, Antalya, Turkey; [3]Akdeniz University, Fac. of Medicine, Dept. of Biochem., Antalya, Turkey; [4]Akdeniz University, Engin. Faculty, Department of Electrical and Electronics Engin., Antalya, Turkey

Abstract: Most public exposure to extremely low frequency electric fields (ELF-EFs) comes from electrical appliances, alternating current (AC) transmission and distribution lines. There was no study examining developmental effects of 50 Hz Electric fields (EFs) on Mismatch Negativity (MMN) recorded from rats. Therefore, our study aimed to investigate MMN, apoptosis and oxidative brain damage in rats exposed to pre and/or postnatal 50 Hz EF at 12 kV/m intensity for 1 hour per day. Forty Wistar male rats were divided into four groups; Control group (C), prenatal group were exposed to EF during pregnancy (Pr), post-natal group were exposed to EF after pregnancy for three months (Po), pre+postnatal group were exposed to EF during pregnancy and continued to be exposed to EF during three months (PP). Pregnant rats of Pr and PP groups were exposed to 50 Hz EF (12 kV/m; 1 h/day) while those of C and Po groups were kept under the same experimental conditions without being exposed to any EF during pregnancy. Following parturition, rats of PP and Po groups were exposed to EF whereas rats of C and Pr groups were kept under the same experimental conditions without being exposed to any EF during 90 days. Post natal day 90, MMN were recorded in urethane-anesthetized rats by electrodes positioned stereotaxically to the surface of the dura. After recordings, brain tissues were removed for histological and biochemical analysis. The MMN amplitude was higher to deviant tones than to standard tones. It was decreased in all experimental groups compared with the C group. 4-hydroxy-2-nonenal (4-HNE) levels were significantly increased in the Po group with respect to the C group whereas they were significantly decreased in the PP group compared

with Pr and Po groups. Protein carbonyl levels were significantly decreased in the PP group compared with C, Pr and Po groups. In conclusion, EF decreased MMN amplitudes possibly induced by lipid peroxidation.

Title: Magnitude of stimulus deviance influences on mismatch activity in common marmosets

Authors: *M. KOMATSU, K. TAKAURA, N. FUJII;
RIKEN Brain Sci. Inst., Saitama, Japan

Abstract: Mismatch negativity (MMN) is a component of event-related potentials evoked by violations of the regularity in sensory stimulus-sequences in human. Recently, MMN has received attention as a clinical and translatable biomarker of psychiatric disorders such as schizophrenia to develop animal models of these psychiatric disorders. In this study, we investigated MMN in common marmosets, which is an important non-human primate model with genetic manipulability. We recorded the electrocorticograms (ECoGs) from two common marmosets with epidurally implanted electrodes covering a wide range of cortical regions. The 28- or 32- channel ECoG array was epidurally implanted on the left hemisphere of each marmoset. ECoG recordings were conducted in passive listening condition with a roving oddball paradigm. Repetitive tone-sequences with 20 types of frequency (250 - 6727 Hz with an interval of 1/4 octaves) are randomly presented. We considered the last tones of sequences as standard, and the first tones of sequences as deviants. First, we calculated ERPs for standards and deviant stimulus, respectively. Then, difference wave is obtained by subtracting the deviant stimulus ERP from the standard stimulus ERP. We observed significant negative and positive components

of the difference wave, which have a peak between 50-250 ms after the onset of the deviants, in the temporal, frontal, and parietal areas of marmosets' brain. Furthermore, we investigated the influence of the difference between standard and deviant frequencies on the amplitude of those significant components. Some of those components in the temporal and frontal areas revealed a correlation between its amplitude and the magnitude of stimulus deviance. These results comparable with MMN in human and macaque monkey, and mismatch activity in common marmoset seems to provide a tool to understand the neural basis of MMN.

Title: Priming effect of a stimulus-repetition: Repetitive presentation of a stimulus facilitates the cortical response to the other stimuli subsequent to the repetition

Authors: *K. TAKAURA, M. KOMATSU, N. FUJII;
RIKEN Brain Sci. Inst. - Wako, Wako City, Saitama, Japan

Abstract: An event-related potential called the mismatch-negativity (MMN) is a possible neural signature of the ability to detect changes in the sensory signal-flow. MMN has been assessed by subtraction of the neural response to the repeatedly presented stimulus (Standard) from the response to the deviant stimuli (Deviant) subsequent to the repetition, which leads to a debate whether MMN can be solely explained by the stimulus-specific adaptation (SSA), a phenomenon of the neural response attenuation with the repetitive presentation of a stimulus. An early literature (Javitt et al., 1996) proposed an additional neuronal mechanism, arguing that the repetition of one stimulus leads to the decrease of the inhibition-level of the neurons not sensitive to the repeated one, but this idea has not received much empirical supports. To address this issue, we examined the effect of the repetition-number on the cortical responses to Standard, Deviant, and the mismatch-activity (MMA), respectively. If the above idea is correct, the population-response to Deviant could be enlarged by the increase in the number of the preceding repetition. We recorded the electrocorticogram from a wide range of the cortical regions in two macaque monkeys passively exposed to the auditory roving oddball-sequence. Trains of 3, 5 or 11 same

tone was pseudo-randomly presented without inter train pauses. We used 20 kinds of tones different in pitch, and the stimulus onset asynchrony was 503 ms. We took the last tone in each train of n-tones (n = 3, 5, or 11) and the first tone of the subsequent train as a pair of Standard and Deviant for n-repetition. As the number of repetition increased, the significantly larger response to Deviant than Standard, i.e. MMA, occurred in more widely distributed cortical regions involving the temporal, frontal and parietal cortices, and MMA in each electrode became larger. Surprisingly, the increment of MMA as a function of the repetition-number was mainly due to the augmentation of the response to Deviant. The attenuation of the response to Standard was less pronounced. We also observed that Deviant following 11-repetition evoked the auditory response in a subset of the electrodes on the frontal cortex and anterior part of the temporal cortex that were not responsive to the stimuli presented with less or without preceding repetition. These results cannot be explained by SSA, and indicate that the repetitive presentation of one-stimulus facilitates the response of the brain to the other stimuli following the repetition, which seems compatible with the proposal by Javitt et al (1996). MMN would relay on not only SSA, but also on the facilitative effect of the stimulus-repetition.

Title: Multiple mechanisms for stimulus-specific adaptation in the primary auditory cortex

Authors: *R. G. NATAN[1], J. J. BRIGUGLIO[1], L. MWILAMBWE-TSHILOBO[1], E. M. GOLDBERG[3,2], M. N. GEFFEN[1];

Abstract: Adaptation to stimulus context is a ubiquitous property of cortical neurons and is thought to enhance efficiency of sensory coding. Yet the specific neuronal circuits that facilitate cortical adaptation remain unknown. In the primary auditory cortex (A1), the vast majority of neurons exhibit stimulus-specific adaptation (SSA), responding weakly to frequently repeated tones and strongly to rare tones in oddball stimuli. This form of history-dependent adaptation may increase cortical sensitivity to rare sounds. Here, we identify three distinct components shaping cortical SSA. The current source density sink amplitude profile across cortical layers in response to common and rare tones revealed that thalamo-cortical inputs to A1 exhibit SSA, albeit at lower levels than spiking responses. Furthermore, we found that two types of inhibitory interneurons contribute to SSA in a complementary fashion. Optogenetic suppression of parvalbumin-positive interneurons (PVs) led to an equal increase in the putative excitatory neuron firing rates to both common and rare tones (C). Suppression of somatostatin-positive interneurons (SOMs) led to an increase in neuronal responses to frequent, but not to rare tones. While the inhibitory effect of SOMs on excitatory neurons increased with successive tone repeats, PVs provided constant inhibition throughout the stimulus sequence. The effects of PVs and SOMs differed across cortical layers, consistent with their distribution across layers. Remarkably, both PVs and SOMs exhibited stimulus-specific adaptation. We constructed a firing rate model of a coupled excitatory-inhibitory neuronal population. Our simulation revealed how inhibitory neurons, despite exhibiting firing rate adaption themselves, increase adaptation in excitatory neurons. Taken together, our results demonstrate that SSA in the auditory cortex is a product of multiple adaptation mechanisms.

Title: On reward prediction errors and sensory representations: a role for dopamine in refining perception

Authors: *R. HOLCA-LAMARRE[1,2], K. OBERMAYER[1,2], J. LUECKE[3,1];
[1]Technische Univ. Berlin, Berlin, Germany; [2]Bernstein Ctr. for Computat. Neurosci., Berlin, Germany; [3]Dept. of Med. Physics and Acoustics, Univ. Oldenburg, Oldenburg, Germany

Abstract: The ventral tegmental area (VTA) contains dopamine releasing neurons whose activity reflects reward prediction errors. Activity in the VTA has a potent effect on cortical sensory representations: pairing stimulation of the VTA with presentation of an auditory tone, for instance, increases the representation area of this tone in the primary auditory cortex. It is unclear why a signal related to reward prediction errors should have such an effect on cortical representations. Here, we use a neural network model to examine this question. We extend a model of synaptic plasticity and representational learning to reproduce the effects of VTA activation on the network's representation: in the model, as in animals, pairing stimulus presentation with VTA activation shifts the synaptic weights of neurons towards the paired stimulus. The network is subjected to a classification task and is rewarded for taking correct classification decisions. Additionally, at each trial, the network makes a prediction about the reward it expects to receive. The difference between the predicted and received reward makes up a reward prediction error; this error activates the VTA. We perform parameter exploration to determine the optimal VTA activation depending on the value of the reward prediction error. We find that the VTA activation profile that is optimal with respect to classification performance in the model matches the activation profile observed in animals. During training, VTA activation refines synaptic weights with respect to the classification task and significantly improves the network's performance on the task. Our model therefore provides an explanation as to why reward prediction error signals affect sensory representations in animals.

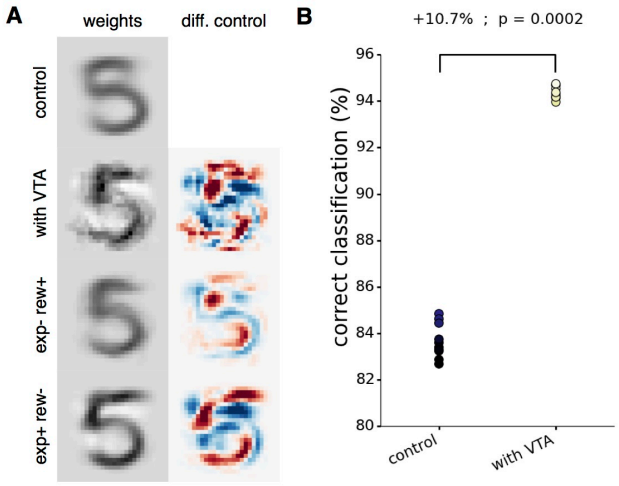

*Figure 1: Modelling the effects of VTA activation in the network refines synaptic weights **(A)** and leads to large improvements in classification performances **(B)**.*

Title: Neural evidence for non-reward prediction errors in the sensory domain

Authors: ***G. HORGA**[1], E. JUNG[2];
[1]Columbia Univ. Med. Ctr. (NYSPI), New York, NY; [2]Barnard Col., NYC, NY

Abstract: Predictive-coding models suggest that the brain uses internal, predictive models of the external world to anticipate forthcoming stimuli and minimize coding of redundant information. A wealth of evidence indicates that similar predictive codes govern reward processing, but little is known about whether predictive coding also supports sensory processing. Here, using an axiomatic approach derived from neuroeconomics we formally tested whether healthy human participants signal (non-reward) sensory prediction errors. Participants completed a probabilistic speech discrimination task that explicitly manipulated expectations for hearing speech or non-speech vocal sounds on each trial (probabilities of speech vs. non-speech: 0, 0.25, 0.5, 0.75, 1). Functional magnetic resonance imaging (fMRI) was acquired while participants performed the task to determine whether neural signals at the presentation of speech or non-speech auditory stimuli conformed to sensory prediction errors. Behaviorally, participants discriminated stimuli more accurately and faster on trials that presented more certain information (0/1>0.25/0.75>0.5), indicating that they incorporated probabilistic information into the decision process. Post-task pleasantness ratings indicated that speech and non-speech stimuli were equally pleasant. Analysis of fMRI data revealed that blood-oxygen-level-dependent signals in voice-selective regions of temporal cortex and ventral striatum tracked non-reward, signed prediction errors. These findings suggest that predictive coding is a general coding scheme used by brain systems outside the reward domain.

Title: Activity of neurons in lateral prefrontal cortex during performance of an auditory short-term memory task

Authors: *B. H. SCOTT[1], P. YIN[2], L. H. LEE[1], A. BROWN[1], M. MISHKIN[1];
[1]Lab. Neuropsychol, NIMH, Bethesda, MD; [2]Neural Systems Laboratory, Inst. for Systems Res., Univ. of Maryland, College Park, MD

Abstract: Short-term memory (STM) for visual stimuli has been shown to engage both prefrontal cortex (PFC) and the modality-specific cortical areas that support visual perception. Although monkeys can perform auditory STM tasks, their ability is limited relative to that in vision and appears to depend on passive retention of a stimulus trace. Neurons in rostral superior temporal cortex (rSTC) carry a potential correlate of this sensory trace, but the contribution of the dorsolateral PFC (dlPFC) to this process is unresolved. We recorded single-unit activity in dlPFC (the caudal portion of the principal sulcus, predominantly its dorsal bank) while a monkey performed a serial delayed-match-to-sample (DMS) task. On each trial, the monkey grasped a bar to initiate the presentation of a sample sound (~300 ms duration), followed by 0-2 nonmatch sounds (delay interval ~1 s), before the sample was presented again as a match; the monkey released the bar to indicate a match. Of 101 recorded units, 39 responded to sound, some at a surprisingly short onset latency (median 44 ms, minimum 22 ms). Firing rate was stimulus-selective in 30% of responsive units. Two classes of task-related effects were identified: First, the auditory response was modulated by task context in one-third of units, with 10/39 showing match suppression (relative to the sample presentation), and 3/39 showing match enhancement. However, suppression and enhancement were equally prevalent for match or nonmatch sounds, indicating that these effects were not stimulus-specific. Second, activity during the first delay period was shifted from baseline in one-half of units, with delay suppression (14/39) being more common than delay enhancement (4/39). Delay suppression was typically sustained throughout the trial duration, and could possibly drive the same effect previously observed in rSTC. Other forms of delay activity were qualitatively different and more variable in dlPFC than in rSTC. As in rSTC, there was little evidence for a sustained, stimulus-specific sensory trace in the delay activity of dlPFC neurons. Unlike rSTC, suppression and enhancement of match responses in dlPFC were not stimulus-specific, but seemed to reflect a generalized modulation of responses

following the sample. Responses in some units were strongly dependent on task engagement. In addition, firing rate in dlPFC was often modulated around the time of the motor response, which was rarely seen in rSTC. These observations confirm that dlPFC receives short-latency auditory inputs, but suggest that activity in this region also encodes domain-general aspects of the serial DMS task.

Title: How the brain discovers patterns in sound sequences

Authors: ***M. CHAIT**[1], N. BARASCUD[1], T. PETSAS[1], M. PEARCE[2], K. FRISTON[1]; [1]UCL, London, United Kingdom; [2]QMUL, London, United Kingdom

Abstract: Patterns or regularities in on-going sound sequences are key cues to understanding complex auditory environments. The pattern of sound often conveys the identity and state of objects within the scene and also enables the listener to predict future events, supporting efficient interaction with the surrounding environment. This presentation will review our recent behavioral and brain imaging findings that demonstrate just how sensitive we are to complex sound patterns, including those that we have never previously encountered and, indeed, maybe unlikely to encounter outside of the laboratory. Our findings suggest that the auditory brain is a remarkably well-tuned 'pattern seeker', continuously scanning the unfolding auditory input for regularities, even when listeners' attention is focused elsewhere. Brain responses reveal online processes of evidence accumulation - dynamic changes in tonic activity precisely correlate with the expected precision or predictability of ongoing auditory input -both in terms of deterministic (first-order) structure and the entropy of random sequences. Source analysis demonstrates an interaction between primary auditory cortex, the hippocampus and inferior frontal gyrus in the process of 'discovering' the regularity within the ongoing sound sequence. The results are consistent with precision based predictive coding accounts of perceptual inference and provide

compelling neurophysiological evidence of the brain's capacity to encode high order temporal structure in sensory signals.

Title: Cortico-striatal interactions during reversal learning with different reinforcement schedules in a two-way active avoidance task

Authors: ***A. L. SCHULZ**[1], M. L. WOLDEIT[1], A. I. GONCALVES[2], M. BROSCH[2], F. W. OHL[1,2];
[1]Leibniz Inst. for Neurobio., Magdeburg, Germany; [2]Otto von Guericke Univ., Magdeburg, Germany

Abstract: Due to their demonstrated importance in reinforcement learning and reward processing, cortico-striatal interactions should also take part in serial reversal learning that demands multiple switches of stimulus-action contingencies and henceforth represents a scenario for cognitive flexibility. While computational models, like the actor-critic variant of temporal difference learning, implicitly assume a modification of cortico-striatal functional coupling in the reinforcement schemes, it is not clear if a task that encompasses multiple contingency changes would repeatedly adjust this cortico-striatal coupling or is based on a different mechanism. Adding to this, reinforcement learning models continuously have fallen short of explaining the different learning dynamics found in many serial reversal tasks for animals. A neurophysiological understanding of sensory cortico-striatal interactions during learning is still in its early stages and previous work has not yet addressed the question how these interactions are modulated in serial reversal tasks. Therefore we trained Mongolian gerbils in an auditory discrimination two-way-active-avoidance task with multiple contingency reversals, employing frequency modulated tones as conditioned stimuli. We used two reinforcement schedules: one

group received symmetric aversive reinforcement on false alarm and miss responses, while the second group only received punishment for misses. Simultaneously we recorded local field potentials from the auditory cortex and ventral striatum and assessed functional coupling of both areas during acquisition and reversal phases by analyzing the neuronal coherence. We expect that cortico-striatal interactions during serial reversal learning of auditory discrimination problems will have a different time course than during the initial discrimination phase. Since preliminary data show that both reinforcement schedules produce different superordinate strategies in the serial reversal task, it is expected that this will also influence auditory cortico-striatal functional coupling.

Title: Auditory discriminative fear conditioning utilizing a visual secondary reinforcer

Authors: *J. M. BOWDEN, S. J. CONNELL, A. POREMBA;
Psychology, Univ. of Iowa, Iowa City, IA

Abstract: Learning to escape aversive stimuli and effectively predicting the consequences of different cues and responses provides animals with an increased chance of survival. Discriminative avoidance conditioning affords the opportunity to examine these specific behaviors. The present experiment investigated the influence of a secondary reinforcer on an auditory discriminative active avoidance conditioning task. Building on the work of Poremba and Gabriel (1997), originally conducted in rabbits, an adaptation of the discriminative active avoidance paradigm was implemented using male Sprague-Dawley rats (N=35). Pilot studies were used to optimize task contingencies and parameters for learning in rats, e.g., separate versus combined footshock and tailshock, delay interval duration, and auditory stimulus characteristics. In the final paradigm, animals were trained to avoid a signaled mild tail and foot shock (US) by spinning a small wheel at least 22.5 degrees using their forepaws as the conditioned response (CR) during the high-frequency auditory cue, the positive conditioned stimulus (CS+). A second

low-frequency auditory cue signaled safety, the negative conditioned stimulus (CS-), and the absence of shock. CS+ and CS- trials were presented with equal probability in random order with an intertrial interval of 20 seconds. The CS+ always preceded the US, and CS presentations had a duration of 3 seconds and were terminated when a response was made. Eleven of the male rats were trained using a 1 s light as a secondary reinforcer following correct responses to the CS+ (successful avoidance of the shock). Preliminary data show increased performance in the group of subjects trained with the secondary reinforcer on three measures. Animals trained without a secondary reinforcer learned the task within 30-80 days and animals trained with the light cue acquired the task within 8-25 days. A higher proportion of animals learned using the secondary reinforcer, with 72.7% successfully acquiring the task compared with 12.5% without the light. These animals also showed significantly steeper learning curves, and higher asymptotic discrimination performance. The results suggest that a visual secondary reinforcer enhances learning during an auditory discriminative avoidance conditioning task. This task will be used to expand exploration of the active avoidance neural circuitry and investigate its implications regarding the cooperation and organization of processing across multiple sensory systems.

Title: Neural correlates of audiomotor map learning

Authors: *M. THOMPSON[1,2], A. B. HERMAN[3], D. C. HARRELL[3], J. HOUDE[3], S. NAGARAJAN[3];
[1]UCSF, San Francisco, CA; [2]UC Berkeley-UCSF Joint Grad. Program in Bioengineering, Univ. of California, Berkeley, Berkeley, CA; [3]Univ. of California, San Francisco, San Francisco, CA

Abstract: Typically, sensorimotor learning studies have used visuomotor adaptation or speech adaptation. In this study, we sought to derive more general principles about audiomotor control

by examining auditory feedback processing through the use of neuroimaging and a magnetoencephalography imaging (MEGI)-compatible touchpad. Initial study was conducted with non-speech tone stimuli, and we are currently extending this paradigm to speech sounds. Subjects learned a novel audiomotor map task, eventually developing an internal model of auditory feedback triggered in response to locations they touched on the touchpad. Following training, 15 subjects were given a target cue via headphones and attempted to reproduce it by touching the corresponding area on the touchpad and subsequently receiving feedback. 10 out of 15 subjects demonstrated better-than-chance responses, improving upon their initial performance, indicating stable learning. In addition to demonstrating an increased rate of correct responses, evidence for development the internal model of auditory expectations was seen in significant MEGI differences in post-learning neural response between correct and incorrect responses. These differences showed efference copy-based suppression in the auditory cortex in correct feedback and error/conflict monitoring in frontal areas in incorrect feedback. Notable frontal lobe suppression was also found in high gamma band in correct responses compared to when the subject passively listened to tones (n=4). Additionally, some left temporal lobe suppression was seen in typical correct responses with expected auditory feedback compared to "surprise" trials in which, after training, subjects correctly identified the location for the probe tone but received unexpected auditory feedback (n=4). Increased activation in areas responsible for error monitoring in incorrect trials and suppression in sensorimotor areas during correct responses is consistent with efference copy comparison. We are now examining speech stimulus learning and adaptation behavior with this paradigm. By investigating speech and non-speech auditory feedback processing without speech motor feedback, we can elucidate more general auditory-motor control effects.

Title: Human auditory cortical response to low-level acoustic features shifts during perceptual enhancement

Authors: *C. HOLDGRAF[1], W. DE HEER[2], B. PASLEY[3], J. RIEGER[3], J. LIN[4], N. CRONE[5], R. T. KNIGHT[3], F. THEUNISSEN[3];

Abstract: Listening to human speech is a hierarchical process in which low-level features such as spectrotemporal energy are combined to create high-level features such as words. This is often treated as a "bottom-up" series of feature extraction steps. However, top-down signals from cortical regions that respond to "high-level" features also influence regions that process lower-level stimulus features. The information we receive from the world is often noisy or incomplete, and these high-level inputs may facilitate making sense of this noisy information by "filtering out" unwanted streams of information or "filling in" missing information in the stimulus. However, there is little evidence to show that high-level auditory/linguistic features affect the representation of specific low-level features in auditory cortex. The present study provides evidence for a shift in the auditory cortical response to low-level acoustic features during a hierarchical perceptual enhancement task. We filtered spoken sentences from the TIMIT database using the modulation transfer function, rendering the sentences unintelligible. We presented these sounds both before and after presentation of an unfiltered complete sentence to patients implanted with electrocorticography (ECoG) grids. We focused on the high gamma band (HG; 80-175 Hz) of the ECoG signal in 7 patients with subdural grids over perisylvian cortices. After hearing the unfiltered sound, comprehension of the following filtered version is enhanced due to the experience with high-level stimulus features (here referred to as "hierarchical perceptual enhancement"). We investigated the influence of high-level sentence context on the neural response to the same sentence's degraded version by constructing linear encoding models of electrode response to acoustic features and comparing model fits to pre- and post-unfiltered stimuli. We found that listening to a filtered sound after hearing its unfiltered version alters auditory cortex response to low-level acoustic features, rendering them more similar to the response to unfiltered speech. We also show that acoustic models built from unfiltered stimuli provide better predictions about brain activity in the post-unfiltered trial. Finally, receptive fields fit on the neural response to filtered speech during perceptual enhancement respond more strongly to speech stimuli than their unintelligible speech counterparts. The results may reflect an automatic process of hierarchical perceptual enhancement that shapes the neural response to low-level acoustic features in order to facilitate processing of speech in noise.

Title: Cortical neuroplasticity in single-sided deafness before and after cochlear implantation

Authors: *H. GLICK, A. SHARMA;
Speech, Language, & Hearing Sci., Univ. of Colorado, Boulder, CO

Abstract: The extent to which sensory pathways reorganize in single-sided deafness (SSD) is not well understood. While cochlear implantation has proved beneficial in bilateral pediatric deafness, there is currently little evidence demonstrating the efficacy of cochlear implantation in children with SSD. The purpose of this study was to examine changes in cortical development and neuroplasticity in adults and children with SSD before and after cochlear implantation. High-density 128-channel electroencephalography (EEG) was used collect cortical auditory, visual, and somatosensory evoked potentials (CAEP, VEP, SSEP) in adults and children with SSD before and after implantation. Behavioral correlates of speech perception in noise were also measured. Prior to implantation, high-density EEG showed abnormal auditory activation patterns and evidence of increased cognitive load and cross-modal re-organization. Post-implantation, there is clear evidence of morphological changes in the auditory cortical responses consistent with increases in auditory speech perception in noise with some residual evidence compensatory changes in neural resource allocation. With further research, it is possible that markers of cross-modal re-organization or evidence of cognitive load may help predict cochlear implant outcomes in SSD patients and guide the intervention and rehabilitation process.

Title: Perceptual learning of auditory frequency discrimination transfers to untrained frequencies with TPE training

Authors: *C. YU[1], Y.-Z. XIONG[1], Y.-X. ZHANG[2];
[1]Peking Univ., Beijing, China; [2]Beijing Normal Univ., Beijing, China

Abstract: Perceptual learning is typically specific to the trained stimuli features. However, recent research on visual learning has shown that such stimulus specificity could be removed with a training-plus-exposure (TPE) procedure, in which subjects are exposed to the to-be-transferred stimulus feature via practicing an irrelevant task (Zhang et al., 2010). Here we extended this visual training method to auditory perceptual learning to study the transfer of learning of auditory tone frequency discrimination (FD). FD learning is known to be specific to the trained tone frequency. In addition, FD is unaffected by learning of temporal interval discrimination (TID) with the same stimuli (Wright, et al, 2010). We thus used the TID task to provide exposure to untrained tone frequencies. In the first experiment, listeners were trained with FD at 1 kHz plus exposure at 4 kHz via TID, which improved FD significantly at both frequencies. As a baseline, listeners trained with 1-kHz FD only did not show learning transfer to 4 kHz, and listeners trained with 4-kHz TID did not improve on FD at either frequency. The results indicate that TPE enabled complete transfer of FD learning from 1 kHz to 4 kHz. We next asked whether the transfer-enabling effect of TPE training is contingent on the neural coding mechanisms. Auditory nerve responses can phase-lock to the sound waveform up to about 5 kHz, rendering higher frequencies to be encoded by a 'place code', while lower frequencies are encoded temporally. In the second experiment, we used TPE to enable transfer of FD learning from 6 kHz to 1 kHz, across the gap between the temporal and place coding mechanisms. The TPE group improved significantly at both 1 and 6 kHz, while the baseline 6-kHz FD training group did not improve at 1 kHz, and the 1-kHz TID training group did not improve on FD at either frequency. The transfer of TPE group to 1-kHz was similar to learning obtained by directly training 1-kHz FD. Thus, TPE enabled complete learning transfer across different coding mechanisms. The current results, combined with previous observations of visual learning transfer, suggest that learning under TPE possibly engages high-level processes that function regardless of modality and the specific neural encoding mechanisms involved.

Title: Trafficking of HCN1 in the early secretory pathway: Discovery of two counteracting ER trafficking signal using Xenopus photoreceptors as a model system

Authors: *S. A. BAKER, J. G. LAIRD, D. M. YAMAGUCHI, Y. PAN;
Biochem., Univ. of Iowa, Iowa City, IA

Abstract: The hyperpolarization-activated cyclic nucleotide gated family of channels (HCN1-4) play diverse roles throughout the nervous and cardiac systems; they can function as pacemakers, shape resting membrane potential, modulate synaptic output, or integrate dendritic signaling. Rod photoreceptors selectively express HCN1, and it functions to carry a feedback current that shapes visual responses under medium and bright light conditions. Rod photoreceptors are linearly compartmentalized with a highly specialized ciliary compartment dedicated to light detection. HCN1 is excluded from this compartment and instead is found concentrated in the soma, known as the inner segment. As part of a long-standing interest in dissecting protein trafficking pathways in photoreceptors we have investigated the mechanisms controlling the localization of HCN1. We first investigated the role of the HCN1 accessory subunit, TRIP8b. In the retina of TRIP8b KO mice, HCN1 levels are reduced but trafficking to the inner segment plasma membrane, and visual function, is maintained. Therefore, we conclude that TRIP8b is not essential for HCN1 trafficking in photoreceptors. To identify other contributors to HCN1 trafficking we examined the localization of a series of HCN1 mutants expressed in the rods of transgenic tadpoles (Xenopus laevis). We identified a di-arginine motif in the C-terminus of HCN1 just distal to the cyclic nucleotide binding domain that functions to retain HCN1 in the ER. As expected, mutating this motif resulted in increased surface expression of HCN1. A second trafficking signal in the N-terminus of HCN1, near the first transmembrane domain, was found to be necessary for ER export. This work leads to a model where these two signals work together to maintain a proper equilibrium of HCN1 levels between ER and the plasma membrane. Since exit from the ER is such an early step in any trafficking pathway, these signals are likely to contribute to the balance of HCN1 trafficking in other cell types.

Title: Development of cone opsin expression in a transgenic zebrafish line with crx-driven trβ2

Authors: *S. S. PATTERSON[1,2], T. YOSHIMATSU[2], T. SURESH[1], R. F. NELSON[1];
[1]Neural Circuits Unit, NINDS, Rockville, MD; [2]Univ. of Washington, Seattle, WA

Abstract: In the transgenic zebrafish line crx:MYFP-2A-trβ2, the highly conserved cone-rod homeobox (crx) gene drives thyroid hormone β2 (trβ2) expression (Suzuki et al., 2013). Crx is expressed early in retinal progenitors that later differentiate into photoreceptors and trβ2 is a necessary for subsequent red cone development. The result is primarily L-opsin expression with scarce G-, B- and UV-opsin expression. This transgenic provides the opportunity to study photoreceptor development and crx, a gene implicated in human photoreceptor degeneration. Larvae were spawned from an outcross of crx:trβ2 and wildtype (WT) adults and phenotyped by MYFP pupil fluorescence. Larval eyes aged 5 - 12 days post-fertilization (dpf) were isolated and perfused with oxygenated MEM containing 20mM L-Aspartate or 10mM CNQX to isolate the photoreceptor (PIII) and ON-bipolar (b2) responses, respectively. Microelectrode ERG responses were recorded to 300ms light stimuli presented at 9 wavelengths (330-650nm), each at 7 irradiances. Spectral sensitivities were calculated with an ERG model summing 4 Hill functions, one for each zebrafish cone type. To examine Vitamin A2 expression, a 5th Hill function was added using a 600nm λmax. Despite early L-opsin dominance, a small 330nm PIII response occurred in crx:trβ2 at 5dpf. The 330nm b2 response was absent\. By 12dpf, the PIII and b2 crx:trβ2 responses increased. All crx:trβ2 amplitudes were smaller than WT amplitudes. Crx:trβ2 PIII spectra showed increasing short wavelength sensitivities and decreasing long wavelength sensitivity from 5 to 12 dpf. At 12dpf, MYFP expression was still widespread but immunostaining showed UV and blue opsin expression in the peripheral retina.600nm A2 sensitivity occurred more often in crx:trβ2 spectra than in WTs. In both genotypes, the percent of spectra with 600nm A2 sensitivity showed a similar downward trend from 5 to 12dpf crx:trβ2 decreasing from 79% to 44% and WT from 62% to 14%. Zebrafish photoreceptor differentiation is normally complete by 4dpf. However, crx:trβ2 spectra and opsin expression suggest blue and UV cones are continuing to develop between 5 and 12dpf. Vitamin A2 is present in wildtype larvae, elevated in crx:trβ2 and decreases through development in both genotypes.

Title: Statistical analysis of zebrafish locomotor response

Authors: *Y. LIU[1], R. CARMER[2,3], G. ZHANG[2], P. VENKATRAMAN[2], S. A. BROWN[2], C. P. PANG[5], M. ZHANG[6,7], Y. F. LEUNG[4], P. MA[1];

Eye Ctr., Chinese Univ. of Hong Kong, Hong Kong, China; [7]Joint Shantou Intl. Eye Ctr., Shantou Univ., Shantou, China

Abstract: Zebrafish larvae display rich locomotor behaviour upon external stimulation. This locomotor behaviour can be simultaneously tracked from many larvae systematically arranged in multi-well plates. The resulting time-series locomotor data have been used to reveal new insights into neurobiology and pharmacology. However, the data are high-dimensional, and are affected by multiple intrinsic and extrinsic factors. These issues pose a statistical challenge for comparing larvae exposed to different stimuli, which cannot be efficiently handled by simple parametric analyses. To address this gap, this study has evaluated the Hotelling's T-squared test for analyzing a visually-driven locomotor behaviour named the visual motor response (VMR). This test is the generalization of the conventional t-test, and is congruent with comparing locomotor profiles from a defined period of time. With this test, various comparisons were conducted using VMR data collected from three wild-type (WT) strains: AB, TL and TLAB, from 3 to 9 days postfertilization. The comparisons show that different WT strains responded differently to light change at different developmental stage, and that sequential technical repeats were similar, if they were collected with the same parameters. Furthermore, the performance of this test was evaluated by a power analysis, which indicates that the test is sensitive for detecting differences between experimental groups with sample number that is amenable to the existing multi-well

plate platform. In addition to the evaluation of this test, our study also investigated the effects of various intrinsic and extrinsic factors that might affect the VMR by multivariate analysis of variance. The results indicate that the larval activity was generally affected by four major factors: stage of the larvae, light stimulus, their interaction, and location in the plate. Nonetheless, different factors affected larval activity to a different extent over time, as indicated by a dynamical analysis of the activity at each second by a conventional analysis of variance. Intriguingly, this analysis showed a negligible effect on larval activity by biological and technical repeats, and their effect size was fairly constant regardless of the light illumination. Thus, the results hint at the possibility to combine the data obtained from biological and technical repeats to enhance the statistical power of analysis, despite the perceived variations between replicates. Together, these investigations have established a statistical framework for analyzing VMR data, a framework that should be generally applicable to other locomotor data with similar structure.

Title: Understanding the contributions of photoreceptors to the visual motor response

Authors: ***P. VENKATRAMAN**[1], R. CARMER[2], C. PANG[3], M. ZHANG[4], Y. LEUNG[5]; [1]Biol. Sci., [2]Statistics, Purdue Univ., West Lafayette, IN; [3]Ophthalmology and Visual Sci., Chinese Univ. of Hong Kong, Hong Kong, Hong Kong; [4]Joint Shantou Intl. Eye Center, Shantou Univ. & The Chinese Univ. of Hong Kong, Shantou, China; [5]Biol. Sciences; Biochem. and Mol. Biology, IU school of Med., Purdue Univ. and Indiana Univ. Sch. of Med., West Lafayette, IN

Abstract: Visual Motor Response (VMR) is a startle locomotor response elicited by the eye; and can be observed in larval zebrafish, when they are presented with varying intensities of light stimuli. Two components of the VMR: ON and OFF responses, arise due to light or dark stimulus. The Light ON response consists of only a rapid response phase which is evident in a scale of seconds; whereas the Light OFF response, in addition to the rapid phase, consists of a sustained response phase which is evident in a scale of minutes. While VMR has been increasingly used to study chemical screening of compounds, the underlying cellular circuitry has not been fully understood. The research reported here has the goal to identify specific contributions of photoreceptors to the VMR. To study how VMR was affected by lack of cones, the *no optokinetic response f*^{w21} (*nof*) zebrafish mutant lacking functional cones was used. Wildtype (WT) and *nof* larvae were presented with light stimuli of varying intensities and the locomotor movements were tracked using an infrared camera. The average locomotor activity was plotted separately for Light ON (transition from darkness to light) and Light OFF responses (transition from light to darkness). Additionally *chokh* mutants were included in the study. Since they are eyeless, any response coming from *chokh,* would be of extra-ocular origin. Light stimuli with intensities ranging from log 0 (1440 lux) to log -3.21 (0.896 lux) were presented to the larvae and the VMR was recorded on 6 dpf (days post fertilization), 7 dpf and 8 dpf. At log 0 and log -2 stimulus intensities, the WT larvae showed a characteristic rapid response phase at stimulus onset. This was absent in the *nof* mutants, suggesting that cones could mediate the Light OFF rapid response phase at high intensity of light. Interestingly at lower intensities, such as log -2.81, the *nof* Light ON responses were comparable to the WT. This suggests that at lower light intensities, rapid response phase of Light ON could be mediated by rods. The *chokh* mutants did not show rapid responses to all the light intensities tested. However, they show a delayed response to stimuli suggesting that these responses could be from extra-ocular sources.

Title: Psychophysical estimation of cone connectivity and noise in the human retina

Authors: ***A. S. MCKEOWN**[1], K. S. BRUCE[2], W. M. HARMENING[3], L. C. SINCICH[2]; [1]Vision Sci., Univ. of Alabama At Birmingham, Birmingham, AL; [2]Univ. of Alabama Birmingham, Birmingham, AL; [3]Univ. of Bonn, Bonn, Germany

Abstract: Detection of photopic stimuli occurs when light captured by a cone photoreceptor produces a signal that downstream neurons can separate from ongoing cellular noise. Stimulating multiple cones simultaneously should alter the relationship between stimulus intensity and the probability of seeing, changes that would be reflected in the psychometric function of the detection process. One parameter that defines this function, threshold, may shift in one of two ways depending on the type of summation exhibited between detectors. When signals from two adjacent cones feed into a single neuron, perceptual threshold may be reduced by a factor of 2 if the inputs add linearly. Alternatively, if cone signals are sampled by two independent neurons, threshold may instead be reduced by a factor of √2 (2-detector summation). Another parameter, slope, may change systematically as noise in the combined inputs is reduced. To learn if these features of cone signaling can be measured psychophysically, we quantified increment sensitivity of single and multiple cones with microstimulation in 3 subjects. We used a multiwavelength adaptive optics scanning laser ophthalmoscope to image and stimulate cones in a 1.2° retinal field. A 130 μs, 543 nm, cone-sized (~3.6 μm) stimulus flash of varying intensity was delivered to each cone in a pair or triplet simultaneously, or to each cone individually, in pseudo-randomly interleaved trials. Psychometric functions were generated by fitting a logistic function to the frequency of seeing data by parametric bootstrapping. In 10 cone pairs tested, we found that single cones had variable perceptual thresholds, and that the slope of the psychometric function increased reliably when multiple cones were stimulated together, indicating a reduction in perceptual noise. We also observed a shift towards lower thresholds, with respect to the individual cones in the pair. After weighting by cone threshold, we computed predicted 2-cone functions from the single cone data that followed either a linear or a 2-detector model, and compared these predictions to observed 2-cone data. Six of the cone pairs exhibited significantly linear summation, three unambiguously followed a two-detector model, and one pair did not match either. In 4 cone triplets tested, summation fell between linear and two-detector predictions, suggesting a mixture of connectivity among these cones. Their psychometric functions had steeper slopes than the pairs, indicating a further reduction of noise with an additional receptor. Our results suggest that cone connectivity and physiological noise can be probed at the single cell level in the human retina through psychophysical measurements.

Title: Cone signal summation varies with inter-cone distance in the human retina

Authors: *K. S. BRUCE[1], W. M. HARMENING[2], W. S. TUTEN[3], A. S. MCKEOWN[4], A. ROORDA[3], L. C. SINCICH[4];
[1]Vision Sci., Univ. of Alabama At Birmingham, Birmingham, AL; [2]Univ. of Bonn, Bonn, Germany; [3]Univ. of California Berkeley, Berkeley, CA; [4]Univ. of Alabama Birmingham, Birmingham, AL

Abstract: The nature of cone connectivity in the retina would suggest that any two cones may be connected to either one or two downstream neurons of a single class. If two cones send signals to one neuron, they may act as one detector, and threshold may be reached by linear summation. If so, only ½ as much light needs to be delivered to each of the two cones as is needed for one cone to reach threshold. Alternatively, if two cones transmit signals to separate neurons, a 2-detector model suggests that 2-cone thresholds would be reached with $1/\sqrt{2}$ the amount of light required for single cones. We hypothesized that inter-cone distance and the type of summation would be related, with more separated cones being more likely feed onto different neurons, thus exhibiting $1/\sqrt{2}$ summation. To examine this, cones were imaged and stimulated using a multiwavelength adaptive optics scanning laser ophthalmoscope that tracked eye motion over a 1.2° patch of retina. We selected cone pairs for targeted delivery of a 45 arcsec spot of 543 nm light, flashed for 130 μs. To measure the effect of inter-cone distance, one anchor cone was common to every pair, while a second cone was selected by systematically varying the inter-cone distance. Increment thresholds were measured 5 times using a self-paced, 20 trial staircase method, and

were interleaved for 3 conditions: stimulation of the anchor cone, the distant cone, or both cones simultaneously. Subjects (n=5) had normal color vision. Cone pairs were located 1.4-3.6° from the fovea. As we found previously, single cone thresholds sometimes differed significantly from one another. To account for this, weighted single cone thresholds were computed to estimate summation. Of 45 pairs tested, 9 demonstrated linear summation (20%; $p<0.05$), 22 showed 2-detector summation (49%; $p<0.05$), and 14 had summation that was non-significant to either model (31%). At each of 6 tested retinal locations, mean cone spacing values were obtained by measuring the inter-cone distance of 500 cones. The inter-cone distance for each pair was normalized by the mean cone spacing at the site, allowing us to analyze our data independent of cone-spacing changes due to eccentricity. When cone signal summation was examined in relation to inter-cone distance, we found summation became exclusively 2-detector as inter-cone distance increased. All 9 linearly summing cone pairs were located within 1.5 cone distances of one another, while the 22 two-detector pairs spanned a range of 0.7-4.4 cone distances. These results suggest that at greater inter-cone distances, cones are likely signaling to more than one downstream retinal neuron, and that this feature of connectivity can be probed psychophysically.

Title: Rgma inhibits angiogenesis via neogenin

Authors: *K. HARADA, Y. FUJITA, T. YAMASHITA;
Dept. of Mol. Neuroscience, Grad. Sch., Osaka, Japan

Abstract: Vascular endothelial growth factor (VEGF) signaling in pathological angiogenesis has been studied; however, in some patients with Age-related Macular Degeneration (AMD) become refractory to further anti-VEGF therapy. The repulsive guidance molecule A (RGMa) was originally identified as an axon repellent in the visual system. It has diverse functions in both developing and adult central nervous system. These functions are mediated by binding of RGMa to its receptor, neogenin. Previously, Lejmi et al. (2008) reported that Netrin-4 inhibited

angiogenesis binding to neogenin. Therefore, we focused on RGMa, a Neogenin receptor, similar manner in Netrin-4 verifying therapeutic effect in AMD. Here, we show that RGMa is involved in angiogenesis and can suppress new blood vessel formation both *in vitro* and *in vivo*. Treatment of human umbilical artery endothelial cells (HUAEC) with recombinant RGMa inhibited vascular endothelial growth factor (VEGF)-induced tubular formation and migration. Knockdown of neogenin in HUAEC abolished the inhibitory effect of RGMa on tubular formation. Thus, we concluded that RGMa is an inhibitory molecule for angiogenesis and suggest that its manipulation could be an alternative for therapeutic strategies in AMD.

Title: Immunoreactivity of the protein Cryptochrome (CRY) in retina of crayfish Procambarus clarkii

Authors: *R. LOREDORANJEL, E. ESCAMILLA-CHIMAL;
UNAM, Mexico City, Mexico

Abstract: Previous works from this laboratory, by immunohistochemistry and WB have shown the presence of the protein cryptochrome (CRY) in both the optic lobe and brain of the crayfish P. clarkii. The presence and participation of CRY in extraretinal synchronization of the circadian system of P. clarkii subsequently has been confirmed a posteriori by other research groups (1). However, despite that both vertebrates and invertebrates CRY has also localized retinal structures and since we have proposed to the retina as a possible pacemaker system multioscillatory crayfish (2). The aim of this work is the location of the CRY protein in retinal structures. To accomplish the above it was made the immunolocalization of CRY in the retina of P. clarkii. Adult animals fed ad libitum, maintained at constant temperature and oxygenation were synchronized in photoperiod light dark (LD) 12:12. The dissection was performed in ZT0 (on light), the retinas were fixed with 4% paraformaldehyde, cryopreserved with 30% sucrose,

included in Tissue Tek's OCT and using a cryostat retinal sections were made to 10µm. Immunofluorescence was performed with a primary antibody anti-*Drosophila* CRY (1:50) and a secondary antibody Dy light 594 (1:100) and the nuclei were counterstained with DAPI (1:1000). A pre-absorption with the blocking CRY-peptide was performed as a control. The results showed that there immunoreactivity in the retina of crayfish Procambarus clarkii specifically was in the rhabdoms, all controls were negatives. As the retina a putative pacemaker of the biological clock, we can propose that CRY can be linked to animal photoreception and to be part of the clock proteins, as in other organisms. 1)Sullivan et al., (2009). Title: Toxicity of intravitreal administration of anti-VEGF drugs to the retina

Authors: *S. ALLODI[1], A. O. FONTES[2], R. M. JAPIASSU[3], G. HOLLMANN[2], M. A. FUSCO[4];

[1]Inst. Biofisica Carlos Chagas Filho, UFRJ, Rio de Janeiro, Brazil; [2]Program of Neurobio., Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Dept. of Ophthalmology, Federal Univ. of São Paulo, São Paulo, Brazil; [4]Inst. of Biomed. Research, Marcilio Dias Navy Hosp., Brazilian Navy, Rio de Janeiro, Brazil

Abstract: VEGF - Vascular Endothelial Growth Factor - is closely linked to the genesis of proliferative vessel disorders of the retina, such as age-related macular degeneration, diabetic retinopathy and retinopathy of prematurity. Neutralizing VEGF drugs have become the main therapeutic choice for the treatment of these conditions. Lucentis® (ranibizumab) is a smaller fragment of a humanized antibody against VEGF and Eylia® (aflibercept) is composed by fragments of VEGF receptors. Studies have revealed that the target of VEGF may include not only endothelial, but also neural cells, and tachyphylaxis, a decreased therapeutic response after repeated administrations of a medication, has been described for these drugs. Therefore, it is necessary to evaluate the toxicity of the intravitreal administration of neutralizing VEGF drugs to the retina on the cellular and molecular basis. A single dose of Lucentis, Eylia or sham (saline) was injected intravitreally in five rabbits per group. Contralateral eyes were left untreated (control). After fifteen days, the retinas were dissected for immunoblotting assays using anti-VEGF, anti-FLK-1 (VEGF receptor), anti-GFAP and anti-phosphohistone H3 (PH3). ANOVA followed by Tuckey test showed no statistically difference between the groups in VEGF ($p=0.65$) and FLK-1 ($p=0.56$), showing similar tendency between them. GFAP showed an increased expression in the Lucentis group in relation to control ($p<0.05$) and Eylia group ($p<0.05$), while PH3 showed an increase in Lucentis ($p<0.05$) in relation to sham. The fact that similar quantity of VEGF was observed in retinas treated with anti-VEGF drugs led to the hypothesis of an overexpression in the treated retinas, since anti-VEGF drugs should knock out the constitutive VEGF present in normal retinas. Thus, the similar amounts of VEGF and FLK-1 both in control and treated retinas may be due to an attempt of the treated retinas to return to the constitutive levels of VEGF needed to maintain the protection of neural cells, since the increase in GFAP and PH3 content in Lucentis may be indicating gliosis, a neurodegenerative condition in the retina. Because the role of constitutive VEGF in the retina is still unkown, the use of neutralizing VEGF drugs should be considered with care.

Title: Role of sigma receptors in the viability of retinal pigment epithelial cells -- studies using the crispr-cas9 system

Authors: *T. A. MAVLYUTOV[1], A. YAO[1], U. CHU[2], M. CHU[1], L. ZHAO[1], H. YANG[1], C. R. MCCURDY[3], A. E. RUOHO[2], L.-W. GUO[1];

Abstract: Sigma receptors play an important role in cellular viability. It has been shown that activation of the Sigma-1 receptor (S1R) has a protective effect in the survival of some neurons. While much less is known about the function of the Sigma-2 receptor (S2R) which is yet to be cloned, it has been reported that activation of S2R induces apoptosis in cancer cells. In the retina, S1R is abundant in ganglion cells and has been shown to be protective. S1R is also present in other retinal neurons although its function remains unclear. While transcripts of S1R were found in the retinal pigment epithelium (RPE) of mouse retina, the presence of the protein product of sigma receptors, in particular, S2R, has never been clearly demonstrated. The function of S1R and S2R in the RPE remain underexplored. Using a unique probe for photoaffinity labeling, we detected high amounts of both sigma-1 and sigma-2 receptors in crude preparations of bovine retinas as well as retinal pigment epithelium (RPE). Binding assay using [3H]-DTG in the presence of non-radioactive (+)-Pentazocine also confirmed high levels of S2R in RPE. Furthermore, in both primary RPE cells isolated from pig retinas and the human ARPE19 cell line, application of a variety of S1R agonists enhanced cellular viability upon toxicity triggered by paraquat, an inhibitor of mitochondrial respiration. In contrast, an antagonist of S2R, CM398, which is highly selective for S2R versus S1R (Ki = 0.43 nM and 560 nM, respectively) protected cell viability in the presence of paraquat. To further define the specific role of S2R, we engineered a S1R knockout single-clone ARPE19 cell line using the CRISPR/Cas9 technology. No significant difference was observed in the protective effect of CM398 between wild type and S1R knockout cells, suggesting that the effect of CM398 was indeed mediated by S2R. Further supporting the S2R-mediated function, PB28, a S2R agonist, reduced cell viability in S1R knockout ARPE19 cells. In light of the critical importance of the RPE in maintaining a healthy retina, S1R agonists and S2R antagonists should be further evaluated for their potential in ameliorating age-related macular degeneration.

Abstract: Ambient light signal has a profound impact on animal's physiological function. In 20 th century, human developed the additional light source, electricity light, lighted up the night time, and it has become a commonplace in human society. Recent studies in human suggested that exposure to the artificial light during nighttime (LAN) is strongly associated with overweight and metabolic diseases. In addition, studies in mice supported that the LAN exposure could cause those metabolic phenotypes without changing the total caloric intake; however, the percentage of daytime food intake was increased under the LAN condition. Whether light alone could affect the metabolism phenotypes remains unanswered. Moreover, the detailed mechanism of how light modulates energy metabolism stays unclear. Recently, intrinsically photosensitive retina ganglion cells (ipRGCs), which expressed novel photo pigments melanopsin, were known to transmit the light signal to control the non-image forming physiological function. Thus, we suspect that whether the melanopsin pathway is involved in the LAN effect on metabolism. Thus, we exposed the mice to light at night (~25 lux) with restricted feeding during the night time and examine their metabolic phenotypes. Here we reported that exposure to dim light during night time cause significant weight gain in mice and glucose intolerance; however, when the melanopsin protein was eliminated from the mice, both the weight gain and glucose intolerance were rescued. Moreover, in Brn3b positive ipRGC elimination mice (preserved circuitry to SCN), we found significant weight gain with normal glucose tolerance. Our data supports the melanopsin light detection signaling pathway and ipRGC circuitry are required in the direct light impact on energy metabolism in mice.

Title: Targeted modulation of Crb1 protein within the recipient retina to improve photoreceptor transplantation efficiency

Authors: *A. B. GRACA, A. GEORGIADIS, C. HIPPERT, P. V. WALDRON, A. J. SMITH, R. R. ALI, R. A. PEARSON;
Univ. Col. London, London, United Kingdom

Abstract: Purpose: Cell transplantation is a potential therapeutic strategy for the irreversible loss of photoreceptors (PRs). We, and others, have shown that immature PRs, derived either from neonatal donors or from stem cells, are able to functionally integrate into wild-type (wt) and diseased retinae. Despite these encouraging results, the number of donor cells that integrate within the recipient retina is small; hence it is essential to identify the barriers that impede donor cell integration and to devise strategies to remove them. We have previously identified the integrity of the outer limiting membrane (OLM) as a key determinant for transplantation outcome. The OLM is a series of adherens junctional protein complexes such as zona occludins (zo-1) and Crumbs 1 (Crb1), that form between Müller glia (MG) and PRs. Molecular disruption of zo-1 using siRNA enhances PR integration in wt recipients, but it also has detrimental effects on the neighbouring RPE. Since in the retina, Crb1 is restricted to the OLM, and the Crb1rd8/rd8 mouse model supports greater levels of integration compared to wt recipients, Crb1 might represent a better option for targeted OLM disruption in order to increase transplantation efficiency. Methods: Target short hairpins (sh) were sub cloned into the mU6 plasmid and tested

for efficiency. The most effective (sequence: 5'-GGAAGTGGATGAATGTGTTTCTGAT-3'; 80% knockdown) was cloned into the AAV pD10.CBA/RFP backbone before being packaged into the recombinant AAVShH10.Y445F vector, referred to herein as AAVShH10.Y444F-shCrb1. A non-targeting hairpin (sequence: 5'-GATCGGACACTCCTCATAA-3'; AAVShH10.Y444F-shControl) was used as a control. Both vectors were tested *in vitro* using MG cell cultures and then injected intravitreally into retinae of wt animals at postnatal day 8 and 18. Contralateral eyes received AAVShH10.Y444F-shControl. Eyes were harvested 3 weeks later and assessed by qRT-PCR and immunohistochemistry. Results: Administration of AAVShH10.Y444F-shCrb1 resulted in a robust reduction of Crb1 in MG cultures and in wt eyes. Histological assessments and immunohistochemistry show a disruption in OLM integrity in regions of viral transduction. No OLM disruption was observed in the eyes injected with control vector. Conclusions: There is a strong correlation between the integrity of OLM and transplanted PR integration. We report efficient knockdown of Crb1 in the retina using AAVShH10.Y444F-shCrb1, which leads to a loss of OLM integrity. Now we are investigating whether AAVShH10.Y444F-shCrb1 vector enables better transplanted PR migration and/or integration.

Title: How visual asymmetry starts in pigeons - characterizing Melanopsin as a potential trigger

Authors: ***R. KLOSE**, F. STRÖCKENS, K. SPOIDA, S. HERLITZE, O. GÜNTÜRKÜN; Ruhr-University Bochum, Bochum, Germany

Abstract: Structural and functional asymmetries of the nervous system, like handedness in humans, are a common feature in vertebrates. However, how the development of lateralization during ontogenesis is triggered remains largely unknown. For the asymmetry of the visual system in pigeons, we have strong evidence for the involvement of the environmental factor light. An asymmetrical position of the pigeon embryo inside the egg results in a stronger right eye light stimulation before hatch. This stimulation induces the development of a lateralized visual system affecting visual-guided behavior in adult pigeons. On the contrary, dark incubated pigeons do not show this asymmetry. However, classic retinal photoreceptors like rods and

cones, which perceive light stimulation in adult animals, are not functionally developed before hatch. This leads to the question, how an early asymmetrical light stimulation of the retina can induce visual lateralization. It has been shown that a third class of photoreceptive molecules occurs in retinal ganglion cells of other species. Since retinal ganglion cells are present at early developmental stages and already possess functional connections to primary visual areas before hatch, retinal ganglion cell bound photoreceptors could serve as a potential trigger for visual lateralization. Here we addressed the question if one of these photosensitive molecules, Melanopsin, could be such a trigger for asymmetry formation. To proof the particular role of Melanopsin during lateralization in pigeons, we were already able to sequence two isoforms of the Melanopsin gene in pigeons as well as demonstrating the expression of Melanopsin in the retina during all critical developmental stages (embryonic day 16 + post-hatch day 2). Now, to further support our hypothesis, we tried to discover if Melanopsin-positive cells can be activated by light. By performing an *in vitro* calcium assay using a HEK cell model, we discovered that both Melanopsin isoforms need the cofactor 9-cis retinal as reported in the literature for other Melanopsin genes. However, isoforms showed different light sensitivities resulting in higher calcium signals evoked by the long isoform. Our results provide for the first time a closer characterization of Melanopsin in pigeons. We currently plan to quantify the expression of both Melanopsin isoforms in the retina over three developmental stages (embryo, hatchling, adult). All together this could deliver a considerable support to our theory that Melanopsin plays a key role in the induction of lateralization in pigeons.

Title: Müller cells as light guiding fibers in caiman

Authors: *A. ZAYAS-SANTIAGO[1], A. SAVVINOV[4], S. AGTE[5], Y. RIVERA[1], J. BENEDIKT[1], L. A. CUBANO[2], A. REICHENBACH[5], S. N. SKATCHKOV[3]; [1]Physiol., [2]Anat., [3]Physiol. & Biochem., Univ. Central Del Caribe, Bayamon, PR; [4]Physical Sci., Univ. de Puerto Rico, Recinto de Río Piedras, Río Piedras, PR; [5]Paul Flechsig Inst. of Brain Res. Fac. of Med., Univ. of Leipzig, Leipzig, Germany

Abstract: This study highlights the newly discovered function of glia: light propagation via nano-fibers (Müller glial stalks) in the inverted retina. In the peripheral retina, photons of light should pass through all sorts of light scattering elements, such as cell bodies, synapses, axons, dendrites, and blood vessels, before reaching the photoreceptors and starting the visual process. This means that without special light guiding objects, vision will be restricted. Müller glial cells, which have a cylindrical fiber-like shape, act as light-guiding optical fibers that contribute to light propagation from the inner retinal surface directly to the outer segments of photoreceptors. Here we show that glial Müller cells in caiman (Caiman crocodilus fuscus): (i) cross all light scattering objects in the retina, (ii) are aligned in the direction of the light's path, (iii) have a higher refractive index than their surrounding elements, that help to trap and to hold the light, and (iv) are tightly connected to the photoreceptor cells at the end of the light pathway. We demonstrate using immunocytochemistry the presence of specific glial proteins such as: GFAP, S100B, and vimentin, which can form intracellular nano-fiber structures. Finally, we show that very thin Müller glial cells in caiman can conduct light signals. A living caiman retinal whole-mount was placed in a supporting chamber on the confocal microscope stage with the endfeet oriented down towards the light coming from the laser. This light was focused to a single endfoot by a 10X objective. The image was captured using another 40X objective at the cone-rod outer segment layer. A double cone photoreceptor (DCP) was observed illuminated, meaning that a single Müller cell endfoot projects light to a single DCP. Caiman Müller cells show both single and multiple endfeet; the cells with multiple endfeet could maximize the number of photons collected and projected to a DCP. Therefore, we suggest that this type of optic fiber alignment can be used as a novel type of "amplifying array" that increases the amount of photons absorbed by a photoreceptor cell. (Authors A.Z-S., A.S. & S.A. contributed equally to this work.)

Title: Phthalazinone pyrazole enhances photoreceptor differentiation and survival: implications for a multitarget mechanism of action

Authors: *J. A. FULLER[1], D. HELM[2], I. RUCZINSKI[3], K. J. WAHLIN[1], C. BERLINICKE[1], R. MACARTHUR[4], P. K. DRANCHAK[4], M. MATTHES[5], M. M. LAVAIL[6], B. KUSTER[2], J. INGLESE[4], D. J. ZACK[1];

Abstract: Retinal degenerations are a heterogeneous group of diseases in which there is a progressive loss of photoreceptors. There are currently no FDA approved therapies to slow photoreceptor loss, and as such, identification of protective compounds has been a long-sought therapeutic goal. Recent advances in stem cell biology has made photoreceptor transplantation an increasingly realistic possibility. However, current methodologies for photoreceptor differentiation and maturation are slow and relatively inefficient. In addition, current photoreceptor transplantation methodologies in animal models show a low integration and survival rate. In an effort to identify novel small molecules that both enhance survival and promote photoreceptor differentiation, we have microscaled (1536 well) assays utilizing cultured primary retinal neurons, and are able to culture in this format for up to 14 days. From a focused library screen of 107 small molecules utilizing cells from a GFP knock-in reporter mouse (Rhodopsin-EGFP), we identified phthalazinone pyrazole (4-[(5-methyl-1H-pyrazol-3-yl)amino]-2H-phenyl-1-phthalazinone, PHPZ), originally identified as a selective Aurora-A inhibitor, that increases the number of photoreceptors in culture in a concentration-dependent format. A qRT-PCR array of 95 photoreceptor-associated genes was performed and we found that the molecule upregulates several rod-specific genes including Rhodopsin, NR2E3, and NRL. Viability assays (CellTiterGlo and Calcein/Ethidium Homodimer) utilizing immunopan-purified photoreceptors shows that the PHPZ specifically enhances cultured photoreceptor survival in a phthalazinone-dependent fashion. Rhodopsin S-334ter rats, a retinitis pigmentosa model, were injected intravitreally at postnatal day 9 with 1 μL of a .15, .075, or .0075 mg/mL solution of PHPZ and sacrificed 10 days later. PHPZ treatment (.15 or .075 mg/mL) significantly increased the number of surviving photoreceptors. A chemical proteomic methodology utilizing Kinobeads™ was used to profile the binding interactions of PHPZ with kinases in retina lysate. Several sub-micromolar interactions with kinases were identified, including GSK3α/β (Kd: 14,

12 nM respectively), DLK/MAP3K12 (122 nM), and STK4/MST-1 (602 nM), which have been proposed to be involved in photoreceptor survival and/or differentiation. These results suggest that a phenotypic primary cell-based screen used in conjunction with chemical proteomic methodologies can be used to identify novel preclinical candidates as well as pharmacological networks that favor enhancement of photoreceptor survival and maturation.

Title: A new role for AMP-activated protein kinase (AMPK) in the circadian regulation of L-type voltage-gated calcium channels (L-VGCCs) in retinal photoreceptors

Authors: C. C.-Y. HUANG, L. SHI, C.-H. LIN, A. J. KIM, M. L. KO, *G. Y.-P. KO;
Vet Integrative Biosci., Texas A&M Univ., College Station, TX

Abstract: The AMP-activated protein kinase (AMPK) is a cellular energy sensor, which is activated when the intracellular ATP production decreases. The activities of AMPK display circadian rhythms in various organs and tissues, indicating that AMPK is part of the circadian regulation for cellular metabolism in these tissues. Disruption of AMPK genetically alters the circadian behavior rhythms in rodents. In vertebrate retina, the circadian clocks regulate many

aspects of retinal function and physiology, including light/dark adaption. We found that the overall retinal ATP content displayed a diurnal rhythm, which was nearly anti-phase to the diurnal and circadian rhythms of AMPK phosphorylation/activation. In addition, AMPK was involved in the circadian phase-dependent regulation of L-type voltage-gated calcium channels (L-VGCCs). In cone photoreceptors, the L-VGCCs are essential for sustained neurotransmitter release and crucial for retinal light sensitivities. The protein expression and currents of L-VGCCs are higher at night and lower during the mid-day. The activation of AMPK dampened the L-VGCC currents at night with a corresponding decrease in protein expression of the L-VGCCα1 pore-forming subunit, while inhibition of AMPK increased the L-VGCC current during the day. The AMPK appeared to be upstream of extracellular-signal-regulated kinase (ERK) and mammalian/mechanistic target of rapamycin complex 1 (mTORC1) in regulating the circadian rhythm of L-VGCCs. Hence, we demonstrated that in addition to serving as a cellular energy censor, AMPK integrates into the cell signaling network to regulate the circadian rhythm of photoreceptor physiology. Ajou Univ. Sch. of Med., Suwon, Korea, Republic of; [3]Neurol., [4]Ophthalmology, Asan Med. Center, Univ. of Ulsan Col. of Med., SEOUL, Korea, Republic of

Abstract: Loss of pericytes, an early hallmark of diabetic retinopathy (DR), results in the breakdown of blood-retinal barrier. Endoplasmic reticulum (ER) stress is thought to be involved in this process. This study is to test ursodeoxycholic acid (UDCA) that is known to ameliorate ER stress on pericyte loss in DR of streptozotocin (STZ)-induced diabetic mice. To assess the extent of DR, the integrity of retinal vessels and density of retinal capillaries in STZ-induced diabetic mice were measured. In addition, the induction of ER stress and unfolded protein response (UPR) were assessed in diabetic mice and human retinal pericytes exposed to advanced glycation end products (AGE) or modified low-density lipoprotein (mLDL). Leakage of fluorescein dye on angiography and decreased density of retinal capillaries were improved in UDCA-treated diabetic mice compared to non-treated diabetic group. Among the UPR markers, the expressions of markers involved in the PERK pathway were increased in STZ-induced diabetic mice, as well as AGE or mLDL-exposed retinal pericytes in culture. UDCA treatment blunted the increase of UPR markers in these cases. Administration of UDCA also inhibited mLDL- and AGE-induced death of cultured pericytes. UDCA attenuated UPR in retinal cells of DR models, *in vitro* and *in vivo*. Likely as a result, UDCA ameliorated vascular integrity and pericyte loss in the retina of STZ-induced diabetic mice. This suggests that UDCA, putatively a chemical chaperone that alleviates ER stress, may prove effective in protecting against diabetic retinopathy.

Title: Generation of Sox4 mutant zebrafish using CRISPR/Cas9

Authors: ***W. WEN**[1], L. PILLAI-KASTOORI[2], S. WILSON[2], A. KRISHNA[2], A. MORRIS[2]; [1]Univ. of Kentucky, Lexington, ; [2]Univ. of Kentucky, Lexington, KY

Abstract: Objective: Sox4 is a member of the group C SRY-box containing transcription factors. It promotes differentiation of multiple neuronal lineages and is required for neural progenitor survival. Zebrafish have two co-orthologs of the mammalian sox4: sox4a and sox4b. They are strongly expressed in the developing zebrafish eye. Morpholino-mediated sox4a/b knockdown in zebrafish leads to elevation in Hh activity, causing ocular coloboma and reduced number of mature rod photoreceptors. The effectiveness of morpholino is reduced by 4 days post fertilization (dpf) in zebrafish due to rapid cell proliferation. In order to study the role of sox4 in ocular development at later developmental stages as well as during adult retina regeneration, we generated sox4a and sox4b mutant zebrafish lines using CRISPR/Cas9. Methods: Sox4a and sox4b CRISPR target sites were identified and the corresponding single strand guide RNA (sgRNA) oligos were designed using the ZiFiT online software. sgRNAs and the Cas9 mRNA were synthesized according to the published protocol, and were microinjected into fertilized zebrafish embryos (F0) at the one-cell stage. F0s were raised to adulthood and screened for germline transmission by outcrossing with wild-type (WT). F1s were screened for inheritance of sox4 mutant allele using high resolution melting analysis (HRMA) and sequencing. F1 heterozygous mutants were raised to adulthood and outcrossed with WT to generate F2s. F2s were incrossed to generate F3s, of which 25% were expected to be homozygous mutant for sox4. Individuals with ocular coloboma were fixed with 4% paraformaldehyde at 5 dpf and cryosectioned for immunohistochemistry. Results: Founders carrying frameshift mutations in sox4 were successfully generated at the sox4aC1, sox4aC2, and sox4bC2 loci (C1 targets upstream of the HMG domain, C2 targets upstream of the transactivation domain). Mutant alleles were stably passed to the F1-F3 generations. Sox4aC1, sox4aC2, and sox4bC2 homozygous mutant individuals were identified in the F3 generation. Occasionally, ocular coloboma was observed in either heterozygous or homozygous sox4bC2 mutant embryos. However, the penetrance of ocular coloboma was less than 2%. Conclusion: Sox4a and sox4b mutant zebrafish were generated by CRISPR/Cas9. Perhaps due to functional redundancy between sox4a and sox4b, the ocular coloboma phenotype was only observed in a small proportion of sox4b mutants. Future plans include crossing the sox4a and sox4b mutants to generate sox4a/b double mutants, and characterizing the mutant alleles *in vivo* to verify that they cause a loss of function in Sox4.

Title: Identification and characterization of intrinsically photosensitive retinal ganglion cells in the common snapping turtle, Chelydra serpentina

Authors: C. R. HELLER[1], S. C. BEHLING[2], E. N. SUTTER[2], A. E. TURNER[1], E. A. ULANDAY[2], *J. A. DEMAS[3];
[1]Physics, [2]Biol., [3]Physics & Biol., St. Olaf Col., Northfield, MN

Abstract: In freshwater turtles, the navigation of hatchlings towards water is crucial to survival. Previous studies have shown that hatchling snapping turtles navigate using light cues. The retinal substrate for this behavior is not well understood. However, in neonatal mice, which lack functional rods and cones, phototactic behavior is mediated by intrinsically photosensitive retinal ganglion cells (ipRGCs). These findings raise two questions: are ipRGCs present in turtle retinas? If so, do ipRGCs mediate hatchling navigation? Using a multi-electrode array, we recorded *in vitro* from the retinas of hatchling and juvenile snapping turtles (Chelydra serpentina).To identify ipRGCs, we compared RGC responses to 60 s light flashes (480 nm, 5e14 photons/cm^2/s) before and after the addition of a neurotransmitter antagonist cocktail (CNQX, D-APV, APB, hexamethonium bromide, atropine, bicuculline, CGP52432, strychnine). In both hatchlings and juveniles, most RGCs stopped responding to light after adding the cocktail. However, a subset of RGCs continued to increase their firing rate in response to the onset of the light flashes. These responses resembled the intrinsic light responses previously characterized in mammalian ipRGCs, including a relatively sustained, long latency (>1s) response. We quantified the absolute sensitivity of these putative ipRGCs to varying irradiances of 480 nm light (1e13 to 1e16 photons/cm^2/s). With increasing irradiance, the amplitude of ipRGC responses increased, while response latencies decreased. We physiologically identified two subclasses of ipRGCs with different absolute sensitivities and response latencies to light. In mammalian ipRGCs, melanopsin mediates this intrinsic response. PCR experiments demonstrated that the turtle retina also expresses melanopsin, suggesting that melanopsin could mediate the intrinsic light response in turtle RGCs. Indeed, the addition of opsinamide, a melanopsin antagonist, significantly attenuated the light responses of turtle ipRGCs. Future work will include characterization of the action spectrum of the turtle ipRGC light response to test its consistency with a melanopsin-based phototransduction mechanism. Additionally, we have

created a behavioral assay to determine whether these cells play a role in hatchling navigation. In a Y-maze, turtles demonstrated robust positive phototactic behavior. We will administer intraocular injections of the neurotransmitter antagonist cocktail to determine whether ipRGCs are sufficient to mediate this phototactic behavior.

Title: Transcriptome analysis of ipRGCs with next-generation sequence

Authors: *N.-F. LIOU[1], H. WANG[2], S. CHEN[1];
[1]Life Sci., [2]Sec Dept. One Life Sci. , Natl. Taiwan Univ., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Intrinsic photosensitive retina ganglion cell (ipRGC) is a special type of retina ganglion cell, which can express melanopsin and sense the light signal. As we know from previous studies, ipRGC is involved in circadian photo-entrainment, pupil reflex and sleep. And ipRGC could be separated into at least five types according to their neurites morphology and cell body size. Moreover, evidence suggests that different types of ipRGC could project to distinct brain area to influence specific physiological functions. However, the differentiation cue or specific marker for individual type of ipRGC remains unclear. Using single cell RNA sequencing technic, we performed transcriptome analysis between ipRGC and regular RGC to identify whether ipRGCs express any specific gene that is important for their specification.

Abstract: Detailed mechanisms of insect phototransduction have been explored in a limited number of species, and particularly in the dipteran *Drosophila* melanogaster, where rhodopsin photoisomerization activates a Gq-protein, initiating a cascade leading to activation of IP3 and diacylglycerol. This cascade opens transient receptor potential (dTRP) and TRP-like (dTRPL) ion channels via uncertain mechanisms. The relative contributions of dTRP and dTRPL channels to total light-activated currents under physiological conditions are not yet certain, but dTRP channels probably dominate. Insects utilize a wide range of visual environments and lifestyles that impose varying constraints on visual function, with resultant changes in phototransduction machinery. For example, *Drosophila* fly rapidly under mainly bright light conditions, but cockroaches occupy a primarily terrestrial, nocturnal or crepuscular environment that requires greater visual sensitivity but less rapid responses. Electrophysiological evidence suggests that cockroach phototransduction makes major contributions to this environmental adaptation, including a greater role for the homologous pTRPL rather than pTRP channels. We created a transcriptome of Periplaneta compound eye retina and assembled mRNA sequences for three opsins and two TRP channels. Relative mRNA abundances in normal retina were estimated from representation in the transcriptome and by quantitative PCR (qPCR). Phylogenetic analysis indicated that two opsins (pGO1 and pGO2) are green absorbing and one (pUVO) is UV absorbing, with pGO1 mRNA being 10-100 times more abundant than the others. The two TRP genes were similarly identified as pTRP and pTRPL, with pTRPL mRNA being 10 times more abundant than pTRP. We developed protocols for *in vivo* RNA interference (RNAi) based gene silencing to suppress translation of these genes by injecting long (500-700 bp) double stranded RNA (dsRNA) into the cockroach head hemolymph. Gene suppression in RNAi treated animals was measured by qPCR. Photoreceptor function was examined by electroretinograms (ERG) of intact eyes, and by whole-cell patch clamp recordings of single photoreceptors in dissociated ommatidia. Injection of dsRNA corresponding to the major green opsin, pGO1 caused almost

complete elimination of phototransduction within seven days. RNAi of the TRP and pTRPL genes proceeded more slowly, taking up to 21 days, and reduction of pTRPL had a more profound effect on light response, supporting a more important role for pTRPL than pTRP in Periplaneta phototransduction.

Title: Mammalian cone photoreceptors are capable of extraordinarily rapid release and maintain a large number of ribbon-tethered vesicles in reserve

Authors: *C. P. GRABNER[1], S. H. DEVRIES[2];
[1]Dept. of Ophthalmology, Chad Grabner, Chicago, IL; [2]Physiol. and Ophthalmology, Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: One of the first processing steps in vision occurs when the steady changes in membrane voltage produced in a cone photoreceptor by light are transmitted to postsynaptic neurons at ribbon synapses that can mediate both transient and sustained release. Cone bipolar cells further transform the cone output in a type-selective manner through the expression of different glutamate receptors and by the position and number of their contacts at the cone terminal. In order to understand the complex transformations that occur at the cone synapse, we began by directly determining the properties of release by performing membrane capacitance measurements in the ground squirrel, which has a cone dominant retina. In particular, we wanted to understand the relationship between ribbon recovery from depression and the recovery of postsynaptic Off bipolar cell glutamate receptors from desensitization. Peak release was obtained during steps to -10mV, while steps to more positive potentials showed incremental reductions as the Nernstian drive for Ca^{2+} decreased. For steps to voltages more negative than -10 mV, release was delayed, consistent with the activation kinetics of Ca^{2+} channels being voltage-dependent. To more carefully explore the kinetic phases of release, pulse duration was varied while V_m was stepped to -10 mV. This approach revealed two rapid kinetic phases for release with τ's of 0.5

and 7 ms, and assuming 20 ribbons/cone terminal, each phase involved 13 and 7 vesicles/ribbon, respectively, which equates to instantaneous release rates of ~26,000 and 600 vesicles/s/ribbon. Using brief 1 ms steps in a paired-pulse recovery protocol, or a train of step depolarizations, the primed vesicles refilled at a rate of 13 vesicles/s/ribbon, equivalent to a recovery $\tau \sim 1$ s. A distinct late phase of release emerged with prolonged step depolarizations and had a $\tau \sim 250$ ms and an estimated release rate of 40 vesicles/s/ribbon. Electron microscopy was used to estimate the packing density of vesicles at cone ribbons, and gave a density of ~ 70%, yielding 25 docked vesicles at the ribbon base and a total of 95 vesicles/ribbon. Taken together, the extraordinarily rapid initial release phase emptied most of the docked vesicles within 1 ms, and all docked vesicles were released within 30 ms. The subsequent re-priming of docked vesicles is relatively slow when probed with 1 ms steps, ~ 1 s, and only a continual 1 s step invokes the release of an equivalence of all ribbon tethered vesicles. Thus, ground squirrel cones recover at a rate slower than the postsynaptic recovery rate in some Off cone bipolar cell types (cb2: ~150 ms) and similar to or faster than others (cb3: ~ 800-900 ms).

Title: A threshold non-linearity at the mammalian cone photoreceptor basal synapse

Authors: *S. H. DEVRIES;
Northwestern Univ. Med. Sch., Chicago, IL

Abstract: Purpose: The goal of this study is to investigate the input-output properties of the mammalian cone photoreceptor basal synapse. Cones make two types of synaptic contacts with bipolar cells, invaginating and basal. There are ~20 invaginations per terminal and each is marked at its apex by a synaptic ribbon. Basal contacts involve close, ~20 nm, appositions between the membranes of a cone and Off bipolar cells at the base of the terminal. Receptors at basal contacts are thought to receive transmitter from distant ribbons (200-500 nm). Transmission at such distances is normally associated with spillover, and it is unclear whether basal contacts can sense and respond to the release of a single vesicle from a ribbon or whether

they respond only to multivesicular events. Methods: I used dual cell voltage clamp to record from pairs of synaptically connected cones and Off bipolar cells (types cb1 and cb3) in slices from the ground squirrel retina. In a typical experiment, a train of 1 ms pulse depolarizations from -70 mV were applied to a cone and epsc responses were recorded in both the presynaptic cone (via the glutamate transporter) and postsynaptic bipolar cell. With small depolarizations, the cone events fluctuate and have quantal-type properties. Results: For a train of cone depolarizations, I plotted the amplitude of the fluctuating responses in the cone versus the bipolar cell. The strength of the cone stimulus was then adjusted to obtain an extended plot of responses. Cone responses were converted from pA to quanta based on a fluctuation analysis, and a linear range was established. Bipolar cell responses were not normalized. The scatter plots for cb1a cells were striking in that they typically had a range of 0-10 cone vesicles released during which no postsynaptic response could be detected. Only at stronger depolarizations were responses evident. An analysis of spontaneous release at the cone to cb1a cell synapse also consistently showed a failure to respond at the quantal level, but occasional responses to multivesicular events were observed. Cb3 cells demonstrated a similar although less marked response non-linearity. Conclusions: The striking result for the cb1a cell, and to a lesser extent for the cb3 cell types, is the failure to reliably detect single quantal events. One possible mechanism for this failure is the distance between the ribbon release sites and the basal contacts of the recorded bipolar cells.

Title: Integration of luminance, chromatic signals and melanopsin activation in human ipRGC processing

Authors: *P. BARRIONUEVO, D. CAO;
Ophthalmology and Visual Sci., Univ. of Illinois At Chicago, Chicago, IL

Abstract: Intrinsically photosensitive retinal ganglion cells (ipRGCs) express melanopsin, a photopigment that can respond to light directly. In addition, these cells receive afferent inputs from rods and cones. Primate ipRGCs display S-OFF, L+M ON, and melanopsin ON response property. We investigated the integration of luminance and chromatic signals with melanopsin activation in ipRGCs processing by measuring human pupillary flickering responses. Using a lab-developed five primary photostimulator that can control the excitations of rods (R), three types of cones (S, M, L) and melanopsin-mediated ipRGCs (I) independently, we measured pupillary responses to sinusoidal stimuli that modulated rod, cone and melanopsin excitations in isolation or together but with relative phase varied. We used three types of cone stimuli, including cone luminance (LMS), equiluminant L vs. M [L/(L+M)], and S-cone (S) modulations. The temporal frequency was 1 Hz at 200 Td and 2000 Td. Consensual pupil recordings were obtained from the left eye with an EyelinkII eyetracker (Sampling rate 250Hz, spatial resolution<0.01mm). The results showed that S-cone-driven pupillary responses were out of phase with respect to I, LMS and R responses, with LMS producing the largest responses but S-cones producing the weakest responses among the isolated conditions. Melanopsin-driven pupillary responses were approximately linear with melanopsin contrast (2% to 18%), maintaining phase near 0°. S-cone-driven contrast response (10% to 85%), however, saturated at ~50%; with the response phase of 180° for the entire contrast range tested. Variation of I phases with respect to LMS, S, L/(L+M) and R signals could be described by a vectorial summation model of the weighted isolated responses, suggesting that melanopsin activation is linearly combined in ipRGCs with cone luminance and chromatic signals to control phasic pupil responses. Melanopsin contribution was small in combination with LMS but dominant in combination with R, S, and L/(L+M). Because S-cone contribution is very weak with respect to other inputs, out-of-phase S-cone input is usually masked by other photoreceptor inputs. Our results suggest that ipRGCs receive signals from retinal pathways involved in luminance and chromatic processing. The luminance and chromatic signals are integrated linearly with melanopsin signal in ipRGCs. The weightings from the vector summation models indicated that ipRGCs received strong synaptic inputs from diffuse bipolars in the magnocellular pathway for luminance processing but weak inputs from bipolars or amacrines in the parvocellular and koniocellular pathways for chromatic processing.

Title: Turtle visual cortex studied by combining wide-field calcium imaging and electrophysiology

Authors: *M. A. LAUTERBACH, M. HEMBERGER, M. SHEIN-IDELSON, G. LAURENT; Dept. of Neural Systems, Max Planck Inst. For Brain Res., Frankfurt, Germany

Abstract: Reptilian cerebral cortex contains 3 layers, similar to hippocampal and piriform cortices of mammals. Pyramidal cells are found only in layer 2, the only real soma layer, which is thought to be equivalent to (output) layers 5/6 of mammalian isocortex [1]. Turtle cortex offers well-known experimental advantages: it is resistant to anoxia and operates at room temperature. Cortical slabs can be cut in orientations that minimize lesions and keep inter-neuronal connections intact. The entire brain can even be extracted and kept *in vitro* for several days. Finally, the sparse neuronal activity observed there is well adapted to calcium imaging, where each action potential can be observed as a prolonged signal. Processing of visual information in turtle cerebral cortex is not understood, and clear single-neuron receptive field properties have yet to be discovered there [2]. Our lab combines *in vivo* and more reduced approaches to understand the functions and operations carried out by this simple cortex. Here we show network analysis of activity in the visual cortex of turtles (Trachemys scripta/Chrysemys picta) using a combination of electrophysiology and calcium imaging. Advanced image processing enables calcium imaging in wide-field mode (single-photon excitation) and thus the fast monitoring of large fields of view in combination with electrophysiological methods. Sensitivity is sufficient to resolve sub-threshold signals in cell bodies and calcium signals elicited by single action potentials can be detected even in dendrites. Using AM-dyes, hundreds of neurons can be stained and monitored very easily. A depth penetration of more than 100 µm is obtained, sufficient to image cortical layer 2 from the ventricular surface in an *ex vivo* preparation. By combining imaging with patch-clamp recordings of one or a few interneurons, the distributed and coordinated effects of single interneurons on regularly spiking neurons can be analyzed. By combining imaging with multi-electrode array (MEA) recordings, electrical signals from hundreds to thousands of spiking neurons can be observed. After spike sorting (i.e. the assignment of the electrical signals to discrete neurons) electrical activity can be correlated with sub- and supra- spike-threshold calcium signals enabling a broad ensemble view of stimulus-evoked and spontaneous activity in this system. Abstract: Recent fMRI studies examining resting state functional connectivity (RSFC) have provided insight into the inter-areal functional networks in the human brain. However, due to the spatial resolution limit of fMRI, the existence and properties of intra-areal RSFC remain unclear. To explore the RSFC in a finer scale, we imaged intrinsic optical signals in anesthetized monkey visual cortex (V1 V2 and V4) without visual stimulation. In these spontaneous conditions, slow (<0.4Hz) hemodynamic fluctuations exhibited multi area-specific topographic patterns, most of which matched the known functional maps (e.g. ocular dominance, orientation, and color maps) obtained in visual stimulation conditions. Novel spontaneous patterns were also observed, mainly in area V4, and did not match any known functional maps in this area. Within one area, temporal fluctuations of spontaneous activity in orthogonal functional domains were negatively correlated, while fluctuations in the same type of domains in different visual areas were positively correlated. These findings demonstrate that slow ongoing optical signal contains fine-scale network information which is tightly related to the underlying anatomical and functional networks. Optical imaging of RSFC thus provides a new way in exploring intrinsic network properties, particularly useful for cortical areas that are difficult to be studied in regular stimulus or task paradigms.

Title: Coordinated neocortical activity at cellular resolution during visual processing

Authors: *Z. MA[1], Y. KARIMIPANAH[1], J.-E. MILLER[2], R. YUSTE[2], R. WESSEL[1]; [1]Physics, Washington Univ. In St. Louis, Saint Louis, MO; [2]Dept. of Biol. Sci., Columbia Univ., New York, NY

Abstract: The highly interconnected nature of cerebral cortex supports the hypothesis that cortical function emerges from coordinated neural activity across scales of space and time. Testing this tantalizing coordination hypothesis ultimately requires recording neural activity at spatial scales from synapses, dendrites, neurons, microcircuits to brain regions and during sensory processing. Here we performed two-photon population calcium imaging of layer 2/3 neurons in primary visual cortex of awake and behaving mice during three conditions of visual stimulation: black screen, drifting grating, or natural movie. For each mouse and stimulus condition we obtained the inferred spike trains from some 100 closely-spaced neurons for several minutes. We analyzed the population of spike trains for each mouse and condition with respect to (i) the statistical properties of individual spike trains, (ii) the pairwise correlation of spike trains, and (iii) the coordination across neurons and time for all spike trains of a given data set. The analysis of the population of spike trains revealed three important features. First, spike trains showed a broad distribution of mean rates and highly irregular spiking. The latter resulted in a broad distribution of the coefficients of variation of the inter spike intervals with a population mean larger than one. Second, pairs of spike trains were weakly correlated resulting in a distribution of small values of cross correlation coefficients for all pairs. Third, neuronal avalanches, which are cascades of contiguous spikes within the population of imaged neurons, had power law size and duration distributions, while shuffled results didn't. Furthermore,

avalanche sizes and durations followed a scaling relation, which is an important fingerprint of a dynamical critical system. In addition, the statistical properties of the population spike trains were largely independent of the stimulus condition, thus indicating a dominant contribution from intracortical dynamics. Taken together, this collection of quantitative observations of cortical population activity during visual stimulation provides valuable constraints for future models of cortical dynamics and sensory processing.

Abstract: Sensory informations are computed in the cortex by networks of co-activated neurons forming functional ensembles. Visual processing in the cortex underlies several aspects of neuronal characteristics such as anatomical, electrophysiological and molecular. In particular, the coupling of spiking activity is an important indicator of the dynamic within a neuronal population. The activity of a neuron classified as a ‘soloist’ is distinct from the firing pattern of a so called ‘chorister’*. These two classes correlate differently their firing rate with the global populational activity*. In the present investigation, we sought to examine the relationship between the firing patterns (fast or regular spiking) of cortical neurons simultaneously recorded from the cat’s primary visual cortex and their tendency to act as a soloist or a chorister. We observed that fast-spiking neurons which are commonly attributed to putative inhibitory interneurons mainly correlate their firing with the neuronal population (choristers). On contrary, regular spiking neurons considered as putative excitatory pyramidal neurons exhibited weak coupling activity with their neighboring population (soloists). Major consequences may arise

from this research. Importantly, estimating the correlation of spike-trains of neurons with their neighboring assembly is a predictive indicator of their neuron-type. These results give new insights into visual coding by demonstrating how putative inhibitory interneurons frame the neuronal responses of principal cells within neuronal-assemblies. *M. Okun, N.A. Title: Irregular spiking and broad bate distributions both arise as emergent properties of sparsely connected recurrent networks

Authors: *Y. KARIMIPANAH[1], Z. MA[2], R. WESSEL[2];
[1]Washington Univ. In St.Louis, University City, MO; [2]Physics, Washington Univ. In St.Louis, St. Louis, MO

Abstract: Cortical neurons *in vivo* fire irregularly, the distribution of time-averaged firing rates resembles a lognormal function, and the collective activity is coordinated, often showing signs of scale-free dynamics. These non-trivial properties of cortical activity pose the question as to what clues they provide about the underlying cortical microcircuits. Previous theoretical attempts to address this question have focused either on the single-neuron spiking or on the population activity, but not on both. Here we ask to what extent the statistical properties of single-neuron and network activity can arise together as emergent properties of a structured recurrent network. We use a network of identical binary probabilistic integrate and fire model neurons. Connections are excitatory and are chosen at random with a sparse connectivity, thus resulting in a distribution of the number of inputs (in degree) for all neurons. All chosen connections have

identical synaptic strength and synaptic time constant. Varying the synaptic strength from low to high, the network undergoes a transition from a phase of short-lasting population activity (sub-critical), to a highly variable (scale-free) population activity (critical) phase, followed by a phase of long-lasting population activity (super-critical). Surprisingly, right near the critical point of network activity, the single neuron spiking undergoes a phase transition from Poisson spike trains to irregular spiking, characterized by a broad distribution of the coefficient of variation (CV) with a population average above 1. However, using a model of synaptic depression we showed that adding adaptation to the network shifts this transition from the critical point toward the super-critical regime. Moreover, It is shown that further increasing the average synaptic length will eventually make the network to end up at a third phase of regular spiking. In the irregular spiking regime, the distribution of CVs in a network of identical neurons results from the distribution of in degrees; the CV increases with increasing in degree. The distributions also turn out to remain very broad even over very long simulation runs. In addition, imposing a modular connectivity to the network is capable of producing lognormally distributed rates. In conclusion, this investigation indicates that irregular spiking and scale-free network activity can coexist as emergent properties of a recurrent network with structure, without any need to impose certain characteristics to the dynamics of individual neurons.

Title: Dynamics of cortical noise correlations during vision

Authors: ***N. WRIGHT**[1], M. HOSEINI[1], W. P. CLAWSON[2], J. POBST[1], T. CROCKETT[1], W. L. SHEW[3], R. WESSEL[1];

[1]Physics, Washington Univ. In St. Louis, Saint Louis, MO; [2]Electrical Engin., [3]Physics, Univ. of Arkansas, Fayetteville, AR

Abstract: The cortex is an interaction-dominated network; the majority of inputs to a neuron have their source in other cortical neurons. Spontaneous and evoked events dynamically reorganize these connections via adaptation. Not surprisingly, then, neuronal sensory responses can be highly variable across repetitions of a given stimulus, and this variability can be coordinated across a population of neurons. This "noise correlation" likely affects population coding, and given its source, lies at the heart of the interaction between sensory input and cortical circuitry in sensory representation. Understanding this interaction requires a reliable measure of noise correlations in ongoing and evoked cortical activity. This fundamental issue has yet to be fully addressed. To this end, we have simultaneously recorded the membrane potential (V) from up to two cortical neurons, as well as the nearby local field potential (LFP), in the turtle eye-attached wholebrain *ex vivo* preparation. In a parallel set of experiments, we monitored the LFP at several locations using a microelectrode array. Each LFP reflected the net activity in a small volume of cortex, and each membrane potential reflected the spiking activity of the pool of presynaptic neurons. We calculated noise correlations (the Pearson cross-correlation functions of the band-pass filtered recordings (0.1 to 100 Hz) after trial averages had been subtracted) for V-V, V-LFP, and LFP-LFP pairs before and after visual stimulation. We find that for V-V and V-LFP pairs, noise correlation values, and the degree to which they are modulated by visual stimulation, vary greatly across trials and pairs, leading to across-trial and across-pair averages that are small relative to some single-trial values. Nevertheless, there can be significant population trends, depending on the frequency band considered. In contrast, LFP-LFP pairs were remarkably consistent across trials and pairs. We reproduced several aspects of these results using a simple network model. We repeated this analysis for spontaneous oscillations, that is, large V and LFP events that occurred in the absence of visual stimulation. We find a frequency-dependent relationship between noise correlations for the two oscillation types. We interpret this result in the context of the cortical architecture, and hypotheses relating the frequency content of inputs to the location of their sources. Together, these results contribute to a clearer picture of the nature of noise correlations in the visual cortex, how they can depend on recording technique, and how sensory input engages the inherent intracortical connectivity to generate the visual response.

Title: Dissecting the inhibitory mechanisms of reliable coding in mouse primary visual cortex

Authors: *R. V. RIKHYE, M. SUR;
Dept of Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Neurons in the primary visual cortex (V1) respond to full-field natural scenes with spike trains that are highly reliable between trials. While it has been argued that local inhibitory interneurons are responsible for modulating reliable coding, no study has yet systematically detailed the role of different interneuron subtypes. Our goal was to show how Parvalbumin (PV), Somatostatin (SST) and Vasoactive Intestinal Peptide (VIP) expressing interneurons modulate reliable coding in mouse V1. Specifically, we aimed to: (1) show how subnetworks of these interneurons process natural scenes and (2) determine how they contribute to reliable coding. To address these questions, we performed *in vivo* two-photon calcium imaging in awake, head-fixed mice by conditionally expressing GCaMP6f in PV, SST or VIP neurons. This allowed us to minimize the effect of contamination from nearby excitatory neurons and permitted us to study population coding within these interneuron subnetworks. SST neurons also preferred lower spatial frequencies than PV neurons, consistent with their role in integrating information from a larger visual area. Not surprisingly, VIP neurons responded poorly to gratings. PV neurons responded strongly, but unreliably, to full-field natural scenes. In contrast, SST neurons were more selective and were highly reliable between trials. SST cell reliability was comparable to excitatory neurons. This suggests that SST neurons are selectively driven by specific features in natural scenes and, consequently, provide reliable dendritic inhibition on their target cells. We also found that VIP neurons responded more strongly to natural scenes than gratings, suggesting that these interneurons are driven more by “salient” stimuli. Next, we investigated how these interneurons modulated pyramidal cell reliability. To do so, we conditionally expressed ChR2 in both PV or SST neurons and GCaMP6f in pyramidal neurons. We reasoned that reliability arose due precisely timed excitatory (E) and inhibitory (I) synaptic currents. Thus, we used a stimulation protocol to decorrelate these E- and I-currents in pyramidal cells. Specifically, we pulsed a blue LED for 100ms at random times during a natural movie. This allowed us to activate PV/SST neurons during periods when pyramidal cells were most reliable. We

discovered that activating SST neurons during epochs of reliability increased reliability. In contrast, stimulating PV neurons reduced reliability. Taken together, our work demonstrates that SST neurons play an important role in shaping the reliability of pyramidal cell responses to natural scenes in mouse visual cortex.

Abstract: Recent studies have applied dimensionality reduction to neural population activity to uncover evidence of neural mechanisms underlying decision-making, motor control, olfaction, working memory, and other behavioral tasks. These techniques provide quantitative measures of population-level structure in neural data. However, it is currently unclear how the outputs of dimensionality reduction (e.g., dimensionality and percentage of overall variance that is shared among neurons) are influenced by the number of recorded neurons and trials, as well as the underlying network structure. To this end, we applied factor analysis to recordings of spontaneous activity from Utah arrays implanted in visual area V1 of anesthetized macaque monkeys. Factor analysis can separate the raw spike count covariance matrix into a shared

component and a private component. We calculated the dimensionality of the population activity and the percentage of spike count variance shared with other recorded neurons (termed 'percent shared'). We repeated this analysis for various neuron and trial counts for each data set. We observed that dimensionality increased with neuron count and trial count, while percent shared remained stable over a wide range of neuron and trial counts. To extrapolate our findings to a larger number of neurons and trials, we investigated whether network models with a balance of excitation and inhibition have similar scaling properties as biological networks. We simulated neurons from networks with two difference structures, non-clustered (i.e., random connections) and clustered (i.e., structured connections), and applied the same analysis used on experimental data. We found that clustered network models showed similar scaling trends as V1 recordings within the experimental range of neuron and trial counts. Non-clustered networks did not show these trends. We then scaled up the number of neurons and trials for the network models and found that the clustered network dimensionality plateaued and percent shared remained stable with increasing neuron and trial count. Lastly, we varied the number of clusters represented in the set of neurons sampled. We observed that dimensionality increased with cluster representation, while percent shared remained stable. Taken together, our results show that the outputs of dimensionality reduction depend on the number of trials and neurons sampled, the underlying network structure, and the number of clusters represented in the neurons sampled. More broadly, these results demonstrate how spiking network models can provide vital context to population analyses based on a limited sampling of neurons and trials in experiments.

Title: Adaptive tuning of mutual information in visual cortex

Authors: *W. CLAWSON[1], N. C. WRIGHT[2], J. YANG[1], R. WESSEL[2], W. L. SHEW[1]; [1]Univ. of Arkansas, Fayetteville, AR; [2]Washington Univ., St. Louis, MO

Abstract: Coding mechanisms in visual cortex adapt to accommodate changes in sensory input. It is often supposed that such adaptation serves to improve coding of the visual input. Conversely, it stands to reason that during a transient period following a large change in visual input, coding will be relatively less effective. Such adaptive changes in coding have largely been studied at the level of one or two neurons. However, sensory information processing in the cortex is not carried out by isolated neurons; it depends on dynamic interactions among large populations of neurons . How such population dynamics emerge from many interacting single neurons is a highly non-trivial problem and remains poorly understood. Our recent experiments in visual cortex of turtles suggest a new principle relating adaptation and population dynamics. We found that adaptation tunes the interactions among cortical neurons to a special regime of population dynamics, called criticality. The transient response following a large change in stimulus was not consistent with criticality. The defining feature of criticality is that it is poised at the boundary between two distinct regimes of population dynamics: one with strongly coordinated population activity, the other with weak coordination. The possibility that adaptation tunes the cortex to criticality is important because other studies suggest that information transmission from stimulus to population response is optimized in networks which operate at criticality. This possibility is in line with the idea that adaptation improves coding, but has not yet been tested directly in any experiment. This is the aim of the work we present here. We studied the *ex vivo*, eye-attached, whole-brain preparation in turtles. We presented dynamic visual stimulation to the retina and measure population activity with high-density, three-dimensional microelectrode arrays. We found that foreground stimuli were better distinguished by population neural response during times when the system is more adapted (i.e. closer to steady state). Distinguishability of stimuli was quantified by computing mutual information between stimulus and response. Compared to transient visual response, steady-state visual response had higher mutual information and showed signatures of being closer to criticality. These findings support the hypothesis that adaptation in visual cortex tunes population dynamics to criticality, a regime that is favorable for discriminating visual stimuli.

Title: Intermittent ensemble oscillations emerge dynamically from cortical circuits of irregular spiking neurons

Authors: *M. HOSEINI[1], J. POBST[1], N. WRIGHT[1], W. CLAWSON[2], W. SHEW[3], R. WESSEL[1];

Abstract: The ubiquity of local field potential (LFP) oscillations in cerebral cortex begs the question as to what these mesoscopic phenomena reveal about the underlying microcircuits. To address this question, we recorded neuronal oscillations in the visual cortex of turtle. This preparation was chosen for two reasons. First, the LFP oscillations generated in this cortex are sufficiently large to permit the single-trial analysis of neuronal oscillations without the need for averaging. Second, the turtle *ex vivo* eye-attached whole-brain preparation facilitates the combined LFP and simultaneous membrane potential recording from adjacent neurons. The single-trial analysis revealed six important features of cortical oscillations. (i) Evoked and ongoing epochs of LFP oscillations are qualitatively similar. Both exhibit large increases in power with peaks in multiple frequency bands. (ii) Epochs of LFP oscillations are intermittent and of variable (trial-to-trial) peak frequency and duration. (iii) Single neuron spiking remains largely irregular and of low rate (compared to oscillation peak frequency) during epochs of LFP oscillations. (iv) Throughout an LFP oscillation epoch, the phase drifts, thus indicating the absence of autocoherence. (v) The fluctuating aspects of LFP oscillations can co-vary across spatially separate cortical recording sites. However, the grouping of recording sites by coherence can fluctuate from trial-to-trial. (vi) Membrane potential oscillations exhibit a large increase in power, but are broadband in the 0 to 100 Hz range, both for ongoing and evoked epochs of oscillation. We reproduced the observed intermittent ensemble oscillations in a model network, consisting of excitatory and inhibitory model neurons with the characteristics of regular-spiking pyramidal neurons, and fast-spiking and low-threshold spiking interneurons. In conclusion, this work suggests biologically plausible mechanisms for the stochastic generation of episodes of intermittent ensemble oscillations with irregular spiking neurons in cortical circuits.

Title: Sparseness and redundancy of visual stimulus encoding in primary visual cortex

Authors: *S. P. DUARTE, J. SCHUMMERS;
Max Planck Florida Inst., Jupiter, FL

Abstract: Neurons in primary visual cortex (V1) respond preferentially to stimulus features within a particular range, such as an oriented bar within a limited range of orientations. From these responses, we can generate tuning curves and then extract the neuron's preferred orientation. By plotting the preferred orientations of populations of neurons across cortical space, we can construct an orientation map. Orientation maps have been well described both at the large scale and cellular levels, where previous studies have shown that orientation transitions smoothly around a central pinwheel and nearby neurons have similar preferred orientations. However, the responses of V1 neurons have been probed using other stimulus features, including direction of motion, location in visual space, spatial and temporal frequency, and preferred eye. The cellular level organization of these other functional maps have been less well described. Additionally, how these functional maps are superimposed on the same cortical space is not well understood. For example, does a single neuron have tuned responses to all of the stimulus features, suggesting that a single neuron may encode all features of a unique stimulus? Or is a single neuron tuned to only one or two features, suggesting that a unique stimulus must be encoded by a population of neurons. Neither the sparseness nor the redundancy of the neural code in V1 have been directly quantified. Here we use two-photon imaging of genetically encoded calcium indicators (GCaMP6s) in the visual cortex of ferrets to explore these questions. We present a battery of simplified visual stimuli in order to extract the receptive field and tuning properties for a variety of stimulus features for hundreds of neurons over the same area of visual cortex. We then construct multiple large scale functional maps of the same region at cellular resolution, including retinotopy, orientation, direction, spatial and temporal frequency and ocular dominance. From these data, we can then examine the range of stimulus features being encoded by individual neurons, as well as how groups of neurons overlap in their representation.

Ultimately, our goal is to determine the level of sparseness and redundancy used in V1 to encode simple visual stimuli, and then extend these principles to the encoding of natural scenes.

Title: Early cortical spontaneous activity reflects the structure of mature sensory representations

Authors: *B. HEIN[1], G. B. SMITH[2], D. WHITNEY[2], K. NEUSCHWANDER[1], D. FITZPATRICK[2], M. KASCHUBE[1];

Abstract: Although spontaneous patterns of neural activity are thought to play an important role in the development of cortical circuits, relatively little is known about the structure of spontaneous activity in the developing cortex and its relation to mature sensory representations. We sought to determine how early patterns of spontaneous activity are related to stimulus evoked patterns in the same animal later in development. Here, we took advantage of the columnar architecture in ferret visual cortex to visualize patchy patterns of spontaneous activity prior to the onset of visual experience and the emergence of the orientation preference map. We used the highly sensitive calcium indicator GCaMP6s to reveal population activity on a single trial basis in chronic recordings of the developing ferret visual cortex. Novel analytical approaches were used to uncover interpretable statistical relations from these data. Prior to eye opening, the correlation structure of spontaneous cortical activity displays robust columnar patterns that resemble the mature organization of the orientation preference map. Although visual stimulation through the closed eyelids evokes strong patterns of activity prior to eye opening, the orientation preference map can only be evoked by visual stimulation after eye opening. We conclude that early spontaneous patterns of cortical activity exhibit an orderly

columnar structure that forms the basis for building sensory evoked representations during cortical development.

Abstract: The mammalian neocortex carries out complex mental processes such as cognition, perception and decision-making through the interactions of billions of neurons connected by trillions of synapses. We are just beginning to understand how networks of neurons become wired together during development to give rise to cortical computations. Recent studies have

shown that excitatory cortical neurons with a shared ontogenetic lineage form vertical columns spanning multiple cortical layers and that these "sister cells" are more likely to be synaptically connected to each other than to nearby, unrelated neurons. However, the precise wiring diagram between sister cells is unknown. Here we show that connectivity between sister cells depends on the laminar position of the pre- and post-synaptic neurons. In contrast to previous studies, we find that although sister cells residing in different cortical layers are more likely to be connected, sister cells located within the same layer are less likely to be connected to each other compared to distance-matched controls. Avoidance of cells that receive common input may be a fundamental principle of information processing within a cortical column. Our findings challenge the prevailing hypothesis that shared developmental lineage is always associated with an increase in connectivity, and suggest that both attraction and repulsion play an important role in shaping cortical circuits.

Title: Representation of the polarity of luminance transitions in layer 2/3 neurons of ferret visual cortex

Authors: *D. E. WHITNEY[1], G. B. SMITH[1], M. KASCHUBE[2], D. FITZPATRICK[1]; [1]Neurosci., Max Planck Inst., Jupiter, FL; [2]Frankfurt Inst. for Advanced Studies, Frankfurt am Main, Germany

Abstract: We recently reported the existence of an ON - OFF map in the superficial layers of ferret visual cortex. Increments or decrements in uniform luminance were found to drive transient responses in largely complementary sets of layer 2/3 neurons. Many layer 2/3 neurons respond preferentially to the presentation of either uniform luminance transitions or grating stimuli; others respond well to both stimuli. Neighboring neurons in layer 2/3 tend to exhibit similar response ratios for uniform luminance transitions versus grating stimuli. To further explore the relationship between the representation of luminance and orientation in layer 2/3, we

examined cortical responses to a drifting edge stimulus, containing a single-oriented contour defined by an ON or OFF luminance transition. Using *in vivo* wide-field epifluorescence calcium imaging, we find that population responses to this stimulus reflect both the polarity of the luminance transition and the contour orientation. The majority of these responses are best described as an intersection of the ON - OFF and orientation maps. Two-photon calcium imaging of layer 2/3 neurons further reveals that ON - OFF discriminability improves in almost all neurons at their preferred orientation. Likewise orientation selectivity is greater in almost all neurons when luminance transitions at the edge boundary match their preferred polarity. Taken together, these results emphasize that sensitivity to the polarity of luminance transitions is a fundamental property of layer 2/3 neurons. Consistent with this idea, we find that ON - OFF and orientation maps exhibit nearly complete coverage across the visual cortex, with complete representations of ON and OFF throughout orientation space. Notably, this coverage appears to occur despite the absence of orthogonality between the two maps.

Title: Experience-dependent and independent development of feature-selective synchronization in rat visual cortex

Authors: ***A. W. ISHIKAWA**, Y. KOMATSU, Y. YOSHIMURA;
Natl. Inst. For Physiological Sciencesphysi, Okazaki, Japan

Abstract: Synchronous firing among visual cortical neurons is considered to play important roles in visual information processing. We investigated the development of synchronized firing between adjacent neurons in primary visual cortex using immature rats at postnatal 13-15 days (P13-15) just after eye opening and three groups of P24-28 rats raised in a normal visual environment without (normal rearing) or with lid suture of both eyes from the day of eye opening (binocular deprivation), or in darkness from birth (dark rearing). We conducted single-unit recordings from multiple neurons located across all cortical layers using a multichannel electrode

and quantified the synchrony of visually-evoked spikes simultaneously recorded from pairs of neurons by computing the cross-correlogram of their spike trains. In normally reared rats at P24-28, synchronized firing preferentially occurred in neuron pairs located in the upper layer (layer 2-4) when the neuron pairs shared similar visual responsiveness. This feature-selective synchronization in the upper layer was almost absent or weak in immature rats and rats subjected to either dark rearing or binocular deprivation. In normally reared rats at P24-28, the dependence of synchronization on visual response similarity in neuron pairs located in the lower layer (layer 5-6) was weaker than that found in the upper layer. A similar weak dependence in the lower layer was also found in rats just after eye opening and visually deprived rats at P24-28. These results showed that feature-selective synchronized firing in the upper layer was established only when rats were reared under a normal visual environment after eye opening. On the other hand, our results showed that weak feature-selective synchronization was already present in the lower layer just after eye opening and the synchronization remained almost unchanged thereafter, independent of visual experience. Therefore, the development of synchronous firing in the primary visual cortex seems to be mediated by different mechanisms in the upper layer, which provides output mainly to higher cortical areas, compared with the lower layer, which provides output mainly to subcortical regions.

Title: Patterns of neural activity in visual cortex of the developing ferret: a comparison of awake and anesthetized states

Authors: ***G. B. SMITH**[1], D. E. WHITNEY[1], B. HEIN[2], K. NEUSCHWANDER[2], M. KASCHUBE[2], D. FITZPATRICK[1];

[1]Max Planck Florida Inst. For Neurosci., Jupiter, FL; [2]Frankfurt Inst. for Advanced Studies, Frankfurt am Main, Germany

Abstract: During development, spontaneous activity is thought to play a key role in patterning the central nervous system prior to the onset of sensory experience, supplementing molecular cues and bridging the gap to experience-dependent mechanisms. In parallel work, we show that the spatial structure of spontaneous activity in the developing visual cortex prior to eye opening is highly correlated with the future orientation map, at a time when the orientation map cannot be evoked through visual stimulation. A key caveat in these experiments, and in several other studies exploring the role of spontaneous activity, is that they were conducted in anesthetized animals. The effects of anesthesia on both stimulus evoked and spontaneous activity remain unclear, with some studies reporting dramatic changes under anesthesia. Here we report the development of a head-restrained preparation for longitudinal awake imaging in the developing ferret, utilizing both wide-field epifluorescence and two-photon imaging of GCaMP signals. We sought to explicitly test the effects of anesthesia on spontaneous and evoked activity in the ferret prior to and shortly following eye opening. Patterns of spontaneous and evoked activity exhibited a prominent modular structure in both the anesthetized and awake states. Under anesthesia, spontaneous activity takes the form of discrete events interleaved with periods of reduced activity. In contrast in the awake cortex, the frequency of events is markedly increased, and events often occur in rapid succession with infrequent quiescent periods. Notably, despite the striking differences in temporal dynamics, the modular patterns of spontaneous and evoked activity are highly similar between awake and anesthetized states, with similar regions tending to be coactive. Similar to results in anesthetized animals, spatial patterns of spontaneous activity recorded prior to eye opening strongly resemble the future orientation map that emerges day later. Therefore, although anesthesia dramatically affects the temporal structure of activity, it does not alter its underlying structure.

Title: The structure of response correlation matrix is stable in the primate visual cortex and reveals the anatomical boundary of V1 and V2

Authors: S. ESTEKI, L. E. HALLUM, V. GARCÍA-MARÍN, J. G. KELLY, *R. KIANI;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Correlations between neural responses have profound effects on the ability of neural populations to compute and encode information. However, the organization of these correlations and the mechanisms that give rise to them are not well understood. Here we investigated the pattern of correlations in the primary and secondary visual cortices (V1 and V2). We used 96-channel microelectrode arrays to simultaneously record visually-evoked and spontaneous activity of tens of neurons in the vicinity of V1-V2 border in two anesthetized macaque monkeys. Histology following the experiments revealed that nearly half of the electrodes were located in each area and recordings were largely limited to layer IV and bottom of layer III. We calculated spike count correlations of all pairs of recorded units, forming a correlation matrix. We found that, although the magnitude of the correlations may depend on the stimulus, the overall structure of the correlation matrix is largely stable; the ranking of pairwise correlations is preserved across all conditions and epochs, including the spontaneous activity. Furthermore, the correlation matrix structure reflects the V1-V2 border -- neurons within each area are more positively correlated with each other than across areas. In fact, unsupervised clustering algorithms could retrieve the location of the anatomical boundary even in the absence of a priori information about the electrode locations. We show that this cortical parcellation is not shaped solely by the distance separating units, their cortical layer, overlap of RFs, orientation preference, or ocular dominance. Rather, the correlation matrix structure is shaped mainly by "common noise": spontaneous activity or the residual fluctuations around the stimulus-evoked response. These fluctuations are temporally broadband across several orders of magnitude (0.01-20Hz) and could not have been caused by low frequency fluctuations in cortical excitability. We suggest that the population response dynamics which give rise to the stability of the correlation structure are furnished by intrinsic connectivity within an area, V1 or V2. The anatomical pattern of lateral connections -- dense connectivity within areas and minimal crossing across areal boundary (Rockland & Lund 1982, 1983) -- supports our hypothesis. The stability of the structure of correlation matrix in visual cortices is reminiscent of previous reports on the primate prefrontal cortex (Kiani et al, Neuron 2015), indicating an organizational principle preserved across sensory and association cortices.

Title: Behavioral-state dependence of cortical activity and visual encoding in a genetic model of autism

Authors: ***M. VINCK**, J. MOSSNER, J. CARDIN;
Yale Univ., New Haven, CT

Abstract: Dysregulation of GABAergic inhibitory function in the brain is a candidate mechanism underlying autism-related neurodevelopmental disorders, but little is known about the relationship between GABAergic cellular dysfunction, altered neural network activity, and cognitive impairments in autism. Global genetic loss of MeCP2 in mouse models recapitulates many Rett phenotypes, including impaired social interactions, cognitive deficits, and repetitive movements, but the cell type-specific role of MeCP2 signaling and the contributions of specific interneuron populations to these phenotypes remain unclear. Recent studies have highlighted the dependence of cortical activity and sensory encoding on behavioral state. Here, we study the behavioral-state dependence of cortical activity and visual encoding while deleting MeCP2 from specific GABAergic interneuron populations (SOM, PV, VIP), using a combination of single-unit and local field potential (LFP) recordings. We find altered cortical activity patterns around behavioral state transitions, revealing a role of the MeCP2 gene in regulating the way in which bottom-up sensory activity is integrated with spontaneous, internal activity.

Abstract: In primary visual cortex, the variance of neuron's firing rate is directly proportional to its mean firing rate (Tolhurst et al., 1983) and the firing rate is generally higher in complex cells than simple cells (Schiller et al., 1976). Here, we introduce a new method for measuring response variability based on the mean variance of the frequency response amplitude (MVFRA). We measured the relation between response variability in the time domain and the frequency domain and quantified the mean variance of the frequency response amplitude in simple cells and complex cells. To measure the response variability of neurons, we used chronically implanted ultra-thin multi-electrode array with impedances of 1-3 MΩ (Swadlow et al, 2005; Lashgari et al, 2012) in primary visual cortex (V1 area) and measured the neuronal responses to gratings drifting at 2 Hz for 2-3 seconds. The gratings could have different orientations (8 orientations with 16 directions) or luminance contrasts (8 contrast). Preliminary results indicate that the stimulus that generate the maximum firing rate not always generate the lowest response variability and that responses with the highest firing rate can be just as variable as those with lower firing rate. Our results suggest that the preferred stimulus of a V1 neuron is better described by the lowest response variability than by the maximum firing rate. These results may have implications to understand how stimuli are best represented by neuronal responses and suggest that responses with low variability may be more reliable for higher brain functions such as attention and decision making.

Title: The stabilized supra linear network (SSN) model explains feature-specific surround suppression in V1

Authors: D. OBEID[1], *K. D. MILLER[2];
[1]Ctr. for Theoretical Neurosci., [2]Cntr Theoretical Neurosci, Columbia Univ., New York, NY

Abstract: We have recently presented the SSN model of sensory cortical integration (Rubin et al., Neuron 2015; Ahmadian et al., Neural Comp. 2013). The main ideas are (1) Individual neurons have supralinear (power-law) input/output (I/O) functions, so that (2) the gain of neural responses (change in response per change in input; slope of the I/O function) increases with network activation; (3) for weak activation (low gain), neurons are only weakly coupled, dominated by their external input (from outside the local network), and responses to different inputs sum supralinearly following the supralinear I/O function; (3) increasing network activation (increasing gain) yields potential instability _ fluctuations in excitatory (E) cells would drive even bigger E cell responses via E->E connections; (4) in broad parameter regimes, the network instead dynamically stabilizes through feedback inhibition; (5) this stabilization is achieved by recurrent input largely cancelling feedforward input, so that net input grows much more slowly than linearly with the feedforward input. As a result, the network adds responses to different inputs sublinearly. The SSN with plausible models of cortical circuitry explained multiple aspects of cortical behavior, including “normalization” (sublinear response summation) that becomes more linear or supralinear for weak inputs, and in which both E and inhibitory (I) neurons are normalized; and orientation-tuned surround suppression in which (i) a strong surround becomes more weakly suppressive or facilitating for a weak center input; (ii) summation field sizes shrink with contrast; (iii) both E and I neurons surround suppress, so the net inhibition received by cells is decreased by surround suppression (Ozeki et al., Neuron 2009; Pecka et al., Neuron 2014). Here we show the SSN model replicates two other sets of results: (1) surround modulation is maximal when the orientation of the surround stimulus matches that of the center stimulus, even when the center stimulus is non-optimal for the cell (Shushruth et al, J. Neurosci. 2012); (2) For surround suppression of plaid center stimuli, a surround with orientation matching one component of the plaid more strongly suppresses that orientation’s contribution to the neural response, rather than non-specifically suppressing responses (Trott et al, J. Neurosci. 2015). These, and the decrease in inhibition with surround suppression in a large-scale model (D. Obeid & K.D. Miller, Cosyne 2015), required the network to have stronger local connectivity

than our previous studies, but previous results are preserved. We are now studying transient dynamics and signal propagation in the network.

Title: Vertical and horizontal structures of neuronal correlations in the cat primary visual cortex

Authors: *H. TANAKA[1], H. TAMURA[2], I. OHZAWA[2];
[1]Kyoto Sangyo Univ., Kyoto-shi/Kyoto, Japan; [2]Osaka Univ., Suita, Japan

Abstract: The firing patterns of nearby cortical neurons are often temporally correlated, which may contribute to numerous aspects of cortical processing. It is known that the correlation occurs on a variety of timescales. In particular, many previous studies noted precise correlation on a timescale of milliseconds and loose correlation on a timescale of tens of milliseconds. In order to fully characterize cortical organization of these correlations, we investigated their spatial extent, laminar organization, and dependence on receptive field (RF) similarities. By penetrating four-shaft arrays of microelectrode (a4x8x200_400_177, NeuroNexus) perpendicularly into anesthetized cat area 17 and 18 (between A3 and P8 and between L1 and L3), we simultaneously recorded neuronal activities across layers within a horizontal distance of 1.2 mm in response to flashed sequences of sinusoidal gratings or drifting gratings. We computed cross-correlograms (CCGs) based on these activities for neuronal pairs (n= 2426) separated by various distances in horizontal or vertical directions. In order to measure the strength of precise and loose correlations separately, we, using a median filer, dissociated the CCGs into narrow peak

components with a width of <= 8 ms and broad peak components with a width of > 8 ms. We found that loose correlation was widely observed for neuronal pairs horizontally and vertically separated over the whole distance range regardless of the layers. But the incidence was substantially lower in layer 4 than in other layers particularly for short horizontal distances (20% for layer 4 vs. 40~80% for other layers). Loose correlation also accompanied a consistent delay in firing that was monotonically related to the vertical, but not horizontal, distance between the paired neurons (5.85 ms/mm and 7.3 ms between L6 and L2/3). These patterns of loose correlation are consistent with the previous proposal that this correlation is mainly mediated by feedback projections from the higher cortical areas. On the other hand, precise correlation was horizontally much more limited with the incidence dropping sharply within 0.4 mm for all layers. Vertically, this correlation was typically observed for pairs of neurons in the same layers, without substantial difference of correlation strength between layers. Furthermore, precise correlation was predominantly seen for pairs with similar RF properties, whereas loose correlation was seen even in pairs showing dissimilar properties. Our results show that neuronal correlations in V1 show markedly different structures for horizontal and vertical dimensions depending on correlation time-scales.

Title: Adaptation to sensory input tunes visual cortex to criticality

Authors: ***W. L. SHEW**[1], W. CLAWSON[1], Y. KARIMIPANAH[2], J. POBST[2], N. C. WRIGHT[2], R. WESSEL[2];
[1]Univ. of Arkansas, Fayetteville, AR; [2]Washington Univ., St. Louis, MO

Abstract: A long-standing hypothesis at the interface of physics and neuroscience is that neural networks self-organize to the critical point of a phase transition, thereby optimizing aspects of

sensory information processing. This idea is partially supported by strong experimental evidence for critical dynamics observed in the cerebral cortex, but the impact of sensory input on these dynamics is largely unknown. Thus, the foundations of this hypothesis - the self-organization process and how it manifests during strong sensory input - remain unstudied experimentally. Thus, a basic question remains open: does strong sensory input drive cortical network dynamics away from criticality? Indeed, sufficiently strong input may increase the overall excitability of a network by bringing neurons closer to their firing thresholds and potentially tipping the network into a high firing rate regime that is inconsistent with critical dynamics. Previous theoretical work suggests that adaptation, i.e. activity-dependent changes in neural interactions, may serve to mitigate this tendency and maintain criticality. Here we address this problem experimentally in the *ex vivo*, eye-attached, whole-brain preparation in turtles. We presented diverse visual stimuli to the retina and measure population activity in visual cortex using high-density microelectrode arrays. We show, in our experiments and in a computational model, that strong sensory input initially elicits cortical network dynamics that are not critical, but adaptive changes in the network rapidly tune the system to criticality. This conclusion is based on observations of multifaceted scaling laws, predicted to occur at criticality. Our findings establish sensory adaptation as a self-organizing mechanism which maintains criticality in visual cortex during sensory information processing.

Title: Difference of VEFs with mental arithmetic tasks and verbal fluency task

Authors: *Y. GOTO;
Intl. Univ. of Hlth. and Welfare, Okawa City, Japan

Abstract: The aim of this study was to investigate the detailed spatiotemporal brain processes of divided attention which related to two types of mental arithmetic tasks (simple and complex Calculation) and the verbal fluency task using visual evoked magnetic fields. Fourteen healthy volunteers (8 women and 6 men, mean age 27.7±6.8 years) participated in this study. The magnetoencephalography (MEG) was acquired using a whole-head 306-channel sensor array

(Vectorview, ELEKTA Neuromag, Helsinki) that comprises102 identical triple-sensor elements. Each sensor element consists of two orthogonal planar-type gradiometers and one magnetometer. In this study, we analyzed MEG data recorded by the 204-channel planar-type gradiometers. A hemifield black-white checkerboard pattern was phase-reversed at a rate of 1 Hz presenting or left visual hemifield with (task +) or without (task -) mental arithmetic tasks and verbal fluency task. The entire stimulating field subtended an angle of 15°; each individual square of the checkerboard subtended 50' of arc measured at the subject's eye. The mean luminance of stimulation was 30 cd/m2 and the contrast was 97 %. The subjects were instructed to fixate on a red dot placed 0.2° of arc laterally from the stimulated hemifield. The VEFs signals were bandpass filtered between 0.1-1000 Hz. Analog data were digitized at a sampling rate of 1000 Hz/channel, and 100 responses of 350 ms epochs in each session were averaged using a computer. The amplitudes and latencies of VEFs components were measured. Lower amplitude distribution of three distinct components (N75m, P100m, N145m) were identified the contralateral to hemifield stimulation in each task to compare without task. In latency changes by left hemifield stimulation, the mental arithmetic tasks were significantly delayed in comparison with task(-) and successive subtraction in P100m. In right hemifield stimulation, no significant changes were observed. Amplitude changes in N75m on left hemifield stimulation were significantly decreased in mental arithmetic tasks. In addition, the distribution of high-gamma band activities was decreased in the right occipital area with left hemifield stimulation by all tasks (+) condition. In contrast, those were increased in the left occipital area with right hemifield stimulation by the all mental tasks. This study identified and documented that statistical the significantly changes in PR-VEFs were observed during mental arithmetic tasks and verbal fluency task. Our results suggest that these changes are the evidence of the inhibition of the visual information processing in the primary visual cortex by the tasks.

Title: Impact of visual familiarity on neuronal representations in inferior temporal cortex and behavior

Authors: *K. MOHAN, W. J. JOHNSTON, D. J. FREEDMAN;
Dept. of Neurobio., The Univ. of Chicago, Chicago, IL

Abstract: We have a remarkable ability to recognize a huge number of familiar visual stimuli. Furthermore, the relative novelty or familiarity of stimuli has a marked impact on attention and behavior. For example, the presence of a lion in your living room attracts your attention since it is a novel event that is unexpected and out of context. Here, we explore how familiarity impacts the neuronal representation of visual stimuli, and the relationship between neuronal and behavioral effects of familiarity. Previous work revealed that activity of neurons in the inferior temporal cortex (ITC) show changes in both visual responsiveness and stimulus selectivity as a result of long-term familiarity. In this study, we examined the impact of both long-term and short term (within session) familiarity on neuronal activity in ITC. Monkeys were familiarized with an image set and then trained to perform a dimming-detection task with novel and familiar images (100 images) shown ~50 times each. In the task, a series of images are presented for 400 ms each; on each trial, all images in the sequence have an equal probability of dimming (i.e. a subtle decrease in luminance). The monkey is required to release a lever if he detects dimming or hold on, if he does not. We recorded from 70 ITC neurons in one monkey during the task. We find that among stimulus selective neurons (50/70), novel stimuli evoke significantly higher average firing rates than familiar stimuli, consistent with previous reports. We also examined within-session changes in responses to the novel and familiar stimuli. This revealed distinct sub-populations of neurons which showed either increases or decreases in average firing rate within session, as well as changes in their parameters of stimulus selectivity. We also investigated the behavioral impact of stimulus novelty and familiarity by examining the animals' gaze patterns during free viewing of arrays of novel and familiar stimuli. In each trial, the subject was shown two images simultaneously presented at 3° to the left and right of fixation, and was allowed to freely view the images for 5 s. The images systematically varied in their familiarity - novel, intermediately familiar (~1000 viewings), and highly familiar (~10,000 viewings). We observed a systematic novelty bias in viewing times for both the intermediately and highly familiar stimuli compared to novel stimuli in the early (200-1500 ms) but not late (1700-5000 ms) viewing period. We examine and compare the time course of emergence of neuronal and behavioral familiarity signals. Our results will provide insights into the mechanisms underlying experience-dependent changes in ITC activity and their impact on behavior.

Title: Sequential processing of sensory and decision signals in posterior parietal cortex

Authors: *G. IBOS[1], D. J. FREEDMAN[2];
[2]Neurobio., [1]The Univ. of Chicago, Chicago, IL

Abstract: Neurons of the lateral intraparietal area (LIP) encode a wide range of sensory, cognitive and motor factors, and are known to be engaged during visual decision making tasks in which stimuli must be evaluated and used to flexibly guide action. To better understand the mechanisms by which LIP transforms a sensory signal into decision related encoding, we trained two monkeys to perform a delayed conjunction matching (DCM) task in which they had to indicate whether test stimuli matched a previously a presented sample while ignoring task-irrelevant distractors simultaneously shown in the opposite hemifield. Sample, test and distractor stimuli were high contrast random-dot motion patterns that parametrically varied in both their direction (among 8 evenly spaced directions) and color (8 colors from red to yellow). On each trial, one of two sample stimuli, composed of a conjunction of one direction (90° or 270°) and one color (yellow or red), was shown either inside or outside the receptive field (RF) of the neuron being recorded. Monkeys were rewarded for releasing a lever to test stimuli that matched the sample in direction, color and position. We recorded the activity of 74 LIP neurons, and found that 56/74 neurons differentiated between matching and non-matching test stimuli, or showed selectivity for the visual features of test stimuli. We computed two ROC-based selectivity measures: 1) a “sensory ROC” (sROC), comparing responses to each of the two match stimuli; 2) a “decision ROC” (dROC) comparing responses to match and non-matching stimuli. A sensory-decision Index ((sROC-dROC) / (sROC+dROC)) measured the relative strength of sensory encoding compared to the strength of decision encoding. This revealed a continuum of selectivity with some neurons showing pure visual selectivity, some showing pure decision selectivity, and some showing mixed selectivity. Decision related signals were not related to motor preparation, as few LIP neurons encoded information about match stimuli that were located outside LIP neurons’ RFs. In addition, a support-vector machine classifier was able to accurately decode both the visual features and the behavioral decision associated with match stimuli. An examination of the time-course of visual feature and decision related encoding in LIP revealed a shorter latency of visual (~50 ms after stimulus onset) compared to decision related (~120 ms) signals. Together, this suggests that sequential computations take place within

populations of LIP neurons starting with the integration of sensory information followed by a transformation into decision-related encoding.

Title: Task dependence of visual and mnemonic encoding in parietal and prefrontal cortices

Authors: *A. SARMA[1], X.-J. WANG[2], D. J. FREEDMAN[1];
[1]Dept. of Neurobio., Univ. of Chicago, Chicago, IL; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Prior studies have shown that neuronal activity in the lateral intraparietal (LIP) area and prefrontal cortex (PFC) can reflect the learned category membership of visual stimuli. A recent study from our group examined how category representations in LIP develop during learning, and how neuronal encoding of working memory in LIP and PFC are influenced by task demands. This study suggested that neuronal representations of working memory in LIP are task specific, while PFC plays a more general role in working memory. Here, we aim to further examine the task dependence of neural representations in LIP and PFC. The primary goal of this project is to understand how task demands influence neuronal encoding in LIP and PFC by recording from these areas while monkeys flexibly switch between feature-matching and category-matching tasks. Two monkeys were previously trained to perform a delayed match to sample (DMS) task using 360° of motion directions as sample and test stimuli. Monkeys released a lever to indicate whether a test stimulus and sample stimulus, separated by a memory delay period, showed the same motion direction. Monkeys were then trained on a delayed match to category (DMC) task (using the same stimuli) in which they indicated whether sample and test stimuli were in the same category, defined by an arbitrary category boundary. For this study, the two monkeys previously trained on the DMS and DMC tasks were trained to switch between

DMS and DMC tasks on a trial-by-trial basis. Monkeys were cued by a colored fixation point to release the lever when sample and test stimuli were either identical matches (DMS rule) or category matches (DMC rule). Motion stimuli and task timings were identical between these two types of trials; only the color of the fixation point was different. Furthermore, 50% of trials had an ambiguous task rule cue until halfway through the delay period. These ambiguous cue trials were indicated through the fixation point by a third color. We recorded from neurons in LIP (N=55) and PFC (N=210) while monkeys switched between DMS and DMC tasks. The results of this experiment will indicate whether neuronal representations in LIP and PFC are task dependent on a short time scale (trial-to-trial). Examination of activity in LIP and PFC will reveal the flexibility and timing of encoded information about motion direction, learned categories, task rule, and match decision during various epochs of the task. Ambiguous cue trials will show whether feature information is encoded in working memory in LIP when multiple later decisions need to be made. Simultaneous recordings in PFC and LIP will reveal how activity in these areas is coordinated under differing task demands.

Title: Semi-chronic population recordings from parietal and prefrontal networks during a rapid spatial categorization task

Authors: ***N. Y. MASSE**, J. M. HODNEFIELD, D. J. FREEDMAN;
Neurobio., Univ. of Chicago, Chicago, IL

Abstract: How we interact with objects in the environment is often based on their relative spatial location, such as deciding whether to reach for a jar on a high shelf, or whether a car is far enough away to safely cross the street. Both the posterior parietal (PPC) and prefrontal (PFC) cortices have been shown to encode spatial information, but how this information is transformed into a categorical decision is poorly understood. Here, we use a novel, rapid decision-making task to study how spatial information is encoded and categorized in the fronto-parietal network. We trained two monkeys to perform a spatial categorization task using a rapid series of flashed

stimuli. The monkeys maintained visual fixation on a central point while a series of 3 to 60 (mean of 14) white, red and green dot flashes (0.2° radius) appeared within a 13° x 26° zone in one hemifield. Flashes occurred once every 160 ms. The monkeys had 400 ms to manually release a touch bar after a red flash appeared in a 4° x 4° target zone whose center was located 6.5° away from the fixation point, or whether a green flash appeared in an adjacent target zone of equal size and eccentricity. White flashes were to be ignored. The two target zones were fixed throughout the training and recording sessions. The monkeys responded selectively to red and green flashes in their respective target zones (88.6 ± 0.5% response rate when flash occurred in correct target zone, 45.2 ± 1.1% response rate when flash occurred in incorrect target zone). We also trained the monkeys to perform a flash mapping task, which was similar to the task above except that the monkeys simply had to maintain fixation throughout the trial. During the task, we recorded from populations of neurons from PPC and PFC using two 32-channel semi-chronic microdrive systems (Gray Matter Research, MT). Across 36 sessions from two monkeys, we recorded from over 350 PPC and 500 PFC isolated single units. Linear classification analysis of the neural population response reveals that spatial information first develops within 100 ms of flash onset in areas ventral to the principal sulcus in PFC, before spreading to areas dorsal to the principal sulcus and to the PPC. Classification accuracy was significantly lower for both PFC and PPC neural responses during the flash mapping task, suggesting that spatial encoding in these areas is context dependent. Further analysis will focus on the putative mechanisms that underlie the transformation of spatial information into a categorical decision.

Title: Neurons in the lateral prefrontal cortex compensate for the asymmetries of their sensory inputs during memory-guided comparisons of visual motion

Authors: *K. MICHALOPOULOS[1,2], P. M. SPINELLI[1,2], T. PASTERNAK[1,2];
[1]Dept. of Neurobio. and Anat., [2]Ctr. for Visual Sci., Univ. of Rochester, Rochester, NY

Abstract: Comparing two visual motion stimuli that occur at different times require processing and storage of the initial stimulus, followed by its retrieval and comparison to the current stimulus. Such tasks demand coordination of processes involving bottom-up sensory information and top-down cognitive signals. This coordination is likely to take place in the lateral prefrontal cortex (LPFC) since it receives inputs from the motion processing area MT and its activity reflects task engagement and participation in sensory maintenance. When motion comparisons involve stimuli presented at the fovea, neurons in the LPFC show direction selective (DS) responses indicative of their MT origins and display anticipatory and memory-related activity, the likely components of its top-down influences. Little is known about LPFC activity during tasks involving motion presented outside the fovea. This question is of interest because of the connectivity between LPFC and the highly retinotopic area MT: while the information about the contralateral motion can be supplied directly by MT in the same hemisphere, the ipsilateral motion represented by MT in the opposite hemisphere, can only reach LPFC indirectly, most likely via callosal connections from the opposite LPFC. We examined how the LPFC neurons represent and utilize motion information that originates in the ipsilateral and contralateral hemifields while monkeys compared directions of two stimuli, S1 and S2, separated by a delay. During S1, responses to the contralateral motion were stronger and preceded ipsilateral responses by ~40ms, an indication of the apparent dominance of direct inputs from the ipsilateral MT. The asymmetry between contralateral and ipsilateral responses during S1 was not reflected in their DS activity, since it was equally robust for both stimulus locations. During S2, responses to ipsilateral but not contralateral motion were enhanced, eliminating the dominance of the contralateral stimuli observed during S1. In addition, the activity of many neurons during and after S2 presented in either of the two hemifields was modulated by the direction of S1, reflecting the difference between current and remembered stimuli and was predictive of the perceptual report. These results demonstrate that the process of memory-guided stimulus comparisons seamlessly incorporates sensory information from both hemispheres. Thus, while the sensory components of the LPFC activity reflect the difference between their direct and indirect origins, it appears that its cognitive components can compensate for the inequalities in their bottom-up sensory signals.

Title: Mechanisms of perceptual learning and learning interference in visual categorization

Authors: *L. SHA, R. KIANI;
Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Practice is the basis of visual expertise; it improves the speed and accuracy of acting on visual information. This improvement, known as perceptual learning, could stem from different mechanisms: (i) better representation of visual features, (ii) improved interpretation (i.e., optimal weighting) of visual information for decision-making, or (iii) improved decision strategies for committing to appropriate choices. While changes in the representation and weighting are well established, changes in decision strategy remain underexplored. Here, we investigate all three mechanisms. Six human subjects categorized multi-feature silhouettes with one informative feature whose attributes (e.g., width, height, and polarity) were quantitatively modified from trial to trial. The category boundary was defined on multiple attributes, forming a slanted hyperplane in the attribute space. Learning occurred based on distinct auditory feedbacks for correct and incorrect choices. We recorded changes in accuracy and reaction times (RT) to quantify learning. Accuracy improved with practice, ultimately shaping well-defined psychometric functions with monotonically increasing accuracy as a function of distance from the category boundary. RTs changed correspondingly; they decreased for the far stimuli and increased for those near the category boundary. Following training, we tested learning interference by introducing a second block, where subjects learned new categories defined either by rotating the hyperplane of category boundary in the same attribute space (similar condition) or by changing the informative attributes and features (dissimilar condition). Then, subjects were retested for the categorization of the first block. Accuracy significantly diminished and subjects took more trials to recover following similar blocks, demonstrating learning interference. Using decision-making models and psychophysical kernel analyses, we show that behavioral changes in perceptual learning result from (i) increased sensitivity to visual attributes, (ii) optimal weighting of the attributes to match the imposed category boundary, and (iii) increased decision criterion to adjust speed-accuracy tradeoff. Our results indicate that, in addition to changes in the representation and interpretation of sensory information, adjustments of decision strategy account for a sizeable portion of learning effects. On the other hand, learning interference was chiefly manifested by suboptimal weighting of feature attributes, suggesting that visual sensitivity and decision strategy can be preserved across interfering learning episodes.

Title: Post-error adjustments of decision strategy are informed by decision confidence

Authors: *B. PURCELL, R. KIANI;
New York Univ., New York, NY

Abstract: The ability to flexibly adjust our decision strategy following negative outcomes is vital to survival. After negative feedback, humans often slow down to respond on subsequent decisions. This post-error slowing (PES) prevents additional errors at the cost of deliberation time. Here, we directly test the hypothesis that PES is shaped not solely by negative feedback, but by a comparison of the expected and actual outcomes of past decisions. An unanticipated negative feedback indicates that the decision-making process is not appropriately tuned to the situation and calls for a revision. We measured post-error changes in the behavior of humans performing a reaction time version of a direction-discrimination task with stochastic moving dots. We manipulated task difficulty by randomly varying the motion strength (percentage of coherently moving dots) across trials. Subjects simultaneously reported the net direction of motion (up or down) and their confidence by making a saccadic eye movement to one of two possible targets above or below the dot patch (Kiani et al., 2014). The targets were elongated horizontal bars and the landing point of the saccade on the target indicated confidence. We found that post-error adjustments in decision-making were highly dependent on subjects' expectations. Errors associated with higher confidence produced large elevations of reaction times on the next trial, especially for weaker motion strengths. In contrast, PES was substantially reduced following lower-confidence errors. In both conditions the overall accuracy and psychophysical thresholds remained unchanged. The observed pattern is best explained through a mixture of increased decision bound and decreased sensitivity to incoming evidence. These results challenge the proposal that negative feedback drives PES through purely adaptive changes in decision bound or purely maladaptive distraction effects. Instead, the magnitude of mismatch between actual and expected outcomes drives changes in the stimulus sensitivity and decision strategy, which determine the magnitude of PES.

Title: Making decisions about observed actions

Authors: *A. PLATONOV;
Dept. of Neurosci., Univ. of Prma, Parma, Italy

Abstract: Despite significant progress in identifying brain circuit for processing action observation, there is no general framework to establish a relationship between this brain activity and its behavioural correlates. We propose that varying the amount of dynamic noise in action movies as done previously in random dot motion direction discrimination studies, provides such paradigm. In 4 experiments 10 human subjects discriminated between two manipulative hand-actions in a 2AFC. In experiments 1-3, observers were presented with rolling/rotation movies, in experiment 4 with a dragging/grasping pair. In each movie a male or female actor manipulated one of two objects. Actions were presented at 2 depths and 5 fronto-parallel positions, resulting in 40 movies per action. On every frame in each movie, a percentage of randomly chosen dot-pixel pairs separated by a distance randomly defined from within a fixed interval was scrambled. By manipulating this percentage, we set signal strength at different levels from nearly 0 to 100%. In experiment 1, observers reacted at the end of a trial. For each full action movie, we created two additional copies retaining only the static or dynamic component. Accuracy changed as a function of stimulus strength following a classical psychometric function. Neither static nor dynamic component alone could account for these results. In experiment 2, 3 and 4, the subjects watched full action movies and responded as soon as they made a decision. Different observers took part in experiment 2 and 3, and all accomplished the same amount of full action movie blocks in the training prior to testing. Observers in experiment 2 discriminated between 2 actions while, in experiment 3, action discrimination blocks were randomly intermingled with blocks in which subjects discriminated gender (male/female). The response time and accuracy were closely coupled in all three experiments. The data were well fit by a proportional rate diffusion model with 3 parameters (bound, drift rate and residual time), the threshold ratio being close to 3.5 (characteristic for diffusion models). Changing task in experiment 3 significantly affected drift rate, a factor 3 increase in gender discrimination revealing a faster evidence accumulation rate for the same visual input. In experiment 4, as the observers received no preliminary training,

their data suggest that learning templates for new actions of the same class play very little role in action discrimination. Our results posit action observation as an ethologically valid extension of motion direction discrimination for decision making studies.

Title: Dissociable adjustments at abstract accumulator and motor preparation levels in different urgency regimes

Authors: *N. A. STEINEMANN[1], R. G. O'CONNELL[2], S. P. KELLY[1,3];

Abstract: The prevalent view from mathematical psychology that speed-emphasis in decision-making tasks leads to decreased decision thresholds, has recently been challenged by findings of the opposite effect in frontal eye field and lateral intraparietal area in monkeys. Employing human electroencephalography, correlates associated with decision formation, like the centro-parietal positivity (CPP) can be acquired simultaneously with signals of motor preparation. In the current study we analyze motor preparation activity in the mu band (8-14 Hz) separately over motor cortex contralateral and ipsilateral to the correct movement in order to assess the effects of urgency on the separate, competing accumulators for the two alternatives at the motor level, and compare these dynamics with those observed at the abstract accumulator level (the CPP). We employed a two alternative forced-choice contrast discrimination paradigm as well as a random dot motion (RDM) task. In both, we manipulated speed versus accuracy emphasis, and additionally in the RDM task we manipulated the level of counter-evidence, i.e., motion towards the incorrect alternative direction. In both experiments, the average CPP appeared to reach higher thresholds in the speed the the accuracy condition, but analysis of peak CPP amplitude over response time quantiles revealed that for early RTs in common with both conditions, CPP amplitude tended to be higher for the accuracy condition, and in both speed and accuracy

conditions, this amplitude-at-RT steeply decreased over increasing reaction times consistent with a collapsing bound. In contrast, contralateral motor preparation signals at response time showed a stable level across RT bins . Ipsilateral (unchosen) motor preparation, however, showed a clear increase for the speed condition, and both contralateral and ipsilateral motor preparation built more steeply, consistent with an additive urgency signal exerted at the motor level. In ongoing analyses we are testing whether models incorporating these and other features of the neurophysiological data accurately describe the behavioral data.

Title: Laminar differences in neural activity covarying with action choice in dorsal premotor cortex

Authors: *C. CHANDRASEKARAN[1], D. PEIXOTO[2,6,3], W. T. NEWSOME[2,7], K. V. SHENOY[1,2,4,5];

Abstract: Dorsal premotor cortex (PMd) is involved in choosing appropriate motor actions on the basis of visual cues. However, we currently do not understand how the action selection process unfolds in the underlying circuit in PMd. We addressed this question by recording with

linear multi-contact electrodes (16 contacts, 150 μm) in PMd of monkeys performing a visual discrimination reaction time (RT) task. Monkeys discriminated the dominant color in a central static checkerboard containing mixtures of isoluminant red and green squares, and then reached to either a red or green target (presented prior to the checkerboard) as the behavioral report. Changing checkerboard difficulty modulated the monkeys' accuracy and induced a range of RTs. Thus, the task induces rich behavior, which allows study of the neural correlates of this deliberative action selection process. We have previously demonstrated that a diverse PMd neural population covaries with action choice. A subpopulation of these cells had properties consistent with a candidate decision variable (Chandrasekaran et al., SFN 13, 14). Here we report physiological data from 416 single and 131 multi-units in monkey T PMd (385 from U-probes). The PMd units fell into two broadly overlapping classes. The first class of cells modulated their responses with checkerboard onset;the response duration covaried with RT. The other class is perimovement cells that respond around movement onset (104 units, 17%). The first class can be subdivided into cells, which on checkerboard onset either suppress (105, 20%) or enhance their firing rates (348, 63%). The responses of enhanced cells were consistent with a candidate decision variable. We captured this diversity using a visuomotor index. To test for an organization as a function of depth, we related the visuomotor index to the electrode contact at which the unit was recorded; contact 1 was superficial and 16 the deepest. We pooled across days to identify distributions of contact indices for each cell class. Although pooling likely reduced depth differences, enhanced units were more likely in superficial electrodes when compared to suppressed (7 vs 11, $p < .001$) and perimovement units (7 vs 10, $p<.001$). Perimovement and suppressed units were not found at different depths ($p > .05$). Consistent with this finding, the visuomotor index decreased with increases in depth ($r=-0.66$, $p<.01$). Finally, on average, choice predictive activity was present at least 27 ms ($p<.001$) earlier in superficial electrodes (1-6) than deeper electrodes (10-14). This basic statistical analysis suggests a depth, and thus laminar, organization of functional neural populations in PMd mediating action choice.

Title: Dorsal premotor cortex reflects decision making only when concrete actions are available

Authors: *M. WANG[1], C. CHANDRASEKARAN[2], D. PEIXOTO[3,1,5], W. T. NEWSOME[3,6], K. V. SHENOY[2,3,1,4];
[1]Neurosciences Program, [2]Electrical Engin., [3]Neurobio., [4]Bioengineering, Stanford Univ., Stanford, CA; [5]Champalimaud Neurosci. Inst., Lisbon, Portugal; [6]Stanford Univ. / HHMI, Stanford, CA

Abstract: Lesion and physiological studies suggest that dorsal premotor cortex (PMd) is involved in decisions based on visual cues. We previously demonstrated that subpopulations of PMd neurons may reflect a candidate decision variable in decision making tasks (Chandrasekaran et al., Peixoto et al. SFN 13, 14). However, in these studies, the perceptual decisions were explicitly linked to real or potential action plans. Here we focused on dissecting the degree to which neural dynamics in PMd reflect the processes of perceptual decision making and action selection. We trained monkey T to reach to a target whose color matched the dominant color in a central red-green checkerboard. To dissociate between perceptual decision (regarding the dominant color) and action selection (reach to either the left or right target), we used two task design manipulations. First, on a trial-by-trial basis we randomized the target configuration so that on some trials, the left target was red and the right target was green, and vice versa. Second, we used two types of trials which were interleaved. One was the classic design in which targets appeared first, followed by the checkerboard ("TargFirst"). In the new design, the presentation was reversed, so the checkerboard appeared first, followed by the targets ("StimFirst"). In the time period after the checkerboard is presented and the targets have yet to appear, there is not enough information to form an action plan because the target configuration is randomized. Psychophysical thresholds were largely similar in the two conditions (signtest, $p = 0.16$). We recorded from 33 units in PMd (9 single units, 24 multiunits; single electrodes). Consistent with our previous reports, in the TargFirst condition, PMd did not respond after target onset, and had properties consistent with a candidate decision variable after checkerboard onset. In contrast, in the StimFirst condition, we found the reverse: PMd did not respond after checkerboard onset ($p > 0.05$), but did become choice predictive in a lawful manner after target onset. Stated differently, information from the targets and from the checkerboard were each necessary, but not sufficient, to modulate PMd neurons; only when both types of information were available did PMd activity change. Several studies have suggested that both premotor and

parietal areas are involved in decision making. By using task designs that separate perceptual decisions from action selection, we suggest that PMd is engaged only when concrete actions are available and it is not involved in forming purely perceptual decisions. Thus, unlike parietal areas, neural dynamics in PMd might be more tightly linked to action selection processes.

Title: What does LIP do when a decision is dissociated from planning the next eye movement?

Authors: *N. SO[1], M. N. SHADLEN[1,2,3];
[1]Neurosci., Columbia Univ. Med. Ctr., New York, NY; [2]Kavli Inst. for Brain Sci., New York, NY; [3]Howard Hughes Med. Inst., New York, NY

Abstract: Neurons in the lateral parietal area (LIP) reflect the accumulation of evidence when a decision is communicated by an eye movement into, or away from, a neuron's response field (RF). In most experiments, a saccadic choice follows the decision immediately or after a memory delay. However, not all decisions precipitate an immediate action. In fact, under conditions requiring a sequence of eye movements, LIP neurons represent only the next eye movement (Mazzoni et al. 1996). Therefore, when a decision is not communicated with the next eye movement, LIP might not reflect the decision formation but instead represent only the next eye movement. We trained a rhesus monkey to decide the net direction of motion in a stochastic random dot display. Although the monkey ultimately indicated its choice with a saccadic eye movement, it first made a sequence of irrelevant eye movements, away from and back to the original point of fixation. The intervening steps did not impair the monkey's performance on the discrimination task. We examined the response of LIP neurons during decision formation with and without a choice target in the RF. Despite the fact that the next eye movement was always to

an irrelevant target outside the neuron's RF, LIP activity reflected the accumulation of evidence supporting the ultimate saccadic choice towards the neuron's RF. After decision formation, as the intervening saccade displaced the choice target from the neuron's RF, these neurons no longer represented the choice information. Instead, the information was represented by other LIP neurons as the irrelevant eye movements brought a choice target into their RF. Then, with acquisition of the original fixation, the LIP neurons that reflected decision formation were reanimated to represent the choice information. The restored choice-related activity was correlated with the decision-related activity the same neuron represented during decision formation, despite the intervening eye movements. Thus, even when a decision is to be reported after irrelevant eye movements, LIP neurons exhibit decision-related activity, and they do so again around the time of the ultimate, relevant eye movement to report the choice. During the intervening eye movements, the choice information is represented in other LIP neurons with different RF locations. Together, these results expose an unexpected capacity of LIP neurons, as a population, to mediate a decision-related computation spanning multiple oculomotor actions.

Title: Primate saccade target selection relies on feedback competitive signal integration

Authors: ***J. GOOSSENS**, J. KALISVAART, A. NOEST, A. VAN DEN BERG, R. MASSOUDI, P. BREMEN;
Donders Inst. For Brain Cognitin and Behaviour, Dept. Cognitive Neurosci., Nijmegen, Netherlands

Abstract: It is often assumed that decision-making involves neural competition, accumulation of evidence 'scores' over time, and commitment to a particular alternative once its 'scores' reach decision-threshold first. So far, however, neither the first-to-threshold rule, nor the nature of competition (feed-forward or feedback inhibition), has been revealed by experiments. Here, we

presented two simultaneously-flashed targets that reversed their intensity difference during presentation, and instructed subjects to saccade towards the brightest target. Both humans (n=6) and monkeys (n=2) preferentially chose the target that was brightest during the first stimulus phase. Unless this first phase was too short, primacy persisted even if the second, reversed-intensity phase lasted longer. This effect did not result from premature commitment to the initially-dominant target; a strong target imbalance in the opposite direction later on drove nearly all responses towards that location. Moreover, there was a non-monotonic relation between primacy and target imbalance; increasing this imbalance beyond 40 cd/m2 caused an attenuation of primacy. These are the hallmarks of hysteresis, predicted by models in which target-representations compete through strong feedback. Preliminary analysis indicates that this behavior is reflected in the single-unit activity of cells in the Frontal Eye Fields.

Title: Monkeys behaving badly: probing macaque subjects' internal task strategies with psychophysical reverse correlation

Authors: *A. G. BONDY[1,2], B. G. CUMMING[1];
[1]Lab. of Sensorimotor Res., Natl. Eye Institute, NIH, Bethesda, MD; [2]Brown-NIH Neurosci. Grad. Partnership Program, Brown Univ., Providence, RI

Abstract: Our understanding of the neurobiology of perceptual decision making relies heavily on studies where animal subjects perform threshold psychophysics. A fundamental premise is that the behavioral relevance of sensory evidence is under the experimenter’s control, typically examined with threshold measures. However, these provide no guarantee that animals correctly perform the task assigned. Understanding the rules used by animals to render perceptual reports is critical to the interpretation of many studies. We used psychophysical reverse correlation to measure macaque subjects’ internal task strategies, in a coarse orientation discrimination task. Animals reported the orientation of a stimulus from two orthogonal alternatives, which were

fixed within a session. The stimuli consisted of dynamic white noise filtered in the Fourier domain. The filter's center orientation varied between the two discriminanda, and its angular width controlled task difficulty. Some trials were filtered with an infinitely broad angular component, thus containing a uniform distribution of orientations on average. The animal's decision rule (or "psychophysical kernel") was calculated as the difference between the two choice-conditioned mean orientation power spectra of these trials. The orientation of this kernel describes which stimulus orientations most strongly influenced the animals' choices. The kernel orientation frequently deviated from the discriminanda, providing objective evidence that the animals did not do the task as assigned. The magnitude of deviation predicted the day to day variability in behavioral threshold (r=0.32). To explore the effect of recent training history, we kept the discriminanda fixed for multiple days. Following a change in the discriminanda, the kernels initially reflected the previous task. Remarkably, the time constant for aligning the kernel to the new task was approximately 10 training days (50,000 trials). In striking contrast, human subjects were able to switch their decision rule within a single session. The accuracy of the kernel in predicting individual choices (approximately 52% on average) provides an estimate of internal noise. If animals treat all trials equally (as they should if they are at threshold), this estimate should not change with signal strength, providing a useful metric of whether subjects are performing at threshold. Psychophysical reverse correlation provides powerful tools to assess whether animal subjects do the task they have been set. This information is essential for interpreting many studies, especially those employing dynamic changes in task.

Title: Uncertainty decoded from population activity in macaque primary visual cortex is used in perceptual decisions

Authors: *E. Y. WALKER[1], R. J. COTTON[1], W. J. MA[2], A. S. TOLIAS[1];
[1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: Organisms typically base their perceptual decisions on noisy and ambiguous sensory observations. There can be top-down sensory uncertainty due to ambiguity and bottom-up sensory uncertainty due to noise in the perception system. In many tasks, optimal performance requires the brain to represent and utilize, on every trial, knowledge about the level of both bottom-up and top-down uncertainty. In earlier work, we introduced a simple orientation classification task with controlled top-down and bottom-up sensory uncertainty for which optimal performance requires the observer to utilize sensory uncertainty on a trial-by-trial basis, and demonstrated that both humans and monkeys do so. Here, our goal is to identify the neural substrates of this computation. The theoretical framework of probabilistic population coding (PPC) postulates that the brain decodes sensory uncertainty from a noisy pattern of population activity through a "likelihood function" over the stimulus. This function represents the probability of the observed pattern given each hypothesized stimulus value, and the width of this function is a proxy of sensory uncertainty. We hypothesized that the width of the likelihood function that can be decoded from trial-to-trial population activity in primary visual cortex (V1) is informative about the animal's decision. To test this hypothesis, we trained macaque monkey on our classification task. We implanted a chronic multi-electrode array in V1 to record the population activity while the monkey performed the classification task. On each trial, we decoded from single-trial V1 population activity the width of the likelihood function under a Poisson-like population coding model. The monkey's trial-by-trial classification decisions were better predicted by a Bayesian model utilizing the width of the likelihood function than by a non-Bayesian model only utilizing a point estimate of the stimulus orientation. We also tested the models on a shuffled data where the widths of the likelihood functions were shuffled among trials with identical stimulus condition, effectively removing trial-by-trial correlation between the likelihood width and the monkey's decision, while keeping the average correlation between likelihood widths and stimulus orientations intact. We observed that Bayesian model's performance dropped significantly on the shuffled data when compared to the fits on the original data, supporting our hypothesis that trial-by-trial variation in the likelihood width is informative about the decision. This result provides population-level physiological evidence in support of the PPC framework.

Title: Serial dependence in visual perception and stimulus representation in primary visual cortex

Authors: *E. ST. JOHN-SAALTINK[1], P. KOK[1], H. C. LAU[2,1], F. P. DE LANGE[1];
[1]Donders Inst. for Brain, Cognition and Behaviour, Radboud Univ., Nijmegen, Netherlands;
[2]Psychology, Univ. of California Los Angeles, Los Angeles, CA

Abstract: Our perception of the world is partly determined by our knowledge of the statistical regularities in the environment, such as the fact that the world is stable over short time scales. This is reflected by the fact that visual perception is serially dependent, with previously seen stimuli biasing the perception of subsequent stimuli (Fischer & Whitney, 2014). The neural mechanisms of this effect are unclear. Does this trial history effect occur at the level of the higher-order areas involved in perceptual decision making (Gold & Shadlen, 2007), or do preceding stimuli bias stimulus representations at the earliest levels of sensory processing? In this study, we acquired fMRI data in 24 healthy human participants while two grating stimuli were briefly presented in the left and right visual field. On each trial, participants reported the orientation of the grating at the location indicated by a post-stimulus response cue. We used multivariate pattern analysis to extract orientation specific BOLD signals from the primary visual cortex on every trial. We applied multiple regression analyses to isolate the influence of the current and previous stimuli on the behavioural and neural responses. In line with previous reports (Fischer & Whitney, 2014; Liberman, Fischer, & Whitney, 2014), perceived orientation was consistently biased towards the orientation of the preceding stimulus. Strikingly, the orientation signal in V1 was similarly biased towards the orientation presented on the previous trial, suggesting that recently seen stimuli alter low-level sensory representations. Serial dependence was spatially specific such that stimuli on the current trial only showed an influence of previous stimuli at the same location, both in terms of brain and behavior. Finally, when stimulus and perceptual choice diverged, trials were biased by previous choice, rather than previous stimulus. Our study extends previous behavioral reports by revealing a trial history effect at the earliest levels of sensory cortex. This biasing process is spatially specific, and governed by previous choice rather than stimulus. Together, these findings elucidate how our perception is shaped by our perceptual history.

Title: The interplay between long-and short-term memory traces in sequential visual decision making

Authors: *J. FISER, J. ARATO, A. KOBLINGER;
Dept. of Cognitive Sci., Central European Univ., Budapest, Hungary

Abstract: Past experience strongly guides sensory processing and influences every perceptual decision. Yet, due to contradictory findings in the literature, the exact pattern of these effects is unclear and a convincing general computational framework underlying these effects is still missing. Even in the simplest version of the problem, making a forced choice between two hypotheses based on noisy sequential input, the field is divided over how basic statistics of the input (e.g. appearance frequencies) and various significant patterns (e.g. repetition) jointly determine the observer's behavior. We used the above model problem in 7 experiments to tease apart the relative contributions of each effect on human sequential decision making. Observers performed a 2-AFC decision making ("Which of the two shapes is seen?"), while we independently modulated the level of pixel-noise, the appearance frequency of the elements coming from the two classes at two different time scales, and the ratio of repetition/alternation in the sequence. We found that the noise level of the stimulus systematically modulated the strength of each contributing factor to decision making. However, instead of a simple interpolation between long-term probabilities and veridical choice as it would be predicted by adaptation or priming, different pairings of short- and long-term appearance probabilities produced various characteristic under- and over-shootings in choice performances. This rules out a number of earlier models proposed for explaining human behavior in such tasks. We also found that human performance measured by correct answers and by reaction times yielded opposing results under some conditions indicating that RT measures tap into motor rather than cognitive components of sequence coding. By controlling the base-rate probabilities and repetitions/alternations independently, we also observed that despite the two measures being correlated in general,

repetition/alternation is a factor independently influencing human judgment. To assess the generality of our findings, we run behavioral studies with adult rats asking them to choose between two full-field stimuli of different brightness. We found that rats replicated the striking results of humans, by choosing the frequent stimulus of recent past fewer times under high uncertainty after experience with particular long-term appearance statistics. Through simulations, we confirmed that our results can be captured by a probabilistic model of human visual decision making that balances long- and short-term summary statistics of sequences, and in parallel, also encodes salient features, such as repetitions in the sequence.

Title: Dissociating sensory from decision processes in human perceptual decision making

Authors: *P. MOSTERT, P. KOK, F. P. DE LANGE;
Donders Inst. For Brain, Cognition & Behaviour, Nijmegen, Netherlands

Abstract: Theoretical frameworks posit that perceptual decisions arise from a cascade of functionally distinct stages. In the sensory stage, the physical stimulus is encoded into internal sensory evidence, while during the subsequent decision stage, this sensory evidence is integrated over time into a decision variable. Identifying and dissociating these stages at the neural level will advance our understanding of perceptual decision making and has become a central goal within the field. We adopted a novel approach to dissociate sensory- from decision-related activity in MEG, while subjects were making perceptual decisions about the presence/absence of a grating embedded in noise. We used a functional localizer, in which subjects were exposed to grating stimuli while performing a task at fixation, in order to isolate neural signals related to sensory processing in the absence of decision making and attention. A multivariate decoder was trained on this data to identify a sensory-specific neural signature. We subsequently employed this decoder to trace sensory processing over time during perceptual decision making. In addition, we conducted an analysis in which we trained a decoder on the data obtained during the perceptual decision making task itself, without making use of the functional localizer, to extract

the neural signal that collectively underlies sensory processing and decision making. The results showed that sensory-related activity was specific to early time windows and consistent with occipital sources. Interestingly, we observed that the stimulus information was sustained when it was attended and relevant for the task at hand. Furthermore, the stimulus information faithfully reflected the physical stimulus, regardless of the eventual behavioral decision. Decision-related activity, on the other hand, was longer-lasting and more prominent during later time windows. It showed a ramping temporal profile and was localized to parietal and frontal cortex. Furthermore, decision-related activity was confined to a later time window when no grating was presented, but included the early time points when a grating was presented - the time window that was previously associated with sensory processing. We suggest that this early decision-related activity may reflect fluctuations in latent confounding variables, such as attention. In conclusion, our approach provides a novel way to reliably extract the neural dynamics of sensory processing during perceptual decision making, uncontaminated by decision processes or other confounding variables.

Title: Eye-opener: pupil dilation signals decision uncertainty

Authors: *A. E. URAI[1,2], J. W. DE GEE[1,2], T. H. DONNER[2,3];
[1]Dept. of Neurophysiol. and Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [2]Dept. of Psychology, [3]Amsterdam Brain and Cognition, Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: Purpose: Neuromodulators released from ascending brainstem systems gate cortical plasticity and perceptual learning, and have been implicated in signaling uncertainty during

decision-making. During perceptual decisions, observers' certainty about successful decision outcomes increases monotonically with the strength of sensory evidence on correct trials, but follows the opposite pattern on error trials: if sensory evidence is strong but the observer chooses wrongly, the internal decision variable is more likely to be close to the decision criterion (leading to larger uncertainty). Here, we used pupil dilation at constant luminance as a proxy for neuromodulatory brain state. During a protracted perceptual decision with feedback, we systematically manipulated decision uncertainty. We asked how, and at which time during the trial, this manipulation modulates the amplitude of pupil dilation. **Methods** We measured pupil diameter in 27 human observers performing a 2-interval forced choice task. Dynamic random dot patterns with varying motion coherence were shown in two successive intervals, and observers judged which interval contained stronger motion. The strength of sensory evidence (i.e., coherence difference between intervals) varied from trial to trial. After ~2 s following response, observers received auditory positive or negative feedback. **Results** As predicted, reaction time, a proxy of decision uncertainty, decreased with sensory evidence on correct trials, but increased with sensory evidence on error trials. Pupil dilation during decision formation scaled with sensory evidence, and hence certainty, in this same way. Pupil dilation after feedback, on the other hand, reflected decision uncertainty only on correct trials. Following negative feedback, the pupil dilated robustly, but dilation amplitude was unrelated to sensory evidence. Applying a reinforcement learning model to our data, preliminary results indicate that observers, whose decision-linked pupil dilation most precisely tracks uncertainty across trials, show higher learning rates. **Conclusions** Pupil dilation during protracted perceptual decisions reflects decision uncertainty. The precision of this uncertainty coding might drive perceptual learning. After feedback, the pupil reflects prediction errors (i.e., the difference between decision certainty and received feedback) only after positive, not negative, feedback. Ongoing pharmacological interventions during magnetoencephalography and pupillometry recordings aim to uncover neuromodulation-induced changes in cortical dynamics during perceptual learning.

Abstract: Purpose The brainstem locus coeruleus (LC) sends widespread modulatory (noradrenergic) projections to the cortex (including visual and parietal cortex), and it is connected with other neuromodulatory brainstem centers. In monkeys, the LC exhibits transient activations during visual decisions. These activations are thought to be caused by top-down input from frontal cortical regions (e.g., anterior cingulate cortex, ACC) and to drive pupil dilation. We used high-resolution fMRI to track transient LC responses in humans during a visual yes-no contrast detection task. We tested for the link between these LC responses and (i) decision-related (non-luminance mediated) pupil dilation; (ii) decision-related responses in dopaminergic midbrain centers (substantia nigra, SN; ventral tegmental area, VTA), and the cholinergic basal forebrain (BF); and (iii) the computations leading to a simple decision, such as the accumulation of sensory evidence. **Methods** Human subjects (N=15) performed a near-threshold contrast detection task during concurrent whole-brain fMRI (1.79x1.79x3.0 mm) and pupillometry. They viewed a continuous stream of dynamic black and white noise centered around the fixation mark on a grey background. Each trial started with an auditory cue, followed by, in 50% of trials, the superposition of a low-contrast target grating onto the noise. Subjects reported their yes-no judgment about target presence by a button press. To quantify the effect of pupil-linked neuromodulation on the protracted decision process (median RT: 2.08 s), we fitted a sequential sampling (drift diffusion) model to the reaction time distributions for yes and no choices, separately for high and low pupil dilation trials. **Results** The amplitudes of decision-related LC responses correlated with pupil dilation amplitude on a trial-by-trial basis. Significant pupil-coupling was also evident for SN/VTA (not BF), but this effect did not explain the LC-pupil coupling. Decision-related LC responses were also correlated with responses in the ACC, the putative driver of decision-related LC activation. Drift diffusion modeling revealed a selective bias of the accumulation ("drift criterion" parameter) towards yes-choices under high pupil dilation. **Conclusion** Decision-related pupil dilation reflects LC responses. These, in turn, cause a transient boost in neuromodulation in cortical networks that pushes the accumulation of sensory evidence during yes-no decisions toward "yes".

Title: Decision-related oscillatory activity in human visual cortex is linked to pupil dilation

Authors: *T. MEINDERTSMA[1,2,3], N. A. KLOOSTERMAN[1,2], G. NOLTE[3], A. K. ENGEL[3], T. H. DONNER[1,2];

Abstract: Introduction Behavioral report of the disappearances of salient visual targets is accompanied by a transient, retinotopically global modulation of population activity in human visual cortex. This signal is contingent on behavioral report of the (illusory or physical) target disappearance and its strength predicts the stability of the subsequent perceptual state. We used magnetoencephalography (MEG) to test if this novel top-down signal is associated with (i) the perceptual decision or the resulting motor response, and (ii) a transient boost of neuromodulation. We used pupil dilation at constant luminance as a non-invasive proxy of central neuromodulator release. **Methods** We performed simultaneous MEG and pupil diameter recordings in N=28 human subjects during the spontaneous ("motion-induced blindness" illusion) or physical temporary disappearances of a salient visual target (full contrast Gabor, size: 2 deg, spatial frequency: 2.5 deg^{-1}) surrounded by a moving flow field. Subjects reported these perceptual changes by overt motor response (button press), or covert counting (report of total after run). We characterized the effects of (i) motor report and (ii) pupil dilation amplitude on the modulations of MEG power over visual cortex around perceptual changes. **Results** As in earlier studies, a transient modulation of MEG power in the beta frequency range (12-36 Hz) over visual cortex reflected the content of behavioral report (suppression for target disappearance, enhancement for reappearance). An analogous modulation occurred in the alpha range (8-12 Hz). Both modulations occurred at the median response time (from the overt report condition) during both overt report and covert counting. The modulations were enhanced under high pupil dilation.

Conclusions The power modulation in visual cortex reflects a top-down signal linked to the perceptual decision, irrespective of the overt motor action. This, together with the boost under increased pupil dilation, is consistent with an origin in neuromodulatory brainstem centers. Ongoing analyses aim at quantifying the effect of Bayesian surprise, a putative driver of phasic responses in these centers, on the decision-related top-down signal in visual cortex.

Title: Effects of noradrenaline on visual evidence accumulation in human cortex

Authors: *N. A. KLOOSTERMAN[1,2], J. W. DE GEE[1,3], T. H. DONNER[1,2,3];
[1]Dept. of Psychology, Univ. of Amsterdam, Amsterdam, Netherlands; [2]Amsterdam Brain and Cognition, Amsterdam, Netherlands; [3]Dept. of Neurophysiol. and Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany

Abstract: Purpose: Perceptual decision-making entails the accumulation of sensory evidence towards thresholds for alternative choices. This accumulation results from recurrent interactions in networks of association cortex producing persistent activity. Recurrent cortical interactions are shaped by the catecholamine noradrenaline (NA): NA boosts persistent activity and dampens trial-to-trial variability of cortical neurons. However, it is unknown how NA shapes the cortical network dynamics underlying perceptual decisions. Here, we manipulated central NA levels with atomoxetine (selective NA reuptake inhibitor) and characterized the effects on the dynamics of an elementary visual decision by magnetoencephalography (MEG) and computational (drift diffusion) modeling of choice behavior. **Methods:** Human subjects (N=18) performed a spatial 2AFC discrimination task, comparing the contrast of two Gabor patches (diameter 20°) in the

lower left/right visual field. Subjects reported the location of the higher contrast ("target") by left or right hand button press (variable stimulus-response mapping, free response paradigm). Two contrast differences were titrated to the individual 85% ("easy") or 70% ("hard") correct levels. Each subject performed four experimental sessions, with administration of atomoxetine or placebo (randomized, double-blind, within-subjects design). We fitted the drift diffusion model to the reaction time distributions (separately for drug conditions) and performed time-frequency analysis on the MEG to assess the effects of drug on frequency-specific modulations of the cortical power spectrum during decision formation. **Results:** Compared to placebo, atomoxetine enhanced beta-band (12-36 Hz) power over occipital and parietal cortex from ~0.5 s after stimulus onset until after the response (median RT: 0.96 s). Atomoxetine also enhanced gamma-band (50-60 Hz) power over a range of regions including frontal cortex. Both drug effects were spatially global, riding on top of selective modulations that were lateralized with respect to target or response. Drift diffusion modeling showed a selective reduction of the trial-to-trial variability of drift rate under atomoxetine. This effect was highly significant when only drift rate and drift rate variability were free to vary with drug condition. It was also significant and selective in a model with four model parameters free to vary. **Conclusion:** Boosting central NA levels alters cortical network dynamics in the beta- and gamma-bands during decision formation and reduces the trial-to-trial variability of visual evidence accumulation.

Title: Circuit mechanisms underlying visual responses of the anterior cingulate cortex

Authors: *R. HUDA[1], G. PHO[1], I. R. WICKERSHAM[2], M. SUR[1];
[1]Brain and Cognitive Sci., Picower Inst. for Learning and Memory, MIT, Cambridge, MA;
[2]McGovern Inst. for Brain Research, MIT, Cambridge, MA

Abstract: Neural dynamics in sensory cortices are shaped by bottom-up inputs relaying the physical features of sensory stimuli and by top-down projections that modulate their encoding. The anterior cingulate division of the prefrontal cortex is known to provide top-down input to the visual cortex. Here, we use multiple approaches to delineate the functional role of visual inputs to the anterior cingulate cortex (ACC) and of the feedback from ACC to V1. Using rabies virus-mediated anatomical tracing to identify sources of inputs to the ACC, we found that V1 as well as other cortical and subcortical brain regions project to the ACC. Using rabies viruses that express the genetically encodable calcium indicator GCaMP6f and two-photon microscopy, we characterized the functional properties of ACC-projecting visual cortex neurons in passively viewing, awake head-fixed mice. We found that many of these neurons are tuned to the orientation and direction of drifting gratings. Next, we expressed GCaMP6s in the ACC and imaged the calcium activity of ACC axons found in layer 1 of V1. A subset of ACC axons were visually driven and displayed sharply tuned responses to the orientation and direction of drifting gratings. To assess the contribution of V1 to this property, we used a chemogenetic approach. We expressed the inhibitory hM4Di DREADD (designer receptors exclusively activated by designer drugs) in V1, GCaMP6s in the ACC, and monitored the calcium responses of ACC axons to oriented drifting gratings before and after systemic application of the DREADD agonist clozapine-N-oxide (CNO). While CNO application in control animals had no effect on the visual responses of ACC axons, it reduced responses in DREADD expressing animals. Together, these findings show that a projection from the visual cortex contributes to the visual responsiveness of the ACC. Since the ACC has been proposed to play a crucial role in cognition, and in particular reward processing, we propose that the ACC processes visual information in the context of its behavioral significance and relays a saliency signal back to the visual cortex to modulate the encoding of relevant visual stimuli.

Title: Characteristics of eye-position gain field populations in AIT and LIP determined through genetic algorithm modeling of monkey data

Authors: *S. R. LEHKY[1], M. E. SERENO[2], A. B. SERENO[3];
[1]Computat. Neurobio. Lab., Salk Inst., La Jolla, CA; [2]Dept. of Psychology, Univ. of Oregon, Eugene, OR; [3]Dept. of Neurobio. and Anat., Univ. of Texas Hlth. Sci. Ctr., Houston, TX

Abstract: We have previously demonstrated (Sereno et al. 2014) differences between eye-position spatial maps in lateral intraparietal cortex (LIP) and anterior inferotemporal cortex (AIT) of macaque monkeys, based on population decoding of gaze angle modulations of visual responses. The LIP spatial map was approximately veridical to physical space while the AIT map was highly distorted with compression towards central fixation. Here, using a genetic algorithm, we quantify statistical differences in gain field population characteristics underlying those different spatial maps. We created a population of model neurons whose responses were modulated by eye position to form gain fields, each neuron having a different gain field. An intrinsic decoding method, namely multidimensional scaling, was used to recover an eye-position spatial map from the model population. We then used a genetic algorithm to modify the characteristics of gain field populations until the recovered spatial maps closely matched those derived from monkey neurophysiological data. The primary differences found were that AIT gain fields on average operated on smaller spatial scales and had smaller dispersions than LIP gain fields. Thus, differences in the characteristics of gain field populations for different cortical areas may underlie differences in the representation of space.

Title: Anticipating a moving target: role of vision and reinforcement

Authors: *A. MONTAGNINI[1], J.-B. DAMASSE[1], L. MADELAIN[1,2], L. PERRINET[1]; [1]Inst. de Neurosciences De La Timone, Marseille, France; [2]SCALab, Univ. de Lille Nord de France, Villeneuve d'Ascq, France

Abstract: Humans are able to accurately track a moving object with a combination of saccades and smooth eye movements. These movements allow us to align and stabilize the object on the fovea, thus enabling high-resolution visual analysis. When predictive information is available about target motion, anticipatory smooth pursuit eye movements (aSPEM) are efficiently generated before target appearance, which reduce the typical sensorimotor delay between target motion onset and foveation. It is generally assumed that the role of anticipatory eye movements is to limit the behavioral impairment due to eye-to-target position and velocity mismatch. However, little is known about the actual effect of target visibility on aSPEM and on the relative plasticity of this anticipatory behavior with respect to manipulations of reinforcement of different nature (perceptual or monetary). By manipulating the probability for target motion direction we were able to bias the direction and mean velocity of aSPEM (baseline condition), as measured during a fixed duration gap before target ramp-motion onset. This suggests that probabilistic information may be used to inform the internal representation of motion prediction for the initiation of anticipatory movements. To further understand the nature of aSPEM, in the first test condition we degraded the visibility of the moving target by transiently hiding it at random intervals (cumulative target blank duration=50% of motion-ramp duration). Despite being able to accurately track (pursuit gain did not significantly differ with respect to the baseline condition), anticipatory smooth pursuit was significantly reduced, suggesting a direct role of vision for the modulation of movement anticipation. Results of this first experiment suggest that accurate vision may act as an ecological reinforcer for anticipatory eye movements: thus we further tested, with two distinct experiments based on a gaze-contingent paradigm, whether aSPEM is affected by reinforcement contingencies. First, on the ground of the measured anticipatory eye-velocity, we artificially manipulated online the discriminability of a small detail (position of a Landolt-stimulus gap) of the otherwise highly visible moving target. Second, we associated a monetary reward to a criterion-matching anticipatory velocity. We observed modulations of anticipatory velocity depending on the reinforcement contingencies in both cases. Taken together, our results suggest that anticipatory eye movements are permeable to different manipulations, in particular those affecting the behavioral consequences of pursuit, either at the purely sensory or reward related level.

Title: Eyes off the prize: Impact of visual discomfort in college population

Authors: *J. F. AWAD[1,2], K. LEE[3], T. GORJI[2], A. S. HOCHMAN[2], S. A. DREW[2];
[1]California State University, Northridge, Reseda, CA; [2]Psychology, [3]California State University, Northridge, Northridge, CA

Abstract: Visual discomfort is a common condition associated with performing near work tasks such as reading or viewing computer screens. Symptoms can include headaches, eye strain, double vision, blurred vision, and sensitivity to light. Two ocular systems contribute to near work performance: the accommodative system, in which the lens of the eye thickens to keep a target in focus, and the vergence system, involving the coordination of the two eyes to keep a target centered on the retina. Disorders of both of these systems have been found to be associated with visual discomfort symptoms. The Conlon Visual Discomfort Survey (VDS) has been found to reliably be associated with accommodative insufficiency (AI) while the Convergence Insufficiency Symptom Survey (CISS) has similarly been found to be associated with convergence insufficiency (CI). Given the high degree of near work associated with student success, the prevalence of visual discomfort in the college population is of great interest and relevance. Though a few studies have assessed the prevalence of visual discomfort in the college population, few have considered a model predicting the impact of these ocular dysfunctions on academic performance. A large sample of undergraduate students participated in this study. More than 40% of participants fell into the high symptom category for the VDS, and more than 65% of participants fell into the high symptom category for the CISS. Significant correlations were observed between VDS symptom scores and cumulative GPA. These preliminary data suggest a high prevalence of visual discomfort in the university population, with a significant impact on academic performance. Subsequent multiple regression analysis revealed both VDS and CISS significantly account for a portion of the variance in GPA.

Title: Palisade endings are a constant feature in the extraocular muscles of frontal-eyed, but not lateral-eyed, animals

Authors: *R. BLUMER[1], B. MAURER[1], J. STREICHER[1], B. GESSBAUER[1], E. PECHRIGGL[2], M. BLUMER[2], M. A. DAVIS-LÓPEZ DE CARRIZOSA[3], A. K. HORN[4], P. J. MAY[5], R. R. DE LA CRUZ[3], A. M. PASTOR[3];

Abstract: Proprioception from extraocular muscles (EOMs) provides the brain with eye position signals. Surprisingly, classical proprioceptors (muscle spindles and Golgi tendon organs) are absent from the EOMs of most mammals. Instead, palisade endings are a unique feature of mammalian EOMs. They consist of a dense ramification of axonal branches and nerve terminals at the tip of individual muscle fibers. For a century, palisade endings have been considered as sensory structures substituting for classical proprioceptors in EOMs. Interest in palisade endings was reignited when molecular analysis and neuronal tracing experiments determined that palisade endings are cholinergic and originate from the EOM motor nuclei. To date, palisade endings have been found in all species investigated and it has been assumed that they are a general feature of EOMs. In the present study, we used immunohistochemical techniques to test this hypothesis and extended our investigation to 11 species; some frontal-eyed (human, monkey, cat, and ferret), and others lateral-eyed (pig, sheep, rabbit, rat, mouse, gerbil and guinea pig). In all frontal-eyed species, palisade endings are a constant feature in the rectus EOMs and the medial recti always contain the highest number of palisade endings (from 36 in ferrets to 85 in humans). In the lateral-eyed animals, palisade endings are constantly found in even-toed ungulates (sheep and pigs) and in rabbits. However, their density is rather low (12 - 14 in the medial recti). In rats, palisade endings are an exceptional feature: most extraocular muscles lack them. In mice, gerbils and guinea pigs, palisade endings are completely absent. Structural analysis of palisades revealed that the number of segments and the cumulative length, area and volume covaried. These features correlated with the mass of the species, following two different

allometric relations (for lateral-eyed and frontal-eyed animals, respectively), such that the largest species had the highest structural complexity. Staining with α-bungarotoxin shows that palisade endings, with few exceptions in frontal-eyed animals, lack acetylcholine receptors. In lateral-eyed animals, palisade endings in sheep and pigs also lack acetylcholine receptors; whereas palisade endings in rabbits and in rats (when present) have such receptors. Our results demonstrate that palisade endings are not a universal feature of mammalian EOMs. So if they are proprioceptors, not all species require them. Their absence in some lateral-eyed animals suggests a role in conjugacy. In fact, since the medial rectus has highest density of palisade endings, palisade endings likely play a special role in convergence.

Title: Frontal Eye Fields read out, but do not assign, priority

Authors: *D. K. WOOD[1,2], E. BERTHIAUME[1], J. I. GLASER[1,2], P. N. LAWLOR[1,2], P. RAMKUMAR[2], K. P. KÖRDING[1,2], M. A. SEGRAVES[1];
[1]Northwestern Univ., Evanston, IL; [2]Rehabil. Inst. of Chicago, Chicago, IL

Abstract: A fundamental question in sensorimotor neuroscience is how we decide where to look next. One theory posits that oculomotor circuits contain a map of top-down and bottom-up priority, and that the decision of where to look next is accomplished by reading out the peaks in this priority map. The Frontal Eye Field (FEF) has been implicated in these processes, but it is not clear whether the FEF is involved in assigning priority or simply reading it out. If it is involved in assigning priority, it should passively respond to task-relevant visual inputs prior to detection. If not, it should only encode the priority of those locations where a potential target has been differentiated from the background and tagged. This issue is complicated by the fact that FEF is typically studied using stimuli and tasks that do not accurately reflect the real world. For example, saccade targets are often flashed abruptly and against a uniform background, making

target detection trivial. By contrast, most objects in the natural world are relatively static against a cluttered background, making target detection far more difficult. On the basis of these artificial tasks, previous studies have suggested that FEF passively encodes the task-relevance of visual objects - i.e., regardless of whether the target has been detected or attended to. We tested this by recording single units in FEF while macaques performed a novel target fade-in task. Monkeys fixated centrally and covertly searched for a peripheral target (a fly) that was either abruptly flashed or gradually faded into view. They then reported awareness of the target by making a saccade to it. We also varied the complexity of the background (i.e., uniform black, phase-scrambled scene, or natural scene) to measure the impact of distracting information on behavior and FEF responses. For the scrambled and natural backgrounds, visual cells responded vigorously only when the target was flashed into the receptive field. Critically, there was no graded increase in activity during the fade-in trials, for any cell type. The exception to this was during fade-in trials with a uniform black background; in these trials, there was an abrupt visual response when the target visibility passed psychophysical threshold. This suggests that FEF does not passively represent target location or accumulate evidence for saccade selection on the basis of target relevance. That is, in order for a spatial location to be assigned priority in FEF, potential targets must be differentiated from background and recognized as such. These results imply that passive relevance-based selection of space is performed upstream of the FEF in tasks that more closely resemble natural behavior.

Title: Representation of visual salience by frontal eye field neurons

Authors: *A. ASADOLLAHI[1,2], H. SHAHABI[1], F. DIDEHVAR[1], M. MOGHIMI[1], M. PARSA GHARAMALEKI[2], B. NOUDOOST[2];
[1]Ferdowsi Univ. of Mashhad, Mashhad, Iran, Islamic Republic of; [2]Dept. of Cell Biol. and Neurosci., Montana State Univ., Bozeman, MT

Abstract: Physical salience of visual targets is a key factor in driving attention and gaze toward them. We studied how activity within the frontal eye field (FEF), a key region in control of gaze

and attention, represents stimulus salience and the degree to which this representation guides the behavior. Two static stimuli were simultaneously presented onscreen, one inside the FEF neurons' response field (Sin) and the other outside (Sout). The contrast of the Sin target was constant (50%) while the contrast of the Sout stimulus varied parametrically from 0% to 100% across trials. Increasing the contrast of the Sout stimulus suppressed the visual responses of FEF neurons, indicating visual competition within the FEF. In order to determine the spatial extent of visual competition, we changed the location of the Sout stimulus relative to the Sin stimulus. The presence of the second stimulus had a suppressive effect on the visual responses of FEF neurons, far beyond the inhibitory surround of receptive fields in visual cortices. Moreover, we found that the features of visual targets have a greater impact on saccades when the target is more salient. We used moving gratings as targets and quantified the degree to which saccade endpoints are influenced by the direction of motion of the target (visual guidance). In a free choice task the animal was asked to choose between a moving grating with 50% contrast and another moving grating with 20% or 80% contrast. We found that for saccades to the same target, visual guidance is greater when it is the more salient stimulus. FEF responses not only represent the salience of visual targets, they also reflect the dependence of gaze behavior on target salience: greater FEF activity corresponds to greater visual guidance across trials. Our results implicate the FEF activity as a neural basis for the behavioral and attentional prioritization of salient stimuli.

Title: Neural basis of spatial mislocalization during smooth eye-movements

Authors: ***F. BREMMER**[1], S. DOWIASCH[1], G. BLOHM[2];
[1]Philipps-Universität Marburg, Marburg, Germany; [2]Ctr. for Neurosci. Studies, Queen's Univ., Kingston, ON, Canada

Abstract: The dependence of neuronal discharge on the position of the eyes in the orbit is a functional characteristic of many visual cortical areas of the macaque. It has been suggested that

these eye-position signals provide relevant information for a coordinate transformation of visual signals into a non-eye-centered frame of reference. This transformation could be an integral part for achieving visual perceptual stability across eye movements. Previous studies demonstrated close to veridical eye-position decoding during stable fixation as well as characteristic erroneous decoding across saccadic eye-movements. Here we aimed to decode eye-position during smooth-pursuit. We recorded neural activity in the ventral intraparietal area (VIP) of two macaque monkeys during steady fixation, saccades and smooth-pursuit. Then, we aimed to determine the temporal and spatial accuracy of eye-position as decoded from the neuronal discharges. Confirming previous results, during steady fixation the activity of the majority of neurons depended linearly on horizontal and vertical eye-position. The application of a previously introduced computational approach (isofrequency-decoding) allowed eye-position decoding with considerable accuracy during fixation. In a second step, we applied the same decoder on the activity of the same neurons as recorded during smooth-pursuit. On average, the decoded signal during smooth pursuit was ahead of the current eye position. Previous behavioral studies in humans have shown a mislocalization of briefly flashed stimuli during smooth pursuit. This localization error, however, is spatially not symmetric. Instead, it is found only in the visual hemifield ahead of the fovea. Remarkably, a model combining the constant lead of the decoded eye-position, as found in our current study, with a previously described attentional bias ahead of the pursuit target describes the asymmetric mislocalization pattern during smooth pursuit.

Abstract: Objective. The act of blinking is an integral function that aids in preservation of corneal integrity. Counting blinks in humans provides valuable physiological and behavioral data. However, awareness on the part of the subject that his or her eye blinks are being counted may impact blink rate. The goal of this study was to provide direct experimental evaluation of this hypothesis. **Methods.** Thirty adult males (27.5 ± 6.7 y, 25 right-handed) provided written consent prior to enrollment. All participants had normal vision and no known neurological disorders. The study conformed to the Declaration of Helsinki. All forms and procedures received prior approval by the Institutional Review Board at Boston University School of Medicine. Six trained raters counted blinks from videos of participants' faces during eight unique epochs, consisting of four situations (spontaneous, conversation, fixation, viewing images) and two conditions (naïve and informed). Only full occlusions of the eye where treated as blinks. For each situation, minute-by-minute blink counts were entered into linear mixed model analysis with *time* and *condition* as repeated measures. **Results.** Average inter-rater reliability was 0.97. Data from one participant was excluded for excessive blinking across all epochs. While viewing images, there was a main effect of *time*, $F(2,252) = 10.6$, $p < 0.001$, indicating blink counts increased overall with time. There was no main effect of *condition*, $F(1,28) = 0.1$, $p > 0.1$, indicating average blink rate did not vary according to whether the subject was informed that blinks were counted. There was a *time x condition* interaction between the two main factors, $F(2,252) = 3.3$, $p < 0.001$, indicating that blink rate over time was impacted by being informed that blinks were counted. Paired-sample t tests revealed that blink counts were lower in naïve vs. informed conditions during minute one ($p < 0.01$), but higher during minute three ($p < 0.01$), and were equivalent across all other time-points (all p values > 0.05). During fixation, there was a main effect of *time*, $F(2,56) = 7.0$, $p < 0.01$, indicating blink counts increased overall with time. However, neither the main effect of *condition*, nor its interaction with *time* was significant (all F values < 1, all p values > 0.4). No other effects were observed in any of the other situations, (all F values < 2.28, all p values > 0.05). **Conclusions.** Being informed that ones blinks are being counted has a transitory impact on minute-to-minute blink counts, but not average blink rate while viewing images. **Acknowledgements.** This study was funded by the Neuroscience Research Unit of Pfizer Inc. Title: Frontal eye field correlates of saccade remapping and planning in natural scenes

Authors: *J. I. GLASER[1], P. RAMKUMAR[1], P. N. LAWLOR[1], D. K. WOOD[2], M. A. SEGRAVES[2], K. P. KORDING[1];

Abstract: How is visual information transferred across eye movements (saccades) so that we can plan future saccades and maintain a stable perception of the world? One theory is remapping, where neurons' receptive fields (RFs) preemptively shift prior to saccade onset. According to this theory, neurons will respond to visual stimuli in their future receptive fields earlier than new visual information can reach the neurons. While remapping has been demonstrated in paradigms with flashed-on stimuli and uniform background images, it has not been investigated with stationary targets in complex natural scenes. Here, we analyzed recordings from the Frontal Eye Field (FEF), a region involved in saccade planning, while monkeys searched natural scenes for an embedded target. We found that during the saccade, or very soon after the saccade landing, many neurons had enhanced firing rates when the search target's final post-saccadic location would be in the neuron's receptive field (RF). We ensured that the response was in fact due to the target being in the upcoming RF rather than the previous RF (which often had significant overlap with the upcoming RF), using a generalized linear modeling approach. This enhanced response occurred too quickly for new visual information to have reached the FEF, suggesting that the enhanced response was in fact due to remapping. Moreover, we found that when the target was in the upcoming RF, a higher firing rate was predictive of the target being foveated more rapidly, thus demonstrating that this remapped visual information was used for saccade planning.

Title: Brain circuits underlying visual stability across eye movements: oscillatory dynamics disentangle processing of multiple items

Authors: *D. MCLELLAND[1], J. SCHUSTER[2], F. HAMKER[2], R. VANRULLEN[1];

Abstract: Despite our regular saccadic eye movements, our perceptual experience is of a stable visual world. This stability has been the focus of extensive research, and has been linked to saccadic remapping at the physiological level, and attention at the cognitive level. Ziesche and Hamker (2011, J Neurosci 31:17392; 2014, Front Comp Neuro 8:25) have developed a network model of the brain circuits underlying visual stability, and shown that it captures a set of important features characterizing peri-saccadic activity/behavior. Here, however, we show that testing with multiple simultaneous stimuli uncovers a shortcoming of the model: the stimuli are processed normally with independent "attention pointers" when they are spatially distant from each other, but interfere when close, such that they are represented by a single attention pointer midway between the two stimuli. We have recently shown that both attention and peri-saccadic remapping processes are linked to oscillatory brain activity at theta frequency (~7Hz). In the literature, one hypothesized role of oscillatory activity is in enabling the processing of multiple items by segregating the relevant neural activity in the temporal domain. We set out to test this theory in the context of the visual stability model. We first developed a spiking network version of the model (the original is rate coded), such that temporal interactions between units are meaningful at a timescale relevant for the oscillatory activity. Using this model, we were able to show how oscillatory neural activity can resolve the issue of item multiplexing. Specifically, we tested two major models of oscillatory processing: i) communication-through-coherence (Fries, 2009, Ann Rev Neurosci 32:209), by which coherent gamma frequency (~40 Hz) activity between brain regions enables selective processing of a single item, and a theta-frequency oscillation structures switching between items; and ii) theta-gamma coding (Lisman & Jensen 2013, Neuron 77:1002), whereby a different item is processed on each cycle of a gamma oscillation, and this ordered sequence of activity is repeated or updated on each theta cycle. Further, we explore the interaction between the timing of the neural oscillations and the saccade

event. These results serve both as a functionally useful and experimentally testable update to models of saccadic updating, and as a further example of how oscillatory processing may be a general mechanism across diverse brain operations.

Title: Directional precision for saccades and smooth pursuit in humans and macaque monkeys

Authors: *J. CHURAN[1], D. BRAUN[2], F. BREMMER[1], K. R. GEGENFURTNER[2];
[1]AG Neurophysik, Philipps-University, Marburg, Germany; [2]Dept. of Psychology, Justus-Liebig-University, Giessen, Germany

Abstract: Primates use a combination of saccades and smooth-pursuit eye movements (SPEM) to track moving targets. This requires a fast and accurate interaction of the two different oculomotor systems. We investigated the interaction of these systems by measuring the precision of eye movements in human subjects and in head-unrestrained non-human primates. We compared the directional precision of pure SPEM with the precision of a combination of an initial saccade followed by a SPEM. Combinations of initial saccades and SPEMs were elicited by the ramp paradigm while saccade-free SPEMs were produced in response to a step-ramp target with an appropriate timing. The motion direction was mainly horizontal with a randomly chosen vertical component in the range of +-20 degrees. We investigated how well the vertical component of the target motion was reflected in the eye-movement direction. To quantify the directional precision for the two conditions, oculometric functions were constructed. From these oculometric functions then direction thresholds were calculated for pursuit and saccades. These direction thresholds indicated the speed of vertical target motion required to influence the vertical eye-movement component. We found some differences in the absolute performance levels of humans and monkeys: Humans reached lower asymptotic thresholds than monkeys (1-2 deg for humans, ~6 deg for monkeys), while monkeys reached their asymptotic threshold much faster than humans (300-400 ms for humans, 200 ms for monkeys). Beyond these differences

humans and monkeys showed a remarkably similar pattern of differences between SPEMs and saccades. We found that, for both humans and monkeys in the ramp condition, the oculometric thresholds were significantly lower during the initial saccade than during pure pursuit responses at the same time relative to the onset of the stimulus. Thus we conclude that, while the saccadic system in humans and monkeys has a longer latency than the SPEM-system, it also has a better directional precision.
